One of the volumes of Swift's miscellanies contains almost entirely of letters between him and the dean. He published a prose translation of Pericles; to which he added the belt notes of former editors, together with many judicious ones of his own. This work was printed at London, 1739, in 12mo. Biographical Dictionary. SHERIDAN (Mrs Frances), wife to Thomas Sheridan, M. A. was born in Ireland about the year 1724, but descended from a good English family which had removed thither. Her maiden name was Chamberlaine, and she was grand-daughter of Sir Oliver Chamberlaine. The first literary performance by which she distinguished herself was a little pamphlet at the time of a violent party-dispute relative to the theatre, in which Mr Sheridan had newly embarked his fortune. So well-timed a work excited the attention of Mr Sheridan, and by an accident discovered his fair patroness, to whom he was soon afterwards married. She was a person of the most amiable character in every relation of life, with the most engaging manners. After lingering some years in a very weak state of health she died at Blois in the south of France, in the year 1767. Her "Sydney Biddulph" may be ranked with the first productions of that class in ours or in any other language. She also wrote a little romance in one volume called Newfand, in which there is a great deal of imagination productive of an admirable moral. And she was the author of two comedies, "The Discovery" and "The Dupe."

SHERIFF, an officer, in each county in England, nominated by the king, invested with a judicial and ministerial power, and who takes place of every nobleman in the county during the time of his office. The sheriff is an officer of very great antiquity in this kingdom, his name being derived from two Saxon words, signifying the regio, bibliis, or officer of the shire. He is called in Latin vice-comes, as being the deputy of the earl or comitatus, to whom the custody of the shire is said to have been committed at the first division of this kingdom into counties. But the earl, in process of time, by reason of their high employments and attendance on the king's person, not being able to transact the business of the county, were delivered of that burden; referring to themselves the honour, but the labour was laid on the sheriff. So that now the sheriff does all the king's business in the county; and though he be still called vice-comes, yet he is entirely independent of, and not subject to, the earl; the king, by his letters patent, committing custodia comitatus to the sheriff, and to him alone.

Sheriffs were formerly chosen by the inhabitants of the several counties. In confirmation of which it was ordained, by statute 28 Edw. I. c. 8, that the people should have an election of sheriffs in every shire where the sheriffalty is not of inheritance. For anciently in some counties the sheriffs were hereditary; as we apprehend they were in Scotland till the statute 20 Geo. II. c. 43; and still continue in the counties of Wiltmore, and day; the city of London having also the inheritance of the sheriffalty of Middlesex vested in their body by charter. The reason of these popular elections is assigned in the same statute, c. 13: "that the commons might choose such as would not be a burden to them." And herein appears plainly a strong trace of the democratic part of our constitution; in which form of government it is an indispensible requisite, that the people should choose their own magistrates. This election was in all probability not absolutely vested in the commons, but required the royal approbation. For in the Gothic constitution, the judges of their county-courts (which office is executed by the sheriff) were elected by the people, but confirmed by the king; and the form of their election was thus managed; the people, or incola territorii, chose twelve electors, and they nominated three persons, ex quibus rex unum confirmabit. But, with us in England, these popular elections, growing tumultuous, were put an end to by the statute 9 Edw. II. ft. 2, which enacted, that the sheriffs should from thenceforth be appointed by the chancellor, treasurer, and the judges; as being persons in whom the same trust might with confidence be reposed. By statutes 14 Edw. III. c. 7. 23 Hen. VI. c. 8. and 21 Hen. VIII. c. 20. the chancellor, treasurer, precentor of the king's council, chief justices, and chief barons, are to make this election; and that on the morrow of All Souls, in the exchequer. And the king's letters patent, appointing the new sheriffs, used commonly to bear date the first day of November. The statute of Cambridge, 12 Ric. II. c. 2. ordains, that the chancellor, treasurer, keeper of the privy-sale, steward of the king's house, the king's chamberlain, clerk of the rolls, the justices of the one bench and the other, barons of the exchequer, and all other that shall be called to ordain, name, or make justices of the peace, sheriffs, and other officers of the king, shall be sworn to adjudge independently, and to name no man that faith to be put in office, but such only as they shall judge to be the best and most sufficient. And the custom now is (and has been at least ever since the time of Fortescue, who was chief justice and chancellor to Henry the sixth), that all the judges, together with the other great officers, meet in the exchequer chamber on the morrow of All Souls yearly, (which day is now altered to the morrow of
of St Martin by the last act for abbreviating Michaelmas term, and then and there propose three persons to the king, who afterwards appoints one of them to be sheriff. This custom of the twelve judges proposing three persons seems borrowed from the Gothic constitution before-mentioned; with this difference, that among the Goths the 12 nominors were first elected by the people themselves. And this usage of ours, at its first introduction, there is reason to believe, was founded upon some statute, though not now to be found among our printed laws; first, because it is materially different from the direction of all the statutes before-mentioned; which it is hard to conceive that the judges would have countenanced by their concurrence, or that Fortescue would have inserted in his book, unless by the authority of some statute; and also, because a statute is expressly referred to in the record, which Sir Edward Coke tells us he transcribed from the council book of 3d March, 34 Hen. VI. and which is in substance as follows. The king had of his own authority appointed a man sheriff of Lincolnshire, which office he refused to take upon him; whereupon the opinions of the judges were taken, what should be done in this behalf. And the two chief judges, Sir John Fortescue and Sir John Prichard, delivered the unanimous opinion of them all; "that the king did an error when he made a person sheriff that was not chosen and preferred to him according to the statute; that the person refusing was liable to no fine for disobedience, as if he had been one of the three persons chosen according to the tenor of the statute; that they would advise the king to have recourse to the three persons that were chosen according to the statute, or that some other person might be introduced to occupy the office for this year; and, that the next year, to eschew such inconveniences, the order of the statute in this behalf made be observed." But, notwithstanding this unanimous resolution of all the judges of England, thus entered in the council-book, and the statute 34 and 35 Hen. VIII. c. 25. § 61. which expressly recognizes this to be the law of the land, some of our writers have affirmed, that the king, by his prerogative, may name whom he pleases to be sheriff, whether chosen by the judges or not. This is grounded on a very particular case in the fifth year of queen Elizabeth, when, by reason of the plague, there was no Michaelmas term kept at Westminster; so that the judges could not meet there in cragg a unnanimem to nominate the sheriff; whereupon the queen named them herself, without such previous assembly, appointing for the most part one of two remaining in the last year's list. And this case, thus circumstanced, is the only authority in our books for the making these extraordinary sheriffs. It is true, the reporter adds, that it was held that the queen by her prerogative might make a sheriff without the election of the judges, non obstante alio, statute in contradistinction; but the doctrine of non obstante, which fets the prerogative above the laws, was officially demolished by the bill of rights at the revolution, and abdicated Westminster-hall when king James abdicated the kingdom. However, it must be acknowledged, that the practice of occasionally naming what are called per-kef-farrants, by the sole authority of the crown, hath uniformly continued to the reign of his present majesty; in which, it is believed, few (if any) instances have occurred. Sheriffs, by virtue of several old statutes, are to continue in their office no longer than one year; and yet it hath been said that a sheriff may be appointed durantem bene placito, or during the king's pleasure; and so is the form of the royal writ. Therefore, till a new sheriff be named, his office cannot be determined, unless by his own death, or the demise of the king; in which last case it was usual for the successor to find a new writ to the old sheriff; but now, by statute 1 Anne, c. 8. all officers appointed by the preceding king, may hold their offices for six months after the king's demise, unless sooner displaced by the successor. We may further observe, that by statute 1 Will. III. c. 11. no man that has served the office of sheriff for one year can be compelled to serve the same again within three years after. We shall find it is of the utmost importance to have the sheriff appointed according to law, where we consider his power and duty. These are either as a judge, as the keeper of the king's peace, as a magistrate or officer of the superior courts of justice, or as the king's bailiff.

In his judicial capacity he is to hear and determine all causes of 40 shillings value and under, in his county-court; and he has also a judicial power in divers other civil cases. He is likewise to decide the elections of knights of the shire (subject to the control of the House of Commons), of coroners, and of verderors; to judge of the qualification of voters, and to return such as he shall determine to be duly elected.

As the keepers of the king's peace, both by common law and special commission, he is the first man in the county, and superior in rank to any nobleman therein, during his office. He may apprehend, and commit to prifon, all persons who break the peace, or attempt to break it; and may bind any one in a recognizance to keep the king's peace. He may, and is bound, ex officio, to pursue and take all traitors, murderers, felons, and other misdeemers, and commit them to goal for false custody. He is also to defend his country against any of the king's enemies when they come into the land; and for this purpose, as well as for keeping the peace and pursuing felons, he may command all the people of his county to attend him; which is called the poissa comitatus, or power of the county; which sum is every person above 15 years old, and under the degree of a peer, bound to do without warning, under pain of fine and imprisonment. But though the sheriff is thus the principal conservator of the peace in his county, yet, by the express directions of the great charter, he, together with the confiable, coroner, and certain other officers of the king, are forbidden to hold any pleas of the crown, or, in other words, to try any criminal offence. For it would be highly unbecoming, that the executioners of justice should be also the judges; should impose, as well as levy, fines and amercements; should one day condemn a man to death, and personally execute him the next. Neither may he act as an ordinary justice of the peace during the time of his office; for this would be equally incon-
SHERLOCK, in Scotland. See Law, Part iii. sect. 3.

SHERLOCK (William), a learned English divine in the 17th century, was born in 1641, and educated at Eaton school, where he distinguished himself by the vigour of his genius and his application to study. Thence he was removed to Cambridge, where he took his degree. In 1669 he became rector of the parish of St George, Botolph-lane, in London; and in 1671 was collated to the prebend of Paneras, in the cathedral of St Paul's. He was likewise chosen master of the Temple, and had the rectory of Thetford in Hertfordshire. After the Revolution he was furnished from his preferment, for refusing the oaths to king William and queen Mary; but at last he took them, and publickly justified what he had done. In 1691 he was installed dean of St Paul's. His Vindication of the Doctrine of the Trinity engaged him in a warm controversy with Dr South and others. Bishop Burnet tells us, he was "a clear, a polite, and a strong writer; but apt to assume too much to himself, and to treat his adversaries with contempt." He died in 1707. His works are very numerous; among these are, 1. A discourse concerning the knowledge of Jesus Christ, against Dr Owen. 2. Several pieces against the Papists, the Socinians, and Dissenters. 3. A practical Treatise on Death, which is much admired. 4. A practical Discourse on Providence. 5. A practical Discourse on the future Judgment; and many other works.

Vol. XVII.

SHERLOCK (Dr Thomas), bishop of London, was the son of the preceding Dr. William Sherlock, and was born in 1678. He was educated in Catherine-hall, Cambridge, where he took his degrees, and of which he became master; he was made master of the Temple very young, on the resignation of his father; and it is remarkable that this mastership was held by father and son successively for more than 70 years. He was at the head of the opposition against Dr Hoadley bishop of Bangor; during which contest he published a great number of pieces. He attacked the famous Collins's "Grounds and Reasons of the Christian Religion," in a course of six sermons, preached at the Temple-church, which he entitled, "The use and Intent of Prophecy in the several Ages of the World." In 1728, Dr Sherlock was promoted to the bishopric of Bangor; and was translated to Salisbury in 1734. In 1747 he refused the archbishopric of Canterbury, on account of his ill state of health; but recovering in a good degree, accepted the see of London in the following year. On occasion of the earthquakes in 1750, he published an excellent Pastoral Letter to the clergy and inhabitants of London and Westminster; of which it is said there were printed in 4to, 50,000; 8vo, 20,000; and in 12mo, about 30,000; besides pirated editions, of which not less than 50,000 were supposed to have been sold. Under the weak state of body in which he lay for several years, he revised and published 4 vols of sermons in 8vo, which are particularly admired for their ingenuity and elegance. He died in 1762, and by report worth 150,000l. "His learning," says Dr Nicholas, "was very extensive: God had given him a great and an understanding mind, a quick comprehension, and a solid judgment. These advantages of nature he improved by much industry and application. His skill in the civil and canon law was very considerable; to which he had added such a knowledge of the common law of England as few clergymen attain to. This it was that gave him that influence in all causes where the church was concerned; as knowing precisely what it had to claim from its constitutions and canons, and what from the common law of the land." Dr Nicholas then mentions his confitant and exemplary piety, his warm and fervent zeal in preaching the duties and maintaining the doctrines of Christianity, and his large and diffusive munificence and charity; particularly by his having given large sums of money to the corporation of clergyman's sons, to several of the hospitals, and to the society for propagating the Gospel in foreign parts; also his bequesting to Catherine-hall in Cambridge, the place of his education, his valuable library of books, and his donations for the founding a librarian's place and a scholarship, to the amount of several thousand pounds.

SHERRIFFE of Mecca, the title of the descendants of Mahomet by Hassan ibn Ali. These are divided into several branches, of which the family of Ali Binuni, consisting at least of three hundred individuals, enjoy the sole right to the throne of Mecca. The Ali Binuni are, again, subdivided into two subordinate branches, Darii Sajid, and Darii Barkad, of whom sometimes the one, sometimes the other, have given sovereigns to Mecca and Medina, when these were separate states.

Not only is the Turkish Sultan indifferent about the order of succession in this family, but he seems even to
Sheriff's foment the dissensions which arise among them, and favours the strongest, merely that he may weaken them all. As the order of succession is not determinately fixed, and the sheriffs may all aspire alike to the sovereign power, this uncertainty of right, aided by the intrigues of the Turkish officers, occasions frequent revolutions. The grand sheriff is seldom able to maintain himself on the throne; and it often happens that his reign is not disturbed by the revolt of his nearest relatives. There have been instances of a nephew succeeding his uncle, an uncle succeeding his nephew; and sometimes of a person from a remote branch, coming in the room of the reigning prince of the ancient house.

When Niebuhr was in Arabia, in 1763, the reigning Sheriff of Mefad had reigned fourteen years on the throne, and, during all that period, had been continually at war with the neighbouring Arabs, and with his own nearest relations sometimes. A few years before, the Pacha of Syria had deposed him, and raised his younger brother to the sovereign dignity in his stead. But after the departure of the caravan, Jafar, the new sheriff, not being able to maintain himself on the throne, was obliged to resign the sovereignty again to Mefad. Achmet, the second brother of the sheriff, who was much beloved by the Arabs, threatened to attack Mecca while Niebuhr was at Jadda. Our traveller was soon after informed of the termination of the quarrel, and of Achmet's return to Mecca, where he continued to live peaceably in a private character.

These examples show that the Mussulmans observe not the law which forbids them to bear arms against their holy places. An Egyptian Bey even presumed, a few years since, to plant some small cannons within the compass of the Kaba, upon a small tower, from which he fired over that sacred mansion, upon the palace of Sheriff Mefad, with whom he was at variance.

The dominions of the sheriff comprehend the cities of Mecca, Medina, Jambo, Taif, Sadie, Ghunude, Hali, and thirteen others less considerable, all situated in Hejjas. Near Taif is the lofty mountain of Gazzan, which, according to Arabian authors, is covered with snow in the middle of summer. As these dominions are neither opulent nor extensive, the revenue of their sovereign cannot be considerable.

He finds a rich resource, however, in the imposts levied on pilgrims, and in the gratuities offered him by Mussulman monarchs. Every pilgrim pays a tax of from ten to an hundred crowns, in proportion to his ability. The Great Mogul remits annually sixty thousand rupees to the sheriff, by an allusion upon the government of Surat. Indeed, since the English made themselves masters of this city, and the territory belonging to it, the Nabob of Surat has no longer been able to pay the sum. The sheriff once demanded it of the English, as the possessors of Surat; and, till they should satisfy him, forbade their captains to leave the port of Jadda. But the English disregarding this prohibition, the sheriff complained to the Ottoman Porte, and they communicated his complaints to the English ambassador. He at the same time opened a negotiation with the nominal Nabob, who resides in Surat. But these steps proved all fruitless: and the sovereign of Mecca seems not likely to be ever more benefited by the contribution from India.

The power of the sheriff extends not to spiritual matters; these are entirely managed by the heads of the clergy, of different sects, who are resident at Mecca. Rigid Mussulmans, such as the Turks, are not very favourable in their sentiments of the sheriffs, but suspect their orthodoxy, and look upon them as secretly attached to the tolerant sect of the Zeidi.

SHELTAND, the name of certain islands belonging to Scotland, and lying to the northward of Orkney. There are many convincing proofs that these islands were very early inhabited by the Picts, or rather by those nations who were the original possessors of the Orkneys; and at the time of the total destruction of these nations, if any credit be due to tradition, their woods were entirely ruined. It is highly probable that the people in Shetland, as well as in the Orkneys, flourished under their own princes dependent upon the crown of Norway; yet this seems to have been rather through what they acquired by fishing and commerce, than by the cultivation of their lands. It may also be reasonably presumed, that they grew thinner of inhabitants after they were annexed to the crown of Scotland; and it is likely that they revived again, chiefly by the very great and extensive improvements which the Dutch made in the herring-fisery upon their coasts, and the trade that the crews of their buffs, then very numerous, carried on with the inhabitants, necessarily resulting from their want of provisions and other conveniences, which in those days could not be very considerable.

There are many reasons which may be assigned why these islands, though part of the British dominions, have not hitherto been better known. They were commonly placed two degrees too far to the north in all the old maps, in order to make them agree with Ptolemy's description of Thule, which he affected to be in the latitude of 63 degrees; which we find urged by Camden as a reason why Thule must be one of the Shetland isles, to which Speed also agrees, though from their being thus wrong placed he could not find room for them in his maps. Another, and that no light cause, was the many fabulous, fabulous, and impertinent relations published concerning them, as if they were countries inhospitable and uninhabitable; and lazzily, the indolence, or rather indifference, of the natives, who, contenting themselves

(a) The tradition is, that this was done by the Scots when they destroyed the Picts; but is more probably referred to the Norwegians rooting out the original possessors of Shetland.

(b) They represented the climate as intensely cold; the soil as composed of crags and quagmire, so barren as to be incapable of bearing corn; to supply which, the people, after drying fish-bones, powdered them, then kneaded and baked them for bread. The large fish-bones were told to be all the fuel they had. Yet, if so dreary a country, and in such miserable circumstances, they were acknowledged to be very long-lived, cheerful, and contented.
She is a very curious and interesting country, as far as the Shetland and Orkney islands are concerned. These islands are well situated for trade, being near three times as much land as the Orkneys; they are far better off than the islands of Madeira, and not inferior to the provinces of Utrecht, Zealand, and all inaccessable places, the mountain ash is still found growing wild. That is difficult, says the want of wood at present does not arise entirely from the soil or climate, appears from various experiments; some gentlemen having raised ash, maple, horse chestnuts, etc., in their gardens. Though the inhabitants are without either wood or coal, they are very well supplied with fuel, having great plenty of heath and peat. The black cattle in this country are in general of a larger size than in Orkney, which is owing to their having more extensive pastures; a clear proof that further improvements might be made in respect to this. Their hores are small, but strong, stout, and well-shaped, live very hardy, and to a great age. They have likewise a breed of small swine, the feth of which, when fat, is esteemed very delicious. They have no goats, hares, foxes, and in general no wild or venomous creatures of any kind except rats in some few islands. They have no moor-fowl, which is perhaps the more remarkable, as there are everywhere immense quantities of heath; but there are many sorts of wild and water fowl, particularly the dunter-goos, clack-goos, solan-goos, swans, duck,
Shetland. Ducks, teal, whaps, foils, lyres, kitiwalks, maws, plows, cormorants, &c. There is likewise the amber-goofes, which is said to hatch her egg under her wing. Eagles and hawks, as also ravens, crows, mews, &c., abound here.

All these islands are well watered; for there are everywhere excellent springs, some of them mineral and medicinal. They have indeed no rivers; but many pleasant rills or rivulets, which they call burns, of different sizes; in some of the largest they have admirable trouts, some of which are of 15 and even of 20 pounds weight. They have likewise many fresh water lakes, well floted with trout and eels, and in most of them there are also large and fine flounders; in some very excellent cod. These fresh-water lakes, if the country was better peopled, and the common people more at their ease, are certainly capable of great improvements. The sea-coasts of the main land of Shetland, in a straight line, are 55 leagues; and therefore there cannot be a country conceived more proper for establishing an extensive fishery.

What the inhabitants have been hitherto able to do, their natural advantages considered, does not deserve that name, notwithstanding they export large quantities of cod, tulk, ling, and skate, in such quantities that the bounty allowed by acts of parliament amounts from L. 1400 to L. 2000 annually. They have, besides, haddocks, whiting, turbot, and a variety of other fish. In many of the inlets there are prodigious quantities of excellent oysters, lobsters, mussels, cockles, and other shell-fish. As to amphibious creatures, they have multitudes of otters and seals; add to these, that amber, ambergris, and other spoils of the ocean, are frequently found upon the coasts.

The inhabitants are a stout, well-made, comely people; the lower sort of a swarthy complexion. The gentry are allowed, by all who have conversed with them, to be most of them polite, shrewd, sensible, lively, active, and intelligent persons; and these, to the number of 100 families, have very handsome, strong, well-built houses, neatly furnished; their tables well served, polished in their manners, and exceedingly hospitable and civil to strangers. Those of an inferior rank are a hardy, robust, and laborious people, who, generally speaking, get their bread by fishing in all weathers in their yaws, which are little bigger than Graveend wherries; live hardily, and in the summer feast mostly on fish; their drink, which, in reference to the British dominions, is peculiar to the country, is called bland, and is a sort of butter-milk, long kept, and very strong. Many live to great ages, though not so long as in former times. In respect, however, to the bulk of the inhabitants, from the poorness of living, from the nature of it, and from the drinking great quantities of corn-spirits of the very worst sort, multitudes are afflicted with an invertebrate scurvy; from which those in better circumstances are entirely free, and enjoy as good health as in any other country in Europe. As they have no great turn to agriculture, and are persuaded that their country is not fit for it, they do not (though probably they might) raise corn enough to support them for more than two-thirds of the year. But they are much more successful in their pasture-grounds, which are kept well inclosed, in good order, and, together with their common, supply them plentifully with beef and mutton. They pay their rents generally in butter at Lammas, and in money at Martinmas. As to manufactures, they make a strong coarse cloth for their own use, as alp. linen. They make likewise of their own wool very fine stockings. They export, besides the different kinds of fish already mentioned, some herrings, a considerable quantity of butter and train-oil, otter and seal skins, and no inconsiderable quantity of the fine stockings just mentioned. Their chief trade is to Leith, London, Hamburgh, Spain, and to the Straits. They import timbers, deals, and some of their beet oats, from Norway; corn and flour from the Orkneys, and from North Britain; spirits, and some other things from Hamburgh; cloths and better sort of linen from Leith; groceries, houfehld furniture, and other necessaries from London. The superior-duties to the earl of Morton are generally let in farm; and are paid by the people in butter, oil, and money. The remains of the old Norwegian constitution are still visible in the division of their lands; and they have some udalmen or freeholders amongst them. But the Scots laws, customs, manners, drefs, and language, prevail; and they have their shire, and other magistrates for the administration of justice, as well as a custom-house, with a proper number of officers. In reference to their ecclesiastical concerns, they have a prebendary, 12 ministers, and an itinerant for Foula, Fair Island, and the Skerries. Each of these ministers has a stipend of between 40 and 50 pounds, besides a house and glebe free from taxes. The number of souls in these islands may be about 20,000.

SHEW-BREAD, the loaves of bread which the priest of the week put every Sabbath-day upon the golden table in the sanctuary, before the Lord, in the temple of the Jews. They were twelve in number, and were offered to God in the name of the twelve tribes of Israel. They were shaped like a brick, were ten palms long and five broad, weighed about eight pounds each. They were unleavened, and made of fine flour by the Levites. The priests set them on the table in two rows, fix in a row, and put frankincense upon them to preserve them from moulding. They were changed every Sabbath, and the old ones belonged to the priest upon duty. Of this bread none but the priests might eat, except in cases of necessity. It was called the bread of faces, because the table of the shew-bread, being almost over against the ark of the covenant, the loaves might be said to be set before the face of God. The original table was carried away to Babylon, but a new one was made for the second temple. It was of wood overlaid with gold. This, with the candlestick and some other spoils, was carried by Titus to Rome.

SHIELD, an ancient weapon of defence, in form of a light buckler, borne on the arm to fend off lances, darts, &c. The form of the shield is represented by the escutcheon in coats of arms. The shield was that part of the ancient armour on which the perons of distinction in the field of battle always had their arms painted; and most of the words used at this time to express the place that holds the arms of families are derived from the Latin name for a shield, scutum. The French escu and escuison, and the English escutcheon, or, as we commonly speak it, escutcheon, are evidently from this origin; and the Italian scudo signifies both the shield of arms and that used in war. The Latin name scutum, for the same thing, seems also to be derived from
The shield in war, among the Greeks and Romans, was not only useful in the defence of the body, but it was also a token, or badge of honour, to the wearer; and he who returned from battle without it was always treated with infamy afterwards. People have at all times thought this honourable piece of the armour the properest place to engrave, or figure on the signs of dignity of the possessor of it; and hence, when arms came to be painted for families in aftertimes, the heralds always chose to represent them upon the figure of a shield, but with several exterior additions and ornaments; as the helmet, supporters, and the ruff.

The form of the shield has not only been found different in various nations, but even the people of the same nation, at different times, have varied its form exceedingly; and among several people there have been shields of several forms and fizes in use, at the fame period of time, and suited to different occasions. The most ancient and universal form of shields, in the earlier ages, seems to have been the triangular. This we see from the several figures engraved on it, as marks of distinction of the person who wore it.

This we see from the several figures engraved on it, as marks of distinction of the person who wore it.

The shield in war, among the Greeks and Romans, was not only useful in the defence of the body, but it was also a token, or badge of honour, to the wearer; and he who returned from battle without it was always treated with infamy afterwards. People have at all times thought this honourable piece of the armour the properest place to engrave, or figure on the signs of dignity of the possessor of it; and hence, when arms came to be painted for families in aftertimes, the heralds always chose to represent them upon the figure of a shield, but with several exterior additions and ornaments; as the helmet, supporters, and the ruff.

The form of the shield has not only been found different in various nations, but even the people of the same nation, at different times, have varied its form exceedingly; and among several people there have been shields of several forms and sizes in use, at the same period of time, and suited to different occasions. The most ancient and universal form of shields, in the earlier ages, seems to have been the triangular. This we see from the several figures engraved on it, as marks of distinction of the person who wore it.

The shield in war, among the Greeks and Romans, was not only useful in the defence of the body, but it was also a token, or badge of honour, to the wearer; and he who returned from battle without it was always treated with infamy afterwards. People have at all times thought this honourable piece of the armour the properest place to engrave, or figure on the signs of dignity of the possessor of it; and hence, when arms came to be painted for families in aftertimes, the heralds always chose to represent them upon the figure of a shield, but with several exterior additions and ornaments; as the helmet, supporters, and the ruff.
Shifters.  

SHIFTERS, on board a man of war, certain men who are employed by the cooks to shift and change the water in which the fish or fish is put, and laid for some time, in order to fit it for the kettle.

SHIFTING a tackle, in sea language, the act of removing the blocks of a tackle to a greater distance from each other, on the object to which they are applied in order to give a greater scope or extent to their purchase. This operation is otherwise called shifting. Shifting the helm denotes the alteration of its position, by putting it towards the opposite side of the ship. Shifting the royal, signifies changing its position on the capterm, from the right to the left, and vice versa.

SILLING, an English silver coin equal to twelve pence or the twentieth part of a pound.

Freherus derives the Saxon silling, whence our shilling, from a corruption of fitqua; proving the derivation by several texts of law, and, among others, by the 26th law, De annuis legatis. Skinner deduces it from the Saxon feild " shield," by reason of the escutcheon of arms thereon.

Bishop Hooper derives it from the Arabic scheed, signifies a weight; but others, with greater probability, deduce it from the Latin siliquae, which signified in that language a quarter of an ounce, or the 48th part of a Roman pound. In confirmation of this etymology, it is alleged, that the shilling kept its original significane, and bore the same proportion to the English pound as siliquae did to the Roman and the Greek, being exactly the 48th part of the Saxon pound; a discovery which we owe to Mr. Lambard*

However, the Saxon laws reckon the pound in the round number at 50 shillings, but they really coined out of it only 48; the value of the shilling was fivepence; but it was reduced to fourpence above a century before the conquest; for several of the Saxon laws, made in Athelstan's reign, oblige us to take this at its true value. Thus it continued to the Norman times, as one of the Conqueror's laws sufficiently arients; and it seems to have been the common coin by which the English payments were adjusted. After the conquest, the French sildus of twopence, which was in use among the Normans, was called by the English name of silling, and the Saxon shilling of fourpence took a Norman name, and was called the great, or great coin, because it was the largest English coin then known in England.

It has been the opinion of the bishops Fleetwood and Gibbon, and of the antiquaries in general, that, though the method of reckoning by pounds, marks, and shillings, as well as by pence and farthings, had been in constant use even from the Saxon times, long before the Norman conquest, there never was such a coin in England as either a pound or a mark, nor any shilling, till the year 1504 or 1505, when a few silver shillings or twelve-pences were coined, which have long since been solely confined to the cabinets of collectors.

Mr. Clark combats this opinion, alleging that some coins mentioned by Mr. Folkes, under Edward I. were probably Saxon shillings new minted, and that the archbishop Aelric expressly says, that the Saxons had three names for their money, viz. mancuses, shillings, and pennies. He also urges the different value of the Saxon shilling at different times, and its uniform proportion to the pound, as an argument that their shilling was a coin; and the testimony of the Saxon glossars, in which the word we have translated pieces of silver is rendered shillings, which, he says, they would hardly have done, if there had been no such coin as a shilling then in use. Accordingly the Saxons expressed their shilling in Latin by felius and argentus. He further adds, that the Saxon shilling was never expressed by solidus till after the Norman settlements in England; and howsoever it altered during the long period that elapsed from the conquest to the time of Henry VII. it was the most constant denomination of money in all payments, though it was then only a species of account, or the twentieth part of the pound Sterling; and when it was again revived as a coin, it leftened gradually as the pound Sterling leftened, from the 28th of Edward III. to the 43d of Elizabeth.

In the year 1560 there was a peculiar sort of shilling struck in Ireland, of the value of ninepence English, which passed in Ireland for twopence. The motto on the reverse was, posid Deum adjutorem meum. Eighty-two of these shillings, according to Malynes, went to the pound; they therefore weighed 69 grains, one-fourth each, which is somewhat heavier in proportion than the English shilling of that time, 62 grains. Whereof went to the pound, each weighing 92 grains, seven-eighths; and the Irish shilling being valued at the Tower at ninepence English, that is, one-fourth part less than the English shilling, it should therefore proportionably weigh one-fourth part less, and its full weight be somewhat more than 62 grains; but some of them found at this time, though much worn, weighed 69 grains. In the year 1598, five different pieces of money of this kind were struck in England for the service of the kingdom of Ireland. These were shillings to be current in Ireland at twopence each; half shillings to be current at sixpence, and quarter shillings at threepence. Pennies and halfpennies were also struck of the same kind, and sent over for the payment of the army in Ireland. The money thus coined was of a very base mixture of copper and silver, and the two years after there were more pieces of the same kinds struck for the same service, which were still worse; the former being three ounces of silver to nine ounces of copper; and the latter only two ounces eighteen pennyweights to nine ounces two pennyweights of the alloy.

The Dutch, Fleming, and Germans, have likewise their shilling, called fielun, sfellings, galin, &c. but these not being of the same weight or fineness with the English shilling, are not current at the same value. The English shilling is worth about 23 French sols; those of Holland and Germany about 11 sols and an half; those of Flanders about nine. The Dutch shillings are also called fol de gros, because equal to twelve gros. The Danes have copper shillings worth about one-fourth of a farthing Sterling.

SHILOH is a term famous among interpreters and commentators upon Scripture. It is found (Gen. xlix. 10.) to denote the Messiah. The patriarch Jacob foretells his coming in these words; "The sceptre shall not depart from Judah, nor a lawgiver from between his feet, until Shiloh come; and unto him shall the gathering of the people be." The Hebrew text reads, עלש מהלל כי עד שילה קומ, All Christian commentators agree, that this word ought to be understood of the Messiah, or Jesus Christ; but all are not agreed about

---

† Gram. Saxonic. p. 15.
about its literal and grammatical signification. St Jerome, who translates it by *Quis intendat ejf,* manifestly reads *Shiloh* "he went," instead of *Shiloh.* The Septuagint have it

衣物的

(As if they had read καὶ instead of ἐκ, i.e. "Until the coming of him to whom it is reserved," or, "Till we see arrive that which is reserved for him.")

It must be owned, that the signification of the Hebrew word *Shiloh* is not well known. Some translate, "the sceptre shall not depart from Judah, till he comes to whom it belongs!" יִשָּׁלוֹה or יִשָּׁלֹה instead of יִשָּׁבָה. Others, "till the coming of the peace-maker!" or, "the pacific;" or, "of prosperity," יִשָּׁלוֹה propterus ejf. *Shiloh* signifies, "to be in peace, to be in prosperity;" others, "till the birth of him who shall be born of a woman that shall conceive without the knowledge of a man," יִשָּׁלוֹה or יִשָּׁלֹה.

Sometimes *Shiloh* signifies, "his kingdom will be established among his people;" but soon after the coming of the Messiah, it was because the kingdom of Saul at Shiloh was acknowledged as king, or confirmed at Shiloh. But in what part of Scripture is it said, that Saul was acknowledged as king or confirmed at Shiloh? If we would understand it of Jeroboam, son of Nebat, the matter is still as uncertain. The Scripture mentions no assembly at Shiloh that admitted him as king. A more modern author derives *Shiloh* from יִשָּׁלֹה, *fatigare,* which sometimes signifies to be weary, to suffer; "till his labour, his sufferings, his passion, shall happen."

But not to amuse ourselves about seeking out the grammatical signification of *Shiloh,* it is sufficient for us to know, that the ancient Jews are in this matter perfectly agreed with the Christians: they acknowledge, that this word stands for the *Messiah* the King. It is thus that the paraphrasts Onkelos and Jonathan, that the ancient Hebrew commentators upon Genesis, and that the Talmudists themselves, explain it. If Jesus Christ and his apostles did not make use of this passage to prove the coming of the Messiah, it was because then the completion of this prophecy was not sufficiently manifest. The sceptre still continued among the Jews; they had still kings of their own nation in the persons of the Herods; but soon after the sceptre was entirely taken away from them, and has never been restored to them since.

The concealed Jews seek in vain to put forced meanings upon this prophecy of Jacob; saying, for example, that the sceptre intimates the dominion of strangers, to which they have been in subjection, or the hope of seeing one day the sceptre or supreme power betted again among themselves. It is easy to perceive, that all this is contrived to deliver themselves out of perplexity. In vain likewise they take refuge in certain princes of the captivity, whom they pretend to have fulfilled beyond the Euphrates, exercising an authority over their nation little differing from absolute, and being of the race of David. This pretended succession of princes is perfectly chimerical; and through at certain times they could show a succession, it continued but a short time, and their authority was too obscure, and too much limited, to be the object of a prophecy so remarkable as this was.

**SHINGLES,** in building, pieces of wood fawn to a certain scantling, or, as is more usual, cleat and made like wedges. There are different sizes; the largest three feet by about six inches, and in thickness tapering from less than three fourths to about the ninth of an inch. There are some two feet, and others eighteen inches in length; these have breadth and thickness corresponding to their length. They are made of different kinds of wood, but cedar affords the lightest and most durable.

**Shingles** are made in, and great numbers annually exported from, many parts of the United States. The want of them is in many countries supplied by thatch, tiles, and slates: the first of these is inferior in every respect; the two others are more secure from fire, but on account of their great weight embarrass the architect, and are not so fit for the construction of large roofs.

**SHIP,** a general name for all large vessels, particularly those equipped with three masts and a bowprit: the masts being composed of a lower mast, topmast, and top-gallant-mast: each of these being provided with yards, sails, &c. Ships, in general, are either employed for war or merchandise.

**Sails of War** are vessels properly equipped with artillery, ammunition, and all the necessary martial weapons and instruments for attack or defence. They are distinguished from each other by their several ranks or classes, called *rates,* as follows: Ships of the first rate mount from 100 guns to 110 guns and upwards; second rate, from 90 to 98 guns; third rate, from 64 to 74 guns; fourth rate, from 50 to 60 guns; fifth rate, from 32 to 44 guns; and sixth rates, from 20 to 28 guns. See the article *Rates.* Vessels carrying less than 20 guns are denominated *flops,* *cutters,* *fire ships,* and *bombs.*

It has lately been procured to reduce the number of these rates, which would be a saving, and also productive of several material advantages.

In Plate CCCCL, is the representation of a first rate, with rigging, &c. the several parts of which are as follow:

Bunt-lines, 68; Cross-trees, 69; Cap., 70; Foretop-gallant-mast, 71; Shrouds, 72; Yard and fall, 73; Backstays, 74; Stay, 75; Lifits, 76; Clew-lines, 77; Braces and pendants, 78; Bowlines and bridles, 79; Flag-staff, 80; Truck, 81; Flag-strap, 82; Flag of the lord-high admiral, 83; Mainmast, 84; Shrouds, 85; Laniards, 86; Runner and tackle, 87; Futtock-shrouds, 88; Top-lantern, 89; Crane of ditch, 90; Stay, 91; Preventer stay, 92; Stay-tackles, 93; Wobbling of the masts, 94; Jeets, 95; Yard-tackles, 96; Lifits, 97; Braces and pendants, 98; Horfes, 99; Sheets, 100; Tacks, 101; Bowlines and bridles, 102; Crow-foot, 103; Cap, 104, 160; Backstays, 161; Derrick and bridles, 123; Birds, 124; Clew-bits, 125; Cross-trees, 126; Stay, 127; Main-topmast, 128; Shrouds and laniards, 129; Yard and fall, 130; Backstays, 131; Stay, 132; Stay-fall and halliards, 133; Lifits, 134; Braces and pendants, 135; Bowlines and bridles, 136; Clew-lines, 137; Flagstaff, 138; Truck, 139; Flag-strap, 140; Flag-standard, 141; Main-topmast, 142; Shrouds and laniards, 143; Cap, 144; Yard and fall, 145; Block for signal halliards, 146; Sheets, 147; Pendant lines, 148; Peck-brails, 149; Stayfall, 150; Stay, 151; Derrick and span, 152; Top, 153; Crossjack-yard, 154; Crossjack-lifits, 155; Crossjack braces, 156; Crossjack slings, 157; Main-topmast, 158; Shrouds and laniards, 159; Yard and fall, 160; Backstays, 161; Stay, 162; Halliards, 163; Lifits, 164; Braces and pendants, 165; Bowlines and bridles, 166; Sheets, 167; Clew-lines, 168; Stayfall, 169; Cross-trees, 170; Cap, 171; Flagstaff, 172; Flag-strap, 173; Truck, 174; Flag-union, 175; Ensign-strap, 176; Truck, 177; Ensign, 178; Stern ladder, 179; Bower cable.

Fig. 2. Plate CCCCLI is a vertical longitudinal section of a drift rate ship of war, with references to the principal parts, which are as follow:

E, The lower gun-deck forward, 34, The knees fore and aft, 35, The spirketings, or the drift break next to each deck, the next under the beams being called clamps, 36, The beams of the middle gun-deck fore and aft, 37, The carlings of the middle gun-deck fore and aft, 38, The fore-bits, 39, The after or main bits, 40, The hatchway to the gunner's and boatswain's forecastle rooms, 44, The jec-capitan.

F, The orlop, 42, 43, 44, The gunner's, boatswain's, and carpenter's forecastle rooms, 45, The beams of the lower gun-deck, 46, 47, The pillars and the riders, fore and aft, 48, The bulkhead of the fore-rooms.

I, The orlop amidships, 63, The cable tire, 64, The main hatchway.

K, The lower gun-deck amidships, 65, The ladder leading up to the middle gun-deck, 66, The lower tire of ports.

N, About the mainmait, 84, The gangways off the quarter-deck, 85, The bulkhead of the coach, 86, The forecastle down to the middle gun-deck, 87, The beams of the upper deck, 88, The gratings about the mainmait, 89, The coach or council-chamber, 90, The forecastle up to the quarterdeck.

S, The state-room, out of which is made the bed-chamber and other conveniences for the commander in chief, 98, The entrance into the gallery, 99, The bulkhead of the great cabin, 100, The stern lights and after galleries.

T, The ward-room, allotted for the lieutenants and marine officers, 101, The lower gallery, 102, The steerage and bulkhead of the wardroom, 103, The whipstaff, commanding the tiller, 104, The after forecastle leading down to the lower gun-deck.

V, Several officers cabins about the mainmait, where the folders generally keep guard.

The section of a windlass ship of war, showing the various frames and hatchways.
Ships are also sometimes named according to the different modes of their construction. Thus we say, a cat-built ship, &c.

To Ship, is either used actively, as to embark any person or put any thing aboard ship; or passively, to receive any thing into a ship; as, "we flapped a heavy tea at three o'clock in the morning."

To Ship, also implies to fix anything in its place; as, to ship the oars, that is, to put them in their rowlocks; to ship the swivel guns, is to fix them in their sockets; to ship the handspikes, &c.

Machine for drawing Bolts out of Ships, an instrument invented by Mr. William Hill for this purpose. His account of which is as follows.:

"First, The use of this machine is to draw the kelson and dead-wood bolts out, and to draw the knee of the head bolts. Secondly, The heads of the kelson bolts heretofore were all obliged to be driven thro' the kelson, the timbers, and keel, to get them out: by this means the kelson is often entirely destroyed, and the large hole the head makes materially wounds the floors; and frequently, when the bolt is much corroded, it tears, and the bolt comes out of the side of the keel.—Thirdly, The dead wood bolts that are driven with two or three drizels, are seldom or never get out, by which means the dead-wood is condemned, when some of it is really serviceable. Fourthly, In drawing the knee of the head-bolts, sometimes the knee starts off, and cannot be got to again, but the upper is forced up, and with this machine may be drawn in; for it has been proved to have more power in lifting a bolt than the machinery."
**Management of Swings at Single Anchor.** is the method of taking care of a ship while riding at single anchor in a tide-way, by preventing her from fouling her anchor, &c. The following rules for this purpose, with which we have been favoured by Mr. Henry Taylor* of North Shields, will be found of the utmost consequence.

1. **When the ship will back.**

   - If the wind is cro's, or nearly cro's, off shore, or in the opposite direction, ships will always back. This is done by the mizen-topgallant, as it is, by the mizen-topgallant, and, if possible, by the topgallant staysail.
   - In backing, a ship should always wind with a taught cable, that it may be certain the anchor is drawn round. In case there is not a sufficiency of wind for that purpose, the ship should be hove up.

2. **How the yards ought to be braced.**

   - When the wind is so far aft that the ship will not back (which should not be attempted if, when the tide eases, the ship forges ahead, and brings the buoy on the lee quarter), the main yards must be set ahead; if the wind is far aft, and blows fresh, the utmost care and attention is necessary, as ships riding in this situation often break their braces and come to windward of their anchors again.
   - It should be observed, that when the ship lies in the rock light situation, the after yards must be braced forward, and the fore yards the contrary way; the will lay fife, as the buoy can be kept on the lee quarter, or suppoze the helm is sport, as long as the buoy is on the larboard quarter. With the helm thus, and the wind right ait, or nearly so, the larboard main and fore braces should be hauled in. This supposes the main braces to head forward.

3. **Riding windward side in danger of breaking her helm.**

   - When the ship begins to tend to leeward, and the buoy comes on the weather quarter, the first thing to be done is to brace about the fore yard; and when the wind comes near the beam, set the fore-bygallant, and keep it flanging until it shakes; then brace all the yards sharp forward, especially if it is likely to blow strongly.

   - When laying in the aforesaid position, and the breaks her sheer, brace about the main yard immediately; if she recovers and brings the buoy on the lee or larboard quarter, let the main yard be again braided about; but if she comes to a leeward the other way, by bringing the buoy on the other quarter, change the helm and brace the fore-yard to.

4. **Tending to leeward when the ship must be let as head.**

   - When the ship tends to windward and must be let as head, hoist the fore-topgallant as soon as it will stand, and when the buoy comes on the lee quarter, haul down the fore-bygallant, brace to the fore-yard, and put the helm a-lee; for till then the helm must be kept a-weather and the yards full.

   - When the ship rides leeward tide, and the wind in.

   - How to create care should be taken to give her more care manageable in time, otherwise the anchor may flart, and probably it will be troublesome to get her brought up again; and this care is the more necessary when the ship rides in the hause of another ship. Previous to giving a long service it is usual to take a weather-bit, that is, a turn of the cable over the windlass end, so that in veering away the ship will be under command. The service ought to be greased, which will prevent its chafing in the hause.

   - If the gale continues to increase, the topmasts should be struck in time; but the fore-yard should seldom, if ever, be lowering down, that in case of parting the fore staysail may be ready to be set. At such times there should be more on deck than the common anchor-watch, that no accident may happen from inattention or falling asleep.

   - In a tide-way a second anchor should never be let go but when absolutely necessary; for a ship will sometimes ride easier and safer, especially if the sea runs high, with a very long scope of cable and one anchor, than with two.

---

* It has been thought by some theorists, that ships should be sheeted to leeward of their anchors; but experience and the common practice of the best informed seamen are against that opinion; for it is found, that when a ship rides leeward tide and sheeted to windward, with the wind two or three points upon the bow, and blowing hard in the interval between the squalls, the sheet will draw her towards the wind's eye; so that when the next squall comes, before she be profit able of her anchor, it is probable there will be a lull again, and the spring which she is got by the sheet will greatly ease her during the squall.

Every seaman knows that no ship without a rudder, or the helm left loose, will wear; they always stand in such situations fly to; this proves that the wind pressing upon the quarter and the helm alee, a ship will be left liable to break her sheet than when the helm is a-weather. Besides, if the helm is a-lee when the breaks her sheet, it will be a-weather when the wind comes on the other quarter, as it ought to be until the either swinging to leeward, or bringing the buoy on the other quarter. Now if the ship breaks her sheet with the helm a-weather, it throws her head to the wind suddenly as fierce to give time to brace the yards about, and very probably she will fall over her anchor before the fore staysail can be got up.
The "hilofo-"physical Ship.

The particular duty of the chief mate.

Method for the safe removal of sunk Ships as have been driven on shore.

Philosophical Transactions, vol. lxx. part r.

Shi [371] Shi

left length and two cables, however, it is advisable, as a preventive, when ships have not room to drive, and the night is dark, to let fall a second anchor under foot, with a range of cable along the deck. If this is not thought necessary to be done, the deep-sea lead should be thrown overboard, and the line frequently handled by the watch, that they may be assured the rides fall.

If at any time the anchor-watch, presuming on their own knowledge, should wind the ship, or suffer her to break her anchor without calling the mate, he should immediately, on the very first opportunity, oblige the crew to heave the anchor in sight; which will prevent the committal of the like fault again; for besides the share of trouble the watch will have, the rest of the crew will blame them for neglecting their duty.

Prudent mates seldom lie a week in a road-stead without having their anchor in sight, even though they have not the least suspicion of its being foul. There are other reasons why the anchor should be looked at; sometimes the cable receives damage by sweeping wrecks or anchors that have been lost, or from rocks or fiones; and it is often necessary to trip the anchor, in order to take a clearer birth, which should be done as often as any ship brings up too near.

On January 1, 1779 (says Mr. Barnard), in a most dreadful storm, the York East Indiaman, of eight hundred tons, homeward bound, with a pepper cargo, parted her cables in Margate roads, and was driven on shore, within one hundred feet of the head and thirty feet of the side of Margate pier, then drawing twenty-two feet six inches water, the flow of a good spring tide being only fourteen feet at that place.

On the third of the same month I went down, as a ship-builder, to assist, as much as lay in my power, my worthy friend Sir Richard Hodham, to whom the ship belonged. I found her perfectly upright, and her shore (or side appearing) the same as when first built, but sunk to the twelve feet water-mark fore and aft in a bed of chalk mixed with a stiff blue clay, exactly the shape of her body below that draft of water, and from the rudder being torn from her as the struck coming on shore, and the violent agitation of the sea after her being there, her stem was so greatly injured as to admit free access thereto, which filled her for four days equal to the flow of the tide. Having fully informed myself of her situation and the flow of spring tides, and being clearly of opinion she might be again got off, I recommended, as the first necessity (step) the immediate discharge of the cargo; and, in the progress of that business, I found the tide always flowed to the same height in the hold. The firm tight bulkheads or partitions were made as near the extremes of the ship as possible. The ceiling or inlaid planks of the ship were very securely caulked up to the lower deck, and the whole formed a complete ship with a flat bottom within side, to swim the outside leaky one; and the bottom being deprived of fix feet below the external water, refitted the ship's weight above it equal to five hundred and eighty-one tons, and safely conveyed her to the dry-dock at Deptford."

"The moment the ship lifted I discovered she had received more damage than was at first apprehended, her leaks being such as filled her from four to eighteen feet water in an hour and an half. As nothing effectual was to be expected from pumping, several scuttles or holes in the ship's side were made, and valves fixed thereon, to draw off the water at the lowest ebb of the tide, to facilitate the discharge of the remaining part of the cargo; and, after many attempts, I succeeded in an external application of sheepskin sewed on a fall and thrust under the bottom, to stop the body of water from running so furiously into the ship. This business effected, moderate pumping enabled us to keep the ship to about six feet water at low water, and by a vigorous effort we could bring the ship so light as (when the cargo should be all discharged) to be easily removed into deeper water. But as the external application might be disturbed by so doing, or totally removed by the agitation of the ship, it was absolutely necessary to provide some permanent security for the lives of those who were to navigate her to the river Thames. I then recommended as the cheapest, quickest, and most effectual plan, to lay a deck in the hold, as low as the water could be pumped to, framed so firmly and securely, and caulked so tight, as to swim the ship independent of her own leaky bottom.

"Beams of fir timber twelve inches square were placed in the hold under every lower deck beam in the ship, as low as the water would permit; these were in two pieces, for the convenience of getting them down, and also for the better fixing them of an exact length, and well bolted together when in their places. Over these there were laid long Damicke deals of two inches and an half thick, well nailed and caulked. Against the ship's side, all fore and aft, was well nailed a piece of fir twelve inches broad and fix inches thick on the lower and three inches on the upper edge, to prevent the deck from rising at the side. Over the deck, at every beam, was laid a crofs piece of fir timber fix inches deep and twelve inches broad, reaching from the pillar of the hold to the ship's side, on which the shores were to be placed to refit the pressure of the water beneath. On each of these, and against the lower-deck beam, at equal distances from the side and middle of the ship, was placed an upright shore, fix inches by twelve, the lower end let two inches into the crofs piece. From the foot of this shore to the ship's side, under the end of every lower deck beam, was placed a diagonal shore fix inches by twelve, to eafe the ship's deck of part of the strain by throwing it on the side. An upright shore of three inches by twelve was placed from the end of every crofs piece to the lower deck beams at the side, and one of three inches by twelve on the midship end of every crofs piece to the lower deck beam, and nailed to the pillars in the hold. The firm tight bulkheads or partitions were made as near the extremes of the ship as possible. The ceiling or inlaid planks of the ship were very securely caulked up to the lower deck, and the whole formed a complete ship with a flat bottom within side, to swim the outside leaky one; and the bottom being depressed fix feet below the external water, refitted the ship's weight above it equal to five hundred and eighty-one tons, and safely conveyed her to the dry-dock at Deptford."
SHIP-BUILDING.

SHIP-BUILDING, or NAVAL ARCHITECTURE, is the art of constructing a ship so as to answer a particular purpose either of war or merchandise. To whom the world is indebted for the invention of ships is, like all other things of equal antiquity, uncertain. A very small portion of art or contrivance was seen in the first ships; they were neither strong nor durable; but confided only of a few planks laid together, without beauty or ornament, and just so compassed as to keep out the water. In some places they were only the hulks or flocks of trees hollowed, and then confided only of one piece of timber. Nor was wood alone applied to this use; but any other buoyant materials, as the Egyptian reed papyrus, or leather, of which the primitive ships were frequently composed; the bottom and sides being extended on a frame of thin battens or scantlings, of flexible wood, or begirt with sarsens, such as we have frequently beheld amongst the American savages. In this manner they were often navigated upon the rivers of Ethiopia, Egypt, and Salaman Arabia, even in later times. But in the third of them, we find no mention of any thing but leather or hides sewed together in a vessel of this kind, Dardanus secured his retreat to the country afterwards called Troy, when he was compelled by a terrible deluge to forsake his former habitation of Samothrace. According to Virgil, Charon's infernal boat was of the same composition. But as the other arts extended their influence, naval architecture likewise began to emerge from the gloom of ignorance and barbarism; and as the ships of those ages were increased in bulk, and better proportioned for commerce, the appearance of those floating citadels of martial form, full of living men, flying with seemingly expanded wings over the surface of the untravelled ocean, struck the ignorant people with terror and astonishment; and hence, as we are told by Aristophanes, arose the fable of Perseus flying to the Gorgons, who was actually carried thither in a ship! Hence, in all probability, the famous story of Triplexanus riding on a winged dragon is deduced, only because he failed from Athens, in the time of a great dearth, to a more plentiful country, to supply the necessities of his people. The fiction of the flying horse Pegasus may be joined with these, who, as several mythologists report, was nothing but a ship with feet, and thence fled to be the offspring of Neptune the sovereign of the sea; nor does there appear any other foundation for the stories of griffins, or of ships transformed into birds and fishes, which we so often meet with in the ancient poets. So acceptable to the world ages of the world were inventions of this nature, that whoever made any improvements in navigation or naval architecture, building new ships better fitted for strength or swiftness than those used before, or rendered the old more commodious by additional contrivances, or discovered countries unknown to former travellers, were thought worthy of the greatest honours, and often associated into the number of the deified heroes. Hence we have in astronomy the signs of Aries and Taurus, which were no other than two ships: the former transported Phryxus from Greece to Colchos, and the latter Europa from Phoenicia to Crete. Argos, Pegaseus, and Perseus, were likewise new ships of a different sort from the former, which being greatly admired by the barbarous and uninstructed people of those times, were translated among the stars, in commemoration of their inventors, and metamorphosed into constellations by the poets of their own and of succeeding ages.

The chief parts, of which ships anciently consisted, were three, viz. the belly, the prow, and the stern: these were again composed of other smaller parts, which shall be briefly described in their order. In the description, we chiefly follow Scheffer, who hath so copiously treated this subject, and with such industry and learning collected whatever is necessary to illustrate it, that very little room is left for enlargement by those who incline to pursue this investigation.

In the belly, or middle part of the ship, there was carina, or the "keel," which was composed of wood; it was placed at the bottom of the ship, being designed to cut and glide through the waves, and therefore was not broad, but narrow and sharp; whence it may be perceived that not all ships, but only the greves, which ships of war are called, whose bellies were straight and of a small circumference, were provided with keels, the rest having usually flat bottoms. Around the outside of the keel were fixed pieces of wood, to prevent it from being damaged when the ship was first launched into the water, or afterwards struck on any rocks; these were called circumutorum, in Latin circuli.

Next to the keel was the "pump," or "well-room," within which was contained the actum, or "pump," through which water was conveyed out of the ship.

After this, there was immersum, or the "second keel," somewhat resembling what is now called the keelson, it was placed beneath the pump, and called fundatus, or "sunken." By some it is falsely supposed to be the same with foresi.

Above the pump was an hollow place, called by Herodotus nagean, by Pollux nutes, and by others, because large and capacious, after the form of a belly; by the Latin, fonsa. This was formed by crooked ribs, with which it was surmounted, which were pieces of wood rising from the keel upwards, and called by Hesychius ruma, and by others, rima, the belly of the ship being contained within them: in Latin, cotl, and in English, timbers. Upon these were placed certain planks, which Aristophanes calls ekerum, or "corkings.

The termus, latus, or "sides" of the ship, compassed all the former parts on both hands; these were composed of large rafters extending from prow to stern, and called latera, and enkerum, because by them the whole fabric was begirt or surrounded.

In both these sides the rowers had their places, called ruma, and erume, in Latin fori, and transi, placed above one another; the lowest was called subi, and those that laboured therein, superi, in the middle, ej, the man ej, the uppermost ej, whence the

SHIP-BUILDING.

2. πρώην, the "prow or fore-deck," whence it is sometimes called μερών, and commonly distinguished by other metaphorical titles taken from human faces. In some ships there is mention of two prows, as also two sterns; such was Danaë's ship adorned by Minerva when she fled from Egypt. It was usual to beautify the prow with gold and various sorts of paint and colours; in the primitive times red was most in use; whence Homer's ships were commonly dignified with the titles of μερών, and μερώνωρ, or "red-faced," the blue likeness, or sky-like, was frequently made use of, as bearing a near resemblance to the colour of the sea; whence we find ships called by Homer μερώνες, and by Ἀρίστοφανας κόσμια μοίες. Several other colours were also made use of; nor were they barely varnished over with them, but very often annealed by wax melted in the fire, so as neither the sun, winds, nor water, were able to deface them. The art of doing this was called from the wax τετρισσαμένος, from the fire θυσία, which is described by Vitruvius, and mentioned in Ovid.

Carulea cerata acceptaundo ratas.

The azure waves receive the waxed ships.

After all, the ship being bedecked with garlands and flowers, the mariners also adorned with crowns, the was launched into the sea with loud acclamations and other expressions of joy; and being purified by a priest with a lighted torch, an epistle and brimstone, or after some other manner, was consecrated to the god whose image the bore.

The ships of war of the ancients were distinguished from other kinds of vessels by various turrets and accommodations of building, some to defend their own soldiers, and others to annoy the enemy; and from one another, in latter ages, by several degrees or ranks of oars, the most usual number of which was four or five, which appear not to have been arranged, as some imagine, on the same level in different parts of the ship; nor yet, as others have supposed, directly above one another's heads; but their seats being placed one behind another, ascended gradually, like stairs. Ptolemy Philopater, urged by a vain-glorious desire of exceeding all the world besides in naval architecture, is said to have enlarged the number of banks to 40; and the ship being otherwise in equal proportion, raised her to such an enormous bulk, that the appeared at a distance like a floating mountain or island; and, upon a nearer view, like a prodigious castle on the ocean. She was 280 cubits long, 38 broad, and 48 high (each cubic being 1 English foot 5½ inches), and carried 400 rowers, 400 oarsmen, and 3000 soldiers. Another which the same prince made to sail on the Nile, we are told, was half a stadium long. Yet these were nothing in comparison of Hiero's ship, built under the direction of Archimedes; on the structure whereof Mofchion wrote a whole volume. There was wood enough employed in it to make 50 galleys; it had all the variety of apartments of a palace; such as banqueting-rooms, galleries, gardens, fishponds, stables, mills, baths, and a temple to Venus. The floors of the middle apartment were all laid, and represented in various colours the stories of Homer's Iliad. The ceilings, windows, and all other parts, were finished with wonderful art, and embellished with all kinds of ornaments. In the uppermost apartment there was a spacious gymnium, or place for exercise, and water was conveyed to the garden by pipes, some
SHIPBUILDING.

Some of hardened clay, and others of lead. The floors of the temple of Venus were inlaid with agates and other precious stones; the inside lined with cypress wood; the windows adorned with ivory paintings and small statues. There was likewise a library. This vessel was adorned on all sides with fine paintings. It had 20 benches of oars, and was encompassed with an iron rampart, eight towers, with walls and bulwarks, furnished with machines of war, particularly one which threw a stone of 500 pounds, or a dart 12 cubits long, the space of half a mile, with many other particulars related by Athenaeus. Caligula likewise built a vessel adorned with jewels in the poop, with fans of many colours, and furnished with large porticoes, banquets, and banquet-rooms, besides rows of vines, and fruit-trees of various kinds. But these, and all such monstrous fabrics, served only for show and ostentation, being rendered by their vast bulk unwieldy and unfit for service. Athenaeus informs us, the common names they were known by, were Cyclopes, or Ætna, i.e. "islands, or mountains," to which they seemed nearly equal in bigness; confounding, as some report, of as many materials as would have composed 50 triremes, or ships of three banks.

The vessels employed by the northern nations appear to have been still more imperfect than those of the Romans; for a law was enacted in the reign of the emperor Honorius, 24th September, A. D. 418, inflicting capital punishment on any who should intrude the barbarians in the art of ship-building; a proof at once of the great estimation in which this science was then held, and of the ignorance of the barbarians with regard to it.

The fleet of Richard I. of England, when he weighed anchor for the holy war from Messina, in Sicily, where he had passed the winter, A. D. 1190-1, is said to have consisted of 150 great ships and 53 galleys, besides banks, tartans, &c. What kinds of ships these were is not mentioned. To the crusaders, however pernicious in other respects, this science seems to owe some improvements; and to this particular one we are indebted for Richard's marine code, commonly called the "Laws of Oleron," from the name of a small island on the coast of France, where he composed them, and which most of the nations in Europe have made the basis of their maritime regulations. Those ships, if they merited the name of ships, were probably very small, as we find that so long after as the time of Edward I. anno 1304, 40 men were deemed sufficient to man the belt and largest vessels in England; and that Edward the Third, anno 1335, ordained the mayor and sheriffs of London to "take up all ships in their port, and all other ports in the kingdom, of the burden of 40 tons and upwards, and to furnish the same with armed men and other necessaries of war, against the Scots his enemies, confederated with certain persons of foreign nations." Edward the Third's fleet before Calais, anno 1347, consisted of 738 English ships, carrying 14,926 mariners, being on an average but 20 men to each ship; 15 ships and 459 mariners, from Bayonne in Guiprue, being 30 men to each ship; 7 ships and 184 men from Spain, which is 26 men to each ship; one from Ireland, carrying 25 men; 14, from Flanders, with 133 men, being scarcely 10 men to each ship; and one from Guelder, with 24 mariners. Fifteen of these were called the king's own ships, manned with 419 mariners, being somewhat under 17 to each ship.

Historians represent the vessels of Venice and Genoa as the largest and the best about this time, but they were soon exceeded in size by the Spanish vessels called carracks, some of which carried cannon; and these again were exceeded by the vessels built by the northern people, particularly those belonging to the Hanse towns.—In the 14th century, the Hanseatics were the sovereigns of the northern seas, as well without as within the Baltic; and their ships were so large, that foreign princes often hired them in their wars. According to Hakluyt, an English ship from Newcastle, of 200 tons burden, was feized in the Baltic by those of Wismar and Rølck, anno 1394; and another English vessel of the same burden was violently feized in the port of Libron, anno 1412.

Soon after ships of a much larger size were constructed. It is mentioned that a very large ship was built, anno 1449, by John Taverner of Hull; and in the year 1455, king Henry IV., at the request of Charles king of Sweden, granted a licence for a Swedish ship of the burden of a thousand tons or under, laden with merchandise, and having 120 persons on board, to come to the ports of England, there to dipose of their lading, and to trade back with English merchandise, paying the usual customs. The invention of the trombon, an eminent merchant, who had been five times mayor of Bristol, in Ratcliff-church at Bristol, anno 1474, mentions his having forfeited the king's peace, for which he was condemned to pay 300 marks; in lieu of which sum, king Edward IV. took of him 2470 tons of shipping, amongst which there was one ship of 900 tons burden, another of 500 tons, and one of 400, the rest being smaller.

In the year 1506, king James IV. of Scotland built the largest ship which had hitherto been seen, but which was lost in her way to France in the year 1512, owing probably to a defective construction, and the unskilfulness of the crew in managing so large a ship—About this time a very large ship was likewise built in France. In the fleet fitted out by Henry VIII., anno 1512, there was one ship, the Regent, of 1000 tons burden, one of 500, and three of 400 each. A ship still larger than the Regent was built soon after, called Henri Grace Dieu! In the year 1522 the first voyage round the globe was finished.

The English naval historians think that ships carried cannon on their upper decks only, and had not gunsports before the year 1545; and it is certain that many of the largest ships in former times were fitted out from harbours, where ships of a moderate size now would not have water enough to float them. In 1575 the whole of the royal navy did not exceed 24 ships, and the number of merchant-ships belonging to England amounted to no more than 135 vessels above 100 tons, and 656 between 40 and 100 tons. At Queen Elizabeth's death, anno 1603, there were not above four naval merchant-ships in England of 400 tons burden each.—Trad,
the smallest 600 tons, carrying 150 men and 30 guns. Smaller vessels were occasionally hired by her from private owners.

In the memorable sea-fight of Lepanto between the Turks and Christians, anno 1571, no vessels were employed but galleys; and it would appear from the carcases of some of them, which are still preserved in the arsenal at Venice, that even these were not so large or so well constructed as those of our times. The Invisible Armada, as Spanish vanity styled it, once the terror and admiration of nations, in the pompous and exaggerated descriptions of which the Spanish authors of those times dwelt with so much apparent pleasure, consisted of 130 ships, near 100 of which were the flanched that had yet been seen on the ocean. The largest of these, however, would be no more than a third-rate vessel in the British navy, and they were so ill constructed that they would neither move easily, fail near the wind, nor be properly worked in tempestuous weather. The whole of the naval force collected by Queen Elizabeth to oppose this formidable fleet, including hired vessels, tenders, storeships, &c. amounted to no more than 1,300 ships, near 100 of which were the flanched that had yet been seen on the ocean.

Ship-building began now to make a considerable progress in Britain. Both war and trade required an increase of shipping; so that, in the year 1670, the annual charge of the navy was reported to be £7,500,000; and in 1678 the navy consisted of 83 ships, of which 58 were of the line. At this time the exports amounted to ten millions per annum; and the balance of trade was two millions. In 1689 there were 173 ships, great and small, in the royal navy, and it has been constantly increasing; so that in 1761 the ships in the navy amounted to 372, of which 129 were of the line; and in the beginning of the year 1795, the total amount was above 430.

As ships of the common construction are found to be very defective in many particulars, various methods have therefore from time to time been proposed to remove some of the bad qualities they possess. As it would be an endless task to enumerate the different inventions for this purpose, therefore a few of them only will be mentioned.

In 1663 Sir William Petty constructed a double ship, or rather a single ship with a double bottom, which was found to fail considerably farther than any of the ships with which it had an opportunity of being tried. Her first voyage was from Dublin to Holyhead; and in her return, she turned into that narrow harbour against wind and tide, among rocks and ships, with such dexterity as many ancient seamen confessed they had never seen the like.

This vessel with 70 tons load was lost in a dreadful tempest.

This subject was again revived by Mr. Gordon, in his Principles of Naval Architecture, printed at Aberdeen anno 1784; where, having delivered his sentiments on the construction of large mails, he says: "These experiments likewise point out to us methods by which two vessels may be laterally connected together, though at a considerable distance from each other, in a manner sufficiently strong, with very little increase of weight or expense of materials, and without exposing much surface to the action or influence of the wind or the waves, or obstructing their motion in any considerable degree, and consequently without being much opposed by them on that account under any circumstances; and if vessels are judiciously constructed with a view to such a junction, it would be no easy matter to enumerate all the advantages that may be obtained by this mean."

He then enumerates the advantages that double vessels would have over those of the common construction. Soon after double ships were actually built by Mr. Miller of Dallington.

Another plan was proposed by Mr. Gordon to make a ship fail fast, draw little water, and to keep a good wind. For this purpose, the bottom (he says) should be formed quite flat, and the sides made to rise perpendicular from it, without any curvature; which would not only render her more steady, as being more opposed to the water in rolling, but likewise more convenient for rowing, &c. while the simplicity of the form would contribute greatly to the ease and expedition with which she might be fabricated. Though diminishing the draught of water of the ship, ceteris paribus, undoubtedly the most effectual method of augmenting the velocity with which vessels go before the wind; yet, as it proportionally diminishes their hold of the water, it renders them extremely liable to be driven to leeward, and altogether incapable of keeping a good wind. This defect may, however, be remedied, in a simple and effectual manner, by proportionally augmenting the depth of keel, or, as far as a keel would be inconvenient on many accounts, proportionally increasing their number; as, in place of adding a keel eight feet deep to a vessel drawing fix feet water, to afford to different parts of her flat bottom, which would be well adapted for receiving them, fix different keels of two feet deep each at equal distances from each other, with proper intervals between; which will be found equally effectual for preventing these pernicious effects. Four such, indeed, would have answered the purpose as well as the eight feet keel, were it not for the superior preservation or resistance of the lower water (A).

Thus then it appears, that a vessel drawing eight feet water only, keels and all, may be made to keep as good a wind, and perhaps as well as if the whole were not so much opposed, or by the creating the number of keels or the raising the depth of the keel is increased, the vessel would be rendered more steady, and be enabled to face the wind better.
SHIP-BUILDING.

Book I. Containing the Method of delineating the Form of Sections of a Ship.

Chap. I. Of the Properties of Ships.

A ship ought to be constructed so as to answer the particular purpose for which she is intended. It would be an easy matter to determine the form of a ship intended to fail by means of oars; but, when sails are used, a ship is then acted upon by two elements, the wind and water: and therefore it is much more difficult than is commonly imagined to ascertain the form of a ship so as to answer in an unfavourable as well as a favourable wind; the ship at the same time having a cargo of a certain weight and magnitude. Every ship ought to fail well, but particularly when the wind is upon the beam; for this purpose a consideration of the length in proportion to the breadth is necessary; and the plane of resistance should be the least possible. The main frame should also be placed in a proper situation. A ship, or according to the experiments of Mr. Chapmann, its place is variable with the velocity of the wind; the mean place of the main frame has, however, been generally eliminated to be about one-twelfth of the length of the keel before the middle. Without a sufficient degree of stability a ship will not be able to carry a press of sail: a great breadth in proportion to the length and low upper-works will augment the stability. The following particulars being attended to, the above property will be gained, and the ship will also steer well. The wing tricorn should be carried pretty high; the fathom-pieces well formed, and not fall below the load water-line: the lower part of the frame to be a portion of a circle, and to have a considerable rake; the forecastle to be nearly perpendicular to the keel; and all the upper works kept as low as possible.

Many ships from construction are liable to make much lee-way. This may in a great measure be avoided by giving the ship a long keel, little breadth, and a considerate good depth in the hold; whence the bow will meet with little resistance in comparison to the side, and therefore the ship will not fall much to the leeward.

Another very great retardation to the velocity of a ship is her pitching. The principal remedy for this is to smoothly increase the length of the keel and floor, to diminish the rising afore and abaft, and to construct the hull in such a manner that the contents of the fore-body may be duly proportioned to the contents of the after-body.

In a ship of war the lower tier of guns ought to be of a sufficient height above the water, otherwise it will be impossible to work the lee-guns when it blows hard. This property will be obtained by giving her a long floor-timber, little rising, a full midship frame, light upper works, and the wing tricorn not too high: And in every ship the extreme breadth ought always to be higher afore and abaft than at midships.

A merchant ship, besides being a fast sailor, ought Properties to carry a considerable cargo in proportion to its length, to fail with little ballast, and to be navigated with few hands.

That a ship may take in a considerable cargo, it should to take in a great cargo,
should have a great breadth and depth in proportion to its length, a full bottom, and a long and flat floor. But a ship of this construction will neither fail fast, nor carry much fail.

If a ship be filled out much towards the line of flotation, together with low upper works, she will require little ballast: and that ship which is stiff from construction is much better adapted for failing fast than one which, in order to carry the same quantity of canvas, is obliged to be loaded with a much greater weight: for the resistance is as the quantity of water to be removed, or nearly as the area of a transverse section of the immersed part of the body at the midship frame; and a body that is broad and shallow is much stiffer than one of the same capacity that is narrow and deep.

"The advantages (says Mr Gordon) are numerous, important, and obvious. For it is evident, that by enlarging, perhaps doubling, the breadth of vessels, and forming their bottoms flat and well furnished with keels, they must, in the full place, become much fleadier, roll little, if any, and be enabled to carry greatly more load,: and that in a manner inferior to the same time that they would be in no danger of being dismantled or overfet, unless the masts were of a molt extraordinary height indeed. Secondly, They would have little or no occasion for ballast, and if any was used, could incur less danger from its shifting. Thirdly, That there would be much more room upon deck, as well as accommodation below; the breadth being so much increased without any diminution of the height above the load-water line. Fourthly, That they would deviate much from the intended course, and penetrate the water much easier in the proper direction: for doubling the breadth, without any increase of weight, would diminish the depth or draught of water one half; and though the extent of the directly opposing surface would be the same as before, yet the vessel in moving would meet with half the former resistance only: for the great is the difference between the preflure, force, or reaction, of the upper and the under water. Fifthly, That they would by this means be adapted for lying unsupported in docks and harbours when dry, be rendered capable of being navigated in shallow water, and of being benefited by all the advantages attending that very important circumstance; and it is particularly to be observed, that making vessels which may be navigated in shallow water, may, in many respects, justly be regarded as a matter of equal importance with increasing the number of harbours, and improving them, as having identically the same effects with regard to navigation; at the same time, that the benefits which would result from such circumstances are obtained by this means without either expence, trouble, or inconvenience: besides, it would not only enable vessels to enter many rivers, bays, and creeks, formerly inaccessible to ships of burden, but to proceed to such places as are most land-locked, where they can lie or ride most secure, and with least expence of men and ground tackle. As ships of war would carry their guns well by being fo steady, there could be but little occasion for a high topside, or much height of hull above water; and as little or no ballast would be required, there would be no necessity, as in other vessels, for increasing their weight on that account, and thereby precluding them deeper into the water. These are very important circumstances, and would contribute much to improve the failing of such vessels." From whence it appears, that there would be united, what has hitherto been deemed irreconcilable, the greatest possible stability, which is nearly as the area of a transverse section of the immersed part of the body at the midship frame: and a body that is broad and shallow is much stiffer than one of the same capacity that is narrow and deep. A ship of this construction may take in a considerable cargo in proportion to her size; but if deeply loaded will not fail fast, for then the area of a section of the immersed part at the midship frame will be very considerable; and as the falls of such a ship must necessarily be large, more hands will therefore be required.

The less the breadth of a ship, the fewer hands will be necessary to work her; as in that case the quantity of fail will be less, and the anchors also of less weight. We shall gain much (says M. Bouguer) by making the extreme breadth no more than the fifth or sixth part Navire.

In order to obtain the preceding properties, very opposite rules must be followed; and hence it appears to be impossible to construct a ship so as to be possessed of them all. The body, however, must be so formed, that as many of these properties may be retained as possible, always observing to give the preference to those which are most required. If it is known what particular trade the ship is to be employed in, those qualities are then principally to be adhered to which are most essentially necessary for that employment.

It may easily be demonstrated that small ships will not have the same advantages as large ones of a similar form, when employed in the same trade: for a large ship will not only fail faster than a small one of a similar form, but will also require fewer hands to work her. Hence, in order that a small ship may possess the same advantages as a large one, the corresponding dimensions will not be proportional to each other. The reader will see in Chapman's Architetaura Nuvalis Mercatoria ample tables of the several dimensions of ships, of different classes and sizes, deduced from theory combined with experiments. Tables of the dimensions of the principal ships of the British navy, and of other ships, are contained in the Ship-builder's Repository, and in Murray's Treatise on Ship-building.

CHAP. II. Of the different Plans of a Ship.

When it is proposed to build a ship, the proportional size of every part of her is to be laid down; from whence the form and dimensions of the timbers, and of every particular piece of wood that enters into the construction, is to be found. As a ship has length, breadth, and depth, three different plans at least are necessary to exhibit the form of the several parts of a ship: these are usually denominated the sheer plan, the half breadth and body plan.

The sheer plan or draught, otherwise called the plan of elevation, is that section of the ship which is made on a vertical plane passing through the keel. Upon elevation, this plan is laid down the length of the keel; the height and rake of the stem and sternpost; the situation

Vol. XVII.
and height of the midship and other frames; the place
of the masts and channels; the projection of the head
and quarter gallery, and their appendages; and in a ship
of war the positions and dimensions of the gun-ports.
Several imaginary lines, namely, the upper and lower
heights of breadth lines, water lines, &c. are also drawn
in this plan.

The \textit{half-breadth} or \textit{floor-plan}, or, as it is frequently
called the \textit{horizontal} plane, contains the several half-
breadths of every frame of timbers at different heights;
ribs, water lines, &c. are also described on this
plane.

The \textit{body plan}, or \textit{plane of section}, is a section of the
ship at the midship frame or breadth frame, perpendicular
to the two former. The several breadths, and the
particular form of every frame of timbers, are described
on this plane. As the two sides of a frame are similar to
each other, it is therefore unnecessary to lay down both;
hence the frames contained between the main frame and
the flem are described on one side of the middle line,
commonly on the right hand side, and the after frames
are described on the other side of that line.

Several lines are described on these planes, in order
the more readily to affilt in the formation of the tim-
ers; the principal of which are the following:

The \textit{top-timber line}, is a curve limiting the height of
the ship at each timber.

The \textit{top-timber half-breadth line}, is a section of the
ship at the height of the top-timber line, perpendicular
to the plane of elevation.

The \textit{height of breadth lines}, are two lines named the
upper and lower heights of breadth. These lines are
described on the plane of elevation to determine the
height of the breadth part of the ship at each timber;
and being described in the body plan, limits the height
and breadth of each frame at its breadth part.

The \textit{half-breadth}, is a section of the ship at the
breadth part, perpendicular to the sheer plan, and
represents the greatest breadth at the outside of every
timber.

\textit{Water lines}, are lines supposed to be described on the
bottom of a ship when afloat by the surface of water;
and the uppermost of these lines, or that described by
the water on the ship's bottom when sufficiently load-
ed, is called the \textit{load water line}. According as the ship
is lightened, she will rise higher out of the water;
and hence new water lines will be formed. If the ship
be lightened in such a manner that the keel may preserve
the same inclination to the surface of the water, these
lines will be parallel to each other; and if they are par-
allel to the keel, they will be represented by straight
lines parallel to each other in the body plan; otherwise
by curves. In the half-breadth plan, these lines are
curves limiting the half-breadth of the ship at the height
of the corresponding lines in the sheer plan. In or-
der to distinguish the lines, they are usually drawn in
green.

\textit{Rikhard lines}, are curves on a ship's bottom by the in-
tersection of a plane inclined to the plane of elevation;
and are denominated \textit{diagonal} or \textit{horizontal}, according
as they are measured upon the diagonal, or in a direc-
tion perpendicular to the plane of elevation. Both
these answer to the same curve on the ship's bottom,
but give very different curves when described on the
half-breadth plan.
Principal pieces that compose a ship.

1. The rising of the floor, is a curve drawn in the floor plan, at the height of the ends of the floor timbers. It is limited at the main frame or dead flat by the dead rising, and in flat ships is nearly parallel to the keel for some timber's fore and abaft the midship frame; for which reason those timbers are called flat; but in sharp ships it rises gradually from the main frame, and ends on the stem and poop.

2. Cutting down line, is a curve drawn on the plane of elevation. It limits the depth of every floor timber at the middle line, and also the height of the upper part of the dead wood afore and abaft.

3. Timber and room, or room and space, is the distance between the moulding edges of two timbers, which must always contain the breadth of two timbers and an interval of about two or three inches between them. In forming the timbers, one mould serves for two, the foreside of the one being suppoied to unite with the aftside of the other, and so make only one line, which is called the joint of the timbers.

In order to illustrate the above, and to explain more particularly the principal pieces that compose a ship, it will be necessary to give a description of them. These pieces are for the most part represented according to the order of their disposition in fig. 1. Plate CCCCLIV.

A. Represents the pieces of the keel to be securely bolted together and clinched.

B. The sternpost, which is tenanted into the keel, and connected to it by the knee G.

C. The back of the poop, which is also tenanted into the keel, and securely bolted to the poop; the intention of it is to give sufficient breadth to the poop, which seldom can be got broad enough in one piece. C is the self poop, which is fayed (a) to the fore part of the sternpost.

D. The stem, in two pieces, to be scarfined together. The item is joined to the fore foot, which makes a part of both.

E. The apron in two pieces, to be scarfined together, and fayed on the inside of the stem, to support the scarf thereof; and therefore the scarf of the apron must be at some distance from that of the stem.

F. The stem fores, in two pieces, to support the scarf of the apron.

G. The beams which support the deck; and F the knees by which the beams are fainted to the sides of the ship.

H. The wing transom; it is fayed across the sternpost, and bolted to the head of it, and its extremities are fainted to the fashion pieces. L, is the deck transom, parallel to the wing transom. M, N. Two of the lower transoms; these are fainted to the sternpost and fashion pieces in the same manner as the wing transom.

Q. The knee which fants the transom to the ship's side. And, O. The fashion-piece, of which there is one on each side. The keel of the fashion piece is connected with the dead-wood, and the head is fainted to the wing transom.

R. S. Breast-hooks: these are fayed in the inside to the item, and to the bow on each side of it, to which they are fainted with proper bolts. There are generally four or five in the hold, in the form of that marked K, and one in the form of that marked S, into which the lower deck planks are rabbed: There is also one immediately under the haufe holes, and another under the second deck.

T. The rudder, which is joined to the sternpost by the rudder irons, upon which it turns round in the goings, fastened to the sternpost for that purpose. There is a mortise cut in the head of the rudder, into which a long bar is fitted called the tiller, and by which the rudder is turned.

U. A floor timber; it is laid across the keel, to which it is fastened by a bolt through the middle. V, W, V, V, V, The lower, the second, third and fourth futtocks. W, W, The top timbers. These represent the length and scarf of the feveral timbers in the midship frame.

X. The pieces which compose the kelfon. They are scarfined together in the same manner as the keel, and placed over the middle of the floor-timbers, being fcoarsed about an inch and a half down upon each side of them, as represented in the figure.

Y. The favelor pieces of the knee of the head; the lower part of which is fayed to the item, and its keel is scarfined on the head of the fofront. It is fainted to the bow by two knees, called checks, in the form of that represented by Z; and to the item, by a knee called a standard, in the form of that marked r.

a. The cathead, of which there is one on each side of the bow, projecting so far as to keep the anchor clear of the ship when it is hove up.

b. The bits, to which the cable is fainted when the ship is at anchor.

c. The fide counter timbers, which terminate the ship abaft within the quarter gallery.

d. Two pieces of dead wood, one afore and the other abaft, fayed on the keel.

Fig. 2. is a perspective representation of a ship framed and ready for the planking; in which A, A is the keel; B, the sternpost; C, the item; K, L, M, the transoms; F, F, F, F, F, F, the ribsband.

CHAP. III. Containing Preliminary Problems, &c.

The general dimensions of a ship are the length, breadth and depth.

To ascertain those dimensions that will best answer the intended purpose, is no doubt, a problem of considerable difficulty; and, from theory, it may be shewn, that there are no determinate proportions subsisting between the length, breadth and depth, by which these dimensions may be settled; yet, by combining theory and practice, the proportional dimensions may be approximated to pretty nearly.

As ships are confructed for a variety of different purposes, their principal dimensions must therefore be altered accordingly, in order to adapt them as nearly as possible to the proposed intention; but since there is no fixed standard whereby to regulate those dimensions, the methods therefore introduced are numerous, and in a great measure depend upon custom and fancy.

With regard, however, to the proportional dimen-
fions, they perhaps may be inferred from the circle. Thus, if the extreme breadth be made equal to the diameter, the length at the load water line, or the distance between the rabbits at the stem and poilt at that place, may be made equal to the circumference of the same circle; and the depth of the hold equal to the radius, the upper works being continued upwards according to circumstances. A ship formed from these dimensions, with a bottom more or less full according as may be judged necessary, will no doubt answer the proposed intention. Nevertheless, one or other of these dimensions may be varied in order to gain some essential property, which the trade that the vessel is intended for may require.

The following hints are given by Mr Hutchinfon towards fixing rules for the best construction of ship bottoms.

1. I would recommend (says he), to prevent ships-bottoms from hogging* upwards amidship, to have the fore and after part of their keels deep enough, that the upper part may be made to admit a rabbit for the garboard strake, that the main body and bearing part of the ship bottoms may be made to form an arch downwards in their length, supposing with the same heer as their bends, at the rate of about 2 inches for every 30 feet of the extreme length of the keel towards the midship or main frame, which may be reckoned the crown of the arch; and the lower part of the keel to be made straight, but laid upon blocks so that it may form a regular convex curve downwards at the rate of about an inch for every 30 feet of the extreme length of the keel, the lowest part exactly under the main frame; which curve, I reckon, is only a sufficient allowance for the keel to become straight below, after they are launched afloat, by the pressure of the water upwards against their floors amidship, which causes their tendency to hog. And certainly a straight keel is a great advantage in sailing, as well as to support them when laid upon level ground or on straight blocks in a repairing dock, without taking damage.

2. As square sterned ships, from experience, are found to answer all trades and purposes better than round or pink squared ships, I would recommend the fore part of the stern to be took on account of drawing the water lines in the draught, only to have a few inches rake, that the after part may stand quite upright perpendicular to the keel: and for the sake of the stem I would propose the rabbit for the hudding ends for the entrance, and bows from the keel upwards, to form the same curve as the water line from the stem at the harp pin towards the main breadth, and the bows at the harpin to be formed by a sweep of a circle of half the threes-fourths of the main breadth; and the main trunm to be three-fourths of the main breadth: and the buttocks, at the load or failing mark aft, to be formed, in the same manner as the bows at the harpin, with a sweep of a circle of half the three-fourths of the main breadth, to extend just as far from the stem and stern poilt as to admit a regular convex curve to the main frame, and from there down to the keel to form regular convex water lines, without any of those unnatural, hollow, concave ones, either in the entrance or run; which rules, in my opinion, will agree with the main body of the ship, whether she is designed to be built full for burden or sharp below for sailing.

3. This rule for taking the stem will admit all the water-lines in the ship's entrance to form convex curves all the way from the stem to the midship or main frame, which answers much better for sailing as well as making a ship more easy and lively in bad weather. And the bows should flange off, rounding in a circular form from the bends up to the gunwale, in order to meet the main breadth the sooner, with a sweep of half the main breadth at the gunwale amidships; which will not only prevent them greatly from being plunged under water in bad weather, but spread the landing fore-stripping the more, to support these material masts and falls forward to much greater advantage than in those over sharp bowed ships, as has been mentioned. And as the failing trim of ships in general is more or less by the stern, this makes the water-lines of the entrance in proportion the sharper to divide the particles of water the easier, so that the ship may pass through it with the least refistance.

4. The run ought to be formed shorter or longer, fuller or sharper, in proportion to the entrance and main body, as the ship is designed for burden or falling fast. The convex curves of the water lines should lessen gradually from the load or falling mark aft, as has been mentioned, downwards till a fair straight taper is formed from the after part of the floor to the sternpost below, without any concavity in the water lines, which will not only add buoyancy and burden to the after body and run of the ship, but, in my opinion, will help both her falling and steering motions; for the pressure of the water, as it closes and rises upon it to come to its level again, and fill up that hollow which is made by the fore and main body being pressed forward with fall, will impinge, and act with more power to help the ship forward in her progressive motion, than upon those unnatural concave runs, which have so much more flat dead wood, that must, in proportion, be a hindrance to the stern being turned so easily by the power of the helm to steer the ship to the greatest advantage.

Many and various are the methods which are employed to describe the several parts of a ship. In the following problems, however, these methods only are given which appear to be most easily applied to practice, and which, at the same time, will answer any proposed purpose.

PROB. 1. To describe in the plane of elevation the form or curvature of the top-timbers. Let QR (fig. 3) be the length of the ship between the wing trammel and the rabbet of the stem. Then, since it is generally agreed, especially by the French contructors, that the broadest part of the ship ought to be about one-twelfth of the length before the main frame or dead flat; therefore make $C$ equal to five-twelfths of QR, and $C$ will be the elevation of the main frame: space the other frames on the keel, and from these points let perpendiculars be drawn to the keel. Method of determining the top-timber line. Let $OP$ be the height of the ship at the main frame, $VF$ the height at the aftermost frame, and $RK$ the height at the stem. Through $P$ draw $EPL$ parallel to the keel; describe the quadrants $PGI$, $PMN$, the radius being $PG$; make $PH$ equal to $EPL$, and $PQ$ equal to $KL$, and draw the parallels $GH$, $OM$: Divide $GH$ similar to $GC$, and $OM$ similar to $OR$. Through these points of division draw lines perpendicular to $EL$, and the several portions of these perpendiculars contained between $EL$ and the arch will be the risings of the top.
SHIP BUILDING.

FRAMES of a Ship.
Book I.

SHIP-BUILDING.

These rules, it is evident, are variable at pleasure; and any person acquainted with the first principles of mathematics may apply calculation to find the radii of the several sweeps.

Pro. V. To describe the main frame or dead-flat.

This frame is that which contains the greatest space, of the and the particular form of each of the other frames depends very much on it. If the ship is intended to carry a great burden in proportion to her principal dimensions, this frame is made very full; but if the ship is intended to sail fast it is usually made sharp. Hence arises diversity of opinions respecting its form; each constructor using that which to him appears preferable. In order to save repetition, it is judged proper to explain certain operations which necessarily enter into all the different methods of constructing this frame.

In the plane of the upper side of the keel produced, draw the line AB (fig. 5) equal to the proposed breadth of the ship; bisect AB in C, and draw AD, CE, and BF, perpendicular to AD. Then, since the two sides of a ship are similar, it is therefore thought sufficient to describe the half of each frame between the main line and the stern on one side of the middle line CE, and the half of each of those before the main frame on the other side of it. The first half is called the after-body, and the other the fore-body. The after-body is commonly described on the left side of the middle line; and the fore-body on the right side of it; hence the line AD is called the side line of the after-body, and BF the side line of the fore-body. Make AD and BF each equal to the height of the ship at the main frame. Make AG, BG, and AH, BH, equal to the lower and upper heights of breadth respectively, taken from the sheer plan. Let I be the load water line, or line of floatation when the ship is loaded, and KK the height of the rising line of the floor at this frame. Make CN, CO, each equal to half the length of the timber, and JO, ON, equal to the heads of the frames at the main frame. From the centre of the reconciling arch made on the floor timber, thro' which draw perpendiculars to AD. Make CM, EM, each equal to half the thickness of the sternpost, and CN, EN, equal to half the thickness of the stern, and join m, n, m, n, m.

Method I. Of describing a main frame. — From the centre a (fig. 5), in the lower breadth line, describe the lower breadth sweep GC, make NB equal to the proposed radius of the floor sweep, and from the centre b describe the floor sweep NF. Let the radius of the reconciling sweep be AG, equal to about the half of AC; then make AB equal to NB, and AM equal to GA. Now from the centre a, with an extent equal to GM, describe an arch, and from the centre b, with the extent GB, describe an arch intersecting the former in c, which will be the centre of the reconciling sweep. Join Nm, by an inverted curve, the centre of which may be in the line b N produced downwards; or it may be joined by two curves, or by a straight line if there is little rising; and hence the lower post of the main frame will be described.

In order to form the top timber, make Fk equal to such part of the half breadth, agreeable to the proposed round of the side, as one-seventh; join Hl, and make k i equal to about two-thirds of Hk; make the angle HI/ equal to i H l/; and from the centre l at the distance...
To describe a main frame of an intermediate capacity, that is neither too flat nor too sharp.—Divide the line AX (fig. 6), which limits the head of the floor timber, into three equal parts; and make a b equal to one of them. Divide the line a b, the perpendicular distance between the load water line and the plane of the upper side of the keel, into seven equal parts; and set off one of these parts from d to e, and from e to m. Let GH be the lower deck, join G m, and produce it to q. Draw the straight line V a, bisect it in n, and from the points m, n, describe arches with the radius G q intersecting each other in P, which will be the centre of the arch n a.

The centre of the arch V n is found by describing arches downwards with the same radius. With an extent equal to one a, and a half of b s, describe arches from the points b, s, intersecting each other in A, and from this point as a centre describe the arch e b; make a d equal to d m, and join A m, A l. Then, in order to reconcile two arches so as to make a fair curve, the centres of these arches, and of the points of contact, must be in the same straight line. Hence the point k will be the centre of the arch a m, and s the centre of the arch a l. The arch l m is described from the centre A.

To form the top timber, set back the tenth part of the half breadth from K to S upon the line of the second deck; then with an extent equal to two-thirds of the whole breadth describe an arch through the points S and H, the upper height of breadth. Again, make M I equal to the fifth part of the half breadth; describe an arch of a circle through the points S and T, taking the diagonal G B for the radius. As this arch is inverted in respect of the arch d S, the centre will be without the figure. Hence one-half of the main frame is formed, and the other half is described by similar operations.

Remark. This frame may be made more or less full by altering the several radii.

II. To describe a main frame of a circular form.—Let the several lines be drawn as before: Then make O a (fig. 7) equal to the half breadth G a, and from the centre a, with the radius G a, describe the arch b G c O. Let d be the head of the floor-timber, and d x the riving. Assume the point f in the arch, according to the proposed round of the second futtock, and describe the arch d f; the centre of which may be found as in the former method: from the centre a, with the distance a d, describe the arch d e O; make d e equal to one-third of d O, and the angle d e b equal to c d b, and from the centre b describe the arch d e. The inverted arch e o may be described as before.

IV. To describe a very full main frame.—Let the vertical and horizontal lines be drawn as before: Let b, fig. 8, be the floor-head, and b x the riving. Divide G c into two equal parts in the point d, and upon c d describe the square b d a c, in which inscribe the quadrant d e a. Divide the line d e into any number of equal parts in the points O, N, M, L, and draw the lines L m, M e, N b, perpendicular to d b. Divide the line G C, the depth of the hold, the riving being deducted, into the same number of equal parts in the points E, F, I, K, and make the lines E p, F q, I r, K s, in the frame, equal to the lines O b, N n, M m, L m, in the squares each.
Book I.

S H I P - B U I L D I N G.

mixtlineal space DNY. Hence the capacity of the frame formed by the straight lines MN, NY will be equal to that of the frame formed by the curve M a D Y; and the frame formed by the straight lines will for the most part be always more susceptible of receiving a bow that will easily divide the fluid. It is also evident, that the cargo or ballast, being lower in the frame formed of straight lines than in the other, it will therefore be more advantageously placed, and will enable the ship to carry more sail (c); so that having a bow equally well or better formed, she will sail faster.

PROB. VI. To describe a stern having a square tuck. Let AB (fig. 114) be the middle line of the port, and let CD be drawn parallel therto at a distance equal to half the thinnest of the port. Make CE equal to the height of the lower part of the fashion-piece above the keel: make GT equal to the height of the extremity G of the transom above the plane of the keel produced, and CH equal to the height of the transom on the port. BT is then to be drawn equal to one sixth or one tenth of GT, and describe the arch CH, the centre of which will be in BA produced: make EH equal to five twelfths of ET: through K draw KL perpendicular to CD, and equal to KE; and with an equal extent to EL describe the arch EL. Make GI equal to the half of ET, and from the centre I describe the arc GM, and draw the reconciliating curve ML:—

Let the curve of the fashion-piece be produced upwards to the point representing the upper height of breadth, as at O. Make ON equal to the top of the timbers, and BN equal to the half-breadth at that place, and join ON. Through N and the upper part of the corner, let arches be described parallel to GH. The taffereå, windows, and remaining part of the stern, may be finished agreeable to the fancy of the artist.

In fig. 12. the projection of the stern on the plane of elevation is laid down, the method of doing which is obvious from inspection.

If the transom is to round aft, then since the fashion pieces are always fixed straight, their planes will intersect the keel or floor planes in a straight line. Let Gg (fig. 14.) be the intersection of the plane of the fashion-piece with the floor plane. From the point g draw W perpendicular to g M: make Wg equal to the height of the tuck, and Wk equal joined will be the intersection of the plane of the fashion-piece with the floor plane. Let the water lines in the floor plane produced meet the line Wk in the points a, b, and draw the perpendiculars na, fa, ba. From the points a, b, (fig. 14.) draw lines parallel to Gg to intersect each corresponding water line in the floor plane in the points 3, 2, 1. From the points G, 3, 2, 1 in the floor plane draw lines perpendicular to Gg, intersecting the water lines (fig. 13.) in the points G, 3, 2, 1; and through these points describe the curve 3, 2, 1 k; and Wg 3, 2, 1 k will be the projection of the plane of the fashion-piece on the floor plane. Through the points G, 3, 2, 1 (fig. 13) draw the lines GF, 3 A, 2 S, 1 H, perpendicular to Wk; and make the lines WF, a A, 3, b H, equal to the lines 2 G, 3, 2, 1, respectively, and Wf is the true form of the plane of the aft side of the fashion-piece. When it is in its proper position, the line WF will be in the same plane with the sheer line; the line a A in the same plane with the water line a 3; the line s S in the same plane with the water line s 2; and the line b H in the same plane with the water line b 1. If lines be drawn from the several points of intersection of the water lines with the rabot of the port (fig. 13.), perpendicular to g M, and curved lines being drawn from these points to G, 3, 2, 1 (fig. 14.) respectively, will give the form and dimensions of the tuck at the several water lines.

PROB. VII. To bevel the fashion-piece of a square tuck by water-lines. As the fashion-piece both rakes and cants, the planes of the water-lines will therefore intersect it higher on the aft than on the fore-side; but before the heights on the fore-side can be found, the breadth of the timber must be determined, which let be b s (fig. 15). Then as it cants, the breadth in the direction of the water-line will exceed the true breadth. In order to find the true breadth, from the aft side of the fashion-piece as directed in the last problem.

Let 15 (fig. 13) be the side of the rabot on the outside of the port, WM the common section of the plan of the fashion-piece and the sheer-plan. Before this last line can be determined, the several water-lines 1, 2, 3, 4, and 5, must be drawn parallel to the keel, which may represent so many tramforms. Let these water lines be formed and ended at the side of the rabot, as in fig. 14. where the rounds aft of the several tramstands are described, limiting the curves of the water lines. Now the line WM must rake so as to leave room for half the thickness of the port, at the tuck: in order to which, produce Wg to r; make r g half the thickness of the port; through r draw a line parallel to g M to intersect g M in b: then with the radius r k, from a the point of the tuck as a centre, describe an arch, and draw the line WM, just to touch the back of that arch.

The line WM being drawn, let any point k in it be assumed at pleasure: from k draw k y perpendicular to g M: through y draw y f (fig. 14.) parallel to g G, intersecting the line M f drawn perpendicular to g M in the point f. From M draw M i perpendicular to y f, and from y draw y n perpendicular to WM (fig. 13.) Make M k (fig. 15) equal to M i (fig. 14.); then M i (fig. 15) being equal to k (fig. 13), join k 1, and the angle 1 sb will be the bevelling to the horizontal plane. Again, make M s M f (fig. 15.) respectively equal to y n (fig. 13.) and M f (fig. 14.), and join z f, and the angle M z f will be the bevelling to the sheer plane.

The bevelling being now found, draw the line a b (fig. 15.) parallel to a n, as or b n being the scantling of the timber. Then a b will be the breadth of the timber on the horizontal plane, and a e is its breadth on the sheer plane, and a e is what it is within a square.

Now as the lines G g, 3 a, 2 b, 1, y s, represent

(c) It is not a general rule, that lowering the cargo of a ship augments her stability. This is demonstrated by the Chevalier de Borda, in a work published by M. de Goimpy upon this subject. See also L'Architecture Na"

vale per M. Vial de Caireix, p. 25.
the aft side of the fashion-piece on the horizontal plane (fig. 14.), dotted lines may be drawn parallel to them to represent the fore-side, making \( n = (\text{fig. } 15.) \) the perpendicular distance between the lines representing fore and aft sides of the fashion-piece. By these lines form the fore-side of the fashion-piece in the same manner as the aft-side was formed. The water lines on the fore-side of the fashion-piece must, however, be first drawn in fig. 15.; thus: Draw the lines \( e, d \) parallel to \( W M \), and whose perpendicular distances therefore may be equal to \( a e \) and \( s e \) (fig. 15.) respectively. Draw a line parallel to \( W F \) (fig. 13.) through the point where the line \( c d \) intersects the fifth water line. Draw a line parallel to \( a A \) through the point where the fourth water line intersects the line \( c d \); in like manner proceed with the other water lines. The fore-side of the fashion-piece is now to be described by means of these new water lines, observing that the distances in the floor plane may be set off from the line \( e b \) and not from \( W M \), as in the former case; and a curve described through the points 5, 3, 2, 1, where these distances reach to, will represent the fore-side of the fashion-piece.

The nearest distance between the points 5, 3, 2, 1, and the aft side of the fashion-piece is what the bevelling is beyond the square when both flock and tongue of the bevel are parallel to the timber. Make \( M p \) (fig. 16.) equal to the breadth of the timber, and \( M 5 \) equal to the perpendicular distance of the point 5 (fig. 13.) from the aft side of the fashion-piece, and join 5 \( p \). In like manner proceed with the others, and the bevellings at these points will be obtained; but, in order to avoid confusion, the perpendiculares 4, 3, 2, (fig. 13.), instead of being laid off from \( M \) (fig. 16.), were set off from points as far below \( M \) as the other extremities of the lines drawn from these points are below the point \( p \).

**Prob. VIII.** To describe the transoms of a round poop.

The transoms are fastened to the stern-post in the same manner that the floor timbers are fastened to the keel, and have a rising called the "flights" similar to the rising of the floor timbers. The upper transom is called the "wing transom," the next the "deck transom," and the others the "first," "second," and "third" transoms, in order. The wing transom has a round aft and a round up; the round up of the deck transom is the same as that of the beams.

The fashion-piece of a square tuck must be first described, together with the three adjacent frames, by the method to be explained. The part of the stern above the wing transom is to be described in the same manner as before, and may therefore be omitted in this place. The part below the keel of the fashion-piece is also the same in both cases. Let fig. 17. represent the fashion-piece of a square tuck, and the three adjoining frames. Divide the interval \( A B \) into four equal parts in the points \( C, D, E, \) and draw the perpendiculares \( A F, C G, D H, E I, \) and \( B K \); these will be portions of water lines answering to the several transoms.

Let these wate lines be described on the floor plan (fig. 18.), in which \( ABC \) represents the wing transom. Describe the arch \( b C \) to reconcile the curves \( A b \) and \( CE \). Let \( L F G \) be the water-line answering to the lower part of the fashion-piece, the distance between the points \( L \) and \( A \) being equal to the excess of the projection of the point \( A \) beyond that of \( B \) (fig. 20.). Draw \( C K \) (fig. 18.) perpendicular to \( AM \), and make the angle \( K C M \) equal to about 25 degrees, and \( C N \) will be the projection of the fashion-piece on the floor plane. Make \( A B \) (fig. 19.) equal to \( AB \) (fig. 17.). Divide it into four equal parts, and draw the perpendiculares \( AF, CH, DI,EK, \) and \( BG \). Make \( AF \) equal to \( CM \), and \( BG \) equal to \( MN \); and draw the curve \( F H I K G \), having a less curvature than the fashion-piece of the square tuck, and \( F H I K \). Make \( M O \), \( MP \), \( MQ \), equal to \( CH, DI, \) and \( EK \) respectively. Divide \( AL \) (fig. 18) into four equal parts, and to these points of division draw curves through the points \( O, P, Q, \) so as to partake partly of the curvature of \( A b C \), partly of that of \( A b C \), and partly of that of \( A b C \). From the line \( D F \) (fig. 18.), and through the extremities of these lines, draw the curve \( F G H I K \). It remains to lay down the projection of the fashion-piece on the plane of elevation. In order to which, divide the line \( AB \), fig. 20. (equal to \( A B \), fig. 17.) into four equal parts, and through the points of division draw the perpendiculares \( AF, CG, DH, EI, \) and \( BK \); make \( AF \) (fig. 20.) equal to the perpendicular distance of the point \( C \) from the line \( BL \) (fig. 18.). In like manner make the lines \( CG, DH, EI, \) and \( BK \) (fig. 20.) respectively equal to the perpendicular distance of the points \( O, P, Q, \), and \( N \), from the line \( BL \) (fig. 18.); and a curve drawn through these points will be the projection of the fashion-piece on the plane of elevation.

**Prob. IX.** To describe the intermediate frames in the after body.

For this purpose the midship and stern frames must be drawn in the plane of projection. As the main frame contains the greatest capacity, and the stern frame is that having the least, it hence follows that the form and dimensions of the intermediate frames will be between these; each frame, however, partaking most of the form of that to which it is nearest.

Let \( ACDE \) (fig. 21.) be the main frame on the plane of projection, and \( FGH \) the stern frame; and let there be any convenient number of intermediate frames, as nine. Draw the floor ribband \( CF \), and the breadth ribband \( GD \). Divide the curves \( CD, FG \) each into the same number of equal parts, as three, in the points \( K, M, L, N \); and draw the second and third ribbands \( KL, MN \). In order to divide these ribbands so as to form fair curves in different sections, various methods have been proposed. One of the best of these, being that which is chiefly employed by the French constructors, is by means of an equilateral triangle, which is constructed as follows.

Draw the line \( ME \) (fig. 21.), limited at \( M \), but produced towards \( E \); take \( M 1 \) equal to any convenient extent; make \( 1, 2 \) equal to twice that extent, \( 2, 3 \) equal to five times, and \( 3, 4 \) equal to seven times the above extent; and continue this division to \( E \), always increasing by two, until there be as many points as there
are frames, including the main and stern frames. Upon ME describe the equilateral triangle MSE, and draw lines from the vertex S to each point of division; then the line SM will be that answering to the main frame, and SE that corresponding to the poop; and the other lines will be those answering to the intermediate frames in order.

Let fig. 23. be the projection of part of the stern on the plane of elevation, together with the eighth and ninth frames. From the points \( L, N, G \), (fig. 21.) draw the lines LO, NP, GQ, perpendicular to the plane of the upper edge of the keel. Make AB (fig. 23.) equal to AF (fig. 21.), and draw the water line BCD. Draw the line BC (fig. 23.) so that it may be parallel to the base of the triangle, and equal to CD (fig. 23.), which produce indifferently towards H. Make BD equal to BC (fig. 23.), and draw the dotted line SD (fig. 22.). The ribbon FC (fig. 21.) is to be applied to the triangle, so that it may be parallel to the base, and contained between the line MS and the dotted line SD. Let CF represent this line; then transfer the several divisions from CF to the ribbon CF (fig. 21.), and number them accordingly. Again, make EF (fig. 23.) equal to LO (fig. 21.), and draw the water line FGH; make BF (fig. 22.) equal to FG (fig. 23.), and draw the dotted line SF; apply the second ribbon KL to the triangle, so that the extremity K may be on the line SM, and the other extremity L on the dotted line SF, and making with SM an angle of about 62° degrees. Let \( K \) be this line, and transfer the divisions from it to the ribbon KL. In like manner make IK (fig. 23.) equal to NP (fig. 21.), and draw the water line KLM. Make BG (fig. 22.) equal to KL (fig. 23.), and draw the dotted line SG; then the ribbon MN is to be applied to the triangle in such a manner that its extremities M and N may be upon the lines SM, SG respectively, and that it may make an angle of about 68 degrees with the line SM; and the divisions are to be transferred from it to the ribbon MN.

The same processes is to be followed to divide the other ribbons, observing to apply the fourth ribbon to the triangle, so that it may make an angle of 86 degrees with the line SM; the fifth ribbon to make an angle of 67 degrees, and the sixth an angle of 60 degrees with the line SM.

The quantities of these angles are, however, far from being rigidly fixed. Some constructors, in applying the ribbons to the triangle, make them all parallel to its base; and others vary the measures of these angles according to fancy. It may also be remarked, that a different method of dividing the base of the triangle is used by some. It is certainly proper to try different methods; and that is to be preferred which best answers the intended purpose.

Besides the frames already mentioned, there are other two laid down by some constructors in the several plans, called balance frames. The after balance frame is placed at one fourth of the length of the ship before the stern-poll; and the other, commonly called the loof frame, at one fourth of the ship’s length aft of a perpendicular to the keel from the rabbit of the stern. Let the dotted line at X, between the fifth and sixth frames, (fig. 23.) be the place of the after balance frame in the plane of elevation. Then, in order to lay down this frame in the plane of projection, its representation must be previously drawn in the triangle. To accomplish this, draw the line SV (fig. 22.) so that the internal \( 5^\circ \) may have the same ratio to \( 5^\circ \) (fig. 22.) that 5 X has to 5 (fig. 24.) (d). Then the several points in the ribbons in the plane of projection answering to this frame are to be found by means of the triangle in the same manner as before.

The loof frame is nearly of the same dimensions as the after balance frame, or rather of a little greater capacity, in order that the centre of gravity of that part of the ship may be nearly in the plane of the midship frame. Hence the loof frame may be easily drawn in the plane of projection, and hence also the other frames in the fore body may be readily described.

PROB. X. To describe the frames in the fore body.

Draw the middle line of the stern AB (fig. 24.); make AC, BD each equal to half the thickness of the stern, and draw the line CD; describe also one half of the main frame CEGFIH. Let \( eF, fG, gH, \) be water lines at the heights of the ribbons on the main frame; also let a be the termination of the floor ribbon, and b that of the breadth ribbon on the item. Divide the interval \( a b \) into three equal parts in the points \( c, d, \) and draw the ribbons \( eF, cG, dH, \) and \( eH. \) Make \( eF, fG, gH, hM \) (fig. 24.) equal to \( e, f, g, h \) (fig. 21.) respectively, and draw the curve \( C I K L M, \) which will be the projection of the loof frame. Or since it is necessary that the capacity of the loof frame should be a little greater than that of the after balance frame, each of the above lines may be increased by a proportional part of itself, as one tenth or one-twentieth, as may be judged proper.

Construct the triangle (fig. 25.) in the same manner as fig. 22. only observing, that as there are fewer frames in the foremost than in the after body, its base will therefore be divided into fewer parts. Let there be eight frames in the fore body, then there will be eight divisions in the base of the triangle before the extremes.

Let fig. 26. represent the item and part of the fore-body in the plane of elevation, and let \( O \) be the place of the loof frame. Divide the interval \( 4, 5 \) (fig. 25.) so that 4, 5 may be to 4Z as 4, 5 to 4, 0 (fig. 26.), and draw the dotted line \( S Z, \) which will be the line denoting the loof frame in the triangle.

Draw the lines \( AB, CD, EF, GH \) (fig. 26.) parallel to the keel, and whose perpendicular distances therefrom may be equal to \( CA, CE, CD, CB \) (fig. 24.), the intersections of these lines with the rabbit of the item, namely, the points I, K, L, M will be the points of termination of the several ribbons on the item in the plane of elevation. Divide 8 A (fig. 25.) so that 8 B, 8 C, 8 D, and 8 E, may be respectively equal to \( BI, DK, FL, \) and \( HM \) (fig. 26.), and draw the dotted lines \( SB, SC, SD, SE \) (fig. 23.) Apply the edge of a slip of card to the first ribbon (fig. 24.), and mark 3 thereon.

(d) It is evident, from the method used to divide the base of the triangle, that this proportion does not agree exactly with the construction; the difference, however, being small, is therefore neglected in practice.
thereon the extremities of the ribband $a, E$, and also the point of intersection of the loft frame. Then apply this slip of card to the triangle in such a manner that the point $a$ may be on the dotted line $SB$, the point $E$ on the line $SM$, and the point answering to the loft frame on the dotted line $SZ$; and mark upon the card the several points of intersection of the lines $S, T, S, Z, \&c.$ Now apply the card to the ribband $aE$ (fig. 24.) as before, and transfer the several points of division from it to the ribband. In like manner proceed with the other ribbands; and lines drawn through the corresponding points in the ribbands will be the projection of the lower part of the frames in the fore body. The projections of the top-timbers of the several frames may be taken from the half breadth plan; and hence each top-timber may be easily described.

In large ships, particularly in those of the French navy, a different method is employed to form the top-timbers in the fore body, which is as follows:

Let $BI$ (fig. 27.) be one fourth of the breadth of the ship, and draw $IK$ parallel to $AB$. Take the height of the foremost frame from the plane of elevation, and lay it off from $A$ to $B$; from the point $B$ draw $EH$ perpendicular to $AB$, and equal to half the length of the wing transom. Let $E$ be the place of the breadth ribband on the main frame, and $F$ its place on the line at the height of the wing transom. With a radius equal to five-sixths of the greatest breadth of the ship describe the quadrant $EFG$ (fig. 28.): Make $EH$ equal to $FG$ (fig. 27.), the point $F$ being at the height of the wing transom. Through $H$ draw $HO$ perpendicular to $EH$, and intersecting the circumference in $O$; then draw $OL$ parallel to $HE$, and $EL$ parallel to $HO$. Divide $EL$ into as many equal parts as there are frames in the fore body, including the main frame, and from these points of division draw the perpendiculars $11, 22, \&c.$ meeting the circumference as in the figure. Take the distance $11$, and lay it off from $G$ (fig. 27.) towards $F$ to the point $t$; and from the same point $G$ lay off towards $F$ the several perpendiculars contained between the straight line and the curve to the points $2, 3, \&c.$ and through these points draw lines parallel to $EG$.

Take any line $AB$ (fig. 29.) at pleasure; divide it equally in two in the point $8$; divide $8B$ in two parts in the point $7$, and continue this method of division until there are as many points as there are frames in the fore body, including the main frame. Upon $AB$ continue the equilateral triangle $ACB$, and draw the lines $C8, C7, \&c.$ Place a slip of card on the parallel $aK8$ (fig. 27.), and mark thereon the points opposite to $a, K, \&c.$; and let them be denoted accordingly. Then apply this slip of card to the triangle, so that the point $a$, which is that answering to the racket of the stem, may be on the line $AC$; that the point answering to $K$ may be on $C8$, and the extremity on the line $CB$; and mark on the card the points of intersection of the lines $C7, C6, \&c.$, and number them accordingly. Now apply this slip of card to the seventh parallel (fig. 23.), the point $a$ being on the line $CD$, and mark on this parallel the point of intersection $7$; slide the card down to the fifth parallel, to which transfer the point $5\times 6$. In like manner proceed with the other parallels.

The point $K$, at the intersection of the line $IK$ with the eighth parallel, is one point through which the tenth frame passes. From this point upwards a curve is to be described as to reconcile with the lower part of this frame already described, and the upper part, forming an inverted arch, which is to terminate at $E$. This top-timber may be formed by two sweeps, whose radii and centres are to be determined partly from circumferences and partly according to fancy. It however may be more readily formed by hand. Let $LM$ (fig. 27.) be the line of the second deck at the main frame, and let $LN$ be the diffuseness of the draught of water, if any. Make $GN$ (fig. 28.) equal to $LN$; draw $NM$ perpendicular to $GN$, meeting the circle in $M$; and through the points $G$ and $M$ draw the parallels $GV$ and $MV$; divide $GN$ as before, and from the several points of division draw perpendiculars terminating in the curve. Transfer these perpendiculars from $L$ upwards (fig. 27.), and through the points thus found draw the lines $11, 22, \&c.$ parallel to $LM$.

Apply a slip of card to the eighth parallel, and mark upon it the point answering to the stem, the eighth and main frames: carry this to the triangle, and place it so that these points may be on the corresponding lines. Then the points of intersection of the lines $C7, C6, \&c.$ are to be marked on the card, which is now to be applied first to the eighth parallel (fig. 27.), then to the seventh, &c. transferring the several points of division in order as before.

Draw the line $HO$ (fig. 27.); mark its length on a slip of card, and apply it to the triangle, so that it may be parallel to its base, and its extremities one on the eighth and the other on the main frame: mark on the card the points of intersection of the several intermediate lines as before; then apply the card to $H0$, and transfer the divisions.

There are now three points determined through which each top-timber must pass, namely, one in the breadth ribband, one in the fifth, and one in the upper ribband. Through these curves are to be described, so as to reconcile with the lower part of the frame, and partake partly of the curvature of the eighth frame, and partly of that of the main frame, but most of that of the frame to which it is nearest; and hence the plane of projection is so far simplified, that it only remains to prove the several frames by water lines.

Another method of describing the frames in the body plan is by sweeps. In this method it is necessary, in the first place, to describe the height of the breadth lines, and the rising of the floor, in the plane of elevation. The half breadth lines are next to be described in the floor plan. The main frame is then to be described by three or more sweeps, and giving it such a form as may be most suitable to the service the ship is designed for. The lower, upper, and top-timber heights of breadth, and the risings of the floor, are to be set upon the middle line in the body plan, and the several half breadth lines are then to be laid off on lines drawn through these points perpendicular to the middle line. A mould may then be made for the main frame, and laid upon the several risings, as in whole mouldings, explained in Chapter V. with this difference, that here an under breadth sweep is described to pass through the point which limits the half breadth of the timber, the centre of which will be in the breadth line of that timber. The proper centres for all the frames being found, and
Preliminary Problem.

The arches described, the bend mould must be so placed on the rising line of the floor, that the back of it may touch the back of the under breadth sweep. But the general practice is, to describe all the floor sweeps with compasses, as well as the under breadth sweeps, and to reconcile those two by a mould which is an arch of a circle, its radius being the same with that of the reconciling sweep by which the midship frame was formed. It is usual for all the floor sweeps to be of the same radius; and in order to find their centres a line is formed on the floor plan for half the breadth of the floor. As this line cannot be described on the surface of a ship, it is therefore only an imaginary line. Instead of it some make use of a diagonal in the body plane to limit the half breadth of the floor upon every rising line, and to erect perpendiculars at the several intersections, in the same manner as for the midship frame.

After the sweeps are all described, recourse is had to moulds, or some such contrivance, to form the hollow of the timbers, much in the same manner as in whole moulding; and when all the timbers are formed, they must be proved by ribbon and water lines, and altered, if necessary, to make fair curves.

The preceding methods of describing the several planes or sections of a ship being well understood, it will be a very easy matter to construct draughts for any proposed ship: and as the above planes were described separately and independent of each other, it is therefore of little consequence which is first described. In the following application, however, the plane of elevation will be first drawn, then part of the floor plan, and lastly the body plan: and in connecting these plans the most rational and simple methods will be employed.

Chapter IV. Application of the foregoing Rules to the Construction of Ships.

Section I. To construct a Ship intended to carry a considerable Burden in proportion to her general Dimensions, and to draw little Water.

Dimensions.

Length between the wing transom and a perpendicular from the rabbit of the item at the height F In.

- 80 0

Of breadth line - 11 0

Main half breadth moulded - 7 6

Half breadth at the height of breadth line at the stern - 6 0

Top-timber half breadth - 17 0

Height of the item above the upper edge of the keel - 13 6

Height of the breadth line at the stern - 12 3

Upper height of breadth at the main frame - 7 4

Lower height of breadth - 5 10

Height of middle line of wales at the stern - 10 0

Height of middle line of wales at the main frame - 6 10

Height of middle line of wales at the stern - 10 6

Breath of the wales - 1 9

Height of top-timber at midships - 14 0

Draw the line a b (fig. 37.) equal to 80 feet, from Apply a convenient scale: divide it into as many equal parts of the plus one as there are to be frames, which let be 10, and through each point of division draw parallel the Construction of Ships.

Make b c equal to 17 feet, the perpendicular height of the stern of the item above the upper edge of the keel, and describe the item by Prob. II. Make a d equal to 10 feet, the height of the middle line of the wales at the item, and d e equal to the proposed rake of the poop, which may be about 2 feet; join d e; and draw the line f g representing the after-side of the poop. Describe the counter and stern by Problem VI. and VII. Make b f equal to 14 feet, the top-timber height at the main frame, and e k equal to 18 feet, the height at the item; and through the three points c, b, k, describe the curve limiting the top-timbers by Problem I. Make b d equal to 10 feet, the height of the middle line of the wales at the item, and b f equal to 6 feet 10 inches, the height at the stern frame; and the curve d H d being described will represent the middle line of the wales. At the distance of 10 feet on each side of this line draw two curves parallel thereto, and the wales will be completed in this plan. Make b l equal to 13 feet, the height of the breadth line at the stern; a m equal to 12 feet, the height at the stern; and h k equal to 5 feet 10 inches and 7 feet 4 inches respectively; and draw the upper breadth line k m and lower breadth line l l. From the line a b lay downwards the breadth of the keel, which may be about one foot, and draw the line l t parallel to a b.

Let the line L r, which is the lower edge of the keel, represent also the middle line of the floor plan. Produce all the perpendiculars representing the frames; make o M (fig. 31.) equal to 11 feet, the main half breadth at midships; through m (fig. 30.) draw the line m n perpendicular to a b, and make p n equal to 7 feet, and draw the main half breadth line NM r by Problem IV. Describe also the top-timber half breadth line PO r, O being equal to 10 feet, and form the projecting part of the item g r s t.

In order that the top-timber line may look fair on the bow, and to prevent the foremost top-timbers from being too short, it is necessary to lift or raise the foot from the round of the bow to the stern. For this purpose the following method is usually employed: Produce the circular tierce before the item in the plane of elevation at pleasure; then place a button to the round of the bow in the half breadth plan, and mark on it the flations of the square timbers and the foot of the item; apply the button to the tierce plan, and place it to the tierce of the ship, keeping the flations of the timbers on the button well with those on the tierce plan for several timbers before dead-flat, where they will not alter; then mark the other timbers and the item on the tierce line produced; through these points draw lines parallel to the keel, to intersect their corresponding timbers and the item in the tierce plan: then a curve described these last points will be the tierce of the ship round the bow, lifted as required: and the heights of the timbers thus lengthened are to be transferred to the body plan as before.

Draw the line AB (fig. 32.) equal to 22 feet, the whole breadth; from the middle of which draw the perpendicular CD; make CE equal to half the thickness of
of the post, and CF equal to half that of the stem, and from the p's into A, E, F, B, draw lines parallel to CD. Make AG, BG each equal to 14 feet, the height at the main frame, and draw the line GG parallel to AB. Make GH, GH each equal to half a foot, the difference between the main and top timber half breadths. From A and B set up the heights of the lower and upper breadth lines to I and K, and draw the straight lines IK, IK. Let CL be the rising at the main frame, and N, P, the extremities of the floor timber. Hence, as there are now five points determined in each half of the main frame, it may be very easily described.

Make CM equal to IA, join MI, and draw the other ribbands NO, PQ. In order, however, to simplify this operation, the rectilinear distance of CM was transferred, and through the points of division the lines NO, PQ were drawn parallel to the floor ribband MI.

Take the distance be (fig. 30.), and lay it off from F to (fig. 32.); also make FB (fig. 32.) equal to F a (fig. 30.); through b draw a parallel to AB, and equal to FR (fig. 31.). In like manner take the heights of each top-timber from fig. 30., and lay them off from C towards D (fig. 32.); through these points draw lines parallel to AB, and make them equal each to each, to the corresponding half-breadth lines taken from the floor plan: Then through the several points a, c, &c., thus found, draw a line c H, which will be the projection of the top-timber line of the fore body in the body plan. Proceed in the same manner to find the top-timber line in the after body.

Transfer the height of the main-breadth line on the stem b l (fig. 30.) from F to a (fig. 32.). Transfer also the heights of the lower and upper breadth lines at timber F (fig. 30.); namely, FW, FX, from F to e and f (fig. 32.); through which draw the parallel eg, fh; make them equal to FS (fig. 31.), and draw the straight line gh. In this manner proceed to lay down the portions of the extreme breadth at each frame, both in the fore and in the after body in the body plan, and draw the upper and lower breadth lines d k, dg I in the fore body and K J, I i in the after body. Hence the portions of the several top-timbers contained between the top-timber and main breadth lines may be easily described. It was before remarked that their forms were partly arbitrary. The midship top-timber has generally a hollow, the form of which is left entirely to the artist, though in some slips, especially small ones, it has none. It is the common practice to make a mould for this hollow, either by a sweep or some other contrivance, which is produced considerably above the top-timber line, in a straight line or very near one. The midship top-timber is formed by this mould, which is so placed that it breaks in four with the back of the upper breadth sweep. The other top-timbers are formed by the same mould, observing to place it so that the straight part of it may be parallel to the straight part of the midship timber, and moved up or down, still keeping it in that direction till it just touches the back of the upper breadth sweep. Some constructors begin at the upper timber, after the mould is made for the midship top-timber, because they think it easier to keep the straight part of the mould parallel to this than to the midship timber; and by this means the top fide is kept from winding. Others, again, make a mark upon the mould where the breadth line of the midship timber crosses it, and with the same mould they form the after timber: this will occasion the mark that was made on the mould when at the main frame to fall below the breadth line of the after timber, and therefore another mark is made at the height of the breadth line at the after timber; the straight part of the mould is then laid obliquely across the breadth lines of the top-timbers, in such a manner that it may intersect the breadth line of the midship timber at one of these marks and the breadth line of the after timber at the other mark; then the several intersections of the breadth lines of the timbers are marked upon the mould; which must now be so placed in forming each timber, that the proper mark may be applied to its proper breadth, and it must be turned about so as just to touch the upper breadth sweep. Any of these methods may make a fair fide, and they may be easily proved by forming another intermediate half-breadth line.

The remaining parts of the frames may be described by either of the methods laid down in Problems IX. and XI. In order, however, to illustrate this still farther, it is thought proper to subjoin another method of forming the intermediate frames, the facility of which will recommend it.

Take FZ (fig. 30.), and lay it from F to k (fig. 32.); then describe the lower part of the foremost frame, making it more or less full according as proposed; and intersecting the ribbands in the points I, m, n. Describe also the aftermost frame o, p, q. Make a β (fig. 30.) equal to F r (fig. 32.), and produce it to a (fig. 31.); also draw γ α, and z (fig. 30.) equal to E r, and E s (fig. 32.) respectively; and produce them to b and c: Make F, s, r, F R (fig. 31.); equal to M, l, M n, P s (fig. 32.) each to each. Let also b h, b, d, and b, h, l, b, l, m, n (fig. 31.) be made equal to M b, NO, PQ, and M o, NG, P q (fig. 32.); then through these points trace the curves a, b, l, b, r, f, i, m, c, and r R k, n, p, and they will be the projections of the ribbands in the floor plane. Now transfer the several intervals of the frames contained between the middle line and the ribbands (fig. 31.) to the corresponding ribbands in the body plan (fig. 32.). Hence there will be five points given in each frame, namely, one at the lower breadth line, one at each ribband, and one at the keel; and consequently these frames may be easily described. In order to exemplify this, let it be required to lay down the frame E in the plane of projection. Take the interval E a (fig. 31.), and lay it from M to a (fig. 32.). Lay off also E v, E e (fig. 31.) from M to v and from P to n (fig. 32.) then through the points F, a, v, and the lower breadth line describe a curve, and it will be the representation of the frame E in the body plan. In like manner the other frames may be described.

The ribbands may now be transferred from the body plan to the plane of elevation, by taking the several heights of the intersection of each ribband with the frames, and laying them off on the corresponding lines in the floor plan; and if the line drawn through these points make a fair curve, it is presumed that the curves of the frames are rightly laid down in the body plan. Only one of these ribbands, namely, the first, is laid down in fig. 30. These curves may also be farther proved, by drawing water lines in the plane of elevation.

I. Of the Sheer Draught or Plane of Elevation.

Draw a straight line (fig. 53) to represent the upper edge of the keel, erect a perpendicular on that end to the right, and from thence set off 182 feet, the length on the gun deck, and there erect another perpendicular; that to the right is called the foremost perpendicular, and the other the after one: upon these two perpendiculars all the foremost and aftermost heights must be set off, which are expressed in the dimensions.

Then set off the distance of the main frame or dead flat from the foremost perpendicular, and at that place erect a third perpendicular, which must be distinguished by the character (9). From dead flat the room and space of all the timbers must be set off; but it will only be necessary to erect a perpendicular at every frame timber; which in the fore body are called dead flat, A C E, &c. and in the after body (2), 1, 3, 5, &c.: hence the distance between the frame perpendiculars will be double the room and space expressed in the dimensions. Then set off the heights of the gun deck afore at midship or dead flat, and abaft from the upper side of the keel; and a curve drawn through these three points will be the upper side of the gun-deck. Set off the thickness of the gun-deck plank below that; and another curve being drawn parallel to the former, the gun deck will then be described at the middle line of the fore body. The centre of the stem is then to be laid down by means of the table of dimensions; from which centre, with an extent equal to the nearest distance of the upper edge of the keel, describe a circle upwards; describe also another circle as much above this first mentioned point, and cutting the inner circle, and the after part of the stern is drawn. Draw another line from the foremost point downwards, parallel to the former, and breaking in fair with the inner circle, and the after part of the stern is drawn. Draw another line from the foremost point downwards, parallel to the former, and breaking in fair with the outer circle, then the whole stern will be formed, except the after or lower end, which cannot be determined till hereafter.

The stern-post must be next formed. Set off on the upper edge of the keel a spot for the aft part of the riblet taken from the dimensions, and from that forward let off another point at the distance of the thickness of the plank of the bottom, which is 4½ inches; and from this last mentioned point draw a line upwards, intersecting the perpendiculars at the height of the lower deck;
SHIP-BUILDING.

Application of the foregoing Rules to the Construction of Ships.

392

Ship

wing transom, and draw another horizontal line in pencil: then take the round aft of the wing transom, and set it forward on the upper line from the point representing the aft side of the wing transom; square it down to the lower line, and the intersection will be the touch of the wing transom; then a curve, similar to that at the middle line, being drawn from the touch of the wing transom to the touch of the lower counter at the side, will be the lower counter at the side. Draw a line from the upper counter upwards, and the whole stern timber at the side will be represented. But as the straight line drawn for the upper part of the side timber should not be parallel to that at the middle line, its rake is therefore to be determined as follows.

Draw a line at pleasure, on which set off the breadth of the stern at the upper counter; at the middle of this line set off the round ast of the upper counter, then through this point and the extremities of the stern describe a curve. Now take the breadth of the stern at the top-timber line, and through the point where that breadth will intersect the curve for the round ast of the stern draw a line parallel to that first drawn, and the distance from the line last drawn to the curve at the middle of the line is the distance that the side timber must be from the middle line at the height of the top-timber line.

The sheer is to be described, which is done by setting off the heights aforesaid, at midship, and aft, and a curve described through these three points will be the sheer. But in order that the sheer may correspond exactly with the dimensions laid down, it will be necessary to proceed as follows: The perpendicular representing timber dead flat being already drawn, set off from that the distances of the other frame timbers, which is double the room and space, as the frames are only every other one; and erect perpendiculars, writing the name under each; then on each of these perpendiculars set off the corresponding heights of the top-timber line taken from the table of dimensions for constructing the bodies, and through these points a curve being described, will represent the sheer of the ship or top timber line agreeable to the dimensions.

The quarter-deck and forecastle are next to be described, which may be done by taking their respective heights and lengths from the dimensions, and describing their curves. In the same manner also, the round-housé may be drawn. The decks being described representing their heights at the middle line, it is then necessary to represent them also at the side. For this purpose take the round of the decks from the dimensions, and set them off below the lower line drawn for the middle, and a curve described both fore and aft, observing to let it be rather quicker than the former, will be the representation of the decks at the side.

The ports come next under consideration. In the placing of them due attention must be paid, so as to preserve strength; or that they shall be so disposed as not to weaken the ship in the least, which is often done by cutting off principal timbers, placing them in too large openings, having too short timbers by the side of them, &c. The frames represented by the lines already drawn must be first consulted. Then with a pencil draw two curves, for the lower and upper parts of the lower deck posts, parallel to the line representing the lower deck; the distances of these lines from

deck; then set up the perpendicular the height of the wing transom, and draw a level line, and where that line intersects, the line first drawn will be the ast side of the wing transom; on the upper part of the middle line set off from that place the distance of the ast side of the stern-post; set off also the distance of the after part from the rabbet on the upper edge of the keel, and a line drawn through these two points will be the ast side of the pole. A line drawn parallel to the first drawn line at the distance of 4 1/2 inches, the thickness of the plank on the bottom, will be the ast side of the rabbet; and hence the stern-post is described, except the head, which will be determined afterwards.

From the dimensions take the several heights of the upper-deck above the gun-deck, aforesaid, and abaft, and set them off accordingly; through these points describe a curve, which will be the under side of the upper deck; describe also another curve parallel thereto, at the distance of the thickness of the plank, and the upper deck will be then represented at the middle line of the ship.

Set off the height of the lower counter, at the middle line, from the upper edge of the keel, and draw a horizontal line with a pencil; then on the pencil line set off the distance the touch of the lower counter is abaft the ast side of the wing transom; from this point to that where the fore part of the rabbet of the stern-post intersects the line drawn for the upper part of the wing transom, draw a curve at pleasure, which curve will represent the lower counter at the middle line. The height of the upper counter is then to be set off from the upper edge of the keel, and a horizontal line is to be drawn as before, setting off the distance the touch of the upper counter is abaft the ast side of the wing transom; and a curve described from thence to the touch of the lower counter will form the upper counter at the middle line.

Both counters being formed at the middle line, the upper part of the stern timber above the counters is to be described as follows: On the level line drawn for the upper side of the wing transom set off the distance of the ast side of the stern timber at the middle line from the ast side of the wing transom, at the height of the top-timber line, and erect a perpendicular; then upon this perpendicular, from the upper edge of the keel, set off the height at the middle line of the top timber line at the ast side of the stern timber; through this point draw a straight line to the touch of the upper counter, and the upper part of the stern timber will be described.

As the stern rounds two ways, both up and ast, the stern timber at the side will consequently alter from that at the middle line, and therefore remains to be represented. Take the round up of the upper counter from the dimensions, and set it below the touch at the middle, and with a pencil draw a level line; take also the round ast, and set it forward from the touch on the touch line, and square it down to the pencil line last drawn, and the point of intersection will be the touch of the upper counter at the side. In the same manner find the touch of the lower counter; and a curve, similar to that at the middle line, being described from the one touch to the other, will form the upper counter at the side.

Take the round up of the wing transom, and set it off below the line before drawn for the height of the stern.
the deck are to be taken from the dimensions, observing, however, to add to these heights the thickness of the deck, as the deck line at the side represents the under part of the deck.

The foremost port is then to be described, observing to place it as far aft as to give sufficient room for the manger; the most convenient place will therefore be to put it between the frames R and T, and equally distant from each. It will then be placed in the most conspicuous point of strength, as it will have a long top-timber on the aft side and a long fourth futtock on the fore side of it. The second port may be placed in like manner between the next two frames, which will be equally well situated for strength as the former; and by proceeding in this manner, the ports on the gun-deck may also be placed, taking care to have two frames between every two ports, all fore and aft.

The upper deck ports are then to be described; and in order to dispose of them in the strongest situation possible, they must be placed over the middle between the gun-deck ports, so that every frame in the ship will run up to the top of the side, by their coming between a gun and upper deck port; and every port will be between the frames, which will in a great measure contribute towards the strength of the ship. With regard to the ports on the quarter-deck, it is not of such material consequence if they cut the head of the frame, as in placing them the situation of the dead eyes must be considered; placing a port where there is a vacancy between the dead eyes large enough to admit of one; observing always to place them as nearly as possible at equal distances from each other and where it happens that they do not fall in the wake of a frame, then that frame must by all means be carried up to the top of the side. The necessary length of the round-house being determined in the dimensions, it may be set off; observing however, to let it be no longer than is just sufficient for the necessary accommodations, as the shorter the round-house the works abaft may be kept lower, and a low flung stern is always accounted the handsomer. Then set off the round of the deck at the foremost end, below the line drawn; the deck at the side may be described by another curve drawn quite ait. Now, from the point for the round of the deck to the stern timber, draw a curve parallel to the top-timber line, and that will be the extreme height of the top of the side abaft, which height continues to range fair along to the foremost end of the round-house, and at that place may have a fall about 14 inches, which may be turned off with a drift scroll. At the fore part of the quarter-deck, the topside may have a rise of 14 inches, which may also be turned off with a scroll. But as the railing of the topside only 14 inches at that place will not be sufficient to unite with the heights abaft, it will therefore be necessary to raise 14 inches more upon that, and break it off with a scroll inverted on the first scroll, and continue these two lines, parallel to the top-timber line, to the distance of about seven feet aft. At the foremost end of the round-house there is a break of 14 inches already mentioned, and in order to make that part uniform with the breaks at the foremost end of the quarter-deck, there must be set down 14 inches more below the former; and at these two heights continue two curves parallel to the top-timber line, from the aft part of the stern to the ends of the two curves already drawn at the foremost end of the quarter-deck. If they should happen not to break in fair with them, they must be turned off with a round; but to make them appear more handsome, the lower line may be turned off with a scroll. These lines being drawn will represent the upper edges of the rails.

The height of the top side at the foremost part of the ship must next be considered; which, in order to give proper height for the forecastle, must have a rise there of 14 inches, the break being at the after end of the forecastle, and turned off as before. But as this part of the ship is still considerably flatter than the after part, it will be necessary to give another of edge, and the wales upon the former, and turn it off with a scroll inverted. Hence this part of the ship will appear more uniform to the after part.

The finishing parts, namely the wales, stern, head, rails, &c. remain to be described. The wales may be first drawn; and as the strength of the ship depends very much on the right placing of them, great care must therefore be taken that they may be as little as possible wounded by the lower deck ports, and so placed that the lower deck bolts shall bolt in them, and also that they come as near as possible on the broadest part of the ship. In the first place, therefore, the height of breadth lines must be chosen for our guide. These heights of breadth are to be taken from the dimensions, and set off on the respective frames, and curves drawn through these points will be the upper and lower heights of the breadth lines. The height of the wales may now be determined; which in general is in such a ship that the upper height of breadth line comes about six inches below their upper edge, and the wales are then placed right upon the breadth lines. Take the heights and breadths of the wales afore, at midhips, and abaft from the table of dimensions; draw curves through the points thus found, and the wales will be represented.

The channel wales are then to be described. They are principally intended to strengthen the top side, and must be placed between the lower and upper deck ports; and the lower edge of them at midships should be placed as low as possible, in order to prevent them from being cut by the upper deck ports afore and abaft. Take their heights and breadths from the dimensions; lay them off, and describe curves through the corresponding points, and the channel wales will be represented.

Lay off the dimensions of the wale rail found in the table; and through the points draw a line parallel to the top-timber line all fore and aft. This rail terminates the lower part of the paint work in the top side; as all the work above this rail is generally painted, and the work of the top side below it painted with a varnish, except the main wales, which are always payed with pitch.

Take the draught of water from the dimensions, and draw the load water-line, which is always done in green. Divide the distance between the load water-line and the upper edge of the keel into five equal parts, and through these points draw four more water-lines.

Set off the centres of the masts on the gun-deck; their rate may likewise be taken from the dimensions. Set off also the centre of the bow-sprit, letting it be
S H I P - B U I L D I N G.

SHIPS.

Application of the foregoing Rules to the Construction of Ships.

The fenders may be then drawn, observing to place them right abreast of the main hatchway, in order to prevent the ship’s side from being hurt by whatever may be hoisted on board. The proper place for them will therefore be at timber 3; and the distance between them may be regulated by the distance between the ports. The cheek-tree may also be drawn, which must be placed at a proper distance abaft the foremast, for the convenience of hoisting home the fore-tack. It may therefore be drawn at the aft side of timber C, from the top of the fiddle down to the upper edge of the channel wales; and the fenders may reach from the top of the fiddle down to the upper edge of the main wales. As the fenders and cheek-tree are on the outside of the planks, wales, &c. the lines representing the wales, &c. should not be drawn through them.

Draw the steps on the side, which must be at the fore part of the main drift or break, making them as long as the distance between the upper and lower deck ports will admit of. They may be about six inches afender, and five inches deep, and continued from the top of the side down to the middle of the main wales.

In order to describe the head, the height of the beak-head must be first determined, which may be about two feet above the upper deck. At that place draw a horizontal line, upon which set off the length of the beak-head, which may be 7½ feet abaft the fore part of the stem, and from thence square a line up to the forecastle deck, which line will represent the aft part of the beak-head, and will likewise terminate the foremost end of the forecastle. The length of the head may now be determined, which by the proportions will be found to be 3½ feet six inches from the fore part of the stem. Set it off from the fore part of the stem, and erect a perpendicular, which will be the utmost limits of the figure forward; then take the breadth of the figure from the proportions, which is four feet four inches, and let it off forward; and another perpendicular being drawn will give the utmost extent of the hair bracket forward, or aft part of the figure. Then draw the lower cheek, letting the upper edge be well with the upper edge of the main wales, and the after end ranging well with the beak-head line; set off the depth of it on the stem; which is about 1½ inches, and let a curved line pass from the after end through the point on the stem, and to break in fair with the perpendicular first drawn for the length of the head, the fore part of the curve will then represent the position of the figure.

The upper cheek may be next drawn; but, in order to know the exact place of it on the stem, the place of the main rail must first be set off on the stem, the upper edge of which may be kept on a level with the beak-head; then setting off the depth of it below that, the place for the upper cheek may be determined, letting it be exactly in the middle between that and the lower cheek: then, by drawing curves for the upper and lower edges of the cheek from the after end parallel to the lower cheek, to break in fair with the perpendicular, drawn for the back of the figure: then the upper cheek will be formed. The upper part may run in a perpendicular as high as where the shoulder of the figure is supposed to come, at which place it may be turned off with a fillet. The distance from the fillet to the heel of the figure is called the hair-bracket.

The head of the block may be formed by continuing the line at the breast round to the top of the hair-bracket, observing to keep the top of it about six inches clear of the upper side of the bowsprit.

Having the distance set off on the stem for placing the main rail, it may next be described, keeping the bag of it as level as possible for the convenience of the gratings, and letting the foremost end rise gradually according to the rise of the upper cheek and hair-bracket, and may turn off on the round of the fillet before drawn for the hair-bracket. To form the after end, set off the size of the head of the rail abaft the beak-head line, and erect a perpendicular; then describe the arch of a circle that perpendicular to break in fair with the lower side of the rail in the middle, and also another from the beak-head perpendicular, to break in fair with the upper side of the rail at the middle, observing to continue the head of it sufficiently high to range with the timber heads above the forecastle.

The head timbers are next to be drawn, placing the stem timber its own thickness abaft the stem, and the foremost must be so placed that the fore side may be up and down with the heel of the block or figure, which has not yet been set off. Take therefore the distance from the breast to the heel on a square which is seven feet, and erect a perpendicular from the lower part of the lower cheek to the lower part of the upper cheek; which perpendicular will terminate the foremost end of the lower cheek and the heel of the figure, and will also terminate the lower end of the hair-bracket; then, by continuing the fame perpendicular from the upper part of the lower deck to the under part of the main rail, the fore side of the foremost head timber will be described; and by setting off its thickness aft, the other side may be drawn. The middle head timber may be spaced between the two former ones; and there may also be one timber
timber placed abaft the stem, at a distance from the stem, equal to that between the others, and the lower end of it may stop on the upper edge of the lower rail.

To describe the middle and lower rails, divide the distance between the lower part of the main rail and the upper part of the upper check equally at every head timber; and curves being described through these points will form the middle and lower rails. The after end of the lower rail must terminate at the after edge of the after head timber.

The cat-head ought to be represented in such a manner as to come against the aft side of the head of the main rail, to rake forward four inches in a foot, and to steve up 5½ inches in a foot, and about one foot six inches figure. The lower part of it comes on the plank of the deck at the side, and the supports under it must form a fair curve to break in with the after end of the middle rail.

The hawse holes must come between the checks, which is the most convenient place for them; but their place fore and aft cannot be exactly determined until they are laid down in the half-breadth plan.

The knee of the head is to project from the breadth of the figure about two inches; and particular care must be taken that in forming it downwards it be not too full, as it is then liable to rub the cable very much: it may therefore have no more substance under the lower check at the heel of the figure than is just sufficient to admit of the hawser holes, and may be 3½ feet distant from the stem at the load water-line, making it run in an agreeable curve to the heel, where it may be 1½ feet from the stem. By continuing the same line downwards, keeping it more distant from the stem as it comes down, the gripe will be formed. The lower part of it must break in fair with the under part of the false keel; and the breadth of the gripe at the broadest place will be found by the proportions to be 4½ feet. As the aft part of the gripe is terminated by the fore foot, or foremost end of the keel, it will now be proper to finish that part as follows: From the line representing the upper edge of the keel set up the depth of the keel, through which draw a line parallel to the former, and it will be the lower edge of the keel. From that point, where the aft side of the stem is distant from the upper edge of the keel by a quantity equal to the breadth of the keel at midships, erect a perpendicular, which will limit the foremost end of the keel; and the after or lower end of the stem may be represented by setting off the length of the scarf from the foremost end of the keel, which may be six feet. Set down from the line representing the lower edge of the keel the thickness of the false keel, which is seven inches; and a line drawn through that point parallel to the lower edge of the keel will be the under edge of the false keel, the foremost end of which may be three inches above the foremost end of the main keel.

The head being now finished, proceed next to the stern, the false and middle timbers of which are already drawn. From the false timber set off forward 14 feet, the length of gallery, and draw a pencil line parallel to the false timber; draw also a line to intersect the touch of the upper counter at the false, producing it forwards parallel to the false as far as the pencil line first drawn; and this line will represent the upper edge of the gallery rim. From which set down eight inches, the breadth of the gallery rail, and draw the lower edge of the rail. At the distance of eight inches from the fore side of the false timber draw a line parallel thereto; and from the point of intersection of this line with the upper edge of the gallery rim, draw a curve to the middle timber parallel to the touches of the upper counter, which line will represent the upper edge of the upper counter rail as it appears on the fore draught. The lower edge of this rail may be formed by setting off its depth from the upper edge. In the same manner the lower counter rail may be described; then take the distance between that and the upper counter rail, and set it off below the rim rail; and hence the rail that comes to the lower floor may be drawn, keeping it parallel to the rim rail. Underneath that, the lower finishing may be formed, making it as light and agreeable as possible.

Set off from the middle timber on the end of the quarter-deck the projection of the balcony, which may be about 2 feet, and draw a line with a pencil parallel to the middle timber. On this line set off a point 1½ inches below the under side of the quarter-deck, from which draw a curve to the false timber parallel to the upper counter rail, which curve will represent the lower side of the foot space rail of the balcony as it appears in the fore draught.

Take the distance between the point of intersection of the upper edge of the upper counter with the middle line, and the point of intersection of the under side of the foot space rail with the middle line, which may be four feet above the floor, and this curve run nearly parallel to it. Then set off the same distance above the curve drawn for the lower edge of the foot space rail, and the upper edge of that rail may then be drawn.

The quarter-piece must be next described, the heel of which must step on the after end of the middle floor. Draw a line with a pencil parallel to the middle timber, and at a distance therefrom, equal to the projection of the balcony. Upon this line set off the round house deck the height of the upper part of the stem or false rail, which may be four feet above the deck. At that height draw with a pencil a horizontal line, and from its intersection with the line first drawn describe a curve to the middle floor rail, observing to make the lower part of this curve run nearly parallel to the false timber, and the lower part about three inches abaft the false timber; and this curve will represent the ait side of the quarter-piece at the outside. There set off the thickness of the quarter-piece, which is one foot six inches, above the curve already drawn; and another curve being described parallel to it from the lower part to the top of the floor, and the quarter-piece...
at the outside will be represented. On the horizontal line drawn for the upper part of the taff-rail set off toward the thickness of the taff-rail, which is one foot; then a curve down to the head of the quarter-piece parallel to the first, and that part of the taff-rail will be described. Instead of a fair curve, it is customary to form the upper part of the taff-rail with one or two breaks, and their curves inverted. Either way may, however, be used according to fancy.

Set off the depth of the taff-rail, which may be about 3½ feet from the deck; set off the number of pieces and middle one of the gallery will then be drawn. The breadth of the rudder at the lower end, which will be determined by the proportions and set off, and a line drawn from the lower hance to the lower end, will represent the back. The head of the rudder should be as high as to receive a tiller above the upper deck. Therefore set off the size of the head above the upper deck, and draw a line from thence to the break at the upper hance, and the aft part of the rudder will be represented all the way up. The boarding should be drawn, by setting off the breadth of it at the keel from the fore side of the rudder, which may be nine inches. Set off also the breadth at the head of the wing transom, which may be a foot. Then a line being drawn through these two points, from the lower part of the rudder to about a foot above the wing transom, and the boarding will be represented. As the boarding is a very nice point, and the working of the rudder depending very much upon it, it should always be very particularly considered. It has been customary to be the rudder to a sharp edge at the middle line, by which the main piece is reduced more than necessary. The rudder should, however, be bearded from the side of the pinnacles and the fore side made to the form of the pinnacles.

The pinnacles and braces may next be drawn. In order to which determine the place of the upper one, which must be so disposed that the flap shall come round the head of the standard, which is against the head of the stern-post on the gun-deck, and meet at the middle line. By this means there is double security both to the brace and standard. To obtain these advantages, it must therefore be placed about four inches above the wing transom; the second must be placed just below the upper one, which may be above the upper one, which may be above the upper one, which may be above the upper one, which may be above the upper one, which may be about the proper lengths.

If, of the half-breath and body plans.—The half-breath
breadth plan must be first drawn. Then produce the lower edge of the keel both ways, and let it also represent the middle line of the half-breadth plan. Produce all the frames downwards, and also the fore and after perpendiculars. Then from the place in the sheer-plan, where the height of breadth-lines intersect the item, square down to the middle line the fore and aft part of the rabbit and the fore part of the item. Take from the dimensions what the item is fitted at that place, and set off half of it from the middle line in the half-breadth plan, through which draw a line parallel to the middle line through the three lines squared down, and the half-breadth of the item will be represented in the half-breadth plan. Take the thickness of the plank of the bottom, which is 4\text{\textfrac{1}{2}} inches, and describe the rabbit of the item in the half-breadth plan.

From the points of interception of the height of breadth lines with the counter timber at the side, and with the counter timber at the middle line, draw lines perpendicular to the middle line of the half-breadth plan, from which set off the half breadth of the counter on the line first drawn; and from this point, to the interception of the line half breadth line with the middle line drawn upwards, and the half-breadth of the counter will be represented at the height of breadth, which will be the breadth part of the item.

Take the main half breadth of timber dead flat from the dimensions, and lay it off from the middle line on dead flat in the half-breadth plan. Take also from the dimensions the main half breadth of every timber, and set off each from the middle line on the corresponding timbers in the half-breadth plan. Then a curve drawn from the end of the line representing the half breadth of the counter through all the points, set off on the timbers, and terminating at the aft part of the item, will be the main half breadth line. Take from the dimensions the top-timber half-breadth, and describe the top-timber half-breadth line in the half-breadth plan, in the same manner as the main half-breadth line.

Take from the dimensions the half breadth of the risings and set it off from the middle line on the corresponding timbers in the half-breadth plan, observing, where the word outside is expressed in the tables, the half breadth for that timber must be set off above or on the outside of the middle line. Then a curve drawn through these points will be the half breadth of rising in the half-breadth plan.

It will now be necessary to proceed to the body plan. Draw a horizontal line (fig. 35.), which is called the base line, from the right hand extremity of which erect a perpendicular. Then set off on the base line the main half breadth at dead flat, and erect another perpendicular, and from that set off the half breadth again, and erect a third perpendicular. The first perpendicular, as already observed, is called the side line of the fore body; the second the middle line; and the third the side line of the after body.

Take from the dimensions the heights of the diagonals up the middle line, and set them from the base up the middle line in the body plan. Take also their distances from the middle line on the base, and set them off. Set off also their heights up the side lines, and draw the diagonals. Then take from the sheer plan the heights of the lower height of breadth line, and set them off upon the middle line in the body plan; through these points lines are to be drawn parallel to the base, and terminating at the side lines. In like manner proceed with the upper height of breadth line.

The rising is next to be set off on the body plan; it must, however, be first described in the floor plan. Take, therefore, the heights from the dimensions, and set them off on the corresponding timbers in the sheer plan, and a curve described through these points will be the rising line in the sheer plan. Then take from the dimensions the rising heights of dead flat. Set it off in the body plan, and draw a horizontal line. Now take all the rising heights from the sheer plan, and set them off in the body plan from the line drawn for the rising height of dead flat, and draw horizontal lines through these points. Take from the half-breadth plan the half breadthths of the rising, and set them off from the middle line in the body plan, and the centres of the floor sweeps of the corresponding timbers will be obtained.

From the half-breadth plan take the main half-breadth lines, and set them off from the middle line in the body plan on the corresponding lines before drawn for the lower height of breadth; and from the extremities of these lines set off towards the middle line the lengths of the lower breadth sweeps respectively.

Take from the dimensions the distance of each frame from the middle line on the diagonals, and set them off from the middle line on their respective diagonal lines. Now these distances being set off, and the lower breadth and floor sweeps described, the shape of the frames below the breadth line may easily be drawn as follows: Place one point of a compass in the distance set off for the length of the lower breadth sweep, and extend the other to the point which terminates the breadth, and describe an arch of a circle downwards, which will intersect the points set off on the upper diagonal lines, letting it pass as low as convenient. Then fix one point of the compasses in the centre of the floor sweep, and extend the other to the point set off on the fourth diagonal, which is the floor head; and describe a circle intersecting as many of the points set off on the diagonals as it will. Then draw a curve from the base of the lower breadth sweep, through the points on the diagonals, to the back of the floor-sweep. Describe also another curve from the back of the floor-sweep through the points on the lower diagonal, and terminating at the upper part of the rabbit of the keel, and that part of the frame below the breadth will be formed. In like manner describe the other frames. Through the extremities of the frames at the lower height of breadth draw lines parallel to the middle line, and terminating at the upper height of breadth line and from thence set off the upper breadth sweeps; now fix one point of the compasses in the centre of the upper breadth sweeps successively, and the other point to the extremities of the frames, and describe circles upwards. Then from the sheer plan take off the heights of the top timber lines, and set them off in the body plan, drawing horizontal lines upon which set off the top-timber half breadthths taken from the corresponding timbers in the half-breadth plan; and by describing curves from the back of the upper breadth sweeps through the points set off on the seventh or upper diagonal; and intersecting the top-timber half breadthths, the timbers will then be formed from the keel.
SHI B U I L D I N G.  

398  

Rule to the 

Save of the 

SOP.  

keel to the top of the side. The upper end of the timbers may be determined by taking the several heights of the upper part of the top side above the top-timber line, and setting them off above the top-timber line on the corresponding timbers in the body plan. The lower parts of the timbers are ended at the rabbet of the keel as follows: With an extent of 4½ inches, the thickness of the bottom, and one leg of the companies at the place where the line for the thickness of the keel intersects the base line; with the other leg describe an arch to intersect the keel line and base. Then fix one point at the intersection of the arch and keel, and from the point of intersection of the keel and base describe another arch to intersect the former. Then from the intersection of theses arches draw one straight line to the intersection of the keel and base, and another to the intersection of the lower arch and keel, and the rabbet of the keel will be described at the main frame. All the timbers in the middle part of the ship which have no rising terminate at the intersection of the upper edge of the rabbet with the base line; but the lower part of the timbers, having a rising, end in the centre of the rabbet that is where the two circles intersect. Those timbers which are near the after end of the keel must be ended by setting off the half-breadth of the keel at the port in the half-breadth plan, and describe the tapering of the keel. Then at the corresponding timbers take off the half-breadth of the keel; set it off in the body plan, and describe the rabbet as before, letting every timber end where the two circles for its respective rabbet intersect.

To describe the side counter or stern timber, take the height of the wing transom, the lower counter, upper counter, and top-timber line at the side; from the shear plan transfer them to the body plan, and through these points draw horizontal lines. Divide the distance between the wing transom and lower counter into three equal parts, and through the two points of division draw two horizontal lines. Draw also a horizontal line equidistant from the upper counter and the top-timber line in the shear plan, and transfer them to the body plan. Now, from the point of intersection of the aft side of the stern timber at the side, with the wing transom at the side in the shear plan, draw a line perpendicular to the middle line in the half-breadth plan. Draw also perpendicular lines from the points where the upper and lower transoms touch the stern-post; from the points of intersection of the stern timber with the two horizontal lines drawn between, and from the intersection of the stern timber with the horizontal line drawn between the upper counter and top-timber line. Then curves must be formed in the half-breadth plan for the shape of the body at each of these heights. In order to which, begin with the horizontal or level line representing the height of the wing transom in the body plan. Lay a slip of paper on that line, and mark on it the middle line and the timbers 37, 35, 33, and 29; transfer the slip to the half-breadth plan, placing the point marked on it for the middle line exactly on the middle in the half-breadth plan, and set off the half-breadths on the corresponding timbers 37, 35, 33, and 29, and describe a curve through these points, and to intersect the perpendicular drawn from the shear plan. In like manner proceed with the horizontal lines at the heights of the counters, between the lower counter and wing transom, above the upper counter and top-timber line; and from the intersections of the curve drawn in the half-breadth plan, with the perpendicular lines drawn from the shear plan, take the distances to the middle line, and set them off on the corresponding lines in the body plan: formation of the half-breadth plan, then a curve described through the several points, thus set off will be the representative of the stern timber.

The round-up of the wing transom, upper and lower counter, may be taken from the sheer draught, and set off at the middle line above their respective level lines in the body plan, by which the round-up of each may be drawn. The round aft of the wing transom may also be taken from the sheer plan, and set off at the middle line, abeam the perpendicular for the wing transom in the half-breadth plan, whence the round aft of the wing transom may be described.

The after body being now finished, it remains to form the fore body: but as the operation is nearly the same in both, a repetition is therefore unnecessary, except in those parts which require a different process.

The foremost timbers end on the stern, and consequently the method of describing the ending of them differs from that which is used in the after body. Draw a line in the body plan parallel to the middle line, at a distance equal to the half of what the stem is sided. In the sheer plan take the height of the point of intersection of the lower part of the rabbet of the stem with the timber which is required to be ended, and set it off on the line before drawn in the body plan. Then take the extent between the points of intersection of the timber with the lower and upper parts of the rabbet, and with one leg of the companies at the extremity of the distance laid off in the body plan describe a circle, and the timbers may then pass over the back of this circle. Now, by applying a small square to the timber, and letting the back of it intersect the point set off for the lower part of the rabbet, the lower part of the rabbet and the ending of the timbers will be described.

The foremost timbers differ also very much at the head from those in the after body; for since the ship carries her breadth so far forward at the top-timber line, it therefore occasions the two foremost frames to fall out at the head beyond the breadth, whence they are called knuckle timbers. They are thus described; The height of the top-timber line being set off in the body plan, set off on it the top half-breadth taken from the half-breadth plan, and at that place draw a perpendicular; then from the sheer plan take the height of the top of the side, and set it off on the perpendicular in the body plan: Take also the breadth of the rail at the top-timber line in the sheer plan, and set it off below the top-timber line at the perpendicular line in the body plan, and the straight part of the knuckle timber to be drawn will be determined. Then from the last mentioned point set off describe a curve through the points set off for the timber down to the upper breadth, and the whole knuckle timber will be formed. It will hence be seen that those timbers forward will fall out beyond the main breadth with a hollow, contrary to the rest of the top side, which falls within the main breadth with a hollow.

The fore and after bodies being now formed, the water lines must next be described in the half-breadth plan, in order to prove the fairness of the bodies. In this draught the water lines are all represented parallel to
the keel; their heights may, therefore, be taken from the sheer plan, and transferred to the body plan, drawing horizontal lines, and the water lines will be represented in the body plan. In ships that draw more water abaft than aforc, the water lines will not be parallel to the keel; in this case, the heights must be taken at every timber in the sheer plan, and set off on their corresponding timbers in the body plan; and curves being described through the several points, will represent the water lines in the body plan.

Take the distance from the middle line to the points where the water lines intersect the different timbers in the body plan, and set them off on their corresponding timbers in the half-breadth plan. From the points where the water lines in the sheer plan intersect the aft part of the rabbet of the sternpost draw perpendiculars to the middle line of the half-breadth plan, and upon these perpendiculars set off from the middle line the half thickness of the sternpost at its corresponding water line; which may be taken from the body plan, by setting off the size of the post at the head and the keel, and drawing a line for the tapering of it; and where the line so drawn intersects the water lines, that will be the half thickness required: then take an extent in the compasses equal to the thickness of the plank, and fix one point where the half thickness of the post intersects the perpendicular, and with the other describe a circle, from the back of which the water lines may pass through their respective points set off, and end at the fore part of the half breadth plan, proceeding in the same manner as with the after part. A line drawn from the water line to the point set off for the half thickness of the post will represent the aft part of the rabbet of the post; and in like manner the rabbet of the stem may be represented. The water lines being all described, it will be seen if the body is fair; and if the timbers require any alteration, it should be complied with.

The cant timbers of the after body may next be described in the half-breadth plan; in order to which the cant of the fashion-piece must first be represented. Having therefore the round aft of the wing transom represented in the half-breadth plan, and also the shape of a level line at the height of the wing transom; then set off the breadth of the wing transom at the end, which is one foot four inches, and that will be the place where the head of the fashion-piece will come: now to determine the cant of it, the shape of the body must be considered; as it must be canted in such a manner as to preserve as great a straightness as is possible for the shape of the timber, by which means the timber will be much stronger than if it were crooked; the cant must also be considered, in order to let the timber have as little bevelling as possible. Let, therefore, the heel of the timber be set off on the middle line, two feet aorc timber 35; and then drawing a line from thence to the point set off on the level line for the wing transom, the cant of the fashion-piece will be described, and will be found situated in the best manner possible to answer the before mentioned purposes.

The cant of the fashion-piece being represented, the cant of the other timbers may now be easily determined. Let timber 29 be the foremost cant timber in the after body, and with a pencil draw timber 28; then observe how many frames there are between timber 28 and the fashion-piece, which will be found to be nine. Apply the following rule to the construction of ships.

Divide the distance between timber 28 and the fashion-piece on the middle line into 10 equal parts: divide also the corresponding points of the main half-breadth section of lines into the same number of equal parts; and draw lines joining the corresponding points as the mistake line with those in the half-breadth line will represent the cant timbers in the after body.

The line drawn for the cant of the fashion-piece represents the aft side of it, which comes to the end of the transoms; but in order to help the construction with regard to the lower transoms, there may be two more fashion-pieces abaft the former; therefore the foremost fashion-piece, or that which is already described in the half-breadth plan, may only take the ends of the three upper transoms, which are, the wing, filling, and deck; the middle fashion-piece may take the four next, and the after fashion-piece the lower ones: therefore set off in the half-breadth plan the siding of the middle and after fashion-piece, which may be 13 inches each; then by drawing lines parallel to the foremost fashion-piece, at the aforesaid distance from each other, the middle and after fashion-piece will be represented in the half-breadth plan.

The fashion-piece and transoms yet remain to be represented in the sheer plan; in order to which, let the number of transoms be determined, which, for large a buck, may be ten below the deck transom: draw them with a pencil, beginning with the wing, the upper side of which is represented by a level line at its height; set off its siding below that, and draw a level line for the lower edge. The filling transom follows; which is merely for the purpose of filling the vacancy between the under edge of the wing and the upper part of the deck plank: it may therefore be represented by drawing two level lines for the upper and lower edge, leaving about two inches between the upper edge and lower edge of the wing transom, and four inches between the lower edge of the gun deck plank; then the deck transom must be governed by the gun-deck, letting the under side of the gun deck plank represent the upper side of it, and setting off its siding below that; the under edge may also be drawn; the transoms below the deck may all be fitted equally, which may be 11 inches; they must also have a sufficient distance between to admit the circulation of the air to preserve them, which may be about three inches.

The transoms being now drawn with a pencil, the fashion-piece must next be described in the sheer plan, by which the length of the transoms as they appear in that plan will be determined. As the foremost fashion-piece reaches above the upper transom, it may therefore be first described: in order to which, draw a sufficient number of level lines in the sheer plan; or, as the water lines are level, draw therefore one line between the upper water line and the wing transom, and one above the wing transom at the intended height of the head of the fashion-piece, which may be about five feet: then take the height of these two level lines, and transfer them to the body plan; and take off two or three timbers and run them in the half-breadth plan, in the same manner as the water lines were done; then from the point where the line drawn for the cant of the fashion-piece, in the half-breadth plan, intersects the
Application of the foregoing Rules to the Construction of Ships.

The half-breadth line drawn for the head of the fashion-piece, draw up a perpendicular to the said line in the sheer plan, making a point. Again, from the intersection of the cant line, with the level line for the wing transom in the half-breadth plan draw a perpendicular to the wing transom in the sheer plan. Also draw perpendiculars from the points where the cant line in the half-breadth plan intersects the level line below the wing transom, and also the water lines to the corresponding lines in the sheer plan; then a curve described through these points will be the representation of the foremost fashion-piece in the sheer plan. In the same manner the middle and after fashion-pieces may be described; observing to let the middle one run up no higher than the under part of the deck transom, and the after to the under side of the fourth transom under the deck. The transoms may now be drawn with ink, as their lengths are limited by the fashion-pieces.

Neither the head nor the foreside of the sternpost are yet described; take, therefore, from the dimensions, the breadth of the post on the keel, and set it off on the upper edge of the keel from the aft side of poit. The head of the post must next be determined, which must just be high enough to admit of the helm-post transom and the tilter coming between it and the upper deck beam; the height therefore that is necessary will be one foot nine inches above the wing transom. Now draw a level line at that height, upon which let off the breadth of the sternpost at that place, taken from the dimensions, and a line drawn from thence to the point let off on the level will be the foreside of the sternpost; observing, however, not to draw the line through the transoms, as it will only appear between them. The inner post may be drawn, by letting off its thickness forward from the sternpost, and drawing a straight line as before, continuing it no higher than the under side of the wing transom.

The cant-timbers in the after body being described, together with the parts dependent on them, those in the fore body may be next formed; in order to which, the foremost and aftermost cant-timbers must first be determined, and also the cant of the foremost ones. The foremost cant-timber will extend far forward as to be named &; the cant on the middle line may be one foot four inches above square timber W, and on the main half-breadth line one foot nine inches above timber Y; in which situation the line may be drawn for the cant; the aftermost may be timber Q. The cant timbers now may be described in the same manner as those in the after body, namely, by tracing them equally between the cant timber & and the square timber P, both on the main half breadth and middle lines, and drawing straight lines between the corresponding points, observing to let them run out to the top-timber half-breadth line, where it comes without the main half-breadth line.

The hawse pieces must next be laid down in the half-breadth plan; the sides of which must look fore and aft with the ship upon account of the round of the bow. Take the fiding of the apron, which may be about four inches more than the item, and set off half of it from the middle line, drawing a line from the main half-breadth to the foremost cant timber, which will represent the foremost edge of the knight head; then from that set off the fiding of the knight-head, which may be one foot four inches, and draw the aft side of it.

The hawse pieces may then be drawn, which are the four in number, by setting off their fodings, namely, one foot six inches parallel from the knight-head and from each other; and straight lines being drawn from the main half-breadth line to the foremost cant timber will represent them.

The hawse holes should be described in such a manner as to wound the hawse pieces as little as possible; they may therefore be placed so that the joint of the hawse pieces shall be in the centre of the holes, whence they will only cut half the hawse pieces. Take the dimensions of the hawse holes, which is one foot six inches, and set off the foremost one, or that next the middle line, on the joint between the first and second hawse piece; then set off the other on the joint between the third and fourth hawse piece; and small lines being drawn across the main half-breadth at their respective places will represent the hawse holes in the half-breadth plan.

The hawse holes should next be represented in the sheer plan. In this class of ships they are always placed in the middle between the cheeks; therefore set off their diameter, namely, one foot six inches, between the cheeks, and draw lines parallel to the cheeks for their upper and lower part. Then to determine their situation agreeable to the half-breadth plan, which is the fore and aft way, draw perpendiculars from the intersections with the main half-breadth line to the lines drawn between the cheeks, and their true situations, the fore and aft way, will be obtained; and, by describing them round or circular, according to the points set off, they will be represented as they appear in the sheer plan.

The apron may be drawn in the sheer plan, setting off its bigness from the item, and letting it come so low that the scarfs may be about two feet higher than the foremost end of the fore foot; by which it will give ship to the scarfs of the item. It may run up to the head of the item.

- The cutting down should next be drawn. Take therefore from the tables of dimensions the different heights there expressed, and set them off from the upper edge of the heel on the corresponding timbers in the sheer plan; then a curve described through the points set off, from the inner post aft to the apron forward, will be the cutting down. Next set off from the cutting down the thickness of the timber strike, which is 3½ inches, and a curve described parallel to the former will represent the timber strike, from which the depth of the hold is always measured.

The kelson is drawn, by taking its depth from the dimensions, and setting it off above the cutting down line, and a curve described parallel to the cutting down will represent the kelson.

The cutting down line being described, the knee of the dead wood abait timber 27, being the after floor timber, may then be represented. Set off the fiding of the floor abait it, and erect a perpendicular in the sheer plan, which will terminate the foremost end of the dead wood; then the fore and aft arm of the knee may be half the length of the whole dead wood, and the up and down arm may reach to the under part of the lower transom; and the whole knee may be placed in such a manner that the upper piece of the dead wood...
wood shall bolt over it, and be of as much substance as
the knee itself; therefore the knee must conseq
sequently be placed its whole thickness below the cutting down
line representing the upper part of the dead wood.

The sheer draught, the body, and half-breadth plans are now finished, from whence the ship may be laid
down in the mould loft, and also the whole frame erect-
ed. As, however, the use of the diagonal lines in the
body plan has not been sufficiently explained, it is therefore thought proper to subjoin the following illu-
nation of them.

The diagonal lines in the body plan are mentioned
in the tables of dimensions merely for the purpose of
forming the body therefrom; but after the body is
formed, they are of very principal use, as at their
stations the ribbands and harpins which keep the body of
the ship together while in her frames are all described,
and the heads of the different timbers in the frame like-
wise determined.

The lowermost diagonal, or No. 1, which is named the
lower firnark, at which place the bevellings are taken
for the hollow of the floors; its situation is gener-
ally in the middle between the keel and the floor
firnark.

Second diagonal is placed in the midhips, about 18
inches below the floor head, and is the station where the
floor ribband is placed in midhips, and likewise the floor
harpin forward; there is also a beveling taken at this
diagonal all the way fore and aft, from which it is termed
the floor firnark.

Third diagonal, terminates the length of the floors,
and is therefore called the floor head. There are likewise
bevellings taken at this diagonal as far forward and aft
as the floor extends. The placing of this diagonal is
of the utmost consequence to the strength of the ship,
it being so near to that part of the bulge which takes
the ground, and of consequence is always liable to the
greatest strain; it should therefore be placed as much
above the bearing of the body in midhips as could be
conveniently allowed by conversion of the timber;
but aore and abaft it is not of so much consequence.

Fourth diagonal is placed in the middle between the
floor head and the fifth diagonal, at which place a rib-
band and harpin are fastened for the security of the first
or lower futtock, from whence it is named the first
futtock firnark. There are also bevellings taken at this
diagonal all fore and aft, which being part of the body
where the timbers most vary, occasions them to be the
greatest bevellings in the whole body.

Fifth diagonal terminates the heads of the first fut-
tocks, and is therefore called the first futtock head. It
should be placed at a convenient distance above the
floor head, in order to give a sufficient scarf to the lower
part of the second futtocks. There are likewise
bevellings for the timbers taken at this diagonal, all fore
and aft.

Sixth diagonal should be placed in the middle be-
tween the first futtock head and the seventh diagonal;
at which place the ribband and harpin are fastened for
the support of the second futtocks. Bevellings are tak-

Vol. XVII.
SH I P-B U I L D I N G.

Book I.

402

Application of the foregoing Rules to the Construction of Ships.

should be introduced to make good the deficiency. Every beam, and also the beam arms, should be stayed at each end with one lodging and one hanging knee; and in those parts of the ship which require the knees to be very acute, such as the after beams of the gun-deck, and in some ships, whose bodies are very sharp, the foremost beams of the gun-deck, there should be knees of iron. Care should be always taken to let the upper side of the knees be below the surface of the beams in large ships one inch and a half, and in small ships an inch, by which means the air will have a free passage between the knees and under part of the deck.

In the conversion of the beams the side next the lodging knee should be left as broad at the end of the beam as can possibly be allowed by the timber, the beam retaining its proper scantling at the end of the lodging knee: by so doing the lodging knees will be more without a square, which consequently makes them the more easy to be provided.

In ships where the beams can be got in one piece, they should be disposed as to have every other one with the butt end the same way; for this reason, that the butts will decay before the tops. In large ships the beams are made in two or three pieces, and are therefore allowed to be stronger than those that are in one piece. The beams in two pieces may have the scarf one-third of the length, and thole in three pieces should have the middle piece half the length of the whole beam. The customary way of putting them together is to table them; and the length of the tablings should be one-half more than the depth of the beam. It is very common to divide the tablings in the middle of the beam, and that part which is taken out at the upper side to be left at the lower side, and then kerfey or flannel is put into the scarf; but in this case the water is liable to lie in the scarf, and must be the means of rotting the beams. If, however, the beams were tabled together in dovetails, and taken through from side to side, putting tar only between them, which hardens the wood; then the water occasioned by the leaking of the decks would have a free passage, and the beam would dry again; and this method would not be found inferior in point of strength to the other. The length of the fore and aft arm of the lodging knee should extend to the side of the hanging knee next to it; but there is no necessity for that arm to be longer than the other. In fastening the knees, care should be taken to let one bolt pass exactly through the middle of the throat, one foot six inches from each end, and the rest divided equally between; observing always to have the holes bored square from the knee. The bolts for the thwartships arms of both hanging and lodging knees may go through the arms of each knee, and drive every one the other way.

In order to draw the beams in the draught, take the moulding of the lower deck beams, and set it off below the line representing the deck at the side, and draw a line in pencil parallel thereto, which will represent the under side of the beams. In like manner represent the under side of the beams for the upper deck, quarter deck, forecastle, and roundhouse. Then take the fiding of the lower deck beams, and place one under and one between each port, all fore and aft, drawing them in pencil. Determine the dimensions of the well fore and aft, which is ten feet, and set it off abait the beam under the eighth port, placing the beam under the ninth port at that distance: those two beams may then be drawn in ink, and will terminate the extent of the well the fore and aft way; and as a beam cannot go across the ship at that place upon account of its being the well and main room, there must therefore be a beam arm between these two beams.

The main hatchway should then be determined, letting the beam that forms the fore part of the well form the aft part of it, and the beam under the next part may form the fore side of it, which beam may also be now drawn in ink; there should also be another beam arm introduced in the wake of the main hatchway.

The fore hatchway may be next determined; the fore side of which should range well up and down with the after end of the forecastle, and it may be fore and aft about four-sevenths of the main hatchway. At the fore side of the fore hatchway there must be a ladderway down to the orlop, which may be as much fore and aft as the beams will allow. The rest of the beams above the fore hatchway may remain as first placed, there being nothing in the way to alter the ship. Then determine on the after hatchway, the foreside of which comes to the aft side of the mainmam room.

There should also be a hatchway, the fore side of which may be formed by the aft side of the beam under the twelfth port; which is for the convenience of the spirit and fish rooms: and there should be a ladderway abaft it to lead down to the cockpit. There may be also another hatchway, the foreside of it to be formed by the aft side of the beam under the eleventh port. The size of the ladder and hatchways must be governed by the beams, as when there is a good shift of beams they should not be altered for ladder and hatchways, unless it is the three principal hatchways, which must always be of a proper size, according to the size of the ship.

The after capstan must be placed between the two hatchways last described, and the beams abaft may stand as they are already shifted, observing only the misenmalt. There should be a small scuttle placed after the second beam from the end of the beam under the bread room: it must be on one of the middle lines, as there is a calling at the middle under the four or five after beams to receive the pillars for the support thereof.

The bits may be placed, letting the foreside of the after ones come against the aft side of the beam abaft the third port, and the foreside of the foremost ones against the next beam but one forward; then at the foreside of each bit there should be drawn a small scuttle for the convenience of handing up the powder from the magazine. The breast hook should also be drawn, which may be three feet the moulding away, and fixed nine tenths of the beams of the lower deck.

The hatchways are to be placed exactly over those on
on the lower deck, each over each; and therefore, where there is a beam arm in the lower deck there must also be one above it in the upper deck, and the same in the middle deck in three-deck ships. It commonly happens in ships of the line that there cannot be a whole beam between the deck below and the beam that supports the floor of the bowspirit, because the bowspirit plies through that place; in this case, there must be a beam arm placed, letting the end come at each beam and the beamhead both: but in ships that the bowspirit will allow of a whole beam, then the ports and the rest of the beams must be consulted in order to space it; and when it so happens that the forecastle comes in the way of a port, then a beam arm must be necessarily introduced.

Having placed the beams according to the disposition of the other beams below, the ladder-ways should be contrived; there should be one next abaft the fore hatchway, which is a single ladder-way; and one next before the main hatch, which is a double ladder-way; the ladders flanding the fore and aft way. There should also be another next abaft the after hatch, and one over the cockpit corresponding with that on the lower deck.

The capstans are next to be considered; the after one is already placed on the lower deck, the barrel of which must pass through the upper deck to receive the wheel and drumhead of the main capstan. In ships having three decks, the upper part of each capstan is in the middle deck; but in ships with one deck there is only one capstan, the upper part of which is placed on the quarter deck. The foremost capstan should be placed in the most convenient spot, to admit of its being lowered down to the orlop out of the way of the long boat; it may therefore be placed between the main and fore hatchways; the beam under the firther part of the lower deck may form the aft side of its room, and the beams on each side of it should be placed exactly over or under the beams on the other decks, and they should be at a distance from each other sufficient to let the drumheads pass between them. The centre of the capstan should then be placed in the middle between the beams which comprise its parts, and the partners should be fitted in such a manner as to shift occasionally when wanted, which is by letting them be in two pieces fitted together. The partners on the lower deck, wherein the capstan stops, must be supported by a pillar on the orlop deck, the lower part of which may be fitted in an oak chock; so that when the pillar is taken away, and the capstan lowered down, that chock serves as a step for the capstan. Those two beams on the orlop, by having the pillar and chock upon them, have therefore the whole weight of the capstan pressing downwards; for the support of them, there should be a carling placed underneath the fore and aft way, with three pillars, one under each beam, and one between; all of them being kept in the kelson, by which the orlop deck will be well supported in the wake of the capstan, and the other decks will feel no strain from it.

The fire hearth is next to be disposed; which is placed differently according to the size of the ship. In three-deckers it is found most convenient to place it on the middle deck; whence there is much more room under the forecastle than there would have been had it been placed there. In all two-deck ships it is placed under the forecastle, because on the deck under them the bits are in the way. It is also under the forecastle in one-deck ships, though confined between the bits; in this case it should be kept as near as possible to the after bits, that there may be more room between it and the foremost bits to make a good galley.

The positions of the main-top- and main-fleet bits are next to be determined; the foremost of which must be placed as to let its foreside come against the aft side of the beam abaft the main hatchway, and pass down to the lower deck, and there step in the beams: admitting it to be a straight piece, it would come at the aft side of the lower deck beam the same as it does at the upper deck beam, in consequence of those two beams ranging well up and down with each other; it must therefore have a cast under the upper deck beam, by which the lower part may be brought forward sufficient to float in the lower deck beam. The aftermost must be placed against the foreside of the beam abaft the mizzen, and step on the beam below; but there is no necessity to provide a crooked piece as before, for the beam of the upper deck may be moved a little farther aft, till it admit of the bit floating on the lower deck beam, unless the beam comes under a port, as in that case it must not by any means be moved. The crooks to the bits should be on the foreside, and in height from the upper deck about one third of the height between it and the quarter deck. With regard to the heads of the bits, the length of the ship's waste should be considered; and if there is length enough from the forecastle to the foremost bits to admit of the spare gear being flowed thereon without reaching farther aft, the quarter deck may then run so far forward that the head of the foremost bits shall tenon in the foremost beam; this gives the mainmast another deck, and admits of the quarter deck being all that the longer; but if there is not the room before mentioned, then the quarter deck must run no farther forward than the after bits, which will then tenon in the foremost beam; and the foremost bits must have a crook piece set on their heads, which is termed a horse, and will be for the purpose of receiving the ends of the cable and the cable hogs.

The length of the quarter deck being now determined, the beams are then to be placed. For this purpose the several contrivances in the quarter deck must be previously consulted. It is necessary to observe, that there are neither carlings nor lodges, the carlings of the hatches excepted, in the quarter deck, round-house, and forecastle; as they would weaken instead of strengthening the beams, which should be as small as the size of the ship will permit, in order that the upper works may be as light as possible. Hence, as there are to be neither carlings nor lodges, the deck will require a greater number of beams, and a good round up, as on the contrary the deck would be apt to bend with its own weight. The most approved rule is therefore to have double the number of beams in the quarter deck as there are in a space of the same length in the upper deck.

Then proceed to shift the beams to the best advantage, consulting the hatchways, ladder-ways, masts, bits, wheel, &c. With respect to the ladder-ways on the quarter decks of all ships, there should be one near the fore part of the great cabin for the officers, and another...
SHIP-BUILDING.

Book I.

Application of the foregoing Rules to the Construction of Ships.

Other near the foremost end of the quarter deck containing double ladders for the conveyance of the men up from the other decks in cases of emergency; and likewise one on each side of the fore part of the quarter deck from the gangway: and in every ship of the line all the beams from the foremost ladder-way to the after one should be open with gratings, both for the admission of air, and for the greater expedition of conveying different articles in the time of action.

Two fuites are to be disposed one on each side of the mainmast, if it happens to come through the quarter deck, for the top tackles to pass through, to hook to the eye bolts drove in the upper deck for that purpose.

The steering wheel should be placed under the forepart of the roundhouse, and the two beams of the quarter deck, which come under it, should be placed conformable to the two uprights, so that they may tenon in them. The quarter deck beams, should be kneed at each end with one hanging and one lodging knee; which adds greatly to the strength of the side. The hanging knees which come in the great cabin may be of iron; their vertical arms to be two-thirds of the length of that of wood, and to reach the spirketing. It should be observed, that the beam abatt, which comes under the screen bulkhead, should round aft agreeable to the round of the bulkhead, for the support of the same.

The forecastle beams should be placed according as the works of the deck will admit. The hatchways are therefore to be considered first. There should be one for the funnel of the fire hearth to pass through, and one over the galley as the funnel of the spirit room to pass through, and a line drawn parallel thereto which will be under that beam of the gun-deck that comes at the second part from aft. The after beam being drawn in, proceed to space the other beams, placing them exactly under those of the gun-deck; and that which comes under the foremost beam of the gun-deck may terminate the fore part of the orlop. Draw the limber strake, by setting off its thickness above the cutting down line, and a line drawn parallel thereto will represent the limber strake. That part of the orlop which is over the after magazine, spirit room, and fifth room, and also that which is over the fore magazine, is laid with thicker planks than the rest of the deck; which is for the better security of those places, the planks being laid over the beams; but in the midhips, from the fore part of the spirit room to the after part of the fore magazine, the beams are laid level with the surface of the deck, and the planks are rabbeted in from one beam to the other.

In order to represent the orlop as just described, the dimensions of the different apartments above mentioned must be determined: Let the aft side of the after beam be the aft side of the after magazine, and from thence draw the bulkhead down to the limber strake; and the foreside of the third beam may be the foreside of the after magazine, drawing that bulkhead likewise, which will also form the aft side of the fifth room; the foreside of the fifth room may be drawn from the aft side of the fifth beam, which will also represent the aft side of the spirit room; then the foreside of the spirit room may be drawn from the foreside of the sixth beam. Hence from the foreside of the sixth beam quite aft the deck will be represented by the two lines already drawn, and the upper side of the beams will be represented by the lower line.

Proceed next to the forepart of the orlop, letting the fore-
foreside of the after bits be the aft part of the foremost magazine, drawing the bulkhead thereof which will come to the aft side of the sixth beam; therefore, from the sixth beam to the foremost end of the orlop, the plank and beams will be represented just in the same manner as before mentioned for the after part of the orlop: then the midship part of the deck will be represented by letting the upper line be the upper side of the plank, and likewise the upper side of the beams; and the lower line will represent the lower edge of the plank, only drawing it from beam to beam, and obverting not to let it pass through the whole moulding.

The hatchways, &c. may now be represented on the orlop, letting the main, fore, and after hatchways, be exactly under those of the gun-deck: there must be one over the fifth room, and one over the spirit room. There must be two fecttles over the after magazine for the passage to the magazine and light room. There should also be one above the fourth beam from forward for the passage to the fore magazine, and one above the well: there should also be one abaft the well: there should also be one above the fifth room, and one above the spirit room.

There should also be two fecttles over the after magazine, for the passage to the main and light room. There should also be one above the fourth beam from forward for the passage to the fore magazine, and one above the well: there should also be one above the fifth room, and one above the spirit room.

The bulkheads for the fore and after parts of the well may be drawn from the lower deck beams to the orlop, and from thence to the limber flrake in the hold. The loft lockers may also be represented, having one above and one abaft the well; there should also be one abaft the foremost magazine, the ends of which may be formed by the after bits. The slips of the mafts may be drawn in by continuing their centres down to the limber slrake; and likewise two crutches abaft the midship slrake divided equally between that and the after part of the cutting down: the breast hooks may also be drawn letting them be five in number below the lower deck hook, and all equally divided between that and the fore slrake. Hence every part of the inboard is described as far as necessary.

CHAP. V. Of the Method of Whole-moulding.

Having now finished the methods of laying down the several plans of a ship, any farther addition on this subject might appear unnecessary. We cannot, however, with propriety, omit to describe the method called whole-moulding, used by the ancients, and which still continues in use among those unacquainted with the more proper methods already explained. This method will be illustrated by laying down the several plans of a long-boat: the length of the keel being 29 feet, and breadth moulded nine feet.

Draw the straight line PO (fig. 37.) equal to 29 feet, the extreme length of the boat, and also to represent the upper edge of the keel. Let \( \odot \) be the station of the midship frame. From the points P, O, and D, draw the lines PT, \( \odot \)M, and OS, perpendicular to PO. Make \( \odot \)M, \( \odot \)N, equal to the upper and lower heights of breadth respectively at the main frame, PT the height of breadth at the transom, and OS the height at the stem. Describe the curve TMS to represent the faer or extreme height of the side, which in a ship would be called the upper height of breadth lines, or upper edge of the wale. Through the points N draw a curve parallel to TMS, to represent the breadth of the upper flrake of a boat, or lower edge of the wale if in a ship. The dotted line TNS may also be drawn to represent the lower height of breadth.

Set off the rake of the port from P to \( \rho \), and draw the line \( \rho T \) to represent the aft side of the port; then \( \rho T \) will represent the round up of the tranom. Set off the breadth of the port from \( \rho \) to \( \sigma \), and from \( \sigma \) to \( \zeta \), and draw the line \( \sigma \zeta \) to represent the foreside of the port, which may either be a curve or a straight line at pleasure. Set up the height of the tuck from \( \rho \) to \( \kappa \).

Let \( \lambda X \) be the thickness of the tranom, and draw the line \( \lambda X \) to represent the foreside of the tranom. There is given the point \( \delta \), the height of the flrake on the foreside of the item; now that side of the item is to be formed either by sweeps or some other contrivance. Set off the breadth of the item, and form the aft side of it.

Set up the dead-rising from \( \odot \) to \( \delta \), and form the rising line \( \rho \) is. Draw the line KL parallel to PO to represent the lower edge of the keel, and another to represent the thickness of the planks or the rabbit. The rabbit on the port and item may also be represented; and the stations of the timbers aligned, as \( \odot \), \( (1) \), \( 1, 2, 3, 4, 5, 6, 7, 8, 9 \); and \( \odot \), \( (A) \), \( A, B, C, D, E, F, G, H \); and the sheer plan will be completed.

The half-breadth plan is to be formed next; for this purpose the perpendiculars TP, \( 9, 8 \), &c. must be produced. Upon \( M \) produced set off the half breadth from the line KL to \( R \) (fig. 38.); set off also the half breadth at the transom from \( K \) to \( L \), and describe the extreme half breadth line \( l \; R \; X \), making the fortop of the curve agreeable to the proposed round of the tranom.

We may next proceed to form the timbers in the body plan. Let \( AB \) (fig. 39.) be the breadth moulded at \( \odot \). Erect the perpendicular CD in the middle of the line \( AB \); draw the line \( m n \) distant therefrom the half thickness of the port, and \( x y \) the half thickness of the stern. Then take off the several portions of the perpendiculars \( \odot, 1, 2, \) &c. intercepted between the upper edge of the keel and the rising line in the forer line, and set them up from \( C \) upon the line \( CD \); through these points draw lines parallel to \( AC \); take off also the several lower heights of breadth at \( \odot, 1, 2, \) &c. from the forer line; and set them up from \( C \) upon the middle line in the body plan; and draw lines parallel to \( AC \) through these points.

Then take off the several half breadths corresponding to each from the floor plan; and set them off on their proper half-breadth lines from the middle line in the body plan.

Construct the midship frame by Problem V. the form of which will in some measure determine the form of the reef. For if a mould be made on any side of the middle line to fit the curve part of it, and the rising line, or that marked bend mould (fig. 40.), and laid in such a manner that the lower part of it, which is straight, may be set upon the several rising lines, and the upper part just touch the point of the half breadth in the breadth line corresponding to that rising upon which the mould is placed, a curve may then be drawn by the mould to the rising line. In this manner we may proceed so far as the rising line is parallel to the lower height of the breadth line. Then a hollow mould must be made, the upper end of which is left straight, as
SHIPBUILDING.

Method of Whole-moulding.

1. In such a manner, that some part of the hollow may touch the side of the keel and the straight part touch the back of the curve before described by the bend mould; and, beginning abaft, the straight part will always come lower on every timber, till we come to the middle timber, when it comes to the side of the keel. Having thus formed the timbers, so far as the whole mouldings will serve, the timbers abaft them are next formed. Their half breadths are determined by the sheer and floor plans, which are the only fixed points through which the curves of these timbers must pass. Some form these after timbers before the whole is moulded, and then make the hollow mould, which will be firther than the hollow of either of these timbers. It is indifferent which are first formed, or what methods are used; for after the timbers are all formed, though every timber may appear very fair when considered by itself, it is uncertain what the form of the side will be. In order to find which, we must form several ribbands and water lines; and if these do not make fair curves, they must be rectified, and the timbers formed from these ribbands and water lines. To using the hollow mould, when it is applied to the curve of each timber, if the straight part is produced to the middle line, we shall as many points of intersection as there are timbers; and if the heights above the base be transferred to the corresponding timbers in the sheer plan, a curve passing through these points is what is called a rising spiral. This may be formed by fixing a point for the aftermost timber that is whole moulded, and transferring that height to the sheer plan. The curve must pass through this point, and fall in with the rising line somewhere abaft dead flat; and if the several heights of this line be transmitted from the sheer to the middle line in the body plan, these points will regulate what is called the bailing down of the hollow mould.

The timbers in the after body being all formed, those in the fore body are formed in the same manner, by transferring the several heights of the rising and breadth lines from the sheer to the body plan; the half breadths corresponding to each height must also be transferred from the floor to the body plan. The fame hollow mould will serve both for the fore and after body; and the level lines, by which the water lines to prove the after body were formed, may be produced into the fore body, and by them, the water lines to prove the fore body, may be described.

Another method of proving the body is by ribband lines, which are formed by defections of planes inclined to the sheer plan, and intersecting the body plan diagonally, as before observed, of which there may be as many as may be judged necessary. As this has been already explained, we shall therefore lay down only one, represented in the body plan by the lines marked dia. These are drawn in such a manner as to be perpendicular to as many timbers as conveniently may be. After they are drawn in the body plan, the several portions of the diagonal intercepted between the middle line and each timber must be transferred to the floor plan. Thus, fix one foot of the compasses in the point where the diagonal intercepts the middle line in the body plan; extend the other foot to the point where the diagonal intercepts the timber; for example, timber 9; set off the fame extent upon the perpendicular representing the plane of timber 9 from the point where it intercepts the line KL on the floor plan; in like manner proceed with all the other timbers both in the fore and after body; and thence shall have the points thro' which the curve must pass. If this should not prove a fair curve, it must be altered, observing to conform to the points as nearly as the nature of the curve will admit; so it may be carried within one point, and without another, according as we find the timbers will allow. For after all the ribband lines are formed, the timbers must, if needful, be altered by the ribband lines: this is only the reverse of forming the ribband lines; for taking the portions of the several perpendiculars intercepted between the line KL and the curve of the ribband line in the floor plan, and setting them off upon the diagonal from the point where it intercepts the middle line, we shall have the points in the diagonal through which the curves of the timbers must pass. Thus the distance between the line KL and the ribband at timber 3 on the floor plan, when transferred to the body plan, will extend on the diagonal from the middle line to the point where the curve of timber 3 intersects that diagonal. The like may be said of all the other timbers; and if several ribband lines be formed, they may be so contrived that their diagonals in the body plan shall be at such distances, that a point for every timber being given in each diagonal, will be sufficient to determine the form of all the timbers.

In laying the timbers upon the keel for a boat, there must be room for two futtocks in the space before or abaft; for which reason, the distance between these two timbers will be as much more than that between the other as the timber is broad. Here it is between \( \alpha \) and \( \beta \); which contains the distances between \( \beta \) and \( \gamma \), and the breadth of the timber besides.

The timbers being now formed, and proved by ribband and water lines, proceed then to form the transom, fashion-pieces, &c. by Problem VI.

This method of whole moulding will not answer for the long timbers afore and abaft. They are generally caulked in the same manner as those for a ship. In order to render this method more complete, we shall here describe the manner of moulding the timbers after they are laid down in the mould loft, by a rising square, bend, and hollow mould.

It was shown before how to form the timbers by the bend and hollow mould on the draught. The fame method must be used in the loft; but the moulds must be made to their proper scantlings in real feet and inches. Now when they are set, as before directed, for moulding each timber, let the middle line in the body plan be drawn across the bend mould, and draw a line across the hollow mould at the point where it touches the upper edge of the keel; and let them be marked with the proper name of the timber, as in fig. 40. The graduations of the bend mould will therefore be exactly the same as the narrowing of the breadth. Thus, the distance between \( \alpha \) and 7 on the bend mould is equal to the difference between the half breadth of timber 7 and that of \( \beta \). The height of the head of each timber is likewise marked on the bend mould, and also the floor and breadth firmarks. The floor firmark is in that point where a straight edged batten touches the back of the bend mould, the batten being so placed...
Book I. SHIP-BUILDING.

Method of whole Moulding.

as to touch the lower edge of the keel at the same time. The several riseings of the floor and heights of the cutting down line are marked on the rising square, and the half breadth of the keel set off from the side of it.

The moulds being thus prepared, we shall apply them to mould timber 7. The timber being first properly fixed to its breadth, lay the bend mould upon it, so as may best answer the round according to the grain of the wood; then lay the rising square to the bottom of the bend mould, so that the line drawn across the bend mould at timber 7 may coincide with the line representing the middle of the keel upon the rising square; and draw a line upon the timber by the side of the square, or let the line be scored or cut by a tool made for that purpose, called a raising knife (e); this line so raised will be the side of the keel. Then the square must be moved till the side of it comes to 7 on the bend mould, and another line must be raised in by the side of it to represent the middle of the keel. The other side of the keel must likewise be raised after the same manner, and the point 7 on the rising square be marked on each side of the keel, and a line raised across at these points to represent the upper edge of the keel. From this line the height of the cutting down line at 7 must be set up, and then the rising square may be taken away, and the timber may be raised by the bend mould, both inside and outside, from the head to the floor firmark; or it may be carried lower if necessary. After the firmarks and head of the timbers are marked, the bend mould may likewise be taken away, and then the hollow mould applied to the back of the sweep in such a manner that the point 7 upon it may intersect the upper side of the keel, before set off by the rising square; and when in this position the timber may be raised by it, which will complete the outside of the timbers. The inside of the timbers may likewise be formed by the hollow mould. The beveling at the keel is given by the cutting down, and the riseings of the floor and head firmarks may be compared and coincide. Notwithstanding which, if the timbers are not very carefully trimmed, the head of the bent mould may be other within or without its proper half breadth; to prevent which a hair breadth staff is made use of.

The half breadth staff may be one inch square, and of any convenient length. Upon one side of it are set off from one end the several half breadths of all the timbers in the after body, and those of the fore body upon the opposite side. On the other two sides are set off the several heights of the sheers, the after body on one side, and the fore body on the opposite. Two sides of the staff are marked half breadths, and the other two sides breadth of the floor.

The staff being thus prepared, and the floor-timbers fastened on the keel, and levelled over, the futtocks must next be fastened to the floor timbers; but they must be set first to their proper half in each and height. The half breadth staff, with the assistance of the rising line 6, leaves to set them to the half breadth; for as the keel of a boat is generally parallel to the horizon, therefore the line at which the plummet is suspended and which is moveable on the ram line, will be perpendicular to the keel. Whence we may by it set the timbers perpendicular to the keel, and then set them to their proper half breadths by the staff; and when the two firmarks coincided, the futtock will be at its proper height, and may be nailed to the floor timbers, and also to the breadth ribband, which may be set to the height of the sheers by a level laid across, taking the height of the sheers by the staff from the upper side of the keel; by which means we shall discover if the ribband is exactly the height of the sheers; and if not, the true height may be set off by a pair of compasses from the level, and marked on the timbers.

Chap. VI. Of the Practice of Ship-building.

The elevation, projection, and half-breadth plans, of a proposed ship being laid down on paper, we must next proceed to lay down these several plans on the mould loft of the real dimensions of the ship proposed to be built, and from which moulds for each separate part are to be made. The method of laying down these plans, from what has been already said, will, it is presumed, be no very difficult task to accomplish, as it is no more than enlarging the dimensions of the original draughts; and with respect to the moulds, they are very easily formed agreeable to the figure of the several parts of the ship laid down in the mould loft. Blocks of wood are now to be prepared upon which the keel is to lie. These blocks are to be placed at nearly equal distances, as of five or six feet, and in such a manner that their upper surfaces may be exactly in the same plane, and their middle in the same straight line. This line is easily done by means of a line stretched a little more than the proposed length of the keel; and the upper planes of these blocks may be verified by a long and straight rule; and the utmost care and precaution must be taken to have these blocks properly bedded. Each block may be about six or eight inches longer than the keel is in thickness; their breadth from 12 to 14 inches, and their depth from a foot to a foot and half.

The dimensions of the keel are to be taken from the mould loft, and the keel is to be prepared accordingly. As, however, it is seldom possible to procure a piece of wood of sufficient length for a keel, especially if for a large ship, it is therefore, for the most part necessary to compound it of several pieces, and these pieces are to be scarf together, and securely bolted, so as to make one entire piece. It must, however, be observed, that the pieces which compose the keel ought to be of such lengths, that a scarf may not be opposite to the step of any of the mast. Rabbets are to be formed on each side of the keel to receive the edge of the planks next to

(e) The term raising is used when any line is drawn by such an instrument instead of a pencil.
to it, or garboard strake, and the keel is to be laid on the blocks (p).

The stem, and the poth, and the several transoms belonging to it, are to be prepared from the moulds, and rabbed in like manner as the keel, to receive the ends of the plank. The transoms are to be bolted to the poth at their middle, each at its respective height, taken from the elevation in the mould loft, and the extremities of the transoms are to be firmly connected with the fashion-pieces. Both stem and poth are then to be erected, each at its respective extremity of the keel. The tenons at the keel of each being let into mortises prepared to receive them, and being fe to their proper rakes or angles with the keel, are to be supported by props or shores. Pieces of wood called dead wood are to be laid upon and fixed to the upper side of the keel towards the fore and aft parts of it; the deepness of the dead wood increasing with its distance from the middle, agreeable to the proposed form of the cutting down line.

A line is to be stretched from the middle of the head of the stem to that of the poth, called the raw line, upon which is a moveable line with a plummet affixed to it. The midship and other frames are to be erected upon the keel at their proper stations. The extremities of each frame are set at equal distances from the vertical longitudinal section of the ship, by moving the frame in its own plane until the plumbline coincides with a mark at the middle between the arms of each frame; and although the keel is inclined to the horizon, yet the frames may also be set perpendicular to the keel by means of the plumbline. The shores which are supporting the frames are now to be securely fixed, that the position of the frames may not be altered. The rigbands are now to be nailed to the frames at their proper places, the more effectually to secure them; and the intermediate vacancies between the frames filled up with felling timbers. For a perspective view of a ship framed, see Plate CCCCLIV. fig. 2.

The frames being now stationed, proceed next to fix on the planks, of which the wales are the principal, being much thicker and flinpler than the rest, as it is represented in the midship frame, Plate CCCXIV. The harpins, which may be considered as a continuation of the wales at their fore ends, are fixed across the hawle pieces, and surround the fore part of the ship. The planks that incline the ship's sides are then brought about the timbers; and the clamps, which are of equal thicknesses with the wales, fixed opposite to the wales within the ship. These are used to support the ends of the beams, and accordingly stretch from one end of the ship to the other. The thickest or strongest planks of the bottom within board are then placed opposite to the several scarfs of the timbers, to reinforce them throughout the ship's length. The planks employed to line the ship, called the ceiling or foot-walling, is next fixed in the interval between the thick stuff of the hold. The beams are afterwards laid across the ship to support the decks, and are connected to the side by lodging and hanging knees; the former of which are exhibited at F, Plate CLVI. See also the article DECK; and the hanging-knees, together with the breadth, thickness, and position of the keel, floor timbers, futtocks, top-timbers, wales, clamps, thick stuff, planks within and without, beams, decks, &c. are seen in the midship frame, Plate CCCXIV, and in that article their several parts have already been explained.

The cable-bits being next created, the carlings and ledges, represented in Plate CLVI, are disposed between the beams to strengthen the deck. The quarter-ways are then laid on the ends of the beams throughout the ship's length, and the spiking fixed close above them. The upper deck is then planked, and the firing placed under the gunnel, or plans, in the waist. The disposition of the latter pieces on the timbers, viz., the water-ways, spiking, upper deck, firing, and gunnel, are also represented in the midship frame, Plate CCCXIV.

Then proceed next to plank the quarter-deck and forecastle, and to fix the partners of the masts and capsterns with the carlings of the hatches. The broad-books are then bolted across the stem and bow within-board, the flap of the forecastle placed on the keel, and the riders, exhibited in the Midship Frame, fayed to the inside of the timbers, to reinforce the sides in different parts of the ship's length. The pointers, if any, are afterwards fixed across the hold diagonally to support the beams; and the crotches flattened in the after hold to unite the half timbers. The steps of the mainmast and capsterns are next placed; the planks of the lower decks and orlop laid; the navel-books fayed to the hawse holes; and the knees of the head, or cutwater, connected to the stern. The figure of the head is then erected, and the trail-board and cheeks fixed on the side of the knee.

The taffarel and quarter-pieces, which terminate the ship's shaff, the former above and the latter on each side, are then disposed, and the stern and quarter galleries framed and supported by their brackets. The pumps, with their well, are next fixed in the hold; the timber boards laid on each side of the keel, and the garboard strake fixed on the ship's bottom next to the heel without.

The hull being thus fabricated, proceed to separate the apartments by bulkheads or partitions, to frame the port-lids, to fix the catheads and chef-trees; to form the hatchways and scuttleways, and fit them with proper covers or gratings. Next fix the ladders at the different hatchways, and build the manger on the lower deck, to carry off the water that runs in at the hawseholes when the ship rides at anchor in a sea. The bread-room and magazines are there lined; and the gunnel, rails, and gangways fixed on the upper part of the ship. The cleats, keels, and ranges, by which the ropes are fastened, are afterwards bolted or nailed to the sides in different places.

The rudder, being fitted with its iron, is next hung to the stern-post, and the tiller or bar, by which it is managed, let into a mortice at its upper end. The

(f) In ships of war, which are a long while in building, it has been found that the keel is often apt to rot before they are finished. Upon this account, therefore, some builders have begun with the floor timbers, and added the keel afterwards.

Improvements in the Masts and Rudder.

Scuppers, or leaden tubes, that carry the water off from the decks, are then placed in holes cut through the ship's sides; and the leaded hemp represented in the Midship Frame, Plate CCCXIV, bolted to the beams and sides above the deck to which they belong. The poop lanterns are last fixed upon their cranes over the stern, and the bilge-waves or cradles placed under the bottom to conduct the ship steadily into the water whilst launching.

As the various pieces which have been mentioned above are explained at large in their proper places, it is therefore superfluous to enter into a more particular description of them here.

CHAP. VII. Of Improvements in the Masts and Rudder.

Since the article Mast was printed, an account of a method for repairing masts of ships when wounded, or otherwise injured, in an easy, cheap, and expeditious manner, by Captain Edward Pakenham of the royal navy, has been published in the tenth volume of the Transactions of the Society for the Encouragement of Arts, &c. Captain Pakenham introduces his invention with the following observations:

"Among the various accidents which ships are liable to at sea, none call more for the attention and exertion of the officer than the speedy refitting of the masts; and having observed, in the course of late war, the very great destruction made among the lower masts of our ships from the enemy's mode of fighting, as well as the very great expense and delay in resubmitting a fleet after an action, particularly across the Atlantic—a very simple expedient has suggested itself to me as a resource in part, which appears to be very speedy and sure, in that the capacity of the meanest seaman will at once conceive it. I therefore think it my duty to state my ideas of the advantages likely to result from it; and I shall feel myself exceedingly happy should they in anywise contribute to remedy the evil.

"My plan, therefore, is, to have the heels of all lower masts fixed as to become the heads; but it is not the intention of the above plan to have the small, slight alteration made in the heels of the present lower masts; for as all line-of-battle ships masts are nine inches in diameter larger at the heel than at the head, it will follow, that by letting in the trellis-trees to their proper depth, the mast will form its own checks or bounds; and I flatter myself the following advantages will result from the above alteration.

"First, I must beg to observe, that all line-of-battle ships bury one-third of their lower masts, particularly three-deckers; therefore, it follows, that if the wounds are in the upper third, by turning the mast so as to make the heel the head, it will be as good as new; for, in eight actions I was present in late war, I made the following observations:

"That in the said actions forty-eight lower masts were wounded, and obliged to be shifted, thirty-two of which had their wounds in the upper third, and of course the ships detained until new masts were made. And when it is considered that a lower mast for a 92 or 74 fliants government in a tum not less than 2000 l. to 2500 l. the advantages across the Atlantic resulting from the above plan will be particularly obvious; not to mention the probability of there being no fit spars in the country, which was the case in the instance of the Iris and Princess Royal: and as I was one of the lieutenants of the Iris at that time, I am more particular in the circumstance of that ship. The Iris had both her lower masts wounded above the other pins in her action with the Car- far, a French 74; and as there were no spars at New York, the Iris was detained five weeks at that place.

Now, if her masts had been fitted on the plan I have proposed, I am confident she would have been ready for sea in 48 hours; and as a further proof, I beg leave to add, that the whole fleet, on the glorious 12th of April, had not the least accident of any consequence except what befell their lower masts, which detained them between eight and ten weeks at Jamaica."

"The delay of a ship while a new mast is making, and probably the fleet being detained for want of that ship, which frequently occurred in the course of late war, the taking of ships'wrights from other work, with a variety of inconveniences not necessary to mention here, must be obvious to every officer that has made the smallest observations on sea actions.

"You will further observe, that this substitute is formed on the most simple principle, fitted to the meanest capacity, and calculated to benefit all ships, from a first-rate down to the smallest merchantmen, in cases of an accident by shot, a spring, or a rottenness, particularly as these accidents generally happen in the upper third of the mast and above the cheeks.

"It might probably be objected, that a difficulty and some danger might arise from the wounded part of the mast being below; but this will at once be obviated, when it is remembered, that as the wounded part is below the wedges, it may with ease be both filled, caulked, and secured, to any size or degree you please, with the addition of its being wedged on each deck."

Fig. 41. represents a mast of a first-rate in its proper state, the figures representing its thickness at the different divisions.

Fig. 42. the same mast inverted, the heel forming the head, and the trellis-trees let into their proper depth, the additional thickness of the mast forming its own cheeks.

Fig. 43. the proposed mast, the figures representing the thickness of the mast in the proposed alteration; a, the heel made square; b, the letting in of the trellis-trees; c, the third proportion of thickness continued up to where the fourch is in the present mast, or at least some little distance above the lower part of the cheeks, which is always looked upon as the weakest part of the mast; and by its being so proportioned, the mast, when turned, will be nearly as strong in the partners as before.

As the expense of a mast is much greater than is generally imagined, it is therefore thought proper to subjoin the following statement of the several articles used in making a 74 gun ship's mainmast.

In order to lessen the enormous expense of masts, a proposal was made some years ago to construct them hollow; and the author having premised several experiments which he had made, proceeds as follows:

"Galileo taught us, that the resistance or strength of a hollow cylinder is to that of a full cylinder, containing the same quantity of matter, as the total diameter of the hollow one is to the diameter of the full one; and these experiments show us, that the strength or resistance of two or more pieces of wood, fastened together at each end, and connected by a pillar, pillars, or framing, in a certain degree, ceteris paribus, as the distance between them and number of pillars, provided the force is applied in the line or direction of the pillars.

"It is surprising that this discovery of Galileo has not been made subversive to more useful purposes. It is particularly applicable to the construction of masts, as not requiring that the hollow cylinder should be made of one solid piece of wood (a).

"However, the foregoing experiments teach us, that the same advantages may be obtained by other forms besides that of a cylinder; and that perhaps not only in a superior degree, but likewise with greater facility of execution; as by adopting a square figure, but more particularly by constructing them of separate pieces of wood, placed at proper distances from each other, in the following or any other manner that may be found most convenient. Fig. 44, 45, and 46, exhibit each the transverse section of a mast, in which the small circles represent the trees or upright pieces of wood, and

the lines the beams or framing of wood, which are employed at proper places and at proper distances from each other, for connecting them together. Perhaps for lid frames of wood, placed at proper distances from each other, and filling up the whole dotted space, would answer better; in which event, the mast could be strongly hooped with iron at those places, and the upright trees formed square, or of any other convenient form.

"It will be evident to those acquainted with this subject, that such masts would be greatly stronger than common ones containing the same quantity of materials. It is likewise evident that they would be less apt to spring, as being supported on a more extended base, and affording many conveniences for being better secured; and that they might be constructed of such wood as at present would be deemed altogether improper for masts: a circumstance of importance to Britain at all times, but more particularly now, when there is such difficulty in procuring wood proper for the kind of masts in common use."

An improvement in the rudder has lately taken place in several ships, particularly in some of those in the service of the East India Company. It will, however, be necessary to describe the usual form of the rudder, in order to shew the advantages it possesses when constructed agreeably to the improved method.

N° 1. (Fig. 47.) represents the rudder according to Papers on the common method of construction; in which AB is Naval Architecture, the axis of rotation. It is hence evident that a space considerably greater than the transverse section of the rudder at the counter must be left in the counter for the rudder to revolve in. Thus, let CAB (N° 2.) be the section of the rudder at the counter; then there must be a space similar to CDE in the counter, in order that the rudder may be moveable as required. Hence, to prevent the water from washing up the rudder, a rudder coat, that is, a piece of tarred canvas, is nailed in such a manner to the rudder and counter as to cover the intermediate space: but the canvas being continually wafted by the sea, soon becomes brittle, and unable to yield to the various turns of the rudder without breaking; in which case the ship is of course left pervious to the waves, even of three or four feet high; in fact, there are few men bred to the sea who have not been witness to the bad effects of such a space being left. So ill guarded against the stroke of the waves; and many ships have, with great probability, been suppoed to foundered at sea, from the quantity of water shipped between the rudder and counter.

It was to remedy this defect that the alteration above alluded to took place; which consists in making the upper part AFG (Fig. 48, N° 1.) of the rudder ABD cylindrical, and giving that part at the same time a cast forward, so that the axis of rotation may by that means be the line AD, passing as usual from E to D, through the centres of the braces which attach the rudder to the stern-post, and from E to A through the

(a) The strength of these cylinders would be still further augmented by having solid pieces of wood placed within them at proper distances, and securely fastened to them, in the same manner, and on the same principles, that nature has furnished reeds with joints; and answering, in some respects, the same purpose as the pillars in the experiments alluded to.
S H I P - B U I L D I N G.

Book I.

Load-water Line and Ship's Capacity.

The weight of the quantity of water displaced by the two parts will be equal, that is, each will be found to be equal, the body of the ship may then be said to be constructed in all respects suitable to her swimming on an even keel, let the shape of the body be whatever it will; and which will be found to be her natural position at the load-water line. But if either of the parts should contain a greater number of cubic feet than the other, that part which contains the great-est will swim the most out of the water, and consequently the other will swim deepest, supposing the ship in her natural position for that construction. In order, therefore, to render the ship suitably constructed to the load-water line in the draught, which is parallel to the keel, the number of cubic feet in the less part must be subtracted from the number contained in the greater part, and that part of the body is to be filled out till it has increased half the difference of their quantities, and the other part is to be drawn in as much: hence the two parts will be equal, that is, each will contain the same number of cubic feet, and the ship's body will be constructed in a manner suitable to her swimming on an even keel.

If it is proposed that the ship laid down on the draught shall not swim on an even keel, but draw more water abaft, then fore, then the fore and after parts of the ship's body below the load-water line are to be compared; and if those parts are unequal, that part which is least is to be filled out by half the difference, and the other part drawn in as much as before.

It will be necessary, in the first place, to calculate the weight of a ship ready equipped for sea, from the knowledge of the weight of every separate thing in her and belonging to her, as the exact weight of all the timber, iron, lead, masts, sails, rigging, and in short all the materials, men, provisions, and every thing else on board of her, from which we shall be able afterwards to judge of the truth of the calculation, and whether the load-water line in the draught be placed agreeable thereto. This is indeed a very laborious task, upon account of the several pieces of timber, &c. being of so many different figures, and the specific gravity of some of the timber entering the construction not being precisely determined.

In order to ascertain the weight of the hull, the timber is the first thing which comes under consideration: the number of cubic feet of timber contained in the whole fabric must be found; which we shall be able to do by help of the draught and the principal dimensions and scantling; observing to distinguish the different kinds of timber from each other, as they differ considerably in weight; then the number of cubic feet contained in the different sorts of timber being reduced into pounds, and added, will be the weight of the timber. In like manner proceed to find the weight of the iron, lead, paint, &c. and the true weight of the whole will be found.

In reducing quantity to weight, it may be observed that a cubic foot of oak is equally to 60 pounds, and the specific gravity of the other materials are as follow:

- Water being 1000
- Lead is 11345
- Iron 7643

Oak is 891.89
Dry elm 702.70
Dry fir 648.64

Sum

1792870 800 870

Agreeable to the above estimate, we find that the eighty gun ship, with everything on board and fit for sea, when brought down to the load water line, weighs 8,182,463 pounds, or nearly 3653 tons. It may now be known if the load water line in the draught be properly placed, by reducing the immersed part of the body into cubic feet. For if the eighty gun ship, when brought down to the load water line, weighs 3653 tons, the quantity of water displaced must also be 3653 tons: now a cubic foot of salt-water being supposed to weigh 74 pounds, if therefore 8182463 be divided by 74, the quotient is 110573, the number of cubic feet which the ship displaces agreeable to her weight.

It is now necessary to find the number of cubic feet contained in the ship's bottom below the load water line by calculation. If the bottom was a regular solid, this might be very easily done; but as it is otherwise, we must be satisfied with the following method by approximation, first given by M. Bouguer.

Take the lengths of every other of the lines that represent the frames in the horizontal plane upon the upper water line; then find the sum of these together, with half the foremost and aftermost frames. Now multiply that sum by the distance between the frames, and the product is the area of the water line contained between the foremost and aftermost frames: then find the area of that part abaft the after frame, which forms a trapezium, and also the part and rudder; find also the area of that part afore the foremost frame, and also the stem and gripe; then these areas being added to that first found, and the sum doubled will be the area of the surface of the whole water line. The reason of this rule will be obvious to those acquainted with the first principles of mathematics.

The areas of the other water line may be found in the same manner: then the sum of all these areas, except that of the uppermost and lowermost, of which only one half of each must be taken, being multiplied by the distance between the water lines (these lines in the plane of elevation being equidistant from each other), and the product will be the solid content of the space contained between the lower and lead water lines.
Add the area of the lower water line to the area of the upper side of the keel; multiply half that sum by the distance between them, the product will be the fo- lid content of that part between the lower water line and upper edge of the keel, supposing them parallel to each other. But if the lower water line is not parallel to the keel, the above half sum is to be multiplied by the distance between them at the middle of the ship.

The solid contents of the keel must be found, by multiplying its length by its depth, and that product by the breadth. Then the sum of these solid contents will be the number of cubic feet contained in the immersed part of the ship's bottom, or that part below the load water line.

Determination of the number of Cubic Feet contained in the Bottom of the Eighty Gun Ship. See Plates CCCCLX. and CCCCLXI.

The fore body is divided into five, and the after body into ten, equal parts in the horizontal plane; besides the parts contained between the foremost timber and the stem, and the aftermost timber and the poilt. The plane of elevation is also divided into five equal parts by water lines drawn parallel to the keel. Thee water lines are also described upon the horizontal plane.

It is to be observed that there must be five inches added to each line that represents a frame in the horizontal plane for the thickness of the planking, that being nearly a mean between the thickness of the plank next the water and that on the lower part of the bottom.

| Sum | 8236 11 |

Cubic Feet contained between the lower and load water lines

| Sum | 33634 |

As the weight of the ship, with every thing on board, found by this calculation, is equal to that found by estimate; it hence appears that the water line is properly placed in the draught. It now only remains to find whether the body is constructed suitably there to, that is, whether the ship will be in her natural position when brought down to that line. For this purpose a perpendicular must be erectcd 27 feet 2 inches abaft dead flat, which will be the middle between the two perpendiculars and the place where the centre of gravity should fall, that the ship may swim on an even keel. The solidity of that part of the bottom contained between the said perpendicular and dead flat is then to be calculated, which will be found to be 25846 feet 7 inches.

Solidity of the Bottom Afore Dead Flat

| Sum | 36523 4 |

Solid content of the Fore Part of the Bottom

| Sum | 62269 11 |

Solidity of the Bottom Aft of Dead Flat

| Sum | 74050 6 |

Solid content of the Aft Part of the Bottom

| Sum | 62269 11 |

Difference

| Sum | 14166 |

Hence the after part of the ship's bottom is too lean by 7083 cubic feet, and the fore part as much too full. The after part must therefore be filled out until it has received an addition of 7083 feet, and the fore part must be drawn in till it has lost the same quantity, and the bottom will then be constructed suitable to the ship's swimming on an even keel.

Chapter IX. Of the Tonnage of a Ship.

This is a question of equal importance and difficulty. By the tonnage of a ship is meant the weight of everything that can with safety and expediency be taken on board that ship for the purpose of conveyance; it is also called the ship's burthen; and it is totally different from the weight of the whole as she floats in the water. It is perhaps best expressed by calling it the weight of the cargo. It is of importance, because it is by this that the merchant or freighter judges of the fitness of
of the ship for his purpose. By this government judge of the ships requisite for transport service, and by this are all revenue charges on the ship computed. It is no less difficult to answer this question by any general rule which shall be very exact, because it depends not only on the cubical dimensions of the ship's bottom, but also on the scantling of her whole frame, and in short on the weight of every thing which properly makes part of a ship ready to receive on board her cargo. The weight of timber is variable; the scantling of the frame is no less so. We must therefore be contented with an average value which is not very remote from the truth; and this average is to be obtained, not by any mathematical discussion, but by observation of the burthen or cargo actually received, in a great variety of cases. But some sort of rule of calculation must be made out. This is and must be done by persons not mathematicians. We may therefore expect to find it incapable of being reduced to any principle, and that every builder will have a different rule. Accordingly the rules given for this purpose are in general very whimsical, measures being used and combined in a way that seems quite unconnected with Aerocometry or the measurement of solids. The rules for calculation are even affected by the interests of the two parties oppositely concerned in the result. The calculation for the tonnage by which the customs are to be exacted by government are quite different from the rule by which the tonnage of a transport hired by government is computed; and the same ship hired as a transport will be computed nearly one half bigger than when paying importation duties. Yet the whole of this might be made a very simple business and very exact. When the ship is launched, let her light-water line be marked, and this with the cubical contents of the immersed part be noted down, and be engrossed in the deed by which the property of the ship is conveyed from hand to hand. The weight of her masts, sails, rigging, and sea-fires, is most easily obtained; and every builder can compute the cubical contents of the body when immered to the load-water line. The difference of these is unquestionably the burthen of the ship.

It is evident from what has been already said in the last chapter, that if the number of cubic feet of water which the ship displaces when light, or, which is the same, the number of cubic feet below the load-water line, found by the preceding method of calculation, be subtracted from the number of cubic feet contained in the bottom below the load water line, and the remainder reduced to tons by multiplying by 74, the number of pounds in a cubic foot of sea water, and divided by 2240, the number of pounds in a ton, the quotient will be the tonnage.

But as this method is very troublesome, the following rule for this purpose is that which is used in the British king's and merchant's service.

Let fall a perpendicular from the fore side of the item at the height of the hawse-holes (u), and another perpendicular from the back of the main poft at the height of the wing transom. From the length between these two perpendiculars deduct three-fifths of the extreme breadth (1), and also at may times 2½ inches as there are feet in the height of the wing transom above the upper edge of the keel; the remainder is the length of the keel for tonnage. Now multiply this length by the extreme breadth, and the product by half the extreme breadth, and this last product divided by 94 is the tonnage required.

Or, multiply the length of the keel for tonnage by the square of the extreme breadth, and the product divided by 188 will give the tonnage.

Calculation of the Tonnage of an Eighty Gun Ship.

I. According to the true method.

Hence an eighty gun ship will not carry the ton. The common rule gives the tonnage she is rated at by about 95 tons. As the body of this ship is fuller than in ships of war in general, there is therefore a nearer agreement between the tonnages found by the two different methods. It may be observed that ships of war carry less tonnage than they are rated at by the common rule, and that most merchant ships carry a great less, than the truth.

(u) In the merchant service this perpendicular is let fall from the fore side of the item at the height of the wing transom, by reason of the hawse-holes being generally so very high in merchant ships, and their items also having a great rake forward.

(1) The breadth underfoot in this place is the breadth from outside to outside of the plank.

The impropriety of the common rule is hence manifest, as there can be no dependence on it for ascertaining the tonnage of vessels.

We shall now subjoin the following experimental method of finding the tonnage of a ship.

Construct a model agreeable to the draught of the proposed ship, to a scale of about one-fourth of an inch to a foot, and let the light and load water lines be marked on it. Then put the model in water, and load it until the surface of the water is exactly at the light water line; and let it be suspended until the water drains off, and then weighed. Now since the weights of similar bodies are in the triplicate ratio of their homologous dimensions, the weight of the ship when light is, therefore, equal to the product of the cube of the number of times the ship exceeds the model by the weight of the model, which is to be reduced to tons. Hence, if the model is constructed to a quarter of an inch scale, and its weight expressed in ounces; then to the constant logarithm of the weight of the model in ounces, and the sum will be the logarithm of the weight of the ship in tons.

Again, the model is to be loaded until the surface of the water coincides with the load water line. Now the model being weighed, the weight of the ship is to be found by the preceding rule: then the difference between the weights of the ship when light and loaded is the tonnage required.
SHIP-BUILDING.

Book I.

Scale of Solidity.

In order to construct this scale for a given ship, it is necessary to calculate the quantity of water displaced by the keel, and by that part of the bottom below each water line in the draught. Since the areas of the several water lines are already computed for the eighty gun ship laid down in Plates CCCCXL. and CCCCLX., the contents of these parts may hence be easily found for that ship, and are as follows.

<table>

Construct any convenient scale of equal parts to represent tons, as scale n° 1, and another to represent feet, as n° 2.

Draw the line AB (fig. 36.) limited at A, but produced indefinitely towards B. Make AC equal to the depth of the keel, 2 feet 3 inches from scale n° 2, and through C draw a line parallel to AB, which will represent the upper edge of the keel; upon which set off C = equal to 21 tons 1853 lbs., taken from scale n° 12.

Again, make AD equal to the distance between the lower edge of the keel and the fifth water line, namely, 6 feet 4 inches, and a line drawn through D parallel to AB will represent the lower water line; and make DB equal to 305 tons 848 lbs., the corresponding tonnage. In like manner draw the other water lines, and lay off the corresponding tonnages accordingly: then through the points A, c, b, e, f, g, h, draw the curve A b e f g h. Through b draw b B perpendicular to AB, and it will be the greatest limit of the quantity of water expressed in tons displaced by the bottom of the ship, or that when she is brought down to the load water line. And since the ship displaces 1788 tons at her light water mark, take therefore that quantity from the scale n° 1, which being laid upon AB from A to K, and KL drawn perpendicular to AB, will be the representation of the light water line for tonnage. Hence the scale will be completed.

Let:

CHAP. X. Of the Scale of Solidity.

By this scale the quantity of water displaced by the bottom of the ship, for which it is constructed, answering to a given draught of water is easily obtained; and also the additional weight necessary to bring her down to the load water line.

1. For Men of War.

Take the length of the gun-deck from the rabbet of the stem to the rabbet of the stern-post; \( \frac{3}{4} \) of this is to be assumed as the height for tonnage, \( L \).

Take the extreme breadth from outside to outside of the plank; add this to the length, and take \( \frac{3}{4} \) of the sum; call this the depth for tonnage, \( D \).

Set up this height from the rabbet, and at that height take a breadth also from outside to outside of plank in the timber when the extreme breadth is found, and another breadth in the middle between that and the rabbet; add together the extreme breadth and these three breadths, and take \( \frac{3}{4} \) of the sum for the breadth for tonnage, \( B \).

Multiply \( L \), \( D \), and \( B \) together, and divide by 49. The quotient is the burthen in tons.

The following proof may be given of the accuracy of this rule. Column 1. is the tonnage or burthen by the king's measurement; col. 2. is the tonnage by this rule; and, col. 3. is the weight actually taken on board these ships at Blackfriars:

2. For Ships of Burthen.

Take the length of the lower deck from the rabbet of the stem to the rabbet of the stern-post; then \( \frac{3}{4} \) of this is the length for tonnage, \( L \).

Add the length of the lower deck to the extreme breadth from outside to outside of plank; and take \( \frac{3}{4} \) of the sum for the depth for tonnage, \( D \).

Set up that depth from the rabbet, and at this height take a breadth from outside to outside. Take another at \( \frac{3}{4} \) of this height, and another at \( \frac{3}{4} \) of the height. Add the extreme breadth and these three breadths, and take \( \frac{3}{4} \) of the sum for the breadth for tonnage, \( B \).

Multiply \( L \), \( D \), and \( B \), and divide by 364. The quotient is the burthen in tons.

This rule rests on the authority of many such trials, as the following:

CHAP. X. Of the Scale of Solidity.
The text contains a mathematical problem related to the pressure on a surface due to fluid and the division of a length. It involves calculations and geometric constructions, likely related to the study of shipbuilding. The text is quite detailed and technical, requiring a background in mathematical and physical principles to understand fully.
provided it has a sufficient degree of stiffnes: but as soon as it begins to give way, it is evident it must bend in a convex manner, since its middle would obey the forces C e and D d, while its extremities would be actually drawn downwards by the forces A a and B b.

The vessel is generally found in such a situation; and since similar effects continually act whilst the vessel is immersed in the water, it happens but too often that the keel experiences the bad effect of a strain. It is therefore very important to inquire into the true cause of this accident.

For this purpose, let us conceive the vessel to be divided into two parts by a transverse section through the vertical axis of the vessel, in which b is the centre of gravity (fig. 51.) of the whole vessel and that of the immersed part are situated: so that one of them will represent the head part, and the other that of the stern, each of which will be considered separately. Let g be the centre of gravity of the entire weight of the first, and $\gamma$ that of the immersed part corresponding. In like manner, let $\gamma$ be the centre of gravity of the whole after part, and $\omega$ that of its immediate portion.

Now it is plain, that the head will be acted upon by the two forces g m and $\gamma$ n, of which the first will press it down, and the latter push it up. In the same manner, the stern will be pressed down by the force, $\omega$ m, and pulled up by the force $\omega$ n. But these four forces will maintain themselves in equilibrium, as well as the total forces reunited in the points G and O, which are equivalent to them; but whilst neither the forces before nor those behind fall in the same direction, the vessel will evidently fulfill efforts tending to bend the keel upwards, if the two points $\gamma$ n are nearer the middle than the two other forces g m and $\omega$ m. A contrary effect would happen if the points $\omega$ n were more distant from the middle than the points $\gamma$ m.

But the first of these two causes usually takes place almost in all vessels, since they have a greater breadth towards the middle, and become more and more narrow towards the extremities; whilst the weight of the vessel is in proportion much more considerable towards the extremities than at the middle. From whence we see, that the greater this difference becomes, the more also will the vessel be subject to the forces which tend to bend its keel upwards. It is therefore from thence that we must judge how much strength it is necessary to give to this part of the vessel, in order to avoid such a consequence.

If other circumstances would permit either to load the vessel more in the middle, or to give to the part immersed a greater capacity towards the head and stern, such an effect would no longer be apprehended. But the definition of most vessels is entirely opposite to such an arrangement: by which means we are obliged to strengthen the keel as much as may be necessary, in order to avoid such a failure.

We shall conclude this chapter with the following practical observations on the hogging and fagging of ships by Mr. Hutchinson of Liverpool:

"When ships with long floors happen to be laid dry upon mud or sand, which makes a solid resistance against the long straight floors amidships, in comparison with the two sharp ends, the entrance and run meet with little support, but are pressed down lower than the flat of the floor, and in proportion hogs the ship amidships; which is too well known from experience in our navigation many total losses, do so much damage by hogging them, as to require a vast deal of trouble and expense to save and repair them, so as to get the hog taken out and brought to their proper heater again: and to do this the more effectually, the owners have often been induced to go to the expense of lengthening them; and by the common method, in proportion as they add to the burden of these ships, by lengthening their too long straight floors in their main bodies amidships, so much do they add to their general weaknees to bear hardships either on the ground or afloat; for the scantling of their old timber and plank is not proportionable to bear the additional burden that is added to them.

"But defects of this kind are best proved from real and incontrovertible facts in common practice. At the very time I was writing upon this subject, I was called upon by my advice by the commander of one of those strong, long, straight floored ships, who was in much trouble and distraction of mind for the damage his ship had taken by the pilot laying her on a hard, gentle flooding sand, at the outside of our docks at Liverpool, where it is common for ships that will take the ground to lie for a tide, when it proves too late to get into our wet docks. After recommending a proper ship carpenter, I went to the ship, which lay with only a small keel, yet was greatly hogged, and the butts of her upper works strained greatly on the lee side; and the teams of her bottom, at the lower futtock heads, vastly opened on the weather side: all which strained parts were agreed upon not to be caulked, but filled with tallow, putty, or clay, &c. with raw bullocks hides, or canvas nailed with battens or her bottom, which prevented her sinking with the flow of the tide, without hindering the preflure of water from righting and clofing the teams again as she floated, so as to enable them to keep her free with pumping. The vessel, like many other instances of ships of this construction which I have known, was saved and repaired at a very great expense in our dry repairing docks. And that their bottoms not only hog upwards, but fag (or curve) downwards, to dangerous and fatal degrees, according to the strain or preflure that prevails upon them, will be proved from the following facts:

"It has been long known from experience, that when ships load deep and very heavy cargoes or materials that are flowed too low, is makes them so very laboursome at sea, when the waves run high, as to roll away their masts; and after that misfortune causes them to labour and roll the more, so as to endanger their working and straining themselves to pieces: to prevent which, it has been long a common practice to leave a great part of their keel and after holds empty, and to flow them so high as possible in the main body at midships, which causes the bottoms of these long straight floored ships to fag downwards, in proportion as the weight of the cargo flowed there exceeds the preflure of the water upwards, so much so as to make them dangerously and fatally leaky.

"I have known many instances of those strong ships of 500 or 600 tons burdens built with long straight floors, on the east coast of England, for the coal and timber trade, come loaded with timber from the Baltic
to Liverpool, where they commonly load deep with rock fall, which is too heavy to hold their holds, so that for the above reasons they flowed it high amidships, and left large empty spaces in their fore and after holds, which caused their long straight floors to sag downward, so much as to make their hold flàunions amidships, at the main hatchways, settle from the beams three of four inches, and their mainmasts fell so much as to oblige them to set up the main rigging when rolling hard at sea, to prevent, the masts being rolled away; and they were rendered so leaky as to be obligèd to return to Liverpool to get their leaks stopped at great expense. And in orde to save the time and expense in discharging them, endeavors were made to find out and stop their leaks, by lacing them afove dry on a level sand; but without effect; for though their bottoms were thus fagged down by their cargoes when afloat, yet when they came a-dry upon the sand, some of their bottoms hogged upwards so much as to raise their mainmasts and pumps so high as to tear their coats from their decks: that they have been obliged to discharge their cargoes, and give them a repair in the repairing dock, and in some to double their bottoms, to enable them to carry their cargoes with safety, flowed in this manner. From this cause I have known one of these large ships to founder.

Among the many instances of ships that have been disfitted by carrying cargoes of lead, one failed from hence bound to Marseilles, which was soon obliged to put back again in great difficulties, having had four feet water in the hold, by the commander’s account, owing to the ship’s bottom fagg ing down to such a degree as made the hold flàunions settle six inches from the lower deck beams amidsthips; yet it is common with these long straight floored ships, when these heavy cargoes are discharged that makes their bottom fagg down, then to hog upwards; so that when they are put into a dry repairing dock, with empty holds, upon straight blocks, they commonly either split the blocks close fore and aft, or damage their keels there, by the whole weight of the ship lying upon them, when none lies upon the blocks under the flat of their floor amidships, that being hogged upwards which was the case of this ship’s bottom; though fagged downwards six inches by her cargo, it was now found hogged so much that her keel did not touch the blocks amidships, which occasioned so much damage to the after part of the keel, as to oblige them to repair it; which is commonly the cafe with these ships, and therefore deserving particular notice.

In order to prevent these defects in ships, “they should all be built with their floors or bottoms lengthwise, to form an arch with the projecting part downwards, which will naturally not only contribute greatly to prevent their taking damage by their bottoms hogging and straining upwards, either aground or afloat, as has been mentioned; but will, among other advantages, be a help to their failing, freeting, flaying, and warming.”

**CHAP. III. Of the Stability of Ships.**

When a vessel receives an impulse or preffure in a horizontal direction, so as to be inclined in a small degree, the v.s.f. will then either regain its former position as the pressure is taken off, and is in this case said to be possessed of stability; or it will continue in its inclined state; or, lastly, the inclination will increase until the vessel is overturned. With regard to the first case, it is evident that a sufficient degree of stability is necessary in order to sustain the efforts of the wind; but neither of the other two cases must be permitted to have place in vessels.

Let CED (fig. 52.) be the section of a ship passing through its centre of gravity, and perpendicular to the ship’s floor and floor plans; which let be in equilibrium in a fluid; AB being the water line, G the centre of gravity of the whole body, and g that of the immersed part AEB. Let the body receive now a very small inclination, so that A E b becomes the immersed part, and g its centre of gravity. From g draw M perpendicular to a b, and meeting G G, produced, if necessary, in M. If, then, the point M thus found is higher than G the centre of gravity of the whole body, the bow will, in this case, return to its former position, the pressure being taken off. If the point M coincides with G, the vessel will remain in its inclined state; but if M be below G, the inclination of the vessel will continually increase until it is entirely overturned.

The point of intersection M is called the metacenter, and is the limit of the altitude of the centre of gravity of the vessel, to which it is impossible for the whole body to remain in a horizontal position, without the assistance of an inclining force. If M be below G, the metacenter coincides with the centre of gravity, the vessel has no tendency whatever to move out of the situation into which it may be put. Thus, if the vessel be inclined either to the right or left side, it will remain in that position until a new force is impressed upon it; in this case, therefore, the vessel would not be able to carry itself, and is hence unfit for the purposes of navigation. If the metacenter is below the common centre of gravity, the vessel will instantly overturn.

As the determination of the metacenter is of the utmost importance in the construction of ships, it is therefore thought necessary to illustrate this subject more particularly.

Let AEB (fig. 52.) be a section of a ship perpendicular to the keel, and also to the plane of elevation, and passing through the centre of gravity of the ship, and also through the centre of gravity of the immersed part, which let be g.

Now let the ship be supposed to receive a very small inclination, so that the line of floatation is a b, and g the centre of gravity of the immersed part a E b. From g draw M perpendicular to a b, and intersecting GM in M, the metacenter, as before. Hence the pressure of the water will be in the direction g M.

In order to determine the point M, the metacenter, the position of g with respect to the lines AB and g G, must be previously ascertained. For this purpose, let the ship be supposed to be divided into a great number of sections by planes, perpendicular to the keel, and parallel to each other, and to that formerly drawn, these planes being fagged equidistant. Let AEB (fig. 53.) be one of these sections, g the centre of gravity of the immersed part before inclination, and g the centre of gravity of the immersed part when the ship is in its inclined state; the distance g g between the two centres of
SHiP-BiUlDING.

Stability of ships.

Now let, H, I, K, be the centres of gravity of the spaces \(AO_a\), \(AE_b\), and \(BO_b\), respectively. From these points draw the lines \(Hb\), \(Ia\), and \(Kb\), perpendicular to \(AB\), and let \(IL\) be drawn perpendicular to \(EO\). Now to ascertain the distance \(y\) of the centre of gravity \(y\) of the part \(AE\) from the line \(AB\), the momentum of \(AE\) with respect to this line must be equal to the difference of the momentums of the parts \(AE\), \(AO\), which are upon different fides of \(AB\). Hence \(AE\times y = \frac{1}{2} \cdot AO \times H\). But since \(g\) is the common centre of gravity of the parts \(AE\), \(BO\), we have the equation \(AE\times y = \frac{1}{2} \cdot AB \times K\). Hence, by expunging the term \(AE\times y = \frac{1}{2} \cdot AO \times H\), and comparing them, we obtian \(AE\times y = \frac{1}{2} \cdot AO \times K\).

Now, since the triangles \(AO\), \(BO\), are supposed infinitely small, their momentums or products, by the infinitely little lines \(Hb\), \(K\), will also be infinitely small with respect to \(AE\times y = \frac{1}{2} \cdot AO \times H\); which therefore being rejected, the former equation becomes \(AE\times y = \frac{1}{2} \cdot AO \times K\) and \(y\) equal to \(\frac{1}{2} \cdot AO \times K\). Whence the centres of gravity \(y\), \(g\), being at equal distances below \(AB\), the infinitely little line \(y\) is therefore perpendicular to \(EO\). For the same reason \(y\), fig. 52., may be considered as an arch of a circle whose centre is \(M\).

To determine the value of \(y\), the momentum of \(AE\) with respect to \(EO\) must be taken, for the same reason as before, and put equal to the momentums of the two parts \(AO\), \(AB\); and we shall then have \(AE\times y = \frac{1}{2} \cdot AO \times K\) and \(AE\times y = \frac{1}{2} \cdot AO \times K\). But since \(g\) is the common centre of gravity of the two spaces \(AE\), \(BO\), we shall have \(AE\times y = \frac{1}{2} \cdot AO \times K\) and \(g\) equal to \(\frac{1}{2} \cdot AO \times K\). Hence \(AE\times y = \frac{1}{2} \cdot AO \times K\) and \(g\) equal to \(\frac{1}{2} \cdot AO \times K\). Because the two triangles \(AO\), \(BO\) are equal, and that the distances \(O\), \(b\), are also evidently equal.

Let \(x\) be the thickness of the section represented by \(AE\). Then the momentum of this section will be \(\frac{1}{2} \cdot BO \times x \times O\), which equation will also serve for each particular section.

Now let \(f\) represent the sum of the momentums of all the sections. Hence \(f\) equal to \(\frac{1}{2} \cdot BO \times x \times O\). Now the first member being the sum of the momentums of each section, in proportion to a plane passing through the keel, ought therefore to be equal to the sum of all the sections, or to the volume of the immersed part of the bottom multiplied by the distance \(y\). Hence \(V\) representing the volume, we shall have \(V \times y = f\), \(\frac{1}{2} \cdot BO \times x \times O\).

In order to determine the value of the second member of this equation, it may be remarked, that when the ship is inclined, the original plane of floatation \(C\) becomes \(C\) when \(Q\) becomes \(Q\). Now the triangles \(NI\), \(BO\), being the same as those in figures 52. and 53.; and as each of these triangles have one angle equal, they may, upon account of their infinite smallness, be considered as similar; and hence \(BO\times N\) = \(\frac{1}{2} \cdot BO\times NI\). Moreover, we have \(\frac{1}{2} \cdot BO\times O\), for the points \(K\) and \(b\) may be considered as equidistant from the point \(O\):

\[\frac{1}{2} \cdot BO \times O \times k = \frac{1}{2} \cdot BO \times O \times \frac{1}{2} \cdot BO \times N,\]

Now, let \(H, I, K\), be the centres of gravity of the spaces \(AO\), \(AE\), and \(BO\), respectively. From these points draw the lines \(Hb, Ia, Kb\), perpendicular to \(AB\), and let \(IL\) be drawn perpendicular to \(EO\). Now to ascertain the distance \(y\) of the centre of gravity \(y\) of the part \(AE\) from the line \(AB\), the momentum of \(AE\) with respect to this line must be equal to the difference of the momentums of the parts \(AE\), \(AO\), which are upon different sides of \(AB\). Hence \(AE\times y = \frac{1}{2} \cdot AO \times H\). But since \(g\) is the common centre of gravity of the parts \(AE\), \(BO\), we have the equation \(AE\times y = \frac{1}{2} \cdot AB \times K\). Hence, by expunging the term \(AE\times y = \frac{1}{2} \cdot AO \times H\), and comparing them, we obtain \(AE\times y = \frac{1}{2} \cdot AO \times K\).

Now, since the triangles \(AO\), \(BO\), are supposed infinitely small, their momentums or products, by the infinitely little lines \(Hb\), \(K\), will also be infinitely small with respect to \(AE\times y = \frac{1}{2} \cdot AO \times H\); which therefore being rejected, the former equation becomes \(AE\times y = \frac{1}{2} \cdot AO \times K\) and \(y\) equal to \(\frac{1}{2} \cdot AO \times K\). Whence the centres of gravity \(y\), \(g\), being at equal distances below \(AB\), the infinitely little line \(y\) is therefore perpendicular to \(EO\). For the same reason \(y\), fig. 52., may be considered as an arch of a circle whose centre is \(M\).

To determine the value of \(y\), the momentum of \(AE\) with respect to \(EO\) must be taken, for the same reason as before, and put equal to the momentums of the two parts \(AO\), \(AB\); and we shall then have \(AE\times y = \frac{1}{2} \cdot AO \times K\) and \(AE\times y = \frac{1}{2} \cdot AO \times K\). But since \(g\) is the common centre of gravity of the two spaces \(AE\), \(BO\), we shall have \(AE\times y = \frac{1}{2} \cdot AO \times K\) and \(g\) equal to \(\frac{1}{2} \cdot AO \times K\). Hence \(AE\times y = \frac{1}{2} \cdot AO \times K\) and \(g\) equal to \(\frac{1}{2} \cdot AO \times K\). Because the two triangles \(AO\), \(BO\) are equal, and that the distances \(O\), \(b\), are also evidently equal.

Let \(x\) be the thickness of the section represented by \(AE\). Then the momentum of this section will be \(\frac{1}{2} \cdot BO \times x \times O\), which equation will also serve for each particular section.

Now let \(f\) represent the sum of the momentums of all the sections. Hence \(f\) equal to \(\frac{1}{2} \cdot BO \times x \times O\). Now the first member being the sum of the momentums of each section, in proportion to a plane passing through the keel, ought therefore to be equal to the sum of all the sections, or to the volume of the immersed part of the bottom multiplied by the distance \(y\). Hence \(V\) representing the volume, we shall have \(V \times y = f\), \(\frac{1}{2} \cdot BO \times x \times O\).

In order to determine the value of the second member of this equation, it may be remarked, that when the ship is inclined, the original plane of floatation \(C\) becomes \(C\) when \(Q\) becomes \(Q\). Now the triangles \(NI\), \(BO\), being the same as those in figures 52. and 53.; and as each of these triangles have one angle equal, they may, upon account of their infinite smallness, be considered as similar; and hence \(BO\times N\) = \(\frac{1}{2} \cdot BO\times NI\). Moreover, we have \(\frac{1}{2} \cdot BO\times O\), for the points \(K\) and \(b\) may be considered as equidistant from the point \(O\):

\[\frac{1}{2} \cdot BO \times O \times k = \frac{1}{2} \cdot BO \times O \times \frac{1}{2} \cdot BO \times N,\]
vertical section passing through the keel, and dividing the ship into two equal and similar parts, at a certain distance from the stern, and altitude above the keel.

In order to determine the centre of gravity of the immersed part of a ship's bottom, we must begin with determining the centre of gravity of a section of the ship parallel to the keel, as ANDFB (fig. 56.), bounded by the parallel lines A B, DF, and by the equal and similar curves AND, BPF.

If the curve of this section were known, its centre of gravity would be easily found: but as this is not the case, let therefore the line C E be drawn through the middle C, E, of the lines AB, DF, and let this line C E be divided into four equal parts by the perpendiculars TH, KM, &c. that the arches of these curves contained between the extremities of any two adjacent perpendiculars may be considered as straight lines. The momentums of the trapeziums DTHF, TKMH, &c. relative to the point E, are then to be found, and the sum of these momentums is to be divided by the sum of the trapeziums, that is, by the surface ANDFB.

The distance of the centre of gravity of the trapezium THED from the point E is: 

$$\frac{1}{6} IE \times (DF + 2 TH)$$

For the same reason, and because of the equality of the lines IE, IL, the distance of the centre of gravity of the trapezium TKMH from the same point E will be:

$$\frac{1}{6} IE \times (TK + 2 KM)$$

In like manner the distance of the centre of gravity of the trapezium NKMP from the point E will be:

$$\frac{1}{6} IE \times (KM + 2 NP)$$

Now, if each distance be multiplied by the surface of the corresponding trapezium, that is, by the product of half the sum of the two opposite sides of the trapezium into the common altitude IE, we shall have the momentums of these trapeziums, namely, 

$$\frac{1}{6} IE \times (DF + 2 TH), \frac{1}{6} IE \times (TK + 2 KM), \frac{1}{6} IE \times (KM + 2 NP)$$

Hence the sum of these momentums will be:

$$\frac{1}{6} IE \times (DF + 2 TH + 2 TK + 2 KM + 2 KM + 2 NP) + 4 QS + 14 AB$$

Whence it may be remarked that if the line C E be divided into a great number of equal parts, the factor or coefficient of the last term, which is here 14, will be $2 + 3 (n - 2)$ or $3 n - 4$, n being the number of perpendiculars. Thus the general expression of the sum of the momentums is reduced to:

$$\frac{1}{6} IE \times (DF + TH + 2 KM + 3 NP + 4 QS + 14 AB)$$

The area of the figure A N D F P B is equal to:

$$IE \times \left(\frac{1}{6} DF + TH + KM + NP + 14 AB\right)$$

Hence the distance E G of the centre of gravity from one of the extreme ordinates D F is equal to:

$$IE \times \left(\frac{1}{6} DF + TH + 2 KM + 3 NP + 14 AB\right)$$

Whence the following rule to find the distance of the centre of gravity G from one of the extreme ordinates D F. To the sixth of the first ordinate add the sixth of the last ordinate multiplied by three times the number of ordinates minus four; then the second ordinate, twice the third, three times the fourth, &c. the sum will be the first term. Then to half the sum of the extreme ordinates add all the intermediate ones, and the sum will be a second term. Now the first term divided by the second, and the quotient multiplied by the interval between two adjacent perpendiculars, will be the distance sought.

Thus, let there be seven perpendiculars, whose values are 18, 23, 28, 30, 31, 30, 25, feet respectively, and the common interval between these perpendiculars 20 feet. Now the sixth of the first term is 18; and as the last term is 0, therefore to add 23, twice 28 or 56, thrice 30 or 90, four times 31 or 120, five times 30 or 150; and the sum is 597. Then to the half of 18+0, or 9, add the intermediate ordinates, and the sum will be 141. Now 597 X 20 = 9940, or 59 feet 4 inches nearly, the distance of the centre of gravity from the first ordinate.

Now, when the centre of gravity of any section is determined, it is easy from hence to find the centre of gravity of the solid, and consequently that of the bottom of a ship.

The next step is to find the height of the centre of gravity of the bottom above the keel. For this purpose the bottom must be imagined to be divided into sections by planes parallel to the keel or water-line (figs. 57, 58.) Then the solidity of each portion contained between two parallel planes will be equal to half the sum of the two opposed surfaces multiplied by the distance between them; and its centre of gravity will be at the same altitude as that of the trapezium abc, (fig. 58.), which is in the vertical section passing through the keel. It is hence obvious, that the same rule as before is to be applied to find the altitude of the centre of gravity, with this difference only, that the word perpendicular or ordinate is to be changed into section. Hence the rule is, to the sixth part of the least section add the product of the sixth part of the uppermost section by three times the number of sections minus four; the second section in ascending twice the third, three times the fourth, &c. the sum will be a first term. To half the sum of upper and lower sections add the intermediate ones, the sum will be a second term. Divide the first term by the second, and the quotient multiplied by the difference between the sections will give the altitude of the centre of gravity above the keel.

With regard to the centre of gravity of a ship, whether it is considered as loaded or light, the operation becomes more difficult. The momentums of every different part of the ship and cargo must be found separately with respect to a horizontal and also a vertical plane. Now the sums of these two momentums being divided by the weight of the ship, will give the altitude of the centre of gravity, and its distance from the vertical plane; and as this centre is in a vertical plane passing through the axis of the keel, its place is therefore determined. In the calculation of the momentums, it must be observed to multiply the weight, and not the magnitude of each piece, by the distance of its centre of gravity.

A more easy method of finding the centre of gravity of a ship is by a mechanical operation, as follows: Construct a block
a block of as tight wood as possible, exactly similar to the parts of the proposed draught or ship, by a scale of about one-fourth of an inch to a foot. The block is then to be suspended by a silk-thread or very fine line, placed in different situations until it is found to be in a state of equilibrium, and the centre of gravity will be pointed out. The block may be proved by fastening the line which suspends it to any point in the line joining the middles of the stem and poa, and weights are to be suspended from the extremities of this middle line at the stem and poa. If, then, the block be properly constructed, a plane passing through the line of suspension, and the other two lines, will also pass through the keel, stem, and poa. Now, the block being suspended in this manner from any point in the middle line, a line is to be drawn on the block parallel to the line of suspension, so that the plane passing through these two lines may be perpendicular to the vertical plane of the ship in the direction of the keel. The line by which the block is suspended is then to be removed to some other convenient point in the middle line; and another line is to be drawn on the block parallel to the line suspending it, as before. Then the point of intersection of this line with the former will give the position of the centre of gravity on the block, which may now be laid down in the draught.

\[
291 \times 13 = 3897.26 \times \frac{1}{6} = 554.43
\]

Now \( \frac{3897.26}{554.43} \times 10 = 70.5 \)

Hence the distance of the centre of gravity of double the plane \( 8g \) from the first ordinate \( 8g \), is

Distance of this ordinate from the after side of stern-post,

- 13.5

Distance of the centre of gravity from the after side of poa,

- 84.0

Distance of the centre of gravity of double the trapezium \( AR8 \) from its ordinate \( AR \),

Distance of this ordinate from the after side of the stern-post,

- 9.0

Distance of the centre of gravity of this plane from the after side of the stern-post,

- 9.0

Distance of the centre of gravity of double the trapezium \( G \) from its ordinate \( G \),

Distance of this ordinate from the after side of the poa,

- 159.22

Distance of the centre of gravity of this trapezium from the after side of the poa,

- 159.22

Distance of the centre of gravity of the fection of the stern-post from the after part of the poa,

- 0.29

Distance of the centre of gravity of the fection of the stern from the after side of the poa,

- 169.76

The
The areas of these several planes, calculated by the common method, will be as follow:

\[ \text{Gravity} \quad \text{Gravity} \]

\[
169.76 = (3 \times 15) - 4 \times \frac{1}{9} \times 21.43 \times 0.4 \]

Hence the distance of the centre of gravity of double the plane 8 b v G from its first ordinate 8 b, is 16.39. 46. 42 |

\[
\times 10 = 169.77 \times 10.03 = 16930.9642 |
\]

Distance of this ordinate from the side of the post

\[
13.56 |
\]

Hence the distance of the centre of gravity of the plane from the side of the post is

\[
84.34 |
\]

Distance of the centre of gravity of the trapezium AR 8 b from its ordinate AR

\[
2.92 |
\]

Distance of this ordinate from the side of the post

\[
153.78 |
\]

Distance of the centre of gravity of the trapezium from the side of the post

\[
156.79 |
\]

Distance of the centre of gravity of the section of the post from its side

\[
0.29 |
\]

Distance of the centre of gravity of the section of the post from the side of the post

\[
169.76 |
\]

The areas of these plans will be found to be as follow:

\[
2356.4642 \text{ for that of double the plane 8 b v G, and its momentum } 2328.3642 \times 84.34 = 196374.266 |
\]

\[
21.52 \text{ for the area of double the trapezium AR b 8, and its momentum 21.52 \times 7.46 = 160.5702 |
\]

\[
15.04 \text{ the area of the forepart trapezium, and its momentum } 15.04 \times 156.7 = 2356.7680 |
\]

\[
0.77 \text{ the area of the section of the post, and its momentum } 0.77 \times 0.29 = 0.2233 |
\]

\[
0.77 \text{ the area of the section of the post, and its momentum } 0.77 \times 169.76 = 130.7125 |
\]

\[
2366.4642 \text{ Sum } 199022.4823 |
\]

Now \[
\frac{199022.4823}{2366.4642} = 84.1, \text{ the distance of the centre of gravity of the whole from the side of the post.}
\]

VII. Determination of the Centre of Gravity of the Seventh Horizontal Section.

Distance of the centre of gravity of double the plane 8 a b G from its first ordinate 8 a.

Hence the distance of the centre of gravity of double the plane from its first ordinate is \(\frac{205.46}{35.16} \times 10.04 = 13.59\)

The distance of this ordinate from the forefoot is \(7.03\)

The product is the area of this plane \(208.2\)

The distance of its centre of gravity from the aft side of the post, being equal to half its length, is \(78.06\)

The centres of gravity of these eight planes being found, the distance of the centre of gravity of the bottom of the ship from the aft side of the post, and also its altitude, may from thence be easily determined.

From the principles already explained, the distance of the centre of gravity of the bottom from the aft side of the post, is equal to the sum of the momentums of an infinite number of horizontal planes, divided by the sum of these planes, or, which is the same, by the solidity of the bottom. As, however, we have no more than eight planes, we must therefore conceive their momentums as the ordinates of a curve, whose distances may be the same as that of the horizontal planes. Now the sum of these ordinates minus \(h\) of the sum of the extreme ordinates being multiplied by their distance, gives the surface of the curve; of which any ordinate whatever represents the momentum of the horizontal plane at the same altitude as those ordinates; and the whole surface will represent the sum of the momentums of all the horizontal planes.

**VIII. Determination of the Centre of Gravity of the eighth Plane.**

This plane is equal in length to the seventh horizontal plane, and its breadth is equal to that of the keel.

The distance between the seventh and eighth planes is three feet, but which is here taken equal to 2 feet 11\(\frac{1}{4}\) inches.

Distance between the aft side of the post and the first ordinate \(13.5\)

Fourteen intervals between the fifteen ordinates, each interval being 10.03 feet \(140.42\)

Distance of the last ordinate from the forefoot \(2.2\)

Hence the length of the eighth plane \(156.12\)

Which multiplied by the breadth \(1.33\)

Now the areas of these several plans being calculated will be as follows.

<table>
<thead>
<tr>
<th>Area of Double Plane</th>
<th>352.2536</th>
<th>Product of Area and Moment</th>
<th>25415.0972</th>
<th>Sum of Areas</th>
<th>374.2756</th>
</tr>
</thead>
<tbody>
<tr>
<td>8 a b G, and its moment</td>

<td>374.2756</td>
<td></td>
<td></td>
</tr>
<tr>
<td>(0.77) the area of the section of the port, and its moment</td>
<td>(0.77 \times 0.29 = 0.2233)</td>
<td>0.2233</td>
<td>374.2756</td>
<td></td>
<td></td>
</tr>
<tr>
<td>(0.77) the area of the section of the stem, and its moment</td>
<td>(0.77 \times 169.76 = 130.7152)</td>
<td>130.7152</td>
<td>374.2756</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Then \(\frac{26182.1242}{374.2756} = 69.95\), the distance of the centre of gravity of the whole section from the aft side of the post.

Now \(\frac{202451.06}{23898.27} = 84.63\), the distance of the
The height of the centre of gravity of the bottom of the ship may be determined by
the same principles. Thus,

To one sixth of the lowermost horizontal section added the product of one sixth of the uppermost section by times the number of sections minus four the second section in ascending, twice the third, three times the fourth, &c.; and to half the sum of the extreme planes and divided by the second sum, gives the altitude of the centre of gravity from the lower edge of the keel.

It now remains to find the height of the metacenter above the lower edge of the keel.

Now \[ \text{Ordinate at 10.03 feet abaft the ordinate } \frac{23}{4}, \text{ of which the cube is } 64, \text{ and } 64 \times \frac{1}{4} = 32. \]

Half the cube of the aftermost ordinate – 32.

Half the cube of the thick-
ness of the stem also 3.14.

Multiply by the distance
between the ordinates

Product \[ \frac{32.14 \times 96.4}{2} = \frac{3094.77}{2} \]

Half the cube of the fore-
most ordinate – 108.

Half the cube of the thick-
ness of the stem also 3.14.

Multiply by the distance
between the ordinates

Product \[ \frac{108.14 \times 5.5}{2} = \frac{594.77}{2} \]

\[ \frac{1}{3} \times 7751726 = 70018.67 \text{ cubic feet; hence } \frac{23}{8} = 70018.67, \]

The solility of the bottom is 2572 \( \frac{1}{3} \) tons = 70018.67.

When a ship is built, she must determine the centre of gravity of the bottom of the ship above the lower edge of the keel.

Now apply to determine the metacenter of the ship of 74 guns, whose centre of gravity we have already found.

Ord. of the Plane of Floatation. Cub. of Ordinates.

The solid of the bottom is 7572 \( \frac{1}{3} \) tons = 70018.67.

New work on the subject is left to us here, except we were to state in a few words the progressive method of rigging ships; but there is no one undertaking more which is purposed, as the nature of the operation is such that all the parts of it may be advancing at the same time. We shall therefore take our leave of ships and ship-building with a few general observations on sail-making, which were omitted under the article Sail, referring our readers for further information to the very elegant work lately published, in
S H I P - B U I L D I N G.

Appendix. two volumes, to, on the Elements and Practice of Rigging and Seamanship.

Sails are made of canvas, of different textures, and are extended on or between the masts, to receive the wind that forces the vessel through the water. They are quadrilateral or triangular, as has been elsewhere described, and are cut out of the canvas cloth by cloth. The width is governed by the length of the yard, gaff, boom, or flap; the depth by the height of the mast.

In the valuable work to which we have just referred, the following directions are given for cutting sails.

"The width and depth being given, find the number of cloths the width requires, allowing for seams, tacking on the leeches, and slack cloth; and, in the depth, allow for tacking on the head and foot. For cuts square on the head and foot, with gores only on the leeches, as some topgallants, &c. the cloths on the head, between the leeches, are cut square to the depth, and the gores on the leeches are found by dividing the depth of the sail by the number of cloths gored, which gives the length of each gore. The gore is set down from a square with the opposite selvage; and the canvas being cut diagonally, the longest gored side of one cloth makes the shortest side of the next; consequently, the first gore being known, the rest are cut by it. In the leeches of topgallants cut hollow, the upper gores are longer than the lower ones; and in falls cut with a roach-leech, the lower gores are longer than the upper ones. This must be regulated by judgment, and care taken that the whole of the gores do not exceed the depth of the leech. Or, by drawing on paper the gored side of one cloth next the selvage; from the square of the given depth on each cloth, and are cut as above; the longest selvage of one serving to measure the shortest selvage of the next, beginning with the first gored cloth next the middle in some falls, and the first cloth next the mast leech in others. For those gores that are irregular no strict rule can be given; they can only be determined by the judgment of the sail-makers, or by a drawing."

"In the royal navy, mizen topfals are cut with three wide; jib and other boom-falls, 3 inches and a half; topgallant and sprit topfals, 3 inches; royal fails, 2 inches and a half; jib and other stay-falls, 3 inches to 4 inches and a half; topgallant and sprit topfals, 3 inches; royal falls, 2 inches and a half; jib and other stay-falls, 3 inches to 4 inches and a half; on the flap or hoist; and for shudding falls, 3 inches to 4 inches on the head. Tablings on the foot and leeches of main and fore courses to be 3 inches to 5 inches broad; sprit course and topfals, 3 inches; topgallant and sprit topfals, 2 inches and a half; royal fails, 2 inches and a half; fore leeches of mizen, driver, and other boom-falls, 3 inches and a half to 4 inches; after leech, 3 inches; and on the foot 2 or 3 inches. Tablings on the after leech of jibs and other stay-falls to be from 2 to 3 inches broad; and, on the foot, 2 to 2 inches and a half; on shudding fall leeches one inch and a half to two inches and a half; and on the foot, from one to two inches.

"Main."

(1) The dipping of the twine in tar, we are persuaded, is a very bad practice, for the reason assigned in Rope-Making. See that article, p. 32.

Elements and practice of Rigging and Seamanship vol. I. p. 91.
Main and fore courses are lined on the leeches, from clue to earing, with one cloth fastened on and twerked or fleted in the middle, and have a middle band half way between the lower reef band and the foot, also four buntline cloths, and eight distances between the leeches, the upper ends of which are carried under the middle band, that the lower side of the band may be rolled up or fleted over the end of the buntline pieces. They have likewise two reef bands; each in breadth one third of the breadth of the canvas; the upper one is one fifth of the depth of the fail from the head, and the lower band is at the same distance from the upper one; the ends of the buntline cloths, which are fleted over the reef bands. All linings are fleted on, and are fleted with 68 to 72 fitches in a yard.

Main, fore, and mizen, topfails have leech linings, main and top linnings, buntline cloths, middle bands and reef bands. The leech linings are made of one breadth of cloth, so cut and fleted as to be half a cloth broad at the head, and a cloth and a half broad at the foot; the piece cut out being half the breadth of the cloth at the one end, and tapering to a point at the other. The middle bands are put on half way between the lower reef and foot, the buntline cloths join the top-linings, and the buntline cloths and top-linings are carried up to the lower side of the middle band, which is fleted on them. The maft lining is of two cloths, and extends from the foot of the fail to the lower reef, to receive the beat or chafe of the mast. The middle band is made of one breadth of canvas, of the same number as the top-lining. It is fleted folded and rubbed down, to make a crease at one third of the breadth; then rolled on the selvages, and fleted along the crease; then turned down, and fleted through both the double and single parts, with 68 to 72 fitches in a yard. It is the opinion of many, that middle bands should not be put on until the fail is half worn.

Main and fore topfails have three and sometimes four reef bands from leech to leech, over the leech linings; the upper one is one eighth of the depth of the fail from the head, and they are the same distance aunder in the royal navy, but more in the merchant service. The reef bands are each of one breadth of canvas put on double; the first flet is fleted twice, and the last turned over, so that the reef holes may be worked upon the double part of the band, which is also fleted with 68 to 72 fitches in a yard.

The top-lining of topfails is of canvas no. 6 or 7. The other linings of this, and all the linings of other fails, should be of the same quality as the fails to which they belong.

Top-linings and mast cloths are put on the fore side, and all other linings on the fore side of fails. Mizzen are lined with one breadth of cloth from the clue five yards up the leech, and have a reef band sewed on, in the same manner as on other fails, at one third the depth of the fail from the head; they have also a neck-piece and a peck-piece, one cut out of the other, so that each contains one yard. Mizzen topfails of 50 guns flits and upwards have three reefs, the upper one is one eighth of the depth of the fail from the head, and the reefs are at the same distance aunder. Mizzen topfails of ships of 44 guns and under have two reefs, one seventh part of the depth of the fail aunder, the upper one being at the same distance from the head. Main and main top

Shippbuilding.

433

Appendix.

Main and fore courses are lined on the leeches, from clue to earing, with one cloth fleted on and twerked or fleted in the middle, and have a middle band half way between the lower reef band and the foot, also four buntline cloths, at equal distances between the leeches, the upper ends of which are carried under the middle band, that the lower side of the band may be rolled up or fleted over the end of the buntline pieces. They have likewise two reef bands; each in breadth one third of the breadth of the canvas; the upper one is one fifth of the depth of the fail from the head, and the lower band is at the same distance from the upper one; the ends of the buntline cloths, which are fleted over the reef bands. All linings are fleted on, and are fleted with 68 to 72 fitches in a yard.

Main, fore, and mizen, topfails have leech linings, main and top linnings, buntline cloths, middle bands and reef bands. The leech linings are made of one breadth of cloth, so cut and fleted as to be half a cloth broad at the head, and a cloth and a half broad at the foot; the piece cut out being half the breadth of the cloth at the one end, and tapering to a point at the other. The middle bands are put on half way between the lower reef and foot, the buntline cloths join the top-linings, and the buntline cloths and top-linings are carried up to the lower side of the middle band, which is fleted on them. The maft lining is of two cloths, and extends from the foot of the fail to the lower reef, to receive the beat or chafe of the mast. The middle band is made of one breadth of canvas, of the same number as the top-lining. It is fleted folded and rubbed down, to make a crease at one third of the breadth; then rolled on the selvages, and fleted along the crease; then turned down, and fleted through both the double and single parts, with 68 to 72 fitches in a yard. It is the opinion of many, that middle bands should not be put on until the fail is half worn.

Main and fore topfails have three and sometimes four reef bands from leech to leech, over the leech linings; the upper one is one eighth of the depth of the fail from the head, and they are the same distance aunder in the royal navy, but more in the merchant service. The reef bands are each of one breadth of canvas put on double; the first flet is fleted twice, and the last turned over, so that the reef holes may be worked upon the double part of the band, which is also fleted with 68 to 72 fitches in a yard.

The top-lining of topfails is of canvas no. 6 or 7. The other linings of this, and all the linings of other fails, should be of the same quality as the fails to which they belong.

Top-linings and mast cloths are put on the fore side, and all other linings on the fore side of fails. Mizzen topfails of 50 guns flits and upwards have three reefs, the upper one is one eighth of the depth of the fail from the head, and the reefs are at the same distance aunder. Mizzen topfails of ships of 44 guns and under have two reefs, one seventh part of the depth of the fail aunder, the upper one being at the same distance from the head. Main and main top

Vol. XVIII.
SHIP-BUILDING.

On main and fore courses, two inches slack cloth should be allowed in the head and foot, and one inch and a half in the leeches, in every yard in length. Topgallant sails have two inches slack in every cloth in the foot, and one inch in every yard in the leech. Studding sails have an inch and a half slack in every yard in going leeches, but no slack in square leeches, and one inch in every cloth in the head and foot.

These directions for sailmaking, we trust may be useful. They are indeed very general, but the limits prescribed will not permit of more minute detail. The sailmaker will find every instruction that he can want in the Elements of Rigging and Seamen's, a work which we therefore recommend to his attention.

SHIP.

Stowing and Trimming of Ships, the method of disposing of the cargo in a proper and judicious manner in the hold of a ship.

A ship's falling, steering, laying, and wearing, and being lively and comparatively easy at sea in a storm, depends greatly on the cargo, ballast, or other materials, being properly stowed, according to their weight and bulk, and the proportional dimensions of the built of the ship, which may be made too crank or too stiff to pass on the ocean with safety. These things render this branch of knowledge of such consequence, that rules for it ought to be endeavoured after, if but to prevent, as much as possible, the danger of a ship over-filling at sea, or being too loose at sea to roll away her masts, &c. by being improperly stowed, which is often the case.

When a ship is new, it is prudent to consult the builder, who may be supposed but acquainted with a ship of his own planning, and most likely, to judge what her properties will be, to advise how the cargo or materials, according to the nature of them, ought to be disposed of to advantage, so as to put her in the best falling trim; and at every favourable opportunity afterwards it will be proper to endeavour to find out her best trim by experiment.

Ships must differ in their form and proportional dimensions; and to make them answer their different purposes, they will require different management in the stowing, which ought not to be left to mere chance, or done at random, as goods or materials happen to come to hand, which is too often the cause that such improper stowage makes ships unfit for sea; therefore the stowage should be considered, planned, and contrived, according to the built and properties of the ship, which if they are not known should be inquired after. If the hold is narrow and high-built in proportion, so that she will not shift herself without a great weight in the hold, it is a certain sign such a ship will require a great part of heavy goods, ballast, or materials, laid low in the hold, to make her stiff enough to bear sufficient sail without being in danger of overfilling. But if a ship be built broad and low in proportion, so that she is stiff and will support herself without any weight in the hold, such a ship will require heavy goods, ballast, or materials, stowed higher up, to prevent her from being too stiff and labourome at sea, so as to endanger her masts being Millions away, and the hull worked loose and made leaky.

In order to help a ship's falling, that she should be lively and easy in her pitching and ascending motions,
ship. it should be contrived by the flowage, that the principal and weightiest part of the cargo or materials should lie as near the main body of the ship and as far from the extreme ends, fore and aft, as things will admit of. For it should be considered, that the roomy part of our ships lengthwise forms a sweep or curve near four times as long as they are broad; therefore those roomy parts at and above the water's edge, which are made by a full harping and a board transm to support the ship steady and keep her from plunging into the sea, and also by the entrance and run of the ship having little or no bearing body under for the preasure of the water to support them, of course should not be flowed with heavy goods or materials, but all the necessary vacancies, broken flowage, or light goods, should be at those extreme ends fore and aft; and in proportion as they are kept lighter by the flowage, the ship will be more likely to fall and rise easy in great seas; and this will contribute greatly to her working and failing, and to prevent her from straining and hogging; for which reason it is a wrong practice to leave such a large vacancy in the main hatchway, as is usual, to coil and work the cables, which ought to be in the fore or after hatchway, that the principal weight may be more easily flowed in the main body of the ship, above the flatteft and lowest floorings, where the preasure of the water acts the more to support it.

Machine for measuring a Ship's Way. We have already described a variety of machines or instruments which have been propofed for this purpofe under the article Log. In this place, therefore, we shall confine ourselves to the machine invented by Francis Hopkinfon, Esq; Judge of the Admiralty in Pennsylvania.—After having thrown the ballfacks to which the common log, and also that particular kind of instrument invente by M. Sauvarez, are liable, he proceeds to difcribe his own machine as follows:

This machine, in its moft simple form, is reprefented by fig. 5. Plate CCCCLIII. wherein A B is a strong rod of iron moveable on the fulcrum C. D is a thin circular plate of brafs rivetted to the lower extremity of the rod. E an horizontal arm connected at one end with the top of the rod A B by a moveable joint F, and at the other end with the bottom of the index H, by a like moveable joint G. H is the index turning on its centre I, and travelling over the graduated arch K; and L is a strong spring, bearing against the rod A B, and contrarily counteracting the preasure upon the palate D. The rod A B should be applied close to the cut water or flem, and should be of fuch a length that the palate D may be no higher above the keel than is neceffary to fecure it from injury when the veffel is aground, or fails in falt water. As the bow of the ship curves inwards towards the keel M, the palate D will be thrown to a distance from the bottom of the veffel, although the perpendicular rod to which it is annexed lies close to the bow above; and therefore the palate will be more faperly acted upon. The arm E should enter the bow somewhere near the hiwic hole, and lead to any convenient place in the focellare, where a smooth board or plate may be fixed, having the index H, and graduated arch K, upon it.

It is evident from the figure, that as the ship is urged forward by the wind, the palate D will be prefled upon by the retailing medium, with a greater or les force, according to the progressive motion of the ship; and this will operate upon the levers so as to immediately affect the index, making the least increafe or diminution of the ship's way visible on the graduated arch; the spring L always counteracting the preasure upon the palate, and bringing back the index, on any relaxation of the force impressed.

This machine is advantageously placed at the bow of the ship, where the current first begins, and acts fairly upon the palate, in preference to the flem, where the tumultuous clashing of the waters caufes a wake, visible to a great distance. The palate D is funk nearly as low as the keel, that it may not be influenced by the heaping up of the water and the damping of the waves at and near the water line. The arch K is to afcerain how many knots or miles the would run in one hour at her then rate of failing. But the graduations on this arch must be unequal; because the reluctance of the spring L will increafe as it becomes more bent, fo that the index will travel over a greater space from one to five miles than from five to twelve. Lastly, the palate, rod, fpring, and all the metallic parts of the instrumt, should be covered with a strong varnish, to prevent ruin from the corrosive quality of the salt water and falt air.

This machine may be coniderably improved as follows: Let the rod or fpear A B (fig. 5.) be a round rod of iron or fteel, and instead of moving on the fulcrum or joint, as at C, let it pas through and turn freely in a focket, to which focket the moveable joint must be annexed, as reprefented in fig. 6. The rod must have a fhoudder to bear on the upper edge of the focket, to prevent its flipping quite down. The rod must alfo pas through a like focket at F, fig. 5. The joint of the lower focket must be fixed to the bow of the ship, and the upper joint or focket must be connected with the horizontal arm E. On the top of the upper focket let there be a small circular plate, bearing the 32 points of the mariner's compafs; and let the top of the rod AB come through the centre of this plate, so as to carry a small index upon it, as is reprefented in fig. 7. This small index must be fixed to the top of the rod on a fquare, fo that by turning the index round the plate, the rod may alfo turn in the fockets, and of course carry the palate D round with it; the little index always pointing in a direction with the face of the palate. The small compafs plate should not be fenned to the top of the focket, but only fitted tightly on, that it may be moveable at pleasure. Suppose then the intended port to bear S. W. from the place of departure, the compafs must be turned on the focket till the fourth-point thereon looks directly to the ship's bow; fo that the fourth-point and north-eaft line on the compafs plate may be precisely parallel with the ship's keel, and in this position the plate must remain during the whole voyage. Suppose, then, the ship to be falling in the direct course of her intended voyage, with her bow-point pointing fourth-welf. Let the little index be brought to the fourth-point on the compafs plate, and the palate D will necessarily precent its bow face towards the point of definition; and this it must always be made to do, be the ship's course what it may. If, on an account of unfavourable winds, the ship is obliged to deviate from her intended course, the little index must be moved fo many points from the fourth-welf
line of the compass plate as the compass in the binnacle shall show that the deviates from her true course; so that in whatever direction the ship shall sail, the plate \(D\) will always look full to the south-west point of the horizon, or towards the part of destination, and consequently will present only an oblique surface to the refilling medium, more or less oblique as the ship deviates more or less from the true course of her voyage. As, therefore, the resistance of the water will operate less upon the plate in an oblique than in a direct position, in exact proportion to its obliquity, the index \(H\) will not show how many knots the vessel runs in her then course, but will indicate how many the gains in the direct line of her intended voyage. Thus, in fig. 9, if the ship's course lies in the direction of the line \(A\) \(B\), but she can sail by the wind no nearer than \(A\) \(C\); suppose, then, her progressive motion such as to perform \(A\) \(C\) equal to five knots or miles in an hour, yet the index \(H\) will only point to four knots on the graduated arch, because the gains no more than at the line \(A\) \(C\) on the true line of her voyage, viz. from \(A\) to \(B\). Thus will the difference between her real motion and that pointed out by the index be always in proportion to her deviation from her intended port, until the ship sails in a line at right angles therewith, as \(A\) \(D\); in which case the plate would present only a thin sharp edge to the refilling medium, the pressure of which should not be sufficient to overcome the friction of the machine and the bearing of the spring \(L\). So that at whatever rate the ship may sail on that line, yet the index will not be affected, showing that she gains nothing on her true course. In this case, and also, when the vessel is not under way, the action of the spring \(L\) should cause the index to point at \(O\), as represented by the dotted lines in fig. 5, and 8.

As the truth of this instrument must depend on the equal pressure of the refilling medium upon the plate \(D\), according to the ship's velocity, and the proportionable action of the spring \(L\), there shou'd be a pin or screw at the joints \(C\) and \(E\), so that the rod may be readily unshipped and taken in, in order to clean the plate from any fouls which it may contract, which would greatly increase its operation on the index \(H\) and thereby render the graduated arch false and uncertain.

Further, the spring \(L\) may be exposed too much to injury from the salt water, if fixed on the outside of the ship's bow. To remedy this, it may be brought under cover, by constructing the machine as represented by fig. 8, where \(A\) \(B\) is the rod, \(C\) the fulcrum or centre of its motion, \(D\) the plate, \(E\) the horizontal arm leading through a small hole into the forecastle; \(M\) is a strong chain fastened at one end to the arm \(E\), and at the other to a rim or barrel on the wheel \(G\), which by means of its teeth gives motion to the semicircle \(I\) and index \(H\). The spring \(L\) is spiral, and enclosed in a box or barrel, like the main spring of a watch. A small chain is fixed to, and passing round the barrel \(N\), is fastened by the other end to the fuzee \(W\). This fuzee is connected with the wheel \(G\), and counteracts the motion of the plate \(D\). \(N\), \(N\) are the two sockets through which the rod \(A\) \(B\) passes, and in which it is turned round by means of the little index \(S\). \(S\) is the small compass plate, moveable on the top of the upper socket \(N\). The plate \(S\) hath an upright rim round its edge, cut into teeth or notches, so that when the index \(K\) is a little raised up, in order to bring it round to any intended point, it may fall into one of these notches, and be detained there; otherwise the preface of the water will force the plate \(D\) from its oblique position, and turn the rod and index round to the direction in which the ship shall then be going. Should it be apprehended that the plate \(D\), being placed so far forward, may affect the ship's litigation or obstruct her rate of sailing, it should be considered that a very small plate will be sufficient to work the machine, as one of three or four inches in diameter would probably be sufficient, and yet not large enough to have any sensible effect on the helm or ship's way.

The greatest difficulty, perhaps, will be in graduating the arch \(K\), (if the machine is constructed as in fig. 5;) the unequal divisions of which can only be ascertained by actual experiment on board of each ship respectively, inasmuch as the accuracy of these graduations will depend on three circumstancies, viz. the position of the fulcrum \(C\) with respect to the length of the rod, the size of the plate \(D\), and the strength or bearing of the spring \(L\). Whether these graduations, however, are once ascertained for the machine on board of any one vessel, they will not want any future alterations, provided the plate \(D\) be kept clean, and the spring \(L\) retains its elasticity.

But the unequal divisions of the graduated arch will be unnecessary, if the machine is constructed as in fig. 8; as for the chain goes round the barrel \(L\), and then winds through the spiral channel of the fuzee \(W\), the force of the main spring \(M\) operates equally, or nearly so, in all positions of the index, and consequently the divisions of the arch \(K\) may in such case be equal.

For all this, it is not expected that a ship's longitude can be determined to a mathematical certainty by this instrument. The irregular motions and impulses to which a ship's continually exposed, make such an accuracy unattainable perhaps by any machinery: But if it should be found, as we flatter ourselves, it will be a fair experiment, that it answers the purpose much better than the common log, it may be considered as an acquisition to the art of navigation.

It should be observed, that in ascertaining a ship's longitude by a time-piece, this great inconvenience occurs, that a small and trifling mistake in the time makes a very great and dangerous error in the distance run: Whereas the errors of this machine will operate no farther than their real amount; which can never be great or dangerous, if corrected by the usual observations made by mariners for correcting the common log.

A-like machine, made in its simple form (as at fig. 5), so constructed as to ship and unship, might occasionally be applied alongside about midships, in order to ascertain the lee-way; which, if rightly shown, will give the ship's precise longitude. As to sea-currents, this and all other machines hitherto invented must be subject to their influence and proper allowances must be made according to the skill and knowledge of the navigator.

Lastly, some discretion will be necessary in taking observations from the machine to be entered on the log-book: that is, the most favourable and equitable moment should be chosen for the observation; not whilst the ship is rapidly descending the declivity of a wave, or is suddenly checked by a stroke of the sea, or is in the very act of plunging. In all cases, periods may be found in which a ship proceeds with a true average velocity;
velocity; to discover which, a little experience and attention will lead the skilful manner (a).

SHIARAUS. See SHRAS.

SHIRE, is a Saxon word signifying a division; but according to some, the same import, is plainly derived from comus, the count of the Franks; that is, the bailiff or alderman (as the Saxons called him) of the shire, to whom the government of it was entrusted. This he usually exercised by his deputy, still called in Latin vicarius, and in English the sheriff, shire or shire-reve, signifying the “officer of the shire,” upon whom, in process of time, the civil administration of it totally devolved. In some counties there is an intermediate division between the shire and the hundred; as lathes in Kent and rapes in Suffolk, each of them containing about three or four hundreds apiece. These had formerly their lathes-reeves and rape-reeves, acting in subordination to the shire-reeve. Where a county is divided into three of these intermediate jurisdictions, they are called triplings, which were usually governed by a tripping reeve. These triplings still subsist in the large county of York, where, by an early corruption, they are denominated ridings; the north, the east, and the west riding.

SHIRL, or Cockle, in mineralogy. See Cockle.

SHIRT, a loose garment, commonly of linen, worn next the body.—Some doubt the propriety of changing the linen when a person is sick. Clean linen promotes perspiration; and it may be renewed as often as the patient pleased, whether the disorder be of the acute or the chronic kind. Except during a crisis in fevers, whilst the patient is in a sweat, a change of linen, if well dried and warmed, may be daily used.

Shirts were not worn by Jews, Greeks, or Romans, but their place was supplied by this twelve of wool. The want of linen among the ancients made frequent washings and ablutions necessary.

SHIVER. See Schissus and Shale.

SHIVERS, in the sea-language, names given to the little rollers, or round wheels of pulleys.

SHOAL, among miners, denotes a train of metallic stones, serving to direct them in the discovery of mines.

SHOE, a term used by the miners of Cornwall and other parts of Great Britain, to express such loose masses of stone as are usually found about the entrances into mines, sometimes running in a straight course from the load or vein of ore to the surface of the earth. These are stones of the common kinds, appearing to have been pieces broken from the strata or larger masses; but they usually contain mindle, or marcellite matter, and more or less of the ore to be found in the mine. They appear to have been at some time rolled about in water, their corners being broken off, and their surface smoothed and rounded.

The antiquity mines in Cornwall are always easily discovered by the sand-stones, these usually lying up to the surface, or very nearly so; and the matter of the stone being a white spar, or debased crystal, in which the native colour of the ore, which is a fining black, easily discovers itself in streaks and threads.

Shoal-stones are of many kinds and the such various appearances, that it is not easy to describe or know them: but the miners, to whom they are of greatest use in the tracing or searching after new mines, distinguish them from other stones by their weight; for if very ponderous, though they look very much like common stones, there is great reason to suspect that they contain some metal. Another mark of them is their being spongy and porous; this is a sign of especial use in the tin countries; for the tin shoal-stones are often so porous and spongy, that they resemble large bodies thoroughly calcined. There are many other appearances of tin shoal-stones, the very hard and firmest stones often containing this metal.

When the miners, in tracing a shoal up hill, meet with such odd stones and earths that they know not what to make of them, they have recourse to sifting, that is, they calcine and powder the stone, etc.; whatever else is supposed to contain the metal, and then washing it in an instrument, prepared for that purpose; and called a washing-boat, they find the earthy matter washed away, and of the remainder, the fony or gravelly matter lies behind, and the metallic matter at the point of the shoal. If the person who performs this operation has any judgment, he easily discovers not only what the metal is that is contained in the shoal, but also will make a very probable guess at what quantity the mine is likely to yield of it in proportion to the ore.

SHOAL, in the sea-language, denotes a place where the water is shallow; and likewise a great quantity of fish, such as a shoal of herrings.

SHOCK, in electricity. The effect of the explosion of a charged body, that is, the discharge of its electricity on any other body, is called the electric shock.

SHOE, a covering for the foot, usually of leather. Shoos, among the Jews, were made of leather, linen, rust, or wood: these of foldiers were sometimes of brass or iron. They were tied with thongs which passed under the soles of the feet. To put on their shoes was an act of veneration; it was also a sign of mourning and humiliation: to bear one’s shoes, or to untie the latchet of them, was considered as the nearest service.

Among the Greeks shoes of various kinds were used. Sandals were worn by women of distinction. The Macedonians wore red shoes. The Grecian shoes generally reached to the middle of the leg. The Romans used two kinds of shoes; the calceus, which covered the whole foot somewhat like our shoes, and was tied above with latchets or finings; and the fies or flipper, which covered only the sole of the foot, and was fastened with leathern thongs. The calceus was always worn along

(a) An ingenious mechanic would probably construct this machine to better advantage in many respects. The author only meant to suggest the principle; experiment alone can point out the best method of applying it. He is sensible of at least one deficiency, viz. that the little index R, fig. 4, will not be strong enough to retain the palate D in an oblique position when the hip is falling by the wind; more especially as the compound plate S, in which notched rim the index R is to fall, is not fixed to, but only fitted tight on the socket N. Many means, however, might not be contrived to remedy this inconvenience.
SHOE [438] SHOE

Shoes, shooting.

The shoes were put on during a journey and at feasts, but it was reckoned effeminate to appear in public with them. Black shoes were worn by the citizens of ordinary rank, and white ones by the women. Red shoes were sometimes worn by the ladys, and purple ones by the coscombos of the other sex. Red shoes were put on by the chief magistrates of Rome on days of ceremony and triumphs. The shoes of senators, patricians, and their children, had a crest upon them which served for a buckle; these were called calcei latici. Slaves wore no shoes; hence they were called creasti from their dusty feet. Phoenix alfo and Caro Uticensis went without shoes. The toes of the Roman shoes were turned up in the point; hence they were called calcei reftrati, repandi, &c.

In the 9th and 10th centuries the greatest princes of Europe were wooden shoes, or the upper part of leather and the sole of wood. In the reign of William Rufus, a great bear, Robert, surnamed the borned, used shoes with long sharp points, buffed with tow, and twisted like a ram’s horn. It is said the clergy, being highly offended, deklaimed against the long-pointed shoes with great vehemence. The point, however, continued to increafe till, in the reign of Richard II. they were of fo enormous a length that they were tied to the knees with chains, sometimes of gold, sometimes of silver. The upper parts of these shoes in Chancer’s time were cut in imitation of a church window. The long-pointed shoes were called pracockes, and continued in fashion for three centuries in spite of the bulls of popes, the decrees of councils, and the declamations of the clergy. At length the parliament of England interposed by an act A.D. 1453, prohibiting the use of shoes or boots with pikes exceeding, two inches in length, and prohibiting all shoemakers from making shoes or boots with longer pikes under severe penalties. But even this was not sufficient: it was necessary to demont the dreadful sentence of excommunication against all who wore shoes or boots with points longer than two inches. The present fashon of shoes was introduced in 1633, but the buckle was not used till 1670.

In Norway they use shoes of a particular construction, confiding of two pieces, and without heels: in which the upper leather fits close to the foot, the sole being joined to it by many plaits or folds.

The shoes or slippers of the Japanese, as we are informed by Professor Thumberg, are made of rice-straw woven, but sometimes for people of distinction of fine slips of rattan. The shoe consists of a sole without upper leather or hind-piece; forwards it is croffed by a strap, of the thickness of one’s finger, which is lined with linen; from the tip of the shoe to the strap a cylindrical ftring is carried, which pairs between the great and second toe, and keeps the shoe fll on the foot. As these shoes have no hind-piece, they make a noise, when people walk in them like slippers. When the Japanef travel, their shoes are flurnished with three ftrings made of twifled straw, with which they are tied to the legs and feet, to prevent them from falling off. Some people carry one or more pairs of shoes with them on their journeys, in order to put on new, when the old ones are worn out. When it rains, or the roads are very dirty, these shoes are soon wetted through, and one continually fees a great number of worn out shoes lying on the roads, especially near the brooks, where travelers have changed their shoes after washing their feet. Instead of these, in rainy or dirty weather they wear high wooden clogs, which underneath are hollowed out in the middle, and at top have a band across like a firrup, and a ftring for the great toe; fo that they can walk without foiling their feet. Some of them have their fraw shoes fastened to these wooden clogs. The Japanef never enter their houses with their shoes on; but leave them in the entry or place them on the bench near the door, and thus are always barefooted in their houses, fo as not to dirty their neat mats. During the time that the Dutch live at Japan, when they are sometimes under an obligation of paying visits at the houses of the Japanef, their own room at the factory being likewise covered with mats of this kind, they wear, instead of the usual shoes, red, green, or black slipppers, which on entering the house they pull off; however, they have flocks on, and shoes made of cotton fuff with buckles in them, which shoes are made at Japan, and can be walked whenever they are dirty. Some have them of black fatin, in order to avoid walking them.

Shoes of an Anchor, a small block of wood, convex on the back, and having a small hole, fufficient to contain, the point of the anchor fluke, on the forefide. It is used to prevent the anchor from tearing or wounding the planks on the ship’s bow, when afcending or descending; for which purpose the flue fides up and down along the bow between the fluke of the anchor and the planks, as being proffed close to the latter by the weight of the former.

To Shoes an Anchor, is to cover the flukes with a broad triangular piece of plank, whose area or superficies is much larger than that of the flukes. It is intended to give the anchor a stronger and safer hold of the bottom in very fift and oozy ground.

Horfe-Shoe. See Farriery, Sect. 47.

SHOOTING, in the military art. See Artillery, Gummer, and Projectiles.

Shooting, in sportmanship, the killing of game by the gun, with or without the help of dogs.

Under this article we shall lay down all the rules which are necessary to be observed in order to render one accomplished and fucceful in the art of shooting.

The first thing which the sportman ought to attend to is the choice of his fowing-piece. Convenience requires that the barrel be as light as possible, at the fame time it ought to poiffes that degree of strength which will make it not liable to burft. Experience, has proved, that a thin and light barrel, which is of equal thickness in every part of its circumference, is much less liable to burft than one which is considerably thicker and heavier, but which, from being badly fired or bored, is of unequal strength in different places.

It is alfo of importance to determine of what length the barrel ought to be, in order to acquire that range which the sportman has occasion for. On this subject we have received the following information from an experienced sportman. We have, at different times, compared barrels of all the intermediate lengths between 28 and 40 inches; and of nearly the fame caliber, that is to lay, from 22 to 26; and these trials were made
The next thing to be considered is, of course, the barrel of the gun. There is a rule in this matter, that the difference of 10 inches in the length of the barrel, which seems to be more than is ever intimated upon among sportsmen, produces no sensible difference in the range of the piece; and therefore, that every one may please himself in the length of his barrel, without either detriment or advantage to the range.

It may appear as an objection to this, that a duck-gun which is five or six feet long kills at a greater distance than a bowing-piece; but this is not owing to its length, but to its greater weight and thickness, which give it such additional strength, that the shot may be increased, and the charge of powder doubled, trebled, and even quadrupled. But a barrel of five or six feet length would be very inconvenient for bowing. Tho' who confult the appearance of the piece, lightness, and the ease with which it is man- aged, will find that a barrel from 32 to 38 inches will answer best.

The next thing to be considered is, of what dimensions the caliber or bore of a bowing-piece ought to be. This matter has been subjected to experiment, and it has been found, that a barrel of 22 or 24, which is the largest caliber usually employed in bowing-pieces, throws its shot as closely as one of the smallest caliber, viz. of 30 or 32 (a).

As to the length and form of the stock, it may be laid down as a principle, that a long stock is preferable to a short one, and at the same time rather more bent than usual; for a long stock fits firmer to the shoulder than a short one, and particularly so when the shotter is accustomed to place his left hand, which principally supports the piece, near to the entrance of the ramrod into the stock.

It is certain, however, that the stock may be so formed as to be better suited to one man than another. For a tall, long-armed man, the stock of a gun should be longer than for one of a short stature and shorter arm. That a straight stock is proper for him who has high shoulders and a short neck; for, if it be much bent, it would be very difficult for him, especially in the quick motion required in bowing at a flying or running object, to place the butt of the gun- stock firmly to the shoulder, the upper part alone would in general be fixed; which would not only raise the muzzle, and consequently shot float high, but make the recoil much more sensible felt, than if the whole end of the stock were firmly placed on his shoulder. Besides, supposing the shotter to bring the butt home to his shoulder, he would scarcely be able to level his piece at the object. On the contrary, a man with low shoulders, and a long neck, requires a stock much bent; for if it is straight, he will, in the act of lowering his head to that place of the stock at which his cheek should rest in taking aim, feel a constraint which he never experiences, when by the effect of the proper degree of bent, the stock lends him some assistance, and, as it were, meets his aim half way.

Having now described the bowing-piece which has been found to answer best, it will next be proper to give some instructions for the choice of gunpowder, shot, and wadding.

The various kinds of gunpowder are well known; but, in the opinion of some experienced sportsmen, Hervey's battle powder is the best. Those who wish to examine the strength of powder, may determine it by drying some of it very well, and then trying how many sheets of paper it will drive the shot through, at the distance of 12 or 15 yards. In this trial, we should be careful to employ the same fixed shot in each experiment, the quantity both of shot and the powder being regulated by exact weight; otherwise we cannot, even in this experiment, arrive to any certainty in comparing the strength of different powders, or of the same powder at different times.

Powder ought to be kept very dry, for every degree of moisture injures it; and if considerable, the tappet (b) is disolved, and the intimate combination of the several ingredients is entirely destroyed. It is observed, that after firing with damp powder the piece becomes very foul, which seems to arise from the diminution of the activity of the fire in the explosion. Flakes of copper or tin are much better for keeping powder in than those made of leather, or than small corks. Their necks ought to be small and well stopped with cork.

The patent milled shot is now very generally used, and size No. 3 is reckoned superior to any other. The size of the shot must vary according to the particular species of game which is the object of the sportsman's pursuit, as well as be adapted to the season. In the first month of partridge shooting, No. 1 is most proper; for, at this time the birds spring near at hand, and we seldom fire at more than the distance of 40 paces; if the shotter takes his aim but tolerably well, it is almost impossible for a bird at this distance to escape in the circle which the shot forms.

As hares fit closer, and are thinly covered with fur at this season, they may easily be killed with this shot at 35 or 35 paces. No. 1 is equally proper for hunting foxes or quails. About the beginning of October, when the partridges are stronger, No. 3 is the most proper shot to be used. Many sportsmen use no powder during the whole season. The directions which have now been given refer only to the patent shot.

We shall now subjoin a table, which will show at a view the number of pellets composing an ounce weight of each sort of shot, the patent and the common, beginning with the smallest size.

---

(a) In speaking of the size of the caliber, we mean by 22 or 24, that so many balls exactly fitting its weight, just one pound; and every caliber is marked in the same way.
For a fouling piece of a common caliber, which is from 2½ to 30 balls to the pound weight, a dram and a quarter, or at most a dram and a half of good powder; and an ounce, or an ounce and a quarter of shot, is sufficient. But when shot of a larger size is used; such as No. 5, the charge of shot may be increased one-fourth, for the purpose of counterbalancing in some degree what the size of the shot loses in the number of pellets, and also to enable it to garnish the more. For this purpose the sportsman will find a measure marked with the proper gauges very convenient to him. An instrument of this nature has been made by an ingenious artist of London, Egg of the Haymarket.

A coincidence of overloading with shot, is the powder has not sufficient strength to throw it to its proper distance; for if the object fired at be distant, one-half of the pellets composing the charge, by their too great quantity and weight, will strike against each other, and be the one which reach the mark will have small force, and will produce but little or no effect.

The use of the wadding is to carry the shot in a body to a certain distance from the muzzle of the piece. It ought to be of soft and pliable materials. The best kind of wadding, in the opinion of an experienced fowler, is a piece of an old hat; but this cannot be obtained in sufficient quantity. Next to it nothing is better than soft brown paper, which combines suppleness with confidence, moulds itself to the barrel, and never falls with the ground within 12 or 15 paces from the muzzle of the piece. Tow answers very well, and cork has been extolled for possessing the peculiar virtue of increasing the range and cleavage of the shot.

The wadding ought to be quite close in the barrel, but not rammed too hard; for if it be rammed too close, or be of a rigid substance, the piece will recoil, and the fact will spread too much. On the other hand, if the wadding be very loose, or composed of too soft materials, such as wool or cotton, the discharge will not possess proper force.

In loading a piece, the powder ought to be slightly rammed down by only pressing the ramrod two or three times on the wadding, and not by drawing up the ramrod and then returning it into the barrel with a jerk of the arm several times. For when the powder is violently compressed, some of the grains must be bruised, which will prevent the explosion from being quick, and will spread the shot too wide. In pouring the powder into the barrel, the measure ought to be held so as that the powder may fall most readily to the bottom. That no grains may adhere to the sides of the barrel, the butt end of the piece may be struck against the ground.

The shot ought never to be rammed down with force; it is sufficient to strike the butt-end of the gun against the ground as before. Then the wadding is to be put down gently. A sportsman ought never to carry his gun under his arm with the muzzle inclined downwards, for this practice loosens the wadding and charge too much.

Immediately after the piece is fired it ought to be re-loaded; for while the barrel is still warm, there is no danger of any moisture lodging in it to hinder the powder and firing, but from falling to the bottom. As it is found that the cinders of the barrel, and perhaps the moisture condensed in it, diminishes the force of the powder in the first shot; it is proper to fire off a little powder before the piece is loaded. Some prime before loading, but this is not proper unless the touch-hole be very large. After every discharge the touch-hole ought to be pricked, or a small feather may be inserted to clear away any humidity or foulness that has been contracted.

The sportsman having loaded, his piece must next prepare to fire. For this purpose he ought to place his hand near the entrance of the ramrod, and at the same time grasp the barrel firmly. The muzzle should be a little elevated, for it is more usual to shoot low than high. This direction ought particularly to be attended to when the object is a little distant; because shot as well as ball only moves a certain distance point blank, when it begins to describe the curve of the parabola.

Practice soon teaches the sportsman the proper distance at which he should shoot. The distance at which the sportsman ought to kill, is from 25 to 35 paces for the footed, and from 40 to 45 paces for the winged, game. Beyond this distance even to 50 or 55 paces, both partridges and hares are sometimes killed; but in general the hares are only slightly wounded, and carry away the shot; and the partridges at that distance present so small a surface, that they frequently escape untouched between the spaces of the circle. Yet it does not follow that a partridge may not be killed with No. 3 patent shot at 60 and even 70 paces distance; but then these shots are very rare.

In shooting at a bird flying, or a hare running across, it is necessary to take aim before the object in proportion to its distance at the time of firing. If a partridge flies across at the distance of 30 or 35 paces, it will be sufficient to aim at the head, or at most but a small foot before it. If it be 50, 60, or 70 paces distant, it is then requisite to aim at at least half a foot before the head. The same practice ought to be observed in shooting at a hare, rabbit, or fox, when running in a cross direction; at the same time making due allowance for...
Shooting

for the distance and quickness of the pace. Another thing to be attended to is, that the shooter ought not involuntarily to stop the motion of the arms at the moment of pulling the trigger; for the instant the hand stops in order to fire, however insensible the time be, the bird gets beyond the line of aim, and the shot will miss it. A sportman ought therefore to accustom himself to have hand while he is taking aim to follow the object. When a hare runs in a straight line from the shooter, he should take his aim between the ears, otherwise he will run the hazard either of missing, at least not of killing dead, or as it is sometimes called clean.

Every part of the piece to be kept clean and dry.

A fowling-piece should not be fired more than 20 or 25 times without being washed; a barrel when foul neither shoots so ready, nor carries the shot so far as when clean. The flint, pan, and hammer, should be well wiped after each shot; this contributes greatly to make the piece go off quick, but then it should be done with such expedition, that the barrel may be reloaded whilst warm, for the reasons we have before advanced. The flint should be frequently changed, without waiting until it misses fire, before a new one is put in. Fifteen or eighteen shots, therefore, should only be fired with the same flint; the expense is too trifling to be regarded, and by changing it thus often much vexation will be prevented.

A gun also should never be fired with the prime of the piece; it may happen that an old priming will sometimes go off well, but it will more frequently contract moisture and freeze in the firing; then the object will most probably be missed, and that because the piece was not fresh primed.

For the information of the young sportman we shall add a few more general directions. In warm weather he ought to seek for game in plains and open grounds, and in cold weather he may search little hills exposed to the sun, along hedges among heath, in fluffles, and in pastures where there is much furze and fern. The morning is the best time of the day, before the dew is exhaled, and before the game has been disturbed. The colour of the shooter's dress ought to be the same with that of the fields and trees; in summer it ought to be green, in winter a dark grey. He ought to hunt as much as possible with the wind, not only to prevent the game from preceiving the approach of him and his dog, but also to enable the dog to scent the game at a greater distance.

He should never be discouraged from hunting and ranging the same ground over and over again, especially in places covered with heath, brambles, high grass, or young coppice wood. A hare or rabbit will frequently suffer him to pass several times within a few yards of its form without getting up. He should be still more patient when he has marked partridges into such places, for it often happens, that after the birds have been sprung many times, they lie so dead that they will suffer him almost to tread upon them before they will rise. Pheasants, quails, and woodcocks do the same.

He ought to look carefully about him, never pausing a bush or tuft of grass without examination; but he ought never to strike them with the muzzle of his gun for it will loosen his wadding. He who patiently beats and ranges his ground over again, without being dis-couraged, will always kill the greatest quantity of game; and if he is shooting in company, he will find game where others have passed without discovering any.

When he has fired he should call in his dog, that he may not have the mortification to see game rise which he cannot shoot. When he has killed a bird, instead of being anxious about picking it up, he ought to follow the reit of the covert with his eye till he see them fly.

Three species of dogs are capable of receiving the due proper instruction, and of being trained. These are for point, the smooth pointer, the spaniel, and the rough pointer. The first is a dog with long curled hair, and seems to be a mixed breed of the water-dog and the spaniel. The smooth pointer is active and lively enough in his range, but in general is proper only for an open country.

The greatest part of these dogs are afraid of water, brambles, andthicknesses; but the spaniel and the rough pointer are easily taught to take the water, even in cold weather, and to range the woods and rough places as well as the plain. Greater dependence may therefore be had on these two last species of dogs than on the smooth pointer.

The education of a pointer may commence when he is only five or six months old. The only lessons which he can be taught at this time are to fetch and carry any thing when desired; to come in when he runs far off, and to go behind when he returns; using, in the one case, the words here, come in, and in the other back or behind. It is also necessary at this period to accustom him to be tied up in the kennel or stable; but he ought not at first to be tied too long. He should be let loose in the morning, and fastened again in the evening. When a dog is not early accustomed to be chained, he disturbs every person in the neighbourhood by howling.

It is also of importance that the person who is to train him should give him his food.

When the dog has attained the age of 10 or 12 months, he may be carried into the field to be regularly trained. At first he may be allowed to follow his own inclination, and to run after every animal he sees. His indiscriminating eagerness he soon abates, and he will pursue only partridges and hares. He will soon become tired of following partridges in vain, and will content himself after having flushed them to follow them with his eyes. It will be more difficult to prevent him from following hares.

All young dogs are apt to rake; that is, to hunt with their noses close to the ground, to follow birds rather by the track than by the wind. But partridges lie much better to dogs that wind them, than to those that follow them by the track. The dog that winds the scent approaches the birds by degrees and without disturbing them; but they are immediately alarmed when they see a dog tracing their footsteps. When you perceive that your dog is committing this fault, call to him in an angry tone hold up: he will then grow uneasy, and agitated, going first to the one side and then to the other, until the wind brings him the scent of the birds. After finding the game four or five times in this way, he will take the wind or himself, and hunt with his nose high. If it be difficult to correct this fault, it will be necessary to put the puzzle peg upon him. This is of very simple construction, consisting of
only of a piece of oak or deal inch board, one foot in
length, and an inch and a half in breadth, tapering a
little to one end; at the broader end are two holes run-
ing longitudinally, through which the collar of the
dog is put, and the whole is buckled round his neck; the
piece of wood being projected beyond his note, is then
fallen with a piece of leather thong; to his under jaw.
By this means the peg advancing seven or eight inches
beyond his front, the dog is prevented from putting his
note to the ground and taking.

As soon as the young dog knows his game you must
bring him under complete subjection. If he is tractable,
this will be easy; but if he is stubborn, it will be nec-
ecessary to use the trailing cord, which is a rope or cord of
20 or 25 fathoms in length fastened to his collar. If
he refuse to come back when called upon, you must
check him smartly with the cord, which will often bring
him upon his haunches. But be sure you never call to
him except when you are within reach of the cord.
After repeating this several times he will not fail to
come back when called; he ought then to be cared for,
and a bit of bread should be given him. He ought now
constantly to be tied up, and never unchained, except
when you give him his food, and even then only when
he has done something to deserve it.

The next step will be to throw down a piece of
bread on the ground, at the same moment taking hold
of the dog by the collar, calling out to him, "take
heed,—softly." After having held him in this manner
for some space of time, say to him, "FEIZE—LAY HOLD."
If he is impatient to lay hold of the piece of bread
before the signal is given, correct him gently with a small
whip. Repeat this lesson until he "takes heed" well,
and no longer requires to be held fast to prevent him
from laying hold of the bread. When he is well ac-
customed to this manage, turn the bread with a flick,
holding it in the manner you do a fowling-piece, and
having done so, cry "FEIZE." Never suffer the dog to eat
either in the house or field without having first made
him take heed in this manner.

Then, in order to apply this lesson to the game, fry
small pieces of bread in hogs lard, with the dung of par-
tridge; take these in a linen bag into the fields, stub-
bles, ploughed grounds, and pastures, and there put the
pieces in several different places, marking the spots with
little cleft pickets of wood, which will be rendered
more distinguishable by putting pieces of card in the
nicks. This being done, call off the dog and conduct
him to these places, always hunting in the wind. After
he has caught the scent of the bread, if he approaches
too near, and seems eager to fall upon it, cry to him in
a menacing tone, "take heed!" and if he does not stop
immediately, correct him with a whip. He will soon
comprehend what is required of him, and will stand.

At the next lesson, take your gun charged only with
powder, walk gently round the piece of bread once or
twice, and fire instead of crying "feize." The next time of
practising this lesson, walk round the bread four or five
times, but in a greater circle than before, and continue to
do this, until the dog is conquered of his, impatience,
and will stand without moving until the signal is given.
When he keeps his point well, and "stands steady" in
this lesson, you may carry him to the birds; if he runs
in upon them, or barks when they spring up, you must
correct him; and if he continues to do so, you must return
to the fired bread; but this is seldom necessary.

When the dog has learned by this use of the bread
to take heed, he may be carried to the fields with the
trail cord dragging on the ground. When he springs
birds for the first time, if he runs after them or barks,
check him by calling out to him, "TAKE HEED." If he point
properly, caress him; but you ought never to hunt
without the cord until he point staunchly.

If the dog runs after sheep, and it is difficult to cure
him, couple him with a ram, and then whip the dog as
long as you can follow him. His cries will at first
alarm the ram; he will run with all his speed, and drag
the dog along with him; but he will at length take
courage, turn upon the dog, and butt him severely with
his horns. When you think the dog is sufficiently chas-
tised, untie him; he will never run at sheep again.

Having now given a few general instructions con-
cerning the best method of training pointers, we shall
subjoin a few observations respecting the most common
species of game, the partridge, pheasant, grouse, wood-
cock, snipe, and wild duck.

Partridges pair in the spring, and lay their eggs (ge-
erally from 15 to 20) during May and part of June.
The young begin to fly about the end of June, and their
plumage is complete in the beginning of October. The
male has a conspicuous horsethief upon his breast, and
an obtuse spur on the hinder part of the leg, which dis-
inguishes him from the female. He is also rather lar-
g than the female.

When a sportsman is shooting in a country where
the birds are thin, and he no longer chooses to range
the field for the bare chance of meeting with them,
the following method will show him where to find them
on another day. In the evening, from sun-set to night-
fall, he should point himself in a field, at the foot of a
tree or a bush, and there wait until the partridges begin
to call or juck, which they always do at that time;
not only for the purpose of drawing together when se-
parated, but also when the birds composing the covey
are not disturbed. After calling in this manner for
some little space of time, the partridges will take to
flight; then, if he mark the place where they alight,
he may be assured they will lie there the whole night,
unless disturbed. Let him return to the same point the
next morning by break of day, and there watch a while;
being careful to keep his dog in a firing, if he is not
under perfect command.

As soon as the dawn begins to peep, the partridges
will begin to call, and soon afterwards will perform
the same manoeuvre as on the preceding evening; that is,
after having called a while, they will take their
flight, and will most commonly settle at a little distance.
There in a few minutes they will call again, and some-
times take a second flight, but that will be to no great
extent. Then as soon as the sun is riven, and the
sportsman can see to shoot, he may cast off his dog and
pursue them.

The pheasant is of the size of a common dunghill Pea-
cock, and lays its eggs generally in the woods, the
number of which is 10 or 12.

Pheasants are accounted stupid birds; for when they
are surprised they will frequently squat down like a rab-
bit, supposing themselves to be in safety as soon as their
heads
Snipe.

Wild duck. here in heads IO'Ve times pools freud be particularly in the

Graves, or mui-game, are found in Wales, in the northern counties of England, and in great abundance in

The woodcock, is a bird of passage; it commonly goes forthward about the end of October, and remains until the middle of March. Woodcocks are fatte in December and January, but from the end of February they are lean. At their arrival they drop anywhere, but afterwards take up their residence in copses of nine or ten years growth. They seldom, however, fly in one place longer than 12 or 15 days. During the day they remain in those parts of the woods where there are void spaces or glades, picking up earth-worms and grubs from the fallen leaves. In the evening they go to drink and wash their bills at pools and springs, after which they repair to the open fields and meadows for the night. It is remarkable, that when a woodcock springs from a wood to go into the open country, he always endeavours to find some glade or opening, which he follows to the boundaries of the wood. In his return he pursues the same path in a good way, and then turns to the right or left opposite to some glade, in order to drop into a thick part of the wood, where he may be sheltered from the wind. He may therefore be watched with advantage in those narrow passes and little alleys on the edges of woods which lead to a pool or spring, or he may be watched in the dusk of the evening near the pools which he frequents.

The *suife* is a bird of passage as well as the woodcock. This bird is scarcely worth shooting till the fruit commences. In the month of November they begin to grow fat. Snipes, like woodcocks, frequent springs, bogs, and marshy places, and generally fly against the wind. The blunt and crook shots are rather difficult; as the birds are small and fly very quickly. The sportman ought to look for them in the direction of the wind; because then they will fly towards him, and present a fairer mark.

Wild duck is also a bird of passage, and arrives here in great flocks from the northern countries in the beginning of winter. Still, however, a great many remain in our marshes and fens during the whole year, and breed.

The wild duck differs little in plumage from the tame duck, but is easily distinguished by its size, which is less; by the neck, which is more slender; by the foot, which is smaller; by the nails, which are more black; and above all, by the web of the foot, which is much finer and fatter to the touch.

In the summer season, when it is known that a team of young ducks are in a particular piece of water, and just beginning to fly, the sportman is sure to find them early in the morning dabbling at the edges of the pool, and amongst the long grass, and then he may get very near to them: it is usual also to find them in those places at noon.

In the beginning of autumn almost every pool is frequented by teams of wild ducks, which remain there during the day, concealed in the rushes. If these pools are of small extent, two shooters, by going one on each side, making a noise, and throwing stones into the rushes, will make them fly up; and they will in this way frequently get shots, especially if the pool is not broad, and contracts at one end. But the surest and most successful way, is to launch a small boat or trow on the pool, and to traverse the rushes by the openings which are found; at the same time making as little noise as possible. In this manner the ducks will suffer the sportsmen to come sufficiently near them to shoot flying; and it often happens that the ducks, after having flown up, only make a circuit, return in a little time, and again alight upon the pool. Then the sportmen endeavour a second time to come near them. If several shooters are in company, they should divide, two should go in the boat, whilst the others spread themselves about the edge of the pool, in order to shoot the ducks in their flight. In pools which will not admit a trow, water spaniels are absolutely necessary for this sport.

In winter they may be found on the margins of little pools; and when pools and rivers are frozen up, they must be watched for in places where there are springs and waters which do not freeze. The sport is then much more certain, because the ducks are confined to those places in order to procure aquatic herbs, which are their only food at this period.

**SHOP-LEITERS.** are those that deal goods privately out of shops; which, being to the value of 5s, though no perfon be in the shop, is felony without the benefit of clergy by the 10 and 11 W. III. c. 23.

**SHORE.** A place washed by the sea, or by some large river.

Count Marigli divides the sea-shore into three portions: the first of which is that track of land which the sea just reaches in storms and high tides, but which it never covers; the second part of the shore is that which is covered in high tides and storms, but is dry at other times; and the third is the defile from this, which is always covered with water.

The first part is only a continuation of the continent, and suffers no alteration from the neighbourhood of the sea, except that it is rendered fit for the g owth of forn plants, and wholly unfit for that of others, by the saline trains and impregnations; and it is scarce to be conceived by any, but those who have observed it, how far on land the effects of the sea reach, to as to make the earth proper for plants which will not grow without this influence; there being several plants frequently found on high hills and dry places, at three, four, and five miles from the sea, which yet would not grow unless in the neighbourhood of it, nor will ever be found elsewhere.
SHORE

The second part or portion of the shore is much more affected by the sea than the former, being frequently washed and beaten by it. Its productions are rendered flat by the water, and it is covered with sand, or with the fragments of shells in form of sand, and in some places with a tartarous matter deposited from the water; the colour of this whole extent of ground is usually dusty and dull, especially where there are rocks and stones, and these covered with a filthy manner.

The third part of the shore is more affected by the sea than either of the others; and is covered with an uniform crust of the true nature of the bottom of the sea, except that plants and animals have their residence in it, and the decayed parts of these alter it a little.

SHORE (Jane), the celebrated concubine of the licentious king Edward IV. was the wife of Mr Matthew Shore, a goldsmith in Lombard street, London. Kings are seldom unsuccessful in their amorous pursuits; therefore there was nothing wonderful in Mrs Shore's removing from Lombard-street to shine at court as the royal favourite. Historians represent her as extremely beautiful, remarkably cheerful, and of most uncommon generosity. The king, it is said, was not less captivated with her temper than with her person: he never made use of her influence over him to the prejudice of any person; and if ever he imported him, it was in favour of the unfortunate. After the death of Edward, she attached herself to the lord Hastings; and when Richard III. cut off that nobleman as an obstacle to his ambitious schemes, Jane Shore was arrested as an accomplice, on the ridiculous accusation of witchcraft. This, however, terminated only in a public penance; excepting that Richard rified her of all her little property: but whatever severity might have been exercised towards her, it appears that she was alive, though sufficiently wretched, under the reign of Henry VIII. when Sir Thomas More saw her poor, old, and thrivel'd, without the least trace of her former beauty. Mr Rowe, in his tragedy of Jane Shore, has adopted the popular story related in the old historical ballad, of her perishing by hunger in a ditch where Shoreditch now stands. But Shaw affirms that the street was so named before her time.

SHORL. See SHORE.

SHORLING and MORTING, are words to distinguish falls of sheep a flouting being the falls after the sheeze are shorn off the sheeps back; and morting, the falls head off after they die or are killed. In some parts of England they understand by a flouting, a sheep whose fleece is shorn off; and by a morting, a sheep that dies.

SHORT (James), an eminent optician, was born in Edinburgh on the 10th of June, O.S. in the year 1716. At ten years of age, having lost his father and mother, and being left in a state of indigence, he was received into Heriot's Hospital, (see Edinburgh Public Buildings, n° 16), where he soon displayed his mechanical genius in constructing, for himself, little chells, bookcases, and other conveniences, with such tools as fell in his way. At the age of twelve he was removed from the Hospital to the High School, where he showed a considerable taste for classical literature, and generally kept at the head of his forms. In the year 1736 he was entered into the university, where he passed through the usual course of education, and took his master's degree with great applause.

By his friends he was intended for the church; but after attending a course of theological lectures, his mind revolted from a profession which he thought little adapted to his talents; and he devoted his whole time to mathematical and mechanical pursuits. He had been fortunate enough to have the celebrated McClaurin for his preceptor, who having soon discovered the bent of his genius, and made a proper estimate of the extent of his capacity, encouraged him to prosecute those studies in which nature had qualified him to make the greatest figure. Under the eye of that eminent master, he began in 1732 to construct Gregorian telescopes; and, as the professor observed in a letter to Dr Jolin, "by taking care of the figure of his specula, he was enabled to give them larger apertures, and to carry them to greater perfection, than had ever been done before him." See Optics, n° 97.

In the year 1736 Mr Short was called to London, at the desire of Queen Caroline, to give instructions in mathematics to William duke of Cumberland; and immediately on his appointment to that very honourable office, he was elected a fellow of the royal society, and patronized by the earls of Morton and Marchfield. In the year 1749 he accompanied the former of those noble lords to the Orkney Isles, where he was employed in adjusting the geography of that part of Scotland; and happy it was for him that he was so employed, as he might otherwise have been involved in a scuffle which took place between the retainers of Sir James Stewart of Barn and the attendants of the earl, in which some of the latter were dangerously wounded.

Mr Short having returned to London, and finally established himself there in the line of his profession, was in 1743 employed by lord Thomas Spencer to make for him a reflector of twelve feet focus, for which he received 660 guineas. He made several other telescopes of the same focal distance with greater improvements and higher magnifiers; and in 1753 finished one for the king of Spain, for which, with its whole apparatus, he received 1200l. This was the noblest instrument of that kind that had then been constructed, and perhaps it has never yet been surpassed except by the astonishing reflectors of Herschel. See Telescopes.

Mr Short was wont to visit the place of his nativity once every two or three years during his residence in London, and in 1766 he visited it for the last time. On the 13th of June 1768 he died, after a very short illness, at Newington Butts, near London, of a mortification in his bowels, and was buried on the 22d of the same month, having completed, within a few days, his fifty-eighth year. He left a fortune of about 20,000l. of which 15,000l. was bequeathed to two nephews, and the rest in legacies to his friends. In gratitude for the hearty patronage of the earl of Morton, he left to his daughter the Lady Mary Douglas, afterwards countess of Aboyne, 1000l. and the reversion of his fortune, should his nephews die without issue; but this reversionary legacy the lady, at the desire of her father, seriously relinquished by a deed in favour of Mr Short's brother Mr Thomas Short and his children. Mr Short's eminence as an artificer is universally known; and we have often heard him spoken of by those who had known.
known him from his youth, as a man of virtue and of very amiable manners.

Short-Hand Writing. See STENOGRAHY.

Short-jointed, in the manage. A horse is said to be short-jointed that has a short pattern; when this joint, or the pattern is too short, the horse is said to have his fore legs from the knee to the coronet all in a straight line. Commonly your short-jointed horses do not manage as well as the long-jointed; but out of the manage the short-jointed are the best for travel or fatigue.

Short-sightedness, a certain defect in vision, by which objects cannot be distinctly seen unless they are very near the eye. See Optical, n. 155.

SHORTFORD, q. d. were close, an ancient custom in the city of Exeter, when the lord of the fee cannot be answered rent due to him out of his tenement, and no dilatory can be levied for the same. The lord is then to come to the tenement, and there take a fone, or some other dead thing off the tenement, and bring it before the mayor and bailiff, and this must do seven quarter days successively; and if on the seventh quarter day the lord is not satisfied of his rent and arrears, then the tenement shall be adjudged to the lord to hold the same a year and a day; and forthwith proclamation is to be made in the court, that if any man claims any title to the said tenement, he must appear within the year and day next following, and satisfy the lord of the said rent and arrears; but if no appearance be made, and the rent not paid, the lord comes again to the court, and prays that, according to the custom, the said tenement be adjudged to him in his demesne as of fee, which is done accordingly, so that the lord hath from thenceforth the said tenement, with the appurtenances to him and his heirs.

SHOT a denomination given to all sorts of balls for fire-arms; those for cannon being of iron, and those for guns, pibols, &c. of lead. See SHOOTING.

Cafe Shot formerly consisted of all kinds of old iron, nails, musket-balls, stones &c. used as above.

Shot of a cable, on ship-board, is the splicing of two cables together, that a ship may ride safe in deep waters and in great roads; for a ship will ride easier by one shot of a cable, than by three short cables out ahead.

Grape Shot. See GRAPE-SHOT.

Patent mild Shot is thus made: Sheets of lead, whose thicknesses corresponds with the size of the shot required, are cut into small pieces, or cubes, of the form of a die. A great quantity of these little cubes are put into a large hollow iron cylinder, which is mounted horizontally and turned by a winch; when by their friction against one another and against the sides of the cylinder, they are rendered perfectly round and very smooth. The other patent shot is cast in moulds, in the same way as bullets are.

Shot-Flags, a fort of flaggon somewhat bigger than ordinary, which in some counties, particularly Derbyshire, it is the custom for the holt to serve his guests in, after they have drank above a halfing.

Small Shot, or that used for fowling, should be well sized, and of a moderate bigness; for should it be too great, then it flies thin, and feathers too much; or if too small, then it hath not weight and strength to penetrate far, and the bird is apt to fly away with it. In order, therefore, to have it suitable to the occasion, it not being always to be had in every place fit for the purpose, we shall let down the true method of making all sorts and sizes under the name of real shot. Its principal good properties are to be round and solid. Take any quantity of lead you think fit, and melt it down in an iron vessel; and as it cools keep it stirring with an iron ladle, skimming off all impurities whatever that may arise at the top; when it begins to look of a greenish colour, stir it round and yellow opium, finely powdered, as will be on aalluring to every 12 or 14 pound of lead; then stirring them together, the ornament will flame.

The ladle should have a notch on one side of the brim, for more easily pouring out the lead; the ladle must remain in the melted lead, that its heat may be the same with that of the lead, to prevent inconveniences, which otherwise might happen by its being either too hot or too cold: then, to try your lead, drop a little of it into water, and if the drops prove round, then the lead is of a proper heat; if otherwise, and the shot have tails, then add more ornament to increase the heat, till it be found sufficient.

Then take a plate of copper, about the bigness of a thumb, which must be made with a hollowness in the middle, about three inches compass, within which must be bored about 40 holes according to the size of the shot which you intend to cast: the hollow bottom should be thin; but the thicker the brim, the better it will retain the heat. Place this plate on a frame of iron, over a tub or vessel of water, about four inches from the water, and spread burning coals on the plate, to keep the lead melted upon it; then take some lead and pour it gently on the coals on the plate, and it will make its way through the holes into the water, and form itself into shot; do this till all your lead be run through the holes of the plate taking care, by keeping your coals alive, that the lead do not cool, and so stop up the holes.

While you are casting in this manner, another person with another ladle may cast some of the shot, placing the ladle four or five inches underneath the plate in the water, by which means you will see if they are defective, and rectify them.

Your chief care is to keep the lead in a just degree of heat, that it be not too cold as to stop up the holes in your plate, nor so hot as to cause the shot to crack: to remedy the heat, you must refrain working till it is of a proper coolness; and to remedy the coolness of your lead and plate, you must blow your fire; observing, that the cooler your lead is, the larger will be your shot; as the hotter it is, the smaller they will be.

After you have done casting, take them out of the water, and dry them over the fire with a gentle heat, stirring them continually that they do not melt; when dry, you are to separate the great shot from the small, by the help of a sieve made for that purpose, according to their several sizes. But those who would have very large shot, make the lead trickle with a flick out of the ladle into the water, without the plate.

If it float on the plate, and yet the plate be not too cool, give but the plate a little knock, and it will run again; care must be had that none of your implements be greasy, oily, or the like; and when the shot, being separated, are found too large or too small for your purpose,
pes, or otherwise imperfect, they will serve again at the next operation.

The sizes of common shot for fowling are from No. 1 to 6, and smaller, which is called musket shot, or duft shot; but No. 5 is small enough for any shooting whatever. The No. 1 may be used for wild geese; the No. 2 for ducks, widgeons, and other water-fowl; the No. 3 for partridges, after the first month, and all the fowl; the No. 4 for partridges, woodcocks, &c.; and the No. 5 for snipes and all the smaller birds.

Tim-Cafe SHORe, in artillery, is formed by putting a great quantity of small iron shot into a cylindrical tin-box called a cannister, that just fits, the bore of the gun. Leaden bullets are sometimes used in the same manner, and it must be observed, that whatever number or sizes of the shots are used, they must weigh with their cases nearly as much as the shot of the piece.

SHOVEL (Sir Claudelye), was born about the year 1600 of parents rather in the lower rank of life. He was put apprentice to a shoemaker; but dreading this profession, determined to make a living by it a few years after, and went to sea. He was at first a cabin boy with Sir Christopher Mynnns, but applying to the study of navigation with indefatigable industry, his skill as a seaman soon raised him above that station.

The coasts of Tripoli having committed great outrages on the English in the Mediterranean, Sir John Narborough was sent in 1674 to reduce them to reason. As he had received orders to try the effects of negotiation before he proceeded to hostilities, he sent Mr Shovel, who was at that time a lieutenant in his fleet to demand satisfaction. The Dey treated him with a great deal of deference, and sent him back without an answer. Sir John dispatched him a second time, with orders to remark particularly the situation of things on shore. The behaviour of the Dey was worse than ever. Upon Mr Shovel’s return, he informed Sir John that it would be possible, notwithstanding their fortifications, to burn all the ships in the harbour. The boats were accordingly manned, and the command of them given to Lieut. Shovel, who seized the guardship, and burnt four others, without losing a man. This action to terrify the Tripolins, that they feared for peace. Sir John Narborough gave so favourable an account of this exploit, that Mr Shovel was soon after made captain of the Sapphire, a fifth rate ship.

In the battle of Bantry-Bay, after the revolution, he commanded the Edgar, and, for his gallant behaviour in that action, was soon after knighted by king William. Next year he was employed in transporting an army into Ireland; a service which he performed with so much diligence and dexterity, that the king raised him to the rank of rear-admiral of the blue, and delivered his commission with his own hands. Soon after he was made rear-admiral of the red, and shared the glory of the victory at La Hogue. In 1694, he bombarded Dunkirk. In 1703, he commanded the grand fleet in the Mediterranean, and did every thing in his power to aid the Protestants who were in arms in the Severn.

Soon after the battle of Malaga, he was prefented by prince George to Queen Anne, who received him graciously, and next year employed him as commander in chief.

In 1705 he commanded the fleet, together with the earls of Peterborough and Monmouth, which was sent into the Mediterranean; and it was owing to him chiefly that Barcelona was taken. After an unsuccessful attempt upon Toulon, he failed for Gibraltar, and from thence homeward with a part of the fleet. On the 22d of October, at night, his ship, with three others, was cast away on the rocks of Scilly. All on board perished. His body was found by some fishermen on the island of Scilly, who stripped it of a valuable ring, and afterwards buried it. Mr Paxton, the purser of the Arundel, hearing of this, found out the fellows, and obliged them to discover where they had buried the body. He carried it on board his own ship to Portsmouth, from whence it was conveyed to London, and interred with great solemnity in Westminster abbey. A monument was afterwards erected to his memory by the direction of the Queen. He married the widow of his patron, Sir John Narborough, by whom he left two daughters, co-heiresses.

SHOVELER, in ornithology, a species of Anas, "SHOULDER-BLADe," a bone of the shoulder, of a triangular figure, covering the hind part of the ribs, called by anatomists the scapula and omaloid. See Anatomy.

SHOUT, CLAMOUR, in antiquity, was frequently used on ecclesiastical, civil, and military occasions, as a sign of approbation, and sometimes of indignation. Thus as Cicer, in an assembly of the people, was exposing the arrogance of L. Antony, who had laid the impudence to cause himself to be inscribed the patron of the Romans, the people on hearing this raised a shout to show their indignation. In the ancient military discipline, shouts were used. 1. Upon occasion of the general’s making a speech or harangue to the army from his tribunal. This they did in token of their approving what had been proposed. 2. Before an engagement, in order to encourage and spur their own men, and fill the enemy with dread. This is a practice of great antiquity; besides which, it wants not the authority of reason to support it; for as mankind are endowed with two senses, hearing and seeing, by which fear is raised in the mind, it may be proper to make use of the ear as well as the eye for that purpose. Shouts were also raised in the ancient theatre, when what was acted pleased the spectators. It was usual for those present at the burning of the dead to raise a great shout, and call the dead person by his name before they set fire to the pile.

SHOWER, in meteorology, a cloud condensed into rain.

SHREWMOUSE. See SORRE.

SHREWSBURY, the capital of Shropshire in England. This town, the metropolis of the county, grew up out of the ruins of Uriconium, an ancient city, now a village called Wrexeter, about four miles from it. The Saxons called it Scrobes Bircg, from the thorns that grew about it; and from hence the present name of Shrewsbury is supposed to have been formed. It is pleasantly situated upon a hill near the Severn, over which there are two handsome bridges. It was a place of note in the Saxon times; after which it was granted by William the Conqueror, together with the title of earl and most of the county, to Roger de Montgomery, who built a castle upon the north side of it, where the Severn, that accompanies it on all other sides, leaves an opening. His son Robert built also a wall across this neck of land, when he revolted from
from Henry I. We learn from *doomday* book, that at that time, when a widow of this town married, the paid 20 shillings to the king, and a virgin to. The abovementioned Roger founded also, and endowed here, a Benedictine monastery and a collegiate church. When old age came upon him, he quitted the world, and spent the rest of his days as a monk in the abbey, and when he died was interred in its church. From the history of this church and monastery, it appears, that ecclesiastical benefits about that time were hereditary. The abbey became so rich afterwards, that the abbots were wealthy, and fat in parliament. Besides this abbey, in after times there were there others, viz. a Franciscan, Dominican, and Augustinian, and likewise two collegiate churches; one dedicated to St Chad and the other to St Mary. In the contest between the emperors Maud and Stephen, this town, and its governor William Fitz-Alan, sided with the emperors. In Henry III.'s time, a part of it was burnt down by the Welsh; and in Richard II.'s reign a parliament was held in it. At a place called *Battlefield*, near this town, Henry Percy the younger, surnamed Hotspur, was killed in an engagement with Henry IV. against whom he had rebelled. The king afterwards built a chapel upon the spot, and endowed it for the support of two priests to pray for the souls of the slain. Two of Edw. IV.'s sons were born here: namely, Richard, duke of York, whom Perkin Warbeck afterwards perforated, and who was murdered in the Tower; and George Plantagenet, who died before his brothers. Here first broke out the sweating-sickness, which carried off great numbers, so suddenly, that those who were seized with it either died or recovered in the space of 2 hours. In the beginning of the civil wars, King Charles I. came hither, and formed an army, with which he marched towards London; but was met by the parliament's forces at Edgehill. He continued here from the 20th of September to the 13th of October, during which time he was joined by prince Rupert, and many of the gentry and nobility of that parts. This town anciently gave title of earl to the Montgomeries, and afterwards to the Talbots, by whom it is still retained. Here is a free grammar-school, with three masters, and several scholars, well endowed by Edward VI. and Queen Elizabeth, and not inferior to many colleges in the universities. It has a good library and chapel, and there are several fellowships appropriated to it in the university of Cambridge. Here are also several hospitals, almshouses, and charity-schools. This town is one of the most flourishing in England, having two great weekly markets for corn, cattle, and provisions; and another for Welch cottons and flannels, of which great quantities are sold. A great trade is carried on with the Welch, who bring their commodities hither, as to the common mart of both nations. The town in large and well-built, and the situation extremely pleasant. There is a very beautiful walk called the *quarry*, between the town walls and the Severn, delightfully shaded with rows of lime-trees, so that it is not inferior to the Mall in St James's Park. The town is also noted for its gallantry and politer, being full of gentry, for whom there are always balls and assemblies once a-week all the year round.-

Here is a fine house and gardens, which belonged to the earl of Bradford; and in the neighbourhood, as Wroxeter, the Roman highway, called Watling-street, may be seen for several miles, where Roman coins are frequently found. In Shrewsbury are 12 incorporated trading companies; and the corporation has a power to try even capital causes of itself, except high treason. It is said that thigh-bones of dead men have been found here a yard long, and teeth three inches round and three long.

SHRIKE. See *LANIER.*

SHRIMP, ichthyology. See *CANCER, n° 5. and 6."

SHRINE, in ecclesiastical history, a place to hold the relics of some saint.

SHROPSHIRE, a county of England, bounded on the north by Worcestershire, Herefordshire, and Radnorshire; on the north by Cheshire; on the west, by Staffordshire; on the south, by Montgomeryshire and Denbighshire, in Wales. Its length is between 40 and 50 miles, its breadth about 36, and its circumference about 210. It is an inland county, containing 890,000 acres, 113,650 inhabitants, and 15 hundreds, in which are 170 parishes, and 15 market towns. It makes a part of three bishoprics, viz. Hereford, Coventry and Lichfield, and St Asaph. Some part of it lies on the north, and some on the south side of the Severn. Besides the Severn, it is also watered by the Teme and Telford, as it is called in Welch, which flows from the mountains of Radnorshire; and by the Tern, which has its rise and name from one of those pools called *leernes,* in Staffordshire. All these abound with fish, especially eels, pikes, lampreys, grayslings, carp, and eels. The air, especially upon the hills, with which the county abounds, is very wholesome. There is as great a diversity of soil as in most other counties. On the hills, where it is poor, is very good pasture for sheep; and in the low grounds, where it is very rich, along the Severn in particular, there is plenty of grass for hay and black cattle, with all sorts of corn. No county is better provided with fuel than this, having in it many inexhaustible pits of coal, and also mines of lead and iron. Over most of the coal-pits in this county lies a stratum or layer of blackish porous rock, of which, by grinding and boiling, they make pitch and tar, which are rather better than the common for caulking ships, as they do not crack, but always continue close and smooth. Quarries of limestone and ironstone are common enough in the county, and the coal in many places is a reddish clay. As it lies, upon the borders of Wales, it was anciently full of castles and walled towns. On the side next that country there was an almost continuous line of castles, to guard the county against the intruders and depredations of the Welch. The borders here, as those between England and Scotland, were called *Marches,* and there were certain noblemen intitule bizones marchies, marchiones de marcha Wallis, "lords of the marches, or magnificies of the marches of Wales," who were vested with a fort of patinaire juriadmin, held courts of justice to determine controversies, and enjoyed many privileges and immunities, the better to enable and encourage them to protect the county against the incursions of the Welsh, and to maintain order amongst the borderers; but they often abused their power, and were the greatest of tyrants.

As to the ecclesiastical government of the county, the far greater part, namely, all that belongs to the bishoprics of Hereford, and of Lichfield and Coventry,
is under the jurisdiction and visitation of the archbishop of Shrewsbury or Salop, and is divided into several

dioceses.

The Oxford circuit includes in it this county, which

furnishes members to parliament, viz. two for the three,

and two for each of the following towns, Shrewsbury,

Ludlow, Wenlock, and Bishop's Castle.

SHROVE-TUESDAY, is the Tuesday after Quin

quagesima Sunday, or the day immediately preceding

the start of Lent; being so called from the Saxon word

shrofit, which signifies "to confess." Hence Shrove-

Tuesday signifies Confession-Tuesday; on which day

all the people in every parish throughout England

(during the Romish times) were obliged to confess their

sins, one by one, to their own parish-priests, in their own

parish-churches; and, that this might be done the more

regularly, the great bell in every parish was rung at ten

o'clock (or perhaps sooner), that it might be heard by

all, and that they might attend, according to the cus

tom then in use.

And though the Roman religion has now given way to

the Protestant religion, the custom of ringing the great
ell in the ancient parish-churches, at least in some of

them, still remains, and obtains in

and about London the name of Pancake bell; perhaps,
because after the confession it was customary for

the several persons to dine on pancakes or fritters.

Mix churches, indeed, have rejected that custom of ringing

the bell on Shrove-Tuesday; but the usage of dressing

on pancakes or fritters, and such like provision, still

continues.

SHROUDS (fervd. Sur.), a range of large ropes

extending from the malt-heads to the right and left side

of the ship, to support the masts, and enable them to
carry sail, &c.

The threads as well as the sails are denominated from

the masts to which they belong. Thus they are the

main, fore, and mizen shrouds; the main-top-mast,

fore-top-mast, or mizen-top-mast shrouds; and the

main-top-gallant, fore-top-gallant, or mizen-top-gallant

shrouds. The number of threads by which a mast is

furnished, as well as the size of rope of which they are

formed, is always in proportion to the size of the mast

and the weight of the sail it is intended to carry.

Bowsprit shrouds are those which support the bows-

prit. Bumkin shrouds are those which support the

bunkins. Futtock shrouds are those which connect the

efforts of the topmast shrouds to the lower threads.

Bentinnick-shrouds are additional threads to support

the masts in heavy gales. Preventer shrouds are similar to

bentinck-shrouds, and are used in bad weather to ease

the lower rigging. See Mast and Sail.

SHRUB, fruit, a little, low, dwarf tree, or a

woody vegetable, of a size less than a tree; and which,

instead of one single stem, frequently from the same

root puts forth several fets or items. See Plant and

Tree. Such are privet, phillyrea, holly, box, honey-

cobble, &c. Shrubs and trees put forth in autumn a kind

of buttons, or gems, in the axis of the leaves; these

buttons are as so many little oval, which, coming to

expand by the warmth of the following spring, open

into leaves and flowers. By this, together with the

height, some distinguishes shrubs from sapranchy, or under

shrubrubs, which are low bushes, that do not put forth

any of these buttons, as lage, thyme, &c.

The two hardiest shrubs we are possessed of are the

ivy and box; these stand the severity of our sharpest

winters unhurt, while other shrubs perish, and trees

have their solid bodies split and torn to pieces. In the

hard winter of the year 1642, these two shrubs suffered

no injury any where; though the yews and holleys,

which are generally supposed very hardy, were that

winter in some places killed, and in others stripped of

their leaves, and damaged in their bark. Ficus-muhla

seem to be somewhat harder than box, but they

sometimes perished, of a great deal of the

broom seemed to occupy the next step of hardiness

beyond those. This lived where the others died, and

where even this died, the juniper shrubs were sometimes

found unhurt. This last is the only shrub that

approaches to the hardiness of the box and ivy, but even

it does not quite come up to them; for while they suffer

nothing in whatever manner they are exposed, the ju

niper, though it bears cold well under the shelter of

other trees, yet cannot bear the vicissitudes of heat and

cold; infomuch that some juniper shrubs were found

half dead and half vigorous; that side which faced the

mid-day sun having perished by the successive thaw

and freezings of its sap; while that which was not ex

posed to the vicissitudes of heat had been the cold

perfectly well. Such shrubs as are not hardy enough to

delay the winter, but appear half dead in the spring,

may often be recovered by Mr Evelyn's method of bear

ing their branches with a flender hazel-rod, to fill

the withered leaves and buds, and give a free pas

sage to the air to the internal parts. Where this fails,

the method is to cut them down to the quick, and if

no part of the trunk appears in a growing condition,

they must be taken off down to the level of the ground.

Philosophical Transactions, Nov. 165.

SHUCKFORD (Samuel), curate of Sheldon in

Norfolk, prebendary of Canterbury, and chaplain in

ordinary to the king, was a learned Englishman. His

manners were those of a philosopher, uncorrupted by

the manners of the world. He wrote a history of the

world, sacred and profane, to serve as an introduction

to Prideaux, in 3 vols 8vo. It is heavily written, but
displays a great deal of erudition. His death, which

happened in 1756, prevented him from carrying it

down to the year 1747 before Chrift, while Prideaux

begins. He wrote also a treatise on the Creation and

Fall of Man, to serve as a supplement to the preface to

his history.

SHUTTLE, in the manufactures, an apparatus

used by the weavers, which guides the thread it contains,
either of woollen, silk, flax, or other matter, so as to make
it form the woof of stuffs, cloths, linens, ribbands, &c.

by throwing the shuttle alternately from left to right,

and from right to left, across between the threads on the

warp, which are stretched out lengthwise on the loom.

In the middle of the shuttle is a kind of cavity, called

the eye or chamber of the shuttle; wherein is included

the spool, which is a part of the thread destined for the

woof; and this is wound on a little tube of paper, rush

or other matter.

The ribband-weiaver's shuttle is very different from

that of most other weavers, though it serves for the

same purpose: it is of box, fix or seven inches long,

one broad, and as much deep; hold with iron at both

ends,
They have no European fruits except oranges, lemons, citrons, and pomegranates. They have bananas, Indian figs, jaques, durions, mangoes, mangofruits, tamarinds, ananas, and cocoa-nuts; they have also abundance of pepper and sugar-canes. The mountains are covered with trees which make good masts. The vegetable of greatest use in the country is the bamboo, which grows chiefly in marshy soils, and is often found of a prodigious size. Cotton trees are found in great numbers; and others that yield kapok, a very fine cotton wool, but so short as to be unfit for spinning, though it answers very well for stuffing mattresses and pillows.

There is no country where elephants abound more than in Siam, or where they are held in greater veneration. They have a few horses, sheep, and goats, besides oxen and buffaloes; but they have no good animal food except the flesh of hogs, their beef and mutton being of a very indifferent quality.

The Siamese are of small stature, but well proportioned; their complexions are swarthy; the faces of both the men and women are broad, and their foreheads, suddenly contracting, terminate in a point, as well as their chins. They have small black eyes, hollow jaws, large mouths made thick pale lips. Their teeth are dyed black, their noses are short and round at the end, and they have large ears, which they think very beautiful. Their hair is thick and lank, and both sexes cut it so short that it reaches no lower than their ears; the women make it stand up on their foreheads; and the men have their beards.

People of distinction wear a piece of calico tied Dres. about their loins, that reaches down to their knees. The men bring up this cloth between their legs, and tuck it into their girdles, which gives it the appearance of a pair of breeches. They have also a muffin shirt without a collar, with wide sleeves, no wrists, and the bottom open. In winter they wear a piece of stuff or painted linen over their shoulders, like a mantle, and they are only worn when the wind is at the east, or when the king's presence, or when any extraordinary occasion. The king of Siam is distinguished by wearing a veil of brocaded satin, with straight sleeves that reach down to the wrists, under such a shirt as we have just described, and it is unlawful for any subject to wear this dress unless he receives it from the king. They wear slippers with piked toes turned up, but no stockings. The king sometimes presents a military vest to the generals; this is buttoned before, and reaches to the knees; but the sleeves are wide, and come no lower than the elbows. All the retinue of the king, either in war or in hunting, are clothed in red. The king wears a cap in the form of a sugar-loaf, encompassed by a coronet of precious stones, and those of his officers have a circle of gold, silver, or of vermilion gilt, to distinguish their quality; and these caps are fastened with a flap under the chin; they are only worn when they are in the king's presence, or when they preside in courts of justice, and on other extraordinary occasions. They have also hats for travelling, but, in general, few people cover their heads notwithstanding the scorching heat of the sun.

The women also wrap a cloth about their middle, which hangs down to the calf of their legs. They cover their breasts with another cloth the ends of which hang over their shoulders. But they have no garment...
corresponding to a shift, nor any covering for their heads but their hair. The common people are almost naked, and wear neither shoes nor flippers. The women wear as many rings on the three left fingers of each hand as they can keep on, and bracelets upon their wrists and ankles, with pendants in their ears shaped like a heart.

For an inferior to stand before a superior is deemed insolent; and therefore slaves and people of inferior rank sit upon their heels, with their heads a little inclined, and their joined hands lifted up to their foreheads. In passing by a superior they bend their bodies, joining their hands, and lifting them towards their heads in proportion to the respect they would show. When an inferior pays a visit, he enters the room sweeping, prostrates himself, and then remains upon his knees, sitting upon his heels without speaking a word till he is addressed by the person whom he visits; for that is of the highest quality must always speak first. If a person of rank visits an inferior, he walks upright, and the master of the house receives him at the door, and waits on him so far as he goes away, but never farther.

The highest part of the house is esteemed the most honourable, and no person comes to lodge under another's feet. The Siamese indeed have but one story, but the rooms rise gradually, and the innermost, which are the highest, are always the most honourable. When the Siamese ambassador came to the French court, some of his retinue were lodged in a floor over the ambassador's head; but they no sooner knew it, than they were struck with the greatest consternation, and ran down tearing their hair at the thoughts of being guilty of what they considered as so unpardonable a crime.

The Siamese never permit such familiarities as are practiced by gentlemen in Europe. Eauniness of access, and affability to inferiors, is in that part of the world thought a sign of weakness, and yet they take no notice of some things which would be looked upon as ill breeding among us, such as belching in company, which no man endeavours to prevent, or so much as holds his hands before his mouth. They have an extraordinary respect for the head, and it is the greatest affront to strike or touch that of another person; nay, their cap must not be used with too much familiarity; for when a servant carries it, it is put on a flick, and held above his head; and when the master stands flick is set down, it having a foot to stand upon. They also show their respect by lifting their hands to the head; and therefore, when they receive a letter from any one for whom they have a great respect, they immediately hold it up to their heads, and sometimes lay it upon their heads.

They are esteemed an ingenious people, and though rather indolent than active in disposition, they are not addicted to the voluptuous vices which often accompany a lapse of ease, being remarkably chaste and temperate, and even holding drunkenness in abhorrence. They are, however, accounted insolent towards their inferiors, and equally obsequious to those above them; the latter of which qualities appears to be particularly inculcated from their earliest youth. In general, their behaviour is extremely modest, and they are averse to loquacity. Like the Chinese, they avoid speaking in the first person; and when they address a lady, it is always with some respectful epithet, intimating personal accomplishments.

No man in this country learns any particular trade, but has a general knowledge of all that are commonly practiced, and every one works six months for the king by rotation; which time, if he should be found perfectly ignorant of the business he is set about, he is doomed to suffer the bastinado. The consequence of this burdensome service is, that no man endeavours to excel in his business, lest he should be obliged to practice it as long as he lives for the benefit of the crown.

The government of this country is extremely oppressive, the king being not only sovereign but proprietor of all the lands, and chief merchant likewise; by which means he monopolizes almost the whole traffic, to the great prejudice of his subjects. The crown is said to be hereditary, but it is often transferred by revolutions, on account of the exorbitant abuse of power in those who exercise the royal office. In his palace, the king is attended by women, who not only prepare his food, and wait on him at table, but even perform the part of valets, and put on all his clothes, except his crown, which is considered as too sacred to be touched by any hand but his own. He shows himself to the people only twice a year, when he distributes his arms to the talismans or priests; and on those occasions he always appears in an elevated situation, or mounted on the back of an elephant. When he takes the diversion of hunting, he is as usual attended by his women on foot, preceded by a guard of 200 men, who drive all the people from the roads through which they are to pass; and when the king stops, all his attendants fall upon their faces on the ground.

All their proceedings in law are committed to writing, and none is suffered to exhibit a charge against another, without giving security to prosecute it, and answer the damages if he does not prove the fact against the person accused. When a person intends to prosecute another, he draws up a petition, and then he sets forth his complaint, and presents it to the assize or head of the band to which he belongs, who transmits it to the governor; and if the complaint appears frivolous, the prosecutor, according to the laws of the country, should be punished; but the magistrates generally encourage prosecutions on account of the perquisites they bring to their office.

Every thing being prepared for hearing, the parties are several days called into court, and persuaded to agree; but this appears to be only a matter of form. At length the governor appoints a day for all parties to attend; and being come into court, the clerk reads the process and opinion of his associates, and then the governor examines upon what reasons their opinions are founded; which being explained to him, he proceeds to pass judgment.

When sufficient proofs are wanting, they have recourse to an ordeal trial, like that of our Saxon ances.

Trial by flours: both the plaintiff and the defendant walk upon burning coal; and he that escapes unhurt is adjudged to be in the right; sometimes the proof is made by putting their hands in boiling oil; and in both these trials, by some peculiar management, one or the other is said to remain unhurt. They have also a proof by water, in
in which he who remains longest under it is esteemed innocent. They have another proof, by swallowing pills, which their priests administer with severe impreca-
tions; and the party who keeps them in his stomach without vomiting is thought to be innocent.

All these trials are made in the presence of the magistrates and people; and the king himself frequently directs them to be performed, when crimes come before him by way of appeal. Sometimes he orders both the informer and prisoner to be thrown to the tigers: and the person that escapes by his not being feized upon by those beasts, is sufficiently justified.

They maintain the doctrine of transmigration, believing in a pre-existent state, and that they shall pass into other bodies till they are sufficiently purified to be received into paradise. They believe likewise that the soul is material, but not subject to the touch; that it retains the human figure after quitting a body of that species; and that when it appears to persons with whom it was acquainted, which they suppose it to do, the wounds of one that has been murdered will then be visible. They are of opinion that no man will be eternally punished; that the good, after several transmigrations, will enjoy perpetual happiness; but that those who are not reformed will be doomed to transmigration to all eternity. They believe in the existence of a Supreme Being; but the objects of their adoration are departed saints, whom they consider as mediators or intercessors for them; and to the honour of this numerous tribe both temples and images are erected.

The men of this country are allowed a plurality of women; but excepting one, who is a wife by contract, the other, are only concubines, and their children deemed incapable of any legal inheritance. Previous to every nuptial contract, an astrologer must be consulted, who calculates the nativity of the parties, and determines whether their union is likely to prove fortunate or otherwise. When his prognostication is favourable, the lover is permitted to visit his mistress three times, at the last of which interviews the relations being present, the marriage portion is paid, when, without any ceremony, the nuptials are reckoned complete, and soon after consummated. A few days after the talap-in visits the married couple, sprinkles water on them, and repeats a prayer for their prosperity.

The practice in Siam respecting funerals, is both to burn and bury the dead. The corpse being laid upon the pile, it is suffered to burn till a considerable part is consumed, when the remainder is interred in a burning-place contiguous to some temple. The reason which they give for not burning it entirely to ashes is, that they suppose the deceased to be happy when part of his remains escapes the fire. Instead of a tombstone, they erect a pyramid over the grave. It formerly was the custom to bury treasures with the corpse; but longer experience evincing, that the sacrilegious light in which robbing the graves was considered did not prevent the crime, they now discontinue the ancient practice, and instead of treasure bury only painted papers and other trifles.

The two principal rivers are the Menan and the Mecon, which rise in the mountains of Tartary, and run to the south; the former passing by the city of Siam, falls into the bay of the same name, in the 13th degree of north latitude; and the latter running through Laos and Cambodia, discharges itself into the Indian ocean in the 9th degree of north latitude.

The capital of the country is Siam, called by the natives Siyothya, situated in the 101st degree of east longitude; and in the 14th degree of north latitude, being almost encompassed by the branches of the river Menan. It is about 10 miles in circumference within the walls, but not a sixth part of the ground is occupied by buildings. In the vacant spaces there are near 300 pagodas or temples, round which are gathered the convents of the priests and their burying-places. The streets of the city are spacious, and some have canals running through them, over which is a great number of bridges. The houses stand on pillars of the bamboo cane, and are built of the same materials; the communication between different families, during the winter season, being carried on as in other tropical countries by means of boats. The grounds belonging to the several tenements are separated by a pallizado, within which the cattle are housed in barns, erected likewise upon pillars, to preserve them from the annual inundation.

SIBBALDIA, in botany: A genus of plants belonging to the class of pentandria, and to the order of pentagonia; and in the natural system arranged under the 5th order, Serulinae. The corypheid is divided into ten segments. The petals are five, and are inserted into the calyx. The styles are attached to the side of the germen. The seeds are five. There are three species belonging to this genus, the procumbens, erecta, and altaica. The procumbens, or reclining fibbaldia, is a native of North Britain, having never been discovered in the southern parts of the island. It grows on Ben-Lo-
mond and Ben-Mor, within a mile of the summit. It is distinguished by a procumbent or trailing stem; by three leaves growing on the top of a small footstalk, which is trifid at the extremity, and somewhat hairy. The flowers are yellow, and blossom in July or Au-
gust.

SIBENICO, or Bibenico, the name of a city and province of Dalmatia. The province of Sibenico runs along the sea for more than 30 miles, and comprehends above 70 islands. The city of Sibenico is situated near the mouth of the river Cherca, in the Gulf of Venice, 35 miles north of Spalato, and 25 south-east of Zara. E. Long. 16° 46', N. Lat. 44° 17'. It belongs to the Venetians. It is defended on one side by a castle, which held out against repeated attacks of the Turks, and towards the sea by a fort.

SIBERIA, a large country, comprehending the most northerly parts of the Russian empire in Asia. It is bounded on the east by the eastern ocean; on the south by Great Tartary; on the west by Russia; and on the north by the Frozen Ocean. It is about 2000 miles in length from east to west, and 750 miles in breadth from north to south.

At what time this country was first inhabited, or by whom it was peopled, we are entirely ignorant: but writings have been found in it when it was discovered, which shows that it must have been early known to a civilized people. The Russians, from whom we have received our knowledge, knew nothing of it before the middle of the 16th century. In the reign of John Baslo-
witz I. indeed, an incursion was made into Siberia,
and some Tartar tribes subdued; but these conquests were not permanent; and we hear of no further communication between Russia and Siberia till the time of John Baflovitz II. It was opened again at that time by means of one Anika Strogonoff, a Russian merchant who had established some salt-works at a town in the government of Archangel. This man carried on a trade with the inhabitants of the north-west parts of Siberia, who brought every year to the town above-mentioned large quantities of the finet fur. Thus he acquired a very considerable fortune in a short time; when at last the czar, perceiving the advantages which would accrue to his subjects from having a regular intercourse with Siberia, determined to enlarge the communication which was already opened. With this view he sent into Siberia a body of troops, which afterwards was increased by Yermac, however, being soon after drowned in an unsuccessful excursion, the Russians began to lose their footing in the country. But fresh reinforcements having feanably been sent, they not only recovered their ground, but pushed their conquests far and wide; wherever they appeared, the Tartars were either reduced or exterminated. New towns were built, and colonies were planted on all sides. Before a century had well elapsed, all that vast tract of country now called Siberia, which stretches from the confines of Europe to the Eastern Ocean, and from the Frozen Sea to the present frontiers of China, was annexed to the Russian dominions.

The air of Siberia is in general, extremely piercing; the cold there being more severe than in any other part of the Russian dominions. The Siberian rivers are frozen very early, and it is late in the spring before the ice is thawed (a). If the corn does not ripen in August, there is little hope of a harvest in this country; and in the province of Jenissei it is sometimes covered with snow before the peasants can reap it. To defend the inhabitants against this extreme severity of the climate, Providence seems more liberally to have dealt out to them wood for fuel and furs for clothing. As the winter's day in the north parts of Siberia lasts but a few hours, and the storms and fakes of snow darkest in the air so much, that the inhabitants, even at noon, cannot see to do any thing without artificial lights, they sleep away the greatest part of that season at

(a) M. Gmelin, M. Muller, and two other philosophers, sat out in the 1733, to explore the dreary regions of Siberia, by desire of the empress Anne of Russia. After spending nine years and a half in observing every thing that was remarkable, they returned to Petterburgh; and an account of this journey was published by M. Gmelin. In order to examine how far the frost had penetrated into the ground M. Gmelin, on the 18th of June, at a place called Jacutia, ordered the earth to be dug in high ground; they found mould to the depth of 11 inches, under which they met with loose sand to two feet and a half further, after which it grew harder, and at half a foot deeper so hard as scarcely to give way to the tools; so that the ground still remained unthawed at not less than the depth of four feet. He made the same experiment in a lower situation; the soil was 10 inches deep, after that a loose sand for two feet and ten inches, below which all was frozen and hard. At Jacutia the inhabitants prefer use cellars several fots of berries, which they reckon among their dainties, perfectly good and fresh all the whole year, though these cellars are scarce fathom deep. At the forrest of Argun, in little more than 30 degrees of latitude, the inhabitants relate that the earth in many places is never thawed above a yard and half, and that the internal cold of the earth will scarce permit a well to be dug, of which they bring an influence that happened not long before the author's arrival at that place. They designed to sink a well near a house at some
Some distance from the river Argun, for which purpose they thawed the earth by degrees, and dug some fathoms till they had penetrated a fathom and a half below the level of the river, but found no spring. Hence perhaps we may venture to assert, that besides the great elevation of the earth in these countries, there is another cause, perhaps latent in the earth itself, of this extraordinary cold, naturally suggested to us by considering the cavity of an old silver mine at Argun, which being exhausted of its ore, now serves the inhabitants in summer time for a cellar to keep their provisions: this place is so extremely cold as to preserve flesh meats from putrefaction in the hottest summers, and to sink the mercury in de L'Ille's thermometer to 146 and 147.

The author travelling from Nerchoi towards Argun, to visit the works of the silver mines in that place, August 1735, came to the river Orkija, near Solonichaia, on July the 11th, from whence he arrived a little before dark at the village of Selventa, distant from the 27 leagues. In this journey he and his fellow travellers for more than four leagues felt it nightly cold soon after they came into a warm air, which continued some leagues; after which the cold returned; and thus are travellers subjected to perpetual vicissitudes of warmth and cold. But it is observed, in general, that the eastern parts are colder than the western, though situated in the same latitude; for as in those eastern regions some tracts of land are much colder than the west, their effects must be felt by the neighbouring parts.

And this conjecture is favoured by the thermometrical observations made with M. de L'Ille's instrument in all parts of Siberia, in which the mercury was depressed to the 226th degree, even in those parts that lie very much towards the south, as in the territory of Selengi, which paid degree answers in Fahrenheit's thermometer to about 55.5 below 0, but the same thermometer sometimes indicated a much greater cold.

At the fort of Kiringa, on Feb. 10. 1738, at 8 in the morning, the mercury stood at 249, which answers nearly to 72 below 0 in Fahrenheit's. On the 23d of the same month it was a degree lower. At the same place, December 11. at three in the afternoon, it stood at 254 in de L'Ille's thermometer, and very near 90 in Fahrenheit's; on December 29. at four in the afternoon, at 263; on November 27. at noon, at 270; January 9. at 275, which several depressions answer in Fahrenheit's to 99.44, 107.73 and 113.65; on January 5. at 5 in the morning, at 264, an hour after at 281, but at eight o'clock it returned to 256, and there remained till 6 in the afternoon; and then rose by degrees till an hour before midnight, when it stood at 202. So that the greatest depression of the mercury answers in Fahrenheit's thermometer to 120.76 degrees below 0, which is indeed very surprising, and what no body ever imagined before.

While this cold lasted at Jenifa, the sparrows and magpies fell to the ground, truck dead, as it were, with the frost, but revived if they were soon brought into a warm room. The author was told also that numbers of wild beasts were found in the woods dead and stiff with the frost, and several travellers had their blood and juices quite frozen in their veiils. The air itself at that time was so dlim, that you would think it changed to ice, as it was a thick fog, which was not dissipable by any exhalations, as in the spring and autumn, and the author could scarce stand three minutes in the porch of his house for the cold.

(a) The oak, though frequent in Russia, it is said, is not to be found through this vast region nearer than the banks of the Argun and Amur, in the dominions of China. The white poplar, the aspen, the black poplar, the common fallow, and several species of the willow, are very common. The Norway and silver fir form great forests; but the former does not grow beyond the 60th degree of north latitude, and the latter not beyond 58 degrees. To this dreary region of Siberia, Europe is indebted for that excellent species of oats called *Avena Sibirica*, and our gardens are enlivened with the gay and brilliant flowers brought from the same country.
The famous marienglas, or lapis specularis, great quantities of which are dug up in Siberia, is by some called Mufcovy or Russian glass; and by others, though with less propriety, ifnglas. It is a particular species of transparent stone, lying in strata like so many sheets of paper. The matrix, or stone in which it is found, is partly a light yellow quartz, or marcaffa, and partly a brown indurated fluid; and this stone contains in it all the species of the marienglas. To render the marienglas fit for use, it is split with a thin two-edged knife; but care is taken that the lamina be not too thin. It is used for windows and lanterns all over Siberia, and indeed in every part of the Russian empire, and looks very beautiful; its lustre and clearness surpassing that of the finest glass, to which it is particularly preferable for windows and lanterns of ships, as it will stand the explosion of cannon. It is found in the greatest plenty near the river Vitim.

Siberia affords magnets of an extraordinary size, and even whole mountains of lodestone. Pit-coal is also dug up in the northern parts of this country. The kamennoe malo, a yellowish kind of alum, im導致ous and smooth to the touch, like tophus, is found in the mountains of Krafnoiarik, Ural, Altaï, Jeniseï, Baidak, Barguzin, Lena, and several others in Siberia.

In this country are not only a great number of fresh water lakes, but likewise several whose waters are salt; and these reciprocally change their nature, the salt sometimes becoming fresh, and the fresh changing into saline. Some lakes also dry up, and others appear where none were ever seen before. The salt lake of Yarmutka, in the province of Tobolsk, is the most remarkable of all, for it contains a salt as white as snow, consisting entirely of cubic crystals. One finds also in Siberia saline springs, salt water brooks, and a hill of salt.

Siberia affords many other things which deserve notice. That useful root called rhubarb grows in vast quantities near the city of Scheginsk. The curious mammoth's bones and horns, as they are called, which are found along the banks of the Oby, Jeniseï, Lena, and Irtish, are unquestionably the teeth and bones of elephants. But whether these elephants teeth and bones were conveyed to these northern regions by the general deluge, or by any other inundation, and were by degrees covered with earth, is a point which might lead us into long and very ruinous disquisitions; we shall therefore only observe, that such bones have likewise been found in Russia, and even in several parts of Germany. A kind of bones of a still larger size than these have also been dug up in Siberia, and seem to have belonged to an animal of the ox kind. The horn of the whale called narval has been found in the earth near the rivers Indigirka and Anadir; and the teeth of another species of whales, called Wolros, about Anadirskoi. The latter are larger than the common tooth, which are brought from Greenland, Archangel, and Kola.

The chain of Siberian mountains reaches from that Mountain, of Werchoturie towards the south as far as the neighbourhood of the city of Orenburg, in a continued ridge, under the name of the Uralian mountains; but from thence it alters its direction westward. These mountains are a kind of boundary between Russia Proper and Siberia. Another chain of hills divides Siberia from the country of the Calmucks and Mongolians. These mountains, between the rivers Irtish and Oby, are called the Altai or Golden Mountains, which name they afterwards lose, particularly between the river Jeniseï and the Baïkal lake, where they are called the Sayanian mountains.

(c) The copper mines of Koliwan, from which gold and silver are extracted, employ above 40,000 people. The silver mines of Nerthinik, beyond the lake Baïkal, employ above 14,000. The whole revenue arising from these mines, according to Mr. Core, is not less than L. 697,182,138.
The inhabitants of Siberia consist of the Aborigines or ancient inhabitants, the Tartars, and Russians.

Some of these nations have no other religion but that of nature; others are Pagans or Mahometans, and some of them have been converted to Chriftianity, or rather only baptized by the Russian missionaries.

SIBITHORIA, in botany: A genus of plants belonging to the class of didyma, and to the order of angiosperma; and in the natural system claffed with those the order of which is doubtful. The calyx is spreading, and divided into five parts, almost to the base. The corolla is divided into five parts in the fame manner, which are rounded, equal, spreading, and of the length of the calyx. The flamina grow in pairs at a distance from each other. The capsule is compressed, orbicular, bilocular, the partition being tranfverfe.- flagration; and to repair the loss which the republic have delivered oracles, have been endowed with a sphere to the cla[f of fpecies, the europea and evolufa. The europea, or baldur money-wort, is a native of South Britain. The items of it are slender, and crepeeping. The leaves are small, round, and notched. The flowers grow under the wings of the leaves, are small, and of a pale red colour. It blooms from July to September, and is found in Cornwall on the banks of rivulets.

SIBYLs, in pagan antiquity, certain women faid to have been endowed with a prophetic spirit, and to have delivered oracles, showing the fates and revolutions of kingdoms. Their number is unknown. Plato speaks of one, others of two, Pliny of three, Aelian of four, and Varro of ten; an opinion which is universally adopted by the learned. These ten Sibyls generally resided in the following places, Peria, Libya, Delphi, Cumae in Italy, Erythraea, Samos, Cumae in Asia, Marape in the Hellepont, Ancony in Phrygia, and Tibirtis. The moft celebrated of the Sibyls is that of Cumae in Italy, whom some have called by the different names of Amalthea, Demiphile, Herophile, Daphne, Manto, Phemonoe, and Daphne. It is faid, that Apollo became enamoured of her, and that to make her felonble of his passion he offered to give her whatever she should ask. The Sibyl demanded to live as many years as the had grains of sand in her hand, but unfortunately forgot to ask for the enjoyment of the health, vigour, and bloom, of which she was then in possession. The god granted her request, but the refus'd to gra- fify the passion of her lover, though he offered her perpetual youth and beauty. Some time after he became old and decrepit, her form decayed, melancholy paleness and haggard looks succeded to bloom and cheerfulness. She had already lived about 700 years when Eneas came to Italy, and, as soon as he had imagined, the had three centuries more to live before her years were as numerous as the grains of sand which she had in her hand. She gave Eneas instructions how to find his father in the infernal regions, and even conducted him to the entrance of hell. It was usual for the Sibyl to write her prophecies on leaves, which she placed at the entrance of her cave; and it required particular care in such as cons- ulated her to take up these leaves before they were dif- perfed by the wind, as their meaning then became incomprehensible. According to the moft authentic his- torians of the Roman republic, one of the Sibyls came to the palace of Tarquin the Second, with nine volumes, which she offered to sell for a very high price. The monarch disregarded her, and the immediately disappeared, and soon after returned, when she had burned three of the volumes. She asked the fame price for the remaining six books; and when Tarquin refused to buy them, she burned three more, and still persisted in demanding the fame sum of money for the three that were left. This extraordinary behaviour astonifhed Tarquin; he bought the books, and the Sibyl intantly vanifhed, and never after appeared to the world. These books were preferred with great care by the monarch, and called the Sibyline verfes. A college of priefts was appointed to have the care of them; and such reverence did the Romans entertain for these prophetick books, that they were consulted with the graetefi feomnity, and only when the state feemed to be in danger. When the capi- tol was burnt in the troubles of Sylla, the Sibylline verfes which were deposited there perifhed in the con- figuration; and to repair the lofs which the republic feemed to have obtained, prieffons were immediately fen to different parts of Greece to collect whatever verfes could be found of the inspired writings of the Sibyl. The fate of three Sibylline verfes which were collected after the conflagration of the capitol is unknown. There are now many Sibylline verfes extant, but they are reckoned universally fpurious; and it is evi- dent that they were composed in the second century by fome of the followers of Chriftianity, who withed to convince the heathens of their error, by affifting the caufe of truth with the arms of pious artifice.

SICERA, a name given to any inebriating liquor by the Hellenic Jews. St Chryfoftom, Theodore, and Theophilus of Antioch, who were Syrians, and who therefore ought to know the signification and nature of sicera, assure us, that it properly signifies palm wine. Pliny acknowledges, that the wine of the palm tree was very well known through all the east, and that it was made by taking a bushel of the dates of the palm tree, and throwing them into three gallons of water; then fqueezing out the juice, it would intoxicate like wine. The wine of the palm tree is white: when it is drunk new, it has the taste of the cocoa, and is sweet as hone- ncy. When it is kept longer, it grows strong, and in- toxicates. After long keeping, it becomes vinegar.

SICILLIAN, in music, denotes a kind of gay sprightly air, or dance, probably invented in Sicily, somewhat of the nature of an English jig; usually marked with the characters, or. It consists of two • rains, the first of four, and the second of eight, bars or measures.

SICILY, is a large ifland in the Mediterranean Sea, adjoining to the southern extremity of Italy, and ex- tends from latitude 36° 25' to latitude 38° 25', and from longitude 12° 30' to longitude 16° 30' east from London. Its greatest length 270 miles, breadth 133; circumference 600; its form triangular, the three an- gles being the promontories of Pelorium, Pachynum, and Lilybium, or as they are now called the Faro, Cape Pafiaro, and Cape Boco. It is divided from Italy by the straits of Messina, reaching from the Tower of Faro, which is the moft northerly part of the ifland, to the Cape dell' Armi, or the Cape of Arms, the moft fem- th part of Calabria. These straits, by the Latins called Freium Siculum, by the Italians Il Faire di Mef- sina, and by us the Faire of Messina, are between 12 and 15 miles over in the broadest places, and in the nar- rowest about a mile and a half; infomuch that when
Mezzina was taken by the Carthaginians, many of the inhabitants are said to have faved themselves by swimming to the opposite coasts of Italy. Hence has arisen an opinion that the island of Sicily was originally joined to the continent, but afterwards separated by an earthquake or some other natural cause. This separation, however, is reckoned by the most judicious among the ancients to be fabulous; and they content themselves with speaking of it as a thing said to have happened.

Anciently this island was called Sicelica, Sicily, and Trinacria or Tritepeta; the two former it held from the Sicelians and Siculi, who peopled a considerable part of the country; the two latter from its triangular figure. Its first inhabitants, according to the most respectable ancient authors, were the Cyclopes and Lastrigones, who are said to have settled in the countries adjoining to Mount Etna; but of their origin we know nothing, except what is related by the poets. After them came the Sicelians, who called themselves the original inhabitants of the country; but several ancient historians inform us that they came from a country in Spain watered by the river Sicenus. Diodorus, however, is of opinion, that the Sicelians were the most ancient inhabitants of this island. He tells us that they were in possession of the whole, and applied themselves to cultivate and improve the ground in the neighbourhood of Etna, which was the most fruitful part of the island: they built several small towns and villages on the hills to secure themselves against thieves and robbers; and were governed, not by one prince, but each city and district by its own king. Thus they lived till Etna began to throw out flames, and forced them to retire to the western parts of the island, which they continued to inhabit in the time of Thucydides. Some Trojans, after the destruction of their city, landed in the island, settled among the Sicelians, and built the cities of Eryx and Egela, uniting themselves with them, and taking the general name of Elymni or Elymnes. They were afterwards joined by some Phoenicians, who settled here on their return from the siege of Troy.

After the Sicelians had for many ages enjoyed an undisturbed possession of the whole of Sicily, or such parts of it as they chose to inhabit, they were visited by the Siculi, who were the ancient inhabitants of Aetolia, properly so called; but being driven out from thence by the Opici, they took refuge in the island of Sicily. Not being contented with the narrow bounds allowed them by the Sicelians, they began to encroach upon their neighbours; upon which a war ensuing, the Sicelians were utterly defeated, and confined to a corner of the island, the name of which was now changed from Sicelica into that of Sicily.

About 300 years after the arrival of the Siculi, the island first began to be known to the Greeks, who established various colonies, and built many cities in different parts of the island; and it is only from the time of their arrival that we have any history of the island. The first of the Greeks that came into Sicily were the Chalcidians of Euboea, under the conduct of Thucylides, who built Naxus, and a famous altar of Apollo, which, as Thucydides tells us, was still standing in his time without the city. The year after, which was according to Dionysius Halicarnassensis, the third of the 17th Olympiad, Archias the Corinthian, one of the Heraclids, laid the foundations of Syracuse. Seven years after, a new colony of Chalcidians founded Leontini and Catana, after having driven out the Siculi, who inhabited that tract. About the same time Lamis, with a colony from Megara, a city of Achaia, settled on the river Fantanuse, at a place called Trotilus, where his adventurers lived some time in common with the Chalcidians of Leontini; but, being driven from thence by the Leontines, he built the city of Thaples, where he died. Upon his death, the colony left Thaples; and under the conduct of Hyblon king of the Siculi, founded Megara Hyblae, where they resided 245 years, till they were driven out by Gelon tyrant of Syracuse. During their abode at Megara, they sent one Pambus, who was come from Megara in Achaia, their original city, to build Selinus. This city was founded about 100 years after the foundation of Megara. Antiphenes and Eunimus, the former a Rhodian, the other a Creton, led each a colony of their countrymen, and jointly built the city of Gela on a river of the same name, establishing in their new settlement the Doric customs, about 45 years after the founding of Syracuse. The inhabitants of Gela founded Argentum 108 years after their arrival in Sicily, and introduced the same customs there. A few years after, Zancle was built by the pirates of Cumæ in Italy; but chiefly peopled by the Chalcidians, Samians, and Ionians, who chose rather to seek new settlements than live under the Periptan yoke. Some time after, Anaxiales, tyrant of Rhegium, drove out the ancient proprietors; and, dividing his lands amongst his followers, called the city Mezzina or Megale, which was the name of his native city in Peloponnesus. The city of Himera was founded by the Zancleans under the direction of Euclides, Simus, and Soclon; but peopled by the Chalcidians and some Syracusan exiles, who had been driven out by the contrary faction.

The Syracusans built Acer, Chalinna, and Camarina; the first 70 years, the second 90, and the third 135, after the foundation of their own city. This is the account which Thucydides, a most judicious and exact writer, gives us of the various nations, whether Greeks or Barbarians, who settled in Sicily. Strabo counts among the ancient inhabitants of Sicily the Mortgetes, who being driven out of Italy by the Oenotrians, settled in that part of the island where the ancient city of Morgantina stood. The Campanians, who assumed the name of Mamertina, that is, invincible warriors, and the Carthaginians, who settled very early in Sicily, ought likewise to be counted among the ancient inhabitants of the island.

Before this period the history of Sicily is blended with fables like the early history of almost every other country. After the settlement of the Greeks in the island, its various revolutions have been traced by their several sources by many writers; but by none with greater accuracy than Mr Swinburne. From his account of his Travels in the Two Sicilies, we have therefore taken the following concise history of this kingdom, which will at once gratify such of our readers as are interested in the fate of a generous people who long struggled in vain for freedom; and at the same time afford them a specimen of the entertainment they may receive from the very elegant work of the author.

3 Greek colonies in Sicily.

4 Carthaginians conquer great part of it.

5 Gelo chosen king.

6 Is succeeded by Hiero.

7 Dionysius the elder and younger.

8 Agathocles.

9 Pyrrhus.

10 The Mamertini, whose Mr Swinburne indignantly styles a crew of miscreants, furnishes Melfina, and, after a general massacre of the citizens, established a republican form of government. Their commonwealth became to troubleform a neighbour to the Greeks, that Hiero II. who had been raised to the chief command at Syracuse in consideration of his superior wisdom and warlike talents, found himself necessitated to form a league with Carthage, in order to destroy this nett of villains. In their defense the Mamertini implored the assistance of Rome, though the Senate had recently punished with exemplary severity one of their own legions for a similar outrage committed at Rhegium. The troops of the Romans gave way to the temptation, and the desire of extending their empire beyond the limits of Italy, called a veil over every odious circumstance attending this alliance. A Roman army crossed the Faro, relieved Melfina, defeated the Carthaginians, and humbled Hiero into an ally of the republic.

Thus began the first Punic war, which was carried on for many years in Sicily with various успехі. The genius of Hamilcar Barca supported the African cause under numberless disappointments, and the repeated overthrows of his colleagues. At last, finding his exertions

SIC [458] SIC

He was succeeded by his son Simon, whose reign was short, and made way for a second son called Roger. In 1127 this prince joined to his Sicilian possessions the whole inheritance of Robert Guiscard (see Naples, dominion 23), and assumed the regal style. The greater part of his reign was taken up in quelling revolts in Italy mainly, but Sicily enjoyed profound peace. In 1154, his son William ascended the throne, and passed his life in war and confusion. William II succeeded his father, and died without issue. Tancered, though badly born, was elected his successor, and after him his son William III, who was vanquished by Henry of Swabia. During the troubles that agitated the reign of his son the emperor Friedrich, peace appears to have been the lot of Sicily. A short lived feudation, and a revolt of the Saracens, are the only commotions of which we read. For greater security, the Saracens were removed to Puglia 400 years after the conquest of Sicily by their ancestors. Under Conrad and Manfred Sicily remained quiet; and from that time the history of Sicily is related under the article Naples, no. 26, 80.

At the death of Charles II, of Spain, his spoils, became an object of furious contention among the princes of Europe. Sicily was ceded to Victor duke of Savoy, by the Spanish, who, not many years after, was forced by the emperor Charles VI. to relitig that fine island, and take Saragossa as an equivalent. But as the Spaniards had no concern in these belligerent, they made a sudden attempt to recover Sicily, in which they failed through the vigilance of the English admiral Bligh. He destroyed their fleet in 1718, and compelled them to drop their scheme for a time. In 1734 the Spanish court resumed their designs with success. The inf. Don Carlos drove the Germans out, and was crowned king of the two Sicilies at Palermo. When he passed into Spain to take possession of that crown, he transferred the Sicilian dominions to his son Ferdinand III. of Sicily and IV. of Naples, and it has ever since remained in the possession of the same family.

Sicily is separated, as we have already observed, from Italy by a narrow strait called the Form of Messina. This strait is still remarkable for the rapidity of its currents of Messina, and the irregular ebbing and flowing of the sea, which sometimes rushes in with such violence as to endanger ships riding at anchor. Anciently it was much more remarkable for Scylla and Charybdis, the one a rock, and the other a whirlpool, between which it was very dangerous to steer, and concerning which so many fables have been related by the ancients. Scylla is a rock on the Italian side, opposite to Cape Pylees, which runs out into the sea on the Sicilian side. Mr. Blaydon informs us, that the navigation of the strait is not even yet performed without danger. He informs us, that the gulf of the current which flows through the strait may be heard for several miles, like the roaring of some large impetuous river confined between narrow banks. In many places the water roves into whirlpools and eddies, which are dangerous to shipping. The current sets exactly for the rock of Scylla, and would certainly have carried any thing thrown into it against that point. Our author, however, is by no means of opinion that the strait is so dangerous as the ancients have represented it; though he thinks that the strait is now probably much wider than formerly, which may have diminished the danger. See Scylla. There are many small rocks, which,
Of the mountains in this island the most noted is Mount Etna, now called Monte Gisello or Mongiello, a volcano whose eruptions have often proved fatal to the neighbouring country.

Were the Sicilians a cultivated people, among whom those arts were encouraged which not only promote the wealth and comfort of a nation, but also exercise the nobler faculties and extend the views of mankind, the circumstances of their government are such, that it might gradually be improved into a free constitution; but to this, the ignorance, superstition, and poverty, of the people seem to be insurmountable obstacles. The monarchical power in Sicily is far from being absolute; and the parliament claims a share of public authority independently of the will of the king, deduced from a compact made between Roger and the Norman barons after the expulsion of the Saracens. This claim is denied by the king, who wishes the nobles to consider their privileges as derived solely from his favour. Hence the government is in a situation which greatly resembles that of England and the other kingdoms of Europe in the feudal times; there are continual jealousies and oppositions between the king and the barons, of which an enlightened people might easily take advantage, and obtain that share in the constitution which might secure them from future oppression. In these disputes, the king has the advantage at least of power if not of right; and several works, in which the claims of the Sicilian barons have been asserted, were publicly burned a few years ago.

As the sovereign holds his court at Naples, Sicily is governed by a viceroy, who is appointed only for three years, though at the end of that term his commission is sometimes renewed. He lives in great state, and, as the representative of the king, his power is very considerable. He precludes in all the courts and departments of government, and is commander in chief of all the forces: he calls or dissolves the parliament when he pleases; and by him all orders, laws, and sentences, must be signed: but his office is far from being desirable, as it generally renders him the object either of the jealousy of the court of Naples, or of the hatred of the Sicilians.

The parliament consists of the nobles, the bishops, and abbots, and the representatives of 43 cities, which are immediately subject to the crown. Those cities which are subject to any of the nobles send no members to the parliament; in these the king has not much authority, and derives little advantage from them. According to the laws, the parliament ought to be assembled at the end of every three years; but the government pays little attention to this rule. The common people are in general very much attached to the nobles, and are inclined to take their part in all their differences with the court; but the magistrates and principal inhabitants of the cities which belong to their feudal lords, with to get rid of their authority, and imagine that they should be left oppressed, if immediately subject to the king; these inclinations are not difficult to the court, and are encouraged by most of the lawyers, who are of great service to government in contending the privileges of the nobles. Many of these privileges are now abridged; and the power of the barons, with respect to the administration of justice in their domains, was very properly limited by the viceroy Caracciolo.
The government of this nobleman was very beneficial to Sicily, as he, in a great measure, cleared the island of the banditti that used to infest it, and made several excellent Regulations for the establishment of social order and personal security. He deserves the thanks of every well-disposed to mankind for having abolished the court of inquisition, which had been established in this country by Ferdinand the Catholic, and made dependent on the authority of the grand inquisitor of Spain. Its last auto da fé was held in the year 1724, when two persons were burned. At length Charles III. rendered it independent of the Spanish inquisitor, and abridged its power, by forbidding it to make use of the torture, and to inflict public punishment. The Marchese Turracci, and his successor the Marchese Tanucci, were both enemies to the hierarchy; and, during their viceregalities, took care to appoint sensible and liberal men to the office of inquisitor: the latter of whom was Ventimiglia, a man of a most humane and amiable character, who heartily wished for the abolition of this diabolical court, and readily contributed toward it. While he held the office of inquisitor, he always endeavored to procure the acquittal of the accused; and when he could succeed no other way, would pretend some informality in the trial. The total abolition of this instrument of the worst tyranny was revered for Caraccioli. A priest being accused to the inquisition, was dragged out of his house and thrown into the dungeon. He was condemned; but, on account of informality, and a violation of justice in the trial, he appealed to the viceroy, who appointed a committee of jurists to examine the proofs. The inquisitor refused to acknowledge the authority of this commission; pretending that to expose the secrets of the holy office, and to submit its decisions to the examination of lay judges, would be so inconsistent with his duty, that he would see the inquisition abolished rather than content it. Caraccioli took him at his word, and procured a royal mandate by which the holy office was at once annihilated. He assembled all the nobility, judges, and bishops, on the 27th of March 1782, in the palace of the inquisition, and commanded the king’s order to be read; after which he took possession of the archives, and caused all the prison to be set open: in these were at that time only two prisoners, who had been condemned to perpetual confinement for witchcraft. The papers relating to the finances were preserved; but all the rest were publicly burned. The positions of the holy office were assigned to the use of churches and charitable institutions; but the officers then belonging to it retained their salaries during their lives. The palace itself is converted into a Colbert House, and the place where heretics were formerly roasted alive for the honour of the Catholic faith, is now changed into a public garden. The cognizance of offences against orthodoxy is committed to the bishops: but they cannot cite any one to appear before them without permission from the viceroy; neither can they confine any person to a solitary prison, nor deny him the privilege of writing to his friends, and conversing freely with his advocate. The nobility are so numerous in this island, that Labat says it is paved with noblemen. The general assembly of parliament is composed of 66 archbishops, bishops, abbots, and priors, which form the Braccio eclesiastico.

SIC [460] SIC

Abolished by Caraccioli.

Fifty-eight princes, 27 dukes, 27 marquises, 27 counts, 1 viscount, and 79 barons, form the militia; and the demanial confides of 43 representatives of free towns. Out of each braccio four deputies are chosen to conduct public business. But the viceroy, the prince of Butera, and the praetor of Palermo, are always the three first. N. B. There are many titled persons that have no seat in the assembly, viz. 62 princes, 55 dukes, 87 marquises, 1 count, and 282 other feudatories. There are three archbishops and seven bishops; and the island, ever since it was conquered by the Saracens, has been divided into three parts or valleys; namely, the Val di Dracce, Val di Noto, and Val di Mazara.

SICINNIUS (Denatus), a tribune of the people, lived a little after the expulsion of the kings from Rome. He was in 120 battles and skirmishes, besides single combats, in all of which he came off conqueror. He served under nine generals, all of whom triumphed by his means. In three of their battles he received 45 wounds in the fore-part of his body, and not one in his back. The senate made him great presents, and he was honoured with the name of the Roman Achilles.

SICYOS, in botany: A genus of plants belonging to the class of monocotyledon, to the order of Jyngeena; and in the natural system arranged under the 34th order, Cucurbitaceae. The male flowers have their calyx quinquedentato, their corolla quinquapartite, and there are three filaments. The female flowers have their calyx and corolla similar; but their style is trident, and their drupa monomero. There are three species, the anguifata, laxiflata, and garcini, which are all foreign plants.

SIDA, fellow or Indian Mustard, in botany: A genus of plants belonging to the class of monadophia, and to the order of polyantra; and in the natural system ranging under the 37th order, Compositae. The calyx is simple and angulate; the style is divided into many parts; there are several capsules, each containing one seed. There are 27 species. 1. The Spinoa; 2. Anguifolia; 3. Alba; 4. Rhombifolia; 5. Almisfolia; 6. Cirtis; 7. Retusa; 8. Triguetra; 9. Jamaica; 10. Carpinifolia; 11. Viscifolia; 12. Cordifolia; 13. Umbelcit; 14. Paniculata; 15. Arostigenuea; 16. Pericifolia; 17. Urens; 18. Arborosa; 19. Occidentalis; 20. Americana; 21. Abutilon; 22. Mauritiana; 23. Alatica; 24. Indica; 25. Cripta; 26. Criptiflata; 27. Ternata. The first 18 species have 15 capsules; the rest are multipapular. They are all natives of warm climates; and most of them are found in the East or West Indies.

The Chinese make cords of the fida abutilon. This plant loves water, and may be advantageously planted in marshes and ditches, where nothing else will grow. From experiments made by the Abbé Cavannilles, a Spaniard, which are inserted in the Mem. de l’Aca.d. Roy., it appears that the plants succeed best when sown in May, and they arrive at perfection in three months and a half. The maceration of the smaller stalks is finished in about 15 days; of the larger in a month. The strength and goodness of the thread appeared to be in proportion to the perfection of the vegetation, and to the distance the plant was kept at from other plants. The fibres lie in strata, of which there are some times six; they are not quite straight, but preserve an undulating direction, so as to form a network in their natu-
SIDDEE, or Sede; an Arabic title, by which the Abyssinians or Habalys are always distinguished in the courts of Hindostan; where, being in great repute for firmness and fidelity, they are generally employed as commanders of forts or in polls of great trust.

SIDEREAL YEAR. See Astronomy-Index.

SIDERIA, in natural history, the name of a genus of crytals, used to express those altered in their figure by particles of iron. These are of a rhomboidal figure, and composed only of six planes. Of this genus there are four known species. 1. A colourless, pellucid, and thin one; found in considerable quantities among the iron ores of the forest of Dean in Gloucestershire, and in several other places. 2. A dull, thick, and brown one; not uncommon in the same places with the former. And, 3. A black and a very glossy kind, a foil of great beauty; found in the same place with the others, as also in Leicestershire and Suff.ck.

SIDERITE, a substance discovered by Mr. Meyer, and by him supposed to be a new metal; but Meffrs. Bergman and Kirwan have discovered that it is nothing else than a natural combination of the phosphoric acid with iron. Mr. Klaproth of Berlin also came to the same conclusion, without any communication with Mr. Meyer. It is extremely difficult to separate this acid from the metal; however, he found the artificial compound of phosphoric acid and iron to agree in its properties with the calx sideri alba obtained by Bergman and Meyer from the cold-short iron extracted from the swampy or marshy ores. The discovery of this substance, however, may be accounted an important affair in chemistry, as we are thus furnished with an immense quantity of phosphoric acid, which might be applied to useful purposes if it could be separated from the metal.

SIDERITIS, IRONWORT, in botany: A genus of plants belonging to the class of didynamia, and to the order of gynoipermia; and in the natural system ranging under the 43d order, Verticillata. The flamina are within the tube of the corolla. There are two rigmas, one of which is cylindrical and concave; the other, which is lower, is membranous, shorter, and theathing the other. The species are 1. The Canariensis, or Canary ironwort, which is a native of Madeira and the Canary islands; 2. The Candicans, which is also a native of Madeira; 3. The Syriaca, a native of the Levant; 4. The Perfilata, a native of the Levant; 5. The Montana, a native of Italy and Aulia; 6. The Elegans; 7. The Romana, a native of Italy; 8. The Iucana, a

native of Spain; 9. The Hyphipillo, a native of Italy and the Pyrenees; 10. The Scordioides, a native of the south of France; 11. The Hirutia, which is indigenous in the south of Europe; 12. The Clasta; 13. The Lanata.

SIDEROXYLON, Iron-wood, in botany: A genus of plants belonging to the class of pentandria, and to the order of monogynia; and in the natural system ranging under the 43d order, Dumpy. The corolla is cut into 10 parts, the laciniae or segments being inclosed alternately; the stigma is simple; the berry contains five seeds. There are several species.

SIDNEY, Sir Philip, was born, as is supposed, at Penhurst in Kent in the year 1554. His father was Sir Henry Sidney, an Irish gentleman, and his mother, Mary the eldest daughter of John Dudley duke of Northumberland. He was sent when young to Christchurch college at Oxford, but left the university at 17 to set out on his travels. After visiting France, Germany, Hungary, and Italy, he returned to England in 1575, and was next year sent by Queen Elizabeth as her ambassador to Randolph emperor of Germany. On his return he visited Don John of Austria, governor of the Netherlands, by whom he was received with great respect. In 1579, when Queen Elizabeth seemed on the point of concluding her long projected marriage with the duke of Anjou, Sir Philip wrote her a letter, in which he dissuaded her from the match with unusual elegance of expression, as well as force of reasoning. About this time a quarrel with the earl of Oxford occasioned his withdrawing from court; during which retirement he is supposed to have written his celebrated romance called Arcadia.

In 1585, after the queen's treaty with the United States, he was made governor of Flushing and master of the horse. Here he distinguished himself so much both by his courage and conduct, that his reputation rose to the highest pitch. He was named, it is pretended, by the republic of Poland as one of the competitors for that crown, and might even have been elected had it not been for the interference of the queen. But his illustrious career was soon terminated; for in 1586 he was wounded at the battle of Zutphen, and carried to Antwerp, where he soon after died. His body was brought to London, and buried in St Paul's cathedral. He is described by the writers of that age as the most perfect model of an accomplished gentleman that could be formed even by the wanton imagination of poetry or fiction. Virtuous conduct, polite conversation, heroic valour,
lour, and elegant erudition, all concurred to render him the ornament and delight of the English court; and as the credit which he enjoyed with the queen and the earl of Leicester was wholly employed in the encouragement of genius and literature, his praises have been transmitted with advantage to posterity. No person was so low as not to become an object of his humanity. After the battle of Zutphen, while he was lying on the field mangled with wounds, a bottle of water was brought him to relieve his thirst; but observing a woe­der near him in a like miserable condition, he said, This man's necessity is still greater than mine: and resigning to him the bottle of water. Besides his Arcadia, he wrote several smaller pieces both in prose and verse, which have been published.

Sidney (Algernon), was the second son of Robert earl of Leicester, and of Dorothy elder daughter of the earl of Northumberland. He was born about the year 1584. During the civil wars he took part against the king, and distinguished himself as a colonel in the army of the parliament. He was afterwards appointed one of king Charles's judges, but declined appearing in that court. During the usurpation of Cromwell, Sidney, who was a violent republican, retired to the country, and spent his time in writing those discourses on government which have been so deservedly celebrated. After the death of the Protector, he again took part in the public transactions of his country, and was abroad on an embassy to Denmark when king Charles was re­stored. Upon this, he retired to Hamburg, and afterwards to Francfort, where he resided till 1657, when he returned to England and obtained from the king a pardon. It has been affirmed, but the story deserves no credit, that during his residence abroad king Charles hired ruffians to affright him. After his return he made repeated attempts to procure a seat in parliament but all of them proved unsuccessful. After the intention of the commons to exclude the duke of York from the throne had been defeated by the sudden dissolution of parliament, Sidney joined with egerneus the councils of Ruflol, Elfex, and Moumouth, who had resolved to oppose the duke's succession by force of arms. Fre­quent meetings were held at London; while, at the same time, a fleet of subordinated conspirators, who were not, however, admitted into their confidence, met and embraced the most desperate resolutions. Keithing, one of these men, discovered the whole conspiracy; and Algernon Sidney, together with his noble associates, was immediately thrown into prison, and no art was left unattempted in order to involve them in the guilt of the meaner conspirators.

Howard, an abandoned nobleman, without a single spark of virtue or honour, was the only witness against Sidney; but as the law required two, his discourses on government, found unpublished in his closet, were conse­quently tried as treason, and declared equivalent to another witness. It was in vain for Sidney to plead that papers were no legal evidence; that it could not be proved they were written by him; and that if they were, they contained nothing treasonable. The defence was over-rulled; he was declared guilty, condemned, and exe­cuted! His attainder was reversed in the first year of king William.

He was a man of extraordinary courage; steady even to obstinacy; of a sincere but rough and boisterous temper. Though he professed his belief in the Christian religion, he was an enemy to an established church, and even, according to Burnet, to every kind of public worship. In his principles he was a zealous republican: government was always his favourite study; and his effo­rds on that subject are a proof of the progress which he made.

Sidon, or Sido, an ancient city of Phoenicia in Asia, famous in Scripture for its riches, arising from the exten­sive commerce carried on by its inhabitants. Heavy judgments were denounced against the Sidonians in account of their wickedness, which were accomplished in the time of Ochus king of Peræa: for that monarch having come against them with an army on account of their rebellion, the city was betrayed by its king; upon which the wretched inhabitants were seized with despair; they set fire to their houses, and 40,000, with their wives and children, perished in the flames.

This city is now called Saida, and, according to Mr Bruce's account, not only its harbour is filled up with fand, but the pavement of the ancient city stood 71 feet lower than the ground on which the present city stands. Volney describes it as an ill-built dirty city. Its length along the sea-shore is about 600 paces, and its breadth 150. At the north­west side of the town is the castle, which is built in the sea itself, 60 paces from the main land, to which it is joined by arches. To the west of this castle is a foreshore 15 feet high above the sea, and about 200 paces long. The space between this foreshore and the castle forms the road, but vessels are not safe there in bad weather. The foreshore, which extends along the town, has a baftion inclosed by a decayed pier. This was the ancient port; but it is so choked up by fand, that boats alone can enter its mouth near the castle. Frak-er-din, emir of the Druses, destroyed all the little ports from Bairout to Acre, by sinking boats and ftones to prevent the Turkish ships from entering them. The bafton of Saida, if it were emptied, might contain 20 or 25 small vessels. On the side of the sea, the town is absolutely without any wall; and that which encloses it on the land side is no better than a prifer wall. The whole artillery does not exceed six cannons, and these are without carriages and gomers. The gar­rison scarcely amounts to 100 men. The water comes from the river Aoula, through open canals, from which it is fetched by the women. These canals serve also to water the orchards of mulberry and lemon trees.

Saida is a considerable trading town, and is the chief emporium of Damascus and the interior country. The French, who are the only Europeans to be found there, have a consul, and five or six commercial houses. Their exports consist in silks, and particularly in raw and spun cottons. The manufacture of this cotton is the principal art of the inhabitants, the number of whom may be estimated at about 5000. It is 45 miles west from Damas­cus. E. Long. 36°. 5'. N. Lat. 37°.

Sidus Georgium, in astronomy, a new primary planet, discovered by Dr Hertouch in the year 1781. By mon­tage foreign, and even by some British philosophers, it is known by the name of Hefchel; an honour which is due to the discoverer. As the other planets are distin­guished by marks or characters, the planet Hertoulch is distinguished by an H, the initial letter of the disco­verer's name, and a cross to show that it is a Christian planet. From many calculations of our best astronom­ers
### SEIGE

**Siege of Siena.**

Siena, in the art of war, is to surround a fortified place with an army, and approach it by passages made in the ground, so as to be covered against the fire of the place.

**Siegen.** A town of Germany in Wetteravia, with a castle and the title of a principality, which it gives to a branch of the house of Nassau. It is seated on a river of the same name in E. Long. 8° 5'. N. Lat. 50° 57'.

**Sienna.** A large, ancient, and celebrated city of Tuscany in Italy; capital of the Siennese, with an archbishop's see, a famous university, and a citadel. It is about four miles in circumference, and surrounded with an old wall. The metropolitan church is much esteemed by travellers; and though it is a Gothic structure, the architecture is admirable. It is built with black and white marble, and the pavement is of Mosaic work. The town is adorned with a great number of palaces, fountains, and superb churches, as also a magnificent hospital. The great area is round, and the houses about it are of the same height, supported by piazzas, under which people may walk in hot or rainy weather; in the middle is a bason, which can be filled with water at any time, to represent a sea-fight with small vessels. The Italian language is taught here with such purity, that a great many foreigners frequent it in that account. It is seated on three eminences, in tertié soil, in E. Long. 11° 11'. N. Lat. 43° 10'.

**Siennese.** A duchy in Italy; bounded on the north by the Florentino, on the south by the Mediterranean sea and the duchy of Calabria, on the east by the Pentingino and Ovietano, and on the west by the Florentino and the Tuscan sea; being about 55 miles in length, and as much in breadth. The soil is pretty tertié, especially in mulberry trees, which feed a great number of silk-worms; and there are several mineral springs. Siena is the capital town.

**Sierra Leona.** A large country on the west coast of Africa, which some extend from the Grain Coast on the south, east to Cape Verga or Vega on the north-west, i.e. between 7° and 16° N. Lat. Others, however, confine the country between Cape Verga and Cape Tagrin. There runs through it a great river of the same name, of which the source is unknown, but the mouth is in longitude 12° 30'. west lat. 8° 5'. north, and is nine miles wide. The climate and soil of this tract of country appear to be, on both sides of the river, among the best in Africa, or at least the most favourable to European constitutions. The heat is much the same as that of the West Indies; but on the higher grounds there is a cool sea breeze, and in the mountainous parts the air is very temperate. According to Lieutenant Matthew, "Sierra Leona, if properly cleared and cultivated, would be equal in fertility and superior in produce to any of the islands in the West Indies;" and others have affirmed, that "the air is better for a man's health than in many places of Europe." These advantages of climate induced the English to establish a factory at Sierra Leona; but they chose not the most healthful situation. For the benefit of a spring of good water they fixed their residence in a low valley, which is often overspread with mists and noisome vapours, while the air is clear and serene on the summits of the hills, to which water from the well might be easily carried.

The animal productions of this country are lions, from which it has its name; leopards, hyenas, musk-cats, and many kinds of weasels; the jimpanze or chimpanzee, a species of simia, which has a still more striking resemblance to the human figure than even the orang outang; porcupines, wild hogs, squirrels, and antelopes. Besides these, which are natives of the country, oxen thrive in it, and even grow fat; oysters are employed in labour, and do not suffer by the climate; but sheep suffer much from the heat, change their wool into hair, grow lean and increase very little; while the hardy goat is here as prolific and large as in any other country. Of the birds which frequent the woods of Sierra Leona we can give no perfect account. A species of crane in mentioned as easily tamed; common poultry multiply fast; ducks thrive well, but geese and turkeys seem not to agree with the climate. Turkeys of all kinds are very common, and sometimes of a large size. Crocodiles or alligators of a non-descript species have been found ten or twelve feet in length, and lizards of six different species. Snakes, which are almost innumerable, haunt the houses in the night in search of poultry; and one was observed with measured 18 feet, but was happily found not to be venomous. Fishes are in great variety both in the sea and in the river. Besides the white, the shark, flunging ray, and porpoise, there are eels, horse-mackerel, tarpons, cavillons, mullets, snappers, yellow-tails, old-maid's, ten-pounders, and some other fishes, all of which, except the eels and ten-pounders, are esteemed fine eating. Oysters are found in great abundance, and another shellfish, which the natives eat. Among the zoophites, none is more worthy of notice than the common sponge, which covers all the sandy beaches of the river, particularly on the Bullock shore, and would fetch a high price in Great Britain.

Of the numerous vegetable productions of Sierra Leona, our limits will permit us only to mention the following. Rice, which is the plant chiefly cultivated, as the natives habitually upon it, grows both...
It prospers indeed best in swamps, though the grain is better in a drier soil. Next to rice the caffado constitutes the chief food of the inhabitants, and is cultivated with great care. The country likewise produces yams, various kinds of potatoes, eddoes, or the arum esculentum. Oil-palm, plantains, and bananas; papaw, guava, oranges and limes; pomelons, melons, and cucumbers; pine-apples, peaches, which dressed like English peas are a good pulse; maize or Indian corn; milk, of which the tallow-tree; nutmeg, yields a fine white juice resembling sugar or molasses, and gums, of great value; cotton, of which the indigo, rape contains with them a friendly intercourse, and a commerce for a better purpose. The king of the island and his neighbours were conducted by the council to another colony founded on the globe, the time, and by the education of children. But no person was to be tried by jury, as well as others; and the council was directed to allot to the blacks employments suited to their present abilities, and to afford them every opportunity of cultivating their talents. All practicable means of maintaining their situation were directed to be used; and the council was especially instructed to promote religion and morals, by supporting public worship and the due observance of the Sabbath, and by the instruction of the people, and the education of children. But no person was to be prevented from performing or attending religious worship in whatever place, time, or manner, he might think fit, or from peaceably inculcating his own religious opinions. Orders were given in choosing the site of a town, to consider health as the first object; and the first town was directed to be called Free Town. Articles for building and cultivation were sent out, besides the cargoes for prosecuting the company's commerce; and schools for reading, writing, and accounts were ordered to be set up for the purpose of instructing the children of such natives as should be willing to put them under the company's care. The leading object of the company was to sublimate, for that disgraceful traffic which has too long fulfilled a fair

The directors having stated the natural advantages of Sierra Leone, and its present miserable condition, observed, that they had not merely to establish a commercial factory, but that, to introduce civilization, cultivation, and a sale trade, the company must provide for the security of the persons and property of the colony. The directors therefore resolved, that three or four vessels should sail at once, with such a number of people as would be able to protect and assist each other; with goods both for trade and for the supply of the colony. Accordingly several vessels failed, having on board a council for the government of the colony and the management of the company's affairs; a number of artists and other servants of the company, some soldiers, and a very few English settlers. The directors were ludicrously cautious in the choice of colonists. They admitted into the society no white man of bad character, or who was not a declared enemy to the slave-trade; and as the chief object of their enterprise was the civilization of the natives, it was with great propriety that they chose more than three-fourths of their settlers from the free negroes in Nova Scotia, who had borne arms for the British government during the American war. The superintendent and council were particularly instructed to secure to all blacks and people of colour, at Sierra Leone, equal rights and equal treatment, in all respects, with whites. They were to be tried by jury, as well as others; and the council was directed to allot to the blacks employments suited to their present abilities, and to afford them every opportunity of cultivating their talents. All practicable means of maintaining their situation were directed to be used; and the council was especially instructed to promote religion and morals, by supporting public worship and the due observance of the Sabbath, and by the instruction of the people, and the education of children. But no person was to be prevented from performing or attending religious worship in whatever place, time, or manner, he might think fit, or from peaceably inculcating his own religious opinions. Orders were given in choosing the site of a town, to consider health as the first object; and the first town was directed to be called Free Town. Articles for building and cultivation were sent out, besides the cargoes for prosecuting the company's commerce; and schools for reading, writing, and accounts were ordered to be set up for the purpose of instructing the children of such natives as should be willing to put them under the company's care. The leading object of the company was to sublimate, for that disgraceful traffic which has too long fulfilled a fair

The directors having stated the natural advantages of Sierra Leone, and its present miserable condition, observed, that they had not merely to establish a commercial factory, but that, to introduce civilization, cultivation, and a sale trade, the company must provide for the security of the persons and property of the colony. The directors therefore resolved, that three or four vessels should sail at once, with such a number of people as would be able to protect and assist each other; with goods both for trade and for the supply of the colony. Accordingly several vessels failed, having on board a council for the government of the colony and the management of the company's affairs; a number of artists and other servants of the company, some soldiers, and a very few English settlers. The directors were ludicrously cautious in the choice of colonists. They admitted into the society no white man of bad character, or who was not a declared enemy to the slave-trade; and as the chief object of their enterprise was the civilization of the natives, it was with great propriety that they chose more than three-fourths of their settlers from the free negroes in Nova Scotia, who had borne arms for the British government during the American war. The superintendent and council were particularly instructed to secure to all blacks and people of colour, at Sierra Leone, equal rights and equal treatment, in all respects, with whites. They were to be tried by jury, as well as others; and the council was directed to allot to the blacks employments suited to their present abilities, and to afford them every opportunity of cultivating their talents. All practicable means of maintaining their situation were directed to be used; and the council was especially instructed to promote religion and morals, by supporting public worship and the due observance of the Sabbath, and by the instruction of the people, and the education of children. But no person was to be prevented from performing or attending religious worship in whatever place, time, or manner, he might think fit, or from peaceably inculcating his own religious opinions. Orders were given in choosing the site of a town, to consider health as the first object; and the first town was directed to be called Free Town. Articles for building and cultivation were sent out, besides the cargoes for prosecuting the company's commerce; and schools for reading, writing, and accounts were ordered to be set up for the purpose of instructing the children of such natives as should be willing to put them under the company's care. The leading object of the company was to sublimate, for that disgraceful traffic which has too long fulfilled a fair
a fair commerce with Africa, and all the blessings which might be expected to attend it. Considerable advantages appeared hereby likely to result to Great Britain, not only from its obtaining several commodities cheaper, but also from opening a market for British manufactures, to the increasing demands of which it is difficult to assign a limit. From this connection, Africa was likely to derive the still more important benefits of religion, morality, and civilization. To accomplish these purposes, it was necessary for the company to possess a tract of land, as a repository for their goods, and which the Africans might cultivate in peace, secure from the ravages of the slave trade. It had been ascertained, beyond a doubt, that the climate and soil of Africa were admirably suited to the growth of sugar, spices, coffee, cotton, indigo, rice, and every other species of tropical produce. The company proposed to instruct the natives to raise these articles, and to let them the seaman, by a spirited cultivation, on its own count. Directions were given to the company's commercial agent to push forward a trade, in a mode prescribed, in the present produce of Africa. Measurers were taken for cultivating, on the company's account, the most profitable tropical produce; and in particular, a portion of long experience in the West Indies was ordered to begin a sugar plantation. A mineralogist and botanist were likewise engaged to go out and explore the country for new articles of commerce.

"Everything being thus settled upon the most equitable and benevolent principles, the ships sailed with the British colonists, to whom, in March 1792, were added 1131 blacks from Nova Scotia. The native chiefs being reconciled to the plan, and made to understand its beneficial tendency towards their people, the colony proceeded to build Free-Town, on a dry and rather elevated spot on the fourth side of the river. It occupied between 70 and 80 acres, its length being about one third of a mile, and its breadth nearly the same; and it contained near 400 houses, each having one-twelfth of an acre annexed, on which a few vegetables were raised. There were nine streets running from north-west to south-east, and three crofs streets, all 80 feet wide, except one of 150 feet, in the middle of which were all the public buildings. These consisted of a governor's house and offices; a large store-house; a large hospital; six or eight other houses, offices, and shops, occupied by the company's servants; and a church capable of containing 800 people. The colonists at first suffered much from the rainy season, against which it was not in their power to provide sufficient protection; but at the end of it they recovered in great measure their health and spirits, and proceeded with alacrity to execute the various purposes of their settlement. To excite emulation in culture, the government gave premiums to those colonists who raised the greatest quantities of rice, yams, eddoes, cabbages, indian corn, and cotton, respectively. To limit the excess of the slave-trade, and gain the favour of the neighbouring chiefs, the directors instructed the governor and council to redeem any native from the neighbourhood, who should be unjustly sold either to or by a British subject. The servants of the company conducted themselves with the utmost propriety, being sober, moral, and exemplary; and from the labours of the clergymen were derived services highly important in every point of view. Before the end of two years from the institution of the colony, order and industry had begun to show their effects in an increasing prosperity. The woods had been cut down to the distance of about three English miles all round the town. By these means the climate had become healthier, and sickness had diminished. The fame of the colony had spread not only along the whole western coast of Africa, but also to parts far distant from the coast; embassies had been received of the most friendly nature from kings and princes several hundred miles distant; and the native chiefs had begun to lend their children to the colony, with full confidence, to be taught reading, writing, and accounts, and to be brought up in the Christian religion. In a word, it was not without grounds that the directors looked forward to that joyful period when, by the influence of the company's measures, the continent of Africa should be rescued from her present state of darkness and misery, and exhibit a delightful scene of light and knowledge, of civilization and order, of peaceful industry and domestic comfort. On their beneficent exertions they hoped with confidence for the blessing of Providence; they were countenanced and supported by the British government; and upon the breaking out of the present war, the French Convention authorized one of their agents to write to the directors, requesting a full account of the design of the institution, and the names of the ships employed in their service, and affuring them of the good wishes of the French government to a noble undertaking. How completely that government fulfilled its promise is very generally known. Having vindicated the rights of man in Europe by the violation of every principle of truth and justice, they determined by the same means to give light and liberty to the Africans; and that they have fully carried their determination into effect will be seen by the following extract of a letter from Mr. Azzelius, the company's botanist, dated Sierra Leone, 15th November 1794. "The West from French have been here and have ruined us. They arrived on the 28th of September last, early in the morning, with a fleet consisting of one large ship, two frigates, two armed brigs, and one cutter, together with two large armed merchant ships, taken by them at the Iles de Los, an English slave factory to the north of our colony, and which they have also destroyed and burnt. So well had they concealed their nation, that we took them at first for English. They had English-built vessels, which were rigged in the English way. They showed the English flag, and had their sails, at least those we saw on deck, dressed like English. In short, we did not perceive our mistake till we observed them pointing their guns. We had not strength sufficient to resist, and therefore our governor gave orders, that as soon as they should begin to fire, the British flag should be struck, and a flag of truce hoisted. Accordingly this was done, but still they continued firing, and did much damage, both within and without the town. They killed two people and wounded three or four. But, as we did not understand the meaning of this proceeding, we asked them for an explanation; and they answered us, that we should displace the flag of liberty, as a proof of our submission. We assured them that it should already have been done, if we had had any, which terminated the hostilities from the ships. In the mean time, most of the inhabitants had fled from the town, having taken with them as much of their property as they could.
property as they conveniently could in such a hurry. I was with the governor, together with a number of others; but as soon as I was certain they were enemies, I went towards my own house with a view to save as much as possible of my property and natural collections; but was received in such a manner, that I could not venture to proceed. My house was situated near the shore, and unfortunately just opposite the frigate which fired. I saw the balls passing through the house, and heard them whizzing about my ears. I saw that I should lose all my property; but life was dearer to me, and I hastened to the woods.

In the afternoon the enemy landed, finding the town almost destitute of people, but rich in provisions, clothing, and other stores. They began immediately to break open the houses and to plunder. What they did not want, they destroyed, burnt, or threw into the river. They killed all the cattle and animals they found in the fields or streets, yards, or elsewhere, not sparing even asses, dogs, and cats. These proceedings they continued the whole succeeding week, till they had entirely ruined our beautiful and prospering colony; and when they found nothing more worth plundering, they set fire to the public buildings and all the houses belonging to the Europeans; and burnt, as they said, by mistake nine or ten houses of the colonists. In the mean time, they were not left idle on the water. They sent three of their vessels to Banca island, a small island several miles higher up the river, which they plundered and burnt, together with some slave ships lying there. They took besides about 10 or 12 prizes, including the company's vessels. Most of these they unloaded and burnt. They took along with them also two of our armed vessels, one of which was a large ship, laden with provisions, and which had been long expected; but the unfortunately arrived a few days too soon, and was taken with her whole cargo. We expected at least to receive our private letters, but even this was refused, and they were thrown overboard. At last, after insisting on us every hardship we could suffer, only sparing our lives and the houses of the colonists, they sailed on the 15th of October last, at noon, proceeding downwards to the Gold Coast, and left us in the most dreadful situation, without provisions, medicines, clothes, houses, or furniture, &c. &c. and I feared much, that most of us should have perished, had not our friends in the neighbourhood, both natives and Europeans, who were so happy as to escape the enemy, been so kind as to find us what they could spare. In the mean time, most of us have either been, or still are, very sick, and many have died for want of proper food and medicine. The worst, however, is now past. At least we are not in any want of provision, although of the coarsest kind, but are deficient of the most necessary articles and utensils for the house, the table, and the kitchen.

"The Sierra Leone colony was established for no other end than to abolish the slave-trade, to enlighten the Africans, and to render them virtuous rational, free, and happy; and those powerful patrons of the rights of man destroyed that colony with many circumstances of the most wanton cruelty. Though Mr Azeez is a Swede, and ought therefore to have been protected by the laws of neutrality, they burnt his house with the red flag deprived him of his trunks, his clothes, and his bed; destroyed the natural curiosities which he had collected at the hazard of his life; and carried away the instruments by means of which only, he could collect more. It is with pleasure, however, that we learn from the proceedings of the general court held on the 25th of February 1795, that the directors do not yet despair of the colony; and that they have adopted the most prudent measures to avert all such calamities in future. That their benevolent labours may be finally crowned with success is our earnest prayer, in which we shall, doubtless, be joined by every good Christian."
SIG

SIGAULTIAN operation, a method of delivery in cases of difficult labour, first practiced by M. Sigault. It consists in enlarging the dimensions of the pelvis, in order to procure a safe passage to the child without injuring the mother. See Midwifery, chap. vii.

SIGEBSECKIA, in Botany: A genus of plants belonging to the class of the Caryophyllaceaem and to the order of Polygynium superflua; and in the natural system ranging under the 49th order, Compositae. The receptacle is paleaceous; the pappus is wanting; the exterior calyx is pentaphyllous, proper, and spreading; the radius is halved. There are three species: 1. The orientalis, which is a native of India and China. 2. The occidentalis, which is a native of Peru.

SIGETH, a town of Lower Hungary, and capital of a county of the same name. It is seated in a morass, which is a native of Virginia. 3. The fixiloloba, a native of Peru.

SIGHT, or Vision. See Anatomy, no. 142. and Index subjoined to Optics.

Imperfections of Sight with regard to Colours. Under the article Colours is given an instance of a strange deficiency of light in some people who could not distinguish between the different colours. In the Phil. Trans. Vol. LXVIII. p. 611, we have an account of a gentleman who could not distinguish a claret colour from black. These imperfections are totally unaccountable from any thing we yet know concerning the nature of this sense.

SIGN, in general, the mark or character of something absent or invisible. See Character.

Among physicians, the term sign denotes some appearance in the human body which serves to indicate or point out the condition of the patient; with regard to health or disease.

SIGN, in algebra. See Algebra, Part I.

SIGN, in astronomy, a constellation containing a 12th part of the zodiac. See Astronomy, no. 318.

Naval SIGNALS. When we send out our fire-fide the account of an engagement, or other interesting operation of an army, our attention is generally so much engaged by the results, that we give but little to the movements which led to them, and produced them; and we seldom form to ourselves any distinct notion of the conduct of the day. But a professional man, or one accustomed to reflection, and who is not satisfied with the mere indulgence of eager curiosity, follows every movement in its movements, endeavours to see their connection, and the influence which they have had on the fate of the day, and even to form to himself a general notion of the whole scene of action at its different interesting periods. He looks with the eye of the general, and sees his orders succeed or fail.

But few trouble themselves farther about the narrative. The movement is ordered; it is performed; and the fortune of the day is determined. Few think how all this is brought about; and when they are told that during the whole of the battle of Culrun, Frederic the Great was in the upper room of a country inn, from whence he could view the whole field, while his ships de camp, on horseback, waited his orders in the yard below, they are struck with wonder, and can hardly conceive how it can be done: but, on reflection, they see the possibility of the thing. Their imagination accompanies the messenger from the inn yard to the scene of action; they hear the General's orders delivered, and they expect its execution.

But when we think for a moment on the situation of the commander of a fleet, confined on board one ship, and this ship as much, or more closely, engaged, than any other of the fleet; and when we reflect that here are no messengers ready to carry his orders to ships of the squadron at the distance of miles from him, and to deliver them with precision and distinctness, and that even if this were possible by sending small ships or boats, the vicissitudes of wind and weather may render the communication tedious that the favourable moment may be irretrievably lost before the order can be conveyed. — When we think of all these circumstances, our thoughts are bewildered, and we are ready to imagine that a sea-battle is nothing but the unconnected struggle of individual ships; and that when the admiral has once "cried havoc, and let slip the dogs of war," he has done all that his situation empowers him to do, and he must leave the fate of the day to the bravery and skill of his captains and sailors.

Yet it is in this situation, apparently the most unfavourable, that the orders of the commander can be conveyed, with a dispatch that is not attainable in the operations of a land army. The scene of action is unincumbered, so that the eye of the General can behold the whole without interruption. The movements which it is possible to execute are few, and they are peculiar. A few words are sufficient to order them, and then the mere fighting the ships must always be left to their respective commanders. This simplicity in the duty to be performed has enabled us to frame a language fully adequate to the business involved, by which a correspondence can be kept up as far as the eye can see. This is the

SIG
...of ancient times.

In the naval occurrences of modern Europe, mention is frequently made of signals. Indeed, as we have already observed, it seems impossible for a number of ships to act in any kind of concert, without some method of communication. Numberless situations must occur, when it would be impossible to convey orders or information by messengers from one ship to another, and certain signals had long been practised by every nation. The idea was therefore, familiar. We find, in particular, that Queen Elizabeth, on occasion of the expedition to Cadiz, ordered her secretaries to draw up instructions, which were to be communicated to the admiral, the general, and the five councilors of war, and by them to be copied and transmitted to the several ships of the navy, not to be opened till they should arrive in a certain latitude. It was on this occasion, (says the historian Guthrie), "that we meet with the first regular set of signals and orders to the commander of the English fleet." But till the movements of a fleet have attained some form of uniformity, regulated and connected by some principles of propriety, and agreed on by perils in the habit of directing a number of ships, we may find that the formation of such signals would be nothing but a parcel of arbitrary marks, appropriated to particular pieces of naval service, such as attacking the enemy, landing the soldiers, &c.; and that they would be considered merely as referring to the final result, but by no means pointing out the mode of execution, or directing the movements which were necessary for performing it.

It was James II. when duke of York, who first considered this practice as capable of being reduced into a system, and who saw the importance of such a composition. He, as well as the king's brother, had always showed a great predilection for the sea service; and, when appointed admiral of England, he turned his whole attention to its improvement. He had studied the art of war under Turenne, not as a paralytic, but as a science, and was a favourite pupil of that most accomplished general. Turenne one day pointed out, saying, "I hold one who will be one of the first princes and greatest generals of Europe." When admiral of England, he endeavoured to introduce into the maritime service all those principles of concert and arrangement which made a number of individual regiments and squadrons compose a great army. When he commanded in the Dutch war, he found a fleet to be little better than a collection of ships, on board of each of which the commander and his ship's company did their best to annoy the enemy, but with very little dependence on each other, or on the orders of the general; and in the different actions which the English fleet had with the Dutch, every thing was confusion as soon as the battle began. It is remarkable that the famous pensiory De Witt, who from a flatefman became a navigator and a great sea commander in a few weeks, made the same representation to the States General on his return from his first campaign.

"In the memoirs of James II. written by himself, we have the following passage: "1665. On the 15th of March the duke of York went to Capeflew, the general rendezvous of the fleet, and hallowed their equipment. He ordered all the flag officers on board with him every morning, to agree on the order of battle and rank. In former battles, no order was kept, and this under the duke of York was the first in which standing in a line and regular form of battle was observed."

"This must be considered as full authority for giving the duke of York the honour of the invention. For whatever faults may be laid to the charge of this unfortunate prince, his word and honour stand unimpeached. And we are anxious to vindicate his claim to it, because our neighbours the French, as usual, would take the merit of this invention, and of the whole of naval tactics, to themselves. True it is, that Colbert, the great and justly celebrated minister of Louis XIV., created a navy for his ambitious and vain-glorious son, and gave it a constitution which may be a model for other nations to copy. By his encouragement, men of the greatest scientific eminence were engaged to contribute to its improvement: and they gave us the first treaties of naval evolutions. But it must ever be remembered, that our accomplishments, though misguided sovereign, was then refusing..."
refiding at the court of Louis; that he had formerly
acted in concert with the French as a commander and
flag officer, and was at this very time aiding them with
his knowledge of sea affairs. In the memorable day at
La Hogue, the gallant Raflle, observing one of Tour-
ville's movements, exclaimed, "There they have got
Pepys's [among them]." This anecdote we give on the
authority of a friend, who heard an old and respectable
officer (Admiral Clinton) say, that he had it from a
gentleman who was in the action, and heard the words
spoken; and we trust that our readers will not be dis-
pleased at having this matter of general opinion es-
tablifhed on some good grounds.

"It was on this occasion, then, that the duke of York
made the movements and evolutions of a fleet the ob-
ject of his particular study, reduced them to a sys-
lem, and composed that "System of Sailing and Fighting
Instructions," which has ever since been confedered as
the code of discipline for the British navy, and which
has been adopted by our rivals and neighbours as the
foundation of their naval tactics. It does great honour
to its author, although its merit will not appear very
 eminent to a careless surveyor, on account of that very
simplicity which confutes its chief excellence. It
unquestionably the result of much judicious reflection
and a skilful combination of innumerable circumstances,
all of which have their influence; and it is remarkable,
that although succeeding commanders have improved
the subject by several subordinate additions, no change
has to this day been made in its general principles or
maxims of evolution.

"Till some such code be established, it is evident that
signals can be nothing but arbitrary and unconnected
hieroglyphics, to be learned by rote, and retained by
memory, without any exercise of the judgment; and the
acquisition of this branch of nautical skill must be a
more trifling task than that of learning the Chinese
writing. But such a code being once settled, the cha-
acter in which it may be exprest becomes a matter of
rational discussion.

"Accordingly, the sailing and fighting instructions of
the duke of York were accompanied by a few of signals
for directing the chief or mobile movements of the
command. These signs were contrived with so much
judgment, and such attention to distinction, simplicity,
and propriety, that there has hardly been any change
found necessary; and they are still retained in the
British navy as the usual signals in all cases where we
are not anxious to conceal our movements from an enemy.

"Notwithstanding this acknowledged merit of the
duke of York's signals, it must be admitted that great
improvements have been made on this subject, considered
as an art. The art military has, in the course of a
century past, become almost an appropriate calling,
and has therefore been made the peculiar study of its
professors. Our rivals the French were sooner, and
more formally, placed in this situation, and the minis-
ters of Louis XIV. took infinite and most judicious pains
to make their military men superior to all others by
their academical education. A more scientific turn was
given to their education, and the advancement of scien-
tific men was liberally given them; and all the nations of
Europe must acknowledge some obligations to them for
information on every thing connected with the art of
war. They have attended very much to this subject,
which has greatly improved it, and have even introduced a
new principle into the art; and by this means have re-
duced it to the most simple form of reference to the
code of sailing and fighting instructions, by making the
signals immediately expressive, not of orders, but of
simple numbers. Those numbers being predicated to the
various articles of the code of instructions, the officer
who sees a signal thrown out by the admiral reads the
number, and reports it to his captain, perhaps without
knowing what it relates. This simplicity and fe-
cency, with an unlimited power of variation, are con-
bined. We believe that M. de la Bourdonnais, a brave
and intelligent officer, during the war 1758, was the
author of this ingenious thought.

"We do not propose to give a System of British sig-
nals. This would evidently be improper. But we shall
shew our readers the practicality of this curious lan-
guage, the extent to which it may be carried, and the
methods which may be practiced in accomplishing this
purpose. This may make it an object of attention to
scientifc men, who can improve it; and the young of-
cier will not only be able to read the orders of the com-
mander in chief, but will not be at a loss, should cir-
cumstances place him in a situation where he must give
orders to others.

"Signals may be divided into

I. DAY SIGNALS.
II. NIGHT SIGNALS; and,
III. SIGNALS IN A FOG.

They must also be distinguished into. 1. Signals of
EVOLUTION, addressed to the whole FLEET, or to
Squadrons of the fleet, or to Divisions of these
squadrons. 2. Signals of MOVEMENTS to be made by
particular ships; and, 3. Signals of SERVICE, which
may be either general or particular.

The great extent of a large fleet, the smoke in time
of battle, and the situation of the commander in chief,
who is commonly in the midst of the greatest confu-
sion, calls for a correspondent language to its
signals and huzzas, frequently makes it very difficult for
the officers of distant ships to perceive his signals with
distinctness. Frigates, therefore, are stationed out of
range of the common signals, to observe the admiral's
signals, and instantly to repeat them. The eyes of all the
signals officers in the private signal-board of war are di-
cussed to the repeating frigates, as well as to the admiral;
and the officers of the repeating frigate, having no other
duty, observe the admiral incessantly, and, being unemblem-
abled by the action, can display the signal with delifercation,
so that it may be very distinctly seen. Being minutely acquainted with
the substitutions, which must be made on board the admiral
when his masts and rigging are in disorder, his (perhaps
imperfect) signal is exhibited by the repeating frigate
in its proper form, so as to be easily understood. And
to facilitate this communication, the commanders of the
different squadrons repeat the signals of the commander
in chief, and the commanders of division repeat the sig-
nals of the commanders of their squadron.

"Every evolution signal is preceded by a signal of AD,
"Evolution:
"ADDITION and PREPARATION, which is general, and
"frequently by a gun, to call attention; and when all the
"signals have been made which direct the different parts
"of that evolution, another signal is made, which marks the
"end of the chief of the complex signal, and divides it from others
"which may immediately follow it: and as the orders of
"the commander in chief may relate either to the move-
"ments of the whole fleet, those of a single division, or
"thos.
Anfwered by the commander to (which signifies, that he intimates this by another general signal. And here it is to be observed, that as soon as the signal is answered by the ships to which it is addressed, it is usual to haul it down, to avoid the confusion which might arise from others being hoisted in the same place. The order remains till executed, notwithstanding that the signal is hailed down.

It may happen that the commander who throws out the signal for any piece of service, fees reasons for altering his plan. He intimates this by a general Annulling signal, accompanying the signal already given. This will frequently be more simple than to make the signals for the movements which would be required for re-establishing the ships in their former situation. All these things are of very easy comprehension, and require little thought for their contrivance. But when we come to the particular evolutions and movements, and to combine these with the circumstances of situation in which the fleet may be at the time, it is evident, that much reflection is necessary for framing a body of signals which may be easily exhibited, distinctly perceived, and well understood, with little risk of being mistaken one for another. We shall take notice of the circumstances which chiefly contribute to give them these qualities as we proceed in describing their different classes.

### I. Of Day Signals.

These are made by means of the ship's fails, or by colours of various kinds.

Those made with fails are but few in number, and are almost necessarily limited to the situation of a fleet at anchor. Thus,

<table>
<thead>
<tr>
<th>Signal Description</th>
<th>Usual Signification</th>
</tr>
</thead>
<tbody>
<tr>
<td>Main top-gallant fail hoisted</td>
<td>Officers and men belonging to the ship to come on board.</td>
</tr>
<tr>
<td>Fore top-fall loose</td>
<td>To prepare for falling.</td>
</tr>
<tr>
<td>Main top-fall loose</td>
<td>To unmoor.</td>
</tr>
<tr>
<td>Main top-fall sheets hauled home</td>
<td>To weigh.</td>
</tr>
<tr>
<td>Main top-fall sheets clewed up, and the yard hoisted</td>
<td>Annull the former signal, and the ship to come to an anchor.</td>
</tr>
<tr>
<td>Top-gallant fails loose, and the sheets flying</td>
<td>Discovering strange fails.</td>
</tr>
<tr>
<td>Main top-gallant fall loose and hoisted. Topfall spread down</td>
<td>Recal ships in chase.</td>
</tr>
<tr>
<td>Mizen top-fall hoisted, and the sheets clewed up</td>
<td>Moor.</td>
</tr>
</tbody>
</table>

Before we proceed to the description of the signals by means of colours, such as flags, banners (or triangular flags), pendants or vane, we must take notice of the offensive distinctions of the various divisions and subdivisions of a fleet, so that we may understand how the same signal may be addressed to a squadron, division, or single ship or ships. We suppose it known that a fleet of ships of war is distributed into three grand divisions (which we shall term squadrons), called the van, centre, and rear. These denominations have not always a relation to the one being more advanced than the other, either towards the enemy, or in the direction of their course.

In a land army, the position of every part is conceived from its reference to the enemy; and the reader, conceiving himself as facing the enemy, easily understands the terms van, centre, and rear, the right and left wing, &c. But the movements of a sea army having a necessary dependence on the wind, they cannot be comprehended unless expressed in a language which keeps this circumstance continually in view. The simplest and most easily conceived disposition of a fleet, is that in which it is almost indispensably obliged to form in order to engage an enemy. This is a straight line, each ship directly ahead of its neighbour, and close hauled. This is therefore called the line of battle. In this position, the two extremities of the fleet correspond to the right and left wings of an army. Suppose this line to be in the direction east and west, the wind blowing from the north-north-west, and therefore the fleet on the starboard tack; the ships heads are to the west, and the weathermost division is undoubtedly the van of the fleet, and the weathermost division is the rear. And it is in conformity to this arrangement and situation that the list of the fleet is drawn up. But the ships may be on the same east and west line, close hauled, with their heads to the west, but the wind blowing from the south-south-west. They must therefore be on the larboard tack. The same ships, and the same division, are still, in fact, the van of the fleet. But suppose the ships heads to be to the eastward, and that they are close hauled, having the wind from the south-south-east or the north-north-east, the ships which were the real van on both tacks in the former situation are now, in fact, the rear on both tacks; yet they retain the denomination of the van squadron of this fleet, and are under the immediate direction of the officer of the second rank, while the other extremity is under the direction of the third officer. This subordination therefore is rather an arrangement of rank and precedence than of evolution. It is, however, considered as the natural order to which the general signals must be accommodated. For this reason, the division which is denominated van in the list of this fleet, is generally made to lead the fleet when in the line of battle on the larboard tack, and to form the weathermost column in the order of sailing in columns; and, in general, it occupies that station from which it can most easily pass into the place of the leading division on the larboard line of battle ahead. Although this is a technical nicety of language, and may frequently puzzle a landman in reading an account of naval operations, the reflecting and intelligent reader will see the propriety of retaining this mode of conceiving the subordinate arrangement of a fleet, and will comprehend the employment of the signals which are necessary for re-establishing this arrangement, or directing the movements while another arrangement is retained.

This being understood, it is easy to contrive various methods...
methods of distinguishing every ship by the place, which the occupies in the fleet, both with respect to the whole line, with respect to the particular squadron, the particular division of that squadron, and the particular place in that division. This may be done by a combination of the position and colour of the pantards and vanes of each ship. Thus, the colour of the pantards may indicate the squadron, their position or mast on which they are hoisted may mark the division of that squadron, and a distinguishing vane may mark the place of the private ship in her own division. The advantages attending this method are many. In a large fleet it would hardly be possible for the commander in chief to find a sufficient variety of single signals to mark the ship to which an order is addressed, by hoisting it alone with the signal appropriated to the intended movement. But by this contrivance one third part of these signals of address is sufficient. It also enables the commander in chief to order a general change of position by a single signal, which otherwise would require several. Thus, suppose that the fore, main, and mizen masts, are appropriated (with the proper modifications) for exhibiting the signals addressed to the van, the centre, and the rear squadrons of the fleet, and that a red, a white, and a blue flag, are chosen for the distinguishing flags of the officers commanding these squadrons; then, if the commander in chief shall hoist a red flag at his mizen top-gallant main head, it must direct the van squadron to take the position then occupied by the rear squadron the evolution necessary for accomplishing this being suppos’d known by the commander of the squadron, who will immediately make the necessary signals to the squadron under his particular direction. In the same manner the distinguishing signal for the leading ship of a squadron being hoisted, along with the signal’s flaggers to the whole fleet, and the signal for any particular service, will cause the three or the nine leading ships to execute that order, &c. &c.

All that has been said hitherto may be considered as so many preparations for the real issu’ of orders by the commander in chief. The most difficult part of the language remains, viz. to invent a number of signals which shall correspond to that almost infinite variety of movements and services which must be performed.

Distinctness, simplicity, and propriety, are the three essential qualities of all signals. A signal must be some object easily seen, strongly marked, so that it may be readily understood, with little risk of its being mistaken for another. When made by flags, banners, or pantards, they must be of the fullest colours, and strongly contrasted. The ships are frequently at a very great distance, so that the intervening air occasions a great degradation of colour. They are seen between the eye and a very variable sky; and in this situation, especially in the morning or evening, or a dark day, it is not easy to distinguish one full colour from another, all of them approaching to the appearance of a black. At the distance of a very few miles hardly any full colours can be distinguished but a scarlet and a blue. Red, blue, yellow, and white, are the colours which can be distinguished at greater distances than any others, and are therefore the only colours admitted as signals. Even these are sometimes distinguished with difficulty. A yellow is often confounded with a dirty white, and a blue with a red. All other dark colours are found totally unitive. But as there are not but a small variety, we must combine them in one flag, by making it striped, spotted, or chequered, taking care that the opposition of colour may be as great as possible, and that the pieces of which the flags are made up may not be too minute. Red must never be striped nor spotted with blue, and the stripes, spots, or chequers, should never be less than one third of the breadth of the flag. Plate CCCCLXVI is a selection by an officer of experience as a set very easily recognized, and little liable to be confounded. Their colours are rereflected by hatching, in the same manner as in her dry (See Heraldry).

Difference of flags, as flags, banners, or pantards, is another distinction by which the expression may be varied. And in doing this, we must recollect, that in light winds it may be difficult to distinguish a flag from a banner as neither are fully displayed for want of wind to detach the fly from the fluff.

And lastly signals may be varied by their position, which may be on any lofty and well detached part of the masts, yards, or rigging.

Simplicity is an eminent property in all signals. They are addressed to persons not much accustomed to combinations, and who are probably much occupied by other pressing duties. It was to be wished that every piece of service could be indicated by a single flag. This is peculiarly desirable with respect to the signals used in time of battle. The rapid succession of events on this occasion call for a multitude of orders from the commander in chief, and his flag is frequently clad over with flags and pantards, so that it is exceedingly difficult for the signal officer of a private ship to distinguish the different groups, each of which make a particular signal.

These considerations are the foundation of a certain and propriety in signals, which directs us to a choice among triety, which, appear altogether arbitrary. Signals which run any risk of being confounded, on account of some resemblance, or because their position hinder us from immediately perceiving their difference, should be appropriated to pieces of service which are hardly possible to be executed, or can hardly be wanted, in the same situation. No bad consequence could easily result though the signal for coming to closer action should resemble that for unmooring, because the present situation of the ships makes the last operation impossible or absurd. Such considerations direct us to select for battle signals, those which are of easy exhibition, are the most simple, and have the least dependence on the circumstance of position; 5o that their signification may not be affected by the damages sustained in the masts or rigging of the flag ship. Such signals as are left easily seen at a distance, should be appropriated to orders which can occur only in the middle of the fleet, &c. &c. Signals which are made to the admiral by private ships may be the same with signals of command from the flag ship, which will considerably diminish the number of signals perfectly different from each other.

By what means signals are distinguished is a subject of great importance. It is accompanied by another small flag for the duty of conveyance. It must be engraved in two books; one for the officer of the flag ship, who is to make the signals, and the other is used
delivered to every private ship. In the first, the evolu-
tions, movements, and other operations of service, are
set down in one column, and their corresponding sig-
nals in another. The first column is arranged, either
alphabetically, by the distinguishing phrase, or systema-
tically, according to the arrangement of the failing and
fighting instructions. The officer whose duty it is to
make the signals, turns to this column for the order
which he is to communicate, and in the other column
he finds the appropriated signal.

In the other book, which is consulted for the inter-
pretation of the signals, they are arranged in the lead-
ing column, either by the flags, or by the places of
their exhibition. The first is the best method, because
the derangement of the flag ship's masts and rigging in
time of action may occasion a change in the place of
the signal.

"The Tactique Navale of the Chevalier de Morogues
contains a very full and elaborate treatise on signals.
We recommend this work to every sea-officer, as full of
information. The art of signals has been greatly sim-
plified since the publication of this work, but we can-
not but ascribe much of the improvements to it. We
believe that the author is the inventor of that sytema-
tic manner of addressing the order or effective signal
to the different squadrons and divisions of the fleet, by
which the art of signals is made more concise, the exe-
cution of orders is rendered more systematic, and the
commanders of private ships are accustomed to consider
themselves as parts of an army, with a mutual depend-
ence and connection. We are ready enough to ac-
knowledge the superiority of the French in manoeuv-
ring, but we affect to consider this as an imputation on
their courage. Nothing can be more unjust; and dear-
ought experience should long ere now have taught us
the value of this superiority. What avails that cour-
age which we would willingly arrogate to ourselves, if
we cannot come to action with our enemy, or must do
it in a situation in which it is almost impossible to suc-
cede, and which needlessly throws away the lives of our
gallant crews? Yet this must happen, if our admirals
do not make evolutions their careful study, and our
captains do not habituate themselves, from their first
hoisting a pendant, to consider their own ship as con-
nected with the masts remote ship in the line. We
cannot think that this view of their situation would be
a least lien the character which they have so justly ac-
brained, of fighting their ship with a courage and firm-
nets unequalled by those of any other nation. And
we may add, that it is only by such a rational study of
their profession, that the gentleman can be distinguished
from the mercenary commander of a privateer."

II. NIGHT SIGNALS.

It is evident, that the communication of orders by
night must be more difficult and more imperfect than
by day. We must, in general, content ourselves with
such orders as are necessary for keeping the fleet toget-
er, by directing the more general movements and
evolutions which any change of circumstances may re-
nder necessary. And here the division and subordinate
arrangement of the fleet is of indispensable necessity,
it being hardly possible to particularise every ship by a
signal of address, or to see her situation. The orders
are therefore addressed to the commanders of the dif-
rent divisions, each of whom is distinguished by his poop
and top-lights, and is in the midst of, and not very re-
move from, the ships under his more particular charge.
Yet even in this unfavourable situation, it is frequently
necessary to order the movements of particular ships.
Actions during the night are not uncommon. Pursuits
and rallyings are still oftener carried on at this time.
The common dangers of the sea are as frequent and
more disastrous. The system of signals therefore is
very incomplete till this part be accomplished.

Night signals must be made by guns, or by lights,
or by both combined.

Gun-signals are susceptible of variety both in num-
ber and in disposition. The only distinct variation which
signals may be varied.

Half-minute guns are as slow as can easily be listened
to as pertaining to one signal. Quarter-minute guns
are much better, and admit of two: very distinct subdivisions. When the gunners, therefore, are well trained
to this service (especially since the employment of
firelocks for cannon), intervals of 15 or 12 seconds
may be taken for slow firing, 8 or 10 seconds for mo-
derate, and 4 or 5 seconds for quick firing. If these
could be reduced one half, and made with certainty and
precision, the expression would be incomparably more
distinct. A very small number of firings varied in this
way will give a considerable number of signals. Thus
five guns, with the variety of only quick and moderate,
will give 20 very distinguishable signals. The same
principle must be attended to here as in the flag signals.
The most simple must be appropriated to the most im-
portant orders, such as occur in the worst weather, or
such as are most liable to be mistaken. Quick firing
should not make part of a signal to a very distant
ship, because the noise of a gun at a great distance is a
lengthened sound, and two of them, with a very short
interval, are apt to coalesce into one long continued
sound. This mode of varying gun-signals by the time
must therefore be employed with great caution, and
we must be very certain of the steady performance of
the gunners.

Note, that a preparatory signal or advertisement
that an effective signal is to be made, is a very neces-
ary circumstance. It is usual (at least in hard weather)
to make this by a double discharge, with an interval of
half a second, or at most a second.

Gun-signals are seldom made alone, except in or-
dinary situations and moderate weather; because ac-
cident may derange them, and inattention may cause
them to close notice, and, once made, they are over,
and their repetition would change their meaning. They
are also improper on an enemy's coast, or where an en-
emy's cruisers or fleets may be expected.

Signals by lights are either made with lights simply signals by
so called, i.e. lanterns thrown in different parts of the
ship, or by rockets. Lights may differ by number, and
by position, and also by figure. For the flag ship al-
ways carrying poop or top-lights, or both, presents an
object in the darkest night, so that we can tell whether
the additional lights are exhibited about the mainmast,
the foremast, the mizenmast, &c. And if the lights
thrown from any of these situations are arranged in cer-
tain distinguishable situations in respect to each other, the
number
Naval Sig. number of signals may be greatly increased. Thus
three lights may be in a vertical line, or in a horizontal
line, or in a triangle, and the point of this triangle may be
up, or down, or forward, or aft, and thus may have many significations.

Lights are also exhibited by signal fires or rockets:
These can be varied by number, and by such differences
of appearance as to make them very distinguish-
able. Rockets may be with flares, with rain fire, or
simple squares.

21. These two species of signals may be combined.

By varying and combining these, a very great number
of signals may be produced, fully sufficient to direct
every general movement or evolution, or any ordinary
and important service. The Chevalier de Morogues
has given a specimen of such a system of night signals,
into which he has even introduced signals of address or
direction to every ship of a large fleet; and has also
given signals of number, by which depths of soundings,
points of the compass, and other things of this kind,
may be expressed both easily and distinctly. He has
made the signals by rockets perfectly similar in point of
number to thse by lanterns, so that the commander
can take either; a choice which may have its use, be-
cause the signals by rockets may cause the presence of a
fleet to be more extensively known than may be conven-
ient.

The commander in chief will inform the fleet by signal,
that guns, or perhaps rockets, are not to be used
that night. This signal, at the same time, directs
the fleet to close the line or columns, that the light sig-

It is of particular importance that the fleet be kept
together. Therefore the leading ships of the fleet, on ei-
then tack, are enjoined to acknowledge the signals of
the commander in chief by a signal peculiar to their
station. Thus the commander in chief learns the posi-
tion of the extremities of his fleet.

In framing a set of night signals, great attention
must be given to their position, that they be not obscured
by the falls. The nature of the order to be given
will frequently determine this. Thus, an order for the
rear ships to make more sail, will naturally direct us to
exhibit the signal at the mainmast; and fo of other
pieces of service. Lanterns exposed in groups, such
as triangles, lozenges, &c. are commonly suspended at
the corners of large frames of laths, at the distance of a
fathom at least from each other. Attempts have been
made to show lights of different colours; but the risk of
mistake or failure in the composition at the laboratory,

24. This precaution is indispensible to prevent mistakes.
Along with this advertising signal he makes the signal of
the movement intended. This not only calls the
attention of the fleet, but makes the ships prepare for
the precise execution of that movement. The com-
manders of divisions repeat the advertising signal, which
informs their ships of their situation, and the private
ships beat their drums or chime their bells. Thus the
whole ships of the fleet close a little, and become a little
better acquainted with their mutual position. It is
now understood that a movement is to be made prece-
tly a quarter of an hour after the advertisement. At

In framing a set of night signals, great attention
must be given to their position, that they be not obscured
by the falls. The nature of the order to be given
will frequently determine this. Thus, an order for the
rear ships to make more sail, will naturally direct us to
exhibit the signal at the mainmast; and so of other
pieces of service. Lanterns exposed in groups, such
as triangles, lozenges, &c. are commonly suspended at
the corners of large frames of laths, at the distance of a
fathom at least from each other. Attempts have been
made to show lights of different colours; but the risk of
mistake or failure in the composition at the laboratory,
Naval Signal: The expiration of this time, the effective signal for this movement is made by the commander in chief, and must be instantly repeated by the commanders of divisions, and then the movement must be made by each ship, according to the failing and fighting instructions. This must be done with the utmost attention and precision, because it produces a prodigious change in the relative position of the ships; and even although the good sense of the commander in chief will select such movements for accomplishing his purpose as produce the smallest alterations, and the least risk of separation or running foul of each other; it is still extremely difficult to avoid these misfortunes. To prevent this as much as possible, each ship which has executed the movement, or which has come on a course thwarting that of the fleet, intimates this by a signal properly adapted, often adding the signal of the tack on which it is now intending, and even its particular signal of recognition. This is particularly incumbent on the flag ships and the leading ships of each division.

After a reasonable interval, the commander in chief will make proper signals for bringing the fleet to a knowledge of their reunion in this new position.

This must serve for a general account of the circumstances which must be attended to in framing a code of signals. The arbitrary characters in which the language is written must be left to the sagacity of the gentlemen of the profession. It must be observed, that the stratagems of war make secrecy very necessary. It may be of immense hazard if the enemy should understand our signals. In time of battle it might frequently frustrate our attempts to destroy them, and at all times would enable them to escape, or to throw us into disorder. Every commander of a squadron, therefore, issues private signals, suited to his particular destination; and therefore it is necessary that our code of signals be susceptible of endless variations. This is exceedingly easy without any increase of their number. The commander needs only intimate that such and such a signal is so and so changed in its meaning during his command.

We cannot leave this article without returning to an observation which we made almost in the beginning, viz. that the system of signals, or, to speak more properly, the manner of framing this system, has received much improvement from the gentlemen of the French navy, and particularly from the most ingenious thought of M. de la Bourdonnais, of making the signals the immediate expressions of numbers only, which numbers may be afterwards used to indicate any order whatever. We shall present our readers with a scheme or two of the manner in which this may be done for all signals, both day, night, and fog. This alone may be considered as a system of signals, and is equally applicable to every kind of information at a distance. Without detracting in the smallest degree from the praise due to M. de la Bourdonnais, we must observe, that this principle of notation is of much older date. Bishop Wilkins, in his Secret and Swift Messenger, expressly recommends it, and gives specimens of the manner of execution; so does Dr Hooke in some of his proposals to the Royal Society. Caspar Schottus also mentions it in his Technica Curiosa; and Kircher, among others of his Curious Projects.

M. de la Bourdonnais's method is as follows:

He chooses pendants for his effective signals, because they are the most easily displayed in the proper order. Several pendants, making part of one signal, may be hoisted by one halyard, being flopped on it at the distance of four or five feet from each other. If it be found proper to throw out another signal at the same time and place, they are separated by a red pendant without a point. His colours are chosen with judgement, being very distinctly recognised, and not liable to be confounded with the addressing signals appropriated to the different ships of the fleet. They are:

For No. 1. Red. For No. 6. Red, with blue tail.
2. White. 7. White, with blue tail.
5. Red, with white tail.
6. Red, with blue tail.

Three sets of such pendants will express every number under a thousand, by hoisting one above the other, and reckoning the uppermost, the next below it, and the lowest unit. Thus the number 973 will be expressed by a red pendant with blue tail, a yellow pendant below it, and a blue one below the last.

This method has great advantages. The signals may be hoisted in any place where best seen, and therefore the signification is not affected by the derangement of the flag ship's masts and rigging. And by appropriating the smaller numbers to the battle signals, they are more simple, requiring fewer pendants.

As this method requires a particular set of colours, it might be its inconveniences. An admiral is often obliged to refit his flag, even in time of action. He cannot much easily take the colours along with him. It is therefore better to make use of such colours as every private ship is provided with. One set of 11 will do with the addition of three, at most of four pendants, of singular make, to mark 100, 200, 300, 400. Two of these flags, one above the other, will express any number under 100, by using the 11th as a substitute for any flag that should be repeated. Thus the 11th flag, along with the flag for eight or for six, will express the number of 88 or 66, &c. Thus we are able to express every number below 500, and this is sufficient for a very large code of signals.

And in order to diminish as much as possible the number of these compound signals, it will be proper that a number of single flag signals be preferred, and even varied by circumstances of position, for orders which are of very frequent occurrence, and which can hardly occur in situations where any obstructions are occasioned by lots of masts, &c. And farther, to avoid all chance of mistake, a particular signal can be added, intimating that the signals now exhibited are numerary signals; or, which is still better, all signals may be considered as numerary signals; and those which we have just now called single flag signals may be set down opposite to, or as expressing, the largest numbers of the code.

This method requires the signal of advertisement, the nulling signal, the signal of address to the particular ship or division, the signal of acknowledgment, the signal of indifference, of difficulty, of danger, and one
It is equally easy to express numbers by night signals. Thus M. de la Bourdonnais proposes, that one discharge of a great gun shall express 7, and that 1, 2, 3, 4, 5, 6 shall be expressed by lights. Therefore, to express 24, we must fire three guns, and show three lights. This is the most perfect of all forms of night and fog signals. For both the manner of firing guns and of exhibiting lights may be varied to a sufficient extent with very few guns or lights, and with great distinctness.

Thus, for guns. Let F mark the firing of a single gun at moderate intervals, and J, a double gun, that is, two discharged at the interval of a second. We may express numbers thus:

<table>
<thead>
<tr>
<th>Number</th>
<th>Signal</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>F</td>
</tr>
<tr>
<td>2</td>
<td>FF</td>
</tr>
<tr>
<td>3</td>
<td>FFF</td>
</tr>
<tr>
<td>4</td>
<td>F,F,F</td>
</tr>
<tr>
<td>5</td>
<td>F,F,FF</td>
</tr>
<tr>
<td>6</td>
<td>F,FF</td>
</tr>
<tr>
<td>7</td>
<td>F,F,F</td>
</tr>
<tr>
<td>8</td>
<td>F,F,FF</td>
</tr>
<tr>
<td>9</td>
<td>F,FF</td>
</tr>
<tr>
<td>10</td>
<td>FF,FF</td>
</tr>
<tr>
<td>100</td>
<td>F,F,F,FF</td>
</tr>
</tbody>
</table>

This might be done with fewer guns if the F's were admitted as the first firing. But it seems better to begin always with the single gun, and thus the double gun beginning a signal distinguishes the tens, &c.

In like manner, a small number of lights will admit of a great variety of very distinct signals, which may serve for all signals to ships not very remote from the commander in chief. For orders to be understood at a very great distance, it will be proper to appropriate the numbers which are indicated by signals made with rockets. These can be varied in number and kind to a sufficient extent, so as to be very easily distinguished and understood. It is sufficient to have shown how the whole, or nearly the whole, notation of signals may be limited to the expression of numbers.

We have taken little notice of the signals made by Dr. Hooke for the coast and alarm signals, where, by the by, he shews a method for conveying intelligence over land very similar to what is now practised by the French with their telegraph.

One great advantage of these numerical signals is, that they may be changed in their signification at pleasure. Thus, in the first method, it can be settled, that on Sundays the colours A, B, C, D, &c. express the cyphers 1, 2, 3, 4, &c. and on Mondays they express the cyphers 0, 1, 2, 3, &c. and on Tuesdays the cyphers 0, 1, 2, &c.; and so on through all the days of the week. This means of secrecy is mentioned by Dr. Hooke for the coast and alarm signals, where, by the by, he shews a method for conveying intelligence over land very similar to what is now practised by the French with their telegraph.
The retreat, - To retreat.
Draw curtains, - To halt.
Two short rolls, - To perform the rank firing.
The bugle march, - To open the battalion.
The grenadier march, - To form the column.
The troope, - To double divisions.
The long roll, - To form the square.
The grenadier march, - To reduce the square to the column.
The preparatives, - To make ready and fire.
The general, - To cease firing.
Two long rolls, - To bring or lodge the colours.

SIGNATURE, a sign or mark impressed upon any thing, whether by nature or art. Such is the general signification of the word; but in the plural number it has been used, in a particular sense, to denote those external marks by which physiognomists and other dabbles in the occult sciences pretend to discover the nature and internal qualities of every thing on which they are found. According to Law, every corporeal object is characterized by signatures peculiar to itself.

The doctrine of signatures, like alchemy and astrology, was very prevalent during the 15th and 16th centuries; and was considered as one of the occult sciences which conferred no small degree of honour on their respective professors. Some of these philosophers, as they thought fit to style themselves, maintained that plants, minerals, and animals, but particularly plants, had signatures impressed on them by the hand of nature, indicating to the adept the therapeutia uses to which they might be applied. Others, such as the mystical theosophists and chemists of that day, proceeded much farther in absurdity, maintaining that every substance in nature had either external signatures immediately discernible, or internal signatures, which, when brought into view by fire or mithrum, denoted its connection with some fidelial or celestial archetype. Of the doctrine of signatures, as it relates merely to the therapeutic uses of plants and minerals, traces are to be found in the works of some of the greatest authors of antiquity; but the celestial signatures, we believe, were discovered only by the moonlight of the monkish ages. Hirlin informs us*, that the marble called aphites, from its being spotted like a serpent, was discovered by those spots to be a sovereign remedy for the bite of that animal; and that the colour of the heamatites or blood-stone intimated that it was fit to be employed to stop an hemorrhage; but we do not recollect his attributing the virtues of these minerals to a fidelial or celestial influence.

SIGNATURE, a signifying of a person's name at the bottom of an act or deed written by his own hand.

SIGNATURE, in printing, is a letter put at the bottom of the first page at left, in each sheet, as a direction to the binder in folding, gathering, and collating them. The signatures consist of the capital letters of the alphabet, which change in every sheet; if there be more sheets than letters in the alphabet, to the capital letter is added a small one of the same form, as A a, B b; which are repeated as often as necessary. In large volumes it is easy to distinguish the number of alphabets, after the first three or four, by placing a figure before the signature, as 5 B, 6 B, &c.

SIGNET, one of the king's seals, made use of in sealing his private letters, and all grants that pass by bill signed under his majesty's hand; it is always in the custody of the secretaries of state.

SIGNET, in Scots law. See Law, Part III. § 17.

SILENE, Catchfly, or Visayan Camomile, in botany: A genus of plants belonging to the class of decandria, and order of trigynia; and in the natural system arranged under the 2nd order, carphylline. The calyx is venticenic; the petals are five in number, bised and unscissored, and crowned by a nectarium; the capsule is cylindrical, covered, and trilocular. There are 26 species, of which 7 are natives of Britain and Ireland. 1. Anglica, the small corn campion or catchly. The stem is weak, hairy, and above a foot high; the leaves are obovate, and grow in pairs at the joints; the flowers are small, white, and entire; they stand on footstalks which issue from the side of the leaves; they are erect, alternate, simple, and lateral. It grows in corn-fields, and flowers in June and July. 2. Nemorum, Nottingham catchly. The stem is about two feet high, and firm; the radical leaves are broad, obtuse, and grow in a tuft; those on the stem are narrow and acute; the flowers are white, and grow in lateral panicles; the petals are bised and curred; the calyx is long, bulbling a little, with ten longitudinal striae. It grows in pastures, and flowers in June and July. 3. Anamna, Tea campion. The stem is two or three feet long, slender, procumbent, and branched alternately: the leaves are long and narrow; the flowers are white, and grow on opposite footstalks, three on each, in unilater al bunches: the calyx is hairy and purplish, and has ten angles. It grows on the south coast, and flowers in June and July. 4. Co- noides, greater corn catchly, or campion. The leaves are narrow and soft; the calyx is conical, with 30 striae; the flowers proceed from the divergences of the stems; the petals are entire. It grows in corn fields, and flowers in June. 5. Nandina, night flowering catchly. The stem is about two feet high, and forked; the calyx has ten angles, is somewhat clammy, and oval, with longer teeth than the other species; the petals are of a reddish white. 6. Armeria, broad-leaved catchly. The stem is about 18 inches high, and erect; with few branches; the leaves are smooth, fleshy, and broad at the base; the flowers terminal, in fayliform bundles, small and red. It may be seen on the banks of rivers, and is in flower in July and August. 7. Acaulis, moss campion. The radical leaves are spread on the ground like a tuft of mosses; the flowers are about an inch long, and naked, bearing each a single purple flower. This last species grows on mountains, and has been found, in Wales and Scotland, within half a mile from their top. It is in flower in July.

SILESIA, a duchy of Germany, bounded on the east by Poland; on the west, by Bohemia and Lower Lusatia; on the south, by a chain of mountains, and a thicket of considerable extent which separates it from Hungary; and to the north, by the marquisate of Brandenburg and Poland. From north west to south east it is about 274 miles, and about 100 where broadest; but it is much contracted at both ends. Upon the frontiers of this country, to the west and south, are very high mountains, and some likewise in other parts of it. One of the ridges upon the frontiers is called the Riphaean mountains, another the Moravian, another the Bohemian, and another the Hungarian, Graspeck, or Carpathians.
S I L  [ 4 7 7 ]  S I L

SILICERNIUM. A branch of the Bohemian is called the Giant Mountains. The winter on these hilly tracks is more severe, sets in sooner, and lasts longer, than in the low lands. The inhabitants use a kind of flakes which they find is deep, as they do in Carniola. Little or no snow is raised in the mountains and some sandy tracks; but the rest of the country is abundantly fruitful, not only in grain, but fruits, roots, pasture, fiax, hops, mad- der, tobacco, and hemp, yielding also fine wine, with considerable quantities of silk and honey. In many places are great woods of pines, fir, beech, larch, and other trees, affording tar, pitch, rosin, turpentine, lamp-black, and timber for all ues. In this country is also found marble of several sorts, some precious flones, lime-flone, millstone, pitcoal, turf, vitriol, some silver ore, copper, lead, iron, and mineral springs. Great numbers of black cattle and hores are brought hither from Poland and Hungary for sale, those bred in the country not being sufficient; but of sheep, goats, game, and venison, they have great plenty. As for wild beasts, here are lynxes, foxes, weasels, otters, and beavers. The rivers, lakes, and ponds, yield fish of several sorts, partic- ularly sturgeons several ells in length, and salmon. Bes- ides a number of smaller streams to water this country, there is the Oder, which traverses it almost from one end to the other; and the Vistula, which after a very long course through it enters Poland. The number of the cities and market-towns is said to be about 200, the county of Glatz included, and that of the villages 5000. The inhabitants, who are computed to be about a million and an half, are a mixture of Germans, Poles, and Moravians. The language generally spoken is Ger- man; but in some places the vulgar tongue is a dialect of the Slavonie. The states consist of the princes and dukes, and those called state-holders, with the nobil- ity, who are immediately subject to the sovereign, and the representatives of the chief cities; but since the country fell under the dominion of the king of Pruf- sia, no diets have been held. The kings, however, when he took possession of the country, confirmed all the other privileges of the inhabitants. With respect to religion, not only Protestants, but Papists, Jews, and Greeks, enjoy full liberty of conscience. The greatest part of Sile sia lies in the diocese of Breslau, but some part of it in the Polish dioceses of Posen and Cracow. The bishop of Breslau holds immediately under the pope with regard to spiritual; but all ecclesiastical benefices, excepting the fee of Breslau, are in the king’s gift. Besides Latin schools, colleges, and seminaries, at Breslau is an university, and at Lignitz an academy for mart- rial exercises. The principal manufactures here are woollen, linens, and cottons of several sorts, with hats, glafs- ware, gunpowder, and iron manufactures. Of these there is a considerable exportation. Accounts are gene- rally kept in rix-dollars, silver groshen, and ducats. With respect to its revolutions and present go- vernment, it was long a part of the kingdom of Poland; afterwards it had several dukes and petty princes for its sovereigns, who by degrees became subject to the kings of Bohemia, until at last king Charles IV. incorporated the whole duchy with Bohemia; and thus it continued in the possession of the house of Austria, until the king of Prussia in 1742, taking advantage of the troubles that ensued upon the death of the emperor Charles VI. and pretending a kind of claim, wrested a great part of it, together with the county of Glatz, from his daughter and heiress Maria Theresa, the late empress dowager; so that now only a small part of it is possessed by the house of Austria, and connected with the empire, the rest being governed by the king of Prussia, without acknowledging any sort of dependence on the crown of Bohemia or the empire. For the administration of justice in all civil, criminal, and feudal cases, and such as relate to the revenue, the king of Prussia has established three supreme judicatories, to which an appeal lies from all the inferior ones, and from which, when the sum exceeds 500 rix-dollars, causes may be moved to Berlin. The Lutheran churches and schools are under the inspection of the upper consiftories, and those of the Papists under that of the bishop’s court at Breslau; but from both an appeal lies to the tribunal at Berlin. As to the revenue, the excite here is levied only in the walled towns, being on the fame footing as in the marquisate of Brandenburg; but in the rest of the country the contributions are fixed, and the fame both in peace and war. The several branches of the revenue are under the management of the war and domain of- ficers of Breslaw and Glogau. The whole revenue aris- ing to the king of Prussia from Silezia and the county of Glatz amounts to about four millions of rix-dollars per annum.

Silezia is divided into Upper and Lower, and each of these again into principalities and lordships; of some of which both the property and jurisdiction belong imme- diately to the sovereign, but of others to his subjects and vassals. In regard to the character of the people, the boors are accounted very dull and stupid; but of those of a higher rank, many have distinguished themselves by their wit and learning, as well as by their military and political talents. However, in general, like their neigh- bours the Germans and Bohemians, they have more of Mars than Mercury in their composition, and their parts are more solid than refining.

SILESIAN EARTH, in the materia medica, a fine astringent bote. It is very heavy, of a firm compact texture, and in colour of a brownish yellow. It breaks easily between the fingers, and does not stain the hands; is naturally of a smooth surface, is readily diffusible in water, and melts freely into a butter-like sub stance in the mouth. It leaves no grittiness between the teeth, and does not ferment with acid men truia. It is found in the perpendicular fissures of rocks near the gold mines at Strigonium in Hungary, and is supposed to be impregnated with the sulphur of that metal. It is a good astringent, and better than most of the boles in use.

SILICERNIUM, among the Romans, was a feast of a private nature, provided for the dead some time after the funeral. It consisted of beans, lettuce, bread, eggs, &c. There were laid upon the tomb, and they foolishly believed that the dead would come out for the repast. What was left was generally burnt on the flone. The word silicernium is derived from flex and causa, i.e. “a supper upon a stone.” Eating what had thus been provided for the dead, was esteemed a mark of the most miserable poverty. A similar entertainment was made by the Greeks at the tombs of the deceased; but it was usual among them to treat the ghosts with the fragments from the feast of the living. See Fu.

SILEX,
SIL, a very soft, fine, bright thread, the work of an insect called bombyx, or the silkworm.

As the silkworm is a native of China, the culture of silkworm in ancient times was entirely confined to that country. We are told that the emperors, surrounded by their women, spent their leisure hours in catching and rearing silkworms, and in weaving tissues and silk veils. That this example was soon imitated by persons of all ranks, we have reason to conclude; for we are informed that the Chinese, who were formerly clothed in fkins, in a short time after were drest in vestments of silk. Till the reign of Justinian, the silkworm was unknown beyond the territories of China, but silk was introduced into Persia long before that period. After the conquest of the Persian empire by Alexander the Great, this valuable commodity was brought into Greece, and thence conveyed to Rome.

The first of the Roman writers extant by whom silk is mentioned, are Virgil and Horace; but it is probable that neither of them knew from what country it was obtained, nor how it was produced. By some of the ancients it was supposed to be a fine down adhering to the leaves of certain trees or flowers. Others imagined it to be a delicate species of wool or cotton; and even those who had learned that it was the work of an insect, shew by their descriptions that they had no distinct idea of the manner in which it was formed. Among the Romans, silk was deemed a drees too expensive and too delicate for men, and was appropriated wholly to women of eminent rank and opulence.

Elaegubulus is said to have been the first man among the Romans who wore a garment of fine silk. Aurelian complained that a pound of silk was sold at Rome for 12 ounces of gold; and it is said he refused to give his wife permission to wear it on account of its exorbitant price.

For several centuries the Persians supplied the Roman empire with the silks of China. Caravans from China verfied the whole latitude of Asia in 243 days, from the Persian Chinef ocean to the sea-cotf of Syria, carrying men till this commodity. Sometimes it was conveyed to the perfons of Guzerat and Malabar, and thence transported by sea to the Persian Gulf. The Persians, with the usual rapidity of monopolists, raised the price of silk to Robertfon's such an exorbitant height, that Jullian, on that part of the great Disquisition concerning India, p. 88, was become of indispenfable ufe, but folicitous to deliver the commerce of his fubjefts from the exactions of his enemies, endeavoured by means of his ally, the Chris- tian monarch of Abyssinia, to wrest fome portion of the filk trade from the Persians. In this attempt he failed; but when he leeff expected it, he by an unfore- seen event, attained, in fome meaure, the object which he had in view. Two Persian monks having been employed as miflamaries in fome of the Chriftian churches, which were elfablifhed (as we are informed by Coimbas) in different parts of India, had penetrated into the coun- try of the Sors, or China. There they observed the labours of the filk worm, and became acquainted with monks, who had attained to the art of working up its productions into fuch a variety of elegant fabrics. The prospect of gain, or perhaps an indignant zeal, excited by feenmg this ini- getive branch of commerce engroffed by unbelieving nations,
There they explained to the emperor the origin of filk, as well as the various modes of preparing and manufacturing it, mysteries hitherto unknown, or very imperfectly understood in Europe; and encouraged by his liberal promises, they undertook to bring to the capital a sufficient number of those wonderful insects, to whose labours man is so much indebted. This they accomplished, by conveying the eggs of the filk worm in a hollow cane. They were hatched by the heat of a dunhill, fed with the leaves of a wild mulberry tree, and they multiplied and worked in the same manner as in those climates where they first became objects of human attention and care. Vault numbers of these insects were soon reared in different parts of Greece, particularly in the Peloponnesus. Sicily afterwards undertook to breed filk worms with equal success, and was imitated, from time to time, in several towns of Italy. In all these places extensive manufactures were established and carried on with filk of domestic production. The demand for filk from the east diminished of course, the republics of the Greek emperors were no longer obliged to have recourse to the Persians for supply of it, and a considerable change took place in the nature of the commercial intercourse between Europe and India.

As filk is the production of a worm, it will be first necessary to give a description of its nature and mode of manufacturing. But before we give any account of the most approved methods of managing filk worms in Europe, it will be proper to present a short description of the method practised in China, the original country of the filk worm. These are two: they either permit them to remain at liberty on mulberry trees, or keep them in rooms. As the finest filk is produced by worms confined in rooms, and as the first method is very simple, it will suffice to describe the second.

To begin with the eggs, which are laid on large sheets of paper, to which they firmly adhere. The sheets are hung up on a beam of the room, with the eggs inward, and the windows are opened in the front to allow the wind; but no hempen ropes must ever come near the worms or their eggs. After some days the sheets are taken down, rolled up loosely with the eggs inward, and then hung up again, during the summer and autumn. At the end of December, or the beginning of January, the eggs are put into cold water, with a little salt dissolved in it. Two days after they take them out, hang them up again, and when dry roll them a little tighter, and enclose each separately, standing on one end in an earthen vessel. Some put them into a lye made of mulberry tree ashes, and then lay them some moments in snow-water, or else hang them up three nights on a mulberry tree to receive the snow rain, if not too violent. The time of hatching them is when the leaves of the mulberry trees begin to open, for they are hatched or impeded according to the different degrees of heat or cold to which they are exposed. When they are ready to come forth, the eggs swell, and become a little pointed.

The third day before they are hatched, the rolls of paper are taken out of the vessel, stretched out, and hung up with their backs toward the sun, till they receive a kindly warmth; and then being rolled up close, they are set upright in a vessel in a warm place. This is repeated the next day, and the eggs change to an alhel grey. They then put two sheets together, and rolling them close tie the ends.

The third day, towards night, the sheets are unrolled and stretched on a fine mat, when the eggs appear blackish. They then roll three sheets together, and carry them into a pretty warm place, sheltered from the south wind. The next day the people taking out the rolls, and opening them, find them full of worms like small black ants.

The apartment chosen for filk worms is on a dry ground, in a pure air, and free from noise. The rooms are square, and very close, for the sake of warmth; the door faces the south, and is covered with a double mat, to keep out the cold; yet there should be a window on every side, that when it is thought necessary the air may have a free passage. In opening a window to let in a refreshing breeze, care must be taken to keep out the gnats and flies. The room must be furnished with nine or ten rows of frames, about nine inches above the other. On these they place rush hurdles, upon which the worms are led till they are ready to spin; and, to preserve a regular heat, loose fires are placed at the corners of the room, or else a warming pan is carried up and down it; but it must not have the least flame or smoke. Cow dung dried in the sun is esteemed the most proper fuel.

The worms eat equally day and night. The Chinese give them on the first day forty-eight meals that is, one every half hour; the next thirty; and third day they have still less. A cloudy and rainy weather takes away their appetite, just before their repast a wisp of very dry straw, the flame of which must be all alike, is held over the worms to free them from the cold and moisture that burdens them, or else the blinds are taken from the windows to let in the full day-light.

Eating so often hastens their growth, on which the chief profit of the filk worm depends. If they come to maturity in 23 or 25 days, a large sheet of paper covered with worms, which at their first coming from the eggs weigh little more than a drachm, will produce 25 ounces of filk; but if not till 28 days, they then yield only 20 ounces; and if they are a month or 40 days in growing, they then produce but ten.

They are kept extremely clean, and are often removed; and when they are pretty well grown, the worms belonging to one hurdle are divided into three, afterwards they are placed on fix, and placed on the number of 20 or more; for being full of humours, they must be kept at a due distance from each other. The critical moment for removing them is when they are of a bright yellow and ready to spin; they must be surrounded with mats at a small distance, which must cover the top of the place to keep off the outward air; and because they love to work in the dark. However, after the third day's labour, the mats are taken away from one o'clock till three, but the rays of the sun must not shine upon them. They are at this time covered with the sheets of paper that were used on the hurdles.

The cocoons are completed in seven days, after which the worm is metamorphosed into a chrysalis; the cocoons are then gathered, and laid in heaps, having first spat apart those designed for propagation upon a hurdle, in a cool airy place. The next care is to kill the moths in these cocoons which are not to be bored. The best way of doing this is to fill large earthen vessels with...
SIL

Silk.

cones in layers of ten pounds each, throwing in four
ounces of salt with every layer, and covering it with
large dry leaves like those of the water-lily, and closely
fopping the mouth of the vessels. But in laying the
cones into the vessels, they separate the long, white, and
glittering ones, which yield a very fine silk, from those
that are thick, dark, and of the colour of the skin of an
onion, which produce a coarser silk.

The silk worm is a species of caterpillar, which, like
all others of the same class, undergoes a variety of
changes, that, to persons who are not acquainted with
objects of this kind, will appear to be not a little fur-
prising.

It is produced from a yellowish coloured egg, about
the size of a small pin head, which has been laid by
a kind of greyish coloured moth, which the vulgar con-
found with the butterfly.

These eggs, in the temperature of this climate, if
kept beyond the reach of the fire and sun shine, may be
preferred during the whole of the winter and spring
months without danger of hatching; and even in sum-
mer they may easily be prevented from hatching if they
be kept in a cool place; but in warmer climates it is
fearfully possible to preserve them from hatching, even
for a few days, or from drying so much as to destroy
them. Hence it is easy in this country to keep the
eggs till the food on which the worm is to be feed be
ready for that purpose. When this food is in perfect-
ion, the eggs need only be exposed to the sun for a day
or two, when they will be hatched with great facility.

When the animal is first protruded from the egg, it
is a small black worm, which is active, and naturally
ascends to the top of the heap in search of food. At this
stage of his growth the silk worm requires to be fed
with the youngest and most tender leaves. On these
leaves if good, he will feed very freely for about eight
days, during which period he increases in size to about
a quarter of an inch in length. He is then attacked
with his first sickness, which confines him in a kind of
lethargic sleep for about three days continuance; during
which time he refuses to eat, and changes his skin, pre-
erving the same bulk. This sleep being over, he begins
to eat again, during five days, at which term he is
grown to the size of full half an inch in length; after
which follows a second sickness in every respect like
the former.

He then feeds for other five days; during which time
he will have increased to about three quarters of an inch
in length, when he is attacked with his third sickness.
This being over, he begins to eat again, and continues
to do so for five days more, when he is attacked by
his fourth sickness, at which time he is arrived at his full
growth. When he recovers this sickness, he feeds once
more during five days with a most voracious appetite;
after which he disdains his food, becomes transparent,
a little on the yellowish cast, and leaves his silky traces
on the leaves where he passes. These signs denote that
he is ready to begin his cocoon, and will eat no more.

Thus it appears that the whole duration of the life
of the worm, in this state of its existence, in our climate,
is usually about 46 days; 28 of which days he takes
food, and remains in his sick or torpid state; but it is
lack to be observed, that during warm weather the periods
of sickness are shortened, and in cold weather lengthen-
ed, above the terms here specified. In very hot cli-
mates it may be said to live faster, and sooner to attain
maturity, than in those that are colder. Dr Anderson
informs us, that at Madras the worm undergoes its
whole evolutions in the space of 22 days. It appears,
however, that it feeds fully as many days in India as in
Europe, the difference being entirely occasioned by
shortening the period of sickness. The longest sickness
he had seen them experience there did not exceed two
days; and during summer it only lasts a few hours.

When the worm has attained its full growth, it
searches about for a convenient place for forming its
cocon, and mounts upon any branches or twigs that are
put in its way for that purpose. After about two days
spent in this manner, it settles in its place, and forms
the cocoon, by winding the silk which it draws from
its bowels round itself into an oblong roundish ball.

During this operation it gradually loses the appear-
ance of a worm; its length is much contracted, and its
thicknes augmented. By the time the web is finisned,
it is found to be transformed into an oblong roundish
ball, covered with a smooth fl filmy skin, and appears
to be perfectly dead. In this state of existence it is called
an aura. Many animals in this state may be often
seen flicking on the walls of out houfes, somewhat re-
sembling a small bean.

In this state it remains for several days entirely mo-
tionless in the heart of the cocoon, after which it bursts
like an egg hatching, and from that comes forth a
heavy dull looking moth with wings; but these wings
never use for flying; it only crawls slowly about in
the place it has been hatched. This creature forces its
way through the silk covering which the worm had
woven, goes immediately in quest of its mate, after
which the female lays her eggs; and both male and fe-
male, without tasting food in this stage of its exis-
tence, die in a very short time.

The silk worm, when at its full size, is from an
inch and a quarter to an inch and a half in length, and
about half an inch in circumference. He is either of a
milk or pearl colour, or blackish; these last are esteem-
ed the best. His body is divided into seven rings, to
each of which are joined two very short feet. He has
a small point like a thorn exactly above the anus. The
fustulence which forms the silk is in his thorax, which
is very long, wound up, as it were, upon two spindles,
as some say, and surrounded with a gum, commonly
yellowish, sometimes white, but seldom greenish. When
the worm spins his cocoon, he winds off a thread from
each of his spindles, and joins them afterwards by
means of two hooks which are placed in his mouth, so
that the cocoon is formed of a double thread. Having
opened a silk worm, you may take out the spindles,
which are folded up in three plaits, and, on stretching
them out, and drawing each extremity, you may extend
them to near two ells in length. If you then scrape the
thread so stretched out with your nail, you scrape off
the gum, which is very like bees wax, and performs
the same office to the silk it covers as gold leaf does to
the ingot of silver it surrounds, when drawn out by the
wire drawer. This thread, which is extremely strong
and even, is about the thickness of a middling pin.

Of silk worms, as of most other animals, there is a
considerable variety of breeds, some of which are much
more hardy, and posses qualities considerably different
from others. This is a particular of much importance
6

Particular
attention
ought to be
paid to the
breed of
silk worms.
Silk. [ 481 ]

to be adverted to at the time of beginning to breed these creatures in any place; for it will make a great difference in the profit on the whole to the undertaker if he rears a good or a bad sort (a). This is a department in respect to the economy of animals that has been in every case much less adverted to than it deserves; and in particular with regard to the silk worm it has been almost entirely overlooked. A few eggs of the silk worm can be easily transported by post in a letter from any part of Europe to another, especially during the winter season. It would therefore be an easy matter for the four different nations, and even of Siberia. Of the seven species of the mulberry (see below) enumerated by Linnaeus, four of these (viz. the white, red, black, and Tartarian), there is every reason to believe could be reared both in Britain and Ireland. The white grows in Sweden; the red is abundant round Quebec; the black delights in bleak situations, exposed to wind on the sea shore; and the Tartarian mulberry is represented as growing in the chilly regions of Siberia. As to the superior qualities of the different species, probably there is very little to be pointed out amongst the four just mentioned with regard to nourishment, except what may be drawn from the following fact: that if the first three are laid down together, the silk worm will first eat the white, then the red, and next the black, in the order of the tendernees of the leaves. The Tartarian seems to hold as high a place in its esteem as either the red or black; but all mulberry yield the white, which seems to be its natural food. In Calabria the red mulberry is used; in Valencia the white; and in Granada, where excellent silk is produced, the mulberries are all black. The white seems to prosper very well in a moist mulberry soil: the black agrees well with a dry, sandy, or gravelly soil; and the white is most luxuriant in a moist rich loam.

Whether any species of mulberry tree be superior to others.

But may be easily reared in temperate climates.

Silk. [ 3 P ]

of this insect, indeed, require a considerable degree of warmth to hatch them, but they can also endure a severe frost. No less than 5400 lbs of silk was raised in 1789 in the cold, sandy territories of Prussia. In the province of Pekin, in China, where great quantities of silk are fabricated, the winter is much colder than even in Scotland. From the information of some Russians who were sent thither to learn the Chinese language, we find that Reaumur’s thermometer was observed from 10 to 15, and even 20 degrees below the freezing point. Nor is it difficult to rear the food of the silk worm in a temperate climate. The mulberry-tree is a hardy vegetable, which bears, without injury, the winters of Sweden, and even of Siberia. Of the seven species of the mulberry (see Morus) enumerated by Linnaeus, four of these (viz. the white, red, black, and Tartarian), there is every reason to believe could be reared both in Britain and Ireland. The white grows in Sweden; the red is abundant round Quebec; the black delights in bleak situations, exposed to wind on the sea shore; and the Tartarian mulberry is represented as growing in the chilly regions of Siberia.

As to the superior qualities of the different species, probably there is very little to be pointed out amongst the four just mentioned with regard to nourishment, except what may be drawn from the following fact: that if the first three are laid down together, the silk worm will first eat the white, then the red, and next the black, in the order of the tendernees of the leaves. The Tartarian seems to hold as high a place in its esteem as either the red or black; but all mulberry yield the white, which seems to be its natural food. In Calabria the red mulberry is used; in Valencia the white; and in Granada, where excellent silk is produced, the mulberries are all black. The white seems to prosper very well in a moist mulberry soil: the black agrees well with a dry, sandy, or gravelly soil; and the white is most luxuriant in a moist rich loam. It may justly be asserted, that Britain possesses some advantages in the rearing of raw silk which are not enjoyed by warmer countries. Even in the south of France, Mr Arthur Young informs us, the mulberry leaves are often nipped by frosts in the bud; but this is for raising fearfully ever the cane in Britain. It is well known that silk, thunder and lightning are hurtful to the silk worm. Now that climate can boast that it is almost wholly exempted from those dreadful storms of thunder and lightning which prevail so much in hot climates. Nature has then furnished us with every thing requisite for the silk manufacture; it remains only for us to improve the advantages which we possess. Let mulberry trees be planted by proprietors of lands, and let a few persons...
Letters on the Culture of Raw Silk on the Coast of Coromandel.

The following method of raising mulberry trees from feed is practised in the south of France, and has been repeated with success in the East Indies by Dr. Anderson of Madras. “Take the ripe berries of the mulberry when it is full of juice and of seeds. Next take a rough horse hair line or rope, such as we dry linen on, and with a good handful of ripe mulberries run your hand along the line bruising the berries and mashing them as much as possible as your hand runs along, so that the pulp and seeds of the berries may adhere in great abundance to the rope or hair line. Next dig a trench in the ground where you wish to plant them, much like what is practised in kitchen gardens in England for crops of various kinds. Next cut the rope or hair line into lengths according to the length of the trench you think fit to make, and plunge the line full of mulbed berries into the trench, and then cover it over with earth, always remembering afterwards to water it well, which is essential to success. The seeds of the berries thus sown will grow, and soon shoot out young suckers, which will bear young leaves, which are the best food for the silk worms.

The facility and rapidity with which young leaves may by this means be produced is evident, for many rows of trenches may thus be filled as can be wished; and it can never be necessary to have mulberry trees higher than our raspberries, currants, or gooseberry bushes. Whenever they get beyond that, they lose their value; and if these trenches succeed, you may have a supply coming fresh up day after day, or any quantity you please.” Thus abundance of these trees might be reared. But as mulberry trees are not yet found in abundance in Britain it were to be wished that some other food could be substituted in their place: attempts have accordingly been made by those who have reared silk worms, and has been found possible to support the silk worms upon lettuce (a).

Miss Henrietta Rhodes, a lady who has made some successful experiments on raising silk worms in England had found that this food could have safety be kept on lettuce for some time. This is pretty generally known by ladies who have turned their attention to this subject; but the found that in general they could not with safety be kept upon that food above three weeks. If longer fed upon that plant, the worms for the most part die without spinning a web at all. She found, however, that they did not always die, but that in some cases they produced very good cocoons, even when fed entirely on lettuce. She therefore with reason supposed that the death of the animal must be occasioned by some extraneous circumstance, and not from the poisonous quality of the food itself; the circumstance the suspected, from some incidental observations, was the coldness of that food; and therefore she thought it was not impossible, but if they were kept in a very warm place, while fed on lettuce, they might attain, in all cases, a due perfection.

General Mordaunt having been informed of this conjecture, resolved to try the experiment. He got some silk worms eggs, had them hatched in his hot-house, and caused them to be all fed upon lettuce and nothing else. They prospered as well as any worms could do, few or none of them died; and they afforded as fine cocoons as they had been fed upon mulberry leaves. As far as one experiment can go, this affords a very exhilarating prospect in many points of view. If one kind of food has been noxious, merely on account of an improper temperature, others may be found which have been hurtful only from a simular cause; so that it is not impossible but we may at last find that this delicate creature may be supported by a variety of kinds of food. Few, however, could be more easily obtained than lettuce; and this plant, when cabbaged (the cobs, or ice lettuce especially, would poisons one quality that the mulberry leaf never can possess, from the want of which many millions of worms die in those countries where silk is now reared; for it is observed, that when the leaves are gathered wet, it is scarcely possible to preserve the worms alive for any length of time; so that during a continuance of rainy weather many of them are unavoidably cut off; but a lettuce, when cabbaged, retains moisture. If gathered, even during rain, the heart of it is dry; so that if the outer leaves be thrown aside at that time, the worms would be continued in perfect health. The expense, too, of cultivating and gathering lettuce, would be so much less than that of gathering mulberry leaves, as to occasion a saving that would be much more than sufficient to counterbalance the expence of heating the conservatory, as a little reflection will show.

But the great point to be now ascertained is, whether it is a fact that worms fed on lettuce, if kept in a due temperature, will continue in good health, in general, till they shall have perfected their cocoon? One experiment is too little to establish this fact with perfect certainty. It would therefore be necessary that more experiments should be made on this subject.

It is said that Dr. Lodovico Bellardi, a learned and ingenious botanist of Turin, has, after a number of experiments, discovered a new method of feeding silk worms, when they are hatched before the mulberry trees have produced leaves, or when it happens that the frost destroys the tender branches. This new method consists in giving the worms dried leaves of the mulberry-tree. One would think that this dry nourishment

(a) It is not improbable, says Dr. Anderson, to whose valuable work entitled the Bee, we have been much indebted in the drawing up of this article, that other kinds of food may be found which will answer the same purpose. The chicorium intybus and common endive might be tried, as they have the same laudable quality with the lettuce.
S I L

Silk would not be much relished by these insects; but repeated experiments made by our author, prove that they prefer it to any other, and eat it with the greatest avidity. The mulberry leaves must be gathered about the end of autumn, before the fruit commences, in dry weather, and at times when the heat is greatest. They must be dried afterwards in the sun, by spreading them upon large cloths, and laid up in a dry place after they have been reduced to powder. When it is necessary to give this powder to the worms, it should be gently moistened with a little water, and a thin coat of it must be placed around the young worms, which will immediately begin to feed on it.

We have mentioned all the different kinds of food, which, as far as we have heard, have been tried with any success to nourish the silk worm; not, however, with great confidence; but as experiments which it might be worth while carefully to consider and perform. We must not omit to mention that one person, who has had much experience in the managing of silk worms, assures us, that the silk produced from any other food than mulberry leaves is of an inferior quality, and that the worms are weaker. We think, however, that there is reason to suspect that the experiment has not been skillfully performed; and therefore, before every other food except mulberry leaves is discarded, the experiment ought to be performed with more attention and care.

We know that many animals in a domestic state can live upon food very different from that which supported them when running wild in the fields. Certain it is, however, that every animal, in its state of nature, partakes of a food peculiar to itself, which is rejected by other animals as if it were of a poisonous quality; and it may be mentioned as a curious fact, as well as an admirable instance of the care of that Being who feeds the fowls of heaven, that notwithstanding the numberless insects that prey upon animals and vegetables, the mulberry tree is left untouched by them all, as the exclusive property of the silk worm, the chief of the insect tribe, which toils and spins for the use of man.

Having now considered the food proper for the silk worm, we shall next consider what situation is most favourable to them. In the opinion of some persons in Britain who have been in the practice of rearing silk worms, they ought always to be kept in a dry place, well sheltered, and possessing a considerable degree of warmth, and which is not exposed to sudden transitions from heat to cold. If the weather be too cold, a small fire must be made; this is of most importance when the worms are ready for spinning. A southern exposure is therefore preferable. Some think light is of great utility to silk worms, others think that they thrive better in the dark. As to what apartments are best accommodated for promoting the health of silk worms, and most convenient for those who have the care of them, they may be various according to the extent of the manufacture or the wealth of the proprietors. Silk worms may be kept in boxes or in shelves. When shelves are to be used, they may be constructed in the following manner: The shelves may be of wicker, ranged at the distance of a foot and a half, and fixed in the middle of the room; their breadth ought to be such, that any person can easily reach to the middle from either side. This is perhaps the simplest and cheapest apparatus for rearing silk worms; but there is another apparatus which may be recommended to those who are anxious to unite some degree of elegance with convenience. This apparatus is the invention of the Rev. George Swayne of Pucklechurch, a gentleman who, greatly to his honour, has studied this subject much, in order to find out the way for promoting the culture of silk among the poor.

This apparatus, with the description of it, we have borrowed from that valuable and patriotic work, the Transactions of the Society for encouraging Arts, Manufactures, and Commerce, Vol. VII. p. 148. The apparatus consists of a wooden frame four feet two inches high, each side six inches and a half wide, divided into eight partitions by small pieces of wood which form grooves, into which the slides run, and are thus easily thrust into or drawn out of the frame. The upper slide (a) in the model sent to the society by Mr. Swayne is of paper only; and designed to receive the worms as soon as hatched; the two next (b, c) are of catgut, the threads about one-tenth of an inch distant from each other; there are for the insects when a little advanced in size; the five lower ones, marked e, f, g, h, i, are of wicker one foot wide, and intended to receive the worms when they are ready for spinning. Under each of these, as well as under those of catgut, are slides made of paper, to prevent the dung of the worms from falling on those feeding below them.

The management of silk worms is next to be attended to. The proper time for hatching them is when the leaves of the mulberry are fully grown, or nearly so; that as soon as these insects are capable of receiving food they may obtain it in abundance. To attempt to hatch them sooner would be hurtful, as the weather would not be sufficiently warm. Besides, as the leaves are necessary to the life of a vegetable, if the young leaves of the mulberry tree are cropped as soon as they are unfolded, the tree will be so much weakened as not to be capable of producing so many leaves as it would otherwise have done; and if this practice be frequently repeated, will inevitably be destroyed.

When the proper season is arrived, the eggs may be hatched either by the heat of the sun, when it happens to be strong enough, or by placing them in a small glass room moderately heated by a stove or fire; and after being exposed for six or seven days to a gentle heat, the silk worms issue from the egg in the form of a small black hairy caterpillar. When Mr. Swayne's apparatus is used, the worms are to be kept on the drawers with paper bottoms till they are grown so large as not readily to creep through the gauze-bottomed drawers; they are then to be placed on those drawers, where they are to remain till their excrements are so large as not readily to fall through; when this is the case, they must be removed to the drawers with the wicker or netting bottoms, and fed thereon till they show symptoms of being about to spin. It is scarcely necessary to mention that the paper slides beneath the gauze and wicker drawers are intended to receive the dung, which should be emptied as often as the worms are fed, at least once a day; or to direct, that when the worms are fed, the slides are to be first drawn out a considerable way, and the drawers to rest upon them.

It has already been mentioned, that wet or damp food is exceedingly prejudicial to these insects. It produces contagious and fatal diseases. To prevent the necessity of giving them wet or damp food, attention ought...
Ought to be kept as clean as possible.

The utmost attention must be paid to preserve the place where silk worms are kept as clean as possible: the house or room must be well ventilated, that no noxious vapours be accumulated. By some experiments of M. Fantus de S. Fond, which are recorded in his history of Languedoc, it appears that the silk worm is much injured by foul air. All decayed leaves must be removed from them, as it is now well known that they emit bad air in great abundance.

One of the most difficult branches of the management of silk worms has hitherto been the cleaning without breaking them. To avoid this inconvenience, the peasants in France and Italy frequently allow the whole litter to remain without ever cleaning them, which is the cause of that unwholesome stench that has been so often remarked by those who visit the places for rearing silk worms in those countries. This difficulty may be effectually removed by providing a net, or, what would be still better, a wire-bottomed frame, wrought into large meshes like a riddle. Have that made of a size exactly sufficient to cover the wooden box in which the worms are kept. When you mean to shift them, spread fresh leaves into the wire basket; and let it down gently over the worms till it comes within their reach. They no sooner perceive the fresh food than they abandon the rubbish below, and creep through the meshes, so as to fix themselves upon the leaves; then by gently raising the fresh basket, and drawing out the board below (which ought to be made to flip out like the flip bottom of a bird's cage), you get off all the excrements and decayed leaves, without commending the worms in the smallest degree; and along with the litter you will draw off an inch or two in depth of the foulest mephitic vapours. To get entirely rid of these, the board, when thus taken out, should be carried without doors, and there cleaned; and the flip board immediately replaced to receive all the excrements and offals. After it is replaced, the wire frame that had been elevated a little, may be allowed to descend to a convenient distance above the board without touching it. Thus will there, be left a vacant space for the mephitic air to fall below the worms, so as to allow them to inhabit a wholesome region of the atmosphere.

When a fresh supply of food is to be given before cleaning, the wire frame ought to be let down as close to the board as can be safely done, and another wire-bottomed frame put over it, with fresh leaves, as before described. When the worms have abandoned that in their turn, let the flip-board, together with the lower wire frame, be drawn out and removed, and so on as often as necessary. To admit of this alternate change, every table, consisting of one flip-board, ought to have two sets of wire-bottomed frames of the same size; the flip-board to be always put into its place immediately after it is cleaned, and the wire frames referred to be afterwards placed over the other. By this mode of management, it is probable that the worms would be saved from the diseases engendered by the mephitic air, and the numerous deaths that are the consequence of it avoided.

Dr Anderson, to whom we have already acknowledged our obligations, and to whom Britain has been much indebted for valuable works on agriculture, for all the fisheries &c. advises those who have the management of silk worms to shew a thin stratum of fresh flaked quicklime upon the flip-board each time it is cleaned, immediately before it is put into its place. This would abhor the mephitic gas, for as soon as it is generated it would descend upon the surface of the quicklime. Thus would the worms be kept continually in an atmosphere of pure air (c). Were the walls of the apartments to be frequently washed with quicklime and water, it would tend much to promote cleanliness at a small expense, and augment the healthiness of the worms as well as that of the persons who attend them.

When the silk worm refuses its food, and leaves filky Mr Swaine's traces on the leaves over which it passes it is a proof that it is ready to begin its cocoon. It is now necessary to form a new receptacle, which is commonly done by pinning together wipers in the shape of inverted cones with broad base. "This method (says Mr Swaine), is utterly fallacious; for below where there are many worms, is exceedingly tedious. Instead of the wipers, the silk worm always weaves an outer cover. The Society for ing or defensive web before it begins the cocoon or the Enclosure oval ball, I apprehended that it caused a needless waste of silk in forming the broad web at the top. The method I made use of is, to roll a small piece of paper (an uncut otau leaf, such as that of an old magazine, is sufficient...
The cocoons which are kept for breeding are called royal cocoons. For selecting and preserving these, we have been favoured with some valuable instructions by Mr. Wright of Piedmont, which we shall present to our readers.—The large and belt cocoons ought to be kept for breed, about an even number of males and females; the cocoons that contain the former are sharper pointed at the ends than those that contain the latter royal cocoons.

Although it should happen that there are more females than males, little inconvenience or ill consequences can arise from it, as one male will serve two or three females, if the time of their coming out of the cocoons answer. About 12 or 15 days after they begin to spin, the cocoons for breed may be laid on sheets of white paper; about this time the moth opens itself a passage through the end of its cocoon, and flutters out. When the female has laid her eggs, which on an average may amount to 250, they are spread upon sheets of paper and hung up to dry in some place where they may not be exposed to the heat of the sun: after being dried they must be kept in a cool well- aired place, where neither vapours nor moisture can reach them. That they may be preserved from external accidents, as insects of different kinds, will destroy them, and mice is their enemy in all the flages of their existence, they should be kept in stone pots or glass bottles with their mouths stopped, and there remain until brought out next season to be hatched.

The cocoons from which the Silk is to be immediately prepared are not to be exposed to the heat of an oven, in order to kill the chrysalis or auricle, which would otherwise ruin the silk. The following directions are given for managing this process by one of the first Silk manufacturers in Italy.

Put your cocoons in long shallow baskets, and fill the spaces within an inch of the top. You then cover them with paper, and put a wrapper over that. These baskets are to be disposed in an oven, whose heat is as near 80 as can be that of an oven from which the bread is just drawn, and after being baked. When your cocoons have remained therein near an hour, you may draw them out: and to see whether all the worms are dead, draw out a dupion from the middle of your basket and open it; if the worm be dead, you may conclude all the rest are so, because the texture of the dupion being stronger than that of other cocoons, it is consequently less easily to be penetrated by the heat. You must observe to take it from the middle of the basket, because in that part the heat is least perceptible. After you have drawn your cocoons from the oven, you must first cover each of them with a woollen blanket or rug, leaving the wrapper beside; and then you pile them above one another. If your baking has succeeded, your woollen cover will be all over wet with a kind of dew, the thickness of your little finger. If there be less, it is a sign your cocoons have been too much or too little baked. If too much baked, the worm, being over-dried, cannot transpire a humour he no longer contains, and your cocoon is burnt. If not enough baked, the worm has not been sufficiently generated by the heat to distil the liquor he contains, and in that case is not dead.

You must let your baskets stand thus covered five or six hours if possible, in order to keep in the heat, as this makes an end of stifling these worms which might have avoided the first impression of the fire. You are like-
How the silk is to be wound from the cocoons.

1. In stripping them of that waste silk that surrounds them, and which served to fallent them to the twigs. This burr is proper to stuff quilts, or other such uses; you may likewise spin it to make stockings, but they will be coarse and ordinary.

2. You must sort your cocoons, separating them into different classes in order to wind them apart. These classes are, the good white cocoons; the good cocoons of all the other colours; the dupions; the cocalons, among which are included the weak cocoons; the good choquette; and, lastly, the bad choquette. In forting the cocoons, you will always find some perforated cocoons amongst them, whose worm is already born; these you must set apart for fleurets. You will likewise find some fouflons, but very few; for which reason you may put them among the bad choquette, and they run up into waste.

The good cocoons, as well white as yellow, are the easiest to wind; those which require the greatest care and pains are the cocalons; you must wind them in cooler water than the others, and if you take care to give them to a good windter, you will have as good silk from them as the rest. You must likewise have a careful windter for the dupions and choquettes. These two species require hotter water than the common cocoons.

The good cocoons are to be wound in the following manner: First, choose an open convenient place for your filature, the longer the better, if you intend to have many furnaces and copperers. The building should be high and open on one side, and walled on the other, as well to screen you from the cold winds and receive the sun, as to give a free passage to the steam of your bacon or copperers.

These copperers or baconers are to be disposed (when the building will admit of it) in a row on each side of the filature, as being the most convenient method of placing them, for by that means in walking up and down you see what every one is about. And these baconers should be two and two together, with a chimney between every couple.

Having prepared your reels (which are turned by hands, and require a quick eye), and your fire being a light one under every bacon, your windter must lay till the water is as hot it can be without boiling. When every thing is ready, you throw into your baconers two or three handfuls of cocoons, which you gently brush over with a wiff about five inches long, cut flumpy like a broom worn out; by these means the threads of the cocoons flick to the wiff. You must disengage these threads from the silk, and purge them by drawing these ends with your fingers till they come off entirely clean. This operation is called la Battue.

When the threads are quite clear, you must pass four of them (if you will wind fine silk) through each of the holes in a thin iron bar that is placed horizontally at the edge of your bacon; afterwards you twit the two ends (which consist of four cocoons each) twenty or twenty-five times, that the four ends in each thread may the better join together in drawing each other, and that your silk may be plump, which otherwise would be flat.

Your windter must always have a bowl of cold water by her, to dip her fingers in, and to sprinkle very often the said bar, that the heat may not burn the thread.

Your threads, when thus twit, go upon two iron hooks called rampins, which are placed higher, and from thence they go upon the reel. At one end of the axis of the reel is a cog-wheel, which catching in the teeth of the post-rampin, moves it from the one to the left, and consequently the thread that is upon it; so that your silk is wound on the reel crosways, and your threads form two hanks of about four fingers broad.

As often as the cocoons you wind are done, or break or diminish only, you must join fresh ones to keep up the number requisite, or the proportions; because, as the cocoons wind off, the thread being finer, you must join two cocoons half wound to replace a new one; thus you may wind three new ones and two half wound, and your silk is from four to five cocoons.

When you would join a fresh thread, you must lay one end on your finger, which you throw lightly on the other threads that are winding, and it joins them immediately, and continues to go up with the reel. You must not wind off your cocoons too bare or to the laft, because when they are near at an end, the barres, that is, the husks, joins in with the other threads, and makes the silk foul and gouty.

When you have finished your first parcel, you must clean your bacons, taking out all the striped worms, as well as the cocoons, on which there is a little silk, which you first open and take out the worm, and then throw them into a basket by you into which you likewise cast the loose silk that comes off in making the Battue.

You then proceed as before with other two or three handfuls of cocoons; you make a new Battue; you purge them, and continue to wind the same number of cocoons as their equivalent, and so to the end.

As was already mentioned, the windter must always have a bowl of cold water by her, to sprinkle the bar, to cool her fingers every time she dips them in the hot water, and to pour into her bacon when necessary, that is, when her water begins to boil. You must be very careful to twit your threads a sufficient number of times, about 25; otherwise your silk remains flat, instead of being round and full; besides, when the silk is not well crossed, it never can be clean, because a gout or rub that comes from a cocoon will pass through a small number of these twils, though a greater will stop it. Your thread then breaks, and you paes what foulness there may be in the middle of your reel be-
the advantages of this construction are, the gaining light, a power of shortening the porty occasion, so as to suit any kind of work, being more portable, and having the gibbet firmly fixed, together with the diminution of price; which, compared with the old loom, is as five pounds, the price of a loom on the old construction, to three pounds ten shillings, the price of one of these contrived by Mr Sholl; and that, as the proportion of light work is to strong work as nine to one, this fort of loom promises to be of very considerable advantage, particularly in making modes, or other black work.

As a plate of this loom, with proper references, will description render its advantages most intelligible, we shall subjoin of it there: Plate CCCCLXV. A, A, The falls; B, D, The break-roll pots; C, The cut tree; D, D, The uprights; E, The burdowm; F, The button; G, The reeds; H, The harness; I, The breast-roll; K, The cheese; L, The gibbet; M, The treddles; N, The tumblers; O, Short counter-frames; P, Long counter-frames; Q, The porry; R, R, Cane-roll pots; S, The cane-roll; T, The weight bar and weight; U, U, Counter-weights; W, The breaking rod; X, X, Cross rods.

SILPHIA, CARRION-BEETLE, in natural history; a genus of animals belonging to the class of insects, and to the order of coleoptera. The antennae are clavate; the clava are perforated; the elytra marginated; the head is prominent; and the thorax marginated. There are 94 species, of which seven only are natives of Britain and Ireland. 1. The cephalus. The margin of the thorax broad. The shells abbreviated, black, with two yellow belts. The thighs of the hind legs large, with a spine near their origin. Length near one inch. It infests dead bodies. 2. The biphylus, is black; the antennae are long and small, and there are two red spots on the middle of each shell. The length is one-third of an inch. 3. The pulybata, is black and oblong; there are four brown spots on the shells: the length is one-fifth of an inch. It lives on trees. 4. The quadriplana. The head, antennae, and legs black. Margin of the thorax and shells are of a pale yellow, with four black spots. The length half an inch. It is found in Cane-wood, near Hampstead. 5. The fabulus, is black; the antennae are short and globular; there are five dries each shell. The shells and wings are short. There are five joints on the two first feet, four on the rest. It lives in sand. 6. The aquatica, is brown, with a green bronze tinge. There are four ribs on the thorax. On each shell there are two dries. The length is one-fifth of an inch. 7. The pulicaria, is black and oblong; the shells are abbreviated; the abdomen is rounded at the extremity; the thorax and shells are black margined; the length is one line. It is found frequently running on flowers.

SILPHIUM, in botany; A genus of plants belonging to the class of syngenesia, and to the order of polygamy necessaria; and in the natural system arranged under the 49th order, composite. The receptacle is paeceous; the pappus has a two-horned margin, and the calyx is squarrose. There are eight species; the laminatum, teresclamatium, perfoliatum, connati, altericum, trilobatum, foliaginoides, and trilobatum. The first six of these are natives of North America.
SILVER, one of the perfect metals, and the whitest and most brilliant amongst them all, is of the specific gravity, according to Bergman, of 10.552; but according to Kirwan, of 11.095. Its ductility is not greatly inferior to that of gold, as a grain of silver leaf measures somewhat more than 51 square inches; and the silver wire used for alchemical purposes measures only the 750th part of an inch in diameter; which is no more than half the thickness of the hair of the human head. It is harder and more elastic than lead, tin, or gold; but leaves so than copper, platinum, or iron: like other metals it grows hard by hammering; but is easily reduced to its former state by annealing. It is more delectable than gold, and is particularly acted upon by sulphurous vapours; hence its surface tarnishes in the air, and assumes a dark brown colour.

"It has been long thought (says Mr. Fourcroy) that silver is indelible by the combined action of heat and air. It is certain, that this metal kept in fusion, without contact of air, does not appear to be feebly altered; yet Junker had affirmed, that by treating it a long time in the reverberatory furnace, in the manner of Isaac Hollandus, silver was changed into a vitreous salt. This experiment has been confirmed by Macquer. That learned chemist exposed silver 20 times successively in a porcelain crucible to the fire of the furnace at Sevres, and at the 20th fusion he obtained a vitriform matter of a golden green, which appeared to be a true glafs of silver. This metal, when heated in the focus of a burning glafs, has always exhibited a white pulvourous matter on its surface, and a greenish vitreous covering on the support it rested upon. These two facts remove all doubt respecting the alteration of silver; though it is much more difficult to calcine than other metallic matters, yet it is capable of being converted after a long time into a white caal, which, treated in a violent fire, affords an olive coloured glafs. It may be possible perhaps to obtain a calx of silver by heating this metal when reduced into very fine laminae, or into leaves, for a very long time in a muftra, as is done with mercury."

Magellan informs us, that by melting in a due proportion with gold or silver, gold becomes greenish or bluish; so that it is capable of producing the white, yellow, red, blue, and green, or silver, colours, or more or less confpicuously according to the various circumstances of heat and proportions of the mixture. Though he makes mention of the vitrifications by Macquer already taken notice of, he denies that it can be calcined by heat alone. "Silver (says he) is so fixed by itself in the fire, that, after being kept a whole month in fusion, it had only lost one sixt part of its weight, which might be on account of some alloy. It is therefore incapable of being calcined by mere heat; and the caal of silver, which can only be made by means of its solution in acids, is reducible to its metallic form without the addition of any oxygenous substance. But when silver is exposed to the violent heat of the solar rays collected by a powerful lens, a kind of smoke is seen surrounding it, which proves at last to be the minute particles of the metal raiied and dispersed by heat, as is evident if a thin plate of gold be exposed to it; for then the particles of silver are seen upon the gold in the same manner as those of gold are seen upon silver in a similar experiment."

By slow cooling after it has been melted, silver crystallizes into quadrangular pyramids. M. Baume observes, that, in cooling, it assumes a symmetrical form, observable on the surface by small fibres resembling the feathers of a pen. M. Fourcroy observes, that the fine button obtained by cupellation, often presents on its surface five or six sides arranged amongst each other like a pentagon; but the crystallization in tetrahedral pyramids has not been observed particularly excepting by Mefirs Tillet and Mongez. It has been supposed that silver melts with a smaller degree of heat than copper; but the late improved thermometer of Mr. Wedgewood shows that this is a mistake; silver requiring 130° of Fahrenheit more than copper to bring it into fusion. It is found in the earth.

1. Native, generally of the fines of 16 carats; and of this there are several varieties. 1. Thin plated or leaved. 2. Capillary, of fine or coarse fibres or arborecent, from Potosi in America and Kuniberg in Norway. 3. A kind is also met with resembling coarse linen in the surface, which in Saxony is called kust钴al. Abundance of this kind is to be met with in Potosi, but more rarely in Saxony and Norway.

4. Sometimes native silver is met with in a crystalline or regularly figured plate with shining surfaces. This is found at Kuniberg, but is very scarce. There appears likewise a kind of crystallization on the thin plates of native silver, their surfaces being full of minute pyramidal crystals. Most of the American silver is of the native kind; so is that at Kuniberg in Norway. It is not, however, met with native so commonly in other European mines. A very small quantity of it is found in the mines of Salberg in Westmanland, and of Loifen in Dalmar, and several other places in Sweden. It has been found in pretty large lumps in clay mixed with nickel, partly decayed or withered; in which situation it formed the compound called the fercus aurifnum, or goode dung ore. 5. A piece of native silver in coal is shewn in the mineralogical academy at Frelberg; and Lohman, quoted by Le Camus, speaks also of a similar silver ore found in a mine of pit-coal. The capillary silver, according to the observations of Henckel and Rome de Lisle, seems to have been produced by a decomposition of red silver ore; and Wallerius affirms, that if sulphur is mixed in a gentle heat with silver, the latter takes a capillary form. 6. Native silver is likewise sometimes found in the form of spider's webs, and for that reason called by the Spaniards aranea.

7. It is met with in branches formed by oolaeadons inferted into one another. Some of these show the mark of a leaf of fern or of a tree; others are cubes or tingle oolaeadons, whose angles are truncated, though these latt are but rare. 8. It is often found discoverd through sand and ochre, as well as in grey limestone in Lower Austria, and in a greenish clay near Schernitz, or mixed with ochre, clay, and calciiform nickel. It is generally alloyed with copper, sometimes with gold, iron, or regulus of antimony; and sometimes it contains even five per cent. of arsenic. That found near Kuniberg contains so much gold, that the colour of it is yellow.

Wallerius distinguishes seven species of native silver; viz. 1. In irregular masses and lumps, at Kuniberg in Norway and other places, in a bed of clay. 2. In a granular and jagged form in America and Norway. 3. Arborecent, in the places already mentioned. 4. In thin

thin leaves, between the fissures of stones, in Norway and Germany. In a capillary form, in the places already mentioned, including the cobweb silver of the Spaniards already mentioned. 6. Crystallized. 7. Superficial. Mr Daubenton enumerates eight varieties of native white silver, of different forms, most of which have been already enumerated. The materials in which this metal is most commonly found in its native state are, baro-selenite, lime-silver, selenite, quartz, chart, flint, ferrapente, gneiss, agate, mica, calcareous sapphire, pyrites, schistus, clay, &c. Sometimes it is met with in large masses, of the weight of 60 pounds or more, in or near the veins of most metallic ores, particularly in Peru and in various parts of Europe, of a white, brown, or yellowish colour. In Norway and at Allsea it is found in the form of solitary cubes and octahedral lumps, of 50 and 60 pounds weight.

2. Native silver alloyed with other metals. 1. With gold, as in Norway, where it contains so much as to appear of a yellow colour. 2. With copper. 3. With gold and copper. 4. Amalgamated with mercury, as in the mines of Salberg. M. Rome de Lisle mentions a native amalgam of silver and mercury found at Mnschel Landberg, in the duchy of Deux Ponts, in a ferruginous matrix, mixed with cinnabar, and crystallized in a hexagonal form, and of a large size. It was before the French revolution preferred in the king's cabinet at Paris. 5. With iron. According to Bergman, this ore contains two per cent. of iron; but Mongez informs us, that it often does not exceed one per cent.

6. With lead, "Silver (says Mr Magellan) is always contained in lead, though the quantity is generally insufficient to deprive the efficacy of separating it. In the reign of Edward I. of England, however, near 1600 pounds weight of silver were obtained, in the course of three years, from a lead mine in Devonshire, which had been discovered about the year 1250. The lead mines in Cardiganshire have at different periods afforded quantities of silver, so that Sir Hugh Middleton is said to have cleared from them £10000 in a month. The same mines in the year 1753 yielded 80 ounces of silver out of every ton of lead. This in lead only one of the foundling houses at Holywell in Flintshire produced, no less than 37521 ounces, or 31263 pounds of silver from the year 1754 to 1756, and from 1754 to 1776. There are some lead ores in England, which, though very poor in that metal, contain between 300 and 400 ounces of silver in a ton of lead; and it is commonly observed, that the poorest lead ores are the richest in silver; so that a large quantity of silver is probably thrown away in England by not having the poorest part of the lead ores properly essayed." 7. Mr Monnet found silver united with arsenic among the ores which came from Guadalcanal canal in Spain, and an ore of the same kind is furnished by the Samion mine near Andenrungen in the Hartz; but Mr Mongez very properly remarks, that these ores must be distinguished from such as have the arsenic in the form of an acid; for in this case they are properly mineralized by it, whilst there can only be a mixture of native silver, or some of its alloys with arsenic in its reguline form. 8. Bergman mentions silver in a flake of union with antimony. The ore yields some smoke when roasted, but has not the garlic smell observable in the arseneous ores. 9. The white silver ore, found in the mines near Freyberg, has the metal united to the regulus of arsenic and iron, the three metallic ingredients being nearly in equal proportions. All the extraneous matters with which the silver is united are sometimes in exceedingly small proportion, but not to be neglected where they exceed the hundredth part of the whole mass.

10. A particular kind of fine silver ores is mentioned by Wallerius under the title of lapis deo, and which contain the following varieties, viz. the calcarious silver ore at Annaberg in Austria, when the metal is mixed with an alkaline lime-stone; the fissafo ore, either white, variegated, or yellowish, found at Schernitz in Hungary; the quartzose white ore in a powdery form, mixed with ferruginous scoria, found at Potosi in America; the dark and variegated quartz-oxide silver ores, with many other subdivisions dishinigished from one another by little citr than their colour.

Silver is found mineralized by various substandes, as,

1. With sulphur in the glassy or vitreous silver ore; though this name seems rather to belong to the minera argentii corona or horn silver ore, to be afterwards taken notice of more particularly. It is dusky, and of the same colour with lead, but quickly becomes very black by exposure to the air, though sometimes it is grey or black even when first broken. It is found either in large lumps, or inherning in quartz, gypsum, gneiss, pyrites, &c. Its specific gravity, according to Kirwan, is 7:200. An hundred parts of it, containing 72 to 77 of silver, and it is rarely contaminated with any other metal.

Professor Brunnic says, it contains 80 marks of silver in the hundred weight. The medium between the glassy ore and the rod silver ore is called rogey, or braustil in Hungary, and brittle glassy ore in Saxony. It is black, and affords a powder of the same colour when pounded. In the mines of Himmelsfort near Freyberg, it is said to have held 140 marks, but these pieces are very scarce at present; and indeed the Hungarian glassy ores in general are now very scarce, as Professor Brunnic informs us, though they are now and then found in the wind-shits, which are frequently covered with a thin membrane or rather crust, of the colour of pyrites. Mr Magellan says, that this ore is nothing else but native silver penetrated by sulphur; for, on being exposed to a flow heat, the former flies off, and the silver remains in the same form. There are nine varieties of it, like sand, flint, or plumbago, the most common kind of any. 1. Brückmann mentions a kind brown on the outside and greenish within. 3. The yellow ore has its colour from some arsenic contained in it, which forms an opusinum with the sulphur. 4. It is also found of a greenish, and blueb colour; the latter is friable, like the foria of metals, and is called at Freyberg Schleirekorn, or the ore of foria. 6. It is found also in the arborescent. 7. Laminated. 8. Crystallized into octahedral or hexagonal prisms, and into ten pyramids with ten faces. 9. Lastly, it is found of a partial, or covering the stones or masses of other ores.

2. The pyrites argenteus of Hencel contains silver 2% combat, and iron mineralized with arsenic. There are three varieties of it. 1. Hard, white, and shining ore, of a compact, lamello, or fibrous texture. The brightest kind has lead silver, only giving 6 to 8 ounces per quintal, and the richest about ten per cent. It is found in Germany and Spain. It contains no sulphur. 2. Of yellowish white colour, and striped texture resembling bismuth, but much harder. It is found in Spain, and yields about 6% per cent. of silver. 3. In the lead lode close to...
the quantity of arsenic is so great, that it would scarcely deserve the name of silver ore if the arsenic were not very easily distilled. It is soft and easily cut; it has a brilliant metallic appearance, and consists of conchoïdal lamines. A quintal contains only from four to six ounces of silver, but it is easily reduced by evaporating the arsenic, after which the silver is left behind slightly contaminated with iron.

3. The red or ruby silver ore, the rothgolden of the Germans, has the metal combined with fulphur and arsenic. It is a heavy shining sub stance, sometimes transparent and sometimes opaque; the colour generally crimson, though sometimes grey or blackish. It is found in stope's mafles, or crystallized in pyramids or polygones, sometimes dendritic or plate, or with radiated inclusions. It is found in quartz, flint, spar, pyrites, sparry iron ore, lead ore, cobalt ore, jasper, baro-felinite, gneifs, &c. When radiated or interlaced, it is called rothgulden blut. It cracks in the fire, and detonates with nitre. Its specific gravity is from 5,400 to 5,684. Bergman informs us, that this kind contains, in the hundred, 60, sometimes 70, pounds of silver, 27 of arsenic, and 13 of sulphur. The darkest coloured ores are the richest, the yellow kinds much poorer; but the most yellow do not belong to this species; being in fact an orniment with 6 or 7 per cent. of silver. This last kind is brought chiefly from Potosi in America, and is called reflector by the Spaniards.

4. The febouris golden, or silver mulm, contains the metal mineralized by sulphur and a small quantity of arsenic and iron. It is of a black footy colour, and was supposed by Cronstedt to contain a good quantity of copper, to which its colour was owing; but later experiments have evinced, that there is no copper at all in it. It is either of a solid or brittle consistence, and of a glafty appearance when broken, or of a hoover texture, and footy or deep black colour; or it is found like mofs, or thin leaves, lying on the surface of other silver ores, of those of lead and cobalt, or in clays, ponderous spar, gneifs, &c. It contains from 25 to 60 per cent. of silver.

5. The miniara argentia alba, the Weißgoldn ore of the Germans, is a heavy, soft, opaque sub stance, fine grained or icily, bright and shining in its fractures, of a white, footy, or lead colour, sometimes crystalized in pyramidal or cylindrical forms, but often in amorphous grains, or resembling mofs, or in the form of thin lamines in crusting other bodies, found in quartz, sparr, feltein, pyrites, blend, lead-ore, cobalt ore, sparry iron ore, fluor, &c. It is very fusible. Its specific gravity is from 5 to 5,300. Its proportion of silver from 10 to 30 per cent. It is found, though not commonly, in Saxony, Hungary, the Hartz, and St Marie aux Mines.

6. The lehferitz, or white silver ore, is an arséneous pyrites, containing silver. It is met with in the Saxony mines so exactly resembling the common arsénical pyrites, that it cannot be distinguished from it by inspection. Cronstedt supposes, that the silver it contains may exist in a capillary form; but Professor Brunnich thinks this is not altogether the case. It is very scarce, but met with near Freyberg. There is likewise a brown mulm having the appearance of rags, met with in the crevasses and upon the lumps of cubic lead ore in a mine near Clauflhal and other places, which contains a great quantity of silver. It is of a whitish shining colour; hard, granulated, and solid, sometimes striking fire with steel. It discovers a mixture of arsenic, by emitting a garlic smell when heated.

7. The lehferitz of the Germans has the metal combined with sulphurated antimony. It is of a dark grey and somewhat brownish colour. A variety of a blackish blue colour is found in the form of capillary crystals, and called febouritz or plumose silver ore. It is met with in Saxony, and contains sometimes a mark or half a pound, sometimes only two, three, or four ounces, and sometimes only a mere trifle of silver, per cent. There is another silver ore, also called lehferitz by the Germans, which contains arsenic and regulus of antimony. This ore is sometimes also found of a dark grey colour; for the most part amorphous, but sometimes crystallized into pyramids. It appears red when scraped, and contains from one to five per cent. of silver. The greatest part of this ore is copper, and the next arsenic. According to Bergman, the copper amounts to 24 per cent. It is found in Transylvania, and a kind was lately discovered in Spain, of a hard solid consistence, and of a greyish blue colour.

8. The goose dung ores contain silver mineralized with sulphur in combination with iron, arsenic, and cobalt. It looks like the weißgulden, excepting that the cobalt, by its decomposition, gives it a rosy appearance. There are two varieties; one of a dull tarnished surface and ferrougous look; the other has a shining appearance like the lehferitz. It contains from 10 to 40 or 50 per cent. of silver. The arsenic is in an acide state, and united to the cobalt.

9. The dal sulphurts contains silver mineralized with sulphurated copper and antimony, and resembles the dark-coloured weißgulden, giving a red powder when rubbed. It is found either solid or crystallized, and is met with in the province of Dal, where it is melted by a very difficult procèss, calculated to determine the different metals it contains. There is another kind which has arsenic united to the rest of the ingredients. It is only the grey copper ore impregnated with silver, of which it contains from one to twelve per cent. the quantity of copper being from 12 to 23 per cent. and the remainder consisting either of sulphur or arsenic, with a little iron. It is the most common of all silver ores; and M. Monnet remarks, that where copper is united to arsenic, silver is always to be found. A variety has been found at Schenmitz, containing a portion of gold also.

10. The pecheblende is an ore of zinc containing silver, and is met with in the Saxon and Hungarian mines among the rich gold and silver ores. It is either of a metallic changeable colour or black. Of these there were formerly two varieties, viz. either in the form of fing scales or in balls, but the latter is now entirely unknown. A black blend is found in Bohemia, which is very heavy, with the surface somewhat elevated like some kinds of hematites, but no silver has yet been extracted from it.

11. The bleigan, potters ore, or galena, contains silver mineralized with sulphurated lead. It is also called pyritic silver, and is of a brown colour, yielding but a very small portion of metal. It is met with at Kunf-
be silver in Norway. When the silver is combined with sulphurated lead and antimony, the ore is called silverda.

12. The mareaeite containing silver has the metal united with sulphurated iron. There are great varieties of this ore holding different proportions of the metal; some produce only half an ounce of silver per cent. A liver-coloured maraeeite is found at Kunberg in Norway, containing from three to three ounces and a half of silver per cent.

13. Silver is found mineralized with sulphurated and arhenical cobalt; the stone sometimes containing denrites. These kinds keep well in water, but generally decay in the air, and lose the silver they contain. It is found at Morgenfern near Freyberg and Annaberg.

14. The butter-riek ore contains silver mineralized by sulphur, with regulars of antimony and barytes. It is found in the form of thin particles or granular spar. Walleius says that it is soft like mud, and feels like butter. He supposes it to be produced from other silver ores washed away by running waters. Boman adds, that the miners look upon it as a certain sign of other ores in the neighbourhood, though some are perfused that it is only an unimpured silver ore, which soon becomeperfect.

15. The combustible silver ore is a black brittle substance, leaving about six per cent. of silver in its ashes. It is in fact a perfect coal in which silver is found.

16. The hornails, or horn silver ore, in which the silver is united with the muriatic acid, is the safest of all the silver ores. It is sometimes found in flowy cubical crystals, but is met with of many different colours. Its principal characteristic is to change to a violaceous brownish colour when exposed to the sunbeams, as happens also to the artificial luna cornea. It is frequently crystallized in a cubic form, though not always of a white colour. Sometimes it resembles an earth easily fusible without smoke. There is a black kind, friable, and easily reducible to powder; the other is in some degree malleable, may be cut with a knife, and takes a sort of polish when rubbed. The vitreous silver ore, which is sometimes mixed with the horn silver, is fusible in nitrous acid; and this affords a method of separating them, the horn silver ore being insoluble in that menstruum. When the horn silver is free from iron, it generally contains 70 per cent. of silver at least; but these ores mostly contain some portion of iron, a small part of which is even united to the marine acid. This kind of ore was first analyzed by Mr. Woule, who discovered the presence of the vitriolic acid in it.

17. Another kind of horn silver ore is mentioned by Mr. Bergman, in which the metal is mineralized by the vitriolic and marine acids, along with some sulphur. He doubts, however, whether the mineralization be perfect in this case, as the sulph and sulphur do not admit of any other than a mechanical union. But since iron is often found in these ores, a maraeeite may thus be sometimes formed.

18. The silver golde dung ore is of a greenish colour, with a mixture of yellow and red. Some think it is a mixture of red silver ore and calx of nickel.

19. The foliaceae silver ore. The colour of this ore is marlode. Some imagine it to be a native silver ore; others that it is a mixture of galena, ochre, and silver. It is sometimes found in the mountain cork, and is so light that it will swim upon water. It contains but one ounce of silver per quintal.

These are all the varieties hitherto observed in which silver is met with in the earth, though it may perhaps occur in various other forms. It would be worth while to examine whether, in those count ies where gold and silver are found in large quantities, the precious metals may not be contained in some proportion in the molten common ores, more especially when the particles of gold and silver have not been able to extricate themselves in such a manner as to lie separate in figures, veins, or hollow places of the mine. A mineralization of silver with alkali is said to have been lately met with at Annaberg in Austria; but the account of it as yet can scarcely be depended upon. Professor Brunniach says, that the silver contained in the limestone at that place appears to be native when the stone is polished.

The purest silver is that which is extracted from luna corneas, and is the only kind that ought to be trusted in the nice operations of chemistry. The process, however, is very tedious, and presents a very unexpected phenomenon, as this metal, though one of the most fixed, is nevertheless volatilized in the operation in such a manner that it exhaled though the pores of the crucible; and small globules of silver are afterwards found in the cover, and even in the support of the crucible. According to Cramer, this loss may be prevented by finewing the crucible with black soaps, and mixing with the luna concia half its weight of oil or tallow, which last must also be added by little and little during the operation.

M. Magellan takes notice of a remarkable appearance observable in dissolving silver in the nitrous acid. He observes, that this acid is its specific menstruum, attacking it even when cold with considerable effervescence, growing hot, and emitting a considerable quantity of orange-coloured fumes, which diminish in proportion as the saturation advances. The metal appears of a pale brown colour in the confide, and the solution becomes quite black. This last appearance, however, is owing to a thin, black, fuliginous sublimation like smut, which is at once formed into a crust on the surface of the thin plates of silver in the first attack of the acid upon them. This is a very singular phenomenon, and hitherto unaccounted for; these black crusts being comminuted into smaller and smaller particles by the action of the acid; and, when the effervescence is over, they are seen distinctly to fall to the bottom of the vessel, and to form a black sediment, leaving the liquid solution quite transparent, but of a blue colour inclining to green.

This colour might be attributed to some small mixture of copper, though the silver used in the experiment was of the purer kind. The chemists of Dijon say, that the nitrous solution of silver looks of a fine blue colour, if the acid be pure and well concentrated; but if it has any mixture of vitriolic or marine, a precipitation of vitriolated silver or luna concia takes place. Afterwards the solution becomes as colourless as water, but gives a lasting black tinge to animal substances. This solution is of great use in chemistry, serving to form the lunar caustic, to purify the common aquafortis from a mixture of the vitriolic and marine acids, and is a very nice test of the excellence of these acids in mineral waters.

Silver does not combine with earth, even by the most violent heat, though Mr. Fourcroy supposes that it might...
ILURIS, in ichthyology, a genus belonging to the order of fishes abdominales. The head is naked; the mouth set round with hairy filaments; the branches have from 4 to 13 rays, the rays of the pectoral fins, or the first dorsal one, is prickly, and dentated backwards. There are 21 species, most of them natives of the Indian and American seas. Mr Hallequin mentions one called the claires by Linneus, and fibilian by the Abbei. If it pricks one with the bone of the breadth-fin, it is dangerous; and our author fav the cook of a Swedish merchant ship die of the poison communicated by the prick of one of these fish. See Electricity, n2. 261.

SIMEON of Durham, the contemporary of William of Malabury, took great pains in collecting the monuments of British history, especially in the north of England, after they had been scattered by the Danes. From these he composed a history of the kings of England, from A.D. 610 to 1135; with some smaller historical pieces. Simeon both studied and taught the sciences, and particularly the mathematics at Oxford; and became preacher of the church at Durham, where he died, probably soon after the conclusion of his history, which was continued by John, prior of Hexham, to A.D. 1156.

SIMIA, the Monkey, a genus of quadrupeds belonging to the class of mammals, and order of primates, in the Linnean system, but by Mr Pennant, he is under the dignoted quadruped. According to the Linnean system, the characteristic of this genus are these: There are four close set teeth on each jaw; single tufts on each side in both jaws, which are longer than the rest, and somewhat remote from them. The grinds are obtuse, and the feet are formed like hands. Mr Pennant gives the following generic description of the simia. There are four cutting teeth in each jaw, and two canine. Each of the feet are formed like hands, generally with flat nails, and, except in one instance, four fingers and a thumb. There are eyebrows both above and below. They are a numerous race; but almost all confined to the torrid zone. They fill the woods of Africa from Senegal to the Cape, and thence to Ethiopia. They are found in all parts of India, and its islands; in Cochin-China, in the south of China, and in Japan; and one is met with in Arabia; and they swarm in the forests of South America, from the I l mus of Darien as far as Paraguay. They are lively, agile, full of frolic, chatter, and grimace. From the structure of their members, they have many actions in common with the human kind. Most of them are fierce and unamiable; some are of a milder nature, and will show a degree of attachment; but in general they are endowed with mischievous intellects; and are filthy, obscene, lascivious, and thieving. They inhabit the woods, and live on trees; feeding on fruits, leaves, and insects. In general they are gregarious, going in vast companies; but the different species never mix with each other, always keeping apart and in different quarters. They leap with vast activity from tree to tree, even
when young, not the Animal}

Simia, Ape, such as wanted tails.

Ceropithecus, Monkeys, such as had tails.

Papions, Baboons, those with short tails; to distinguish them from the common monkeys, which have very long ones.

The principal marks by which the species of this genus are distinguishable from each other, are derived, according to the editors of LINNÆUS, by Ker.

The chimpanzee, the simia troglodytes of LINNÆUS, common in the mountains of Sierra Leone, resembles man more than the orang-outang. This animal was first brought to Europe in 1738, when it was exhibited as a show in London. The following description of one that was kept some months at the colony of Sierra Leone is given by Waddilow, in his Essay on Colonization. He was nearly two feet high; but the full stature is nearly five feet. He was covered with black hair, long and thick on the back, but short and thin on the breast and belly. His face was bare; his hands and his head resembled those of an old black man, except that the hair on his head was straight. He ate, drank, slept, and sat at table, like a human being. At first he crept on all fours, on the outside of his hands; but, when grown larger, he endeavored to go erect, supporting himself by a stick. He was melancholy, but always good natured.

The fos, orang-outang, or great ape, has a flat face, and a deformed resemblance of the human; like those of a man; the hair on the head longer than on the body. The body and limbs are covered with reddish and shaggy hair; longed on the back, thinned on the fore parts. The face and paws are hairy; the buttocks covered with hair. They inhabit the interior parts of Africa, the isles of Sumatra, Borneo, and Java. Are solitary, and live in the most desolate places. They grow to the height of six feet; have prodigious strength, and will overpower the strongest man. The old ones are shot with arrows, the young alone can be taken alive. They live entirely on fruits and nuts. They will attack and kill the negroes who wander in the woods; will drive away the elephants, and beat them with their sticks or pieces of wood; and will throw stones at people that offend them. They sleep in trees; and make a sort of shelter from the inclemency of the weather. They are of a grave appearance and melancholy disposition, and even when young not inclined to frolic. They go erect, and are very swift and agile. These accounts are chiefly taken from Andrew Bate, an English sailor, who was taken prisoner 1599, and lived many years in the inner parts of Congo; his narrative is plain, and forms very authentic. It is preserved in Pott's collection.

The old Simia, of Borneo, was made in Europe in 1741, and was named by WADDILLOW, in his Essay on Colonization. He was nearly two feet high; but the full stature is nearly five feet. He was covered with black hair, long and thick on the back, but short and thin on the breast and belly. His face was bare; his hands and his head resembled those of an old black man, except that the hair on his head was straight. He ate, drank, slept, and sat at table, like a human being. At first he crept on all fours, on the outside of his hands; but, when grown larger, he endeavored to go erect, supporting himself by a stick. He was melancholy, but always good natured.

The chimpanzee, the simia troglodytes of LINNÆUS, common in the mountains of Sierra Leone, resembles man more than the orang-outang. This animal was first brought to Europe in 1738, when it was exhibited as a show in London. The following description of one that was kept some months at the colony of Sierra Leone is given by Waddilow, in his Essay on Colonization. He was nearly two feet high; but the full stature is nearly five feet. He was covered with black hair, long and thick on the back, but short and thin on the breast and belly. His face was bare; his hands and his head resembled those of an old black man, except that the hair on his head was straight. He ate, drank, slept, and sat at table, like a human being. At first he crept on all fours, on the outside of his hands; but, when grown larger, he endeavored to go erect, supporting himself by a stick. He was melancholy, but always good natured.

The chimpanzee, the simia troglodytes of LINNÆUS, common in the mountains of Sierra Leone, resembles man more than the orang-outang. This animal was first brought to Europe in 1738, when it was exhibited as a show in London. The following description of one that was kept some months at the colony of Sierra Leone is given by Waddilow, in his Essay on Colonization. He was nearly two feet high; but the full stature is nearly five feet. He was covered with black hair, long and thick on the back, but short and thin on the breast and belly. His face was bare; his hands and his head resembled those of an old black man, except that the hair on his head was straight. He ate, drank, slept, and sat at table, like a human being. At first he crept on all fours, on the outside of his hands; but, when grown larger, he endeavored to go erect, supporting himself by a stick. He was melancholy, but always good natured.
The figure of this ape had a very great resemblance to that of man, &c. Gmelii Carreri tells us, that he saw one of these apes, which cried like an infant, walked upon its hind-feet, and carried a matt under his arm to lie down and sleep upon.

An orang-outang which Buffon saw is described by him as mild, affectionate, and good-natured. His air was melancholy, his gait grave, his movements measured, his dispositions gentle, and very different from those of other apes. He had neither the impatience of the Barbary ape, the maliciousness of the baboon, nor the extravagance of the monkeys. "It may be alleged, (says our author,) that he had the benefit of instruction; but the other apes which I shall compare with him, were educated in the same manner. Signs and words were alone sufficient to make our orang-outang act; but the baboon required a cudgel, and the other apes a whip; for none of them would obey without blows. I have seen this animal present his hand to conduct the people who came to visit him, and walk as gravely along with them as if he had formed a part of the company. I have seen him sit down at table, unfold his towel, wipe his lips, use a spoon or a fork to carry the viands to his mouth, pour his liquors into a glass, and make it touch that of the person who drank along with him. When invited to take tea, he brought a cup and a saucer, placed them on the table, put in sugar, poured out the tea, and allowed it to cool before he drank it. All these actions he performed without any other instruction than the signs or verbal orders of his master, and often of his own accord. He did no injury to any person: he even approached company with circumspection, and preferred himself as if he wanted to be cared for. He was very fond of dainties, which every body gave him; and as his breast was diseased, and he was afflicted with a tasting cough, this quantity of sweetmeats undoubtedly contributed to shorten his life. He lived one summer in Paris, and died in London the following winter. He ate almost every thing; but preferred ripe and dried fruits to all other kinds of food. He drank a little wine, but spontaneously left it for milk, tea, or other mild liquors. This was only two feet four inches high, and was a young one. There is great possibility that these animals may vary in size and colour, some being covered with black, others with reddish hairs,—They are not the satyrs of the ancients; which had tails (a), and were a species of monkey. Linnaeus's Homo neandrum, an animal of this kind, is unnecessarily separated from his simia satyrus.

To enable the reader to form a judgment of this animal, which has so great a resemblance to man, it may not be unacceptable to quote from Buffon the differences and conformities which make him approach or recede from the human species. "He differs from Id. p. 95, man externally by the flatness of his nose, by the shortness of his front, and by his chin, which is not elevated at the base. His ears are proportionally too-large, his eyes too near each other, and the distance between his nose and mouth is too great. These are the only differences between the face of an orang-outang and that of a man. With regard to the body and members, the thighs are proportionally too short, the arms too long, the fingers too small, the palm of the hands too long and narrow, and the feet rather resemble hands than the human foot. The male organs of generation differ not from those of man, except that the prepuce has no frunum. The female organs are extremely similar to those of a woman.

"The orang-outang differs internally from the human species in the number of ribs: man has only 12, but the orang-outang has 13. The vertebrae of the neck are also shorter, the bones of the pelvis narrower, the buttocks flatter, and the orbits of the eyes funk deeper. He has no spinal procès on the first vertebra of the neck. The kidneys are rounder than those of man, and the ureters have a different figure, as well as the bladder and gall-bladder, which are narrower and longer than in the human species. All the other parts of the body, head, and members, both external and internal, do perfectly resemble those of man, that we cannot make the comparison without being astounded that such a similarity in structure and organization should not produce the same effects. The tongue, and all the organs of speech, for example, are the same in man; and yet the orang-outang enjoys not the faculty of speaking; the brain has the same figure and proportions; and yet he poiffesses not the power of thinking. Can there be a more evident proof than is exhibited in the orang-outang, that matter alone, though perfectly organized, can produce neither language nor thought, unless it be animated by a superior principle? Man and the orang-outang are the only animals who have buttocks and the calf of the legs, and who, of course, are formed for walking erect; the only animals who have a broad chest, flat shoulders, and vertebrae of the same structure; and the only animals whose brain, heart, lungs, liver, spleen, stomach, and intestines, are perfectly similar, and who have an appendix vermiformis, or blind-gut. In fine, the orang-outang has a greater resemblance to man than even to the baboons or monkeys, not only in all the parts we have mentioned, but in the largeness of the face, the figure of the cranium, of the jaws, of the teeth, and of the other bones of the head and

(a) Aelian gives them tails, lib. xvi. c. 21. Pliny says they have teeth like dogs, lib. vii. c. 2. circumstances common to many monkeys. Ptolemy, lib. 7. c. 2. speaks of certain islands in the Indian ocean inhabited by people with tails like those with which satyrs are painted, whence called the illes of satyrs. Keoping, a Swede, pretended to have discovered these bonines causa i; that they would have trafficked with him, offering him live parrots; that afterwards they killed some of the crew that went on shore, and eat them, &c. &c. Annal. Acad. vi. 71.
and face; in the thickness of the fingers and thumb, the figure of the nails, and the number of vertebrae; and, lastly, in the conformity of the articulations, the magnitude and figure of the hands, sternum, &c. Hence, as there is a greater similarity between this animal and man, than between those creatures which resemble him most, as the Barbary ape, the baboon, and monkey, who have all been designed by the general name of _apes_, the Indians are to be excused for associating him with the human species, under the denomination of _orang-outang_, or _wold man_. In fine, if there were a scale by which we could descend from human nature to that of the brutes, and if the essence of this nature confined entirely in the form of the body, and depended on its organization, the orang-outang would approach nearer to man than any other animal. Placed in the second rank of beings, he would make the other animals feel his superiority, and oblige them to obey him. If the principle of imitation, by which he seems to mimic human actions, were a result of thought, this ape would be still farther removed from the brutes, and have a greater affinity to man. But the interval which separates them is immense. Mind, reflection, and language, depend not on figure or the organization of the body. These are endowments peculiar to man. The orang-outang, though, as we have seen, he has a body, members, fenes, a brain, and a tongue, perfectly similar to those of man, neither speaks nor thinks. Though he counterfeit every human movement, he performs no action that is characteristic of man, no action that has the same principle or the same design. With regard to imitation, which appears to be the most striking character of the ape kind, and which the vulgar have attributed to him as a peculiar talent, before we decide, it is necessary to inquire whether this imitation be spontaneous or forced. Does the ape imitate us from inclination, or because, without any exertion of the will, he feels the capacity of doing it? I appeal to all those who have examined this animal without prejudice; and I am convinced that they will agree with me, that there is nothing voluntary in this imitation. The ape, having arms and hands, uses them as we do, but without thinking of us. The similarity of his members and organs necessarily produces movements, and sometimes succession of movements, which resemble ours. Being endowed with the human structure, the ape must move like man; but the same motions imply not that he acts from imitation. Two bodies which receive the same impulse, two similar pendulums or machines, will move in the same manner; but these bodies or machines can never be said to imitate each other in their motions. The ape and the human body are two machines similarly constructed, and necessarily move nearly in the same manner; but parity is not imitation. The one depends on matter, and the other on mind. Imitation presupposes the design of imitating. The ape is incapable of forming this design, which requires a train of thinking; consequently, if he inclines, he can imitate the ape; but the ape cannot even incline to imitate man.

3. Pongo, or Jocko, are considered as one species by Pennant and Gmelin. It inhabits the island of Java, and the interior parts of Guinea. Has no pouches within his cheeks, no tail, and no callosities on the buttocks; which latter are plump and gelly. All the teeth are similar to those of man. The face is flat, naked, and tawny: the ears, hands, feet, breath, and belly, are likewise naked; the hair of the head descends on both temples in the form of trefoils; the hair on the back and loins is in small quantities. It is five or six feet high, and walks always erect on the two hind feet. It has not been ascertained whether the females, of this species or variety, are subject to periodic discharges; but analogy renders this almost unquestionable. This animal is, by Dr Gmelin, considered only as a variety of the orang-outang.

4. The great gibbon, long-armed ape, or _simia lar_, Fig. 3, with a flat swarthy face surrounded with grey hairs: hair on the body black and rough; buttocks bare; nails on the hands flat; on the feet long; arms of a most disproportioned length, reaching quite to the ground when the animal is erect, its natural posture; of a hideous deformity.—Inhabits India, Malacca, and the Molucca isles; a mild and gentle animal; grows to the height of four feet. The great black _ape_ of Mangil, a province in China, seems to be of this kind.

5. The lesser gibbon, or _simia lar minor_, but is much like the former, being only about a foot and a half high; the body and face are of a brown colour, resembles the former. The _simia lar argentea_ is probably a variety of this species.

6. The pigmy, or _simia silvanus_, has no tail; the Fig. 5, buttocks are naked; the head roundish, and the arms shorter than the body. It inhabits Africa; and is not uncommon in our exhibitions of animals; is very tractable and good-natured, and was most probably the pigmy of the ancients. It abounds in Ethiopia, one feat of that imaginary nation; was believed to dwell near the fountains of the Nile, whence it defended annually to make war on the cranes, _i.e._ to steal their eggs, which the birds may be supposed naturally to defend; whence the fiction of their combats.

7. The magot, _simia inanus_, or Barbary ape, has a Fig. 6, long face, not unlike that of a dog; canine teeth, long and strong; ears like the human; nails flat; buttocks bare; colour of the upper part of the body a dirty greenish brown; belly, of a dull pale yellow; grows to above the length of four feet.—They inhabit many parts of India, Arabia, and all parts of Africa except Egypt, where none of this genus are found. A few are found on the hill of Gibraltar, which breed there; probably from a pair that had escaped from the town; as they are not found in any other part of Spain. They are very ill-natured, mischievous, and fierce; agreeing with the character of the ancient Cynocephali. They are a very common kind in exhibitions. By force of discipline they are made to play some tricks; otherwise they are more dull and foolish than the rest of this genus. They assemble in great troops in the open fields in India, and will attack women going to market, and take their provisions from them. The females carry the young in their arms, and will leap from tree to tree with them. Apes were worshipped in India, and had magnificent temples erected to them. When the Portuguese plundered one in Ceylon, they found in a little golden casket the teeth of an ape; a relic held by the natives in such veneration, that they offered 700,000 ducats to redeem it, but in vain; for it was burnt by the viceroy, to stop the progress of idolatry.

11. Papiones, or Baroons. These have short tails, a long face; a broad high muzzle; longish dog-like tusks, or canine teeth; and naked callosities on the buttocks. They are only found in the old world, and are the papiones and _kambir_ of the ancients.

8. The maimon, _simia papio nemestrina_, or pig-tailed baboon,
The baboon, with a pointed face, which is naked, of a swarthy redness; two sharp canine teeth; ears like the human; hair on the limbs and body brown inclosing to all-colour, palest on the belly; fingers black; nails long and flat; thumbs on the hind feet very long, connected to the nearest toe by a broad membrane; tail four inches long, slender, exactly like a pig's, and almost naked; the base spars on the rump red, but small: length, from head to tail, 22 inches. Inhabits the isles of Sumatra and Japan; is very docile. In Japan it is taught several tricks, and carried about the country by mountebanks. Kempfer was informed by one of these people, that the baboon he had was 102 years old.

The great baboon, or Simia papio sphinx, with hazel irides; ears small and naked; face canine, and very thick; middle of the face and forehead naked; and of a bright vermilion colour; tip of the nose of the fame, and ending truncated like that of a hog; sides of the nose broadly ribbed, and of a fine violet hue; the opening of the mouth very small; cheeks, throat, and goat-like beard yellow; hair on the forehead very long, turns black, is black, and forms a kind of pointed crest. Head, arms, and legs, covered with short hair, yellow and black intermixed; the breast with long whitish yellow hairs, the shoulders with long brown hair. Nails flat; feet and hands black; tail four inches long, and very hairy; buttocks bare, red, and dirty; but the face about them is of a most elegant purple colour, which reaches to the middle of the upper part of the thighs.

This was described by Mr. Pennant from a stuffed specimen in Sir Adlton Lever's museum. In August 1779, a live animal of this species was shown at Edinburgh, and in October following at Chester, where being seen by Mr. Pennant, that inquisitive naturalist has described it in his History of Quadrupeds. "It differed little (he observes) in colour from the above, being in general much darker. Eyes much sunk in the head, and small. On the internal side of each ear was a white line, pointing upwards. The hair on the forehead turned up like a tuft. Feet black; in other respects resembling the former. In this I had an opportunity of examining the teeth. The cutting teeth were like those of the rest of the genus; but, in the upper and lower jaw, were two canines, or rather tusks, near three inches long, and exceedingly sharp and pointed. This animal was five feet high, of a most tremendous strength in all its parts, was excessively fierce, libidinous, and strong."

Mr. Schreber says, that this species lives on succulent fruits, and on nuts; is very fond of eggs, and will put eight at once into its pouches, and, taking them out one by one, break them at the end, and swallow the yolks and whites; rejects all flesh-meat, unless it be dressed; would drink quantities of wine or brandy; was less agile than other baboons; very communicative; for it would immediately fling its excrements out of its pouch. That which was shown at Chester was particularly fond of cheese. Its voice was a kind of roar, not unlike that of a lion, but low and somewhat inward. It went upon all fours, and never stood on its hind legs, unless forced by the keeper; but would frequently sit on its rump in a crouching manner, and drop its arms before the belly. Inhabits the hotter parts of Africa.

The little baboon, or Simia papio apesida, has a roundish head, with a projecting muzzle, and roundish naked ears; the hair on the body is yellow, tip with black; the face is brown, and almost naked, having only a few scattered hairs; the nails are all compressed and oblong, except on the thumbs and great toe, the nails of which resemble man; the tail is very short, being hardly an inch long; the body is about the size of a cat. It is uncertain, says Gmelin, if this animal should be considered as a distinct species, or only as a variety of the Simia fciurea.

The mantega, or Simia papio mermon, common, fig. 17, called the assegai apes, but it is improperly named an ape, as it has a tail. It is described in the abridgment of the Philosophical Transactions, n. 290. It had a nose and head 14 inches in length; the nose of a deep rose, face blue, both naked; black eye-brows; ears like the human; on the top of the head a long upright point of hair; on the chin another; two long tufts in the upper jaw; fore feet exactly resembling hands, and the nails on the fingers flat; the fore-part of the body, and the inside of the legs and arms, naked; the outside covered with mottled brown and olive hair. Length, from the nose to the rump, three feet two inches. It was very fierce and falcatus; went on all fours, but would sit up on its rump, and support itself with a flick; in this attitude, it would hold a cup in its hand, and drink out of it. Its food was fruits.

The mandrill, Simia papio maimon, or ribbed nose, fig. 12, baboon, has a short tail, and a thin beard on the chin; and 13, the cheeks are blue and striped, and the buttocks are naked. This species of baboon is found on the Gold Coast, and in the other southern provinces of Africa, where he is called kogho by the negroes, and mandri by the Europeans. Next to the orang-outang, he is the largest of all the apes or baboons. Smith relates, that he had a present of a female mandrill, which was only six months old, and that it was as large as an adult baboon. He adds, that these mandrills walk always on two feet; that they weep and groan like men; that they have a violent passion for women, which they never fail to gratify when they find a woman at a distance from relief. We have given figures both of the male and female, which may be easily distinguished by their size and appearance.

The wood-baboon, or Simia papio sylvatica, with fig. 14, a long dog-like face, covered with a small glossy black skin; hands and feet naked, and black like the face; hair on all parts long, elegantly mottled with black and tawny; nails white; about three feet high when erect; tail not three inches, and very hairy on the upper top. Inhabits Guinea, where it is called by the English the man of the wood.

The brown baboon, or Simia papio platygyros, with pointed ears; face of a dirty white; nose large and broad; hairs round the face short and straight; colour of the upper part of the body brown; of the under, ash-colour; tail about four inches long; taper, and almost bare of hair; beneath is quite naked. The animal which Mr. Pennant called the new baboon, in the first edition, seems by the taperness of the tail, and general form, to be of this kind.

The hog-gig baboon, or Simia papio porcaria, has a short tail, and coloured buttocks; the head is like that of a hog, with a naked snout; the body is of an olive brown colour; the nails are sharp and compressed. Inhabits Africa, and is about three feet and a half high when
Plate 16. The Tartarin, dog-faced baboon of Pennant, and cercopithecus hamadryas of Gmelin, with a long, thick, and strong nose, covered with a smooth red skin; ears pointed, and hid in the hair; head great, and flat; hair on the head, and fore-part of the body as far as the waist; very long and shaggy; grey and olive-brinded; the hair of the head very full, the hair on the limbs and hind part of the body very short; limbs strong and thick; hands and feet dextrous; the nails on the fore-feet flat; those on the hind like a dog's; buttocks very bare, and covered with a skin of a bloody colour; tail scarce the length of the body, and carried generally erect. They inhabit the hottest parts of Africa and Asia; where they keep in vast troops, and are very fierce and dangerous. They rob gardens. They will run up trees when passengers go by, shake the boughs at them with great fury, and chatter very loud. They are exceedingly impudent, indecent, lascivious; most detestable animals in their manners as well as appearance. They range the woods in hundreds; which obliges the owners of the coffee-plantations to be continually on their guard against their depredations. One of them was shown in London some years ago: it came from Mocha, in the province of Yemen, in Arabia Felix in the Perian gulf; and was above five feet high. It was very fierce and untameable; so strong as easily to master its keeper, a stout young man. Its inclinations to women appeared in the most violent manner. A footman, who brought a girl to see it, in order to tease the animal, kifsee, and hugged her: the beast, enraged at being so tantalized, caught hold of a quart pewter-pot, which he threw with such force and to tire an aim, that, had not the man's hat and wig fastened the blow, his skull must have been fractured: but he fortunately escaped with a common broken head.

The white-bearded black wanderer, the Simia filius of Linnaeus, the ouanderou of Buffon, and horn-tailed baboon of Pennant, the cercopithecus filius of Gmelin, has a dog-like face, is naked, and of a duffy colour; a very large and full white or hoary beard; large canine teeth; body covered with black hair; belly of a light colour; tail terminated with a tuft of hair like that of a lion. Its bulk that of a middling fixed dog. It inhabits the East Indies and the hot parts of Africa.

The purple-faced monkey, cercopithecus purpuratus, with a great triangular white beard, short and pointed at the bottom, and on each side of the ears, extended a winged fashion far beyond them; face and hands purple, body black. Inhabit Ceylon. They are very harmless; live in the woods, and feed on leaves and buds of trees; and when taken soon become tame.

Malbrouck, or cercopithecus fuscus, has a long tail, and is bearded; the tail is bushy at the extremity. It is a native of Bengal. This species has cheek pouches, and calluscis on the buttocks; the tail is nearly as long as the body and head; and it is a mistake of Cuvier that this is called a tail; the face is of a cinereous grey colour, with a large muzzle, and large eyes, which have flesh-colored eyelids, and a grey band cross the forehead in the place of eye-brows; the ears are large, thin, and flesh-colored; the upper parts of the body are of a uniform yellowish brown colour, and the lower of a yellowish grey. It walks on all fours, and about a foot and a half from the muzzle to the extremity of the tail. The females menstruate.

Macaque, or cercopithecus cynocephalus, the hare-lipped monkey of Pennant, has no beard; the nostrils are thick and divided; the tail is long and arched, and the buttocks are naked. He has cheek-pouches and calluscis on the buttocks. His tail is from 18 to 20 inches long. His head is large, his muzzle very thick, and his face naked, livid, and wrinkled. His ears are covered with hair. His body is short and stout, and his limbs thick and short. The hair on the superior parts of his body is of a greenish ash-colour, and of a yellowish grey on the breast and belly. He has a small crest of hair on the top of the head. He walks on four and sometimes on two feet. The length of his body, comprehending that of the head, is about 18 or 20 inches.

The dog-headed monkey, cercopithecus cynocephalus, has no beard, and is of a yellow colour; the muzzle is long; the tail long and straight, and the buttocks naked. It is a native of Africa.

The spotted monkey, cercopithecus Diana, with a long white beard; colour of the upper parts of the body reddish, as if they had been tinged, marked with white specks; the belly and chin whitish; tail very long; is a species of a middle size. It inhabits Guinea and Congo, according to Maregrave; the Congolese call it exouima. M. de Buffon denies it to be of that country; but from the circumstance of the curl in its tail, in Maregrave's figure, and the description of some voyagers, he supposes it to be a native of South America. Linnaeus describes his S. Diana somewhat differently: he says it is of the size of a large cat; black, spotted with white; hind part of the back ferruginous; face black; from the top of the nose is a white line palling over each eye to the ears, in an arched form; beard pointed, black above, white beneath, placed on a fatted excrecence; breast and throat white; from the romp, crofs the thighs, a white line; tail long, straight, and black; ears and feet of the same colour; canine teeth, large.

The green monkey, cercopithecus sabaeus, has a black and fatish face; the side of it bounded by long black hairs, falling backwards, and almost covering the ears, which are black, and like the human; head, limbs, and whole upper part of the body and tail covered with soft hair, of a yellowish green colour at their ends, cinereous at their roots; under side of the body and tail, and inner side of the limbs, of a silvery colour; tail very long and slender. Size of a small cat. Inhabit different parts of Africa: keep in great flocks, and live in the woods: are scarce discernible among the leaves, except by their breaking the boughs with their
...about the size of a cat; it was lately in the possession of Mr. Brook, an animal merchant and exhibitor in London. The upper parts of the body are covered with a pale tawny-coloured fur, which is ash-coloured at the roots; the hinder part of the back is orange-coloured, the legs ash-coloured, the belly white, and the tail shorter than the body.

29. King monkey, full-bottom monkey, or cercopithecus regalis, has no thumb on the hands; the head, cheeks, throat, and shoulders, are covered with long, flowing, coarse hairs. Inhabits the forests of Sierra Leona in Guinea, where it is called joy, or, king monkey. It is above three feet high when erect: The head is small, with a short, black, naked face; and the head, cheeks, throat, neck, and shoulders, are covered with long, coarse, flowing hairs, of a dirty yellowish colour, mixed with black, and resembling a full-bottomed wig; the body, arms, and legs, are covered with short hairs of a fine glossy black colour; the hands are naked, and have no thumbs; the feet have five very long slender toes, which are armed with narrow pointed claws; the tail is very long, and is covered with snow-white hairs, having a tuft at the end; the body and limbs are very slender: Its skin is held in high estimation by the negroes for making pouches and gun cases.

IV. SAPAJUS, SAPAI, have prehensile tails, and no cheek-pouches. These animals have long tails, which, at the extremity, is generally deprived of hair on the under side, and covered with a smooth skin; this part they can fold, extend, curl up, and unfold at pleasure; by which they are enabled to hang upon branches, or to lay hold of any thing which is beyond the reach of their hands, using the extremity of the tail like a finger or hand; the partition between the nostrils is very thick, and apertures are situated, on the sides of the nose; the buttocks are clothed with hair, and have no callosities; the females of this subgenus do not menstruate; and this race of animals is only to be found in America: This subdivision of the genus is made with great propriety by Dr. Gmelin, in imitation of the Count de Buffon.

30. The guariba, sapajus Deelezobub, or the preacher monkey, has black shining eyes; short round ears; and a round beard under the chin and throat. The hairs on the body are of a shining black, long, yet lie so close on each other that the animal appears quite smooth: the feet and end of the tail are brown; the tail very long, and always twisted at the end. Size of a fox. Inhabit the woods of Brazil and Guiana in vast numbers, and make a most dreadful howling. Sometimes one mounts on a higher branch, the rest leap, themselves beneath: the first begins as if it was to harangue, and sets up so loud and sharp a howl as may be heard a vast way, and a person at a distance would think that a hundred joined in the cry: after a certain space, he gives a signal with his hand, when the whole assembly joins in chorus; but on another signal is silent, and the orator finishes his address (a). Their clamour is the most disagreeable and tremendous that can be conceived; owing to a hollow and hard bone placed in the throat, which ...

(a) A singular account, yet related by Maregraves and several other writers. Maregraves is a writer of the highest authority, and a most able naturalist, long resident in the Brazils, speaks from his own knowledge.
31. The quato, sapajus panicicus, or four-fingered monkey, has a long flat face, of a swarthly fesh colour: the eyes are sunk in the head; ears like the human; limbs of a great length, and uncommonly slender: the hair is black, long, and rough. There are only four fingers on the hands, being quite deficiente of a thumb; five toes on the feet. The tail is long, and naked below, near the end. The body is slender; about a foot and an half long; the tail near two feet, and so prehensile as to serve every purpose of a hand. They inhabit the neighbourhood of Carthage, Guiana, Brazil, and Peru; associate in wall herds; and are scarce ever seen on the ground. Dampier describes their gambols in a lively manner: "There was (says he) a great company dancing from tree to tree over my head, chattering, and making a terrible noise and a great many grim faces and antic gestures; some broke down dry limbs and flung them at me, others scattered their urine and dung about my ears: at last one bigger than the rest came to a small limb just over my head, and leaping directly at me, made me leap back; but the monkey caught hold of the bough with the tip of its tail, and there continued swinging to and fro, making mouths at me. The females with their young ones are much troubled to leap after the males; for they have commonly two, one fle carries under her arm, the other sits on her back, and claps its two fore-paws about her neck: are very full when taken; and very hard to be got when shot, for they will cling with their tail or feet to a bough as long as any life remains. When I have shot at one, and broke a leg or arm, I have pitied the poor creature to see it lock and handle the broken limb, and turn it from side to side."—They are the most active of monkeys, and quite enliven the forests of America. In order to pass from top to top of lofty trees, whose branches are too dilatan for a leap, they will form a chain, by hanging down, linked to each other by their tails, and swinging in that manner till the lowest catches hold of a bough of the next tree, and draws up the rest; and sometimes they pass rivers by the SAME expedient. They are sometimes brought to Europe; but are very tender, and seldom live long in our climate.

32. The tat, sapajus, capucinus, or weeper, with a round and flat face, of a reddish brown colour, very deformed: the hair on the head and upper part of the body black, tinged with brown; beneath and on the limbs tinged with red: tail black, and much longer than the head and body: the young excessively deformed; their hair very long, and thinly dispersed. In the British museum are specimens of old and young. M. de Buffon has a variety with a white throat. Inhabits Surinam and Brazil: appear as if it was always weeping; of a melancholy disposition; but very full of imitating what it sees done. These probably are the monkeys Dampier saw in the Bay of All Saints, which he says are very ugly, and smell strongly of musk. They keep in large companies; and make a great chattering, especially in stormy weather, feed much on a species of tree which bears a podded fruit, which they feed on.

33. Sapajus laterrillls, or horned sapajus, has two tufts of hair on the head, resembling little horns: is beardles. Inhabits South America. The face, sides, belly, and fore-pants of the thighs are brown; the top of the head, middle of the back, tail, legs, and posterior parts of the thighs, are black; the nails are long and rather blunt; the tail is prehensile and twilled. Perhaps of the same species with the simia apella or capucinus. This, in all probability, is one of the fictitious species, purposefully deformed, by exhibitors of wild beasts, to impose on the public.

34. Saimiri, sapajus fuscus, or orange monkey, has no beard; the hinder part of the head is prominent; and the nails on the four toes of the hind paws are narrower and pointed. It inhabits South America, and is the most beautiful of all the sapajus; its movements are graceful; its face small; its colour a bright yellow; its vifage round, with large vivacious eyes, surrounded by feth coloured rings; it has hardly any forehead; the nose is elevated at the base, and flattened at the point: the mouth is small, the face flat and naked, and the ears are garnished with hair, and a little pointed; the tail is only half prehensile: It bands with ease on two feet, but commonly walks on all four.

V. Sagoins, Sagoins. These have long tails, which are proportionally longer than those of the sapajus, straight, flaccid, entirely covered with hair, and not prehensile; that is, incapable of laying hold of any object: the cheeks have no pouches; and the buttocks, which are covered with hair, have no callosities; the partition between the nostrils is very thick, and the apertures are placed on the sides of the nose. The females do not menstruate. This race of animals is only found in America. The faki, fagonius pinhecia, or fox-tailed monkey, with a swarthly face, covered with short white down: forehead and sides of the face with whitith, and pretty long hair: body with long duncky brown hairs: white or yellowish at their tips: hair on the tail very long and bushy: sometimes black, sometimes reddish; belly and lower part of the limbs a reddish white: length from nose to tail near a foot and a half; tail longer, and like that of a fox: hands and feet black, with claws instead of nails. Inhabits Guiana.

36. The langlin, fagonius iacchus, or blackened mon Fig. 24.
Besides these which we have described, there are a great many species which we have omitted. Those who wish to be better acquainted with the simile, may consult Buffon, Pennant, and Gmelin's edition of the Zoology of Animals by Mr. Ker.

SIMILE, or Similitude, in rhetoric, a comparison of two things, which though different in other respects, yet agree in some one. The difference between a simile and comparison is said to consist in this, that the simile properly belongs to whatever we call the quality of a thing, and the comparison to the quantity. See Comparison, and Ornament, n° 118.

SIMILOR, a name given to an alloy of red copper and zinc, made in the best proportions, to imitate silver and gold.

Simon Maccabees, a celebrated leader and high prist of the Jews, who, after rendering the most important services to his country, was laid trencherously slain by his son-in-law. See the History of the Jews, n° 15.

Simon Magnus, or the Sorcerer, was a native of Gittaon, a village of Samaria. According to the usual practice of the Athenians of that age, he visited Egypt, and there probably became acquainted with the sublime mysteries taught in the Alexandrian school, and learned those theurgy or magical operations by means of which it was believed that men might be delivered from the power of evil demons. Upon his return into his own country, the author of the Clementine Recognitions relates, that he imposed upon his countrymen by high pretensions to supernatural powers. And St Luke attests, that this artful facetious, using forcery, had bewitched the people of Samaria, giving out that he was Jesus great one; and that he obtained such general attention and reverence in Samaria, that the people all gave heed to him from the least to the greatest, saying, "This man is the Great Power of God."

By the preaching of Philip the Deacon, he was with other Samaritans converted to the Christian faith, and admitted into the infant church by the ordinance of baptism. His conversion, however, seems not to have been real; for, upon seeing the miraculous effects of the laying on of the apostles' hands, he offered them money, saying, "Give me also this power, that on whomsoever I lay hands he may receive the Holy Ghost." He probably thought Peter and John magicians like himself, but better skilled in the art of deceiving the multitude.

Being sharply reprievd for this impety, he seems by his answer to have been made siable of his fault; but his repentance, if sincere, was of short duration. Returning to his former practices of imposture, he travelled through various provinces of the empire, oppressing the progres of the Gospel; and arriving at Rome, he led alfarvait numbers of people by his pretended miracles. How long he lived in that metropolis of the world, or in what manner he died, we have no accounts that

that can be fully depended on. The Christian writers tell us, that being raised in the air by two demons, he was deprived of their support by the prayers of St Peter and St Paul, and falling, broke his legs. By some he is thought to have been the person mentioned by Suetonius, who, undertaking to fly in the presence of Nero, fell to the ground with such violence, that his blood spat up to the gallery where the emperor was sitting.

The sum of this impostor's doctrine, divested of allegory, was, that from the Divine Being, as a fountain of Light, flow various orders of sons, or eternal natures, subsisting within the plurality of the divine essence, that beyond these, in the order of emanation, are different classes of intelligences, among the lowest of which are human souls; that matter is the most remote production of the emanative power, which, on account of its infinite distance from the Fountain of Light, possesses flagitious and malignant qualities, which oppose the divine operations, and are the source of evil; that it is the great defect of philosophy to deliver the soul from its tribulations, in matter, and refute it to that divine light from which it was derived; and that for this, a male God had sent one of the first sons among men. To his wife Helen a he also ascribed a similar kind of divine nature, pretending that a female sex inhabited the body of this woman, to whom he gave the name of Eras, Wifeline; whence some Christian fathers have said, that he called her the Holy Spirit. He also taught the transmigration of souls, and disbelieved the resurrection of the body.

Simon (Richard), was born at Dieppe the 15th May 1638. He began his studies among the priests of the Oratory in that city, but quitted their society in a short time. From Dieppe he went to Paris, where he made great progress in the study of the oriental languages. Some time afterwards he joined the society of the Oratory again, and became a priest of it in 1660. In 1670 he published some pieces of a smaller kind. In 1678 his Critical History of the Old Testament appeared, but was immediately suppressed by the intrigues of Melleleus du Parnassus. It was republished the next year after, and its excellence soon drew the attention of foreigners; an edition of it was accordingly published at Amsterdam in Latin, and at London in English.

He died at Dieppe in 1712, at the age of 74.

He certainly possessed a vast deal of learning; his criticism is exact, but not always moderate, and these reigns in his writings a spirit of a sly and singularity which raised him a great many enemies. The most celebrated of these were Le Clerc, Voltaire, Jurieu, Du Pin, and Bedier. Simon wrote an entire volume of the book that were published against him, and displays a pride and obstinacy in his controversial writings which do him little honour.

He was the author of a great many books. The following are the principal: 1. The Ceremonies of the Jews, translated from the Italian of Leo o. Modena, with a supplement concerning the cliés of the Barabians and Samaritans. 2. L'Histoire Critique du Vieux Testament, The Critical History of the Old Testament. This is a very important work, and deserves the attention of every clergyman. He sometimes, however, deviates from the road of integrity, to serve the cause of the church of Rome, particularly in his endeavours to prove the uncertainty of the Hebrew language. These passages have been very justly exposed and corrected by Dr Campbell, in his ingenious Preliminary Difficulties to his new Translation of the Gospels. 3. Critical History of the Text of the New Testament. 4. Critical History of the Versions of the New Testament. 5. Critical History of the principal commentators on the New Testament. 6. Inspiration of the Sacred Books. 7. A Translation of the New Testament. This book was confounded by Cardinal Sarrallez and Bofflet. 8. The History of the rise and progress of Ecclesiastical Revenues, which is commended by Voltaire, as is his Critical History of The Old Testament. It resulted from a quarrel with a community of Benedictines. 9. A new Select Library, which points out the good books in various kinds of literature; and the use to be made of their contents. 10. Critical History of the Belief and Customs of the Nations on the Levant. 11. Critical Letters, &c.

SIMONICAL, is applied to any person guilty of simony. See SIMONY.

Simonides, the name of several poets celebrated in antiquity; but by the Marbles it appears that the eldest and most illustrious of them was born in the 5th Olympiad, 538 years B. C. and that he died in his 90th year; which nearly agrees with the chronology of Eusebius. He was a native of Ceos, one of the Cyclades, in the neighbourhood of Attica, and the preceptor of Pindar. Both Plato and Cicero gave him the character not only of a good poet and musician, but speak of him as a person of great virtue and wisdom. Such longevity gave him an opportunity of knowing a great number of the first characters in antiquity with whom he was in some measure connected. It appears in Fabricius, from ancient authority, that Simonides was contemporary and in friendship with Pittacus of Mytilene, Hipparchus tyrant of Athens, Peuesius king of Sparta, Hiero tyrant of Syracuse, with Themistocles, and with Alcadas king of Thessaly. He is mentioned by Herodotus; and Xenophon, in his Dialogue upon Tyranny, makes him one of the interlocutors with Hiero king of Syracuse. Cicero alludes, what he often has quoted in proof of the modesty and wisdom of Simonides, when Heracles asked him for a definition of God, the poet required a whole day to meditate on so important a question; at the end of which, upon the prince putting the same question to him a second time, he asked two days respite; and in this manner always doubled the delay each time he was required to answer it; till at length, to avoid offending his patron by more disappointment, he frankly confessed that he found the question so difficult, that the more he meditated upon it, the less was his hope of being able to solve it.

In his old age, perhaps from seeing the ref, et which money procured to such as had lost the charms of youth, and the power of attracting mankind by other means, he became somewhat mercenary and avaricious. He was frequently employed by the victors at the games to write panegyrics and odes in their praise, before his pupil Pindar had exercised his talents in their behalf; but Simonides would never gratify their vanity in this particular, till he had first tied them down to a stipulated sum for his trouble; and upon being upbraided for his
meneis, he said, that he had two coffers, in one of which he had for many years put his pecuniary rewards; the other was for honours, verbal thanks, and promises; that the first was pretty well filled, but the last remained always empty. And he made no scruple to confess, in his old age, that of all the enjoyments of life, the love of money was the only one of which time had not deprived him.

He was frequently reproached for this vice; however, he always defended himself with good humour. Upon being asked by Hiero's queen, Whether it was most desirable to be learned or rich? he answered, that it was far better to be rich; for the learned were always dependent on the rich, and waiting at their doors; whereas, he never saw rich men at the doors of the learned. When he was accused of being so fond as to fell part of the provisions with which his table was furnished by Hiero, he said he had done it in order "to display to the world the magnificence of that prince and his own frugality." To others he said, that his reason for accumulating wealth was, that "he would rather leave money to his enemies after death, than be troublesome to his friends while living."

He obtained the prize in poetry at the public games when he was fourscore years of age. According to Suidas, he added four letters to the Greek alphabet; and Pliny assigns to him the eighth string of the lyre; but ten rather leave money to his enemies after death, than be corrupt of the following fragment of this poet. Daedalus had not deprived him. He was called by the learned. When he promised that he would deprive him of all the enjoyments of clerkship after death, admittin, instituting, he, weeping, asked by Hiero's queen, whether in like manner forfeit the true idea of simony, shall forfeit two years value of the benefice or dignity; one moiety to the king, and the other to any one who will sue for the same. If persons also corruptly resign or exchange their benefices, both the giver and taker shall in like manner forfeit double the value of the money or other corrupt consideration. And persons who shall corruptly ordain or license any minister, or procure him to be ordained or licenced (which is the true idea of simony), shall incur a like forfeiture of forty pounds; and the minister himself of ten pounds, besides an incapacity to hold any ecclesiastical prebend for seven years afterwards. Corrupt elections and renunciations in colleges, hospitals, and other elemeny corporations, are also punished, by the same statute, with forfeiture of the double value, vacating the place or office, and a devotion of the right of election, for that term, to the crown.

SIMOON, a hot wind which blows occasionally in the deserts of Africa, and probably in other widely extended countries parched in the same manner by a vertical sun. Its effects on the human body are dreadful. If inhaled in any quantity, it produces instant suffocation, or at least leaves the unhappy sufferer oppressed with asthma and lowness of spirits. The approach of this awful scourge of God is indicated by a redness in the air, well understood by those who are accustomed to journey through the desert; and the only refuge which they have from it, is to fall down with their faces close to the ground, and to continue as long as possible without drawing in their breath.

Mr Bruce, who, in his journey through the desert, suffered from the simoon, gives it the following graphical description: "At eleven o'clock, while we contemplated with great pleasure the rugged top of Cimg, so noble, to which we were fast approaching, where we were to lodge ourselves with plenty of good water, P. 559. Diris our guide cried out, with a loud voice, fall upon your faces, for here is the simoon. I saw from the south-east a haze come, in colour like the purple part of the rainbow, but not so compressed or thick. It did not occupy twenty yards in breadth, and was about twelve feet high from the ground. It was a kind of bluster upon the air, and it moved very rapidly; for I scarce could turn to fall upon the ground with my head to the northward, when I felt the heat of its current plainly upon my face. We all lay flat on the ground as if dead, till Diris told us it was blown over. The meteor or purple haze which I saw was indeed pass'd, but the light air that still blew was of heat to threaten
SIMPSON [503] SIMPSON

thunder itself. For my part, I found diligently in my breast that I had imbibed a part of it, nor was I free of an astralamic sensation till I had been some months in Italy, at the baths of Poreta, near two years afterwards." Though the severity of this blast seems to have passed over them almost insensibly, it continued to blow so as to exhaust them till twenty minutes before five in the afternoon, lasting through all its stages very near six hours, and leaving them in a state of the utmost depression.

SIMPLE, something not mixed or compounded; in which sense it stands opposed to compound.

SIMPLE, in the materia medica, a general name for all herbs or plants, as having each its particular virtue, whereby it becomes a simple remedy.

SIMPLICITY IN WRITING. If we examine the writers whose compositions have stood the test of ages, and obtained that highest honour, "the concurrent approbation of distant times and nations," we shall find that the character of simplicity is the unvarying circumstance which alone hath been able to gain this universal homage from mankind. Among the Greeks, whose writers in general are of the simple kind, the divine poet, the most commanding orator, the finest historian, and deepest philosopher, are, above the rest, conspicuously eminent in this great quality. The Roman writers rise towards perfection according to that measure of simplicity which they mingle in their works; indeed they are all inferior to the Greek models. But who will deny that Lucretius, Horace, Virgil, Livy, Terence, Tully, are at once the simplest and best of Roman writers? unless we add the noble annalist who appeared in after-times; who, notwithstanding the politic turn of his genius, which sometimes intermixes, is admirable in this great quality, and by it far superior to his contemporaries. It is this one circumstance that hath raised the venerable Dante, the father of modern poetry, above the succeeding poets of his country, who could never long maintain the local and temporary honours bestowed upon them; but have fallen under that just neglect which time will ever decrees to those who deform a just simplicity for the florid colourings of fable, contrived phantasies, affected conceits, the mere trapings of composition and Gothic minuteness. It is this hath given to Boileau the most lasting wreath in France, and to Shakespeare and Milton in England; especially to the former, whose writings contain specimens of perhaps the purest and simplest English that is anywhere to be found, except in the Bible or Book of Common Prayer. As it appears from these inferences, that simplicity is the only universal characteristic of just writing, so the superior eminence of the sacred Scriptures in this quality hath been generally acknowledged. One of the greatest critics in antiquity, himself conspicuous in the sublime and simple manner, hath borne this testimony to the writings of Moses and St Paul; and by parity of reason we must conclude, that had he been conversant with the other sacred writers, his taste and candour would have allowed them the same eumenium.

It hath been often observed even by writers of no mean rank, that the "Scriptures suffer in their credit by the disadvantage of a literal version, while other ancient writings enjoy the advantage of a free and embellished translation." But in reality these gentlemen's concern is ill-placed and groundless: for the truth is, "that most other writings are impaired by a literal translation; whereas giving only a due regard to the idiom of different languages, the sacred writings, when literally translated, are then in their full perfection."

Now this is an internal proof, that in all other writings there is a mixture of local, relative, exterior ornament, which is often lost in the translation from one language to another. But in the internal beauty which depend not on the particular construction of tongue, no change of tongue can destroy. Hence the Bible preserves its native beauty and strength alike in every language, by the sole energy of unadorned phrases, natural images, weight of sentiment, and great simplicity.

It is in this respect like a rich vein of gold, which, under the severest trials of heat, cold, and moisture, retains its original weight and splendour, without either loss or alloy; while bolder metals are corrupted by earth, air, water, fire, and asphaltted to the various elements through which they pass.

This circumstance, then, may be justly regarded as sufficient to vindicate the composition of the sacred Scriptures, as it is at once their chief excellence and greatest security. It is their excellence, as it renders them intelligible and useful to all; it is their security, as it prevents their being disfigured by the false and capricious ornaments of vain or weak translators. We may safely appeal to experience and fact for the confirmation of their remarks on the superior simplicity, utility, and excellence, of the fable of the Holy Scripture. Is there any book in the world so perfectly adapted to all capacities? that contains such sublime and exalted precepts, conveyed in such an artless and intelligible strain, that can be read with such pleasure and advantage by the lettered sage and the unlettered peasant?

SIMPOLE. See Oratory, p. 72.

SIMPSON (Thomas), professor of mathematics at the royal academy at Woolwich, fellow of the Royal Society, and member of the Royal Academy at Stockholm, was born at Market Belfworth in Leicestershire in 1710. His father, a stuff-weaver, taught him only to read English, and brought him up to his own business; but meeting with a scientific pedlar, who likewise practised fortune-telling, young Simpson by his advice left off weaving, and professed astrology. As he improved in knowledge, however, he grew disgusted with his pretended art; and renouncing it, was driven to such difficulties for the subsistence of his family, that he came up to London, where he worked as a weaver, and taught mathematics at his spare hours. As his scholars increased, his abilities became better known, and he published his Treatise on Fluxions, by subscription, in 1737: in 1740, he published his Treatise on the Nature and Laws of Chance; and Essays in Speculative and Mixed Mathematics. After these appeared his Doctrine of Annuities and Reversions; Mathematical Diferations; Treatise on Algebra; Elements of Geometry; Trigonometry, Plane and Spherical; Select Exercises; and his Doctrine and Application of Fluxions, which he professes to be rather a new work, than a second edition of his former publication on fluxions. In 1745, he obtained the mathematical professorship at Woolwich academy, and soon after was chosen a member of the Royal Society, when the president and council, in consideration of his moderate circumstances, were pleased to excise his admission-
him. Sometimes even this could not relieve his fatigue. He then had recourse to mathematics, which never failed to satisfy and refresh him. For a long while he restricted himself to a very moderate use of the cordial, fearing that he would soon exhaust the small stock which so limited and abstract a science could yield; till at last he found, that the more he learned, a wider field opened to his view, and scenes that were inexhaustible. Becoming acquainted with subjects far beyond the elements of the science, and with numbers of men celebrated during that period of ardent research all over Europe, he found it to be a more and important study, by which he was as likely to acquire reputation as by any other. About this time, too, a prospect began to open of making mathematics his profession for life. He then gave himself up to it without reserve.

His original incitement to this study as a treat, as something to please and refresh his mind in the midst of feverish tasks, gave a particular turn to his mathematical studies, from which he never could afterwards deviate. Perseverance and elegance are more attainable, and more delightful, in pure geometry, than in any other parts of the science of measure. To this therefore he chiefly devoted himself. For the same reason he preferred the ancient method of studying pure geometry, and even felt a dislike to the Cartesian method of substituting symbols for operations of the mind, and still more was he disgusted with the substitution of symbols for the very objects of discussion, for lines, surfaces, solids, and their affections. He was rather disposed to the solution of an algebraical problem, where quantity alone was considered, to substitute figures and its affections for the algebraic symbols, and to convert the algebraic formula into an analogous geometrical theorem. And he came at last to consider algebraic analysis as little better than a kind of mechanical knack, in which we proceed without ideas of any kind, and obtain a result without meaning, and without being conscious of any processes of reasoning, and therefore without any conviction of its truth. And there is no denying, that if genuine un sophisti cated taste alone is to be consulted, Dr Simson was in the right; for though it must also be acknowledged, that the reasoning in algebra is as strict as in the pure geometry of Euclid or Apollonius, the \textit{report} analyst has little perception of it as he goes on, and his final equation is not felt by himself as the result of ratiocination, any more than if he had obtained it by Pafcal’s arithmetical mill. This does not in the least diminish our admiration of the algebraic analysis; for its almost boundless grasp, its rapid and certain procedure, and the delicate metaphysics and great address which may be displayed in conducting it. Such, however, was the ground of the strong bias of Dr Simson’s mind to the analysis of the ancient geometers. It increased as he went forward; and his veneration (we may call it his love or affection) for the ancient geometry was carried to a degree of idolatry. His chief labours were exerted in efforts to restore the works of the ancient geometers; and he has nowhere bestowed much pains in advancing the modern discoveries in mathematics. The noble inventions, for example, of fluxions and of logarithms, by which our progres in mathematical knowledge, and in the useful application of this knowledge, is so much promoted, attracted the notice of Dr Simson; but he has contented himself with de-
monstrating their truth on the genuine principles of the ancient geometry. Yet was he very thoroughly acquainted with all the modern discoveries; and there are to be seen among his papers discussions and investigations in the Cartesian method, which show him thoroughly acquainted with all the principles, and even expert in the *tours de main,* of the most refined syphobitical analysis (A).

About the age of 25 Dr Simfon was chosen regius professor of mathematics in the university of Glasgow. He went to London immediately after his appointment, and there formed an acquaintance with the most eminent men of that bright era of British science. Among these he always mentioned Captain Halley (the celebrated Dr Edmund Halley) with particular respect; saying, that he had the most acute penetration, and the most just taste in that science, of any man he had ever known. And, indeed, Dr Halley has strongly exemplified both of these in his divination of the work of *Apollonius de Sectiune Solutis,* and the 8th book of his *Conic,* and in some of the most beautiful theorems in Sir Isaac Newton's *Principia.* Dr Simfon also admired the wide and matterly steps which Newton was accustomed to take in his investigations, and his manner of substituting geometrical figures for the quantities which are observed in the phenomena of nature. It was from Dr Simfon that the writer of this article had the remark which has been oftener than once repeated in the course of this Work, "That the 39th proposition of the first book of the *Principia* was the most important proposition that had ever been exhibited to the phyico-mathematical philosopher," and he used always to illustrate to his more advanced scholars the superiority of the geometrical over the algebraic analysis, by comparing the solution given by Newton of the inverse problem of centripetal forces, in the 42d proposition of that book, with the one given by John Bernoulli in the *Memoirs of the Academy of Sciences* at Paris for 1713. We have heard him say, that to his own knowledge Newton frequently investigated his propositions in the syphobitical way, and that it was owing chiefly to Dr Halley that they did not finally appear in that dress. But if Dr Simfon was well informed, we think it great credit was due to him in the syphobitical analysis, when this most successful *practical artificer* (for so we must call Newton when engaged in a task of discovery) found it conducive either to dispatch or perhaps to his very progress.

Returning to his academical chair, Dr Simfon discharged the duties of a professor for more than 50 years with great honour to the university and to himself. It is almost needless to say, that in his prelections he followed strictly the Euclidian method in elementary geometry. He made use of Theodorus as an introduction to spherical trigonometry. In the higher geometry he proceeded from his own Conics; and he gave a small specimen of the *difficult problems* of the ancients, by explaining the properties, sometimes of the conchoid, with their application to the solution of such problems. In the more advanced classes he was accustomed to give Napier's mode of conceiving logarithms, *i.e.* quantities as generated by motion; and Mr Cotes's view of them, as the sums of racinulae; and to demonstrate Newton's lemmas concerning the limits of ratios; and then to give the elements of the fluxionary calculus; and to finish his course with a select set of propositions in optics, gnomonics, and central forces. His method of teaching was simple and perspicuous, his elocution clear, and his manner easy and impressive. He had the respect, and still more the affection, of his scholars.

With respect to his studies, we have already informed the reader that they got an early bias to pure geometry, and to the elegant but perspicuous methods of the ancients.

We have heard Dr Simfon say, that it was in a great measure owing to Dr Halley that he so early directed his efforts to the restoration of the ancient geometries. He had recommended this to him, as the most certain way for him, a very young man, both to acquire reputation, and to improve his own knowledge and talents, and he presented him with a *copy* of Pappus's *Mathematical Collections,* enriched with some of his own notes. The peripatetic of the ancient geometrical analysis, and a certain elegance in the nature of the solutions which it affords, especially by means of the local theorems, soon took firm hold of his fancy, and made him with the fanguine expectation of a young man, direct his very first efforts to the recovery of this in toto; and the restoration of Euclid's *Porisms* was the first task which he set himself. The accomplished geometer knows what a desperate task this was, from the scanty and mutilated account which we have of this work in a single passage of Pappus. It was an ambition which nothing but success could justify in so young an adventurer. He succeeded; and so early as 1718 seemed to have been in complete possession of this method of investigation, which was considered by the eminent geometers of antiquity as their safest guide through the labyrinth of the higher geometry. Dr Simfon gave a specimen of this discovery in 1723 in the *Philosophical Transactions.* And after this time he ceased not from his endeavours to recover that choice collection of *Porisms* which Euclid had collected, as of the most general use in the solution of difficult questions. What some of these must have been is pointed out to Dr Simfon by the very nature of the general proposition of Pappus, which he has restored. Others were pointed out by the lemmas which Pappus has given as helps to the young mathematician towards their demonstration. And, being thus in possession of a considerable number, their mutual relations pointed out a fort of system, of which these made a part, and of which the blanks now remained to be filled up.

Dr Simfon, having thus gained his favourite point, had

(A.) In 1752 the writer of this article being then his scholar, requested him to examine an account which he gave him of what he thought a new curve (a conchoid having a circle for its bafe). Dr Simfon returned it next day with a regular lift of its leading properties, and the investigation of such as he thought his scholar would not so easily trace. In this half scrawl the lines related to the circle were familiarly considered as arithmetical fractions of the radius considered as unity. This was before Euler published his *Arithmetic of the Sines* and Tangents, now in universal use.
had leisure to turn his attention to the other works of the ancient geometers, and the porisms of Euclid now had only an occasional share. The book plan of Apollonius was another task which he very early engaged in, and completed about the year 1758. But, after it was printed, he imagined that he had not given the **posthumous propinquitatis** of Apollonius, and in the precise spirit and order of that author. The impression lay by him for some years; and it was with great reluctance that he yielded to the intreaties of his mathematical friends, and published the work, in 1766, with some emendations, where he thought he had deviated farthest from his author. He quickly repented of this scanty conception, and recalled what he could of the small number of copies which he had given to the bookellers, and the impression again lay by him for years. He afterwards re-corrected the work, and filled with some reluctance allowed it to come abroad as the Re-institution of Apollonius. The public, however, had not been so fallacious as Dr. Simson, and the work had acquired great celebrity, and he was now considered as one of the first and most elegant geometers of the age: for, in the mean time, he had published his Conic Sections, a work of uncommon merit, whether we consider it as equivalent to a complete restitution of the celebrated work of Apollonius Pergaeus, or as an excellent system of this important part of mathematics. It is marked with the same features as the book plan, the most anxious solicitude to exhibit the very text of Apollonius, even in the propositions belonging to the books which had been completely lost. These could be recovered in no other way but by a thorough knowledge of the precise plan proposed by the author, and by taking it for granted that the author had accurately accomplished this plan. In this manner did Viviani proceed in the first attempt which was made to restore the conics of Apollonius; and he has given us a detail of the processes of his conjectures, by which we may form an opinion of its justice, and of the probability how far he has attained the desired object. Dr. Simson's view in his performance was something different; deviating a little in this one case from his general track. He was not altogether pleased with the work of Viviani, even as augmented by the eighth book added by Halley, and his wish was to restore the ancient original. But, in the mean time, an academical text book for conic sections was much wanted. He was much dissatisfied with those in common use; and he was not insensible of the advantage resulting from the consideration of these sections, independent of the cone first introduced by Dr. Wallis. He therefore composed this excellent treatise as an elementary book, not to supercede, but to prepare for the study of Apollonius; and accordingly accommodates it to this purpose, and gives several important propositions in their proper places, expressly as restitution of Apollonius, whom he keeps constantly in view through the whole work.

Much about this time Dr. Simson seriously began to prepare a perfect edition of Euclid's Elements. The intimate acquaintance which he had by this time acquired with all the original works of the ancient geometers, and their ancient commentators and critics, encouraged him to hope that he could restore to his original lustre this leader in mathematical science; and the errors which had crept into this celebrated work, and which still remained in it, appeared of magnitude sufficient to merit the most careful efforts for their removal. The data also, which were in like manner the introduction to the whole art of geometrical investigation, seemed to call more loudly for his amending hand. For it appears that the Saracens, who have preferred to us the writings of the ancients, have consented themselves with admiring these celebrated works, and have availed themselves of the knowledge which they contain; but they have shown no inclination to add to their stock, or to promote the sciences which they had received. They could not do any thing without the synthetical books of the geometers; but, not meaning to go beyond the discoveries which they had made, they neglected all the books which related to the analytic art alone, and the greatest part of them (about 15 out of 30) have irrecoverably perished. The data of Euclid have fortunately been preserved, but the book was neglected, and the only ancient copies, which are but three or four, are miserably erroneous and mutilated. Fortunately, it is no very arduous matter to reinstate this work in its original perfection. The plan is precise, both in its extent and its method. It had been restored, therefore, with success by more than one author. But Dr. Simson's comprehensive view of the whole analytical system point out to him many occasions for amendment. He therefore made its inquisition a joint task with that of the elements. All the data of true geometry will acknowledge their obligations to him for the edition of the Elements and data which he published about 1758. The text is corrected with the most judicious and scrupulous care, and the notes are inestimable, both for their information, and for the tendency which they must have to form the mind of the student to a true judgment and taste in mathematical subjects. The more accomplished reader will perhaps sometimes dispoed to smile at the axioms which seem to pervade the notes, that a work of Euclid must be supposed without error or defect.
SIMSON

Selecion of such as would serve to support and increase his well earned reputation as the RESTORER OF ANCIENT GEOMETRY.

We have been thus particular in our account of Dr Simson's labours in their works, because his manner of execution, while it does honour to his inventive power, and shows his revolt table in mathematical composition, also maintains his reputation, that he carried his respect for the ancient geometers to a degree of superfluous idolatry, and that his fancy, unchecked, viewed them as incapable of error or imperfection. This is difficult to be seen in the emendations which he has given of the texts, particularly in his editions of Euclid. Not only every imperfection of the reading is ascribed to the ignorance of copyists, and every indiftness in the conception, inconclusiveness in the reasoning, and defect in the method, is ascribed to the ignorance or mistake of the commentators; but it is all along asumed that the work was perfect in its kind; and that by exhibiting a perfect work, we restore the genuine original. This is surely gratuitous; and it is very possible that it has, in some instances, made Simson fall in his anxious purpose, and give us even a better than the original. It has undoubtedly made his fault in what should have been his great purpose, viz., to give the world a connected system of the ancient geometrical analyses; such as would, in the first place, exhibit it in its most engaging form, elegant, perspicuous, and comprehensible; and, in the next place, such as should engage the mathematicians of the present age to adopt it as the most certain and successful conductor in those labours and difficult researches in which the demands of modern science continually engage them. And this might have been expected, in the province of speculative geometry at least, from a person of such extensive knowledge of the properties of figure, and who had so eminently succeeded in the many trials which he had made of its powers. We might have expected that he would at least have exhibited in one systematic point of view, what the ancients had done in several detached branches of the science, and how far they had proceeded in the solution of the several speculative classes of problems; and we might have hoped, that he would have instructed us in what manner we should apply that method to the solution of problems of a more elevated kind, daily presented to us in the questions of phisicalo-mathematical science. By this he would have acquired distinguished honour, and science would have received the most valuable improvement.

But Dr Simson has done little of all this; and we cannot say that great helps have been derived from his labours by the eminent mathematicians of this age, who are successfully occupied in advancing our knowledge of nature, or in improving the arts of life. He has indeed contributed greatly to the entertainment of the speculative mathematician, who is more delighted with the conscientious exercise of his own reasoning powers, than with the final refutation of his researches. Yet we are not even certain that Dr Simson has done this to the extent he wished and hoped. He has not engaged the liking of mathematicians in this analysis, by presenting it in the most agreeable form. His own extreme anxiety to tread in the very footsteps of the original authors, has, in a thousand instances, precluded him from using his own extensive knowledge, that he might not employ principles which were not of a class inferior to that of the question in hand. Thus, of necessity, did the method appear tampered. We are deferred from employing a process which appears to restrain us in the application of the knowledge which we have already acquired; and, disgusted with the tedious, and perhaps indited paths, by which we arrive at an object which we see clearly over the hedge, and which we could reach by a few steps, of the facility of which we are otherwise perfectly assured. These prepositions are indeed founded on mistake; but the mistake is such, that all fall into it, till experience has enlarged their views. This circumstance alone has hitherto prevented mathematicians from acquiring that knowledge of the ancient analysis which would enable them to proceed in their researches with certainty, dispatch, and delight. It is therefore deeply to be regretted, that this eminent genius has occupied, in this superfluous paleology, a long and busy life, which might have been employed in original works of infinite advantage to the world, and honour to his country.

Our readers will, it is hoped, consider these observations as of general scientific importance, and as intimately connected with the history of mathematics; and therefore as not improperly introduced in the biographical account of one of the most eminent writers on this science. Dr Simson claimed our notice as a mathematician; and his affectionate admiration of the ancient analysis is the prominent feature of his literary character. By this he is known all over Europe; and his name is never mentioned by any foreign author without some very honourable allusion to his distinguished geometrical elegance and skill. Dr James Moor, professor of Greek in the university of Glasgow, no less eminent for his knowledge in ancient geometry than for his professional talents, put the following apposite inscription below a portrait of Dr Simson:

**GEOMETRIAM, sub TYPANO BARBARO SAVIA**

**SERVITUTE DIU SQUALENTEM, in LIBERTALM ET DECUS ANTIQUUM VINDICAVIT**

**UNUS.**

Yet it must not be understood that Dr Simson's predilection for the geometrical analysis of the ancients did so far mislead him as to make him neglect the sylbo-logical analysis of the present times; on the contrary, he was completely master of it, as has been already observed, and frequently employed it. In his academical lectures to the students of his upper classes, he used to point out its proper province (which he by no means limited by a feantry boundary), and in what cases it might be applied with safety and advantage even to questions of pure geometry. He once honoured the writer of this article with the sight of a very short dissertation on this subject (perhaps the one referred to in the preface to his Conic Sections). In this piece he was perhaps more liberal than the most zealous partisans of the sylbo-logical analysis could desire, admitting as a sufficient equation of the Conic Sections $\ell = \frac{\ell}{p}$, where $\ell$ is the latus rectum, $x$ is the distance of any point of the curve from the focus, $p$ is the perpendicular drawn from the focus to the tangent in the given point, and $\ell$ is the chord of the equicurve circle drawn through the focus. Unfortunately this dissertation was not found among his papers.
Mr. M'Laurin during the progress of his incomparable Treatise of Fluxions, and contributed not a little to the reputation of that work. The spirit of that most ingenious algebraic demonstration of the fluxions of a rectangle, and the very process of the argument, is the same with Dr. Simson's in his dissertation on the limits of quantities. It was therefore from a thorough acquaintance with the subject, and by a just taste, that he was induced to prefer his favourite analysis, or, to speak more properly, to exhort mathematicians to employ it in its own sphere, and not to become ignorant of geometry, while they successfully employed the symbological analysis in cafés which did not require it, and which suffered by its admission. It must be acknowledged, however, that in his later years, the difficulty which he felt at the artificial and frowzy employment on subjects of pure geometry, sometimes hindered him from even looking at the most refined and ingenious improvements of the algebraic analysis which occur in the writings of Euler, D'Alembert, and other eminent masters. But, when properly informed of the subject, he never failed to give them their due praise; and we remember him speaking, in terms of great satisfaction, of an improvement of the infinitesimal calculus, by D'Alembert and De la Grange, in their researches concerning the propagation of sound, and the vibrations of musical cords.

And that Dr. Simson not only was master of this calculus and the symbological calculus in general, but held them in proper esteem, appears from two valuable dissertations to be found in his posthumous works: the one on logarithms, and the other on the limits of ratios. The last, in particular, shows how completely he was satisfied with respect to the solid foundation of the method of fluxions; and it contains an elegant and strict demonstration of all the applications which have been made of the method by its illustrious author to the objects of pure geometry.

We hoped to have given a much more complete and instructive account of this eminent geometer and his works, by the aid of a person fully acquainted with both, and able to appreciate their value; but an accident has deprived us of this visitation, when it was too late to procure an equivalent: and we must request our readers to accept of this very imperfect account, since we cannot do justice to Dr. Simson's merit, unlefs almost equally conversant in all the geometry of the ancient Greeks.

The life of a literary man rarely teems with anecdote; and a mathematician, devoted to his studies, is perhaps more abstained than any other person from the ordinary occurrences of life, and even the ordinary topics of conversation. Dr. Simson was of this class; and having never married, lived entirely a college life. Having no occasion for the commodious house to which his place in the university entitled him, he contented himself with chambers, good indeed, and spacious enough for his sober accommodation, and for receiving his choice collection of mathematical writers, but without any decoration or commodious furniture. His official servant sufficed for valet, footman, and chambermaid. As this retirement was entirely devoted to study, he entertained no company in his chambers, but in a neighbouring house, where his apartment was sacred to him and his guests.

Having in early life devoted himself to the restoration of the works of the ancient geometers, he studied them with unremitting attention; and, retiring from the profligate intercourses of the world, he contented himself with a small society of intimate friends, with whom he could lay aside every restraint of ceremony or reserve, and indulge in all the innocent frivolities of life. Every Friday evening was spent in a party at which he excelled, and took delight in instructing others, till increasing years made him less patient with the dulness of a scholar. The card-party was followed by an hour or two dedicated solely to playful conversation. In like manner, every Saturday he had a less select party to dinner at a house about a mile from town. The Doctor's long life gave him occasion to see the amanuenses of this little theatre several times completely changed, while he continued to give it a personal identity: to that, without any design or wish of his own, it became, as it were, his own house and his own family, and went by his name. In this fate did the present writer first see it, with Dr. Simson as its father and head, respected and beloved by every branched that was for relaxation, and not for the enjoyment of his acknowledged superiority, that he continued this habit of his early youth; and as his notions of a fine talk did not confine in the pleasure of having tossed and gored a good many at day,' his companions were as much at their ease as he wished to be himself; and it was no small part of their entertainment (and of his too), to smile at those innocent deviations from common forms, and those mishakes with respect to life and manners, which an almost total retirement from the world, and incessant occupation in an abstruse science, caused this venerable president frequently to exhibit. These are remembered with a more affecting regret, that they are now 'with the days that are past,' than the mort than pithy apophthegms, uttered in with an emphatical, 'Why, Sir!' or 'No, Sir!' which precludes all reply.

Dr. Simson never exerted his prelatical authority, unless it were to check some infringement of good breeding, or any thing that appeared unkindly to religion or purity of manners; for these he had the highest reverence. We have twice heard him sing (he had a fine voice and most accurate ear) some lines of a Latin hymn to the divine geometer, and each time the rapturous tear flood in his eye.

But we ask the reader's pardon for this digression; it is not however useless, since it paints the man as much as any recital of his studies; and to his acquaintances we are certain that it will be an acceptable memorandum. To them it was often matter of regret, that a person of such eminent talents, which would have made him shine equally in any line of life, should have allowed himself to be so completely devoted to a study which abstracted him from the ordinary pursuits of men, unfitted him for the active enjoyment of life, and kept him out of those walks which they frequented, and where they would have rejoiced to meet him.

Dr. Simson was of an advantageous figure, with a fine countenance, and even in his old age had a graceful carriage and manner, and always, except when in mourning, dressed in white cloth. He was of a cheerful disposition; and though he did not make the first advances
Much has been said of the writings to be found at Sinai and in the plain about it; and such were the hopes of discoveries respecting the wanderings of the Israelites from these writings, that Dr Clayton bishop of Clogher offered L. 500 Sterling to defray the expenses of journey to any man of letters who would undertake to copy them. No man, we believe, undertook this task: and the accurate Danish traveller Niebuhr found no writings there but the names of persons who had visited the place from curiosity, and of Egyptians who had chosen to be buried in that region.

**SINAPIS. Mustard, in botany:** A genus of plants belonging to the class of *Brassicaceae,* and to the order of *Crucifera.* The calyx consists of four expanding strap-shaped deciduous leaves: the integумент of the petals are broad; two glands between the shorter lamina and pellucid, also between the larger and the calyx. There are 17 species; the arvensis, orientalis, batrachites, alba, nigra, pyrenica, peduncularia, chinenis, juncea, crucistaur, alliacea, hispida, milotolga, mea, lavigna, cernua, and japa. Three of these are natives of Britain; the alba, nigra, and arvensis.

1. The *alba,* or white mustard, which is generally cultivated as a salad herb for winter and spring use. This rife with a branching hairy stalk two feet high; the leaves are deeply jagged on their edges and rough. The flowers are disposed in loose spikes at the end of the branches, standing upon horizontal stalks; they have four yellow petals in form of a cross, which are succeeded by hairy pods, that end with long, compressed, oblique beaks; the pods generally contain four white seeds.

2. The *nigra,* or common mustard, which is frequently found growing naturally in many parts of Britain, but is also cultivated in fields for the seed, of which the juice called *mustard oil* is made. This rife with a branching stalk four or five feet high; the lower leaves are large, rough, and very like those of turnip; the upper leaves are smaller and less jagged. The flowers are small, yellow, and grow in spike clusters at the end of the branches; they have four petals placed in form of a cross, and are succeeded by smooth four-cornered pods.

3. The *arvensis,* grows naturally on arable land in many parts of Britain. The seed of this is commonly sold under the title of *Durham mustard.* Of this there are two varieties, if not different species; one with cut, the other with entire leaves. The stalks rise two feet high; the leaves are rough; in the one they are jagged like turnip-leaves, in the other they are long and entire. The flowers are yellow; the pods are turgid, angular, and have long beaks.

**Mustard,** by its acrimony and pungency, stimulates the bowels, and attenuates viscid juices; and hence stands deservedly recommended for exciting appetite, afflicting digestion, promoting the fluid secretions, and for the other purposes of the acrid plants called *mustariis.* It imparts its taint and smell in perfection to aqueous liquors, and by distillation with water yields an essential oil of great acrimony. To rectified spirit its seeds give out very little either of their smell or taste. Subjected to the press, they yield a considerable quantity of mild insipid oil, which is as free from acrimony as that
of almonds. They are applied as an external stimulant to
numb or paralytic limbs; to parts affected with fixed
rheumatic pains; and to the soles of the feet, in the
low stage of acute diseases, for raising the pulse: in this
intention, a mixture of equal parts of the powdered
seed and crumb of bread, with the addition sometimes
of a little bruised garlic, are made into a cataplasm with
a sufficient quantity of vinegar.

SINAPISM, in pharmacy, an external medicine, in
form of a cataplasm, composed chiefly of mustard-seed
pulverized, and other ingredients mentioned in the pre-
ceeding article.

SINCERITY, honesty of intention, freedom from
hypocrisy. See Moral Philosophy, n° 157. SINCIPUT, in anatomy, the foremost of the head,
reaching from the forehead to the coronal future.

SINDY, a province of Hindostan Proper, bounded
on the west by Macran, a province of Perfa; on the
north by the territories of the king of Cabudabar; on the
north-east by those of the Sikhs; on the east by a
sandy desert; and on the south-east by Cutch. It ex-
tends along the course of the river Sinde or Indus from
its mouth to Behker or Bhakor, on the frontiers of
Moulcan. Reckoned that way, it is 300 miles long
and its breadth, in its widest part, is about 160. In
many particulars of soil and climate, and in the general
appearance of the surface, Sindy resembles Egypt; the
lower part of it being composed of rich vegetable mould,
and extended into a wide dell; while the upper part of
it is a narrow slip of country, confined on one side by
a ridge of mountains, and on the other by a sandy desert,
the river Indus, equal at least to the Nile, winding
through the midst of this level valley, and annually
overflowing it. During great part of the south-west
monsoon, or at least in the months of July, August,
and part of September, which is the rainy season in moit
other parts of India, the atmosphere is here generally
clouded; but no rain falls except very near the sea.
Indeed, very few showers fall during the whole year;
owing to which, and the neighbourhood of the sandy
defects, which bound it on the east and on the north-
west, the heats are so violent, and the winds from these
quarters so powerful, that the houses are contrived so
as to be occasionally ventilated by means of apertures on
the tops of them, resembling the funnels of small chimneys.
When the hot winds prevail, the windows are closely
closed; and the lowest part of the current of air, which is always the hottest, being thus excluded,
a cooler, because more elevated, part descends into
the houses through the funnels. By this contrivance
also vast clouds of dust are excluded; the entrance of
which would alone be sufficient to render the houses
uninhabitable. The roofs are composed of thick layers
of earth instead of terraces. Few countries are more
unwholesome to European constitutions, particularly
the lower part of the Delta. The prince of this pro-
vince is a Mahometan, tributary to the king of Can-
dubhar. He resides at Hyderabad, although Tatta is the
capital. The Hindoos, who were the original inhabi-
tants of Sindy, are by this Mahometan governors treat-
ed with great rigour, and denied the public exercise of
their religion; and this severity drives vast numbers of
them into other countries. The inland parts of Sindy
produce faltpetre, sal-ammoniac, borax, bezoor, lapis
lazuli and raw silk. They have also manufacturies of
cotton and silk of various kinds; and they make fine
cabinets, lined with ivory, and finely lacquered. They
also export great quantities of butter, clarified and
wrapt up in duppas, made of the hides of cattle. The
ladies wear hoops of ivory on both their arms and legs,
which when they die are burnt with them. They have
large black cattle, excellent mutton, and small hardy
horses. Their wild game are deer, hares, antelopes,
and foxes, which they hunt with dogs, leopards, and
small fierce creature called a shiahgull.

SINE or Right Sine of an Arch, in trigonometry,
is a right line drawn from one end of that arch, perpen-
dicular to the radius drawn to the other end of the
arch; being always equal to half the cord of twice the
arch. See Trigonometry and Geometry.

SINECURE, a nominal office, which has a revenue
without any employment.

SINEW, a tendon, that which unites the muscles to
the bones.

SINGING, the action of making divers inflections
of the voice, agreeable to the ear, and correspondent to the
notes of a fong or piece of melody. See Music.

The first thing to be done in learning to sing, is to
raise a scale of notes by tones and semitones to an oc-
tave, and descend by the same notes; and then to rise
and fall by greater intervals, as a third, fourth, fifth,
&c. and to do all this by notes of different pitch. Then
these notes are represented by lines and spaces, to which
the syllables fa, sol, la, mi, are applied, and the pupil
taught to name each line and space therein; whence
this practice is called fal-faing, the nature, reason, effects,
&c. whereof see under the article SOLFAING.

SINGING of Birds. It is worthy of observation, that
the female of no species of birds ever fings: with birds it
is the reverse of what occurs in human kind. Among
the feathered tribe, all the cares of life fall to the lot of
the tender sex; theirs is the fatigue of incubation; and
the principal care in nursing the helpless brood: to al-
leviate these fatigues, and to support her under them,
nature hath given to the male the fong, with all the
little blandishments and soothing arts; these he fondly
exerts (even after courtship) on some female contiguous
to the nest, during the time his mate is performing her
parental duties. But that she should be silent is also
another wise provision of nature, for her fong would
discover her nest; as would a gaudiness of plumage,
which, for the same reason, seems to have been denied
her.

On the song of birds several curious experiments and
observations have been made by the Hcn. Daines Bar-
rington. See Phil. Trans. vol. lxxii.

SINGULAR NUMBER, in grammar, that number of
nouns and verbs which stands opposed to plural. See
Grammar, n° 14.

SINISTER, something on or towards the left hand.
Hence some derive the word sinifler, à sinistro; because
the gods, by such auguries, permit us to proceed in our
designs.

SINISTER, is ordinarily used among us for unlucky;
though, in the sacred rites of divination, the Romans
used it in an opposite sense. Thus auro sinistra, or a bird
on the left hand, was esteemed a happy omen; whence,
in
SIR

in the law of the 12 tables, Ave semistra populi magnifier ego.

SINISTER, in heraldry. The sinister side of an effe
celeon is the left-hand side: the sinister chief, the left angle of the chief; the sinister base, the left-hand part of the base.

SINISTER EFFECT, among astrologers, is an appearance of two planets happening according to the succession of the signs; as Saturn in Aries, and Mars in the same degree of Gemini.

SINISTRI, a sect of ancient heretics, thus called because they held the left hand in abhorrence, and made it a point of religion not to receive any thing therewith.

SINKING FUND, a provision made by parliament, confining of the surplusage of other funds, intended to be appropriated to the payment of the national debt; on the credit of which very large sums have been borro
ved for public uses. See National Debt and Revenue.

SIPUNCULA, a genus of the intestina class of worms in the Linnaean system. Its characters are these: the body is round and elongated; the mouth attenuated and cylindrical; and the lateral aperture of the body ragged. There are two species; one found under stones in the European, and the other in the Indian ocean.

SIR, the title of a knight or baronet, which, for dilution's sake, as it is now given indiscriminately to all men, is always prefixed to the knight's Christian name, either in speaking or writing to them.

SIRC-R, any office under the government in Hindo
dostan. It is sometimes used for the state or govern
tment itself. Likewise a province, or any number of Perumals placed under one head in the government books, for convenience in keeping accounts. In common usage in Bengal, the under banyans of European gentle
men are called sirars.

SIRE, a title of honour formerly given to the king of France as a mark of sovereignty.

SIR, was likewise anciently used in the same sense with flour and flegans, and applied to barons, gentle
men, and citizens.

SIRENS, in fabulous history, certain celebrated songresses who were ranked among the demigods of antiquity. Hyginus places their birth among the consequences of the rape of Protopena. Others make them daughters of the river Achelous and one of the muses. The number of the Sirens was three; and their names were Parthenope, Lycas, and Lenara. Some Met. lib. make them half women and half birds; others, half women and half birds. There are antique representations of them still subsisting under both these forms. Pausa
nias tells us, that the Sirens, by the persuasion of Juno, challenged the Muses to a trial of skill in singing; and these having vanquished them, plucked the golden feathers from the wings of the Sirens, and formed them into crowns, with which they adorned their own heads. The Argonauts are said to have been diverted from the enchantment of their songs by the supertlira strain of Orpheus: Ulysses, however, had great difficulty in se
cing himself from seduction. See Odys. lib. xii.

Pope, in his notes to the twelfth book of the Odys
sey, observes, the critics have greatly laboured to explain what was the foundation of this fiction of the Sirens. We are told by some, that the Sirens were queens of certain small islands named Sirinfa, thus lie near Ca-
SIFON, SISON, BASTARD-STONE PARSLEY, blows from the ten inches high. Linnæus first apprehended, that it was the larva of a kind of lizard; but as its fingers are furnished with claws, and it makes a cracking noise, he concluded from these properties, as well as from the situation of the anus, that it could not be the larva of the lizard, and therefore formed of it a new genus under the name of Siren. He was also obliged to establish for this uncommon animal a new order called merenter or gliders; the animals of which are amphibious, breathing by means of gills and lungs, and furnished with arms and claws.

SIREX, in zoology, a genus of animals belonging to the class of insects, and to the order of hymenoptera. The mouth has two strong jaws; there are two truncated palpi or feelers, filiform antennæ, an exserted, stiff, serrated sting, a fuille, mueronated abdomen, and lanceolated wings. There are seven species.

SIRIUS, in botany; a genus of plants belonging to the class of tetrandria and order of manyangled. The calyx is quadrifid; there is no corolla; the nectarium is quadrifid, and crowing the throat of the calyx; the stigmas are below the corolla; the stigma is triad, and the berry trilocular. There is only one species, the myrtillium.

SIRIUS, in astronomy, a bright star in the constellation Canis. See Astronomy, no. 142, &c.

SIRET (Flavius), an eminent Roman engraver on precious stones; his Lacoos, and representations in miniature of antique statues at Rome, are very valuable and scarce. He died in 1737.

SIROCCO, a periodical wind which generally blows in Italy and Dalmatia every year about Easter. It blows from the south-east by south: it is attended with heat, but not rain; its ordinary period is twenty to forty days, and it usually ceases at funet. When the sirocco travels in does not blow in this manner, the summer is almost free to Dalmatia from weatly winds, whirlwinds, and storms. This is, in p. 277.

SISKIN. See Fringilla.

SISON, BASTARD-STONE PARSLEY, in botany: A genus of plants belonging to the class of pentandria, and to the order of digynia; and in the natural system arranged under the 45th order, umbellata. The fruit is egg-shaped and streaked; the involucra are subtetrasiaphraghal. There are seven species; the amomum, inmandatum, foogum, verticillatum, falbum, canadens, and ammi. The four first are natives of Great Britain. 1. The amomum, common bastard parsley, or field fowenwort, is a biennial plant about three feet high, growing wild in many places of Britain. Its seeds are small, fritated, of an oval figure and brown colour. Their tale is warm and aromatic. Their whole flavour is extracted by spirit of wine, which elevates very little of it in diffillation; and hence the spirituous extract has the flavour in great perfection, while the watery extract has very little. A tincture drawn with pure spirit is of a green colour. The seeds have been esteemed apertent, diuretic, and carminative; but are little regarded in the present practice. 2. The inmandatum, leaf water-parnep. The stem is about eight or ten inches high, branched, and...
and creeping; the leaves, below the water, are capillary; above it are pinnated; the umbels are bifid. It grows in ditches and ponds. 3. *Sprintum*, corn parcy, or honeywort. The stems are numerous, slender, trifoliated, branched, and leaning; the leaves are pinnated; the bracteae are ovate, pointed, and ferrated, fix or eight pair, and one at the end; the umbels small and drooping; the flowers minute and white. It grows in corn-fields and hedges. 4. *Verticillatum* verticillate fion, has small leaves in whorls, and capitillary; the stem is long; with few leaves; the common umbel is composed of eight or ten rays, the partial of 18 or 20; both involucres are composed of five or six acute foliols; the flowers are all hermaphrodite, and the petals white.

SISTRUMID, or CISTRUM, a kind of ancient musical instrument used by the priests of Isis and Osiris. It is described by Spon as of an oval form, in manner of a racket, with three fliers traversing it breadthwise; which playing freely by the agitation of the whole instrument, yielded a kind of sound which to them seemed melodious. Mr Malcolm takes the filum to be no better than a kind of a rattle. Osiris observes, that the filum is found represented on several medals, and on talismans.

SISYMTRIUM, water-cresses, in botany: A genus of plants belonging to the class of *tetradyinia*, and to the order of *siliqua*; and in the natural system ranged under the 399th order, *Siliquina*. The silique, or pod, opens with valves somewhat straight. The calyx and corolla are expanded. There are 29 species, of which eight are natives of Britain; the naturmum, or common water-cress; *Sylvestre, water-corrected; Amphibium, water-radish; terrestrum, annual water-radish; Monenfe: Sphorgia, firhweed; *Irio*, broad-leaved hedge-rocker. 1. The naturntum grows on the brinks of rivulets and water ditches. The leaves have from 6 to 8 pair of smooth succulent and seillie pinnae; the flowers are small and white, and grow in short spikes or tufts. The leaves of water-cresses have a moderately pungent taste, emit a quick penetrating smell, like that of mustard seed, but much weaker. Their pungent matter is taken up both by watery and spirituous menstrua, and accompanies the aqueous juice, which ifbs copiously upon expression. It is very volatile, so as to arise in great part in distillation with redilid spirit, as well as with water, and almost totally to exhale in drying the leaves, or infusing by the gentle heat to the confidence of an extract, either the expressed juice, or the watery or spirituous tinctures. Both the infusdified juice, and the watery extract, diffuse to the tafe a saline impregnation, and in keeping throw up crystralline efflorescences to the surface. On distilling considerable quantities of the herb with water, a small proportion of a fusible volatile very pungent oil is obtained.

Water-cresses obtain a place in the Materia Medica for their antiscorbutio qualities, which have been long very generally acknowledged by physicians. They are also supposed to purify the blood and humourus, and to open viliceal obstructions. They are nearly ailed to scceuery-grass, but are more mild and pleasant, and for this reason are frequently eaten as salad. In the pharma- copoeia, the juice of this plant is directed with that of scceuery-grass and Seville oranges: and Dr Cullen has remarked, that the addition of acids renders the juices of the plants siliquose more certainly effectual, by determining them more powerfully to an acecent fermentation.

2. *Silyleire*, or water-rocket. The stem is weak, branched, and above a foot high. The leaves are pinnated; the bracteae lance-shaped, and ferrated; the flowers small, and yellow; and grow frequently in shallow water.

3. *Amphiium*, or water-radish. The stem is firm, erect, and two or three feet high; the leaves are pinnatifid, and ferrated; the flowers are yellow, and in spikes; the pods are somewhat oval, and short. It grows in water.

4. *Terrestrum*, or land-rocket. The leaves are pinnatifid; the pods are filled with seed; the root is annual, and white; the stem is angular, red-green, and smooth.

5. *Murus*, or wall-rocket. The stems are rough, and about eight inches high; the leaves grow on foot-italks, lance-shaped, smooth, lined, and ferrated: the flowers are yellow; the pods a little compressed, and slightly carinated. It grows on sandy ground in the North, Anglefes, &c.

6. *Monenfe*, or yellow rocket. The stem is smooth, and about 6 or 8 inches high; the leaves are pinnatifid; the bracteae remote, generally 7 pair; the flower is yellow; the petals entire; the calyx is cloved. It grows in the Isle of Man.

7. *Irio*, broad-leaved rocket, or hedge mustard; the stem is smooth, and about two feet high; the leaves are broad, naked, pinnated, and helbard-shaped at the end; the flowers are yellow, and the pods erect. It grows on or near the ground.

8. *Sophia*, flixweed. The stem is firm, branched, and two or three feet high; the leaves are multitudinous; the segments are narrow; the flowers are yellow; the petals much less than the calyx; the pods are long, stiff, curved, without style, and erect; the seeds are minute, and yellow. It grows on walls, wall ground, &c.

SISYPHUS, in fabulous history, one of the de- scendants of Eclus, married Merope, one of the pleiades, who bore him Glauceus. He refided at E- pyra in Peloponnesus, and was a very crafty man. Others say, that he was a Trojan secretary, who was punished for discovering secrets of state; and others again, that he was a notorious robber, killed by The- sus. However, all the poets agree that he was puni- shed in Tartarus for his crimes, by rolling a great stone to the top of a hill, which constantly recouled, and, rolling down incessantly, renewed his labour.

SISYRINCHIUM, in botany: A genus of plants belonging to the class of *gynandra*, and order of *irian- dria*; and in the natural system ranged under the 6th order, *Eniate*. The *fpatha* is diphylous; there are 6 plane petals. The capsule is trilocular and inferior.— There are two species, the bermudiana and palmifo- lium.

SITE, denotes the situation of an house, &c. and sometimes the ground-plot or spot of earth it stands on.

SITTA NUTHACH, in ornithology: A genus belong- ing to the class of *acer*, and order of *picus*. It is thus characterized by Dr Latham. The bill is for the Latham's molt part straight; on the lower mandible there is a Ornitholo- small angle; nostrils small, covered with bristles reflect; ey, vol. ii. ed over them; tongue short, horny at the end, and P. 647, &c. jagged; toes placed three forward and one backward;
the middle toe joined closely at the base to both the outermost; back toe as large as the middle one. There are 11 species: the europæa, canadensis, carolinensis, jamaicensis, pusilla, major, navia, furinamenis, cafra, longirostra, and chloris. The europæa, or nut-hatch, is in length near five inches three-quarters, in breadth nine inches; the bill is strong and straight, about three-quarters of an inch long; the upper mandible black, the lower white; the irides are hazel; the crown of the head, back, and coverts of the wings, of a fine bluish grey; a black stroke passes over the eye from the mouth: the cheeks and chin are white; the breast and belly of a dull orange-colour; the quill-feathers dusky; the wings underneath are marked with two spots, one white at the root of the external quills, the other black at the joint of the baffle-wing; the tail consists of twelve feathers; the two middle are grey, the two exterior feathers tint with grey; then succeeds a transverse white spot beneath that the ruff is black: the breast is of a pale yellow; the back toes very strong, and the claws large. The female is like the male, but less in size, and weighs commonly 5 or at most 6 drams. The eggs are six or seven in number, of a dirty white, dotted with rufous; these are deposited in some hole of a tree, frequently one which has been defecated by a woodpecker, on the rotten wood mixed with a little moss, &c. If the entrance be too large, the bird nicely steps up part of it with clay, leaving only a small hole for itself to pass in and out by. While the hen is sitting, if any one puts a bit of flake into the hole, the hifties like a snake, and is so attached to her eggs, that she will sooner suffer any one to pluck off her feathers than fly away. During the time of incubation, the male supplies her with sufficient, with all the tenderness of an affectionate mate.

The bird runs up and down the bodies of trees, like the woodpecker tribe; and feeds not only on insects, but nuts, of which it lays up a considerable provision in the hollows of trees. It is a pretty sight, says Mr. Willoughby, to see her fetch a nut out of her hoard, place it fast in a chink, and then, standing above it with its head downwards, striking it with all its force, break the shell, and catch up the kernel. It is supposed not to sleep perched on a twig like other birds; for when confined in a cage, it prefers sleeping in a hole or corner. When at rest it keeps the head down. In autumn it begins to make a chattering noise, being silent for the greatest part of the year. Dr. Plott tells us, that this bird, by putting its bill into a crack in the bough of a tree, can make such a violent sound as if it was rending afunder, so that the noise may be heard at least twelve score yards.

SITOPHYLAX, ♂ & ♀, formed from sita"corn," and φυλακέω, "keeper," in antiquity, an Athenian magistrate, who had the superintendence of the corn, and was to take care that nobody bought more than was necessary for the provision of his family. By the Attic laws, particular persons were prohibited from buying more than fifty measures of wheat a man; and that such persons might not purchase more, the sitophylax was appointed to see the laws properly executed. It was a capital crime to prevareicate in it. There where 15 of these sitophylaces, ten for the city, and five for the Persians. SIVA, a name given by the Hindoos to the Supreme Being, when considered as the avenger or destroyer. Sir William Jones has shown that in several respects the character of Jupiter and Siva are the same. As Jupiter overthrew the Titans and giants, so did Siva overthrow the Dityas, or children of Diti, who frequently rebelled against Heaven; and as during the contell the god of Olympus was furnished with lightening and thunderbolts by an eagle, so Brahma, who is sometimes represented riding on the Garuda, or eagle, presented the god of destruction with fiery shafts. Siva also corresponds with the Stygian Jove, or Pluto; for, if we can rely on a Persian translation of the Bhâgavat, the fore-reign of Pâtâla, or the infernal regions, is the king of serpents, named Sûranâgâ, who is exhibited in painting and sculpture, with a diadem and sceptre, in the same manner as Pluto. There is yet another attribute of Siva, or Mahâdeva, by which he is visibly distinguished in the drawings and temples of Bengal. To destroy, according to the Vedantas of India, the Sûtras and Pûrânas, and many philosophers of our European schools, is only to generate and reproduce in another form. Hence the god of destruction is held in this country to predominate during the generation, as a symbol of which he rides on a white bull. Can we doubt that the loves and feats of Jupiter Genitor (not forgetting the white bull of Europa), and his extraordinary title of Lapis, for which no satisfactory reason is commonly given, have a connection with the Indian philosophy and mythology?

SIUM WATER PARSNIP, in botany: A genus of plants belonging to the class of pentandria, and order of digynia, and in the natural system ranging under the 45th order, Umbellatae. The fruit is a little ovoid, and streaked. The involucrum is polyphyllous, and the petals are heart-shaped. There are 12 species: the latifolium, angulatifolium, nodiflorum, fiorum, nini rigidius, japonicum, fœae, græcum, fœculum, repens, and decumbens. The three frills are natives of Britain. 1. The latifolium, or great water-parsnip, which grows spontaneously in many places both of England and Scotland on the sides of lakes, ponds, and rivulets. The stalk is erect and furrowed, a yard high or more. The leaves are pinnated with three or four pair of large elliptic pinnas, with an odd one at the end, all serrated on the edges. The stalk and branches are terminated with erect umbels, which is the chief characteristic of the species. Cattle are said to have run mad by feeding upon this plant. 2. The angulatifolium, or narrow-leaved water-parsnip, has pinnated leaves; the axillary umbels are pedunculated, and the general involucrum is pinnatifid. It grows in ditches and rivulets, but is not common. 3. The nodiflorum, reclining water-parsnip, has pinnated leaves, but the axillary umbels are sessile. It grows on the sides of rivulets.

The fum florum, or orikirret, is a native of China, but has been a long time cultivated in Europe, and particularly in Germany. The root is a bunch of flabby fibres, each of which is about as thick as a finger, but very uneven, covered with a whitish rough bark, and has a hard core or pith running thro' the centre. From the crown of this bunch come several winged leaves, consisting of two or three pair of oblong dentated lobes each, and terminated by an odd one. The stalk rises to about two feet, is set with leaves at the joints, and breaks into branches towards the top, each terminating with an umbel of small white flowers, which are succeeded by ariated feec's.
Six

Six clerks extracted from 1 lb. of skirret root 1/2 ounces of pure sugar.

Six clerks, officers in chancery of great account, next in degree below the twelve masters, whose business is to enrol commissions, pardons, patents, warrants, &c., which pass the great seal, and to transact and file all proceedings by bill, answer, &c. They are occasionally clerks, and forfeited their places, if they married; but when the constitution of the court began to alter, a law was made to permit them to marry. Stat. 14. and 15. Hen. VIII. cap. 8. They are also solicitors for parties in suits depending in the court of chancery. Under them are 6 deputies and 60 clerks, who, with the under clerks, do the business of the office.

Six Nations. See Niagara.

Sixth, in music, one of the simple original concords, or harmonic intervals. See Interval.

Sixtus V. (Pope), was born the 13th December 1521, in La Marca, a village in the signiority of Montalto. His father, Francis Peretti, was a gardener, and his mother a servant maid. He was their eldest child, and was called Felix. At the age of nine he was hired out to an inhabitant of the village to keep sheep; but disobliging his master, he was soon after degraded to be keeper of the hogs. He was engaged in this employment when Father Michael Angelino Selleri, a Franciscan friar, asked the road to Ascoli, where he was going to preach. Young Felix conducted him thither, and struck the father so much with his conversation and eagerness for knowledge, that he recommended him to the fraternity to which he had come. Accordingly he was received among them, invested with the habit of a lay brother, and placed under the superintendence, to assist in sweeping the church, lighting the candles, and other offices of that nature; for which and that he would leave the cloister and habit of a gardener, paid him no greater respect. His progress in learning was so surprising, that at the age of 14 he was thought qualified to begin his novitate, and was admitted the year following to make his profession.

He pursued his studies with such unwearying assiduity, that he was soon reckoned equal to the best disputants. He was ordained priest in 1545, when he assumed the name of Father Montalto; soon after he took his doctor's degree, and was appointed professor of theology at Sienna. It was then that he so effectually recommended himself to Cardinal di Carpi, and his secretary Boffius, that they ever remained his steady friends. Meanwhile the severity and obstinacy of his temper incessantly engaged him in disputes with his monastic brethren. His reputation for eloquence, which was now spread over Italy, about this time gained him some new friends. Among these were the Colonna family, and Father Ghiliieri, by whose recommendation he was appointed inquisitor-general at Venice; but he exercised that office with so much severity, that he was obliged to flee precipitately from that city. Upon this he went to Rome, where he was made procurator-general of his order, and soon after accompanied Cardinal Buon Compagnon into Spain, as a chaplain and consultant to the inquisition. There he was treated with great repect, and liberal offers were made him to induce him to continue in Spain, which, however, he could not be prevailed on to accept.

In the mean time, news were brought to Madrid that Pius IV. was dead, and that Father Ghiliieri, who had been made Cardinal Alexandrino by Paul IV. had succeeded him under the name of Pius V. These tidings filled Montalto with joy, and not without reason, for he was immediately invested by the pontiff with new dignities. He was made general of his order, bishop of St. Agatha, was soon after raised to the dignity of cardinal, and received a pension. About this time he was employed by the Pope to draw up the bill of excommunication against Queen Elizabeth.

He began now to cast his eyes upon the papacy; and, in order to obtain it, formed and executed a plan of hypocrisy with unparalleled conftancy and success. He became humble, patient, and affable. He changed his dress, his air, his words, and his actions, so completely, that his most intimate friends declared him a new man. Never was there such an absolute victory gained over the prejudices; never was a fictitious character so long maintained, nor the foibles of human nature so artfully concealed. He courted the ambassadors of every foreign power, but attached himself to the interests of none; nor did he accept a single favour that would have laid him under any peculiar obligation. He had formerly treated his relations with the greatest tenderness, but he now changed his behaviour altogether. When his brother Anthony came to visit him, he lodged him in an inn, and sent him home next day, charging him to inform his family that he was now dead to his relations and the world.

When Pius V. died in 1572, he entered the conclave with the other cardinals, but seemed altogether indifferent about the election, and never left his apartment except to his devotion. When solicited to join any party, he declined it, declaring that he was of no consequence, and that he would leave the choice of a Pope entirely to persons of greater knowledge and experience. When Cardinal Buon Compagnon, who assumed the name of Gregory XIII. was elected, Montalto assured him that he never wished for anything so much in his life, and that none would always recommend him to their confidants, and the favours he had conferred on him in Spain. But the new Pope treated him with the greatest contempt, and deprived him of his pension. The cardinals also, deceived by his artifices, paid him no greater respect, and used to call him, by way of ridicule, the Roman bull: the aat of La Marca.

He now assumed all the infirmities of old age; his head hung down upon his shoulders; he tottered as he walked, and supported himself on a staff. His voice became feeble, and was often interrupted by a cough so exceedingly severe, that it seemed every moment to threaten his dissolution. He interfered in no public transactins, but spent his whole time in acts of devotion and benevolence. Mean time he constantly employed the ablest spies, who brought him intelligence of every particular.

When Gregory XIII. died in 1585, he entered the conclave with the greatest reluctance, and immediately that himself up in his chamber, and was no more thought of than if he had not existed. When he went...
to mafs, for which purpose alone he left his apartment, he appeared perfectly indifferent about the event of the election. He joined no party, yet flattered all.

He knew early that there would be great divisions in the conclave, and he was aware that when the leaders of the different parties were disappointed in their own views, they all frequently agreed in the election of some old and infirm cardinal, the length of whose life would merely enable them to prepare themselves sufficiently for the next vacancy. These views directed his conduct, nor was he mistaken in his hopes of success.

Three cardinals, the leaders of opposite factions, being unable to procure the election which each of them wished, unanimously agreed to make choice of Montalto. When they came to meet him with their intention, he fell into such a violent fit of coughing that every person thought he would expire on the spot. He told them that his reign would last but a few days; that, besides a continual difficulty of breathing, he wanted strength to support such a weight, and that his small experience rendered him very unfit for so important a charge. He conjured them all three not to abandon him, but to take the whole weight of affairs upon their own shoulders; and declared that he would never accept the mitre upon any other terms: "If you are resolved," he added, "to make me Pope, it will only be placing yourselves on the throne. For my part, I shall be satisfied with the bare title. Let the world call me Pope, and I make you heartily welcome to the power and authority." The cardinals swallowed the bait, and exerted themselves so effectually that Montalto was elected. He now pulled off the mask which he had worn for 14 years. No sooner was his election secured, than he started from his seat, flung down his staff, and appeared almost a foot taller than he had done for several years.

When he was asked, according to custom, if he would accept of the Papacy, he replied, "It is trifling to ask whether I will accept what I have already accepted. However, to satisfy any scruple that may arise, I tell you that I accept it with great pleasure, and would accept another if I could get it; for I find myself able, by the Divine assistance, to manage two papacies." His former complaisance and humility disappeared, together with his infirmities, and he now treated all around him with reverence and haughtiness. The first care of Sixtus V., the name which Montalto assumed, was to correct the abuses, and put a stop to the enormities, which were daily committed in every part of the ecclesiastical state. The lenity of Gregory's government had introduced a general licentiousness of manners, which burst forth with great violence, after that Pontiff's death. It had been usual with former Popes to release delinquents on the day of their coronation, who were therefore accustomed to forreder themselves voluntary prisoners immediately after the election of the Pope. At present, however they were fatally disappointed.

When the governor of Rome and the Keeper of St. Angelo waited on his Holiness, to know his intention in this particular, he replied, "What have you to do with pardons, and releasing of prisoners? Is it not sufficient that our predecessor has suffered the judges to remain unemployed these 13 years? Shall we also stain our pontificate with the name of neglect of justice? We have too long seem, with inexpressible concern, the prodigious degree of wickedness that reigns in the state to think of granting pardons. Let the prisoners be brought to a speedy trial, and punished as they deserve, to show the world that Divine Providence has called us to the chair of St Peter, to reward the good, and chastise the wicked; that we bear not the sword in vain, but are the ministers of God, and a revenger to execute wrath on them that do evil."

He appointed commissioners to inspect the conduct of the judges, displaced those who were inclined to lenity, and put others of severe dispositions in their room. He offered rewards to any person who could convict them of corruption or partiality. He ordered the synods of all the towns and fignatories to take a complete list of the disorderly persons within their districts, and threatened the strapado for the smallest omission. In consequence of this edict, the synodic of Albino was scourged in the market-place, because he had left his nephew, an incorrigible libertine, out of his list.

He made very severe laws against robbers and assassins. Adulterers, when discovered, suffered death; and they who willingly submitted to the prostitution of their wives, a custom then common in Rome, received the same punishment. He was particularly careful of the purity of the female sex, and never forgave those who attempted to debauch them.

His execution of justice was as prompt as his edicts were rigorous. A Swiss happening to give a Spanish gentleman a blow with his halberd, was struck by him so rudely with a pilgrim's staff that he expired on the spot. Sixtus informed the governor of Rome that he was to dine early, and that justice must be executed on the criminal before he sat down to table. The Spanish ambassadour and the native introduced him out as disgracing the gentleman by suffering him to die on a gibbet, but to order him to be beheaded. "He shall be hanged (replied Sixtus), but I will alleviate his disgrace by doing him the honour to assist personally at his death." He ordered a gibbet to be erected before his own windows, where he continued sitting during the whole execution. He then called to his servants to bring in dinner, declaring that the act of justice which he had just seen had increased his appetite. When he rose from table, he exclaimed, "God be praised for the good appetite with which I have dined!"

When Sixtus ascended the throne, the whole ecclesiastical state was infested with bands of robbers, who, from their numbers and outrages, were exceedingly formidable; by his prudent and vigorous conduct, however, he in a short time extirpated the whole of these banditti.

Nor was the vigour of his conduct less conspicuous in his transactions with foreign nations. Before he had been pope two months he quarrelled with Philip II. of Spain, Henry III. of France, and Henry king of Navarre. His intrigues indeed in some measure influenced all the councils of Europe.

After his accession to the pontificate, he sent for his family to Rome, with express orders that they should appear in a decent and modest manner. Accordingly, his sister Camilla came thither, accompanied by her daughter and two grandchildren. Some cardinals, in order to pay court to the pope, went out to meet her, and introduced her in a very magnificent dress. Sixtus pretended not to know her, and asked two or three times...
Sixtus [517]

Sixtus.

times who she was: Upon this one of the cardinals said, "It is your father, holy father." "I have but one father (replied Sixtus with a frown), and she is a poor woman at Le Grotte; if you have introduced her in this disguise, I declare I do not know her; yet I think I would know her again, if I saw her in the clothes she used to wear."

Her conduct at last found it necessary to carry her to an inn, and strip her of her finery. When Camilla was introduced a second time, Sixtus embraced her tenderly, and said, "No, we know indeed that it is our father; nobody shall make a prince of you but ourselves." He flipp'd with his father, that she should neither ask any favour in matters of government, nor intercede for criminals, nor interfere in the administration of justice; declaring that every request of that kind would meet with a certain refusal. These terms being agreed to, and punctually observed, he made the most ample provision not only for Camilla but for his whole relations.

This great man was also an encourager of learning. He caused an Italian translation of the Bible to be published, which raised a good deal of discontent among the Catholics. When some cardinals reproached him for his conduct in this respect, he replied, "It was published for the benefit of you cardinals who cannot read Latin."

Sixtus died in 1590, after having reigned little more than five years. His death was ascribed to poison, laid to have been administered by the Spaniards; but the story seems rather improbable. It was to the indulgence of a disposition naturally formed for severity, that all the defects of this wonderful man are to be ascribed. Clemency was a stranger to his bosom; his punishments were often too cruel, and seemed sometimes to border on revenge. Pasquin was dressed one morning in a very nasty shirt, and being asked by Martorio why he wore such dirty linen? replied, that he could get no other, for the pope had made his waferwoman a princess, alluding to Camilla, who had formerly been a laundress. The pope ordered strict search to be made for the author of this lampoon, and offered him his life and a thousand pistoles if he would discover himself. The author was simple enough to make his appearance and claim the reward. "It is true (said the pope), we made such a prince, and we shall keep it; your life shall be spared, and you shall receive the money presently; but we have referred to ourselves the power of cutting off your hands and boring your tongue through, to prevent your being so witty for the future." It is needless to add, that the sentence was immediately executed. This, however, is the only instance of his resorting the many severe satires that were published against him.

But though the conduct of Sixtus seldom excites love, it generally commands our esteem, and sometimes our admiration. He strenuously defended the cause of the poor, the widow, and the orphan: he never refused audience to the injured, however wretched or forlorn their appearance was. He never forgave those magistrates who were capable of partiality or corruption; nor suffered crimes to pass unpunished, whether committed by the rich or the poor. He was frugal, temperate, sober, and never neglected to regard the smallest favour which had been conferred on him before his elevation.

When he mounted the throne, the treasury was not only exhausted, but in debt: at his death it contained five millions of gold.

Rome was indebted to him for several of her greatest embellishments, particularly the Vatican library: it was by him, too, that trade was first introduced into the Ecclesiastical State.

"EYÂ-GUSH, the caracal of Buffon, an animal of the cat kind. See Feli, p. xviii.

SIZAR, or SIZER, in Latin Sinater, an appellation by which the lowest order of students in the universities of Cambridge and Dublin are distinguished, is derived from the word sizer, which in Cambridge, and probably in Dublin likewise, has a peculiar meaning. To sizer, in the language of the university, is to get any fort of viâluts from the kitchens, which the students may want in their own rooms, or in addition to their commons in the hall, and for which they pay the cooks or butchers at the end of each quarter. A size of any thing is the smallest quantity of that thing which can be thus bought: two sizes, or a part of beef, being nearly equal to what a young person will eat of that dish to his dinner; and a size of ale or beer being equal to half an English pint.

The fizaris are divided into two classes, viz. subfizaris or fizaris, and fizaritos or proper fizaris. The former of these are supplied with commons from the table of the fellows and fellow-commoners; and in former times, when these were more scanty than they are now, they were obliged to supply the deficiency by fishing, as is sometimes the case. The proper fizaris had formerly no commons at all, and were therefore obliged to fish the whole. In St John's college they have now some commons allowed them for dinner, from a benefaction, but they are still obliged to fish their supper; in the other colleges they are allowed a part of the fellow-commons, but must size the rest, and from being thus obliged to fish the whole or part of their victuals, the whole order derived the name of fizaris.

In Oxford, the order similar to that of fizar is denominated servitor, a name evidently derived from the ministerial duties which they perform. In both universities these orders were formerly distinguished by round caps and gowns of different materials from those of the pensioners or commoners, the order immediately above them. But about thirty years ago the round cap was entirely abolished in both universities. There is still, however, in Oxford, we believe, a distinction in the gowns, and there is also a trifling difference in some of the small colleges in Cambridge; but in the large colleges the dress of the pensioners and fizaris is entirely the same.

In Oxford, the servitors are still obliged to wait at table on the fellows; and gentlemen-commoners; but much to the credit of the university of Cambridge, this most degrading and disgraceful custom was entirely abolished about 10 or 12 years ago, and of course the fizaris of Cambridge are now on a much more respectable footing than the servitors of Oxford.

The fizaris are not upon the foundation, and therefore while they continue fizaris are not capable of being elected fellows; but they may at any time, if they choose,
S I Z

[518]

S K A

chooses, become pensioners; and they generally fit for scholarships immediately before they take their first degree. If successful, they are then on the foundation, and are entitled to become candidates for fellowships when they have got that degree. In the mean time, while they continue fixture, besides free commons they enjoy many benefactions, which have been made at different times, under the name of fixture's prater, exhibitions, &c. and the rate of tuition, the rent of rooms, and other things of that sort within their respective colleges, is less than to the other orders. But that their education is thus obtained at a less expense, they are not inconsiderable, for fixtures, pensioner-scholars, and even sometimes fellow-commoners, mix together with the utmost cordiality. It is worthy of remark, that at every period this order has supplied the university with its most distinguished officers; and that many of the most illustrious members of the church, many of the most distinguished men in the other liberal professions, have, when under-graduates, been fixtures, when that order was on a less respectable footing than it is now.

SIZE, the name of an instrument used for finding the bigness of fine round pearls. It consists of thin pieces or leaves, about two inches long, and half an inch broad, fastened together at one end by a rivet. In each of these are round holes drilled of different diameters. Those in the first leaf serve for measuring pearls from half a grain to seven grains; those of the second, for pearls from eight grains or two carats to five carats, &c.; and those of the third, for pearls from fix carats and a half to eight carats and a half.

SIZE, is also a sort of paint, varnish, or glue, used by painters, &c.

The threads and parings of leather, parchment, or vellum, being boiled in water and strained, make size. This substance is much used in many trades. The manner of using size is to melt some of it over a gentle fire; and fcooping as much whiting into it as will just colour it, let them be well incorporated together; after which you may whiten frames, &c. with it. After it dries, melt the size again, and put more whiting, and whiten the frames, &c. seven or eight times, letting it dry between each time: but before it is quite dry, between each washing with size, you must smooth and wet it over with a clean brush-pencil in fair water.

To make gold-size. Take gum-animal and asphaltum, of each one ounce; minium, lighthouse of gold, and amber, of each half an ounce; reduce all into a very fine powder, and add to them four ounces of linseed oil, and eight ounces of drying oil: digest them over a gentle fire that does not flame, so that the mixture may only simmer, but not boil; let it stand till it is almost cold, and then strain it through a coarse linen cloth, and keep it for use. To prepare it for working, put what quantity you please in a horse-muscle shell, adding as much oil of turpentine as will difiove it; and making it as thin as the bottom of your feed-lac varnish, hold it over a candle, and then strain it through a linen-rag into another shell; add to these as much vermilion as will make it of a darkish red: if it is too thick for drawing, you may thin it with some oil of turpentine. The chief use of this size is for laying on metals.

The gold-size for burnishing is made as follows: Take fine bole, what quantity you please; grind it finely on a piece of marble, then scrape into it a little beef-suet; grind all well together; after which mix in a small proportion of parchment-size with a double proportion of water, and it is done.

To make silver-size. Take tobacco-pipe clay in fine powder, into which scrape some black-lead and a little Genoa soap, and grind them all together with parchment-size as already directed.

SKATING, an exercise on ice, both graceful and healthy. Although the ancients were remarkable for their dexterity in most of the athletic sports, yet skating seems to have been unknown to them. It may therefore be considered as a modern invention; and probably it derived its origin in Holland, where it was practised, not only as a graceful and elegant amusement, but as an expedient mode of travelling when the lakes and canals were frozen up during winter. In Holland long journeys are made upon skates with ease and expedition; but in general less attention is there paid to graceful and elegant movement, than to the expedition and celerity of what is called journey skating. It is only in those countries where it is considered as an amusement, that its graceful attitudes and movements can be studied; and there is no exercise whatever better calculated to set off the human figure to advantage. The acquirement of most exercises may be attained at an advanced period of life; but to become an expert skater, it is necessary to begin the practice of the art at a very early age. It is difficult to reduce the art of skating to a system. It is principally by the imitation of a good skater that a young practitioner can form his own practice. The English, though often remarkable for feats of agility upon skates, are very deficient in gracefulness; which is partly owing to the construction of the skates. They are too much curved in the surface which embraces the ice, consequently they involuntarily bring the users of them round on the outside upon a quick and small circle; whereas the skater, by using skates of a different construction, lefs curved, has the command of his stroke, and can enlarge or diminish the circle according to his own will and desire. The metropolis of Scotland has produced as many instances of elegant skaters as perhaps any other country whatever; and the institution of a Skating Club about 40 years ago, has contributed not a little to the improvement of this elegant amusement. We are indebted for this article to a gentleman of that Club, who has made the practice and improvement of skating his particular study; and as the nature of our work will not permit the infliction of a full treatise on skating, we shall present our readers with a few instructions.

Those who wish to be proficient should begin at an early period of life; and should first endeavour to throw off the fear which always attends the commencement of an apparently hazardous amusement. They will soon acquire a facility of moving on the inside; when they have done this, they must endeavour to acquire the movement on the outside of the skates; which is nothing more than throwing themselves upon the outer edge of the skate, and making the balance of their body tend towards that side,
SKIDS, or SKEEKS, in sea-language, are long compalling pieces of timber, notched below so as to fit closely upon the wales, extending from the main-wale to the top of the side, and retained in this position by bolts or spike-nails. They are intended for preferring the planks of the side, when any heavy body is hoisted or lowered.

SKIES, or SKY, the blue expanse of air or atmosphere. For the reason of its blue colour and concave figure see OPTICS.

SKILL-CADE. See SCUTELLARIA.

SKULL, in anatomy, the bony case in which the brain is inclosed. See ANATOMY, p. 11. &c.

SKUNK, or SAUKY, a species of ESIX, which see.

SKIRMSH, in war, a slight engagement between small parties, without any regular order; and is therefore easily distinguished from a battle, which is a general engagement between two armies continued for some time.

SKULL-CAP. See SCUTELLARIA.

SKIN, in anatomy, the general covering of the body of any animal. See ANATOMY, p. 74.

SKIN, in commerce, is particularly used for the membrane stripped off the animal to be prepared by the tanner, skinner, parchment maker, &c. and converted into leather, &c. See TANNING.

SKINNER (Stephen), an English antiquarian, born in 1622. He travelled, and studied in several foreign universities during the civil wars; and in 1654, returned and settled at Lincoln, where he practised physic with success until the year 1667, when he died of a malignant fever. His works were collected in folio in 1671, by Mr Henfaw, under the title of Etymologicum Lingue Anglicana, &c.

SKIPP, or SAWY, a species of ESOX, which see.

SKIRS, or SKEERS, in sea-language, are long compalling pieces of timber, notched below so as to fit closely upon the wales, extending from the main-wale to the top of the side, and retained in this position by bolts or spike-nails. They are intended for preferring the planks of the side, when any heavy body is hoisted or lowered.

SKIES (Isle of). See SKY.

SKIFF, a small boat resembling a yawl, usually employed for palling rice.

SKIMMIA, in botany: A genus of the Monogynia order; belonging to the Tetrandria class of plants; and in the natural method ranking under the 40th order, Perannata. The calyx is quadripartite; the corolla consists of four concave petals; and the berry contains four seeds. There is only one species, viz. the japonica.

SKIMMER, BLACK. See SHEARBILL.

SKULL, in anatomy, the bony case in which the brain is inclosed. See ANATOMY, p. 11. &c.

SKULL-CAP. See SCUTELLARIA.

SKY, the blue expanse of air or atmosphere. For the reason of its blue colour and concave figure see OPTICS.

SKY, one of the greatest of the Western Islands of Scotland, so called from Skineath, which in the Erse dialect signifies unget, because the two promontories of Valerinea and Troternish, by which it is bounded on the north-west and north-east, are supposed to resemble wings. The island lies between the thire of Ross and the western part of Lewis. According to the computation of Mr Pennant, Dr Johnson, and Dr Campbell, it is 60 miles in length, and nearly the same in width where broadest; accordingly to others it is 50 miles in length, and in some places 30 broad. The island of Sky is divided between two proprietors; the southern part belongs to the Laird of Macleod, said to be lineally descended from Leod ton to the black prince of Man; the northern district, or barony of Troternish, is the property of Lord Macdonald, whose ancestor was Do
Sky. [ 520 ]

Sky, pald, king, or lord of the Isles, and chief of the numerous clan of Macdonalds, who are counted the most warlike of all the Highlanders. Sky is part of the shire of Inverness, and formerly belonged to the diocese of the Isles: on the south it is parted from the main land by a channel three leagues in breadth; tho' at the ferry of Glenelly, it is so narrow that a man may be heard calling for the boat from one side to the other. Sky is well provided with a variety of excellent bays and harbours.

The face of the country is roughened with mountains, some of which are so high as to be covered with snow on the top at midsummer; in general, their sides are cloathed with heath and grafs, which afford good pasturage for sheep and black cattle. Between the mountains there are some fertile valleys, and the greater part of the land towards the sea-coast is plain and arable. The island is well watered with a great number of rivers, above 30 of which afford salmon: and some of them produce black mussels in which pearls are brotth. The hills, even in the middle of June, some spots of it are covered with snow on the top, and at the end of winter. Thefe, sometimes break in useful torrents that deluge the plains below, and are bred, particularly, the rivers Kilmartin and Ord.

When Mr Knox visited this island in 1786, the number of inhabitants amounted to 15,000; but some gentlemen who refided there affirmed there were 16,000. It is divided into eight parishes, in each of which there is a school, besides three charity-schools in different places.

The minerals found here are lead and iron ore, which, however, have never been wrought to any advantage. Near the village of Sartle, the natives find black and white marcasites, and variegated pebbles. The Appleglen, in the neighbourhood of Loch-fallart, produces beautiful agates of different sizes and colours: stones of a purple hue are, after great rains, found in the rivulets; cryftal, of different colours and forms, abounds in several parts of the island, as well as black and white marble, free-stone, lime-stone, and tale: small red and white coral is found on the southern and western coasts in great abundance. The fuel consists chiefly of peat and turf, which are impregnated with iron ore and falt-petre; and coal has been discovered in several dit restricted places.

The wild birds of all forts most common in the country are, falon geese, gulls, cormorants, cranes, wild geese, and wild ducks; eagles, crows, ravens, rooks, cuckoos, rails, woodcocks, moor-fowl, partridges, plover, wild pigeons, and blackbirds, owls, hawks, nipes, and a variety of small birds. In mild feasons, the cuckoo and rail appear in the latter end of April; the former disappears always before the end of June; the latter sometimes not till September. The woodcock comes in October, and frequently remains till March. The tame forts of fowl are geese, ducks, turkeys, cocks, pullets, and tame pigeons.

The black cattle are here exposed to all the rigours of the severer winter, without any other provender than the tops of the heath and the alga marina: so that they appear like mere skeletons in the spring; though, as the grafs grows up, they soon become plump and juicy, the beef being very tender, and finely interlarded. The amphibious animals are seals and otters. Among the reptiles they reckon vipers, adders, weasels, frogs, toads, and three different kinds of serpents; the firft spotted black and white, and very poisonous; the second yel-

SKY

[ 521 ]

S I A

low, with brown spots, and the third of a brown colour, the smallest and least poisonous.

Whales and cairns, or fun-fish, come in some times to the sounds after their prey, but are rarely pursued with any success. The fishes commonly caught on the coast are herrings, ling, cod, skate, haddock, mackerel, lythe, sge, and dog fish. The average price of hussels at home is L. 13, 13 s. per ton; when fresh, the price is from 3 d. to 5 d.; if cured, from 3 d. to 7 d. The barrel of herrings seldom sells under 19 s., which is owing to the great difficulty of procuring salt, even sometimes at any price; and the same cause prevents many from taking more than are sufficient for their own use.

The kyle of Scalpe teems with oysters, in such a manner, that after some spring-tides, 20 horse-loads of them are left upon the sands. Near the village of Barn- full, the beach yields muscles sufficient to maintain 50 persons per day: this providential supply helps to support many poor families in times of scarcity.

The people are strong, robust, healthy, and prolific. They generally profess the Protestant religion; are honest, brave, innocent, and hospitable. They speak the language, wear the habiliments, and observe the customs that are common to all the Hebrides. The meconium in new-born infants is purged away with fresh butter: the children are bathed every morning and evening in water, and grow up so strong, that a child of 10 months is able to walk alone: they never wear shoes or stockings before the age of eight or ten, and night-caps are hardly known; they keep their feet always wet; they lie on beds of straw or heath, which last is an excellent restorative: they are quick of apprehension, ingenious, and very much addicted to music and poetry. They eat heartily of fish; but seldom regale themselves with fish-meal: their ordinary food consists of butter, cheese, milk, potatoes, colewort, brocolii, and a dish called comb, which indeed is no other than the froth of boiled milk or whey raised with a flick like that used in making chocolate.

A sort of coarse woollen cloth called cloac, or codden, the manufacture of their wives, made into short jackets and stayers, is the common dress of the men. The philibeg is rarely worn, except in summer and on Sundays; on which days, and some other occasions, those in better circumstances appear in tartans, a bonnet, and short hose, and some in a hat, short coat, waistcoat, and breeches, of Scotch or English manufacture. The women are in general very cleanly, and so excessively fond of drefs, that many maid-servants are often known to lay out their whole wages that way.

There are two fairs held annually at Portree, to which almost every part of Skye tends cattle. The first is held in the end of May, and the second in the end of July. The fair commonly continues from Wednesday till the Saturday following. The commodities which are sold in these are horses, cows, sheep, goats, hides, butter, cheese, fish, and wool. The cattle sold in these fairs swim over to the mainland through a mile or half a mile of sea. Thousands of these are yearly exported, at from L. 2 to L. 3 each. Many of them are driven to England, where they are fattened for the market, and counted delicious eating.

In Skye appear many ruins of Danish forts, watch-towers, beacons, temples, and sepulchral monuments. All the forts are known by the term Dun; such as Dun-Skudborg, Dun-Derig, Dun-Skerineis, Dun-David, &c.

Skei-Colour. To give this colour to glafs, set in the furnace a pot of pure metal of fritt from rochetta or bariola, but the rochetta fritt does not; as soon as the metal is well purified, take for a pot of twenty pounds of metal fix ounces of brafs calcined by itself; put it by degrees at two or three times into the metal, flirling and mixing it well every time, and diligently skimming the metal with a ladle: at the end of two hours the whole will be well mixed, and a proof may be taken; if the colour be found right, let the whole stand 24 hours longer in the furnace, and it will then be fit to work, and will prove of a most beautiful sky colour.

SLAB, an outside fappy plank or board sawed of from the fides of a timber-tree. The word is also used for a flat piece of marble.

SLACK-WATER, in sea-language, a small cord passing behind a ship's main-fail or fore-fail, and being reeved through a block attached to the lower part of the yard, is thence transmitted in two branches to the foot of the fall, to which it is fastened. It is used to trufls up the fall as occasion requires, and more particularly for the convenience of the pilot or steerman, that they may look forward beneath it as the ship advances.

SLACK-WATER, in sea-language, denotes the interval between the flux and reflux of the tide, or between the lait of the ebb and the fritt of the flood, during which the current is interrupted, and the water apparently remains in a state of repose.

SLACKEN, in metallurgy, a term used by the miners to express a spongy and semi-vitrified substance, which they used to mix with the ores of metals, to prevent their fusion. It is the fettoria or fettum separated from the surface of the former fusions of metals. To this they frequently add lime-stone, and sometimes a kind of coarse iron-ore, in the running of the poorer gold ores.

SLATE (Steigania), a stone of a compact texture and laminated structure, splitting into fine plates.

Dr. Hill distinguishes four species of steigania. 1. The whitish steigania, being a soft, friable, flaty stone, of a tolerably fine and close texture, considerably heavy, perfectly dull and delititious of brightness, variegated with a pale brown or brownish yellow. This species is common in many counties of England, lying near the surface of the ground. It is generally very full of perpendicular as well as horizontal cavities, many of which are filled up with a spar a little purer and more crystalline than the rest; and is commonly used for covering houses. 2. The red steigania is a very fine and elegant slate, of a smooth surface, firm and compact texture, considerably heavy, and of a very beautiful pale purple, glittering all over with small glossy spangles: it is composed of a multitude of very thin plates or flakes, laid closely and evenly over one another, and cohering pretty firmly; this is very common in the northern parts of England, and is much valued as a strong and beautiful covering for houses. 3. The common blue steigania is very well known as an useful and valuable stone, of a fine smooth texture and glossy surface, moderately heavy, and of a pale greyish blue; composed of a multi-

Vol. XVII.
tude of even plates, laid close upon one another, and easily splitting at the commissures of them: this is also very common in the north parts of England, and is used in most places for the covering of houses. There are other species of this slate, viz., the brownish blue friable Reganum, usually called Coal slate; the greyish black friable Reganum, commonly called fliver; and the greyish blue sparkling Reganum. 5. The friable, luminous, black Reganum, being the Irish slate of the shops: this is composed of a multitude of thin flakes, laid very evenly and regularly over one another, and splits very regularly at the commissures of them. It is common in many parts of Ireland, and is found in some places in England always lying near the surface in very thick strata. In medicine it is used in hemorrhages of all kinds with success, and is taken often as a good medicine in fevers.

The island of Eufdale, one of the Hebrides on the west coast of Scotland, is entirely composed of slate. The stratum it 36 feet thick. About two millions and half, at the rate of twenty shillings per thousand, are sold annually to England, Canada, the West Indies, and Norway.

SLAVE. See Slavery.

SLAVERY is a word, of which, though generally understood, it is not easy to give a proper definition. An excellent moral writer has defined it to be "an obligation to labour for the benefit of the master, without the contract or consent of the servant." But may not be properly called a slave who has given up his freedom to discharge a debt which he could not otherwise pay, or who has thrown it away at a game of hazard? In many nations, debts have been legally discharged in this manner; and in some savage tribes, such is the universal ardour for gaming, that it is no uncommon thing for a man, after having lost at play all his other property, to play on a single throw of dice, himself, his wife, and his children. That persons who have thus lost their liberty are slaves, will hardly be denied; and surely the gratuitous gamester is a slave by his own contract. The debtor, too, if he was aware of the law, and contracted debts larger than he could reasonably expect to be able to pay, may justly be considered as having come under an obligation to labour for the benefit of a master with his own consent; for every man is answerable for all the known consequences of his voluntary actions.

This definition of slavery seems to be defective as well as inaccurate. A man may be under an obligation to labour through life for the benefit of a master, and yet that master have no right to dispose of him by sale, or in any other way to make him the property of a third person; but the word slave, as used among us, always denotes a person who may be bought and sold like a beast in the market. In its original sense, indeed, it was of the same import with noble, illustrious; but vast numbers of the people among whom it had that signification being, in the decline of the Roman empire, by their countrymen to the Venetians, and by them dispersed over all Europe, the word slave came to denote a person in the lowest state of servitude, who was considered as the absolute property of his master. See Phiol., n. 220.

As nothing can be more evident than that all inequalities of rank are, by the law of nature, an equal right to life, liberty, and the produce of their own labour (see Right, n. 5.), it is not easy to conceive what can have first led one part of them to imagine that they had a right to enslave another. Inequalities of rank are indeed inevitable in civil society; and from them results that servitude which is founded in contract, and is of temporary duration. (See Mor. Philos., n. 141.) He who has much property has many things to attend to, and must be disposed to hire persons to attend and serve him; while those who have little or no property must be equally willing to be hired for that purpose. And if the master be kind, and the servant faithful, they will both be happier in this connection than they could have been out of it. But from a state of servitude, where the slave is at the absolute disposal of his master in all things, and may be transferred without his own consent from one proprietor to another, like an ox or an ass, happiness must be for ever banished. "How then came a traffic so unnatural and unjust as that of slaves to be originally introduced into the world?"

The common answer to this question is, that it took its rise among savages, who, in their frequent wars with each other, either massacred their captives in cold blood, or condemned them to perpetual slavery. In support of this opinion we have heard it observed, that the Latin word servus, which signifies not a hired servant, but a slave, is derived from servare, "to preserve," and that such men were called servi, because they were captives, whose lives were preferred on the condition of their becoming the property of the victor.

That slavery had its origin from war, we think extremely probable (c), nor are we inclined to controvert slavery, this etymology of the word servus; but the traffic in men prevailed almost universally long before the Latin lan.

---

(a) Aleam (quod mirere) fobrii inter fera eexerent, tanta lucrandi perdendive temeritate, ut cum omnia dececerunt, extremo ac novilimo jacta de libertate et corpore contendan. Vicit voluntarium servitutem adit; quamvis junior, quamvis robustior, alligari fac et venire patitur.—Tacitus de Mor. Germ.

The savages of North America are equally addicted to gaming with the ancient Germans, and the negroes on the Slave Coast of Guinea perhaps still more.

(e) The Roman orator's definition of slavery, Parad. V. is as accurate as any that we have seen. "Servitus est obedientia fratri ani et abi et atri et carentis fui? whether the unhappy person fell into that state with or without his own contract or consent.

(c) In the article Society, the reader will find another account of the origin of slavery, which we like-wis probable, though we have not transferred it to this place; as it would, in our opinion, be wrong to give to one writer what we know to belong to another. It may be proper, however, to observe here, that between the two articles there is no contradiction, as barbarous wars were certainly our source of slavery.
Slavery.

language or Roman name was heard of; and there is no good evidences that it began among savages. The word נָאָב in the Old Testament, which in our version is rendered servant, signifies literally a slave, either born in the family or bought with money, in contradistinction to יָבִיָּם, which denotes a hired servant: and as Noah makes use of the word גֵּר in the curse which he denounced upon Ham and Canaan immediately after the deluge, it would appear that slavery had its origin before that event. If so, there can be little doubt but that it began among these violent perfons whom our translators have called giants, though the original word גֵּר denotes a right to the land, or is considered as part of the latter's property, and chaffed with his flocks and herds. Thus, when the fared historian describes the wealth of Abraham, he says, that "he had sheep and oxen, and he had maid-servants, and maid-servants, and she-asses, and camels." And when Abimelech wished to make some preparation to the patriarch for the unintended injury that he had done him, "he took sheep and oxen, and maid-servants, and women-servants, and gave them unto Abraham, and restored to him Sarah his wife." The riches and power of Isaac and Jacob are eminated in the very fame manner. Of the former it is said, that "the man waxed great, and went forward and grew, until he became very great; for he had possession of flocks, and possession of herds, and great store of servants, and daughters of slaves; and the Philistines envied him." The latter, we are told, "increased exceedingly, and had much cattle, and maid-servants, and men-servants, and camels, and assss." that we should be put to death.

That the practice of buying and selling servants thus early began among the patriarchs defended to be treated. They were to be bought only of the heathen, but, for if an Israelite grew poor and sold himself either to discharge a debt, or to procure the means of subsistence, he was not be put to death as a slave, but as a hired servant, and restored to freedom at the year of Jubilee. "Both thy bond-men and thy bondmaids (says Moses) shall be of the heathen that are round about you: of them shall ye buy bond-men and bondmaids. And ye shall take them as an inheritance for your children after you, to inherit them for a possession; they shall be your bond-men for ever." unlimited as the power thus given to the Hebrews over their bond-servants of heathen extraction appears to have been, they were strictly forbidden from acquiring such property by any other means than fair purchase: "he that flealeth a man and selleth him," said their great lawgiver, "shall surely be put to death." Whilft slavery, in a mild form, was permitted among the people of God, a much worse kind of it prevailed among the heathen nations of antiquity. With other Spread over the abominable customs, the traffic in men quickly spread from Chaldea into Egypt, Arabia, and over all the world, and by degrees found its way into every known region under heaven (a).

Of this hateful commerce we shall not attempt to trace the progress thro' every age and country, but shall

---

(a) If credit be due to a late account of China, the people of that vast empire have never made merchandise of men or women. The exception however, is so singular, that we should be glad to see it better authenticated; for it is apparent from works of the most undoubted credit, that over all the other eastern countries with which we are acquainted slavery has prevailed from time immemorial, and that some of the Indian nations make long journeys into Africa for the sole purpose of buying slaves.
At that early period, the Phoenicians, and probably the Greeks themselves, had such an established commerce in slaves, that, not satisfied with reducing to bondage their prisoners of war, they scraped not to kidnap in cold blood persons who had never kindled their resentment, in order to supply their foreign markets. In the 14th book of the Odyssey, Ulysses represents himself as having narrowly escaped a snare of this kind laid for him by a sly Phoenician, who had doomed the hero to Libyan slavery; and as the whole narrative, in which this circumstance is told, is an artful fiction, intended to have the appearance of truth to an Italian peafant, the practice of kidnaping slaves could not then have appeared incredible to any inhabitant of that island.

Such were the manners of the Greeks in the heroic age; nor were they much improved in this respect at periods of greater refinement. Philip of Macedon having conquered the Thesians, not only sold his captives, but even took money for premitting the dead to be buried *; and Alexander, who had more generosity than Philip, afterwards razed the city of Thbes, and sold the inhabitants, men, women, and children, for slaves. This cruel treatment of a brave people may indeed be supposed to have proceeded, in the first instance, from the avarice of the conqueror; and in the second, from the momentary resentment of a man who was savage and generous by turns, and who had no command of his passions. We shall not positively assign it to other causes; but from the manner in which the Spartans behaved to their slaves, there is little reason to imagine that had they received from the Thesians the fame provocation with Alexander, they would have treated their captives with greater lenity. "As Sparta (says a humane and elegant writer) slaves were treated with a degree of rigour that is hardly conceivable; although to them, as their husbands and artificers, their spoil and idle matters were indebted for all the necessaries of life. The Macedonian youth, trained up in the practice of deceiving and butchering those poor men, were from time to time let loose upon them in order to show their proficiency in fratageme and massacre. And once, without any provocation, and merely for their own amusement, we are told that they murdered three thousand in one night, not only with the connivance of law, but by its avowed permission. Such, in promoting the happiness of one part of society and the virtue of another, are the effects of slavery."

It has been said, that in Athens and Rome slaves were better treated than in Sparta: but in the former city their treatment cannot have been good, nor their lives comfortable, where the Athenians relished that tragedy of Euripides in which Hecuba, the wife of Priam, is introduced as lamenting that he was chained like a dog at Agamemnon's gate! Of the estimation in which slaves were held in Rome, we may form a tolerable notion from the well known fact, that one of those unhappy beings was often chained at the gate of a great man's house, to give admittance to the guests invited to a feast. In the early periods of the commonwealth, wealth it was customary, in certain fared shews exhibitations, to bid on solemn occasions, to drag through the circus a slave, who had been furoaged to death holding in his hand a fork in the form of a gibbet. But we need not multiply proofs of the cruelty of the Romans to their slaves. If the human combat of the gladiators admet of any apology on account of the martial spirit with which they were thought to inspire the spectators, the conduct of Vedius Pollio must have proceeded from the mofl wanton and brutal cruelty. This man, who flourished not in the earliest periods of the republic, when the Romans were little better than a savage banditti, but in the polished age of Augustus, frequently threw such slaves as gave him the slightest offence into his fishponds to fatten his lampreys; and yet he was suffered to die in peace! The emperor, indeed, upon coming to the knowledge of his cruelty, ordered his lampreys to be destroyed, and his ponds to be filled up; but we do not recollect that any other punishment was inflicted on the savage master. Till the reign of the same emperor the depoitions of slaves were never admitted in the courts of judicature; and then they were received only when persons were accused of treasonable practices.

The origin of slavery in Rome was the same as in every other country. Prisoners of war were of course reduced to that state, as if they had been criminals. The slavery of the Hetrurians, one of the most accomplished generals of the republic, sold his Hetrurian captives to pay the Roman ladies for the jewels which they had presented to Apollo. Fabius, whose cautious conduct saved his country when Hannibal was victorious in Italy, having subdued Tarentum, reduced 30,000 of the citizens to slavery, and sold them to the highest bidder. Coriolanus, when driven from Rome, and fighting for the Volscii, scurped not to make slaves of his own countrymen; and Julius Caesar, among whose faults was cruelty.

(e) In those early times drawing water was the office of the meanest slaves. This appears from Joshua's curse upon the Gibeonites who had deceived him—" Now therefore ye are cursed, and there shall none of you be freed from being bondmen and hewers of wood, and drawers of water, for the house of my God." To this state of bondage Homer makes Hector say, that Andromache would necessarily be brought upon the destruction of Troy.
SLA

(cruelty has never been reckoned, sold at one time fifty-
three thousand captives for slaves. Nor did the slaves
in Rome conduit only of foreigners taken in war. By
one of the laws of the twelve tables, creditors were
empowered to seize their insolvent debtors, and keep them
in their houses till, by their services or labour, they had
discharged the sum they owed; and in the beginning of
the commonwealth they were authorized to sell such
debtors, and even to put them to death. The children
of slaves were the property not of the common-
wealth, or of their own parents, but of their masters;
and thus was slavery perpetuated in the families of
such unhappy men as fell into that state, whether
through the chance of war or the cruelty of a fordid cre-
ditor (a). The consequence was, that the number of
slaves belonging to the rich Patricians was almost incre-
dible. Caius Cæcilius Isidorus, who died about seven
years before the Christian era, left to his heirs 4116
slaves; and if any one of those wretched creatures made
an unsuccessful attempt to regain his liberty, or was
even suspected of such a design, he was marked on the
forehead with a red hot iron (b). In Sicily, during the
most florishing periods of the commonwealth, it seems
to have been customary for masters to mark their
slaves in this manner: at least we know that such was
the practice of Damophilus, who, not satisfied with this
security, put up his slaves every night in close prisons,
and led them out like beasts in the morning to their
daily labour in the field. Hence arose the servile war
in Sicily.

Though many laws were enacted by Augustus and
other patriotic emperors to diminish the power of cre-
ditors over their insolvent debtors; though the influence
of the mild spirit of Christianity tended much to mel-
orate the condition of slaves, even under Pagan masters,
and though the emperor Adrian made it capital to kill
a slave without a just reason; yet this infamous com-
merce prevailed universally in the empire for many ages
after the conversion of Constantine to the religion of
Christ. It was not indeed completely abolished even in
the reign of Justinian; and in many countries which had
once been provinces of the empire it continued long
after the empire itself had fallen to pieces.

It has already been observed, that among the ancient
Germans it was not uncommon for an ardent collector
to lose his personal liberty by a throw of the dice. This
was indeed a strong proof of savage manners; but the
general condition of slaves among those savages seems
to have been much better than among the polished Greeks
and Romans. In Germany the slaves were generally
attached to the soil, and only employed in tending cat-
tle, and carrying on the business of agriculture; for
the menial offices of every great man’s house were per-
formed by his wife and children. Such slaves were fel-
dom beaten, or chained, or imprisoned. Sometimes in-
deed they were killed by their masters in a fit of fo-
den passion; but none were considered as materials of
commerce, except those who had originally been freed-
men, and lost their freedom by play. These, indeed,
the successful gambler was very ready to sell, both be-
cause he felt them an useless burden, and because their
preference continually put him in mind of that state to
which a throw of the dice might one day reduce him-
sel.

Such is the account which Tacitus gives of slavery
among the ancient Germans. The Anglo-Saxons, how-
ever, after they were settled in Britain seem not to
have carried on that traffic so honourably. By a statute
of Alfred the Great, the purchase of a man, a here
or an os, without a voucher to warrant the sale, was
strictly forbidden. That law was, doubtless, enacted
to prevent the selling of men and cattle; but it shows

(p) After a certain number of citations, the law granted to the debtor thirty days of grace to raise the sum
for which he was accountable. The words of the law are: "Exire confellis, rebisque iure judicatis, triginta dieis
jutii fontis. Post dein manum endojacito. Vincito aut nervo, aut compeditibus." "When the debt is confessed,
and the trial past, let there be thirty days of forbearance: afterwards lay hands on him; bind him either with
a cord or fetters." After the thirty days were expired, if the debtor had not discharged the debt, he was led
to the praetor, who delivered him over to the mercy of his creditors; these bound him and kept him in chains
for the space of sixty days. Afterwards, for three market-days successively, the debtor was brought to the tri-
bunal of the praetor; then a public crier proclaimed in the forum the debt for which the prisoner was detained.
It often happened, that rich persons redeemed the prisoner by paying his debts; but if nobody appeared in be-
half of the debtor after the third market-day, the creditor had a right to inflict the punishments appointed by the
law. "Tertius nudinis capite poenas dato aut trans Tiberim peregere venum ducto," that is, "Let him on the
third market-day be punished with death, or fold beyond the Tiber as a slave." If there were several creditors,
they were allowed, in consequence of this severe law, to divide the body of the prisoner into several parts, and
share it among them in proportion to the sum which they demanded.

(c) This is evident from the story of Appius and Virgilia. See Rome, no. 113.

(h) How capriciously and unjustly this infamous mark was imposed, we learn from the story of Reffio. This
man being proscribed, and a reward offered for his head by the triumvirs Octavius, Antony, and Lepidus,
concealed himself from the fury of the tyrants in the bell way that he could. A slave whom he had marked with
the hot iron having found out the place of his retreat, conducted him to a cave, and there supported him for
some time with what he earned by his daily labour. At length a company of soldiers coming that way, and
approaching the cave, the faithful slave, alarmed at the danger his master was in, followed them close, and falling
upon a poor peasant, killed him in his presence, and cut off his head, crying out, "I am now revenged on my master
for the marks with which he has branded me." The soldiers, seeing the infamous marks on his forehead,
and not doubting but he had killed Reffio, snatched the head out of his hand, and returned with it in all
haste to the triumvirs. They were no sooner gone, than the slave conveyed his master to the sea-side, where
they had the good luck to find one of Sextius Pompeius's vessels, which transported them safe into Sicily.
Slavery among the Carthaginians, was that so late as the ninth or tenth century a man, when fairly purchased, was, in England, as much the property of the buyer as the horse on which he rode, or the ox which dragged his plough. In the same country, now so nobly tenacious of freedom and the rights of man, a species of slavery similar to that which prevailed among the ancient Germans (fubmitted even to the end of the sixteenth century. This appears from a commiilion issued by Queen Elizabeth in 1574, for inquiring into the lands and goods of all her bond-men and bond-women in the counties of Cornwall, Devon, Somerset, and Gloucester, in order to compound with them for their manumission, that they might enjoy their lands and goods as freemen. In Scotland they continued an order of slaves or bond-men, who tilled the ground, were attached to the soil, and with it were transferable from one proprietor to another, at a period so late as the thirteenth century; but when or how those villains, as they were called, obtained their freedom, seems to be unknown to every lawyer and antiquary of the present day. Coalliers and salters were, in the same country, slaves till little more than 20 years ago, that they were manumitted by an act of the British legislation, and restored to the rights of freemen and citizens. Before that period the sons of coalliers could follow no business in the town Capua, although they were not allowed to employ slaves in the town Capua, although they might enjoy liberty to seek employment in some of the provinces, exempted from this opprobrium of slavery. The Tyrian traffic in the cities of Lybia and the Carthaginians, was at any period the most extensive and unexampled, found in the camp of Hannibal and Bolimicar, were twenty thousand pair of fletters and manacles, which those generals had provided for such of the Sicilian prisoners as they intended to preserve alive and reduce to a state of slavery.

With the ancient state of the other African nations we are but very little acquainted. The Numidians, And Mauritanians, Getulians, and Garamantes, are indeed mentioned by the Roman historians, who give us ample evidence of the fables which they fought in attempting to preserve their national independence, but we have no particular account of their different manners and customs in that age when Rome was disarming with Carthage the sovereignty of the world. All the African nations of which we know anything, were in alliance with one or other of those rival republics; and as the people of those states appear to have been less enlightened than either the Romans or the Carthaginians, we cannot suppose that they had purer morals, or a greater regard for the sacred rights of man, than the powerful nations by whom they were either protected or oppressed. They would, indeed, infensibly adopt their customs; and the ready market which Marius found for the prisoners taken in the town Capua, although Sallust acknowledges that the fate was contrary to the laws of war, shows that slavery was then no strange thing to the Numidians. It seems indeed to have prevailed through all Africa from the very first peopling of that unexplored country; and we doubt if in any age of the world the unhappy negro was absolutely free of his personal freedom, or even of not being sold to a foreign trader.

It is the common opinion that the practice of making slaves of the negroes is of a very modern date; that it owes its origin to the inroads of the Portuguese on the western coast of Africa; and that but for the cunning or cruelty of Europeans, it would not now exist and would never have existed. But all this is a compilation of mistakes. A learned writer has lately proved, with a force of evidence which admits of no reply, that from the Coast of Guinea a great trade in slaves was carried on.
Slavery was carried on by the Arabs for hundreds of years before the Portuguese embarked in that traffic; or had even seen a woolly-headed negro. Even the wandering Arabs of the desert, who never had any friendly correspondence with the Christians of Europe, have from time immemorial been served by negro slaves. "The Arab must be poor indeed (says M. Sagnier) not to have at least one negro slave. His sole occupation is the care of the herd. They are never employed in war, but they have it in their power to marry. Their wives, who are captive negroes, do all the domestic work, and are roughly treated by the Arabian women, and by the Arabs themselves. Their children are slaves like them, and put to all kinds of drudgery." Surely no man whose judgement is not completely warped by prejudice, will pretend that those roving tribes of savages, so remarkable for their independent spirit and attachment to ancient customs, learned to enslave the negroes from the Europeans. In all probability they have, without interruption, continued the practice of slavery from the days of their great ancestor Ishmael; and it seems evident, that "among the European nations had even seen a woolly-headed negro till the year 1100, when the crusaders fell in with a small party of them near the town of Hebron in Judaea, and were so struck with the novelty of their appearance, that the army burst into a general fit of laughter." Long before the crusades, however, we know with certainty that the natives of Guinea had been exported to sell in foreign countries. In 651 the Mahometan Arabs of Egypt harboured the king of Nubia or Ethiopia, who was a Christian, that he agreed to fend them annually, by way of tribute, a vast number of Nubian or Ethiopian slaves into Egypt. Such a tribute as this at that time, we are told, was more agreeable to the khalif than any other, as the Arabs then made no small account of these slaves. The very proposal of such a tribute, and the elevation in which black slaves were held in Egypt, shows that a commerce in bond-servants could not then be a new branch of trade either to the Arabs or the Ethiopians; but the vast number which the Ethiopian monarch was now compelled to furnish every year, induced him to feed this great drain upon his subjects from the natives of the neighbouring countries. "He ranged accordingly into all that vast blank of geography, upon the map of the world, the spreading bottom of the African continent; and even pushed through it to its farthest extremities in the west. He thus brought the blacks of Guinea, for the first time, into the service and families of the east; and the slaves which he paid in tribute to the Arabs, whether derived from the nearer neighbourhood of Ethiopia, fetched from the Mediterranean regions of Africa, or brought from the distant shores of the Atlantic, were all denominated Ethiopians, from the country by which they were conveyed into Egypt. "At this time, therefore, according to Mr. Whitaker, began that kind of traffic in human flesh, which spoils unhappy Guinea of its sons." 

There are not many authors from whom, in questions of antiquity, we differ with greater hesitation; but, as we meet with a female Ethiopian slave in the Ennuch of Terence, we cannot help suspecting that Guinea was occasionally "spoiled of its sons" at a much earlier period. At any rate, from the observations made by the European travellers who first penetrated into that continent, it appears undeniable that slavery must have prevailed from time immemorial among such of the tribes as had never carried on any commerce with foreign nations. When Battel first visited the Giass*, those people had never before seen a white man; yet they welcomed him and the English, with whom he had come, to their country, invited them to bring their goods on shore, and without hesitation loaded the ship with slaves. The Giass were indeed waging war with the kingdom of Benguela; and being cannibals, who prefer human flesh to all others, the slaves whom they had sold to the English were probably prisoners whom they would have killed and eaten if they had not found an opportunity of otherwise dis-posing of them to greater advantage. But as they had not been invited by the Europeans to eat their prisoners, there can be no reason to suppose that by the Europeans they might have first induced to sell them: for we have seen that this kind of commerce prevailed in Africa among people much more polished than the Giass so early as in the reign of Jugurtha.

That it was not introduced among the negroes either by the Arabs or by the Portuguese, appears still more evident from the behaviour of the Dahomans at the conquest of Whidah, and from the manner in which the people of Angola at the earliest stage of their foreign trade procured a supply of slaves for the Portuguese market. The greater part of the slaves whom the Angolans exported from St. Paul de Louanda were brought from interior countries, some hundreds of leagues distant, where they could not have been regularly purchased had that commerce been till then unknown in those countries. The Dahomans, in the beginning of the year 1727, had never seen a white man: and when their victorious prince and his army, in their rout through Whidah, first met with some Europeans in the town of Sabi, they were so shocked at their complexion and their dress, that they were afraid to approach them, and could not be persuaded that they were men till they heard them speak, and were assured by the Whidaneese that these were the merchants who purchased all the slaves that were sold in Guinea. Slavery, therefore, if it prevailed among the Dahomans before that period, could not have been introduced among them by European or African intrigues: but we are assured by Suelgrave, who was then in the army, that those people treated their captives with such horrid cruelty as was shocking to the natives of the sea-coast, and leaves no room for doubt but that slavery had been practised among them from the earliest ages. A great part of their prisoners were sacrificed to their gods or eaten by the soldiers; and when our author expressed to a colonel of the guard some surprise that a prince so enlightened as the sovereign of Dahomy should sacrifice so many men whom he might have sold to great advantage, he was gravely told, that it had been the custom of the nation, from time immemorial, to offer, after victory, a certain number of prisoners to the gods; and that they elected the old men for victims, because they were of less value at market, and more dangerous from their experience and cunning, than the young men. To those persons who fancy that the wars between the African princes are carried on for the sole purpose of supplying the European ships with slaves, it may be proper to remark, that one of the kings of Dahomy slaughtered at once not only all the captives taken
The facts and numberless others which the reader will find detailed in the 13th volume of the Modern Universal History, by writers who were at the greatest pains to procure authentic information; who were neither biased by interest nor blinded by enthusiasm; and who appear to have held the infamous traffic in utter abhorrence—prove beyond the possibility of doubt, that slavery of the worst kind must have prevailed among all the negro nations before they were visited either by the Portuguese or by the Arabs. These two nations may indeed have been the first who dragged the unhappy negro from his native continent, and made his slavery doubly severe, by compelling him to labour, without his own consent, for masters whom he hardly considered as human beings.

On the beginning of this commerce, or the dreadful cruelty with which it has been carried on to the present day, it is impossible to reflect without horror; but there is some consolation, however small, in knowing that its original authors were not Europeans. The purchase of Guinea blacks for slaves by foreign nations commenced ages before the Portuguese had laid that country open to the intercourse of Europe. Even after they had made many incursions into it, the inhabitants were as regularly purchased for slaves by foreigners as they are now by the maritime Europeans.

"The Arabs of Egypt having reduced all the north of Africa, and carrying with them their love of black servants, would be sure to open a ready communication for themselves to their country. They certainly had one so early as 1512, and before the Europeans had any for that purpose. They went from Barbary by a route that was so much practised, as to be denominated expressly the way of the camels. Meeting together at the town of Cape Canton, that of Valadie near it, the commercial caravan traversed the vaft deserts, of Sarra, which run like the tropic of Cancer over them in a long line across the country; to a place of great population called Had, the Woden or Hoden of our maps, and a little to the south-west of Cape Blanco. From Hoden they turned to the left, and pushed directly into the interior of the continent, to reach Tagaza, the Tagasse or Tagaza of our maps, and lying nearly east of Hoden. Here assuredly they did, as the caravan does certainly at this day; and added to the other wares upon their camels a quantity of salt from those mines of rock-salt, which are extraordinary enough to be noticed as rocks in our maps. This they carried, as they still carry it, to Tombut, the Tombut of the maps, and a town in the heart of the African continent. And from this town they turned on the right for the sea coast again, and reached it in the great kingdom of Mele, the Meli of our maps, to the south of the Gambia, and just at the springing as it were of that grand arch of sea which curves so deeply into the body of the land, and constitutes the extensive gulf of Guinea. At Meli and at Tombut they received a measure of gold for a measure of salt. The caravan collects gold at Tombut to the present time; but at Meli they purchased gold, and also silver, in pieces as large as pebbles. At and Hoden they had a great mart for slaves; the blacks being brought thither from the countries adjoining, and bartered away to the traders. Such was the Slave Coast and the Gold Coast of former days. The staple commodity of Hoden is only transferred now to Whidah; and diverted from the Arabs of Barbary to the Christians of Europe;" by whom the negroes are carried to the continent of America or to the Sugar Islands in the West Indies. In these countries they are all sold as chattels in the market; but they experience very different degrees of servitude from the different masters who hold them as property. Such of them as are reconciled to the appearance of white men, or have been born in the European colonies, feel themselves as happy under a humane master as they could be in their native continent; and we believe that few of them in such circumstances have expressed a desire to return."

In the French West India islands, before the late revolution

(1) The same thing appears from the voyages of M. Sagnier, who had an opportunity of conversing with many tribes of negroes, and who always speaks of slavery as an established practice among them; adding, that such as are sold for crimes are put to death by their own countrymen if they fly from their master. It appears likewise in a still more striking light from Dalzel's History of Dahomy, where we are told that all the Dahomans, from the lowest to the highest, acknowledge the right of the sovereign to dispose of their persons and properties at pleasure; and where we learn, that the sovereign himself assisted Mr Abdon the English governor at Whidah, that all his ancestors had from time immemorial put to death every prisoner of war whom they could not sell as a slave.

(2) In the year 1442, Anthony Gonfalez, a Portuguese adventurer, restored to their native country some Moorish prisoners whom he had two years before forcibly carried off from the coast of Africa. He landed them at Rio del Oro, and received from the Moors in exchange ten blacks and a quantity of gold dust. This transaction proves, that a commerce in black servants was then regularly carried on by the Moors and not by the Portuguese. So early as the year 1502, the Spaniards began to employ a few negroes in the mines of Hispaniola; but in the year following, Orrando, the governor of that island, forbade the further importation of them, alleging that they taught the Indians all manner of wickedness, and rendered them less tractable than formerly; and it was not till the year 1517 that the supply of negroes to the Spanish American plantations became an established and regular branch of commerce. Edward's History of the West Indies, Book IV. Chap. ii.

(3) "I have observed many of my slaves go on board the vessel with joy, on my assurance that they would be well treated and happy on the plantation where I was going to send them. When the Banbarans find that they are trusted by the whites, they never think of making their escape, choosing to be the slaves of Europeans rather than..."
voluntary in the mother country, which has produced in all its dependencies anxiety and mischief, the condition of the negro slaves was better than that of the bondmen among the ancient Germans. "Those of them who cultivated the plantations were attached to the soil, and could not be drawn off to pay debts, or be sold separately from the estate on which they lived. This gave them a lasting property in their huts and little spots of ground, which they might easily cultivate without dread of being turned out of possession, or transferred contrary to their interest and feelings from one proprietor to another. They were under the protection of law as soon as they arrived in the colony. Property millionaires were appointed for the purpose of training them up to a certain degree of religious knowledge, and ample funds were allotted for the maintenance of those celestial bodies. Ill treatment received from his master, or being deprived of his allowance of food and raiment, the slave was directed to apply to the king's attorney, who was obliged to prosecute the master forthwith. That officer was also to prosecute, if by any other means he heard of the abuse; the law adding as the reason, This was to be observed, to check the abuse of power in the magistrate.

We will not in our power to say, that in the British West India colonies slaves are equally protected by law as they were in the West Indies under the old government, and that the same care is taken of their moral and religious improvement. This, however, we are afraid, cannot be said with truth. In the island of Jamaica, before the passing of the consolidated slave act, not many years ago, a white man, whether proprietor or not, who had killed a negro, or by an act of severity been the cause of his death, was, for the first time, entitled to benefit of clergy, and not liable to capital punishment till a repetition of the crime. By the present law, it is enacted, "That if any person, whether owner or superintendent of slaves, shall be convicted of having, by any act of palliation or cruelty, occasioned the death of any negro, it shall be capital for the feu offeree; and for the security of the property, and as a check on those who may have: the punishment of slaves in their power, it is particularly required, that every surgeon or doctor belonging to each estate shall swear to the cause of the death of each negro, to the benefit of his knowledge and belief; and if any negro dies, and is interred by the owner or overseer, without the doctor's having seen or been sent for to fetch negro, in this case, the owner or overseer causing the negro to be so interred is liable to a prosecution for such conduct."

This law must doubtless be productive of good effects; but being a colonial act, it cannot have the vigour of the Code Noir; nor do we know of any attorney in the island who is obliged to defend the rights of the negroes, or prosecute the master whose cruelty has by any means come to his knowledge. The justices and vestry of each parish are indeed constituted a council of precaution, for the express purpose of making full enquiry into the barbarities exercised on slaves, and bringing the authors to punishment at the public expense; and by a new act of Grenada, the justices are required annually to nominate three freeholders to be guardians of the slaves, who are to take an oath to see the law duly executed. These are benevolent regulations; but we doubt if ours are as efficient. History of the West Indies, 2d ed., chap. 5.

In some of the other British islands, we have been confidentially told that the unfortunate sons of Africa have no protection whatever against the tyranny of a feudal owner, or the caprice of a boyish overseer: though it is added, that the humanity of many masters more than supplies the want of laws in every respect; but that of improvement, and that the attachment of others has in them a like effect. In some cases good fence, a regard for their reputation, and a well-informed conviction of their interest, induce men to treat their slaves with discretion and humanity. The slaves of many a planter possess advantages beyond what the labourer even of Britain enjoys; yet these advantages - Ramoyn's 2d ed., p. 60, and in no part of the British colonies are the slaves attached to the soil. This single circumstance, together with the total neglect of their moral and religious culture, makes their situation much less eligible than was that of the French slaves under the old government; and affords a striking proof of what the humane author whom we have just quoted well observes, that "these men and nations whom liberty has exalted, and who therefore ought to regard it tenderly in others, are constantly for restraining its blessings within their own little circle, and delight more in augmenting the train of their dependants than in adding to the rank of fellow-citizens, or in diffusing the benefits of freedom among their neighbours."

Having given this ample detail of the rite and proof of slavery in the world, and shown that it has prevailed in every age, and under all religions, we shall now slavery inquired into in order to proceed to enquire whether a practice so general be in any instance lawful; and if it be, how it must be modified, in order to be rendered consistent with the rights of man and the immutable laws of nature.

That in a state of nature one man has a right to seize upon another, and to compel him by force to labour for his subsistence, is a point which we believe has never been seriously maintained. But independent communities find to each other in the very same relation that individuals do in a state of nature; and therefore it in such a state the man of greater bodily strength or mental sagacity would have no right to convert his weaker neighbour into personal property, neither can the black man who would treat them with the greatest cruelty. Voyages to the Coasts of Africa by M. Ch. Salleri and Brissot, p. 332. 335. English Travels in the Ion.
the more powerful and enlightened nation have a right to carry off by force, or entice by fraud, the subjects of a weaker and more barbarous community for the purpose of reducing them to a state of servitude. This is a truth so obvious as to admit neither of proof nor of denial.

In thus judging the case between two independent nations, we have in our eye that traffic in slaves which is carried on between the civilized Europeans and the barbarous Africans; and the utmost length which we think an apologizing for that trade can go is to contend, that we may lawfully purchase slaves in those countries where from time immemorial they have been a common branch of commerce. But the European right to purchase cannot be better than the African right to sell; and we have never yet been informed what gives one African a right to sell another. Such a right cannot be natural, for the reason which we have elsewhere assigned (see Right): neither can it be adventitious; for adventitious rights are immediately derived from the municipal law, which is the public will of the state. But the state has no authority to deprive an innocent man of his personal freedom, or of the produce of his own labour; for it is only to secure these, by protecting the weak from the violence of the strong, that states are formed, and individuals united under civil government.

It may perhaps be said, that by patiently submitting to governments which authorize the traffic in human flesh, men virtually give up their personal liberty, and yield their governors with a right to sell them as slaves: but no man can yield another with a right which he possesses not himself; and we shall not hesitate to affirm, that in a state of nature, where all have equal rights, no individual can submit himself to the absolute disposal of another without being guilty of the greatest crime. The reason is obvious. From the relation in which men stand to one another as fellow-creatures, and to God as their common Creator, there are duties, incumbent upon each peculiar to himself; in the performance of which he can be guided only by his own reason, which was given him for that very purpose. But he who renounces his personal freedom, and submits unconditionally to the caprice of a master, impiety attempts to fet himself free from the obligation of that law which is interwoven with his very being, and chooses a director of his conduct different from that which God has assigned him. A man therefore cannot put himself in a state of unconditional servitude; and what he cannot do for himself, he fully cannot authorize others to do for him either by a tacit or by an open consent.

These considerations have often made us regret that writers, for whose talents and integrity we have the highest respect, should, without accurately defining what they mean by slavery, have peremptorily affirmed, that, consistently with the laws of nature men may be reduced to servitude as a punishment for crimes, or to discharge debts which they cannot otherwise pay. That such a criminal, who has forfeited his life to the laws of his country, may have his punishment commuted for hard labour, till death in the course of nature shall put a period to his terrestrial existence, is a truth which we apprehend cannot be controverted; but to make such a commutation of punishments consistent with the laws of nature and of nature's God, it appears to us that the kind and degree of labour must be precisely ascertained, and the conduct of the criminal not left to the capricious direction of any individual.

Punishments can be justly inflicted only for one or other of two ends, or for both. They may be calculated either to reform the criminal or to be a warning to the innocent; and those which most effectually answer both these purposes are surely to be preferred to such as answer but one of them. For this reason we consider hard labour as a much fitter punishment for most crimes than death: but to intitle it to preference, the kind and degree of the labour must be ascertained by the law; for if these circumstances be omitted, and the offender delivered over as a slave to the absolute disposal and caprice of a private master, the labour to which he is condemned, instead of operating to his reformation, may be converted into the means of tempting him to the commission of new crimes. A young woman, in the state of servitude, would hardly be able to maintain her virtue against the solicitations of a master who should promise her liberty or a remission of toil upon her yielding to his desires; and the felon, who had long been accustomed to a life of vagrancy and idleness, would not strenuously object to the perpetration of any wickederd to obtain his freedom, or even a diminution of his daily task. Indeed such temptations might be thrown in his way, as human nature could not resist but by means of much better principles than seizers can be supposed to possess. He might be scourged into compliance; or his labour might be increased as to make him for a little reprieve eagerly embrace the most nefarious proposal which his master could make: for being absolute property, there is no earthly tribunal to which he could appeal for justice; and felons do not commonly support themselves under trials by pious meditation on a future state.

By reasoning in this way, we are far from meaning to intimize that slave-holders in general torture their slaves into the commission of crimes. God forbid! Many of them we know to be religious, humane, and benevolent: but they are not infallible; and some of them may be inigated, some of them undoubtedly have been intigated, by avarice and other worse principles, to compel creatures, who are so absolutely their dependents, to execute deeds of darkness too hazardous for themselves. But the morality or immorality of any action, and the moral fitness of any fate, are to be judged of by their natural tendency, if the one were universally practiced and the other universally prevalent (see Moral Philosophy, II. 156.) and as the natural tendency of absolute domestic slavery among such creatures as men is to throw the most powerful temptations to vice in the way both of master and slave, it must be in every instance, even when employed as a punishment, inconvenient with the fundamental principles of moral virtue.

Some writers indeed have maintained, and the civil law seems to suppose, that children are the property of their parents, and may by them be sold as slaves in cases of urgent necessity; but if we duly consider how property is acquired (see Property), and attend to the natural consequences of slavery, we shall soon be convinced that this opinion is very ill founded. The rights of parents refute from their duties; and it is certainly the duty of that man who has been the instrument of bringing into the world an intellectual and moral being,
to do everything in his power to render the existence of that being happy both in the present life and in that which is to come. If this duty be conscientiously discharged, the parent has a manifest right to the gratitude, love, and reasonable obedience, of his child; but he cannot, in consequence of any duty performed, claim a right to transfer that child as property to the uncontrolled disposal of any private matter; for this plain reason, that the man who is considered as the private property of another, cannot reasonably be supposed to enjoy happiness in this world, and is under many temptations to do what most necessarily render him miserable in the next. See Moral Philosophy, n° 138.

If criminals cannot be lawfully reduced to a state of absolute private slavery, much less surely can it be lawful to reduce insolvent debtors and prisoners of war to that state. Many a virtuous man, who has contracted debts with the fairest prospect of paying them, has been suddenly rendered insolvent by fire, by shipwreck, or by the bankruptcy of others with whom he was necessarily engaged in the course of his trade. Such a man can be considered in no respect as criminal. He has been indeed unfortunate; but it would be greatly unjust, as well as shockingly cruel, to add to his misfortune by reducing him to a state to which we have just seen that the vilest felon cannot be reduced without a violation of the laws of morality. Fraudulent bankrupts, indeed, of whom we daily see many, might with great propriety and the freest justice be compelled to extenuate their debts by labouring for the benefit of those whom they have injured; and criminals of other descriptions might be made to work for the benefit of the public: but in both cases the talk to be performed should be ascertained by the law, and the persons of the labourers be protected by the state. If such can be called slaves, their slavery is undoubtedly consistent with every principle of virtue and religion; for they suffer nothing but the due reward of their deeds. Prisoners of war, however, can upon no honest principle be reduced even to this state of mitigated bondage; for they are far from incurring guilt by fighting for their country, that even to their enemies their courage and conduct in such a cause must procure a reward of reward. A vigorous and general war on slavery would certainly a right to prevent the prisoners taken in battle from again drawing their swords against him during the continuance of the war; but there are many ways by which this may be done effectually without chaining the unfortunate captives to the oar, or selling them like cattle to private purchasers, by whom they may be treated with capricious cruelty, and driven to the perpetration of the greatest crimes.

To these conclusions, and the reasoning on which they are built, we are aware it may be objected, that if private slavery were in every instance unlawful and inconsistent with the fundamental principles of morality, it would not have prevailed among the ancient patriarchs, and far less have been authorized by the Jewish law.

In reply to this objection, it may be observed, that Abraham, Isaac, and Jacob, though excellent men, were not characters absolutely perfect; that as their practice does not authorize polygamy or incest among us, it will not authorize the reducing of our fellow-creatures to a state of their servitude; and that from the circumstances of the age in which they lived, many things were permitted to them, and were indeed harmless, which are forbidden to us, and would now be pernicious. The character of Abraham appears to have been much more perfect than that of his son or grandson; and was certainly equal, if not superior, to that of any other mere man of whom we read either in profane or even in sacred history. We are to remember, however, that he was born amidst idolaters, and was probably an idolater himself till enlightened by the inspiration of Jehovah, and called from his kindred and from his father's house. Before his conversion, he must have had much cattle and many slaves, which constituted the riches of that early period; and his case would indeed have been peculiarly hard, had he been commanded to divest himself of his servants, and to depart into a strange country very thinly inhabited, without people to protect his flocks and herds from beasts of prey. Nor would his losses have contributed in any degree to the benefit of his slaves, who, as the ranks of men were then adjusted, could not long have preferred their liberty. Had they not been forcibly reduced to their former state by their idolatrous countrymen, in all probability they would have been, they might have been submitted to it, or perished by hunger. Let it be remembered, too, that the bond-servants of Abraham, though constituting the most valuable part of his property, were not considered as a species of inferior beings, but were treated rather as children than as slaves. This is evident from his speaking of the steward of his house as his heir, when explaining to God of the want of seed. Indeed the manner in which this circumstance is mentioned, shows that it was then the general practice to consider domestic slaves as members of the family; for the patriarch does not say, "I will leave my substance to this Eliezer of Damaicus," but his words are, "Behold to me thou hast given no seed; and lo! one born in my house is my heir!" From this mode of expression, we are strongly inclined to think that captives taken in war were in that age of simplicity incorporated into the family or tribe of the conqueror, as they are said to be at present among the North American Indians, to supply the place of those who had fallen in battle. If so, slavery was then a very mild thing, unattended with the evils which are now in its train, and must often have been highly beneficial to the captive.

The other part of the objection appears at first sight Answer to more formidable; but perhaps a little attention to the other, design of the Mosaic economy may enable us to remove it even more completely than this. We need not inform our theological readers that one great purpose for which the posterity of Abraham were separated from the heathen nations around them, was to preserve the knowledge of the true God in a world run headlong into idolatry. As idolatry appears to have had something in its forms of worship extremely captivating to rude minds, and as the minds of the Israelites at the era of their departure from Egypt were exceedingly rude, every method was taken to keep their separation from their idolatrous neighbours as complete as possible. With this view they were commanded to sacrifice the animals which their Egyptian masters had worshipped as gods, and were taught to consider hogs and such other creatures as the heathen offered in sacrifice, when celebrating their mythical and magic rites, as too unclean to be eaten or even to be touched. Of this di-
S L A [ 532 ]

Section between clean and unclean beasts, God himself aligns the reason: "I am the Lord your God (says he,) who have separated you from other people; ye shall therefore put difference between clean and unclean beasts, and between unclean fowls and clean." For the same reason they were prohibited from intermarrying with the heathen, or having any transaction whatever with them as neighbours; and the seven idolatrous nations of Canaan they were strictly commanded to exterminate. "When the Lord thy God (says Moses) shall deliver them before thee, thou shalt imitate them, and utterly destroy them: thou shalt make no covenant with them, nor show mercy unto them: neither shalt thou make marriages with them: thy daughter thou shalt not give unto his son, nor his daughter shalt thou take to thy son; for they will turn away thy son from following me, that they may serve other gods." 

Under these laws, it is plain that no intercourse whatever could have place between an Israelite and a man of any other nation, unless the latter was reduced to such a state as that he could neither tempt the former nor preside himself the rites of his idolatrous worship. But the Israelites were not separated from the rest of the world for their ownakes only: They were intended to be the repositories of the lively oracles of God, and gradually to spread the light of divine truth thro' other nations, till the fulness of time should come, when in Christ all things were to be gathered together in one. To answer this end, it was necessary that there should be some intercourse between them and their Gentile neighbours; but we have seen that such an intercourse could only be that which subsists between masters and their slaves.

Should this apology for the slavery which was authorized by the Jewish law be deemed fanciful, we beg leave to submit to the consideration of our readers the following account of that matter, to which the same objection will hardly be made. It was morally impossible that between nations differing so widely in religion, customs, and manners, as the Jews and Gentiles, peace should for ever reign without interruption; but when wars broke out, battles would be fought, and prisoners would be taken. How were these prisoners to be disposed of? Cartels for exchange were not then known: it was the duty of the Israelites to prevent their captives from taking up arms a second time against them; they could not establish them among themselves either as artificers or as husbandmen; for their law enjoined them to have no communication with the heathen. There was therefore no other alternative but either to massacre them in cold blood, or to reduce them to the condition of slaves. It would appear, however, that these slaves were raised to the rank of citizens, or at least that their burdens were much lightened, as soon as they were convinced of the truth of the Mosaic revelation, and received into covenant with God by the rite of circumcision. They were then admitted to the celebration of the passover; concerning which one law was decreed to the stranger, and to him that was home-born. Indeed, when we consider who was the legislator of the Jews; when we reflect upon the number of laws enacted to mitigate slavery among them; and call to mind the means by which the due execution of all their laws was enforced, we cannot help being of opinion that the heathen, who was reduced to slavery in Judea, might be happier, if he pleased, than when living as a freeman in his own country. But whether this be so or not, is a matter with which we have no concern. On account of the hardships of their hearts, and the peculiarity of their circumstances, many things, of which slavery may have been one, were permitted to the Jews, which, if practised by Christians, would render them highly guilty.

After treating thus largely of slavery in general, we need not occupy much of the reader's time with the SLAVE-TRADE carried on at present by the merchants of Europe with the natives of Africa. It is well known that the Portuguese were the first Europeans who embarked in this trade, and that their example was soon followed by the Dutch and the English. Of the rise and progress of the English commerce in slaves, the reader will find a sufficient account in other articles of this work. That commerce, though long cherished by the government as a source of national and colonial wealth, was from its commencement considered by the thinking part of the nation as a traffic inconsistent with the rights of man, and suspected to be carried on by acts of violence. These suspicions have been gradually spread through the people at large, and confirmed, in many instances, by evidence incontrovertible. Laws have in consequence been enacted to make the negroes more comfortable on what is called the middle passage, and to protect them against the wanton cruelty of their masters in the West Indies; but the humanity of the nation was roused; and in many years ago a number of gentlemen, of the most respectable characters, finding that no adequate protection can be afforded to persons in a state of hopeless servitude, formed themselves into a society at London, for the purpose of procuring a total abolition of the slave-trade. That the motives which influence the leading men of this society are of the purest kind, cannot, we think, be questioned; for their object is to deliver those who had none to help them, and from whom they can expect no other reward for their labours of love than the blessings of them who are ready to perish. To a cause so truly Christian, who would not pray for success? or who but must feel the most pungent regret, if that success has been rendered doubtful, or even been delayed, by the imprudence of some of the agents employed by the society? This we apprehend to have been really the case. Language calculated only to exasperate the planters cannot serve the negroes; and the legislature of Great Britain will never suffer itself to be forced into any measure by the menace of individuals.

In the year 1793, petitions were presented to parliament for the abolition of this inhuman traffic, which gave a pleasing picture of the philanthropy of the nation; but, unfortunately for the cause of freedom, it was discovered that many of the names subscribed to those petitions had been collected by means not the most honourable. This discovery, perhaps, would never have been made, had not the indecent epithets indiscriminately heaped upon the slave-holders provoked those men to watch with circumspection over the conduct of their opponents. The consequence was, that fulpifications of unfair dealing on the part of the petitioners were exhibited.
slaves... north, being conveyed to the coast of Abyssinia, and there embarked in war merely for the sake of procuring slaves to barter for European commodities.
may enable them to support the rank and discharge the duties of freemen. This is doubtless the reason why it was not expressly prohibited by the divine Author of our religion, but suffered to vanish gradually before the mild influence of his Heavenly doctrines. It has vanished before these doctrines in most countries of Europe; and we trust that the time is at hand when our traffic in human flesh with the inhabitants of Africa shall cease; and that the peril is not very distant when the slaves in the West Indies shall be so much improved in moral and religious knowledge, as they may be safely trusted with their own freedom. To fet them free in their present state of ignorance and depravity, is one of the wilder propositions that the ardour of innovation has ever made. Such freedom would be equally ruinous to themselves and to their masters; and we may say of it what Cicero said of some unmentionable indulgences proposed to be granted to the slaves in Sicily: _Quae cum accidisse, nemo efi, quin intelligat vrere ilias rempelcam; hac ubi veniant, nemo efi, qui ullam fem falultis reliquam efi arbitetur._

**SLAUGHTER.** See Man-Slaughter, Homicide, Murder, &c.

**Sledge,** a kind of carriage without wheels, for the conveyance of very weighty things, as huge stones, bells, &c. The sledge for carrying criminals, condemned for high treason, to execution, is called Murder. The Dutch have a kind of sledge on which they can carry a vessel of any burden by land. It consists of a plank of the length of the keel of a moderate ship, raised a little behind, and hollow in the middle; so that the fides go a little alope, and are furnished with holes to receive pins, &c. The sledge is quite even.

**SLEEP.** See Dreams and Physiology, p. 287.

**Sleep-Walker,** one who walks in his sleep. Many instances might be related of persons who were addicted to this practice; but it will be sufficient to select one remarkable instance from a report made to the Physical Society of Lauffane, by a committee of gentlemen appointed to examine a young man who was accustomcd to walk in his sleep.

The disposition to sleep-walking seems, in the opinion of this committee, to depend on a particular affection of the nerves, which both feizes and quits the patient during sleep. Under the influence of this affection, the imagination represents to him the objects that struck him while awake, with as much force as if they really affected his senses; but does not make him perceive any of those that are actually presented to his senses, except in so far as they are connected with the dreams which engross him at the time. If, during this state, the imagination has no determined purpose, he receives the impression of objects as if he were awake; only, however, when the imagination is excited to bend its attention towards them. The perception obtained in this state are very accurate, and, when once received, the imagination renewes them occasionally with as much force as if they were again acquired by means of the senses. Lastly, these academicians suppose, that the impressions received during this state of the senses disappear entirely when the person awakes; and do not return till the return of the same disposition, in the nervous system.

Their remarks were made on the Sieur Devaud, a lad thirteen years and a half old, who lives in the town of Vevey, and who is subject to that singular affection or disease called Somnambulism or sleep-walking. This lad possesses a strong and robust constitution, but his nervous system appears to be organized with peculiar delicacy, and to discover marks of the greatest sensibility and irritability. His senses of smell, taste, and touch, are exquisite; he is subject to fits of immoderate and involuntary laughter, and he sometimes likewise weeps without any apparent cause.

This young man does not walk in his sleep every night; several weeks sometimes pass without any appearance of a fit. He is subject to the disease generally in the two nights preceding, one fit lasting for several hours. The longest are from three to four hours, and they commonly begin about three or four o'clock in the morning.

The fit may be prolonged, by gently paffing the finger or a feather over his upper lip, and this slight irritation likewise accelerates it. Having once fallen asleep upon a flat surface, his upper lip was thus irritated with a feather, when he immediately ran down the steps with great precipitation, and returned up his walking. This experiment was repeated several times.

The young Devaud thinks he has observed, that, on the evenings previous to a fit, he is sensible of a certain heaviness in his head, but especially of a great weight in his eyelids.

His sleep is at all times unquiet, but particularly when the fits are about to feize him. During his sleep, motions are observable in every part of his body, with startings and palpitations; he utters broken words, sometimes fits up in his bed, and afterwards lies down again. He then begins to pronounce words more distinctly, he rises abruptly, and acts as if he is excited by the dream that then possesses him. He is sometimes in sleep subject to continued and involuntary motions.

The departure of the fit is always preceded by two or three minutes of calm sleep, during which he fliores. He then awakes rubbing his eyes like a person who has slept quietly.

It is dangerous to awaken him during the fit, especially if it is done suddenly; for then he sometimes falls into convulsions. Having risen one night, with the intention of going to eat grapes, he left the house, passed through the town, and went to a vineyard where he expected good cheer. He was followed by several persons, who kept at some distance from him, one of whom fired a pistol, the noise of which instantly awakened him, and he fell down without sense. He was carried home and brought to himself, when he recollected very well the having been awakened in the vineyard; but nothing more, except the fright at being found there alone, which had made him swoon.

"After the fits he generally feels a degree of lati-
tude: sometimes, though rarely, of indisposition. At
the end of one of those fits, of which the gentlemen
of the committee were witness; he was afflicted with
vomiting; but he is always soon restored.
When he is awakened, he never for the most part
recalls any of the actions he has been doing during
the fit.

"The subject of his dreams is circumstanced in
a small circle of objects, that relate to the few ideas
with which at his age his mind is furnished; such as his
lessons, the church, the bells, and especially tales of
ghosts. It is sufficient to strike his imagination the evening
before a fit with some tale, to direct his somnambulism
towards the object of it. There was read to him while
in this situation the story of a robber; he imagined the
very next moment that he saw robbers in the room.
However, as he is much disposed to dream that he is
surrounded with them, it cannot be affirmed that this
was an effect of the reading. It is observed, that when
his supper has been more plentiful than usual, his dreams
are more vivid.

"In their report, the gentlemen of the committee
dwell much on the state of this young man’s senses, on
the impression made upon them by strange objects, and
on the voice they are of to him.

"A bit of strong smelling wood produced in him a
degree of restlessness; the fingers had the same
effect, whether from their smell or their transpiration.
He knew wine in which there was wormwood by the smell,
and said that it was not wine for his table. Metals
make no impression on him.

"Having been presented with a little common wine
while he was in a state of apathy, and all his motions
were performed with languor, he drank of it willingly;
but the irritation which it occasioned produced a deal
of vivacity in all his words, motions, and actions, and
caused him to make involuntary grimaces.

"Once he was observed drolling himself in perfect
darkness. His clothes were on a large table, mixed
with those of some other persons; he immediately per-
cieved this, and complained of it much; at last a small
light was brought, and then he droll’d himself with
sufficient precision. If he is teased, or graven pinched,
he is always able of it, except he is at the time
strongly engross’d with some other thing, and wishes to
strike the offender; however, he never attacks the per-
son who has done the ill, but an ideal being whose
imagination presents to him, and whom he punishes thro’
the chamber without running against the furniture, nor
can the persons whom he meets in his way divert him
from his pursuit.

"While his imagination was employed on various
subjects, he heard a clock strike, which repeated at eve-
ry stroke the note of the cuckoo. There are cuckoos
here, said he; and, upon being desired, he imitated the
song of that bird, immediately.

"When he wishes to see an object, he makes an ef-
fort to lift his eyelids; but they are too light under his
command, that he can hardly raise them a line or two,
while he draws up his eyebrows; the iris at that time
appears fixed, and his eye dim. When any thing is
presented to him, and he is told of it, he always half
opens his eyes with a degree of difficulty; and then
flutters them after he has taken what was offered to him.

"The report infers from these facts, and from many
others relative to the different senses, that their functions
are not suspended as to what the sleep-walker wishes to
two letters, and he eras’d it without injuring them.
Lastly, he made some arithmetical calculations with
great accuracy.

"In order to explain some of the facts observed by
the academicians which we have here mentioned, they
establish two general observations, which result from
what they have said with respect to the senses and the
dreams of this sleep-walker.

1. That he is obliged to open his eyes, in order to
remember objects which he wishes to see; but the
impression once made, although rapidly, is vivid
enough to supercede the necessity of his opening them again, to
view the same objects anew; that is, the same objects
are afterwards preferred to his imagination with as
much force and precision as if he actually saw them.

2. That his imagination, thus warmed, represents
to him objects, and such as he figures to himself, with
as much vivacity as if he really saw them; and, lastly,
that all his senses, being subordinate to his imagination,
seem concentrated in the object with which it is occu-
pied, and have at that time no perception of any thing
but what relates to that object.

"These two causes united seem to them sufficient
for explaining one of the most singular facts that occurred to his observation, to wit, how the young Devaud can write, although he has lost his eyes that, and an obstacle before them. His paper is imprinted on his imagination, and every letter which he means to write is also painted there, at the place in which it ought to stand on the paper, and without being confounded with the other letters; now it is clear that his hand, which is obedient to the will of his imagination, will trace them on the real paper, in the same order in which they are represented on that which is pictured in his head. It is thus that he is able to write several letters, several sentences, and entire pieces of writing; and what seems to confirm the idea, that the young Devaud writes according to the paper painted on his imagination, is that a certain sleep-walker, who is described in the French Encyclopédie (article Somnambulism), having written something on a paper, another piece of paper of the same size was substituted in its stead, which he took for his own, and made upon this blank paper the corruptions he meant to have made on the other which had been taken away, precisely in the places where they would have been.

"It appears from the recital of another fact, that Devaud, intending to write at the top of the first leaf of a white-paper book, Vevey, leaped a moment as if to recollect the day of the month, left a blank space and then proceeded to December 1787; after which he asked for an almanac; a little book, such as is given to children for a new year's gift, was offered to him; he took it, opened it, brought it near his eyes, then threw it down on the table. An almanac which he knew was then presented to him; this was in German, and of a form similar to the almanac of Vevey: he took it, and then said, 'What is this they have given me! here, there is your German almanac.' At last they gave him the almanac of Berne; he took this likewise, and went to examine it at the bottom of an alcove that was perfectly dark. He was heard turning over the leaves, and saying 23, then a moment afterwards 24. Returning to his place, with the almanac open at the month of December, he laid it on the table and wrote in the space which he had left blank the 24th. This scene happened on the 23rd; but as he imagined it to be the 24th, he did not mistake. The following is the explanation given of this fact by the authors of the report.

"The dates 23rd, 24th, and 25th, of the month of December, had long occupied the mind of the young Devaud. The 23rd and 25th were holidays, which he expected with the impatience natural to persons of his age, for the arrival of these moments when their little daily labours are to be suspended. The 25th especially was the object of his hopes; there was to be an illumination in the church, which had been described to him in a manner that quite transported him. The 24th was a day of labour, which came very disagreeably between the two happy days. It may easily be conceived, how an imagination so irritable as that of the young Devaud would be struck with those pleasing epochs. Accordingly, from the beginning of the month he had been perpetually turning over the almanac of Vevey. He calculated the days and the hours that were to elapse before the arrival of his wished-for hol.

...
SLEEPERS, in natural history, a name given to those animals which sleep all winter; such as bears, marmots, dormice, bats, hedgehogs, swallows, &c. These do not feed in winter, have no sensible evacuations, breathe little or none at all, and most of the viscera cease from their functions. Some of these creatures seem to be dead; and others return to a state like that of the fetus before birth: in this state they continue, till by new heat the fluids are attenuated, the animal is restored to life, and the functions begin where they left off.

SLEEPERS, in a ship, timbers lying before and aft in the bottom of the ship as the rungheads do; the lowermost of them is bolted to the rungheads and the uppermost to the futtocks and rungs.

SLEIDIAN (John), an excellent German historian, born of obscure parents, in 1506, at Sleidan, a small town on the confines of the duchy of Juliers. After studying some time in his own country, together with his townsmen the learned John Sturmius, he went to France, and in 1535 entered into the service of the cardinal and archbishop John du Bellay. He retired to Strafburg in 1542, where he acquired the esteem and friendship of the most considerable persons, particularly of James Sturmius; by whose advice and assistance he was enabled to write the history of his own time. He was employed in some public negotiations; but the death of his wife, in 1555, plunged him into such deep melancholy, that he left his memory entirely, and died the year following. In 1555 came out, in folio, De fina Religiosis et Republicis fab Caroli Quinti, &c. in 25 books; from the year 1517, when Luther began to write to the year of its publication; which history was presently translated into most of the languages of Europe. Besides this great work, he wrote, De quaer summis Imperii, libri tres; with some other historical and political pieces.

SLEIGHT of Hand. See Legerdemain.

SLEUTH-HOUNDS, the ancient Scots name of the bloodhound. The word is from the Saxon flæ¡, “the impression that a dear leaves of its foot in the mire,” and bound “a dog”; so they derive their name from following the track. See the article Blood-Hound.

SLEWICK, an ancient and considerable town of Denmark, and capital of a duchy of the same name in the province of Gottorp, with a bishop’s see, secularized in 1586. Chief to it is the old palace of Gottorp, formerly the ducal residence, but at present inhabited by the head or governor. This town was once much more considerable than it is at present, having suffered greatly by the wars of Germany. It is situated on the south of Sley, where there is a good harbour, 60 miles north-west of Lubeck, and 125 south-west of Copenhagen. E. Long. 10; N. Lat. 51° 40'.

SLEWICK, the duchy of, or South Jutland, is about 100 miles in length and 60 in breadth. It is bounded on the north by North Jutland, on the east by the Baltic Sea, on the south by Holstein, and on the west by the ocean. It contains 14 cities, 17 towns, 13 castles, 278 parishes, 1,480 villages, 162 farms, 116 water-mills, and 166 gentlemen’s seats. It is a pleasant, fertile, populous country, and a foreign duchy. Formerly the king of Denmark had half of it, and the other belonged to the house of Holstein-Gottorp; but the former having conquered this duchy, had the possession of it confirmed to him by the treaty of the north in 1720. In 1731, a prince of Bremen-Culmbach was made governor of this duchy, who resides at Gottorp.

SLICH, in metallurgy, the ore of any metal, particularly of gold, when it has been pounded, and prepared for farther working.

The manner of preparing the flitch at Chemnitz in Hungary is this; they lay a foundation of wood three yards deep, upon this they place the ore, and over this there are 24 beams, armed at their bottoms with iron; these, by a continual motion, heat and grind the ore, till it is reduced to powder; during this operation, the ore is covered with water. There are four wheels used to move these beams, each wheel moving six; and the water, as it runs off, carrying some of the metallic particles with it, is received into several basins, one placed behind another; and finally, after having passed through them all, and deposited some sediment in each, it is let off into a very large pit, almost half an acre in extent; in which it is suffered to stand so long, as to deposit all its sediment, of whatever kind, and after this it is let out. This work is carried on day and night, and the ore taken away and replaced by more as often as occasion requires. That ore which lies next the beams, by which it was pounded, is always the cleanest or richest.

When the flitch is wafted as much as they can, a hundred weight of it usually contains about an ounce, or perhaps but half an ounce of metal, which is not all gold; for there is always a mixture of gold and silver, but the gold is in the largest quantity, and usually is two-thirds of the mixture: they then put the flitch into the furnace with some limestone, and thence, or the coir or former molten, and ran them together. The first melting produces a substance called lech; this lech they burn with charcoal, to make it lighter, to open its body, and render it porous, after which it is called soft; to this roth they add sand in such quantity as they find necessary, and then melt it over again.

At Chemnitz they have many other ways of reducing gold out of its ore, but particularly one, in which they employ no lead during the whole operation; whereas, in general, lead is always necessary, after the before mentioned processes. See Gold.

SLIDING Rule, a mathematical instrument, serving to work questions in gauging, measuring, &c. without the use of compasses; merely by the sliding of the parts of the instrument one by another, the lines and divisions whereof give the answers by inspection.

This instrument is variously contrived, and applied by various authors, particularly Everard, Coggehall, Gunter, Hunt, and Partridge; but the most common and useful are those of Everard and Coggehall.

SLIGO, a county, in the province of Connaught, Ireland, 25 miles in length, and as much in breadth; bounded on the east by that of Leitrim, on the west by the county of Mayo, on the north and north-west by the western ocean, and on the south and south-west by
SLING, an instrument serving for casting stones with great violence. The inhabitants of the Balearic islands were famous in antiquity for the dexterous management of the sling: it is said they used three kinds of slings, some longer, others shorter, which they used according as their enemies were either nearer or more remote. It is added, that the first served them for a head-band, the second for a girdle, and that the third they constantly carried in their hand.

SLINGING is used variously at sea; but chiefly for hoisting up casks or other heavy things with slings, i.e. contrivances of ropes spliced into themselves at either end, with one eye big enough to receive the cask or whatever is to be hauled. There are other slings, which are made longer, and with a small eye at each end; one of which is put over the breech of a piece of ordnance, and the other eye comes over the end of an iron crow, which is put into the mouth of the piece, to weigh and hoist the gun as they please. There are also slings by which the yards are bound fast to the cross-tree aloft, and to the head of the mast, with a strong rope or chain, that if the tide should happen to break, or to be frost to pieces in fight, the yard, nevertheless, may not fall upon the hatches.

Slinging a Man overboard, in order to stop a leak in a ship, is done thus: the man is trussed up about the middle in a piece of canvas, and a rope to keep him from sinking, with his arms at liberty, a mallet in one hand, and a plug, wrapped in oakum and well tarred in a tarpawling cloath, in the other, which he is to beat with all dispatch into the hole or leak.

SLOANE (Sir Hans), baronet, eminently distinguished as a physician and a naturalist, was of Scotch extraction, his father Alexander Sloane being at the head of that colony of Scots which King James I. settled in the north of Ireland, where our author was born, at Killiecagh, on the 16th of April 1660. At a very early period, he displayed a strong inclination for more than a common love of nature, and contemplating her works. When about sixteen, he was attacked by a spitting of blood which threatened to be attended with considerable danger, and which interrupted the regular course of his application for three years; he had, however, already learned enough of physic to know that a malady of this kind was not to be removed suddenly, and he prudently abstained from wine and other liquors that were likely to increase it.

By strictly observing this severe regimen, which in some measure he continued ever after, he was enabled to prolong his life beyond the ordinary bounds; being an example of the truth of his own favourite maxim, that sobriety, temperance, and moderation, are the best and most potent preservatives that nature has granted to mankind.

As soon as he recovered from this infirmity, he resolved to perfect himself in the different branches of physic, which was the profession he had made choice of; and with this view he repaired to London, where he hoped to receive that assistance which he could not find in his own country.

On his arrival in the metropolis, he entered himself as a pupil to the great Stafforth, an excellent chemist, bred under the illustrious Stahl; and by his instructions he gained a perfect knowledge of the composition and preparation of the different kinds of medicines then in use. At the same time, he studied botany at the celebrated garden at Chelsea, affiduously attended the public lectures of anatomy and physic, and in short neglected nothing that he thought likely to prove serviceable to him in his future practice. His principal merit, however, was his knowledge of natural history; and it was this part of his character with introduced him early to the acquaintance of Mr Boyle and Mr Ray, two of the most eminent naturalists of that age. His intimacy with these distinguished characters continued as long as they lived; and as he was careful to communicate to them every object of curiosity that attracted his attention, the observations which he occasionally made often excited their admiration and obtained him the applause.

After studying four years at London with unremittent severity, Mr Sloane determined to visit foreign countries for further improvement. In this view he set out for France in the company of two other students, and having crossed to Dieppe, proceeded to Paris. In the way thither they were elegantly entertained by the famous M. Lemery the elder; and in return Mr Sloane presented that eminent chemist with a specimen of four different kinds of phosphorus, of which, upon the credit of other writers, M. Lemery had treated in his book of chemistry, though he had never seen any of them.

At Paris Mr Sloane lived as he had done in London. He attended the hospitals, heard the lectures of Tournemont, De Verney, and other eminent masters; visited all the literati, who received him with particular marks of esteem, and employed himself wholly in study.

From Paris Mr Sloane went to Montpellier; and, being furnished with letters of recommendation from M. Tournemont to M. Chirac, then chancellor of that university, he found easy access, through his means, to all the learned men of the province, particularly to M. Magnol, whom he always accompanied in his botanical excursions in the environs of that city, where he beheld with pleasure and admiration the spontaneous productions of nature, and learned under his instructions to classify them in a proper manner.

Having here found an ample field for contemplation, which was entirely suited to his taste, he took leave of his two companions, whom a curiosity of a different kind led into Italy.

After spending a whole year in collecting plants, he travelled through Languedoc with the same design; and passing through Thoulouse and Bordeaux, returned to Paris, where he made a short stay. About the end of the year 1684 he set out for England, with an intention of settling there as a physician. On his arrival in London, he made it his first business to visit his two illustrious friends Mr Ray and Mr Boyle, in order...
Sloane. [539] Sloane.

Sloane to communicate to them the discoveries he had made in his travels. The latter he found at home, but the former had retired to Essex, to which place Mr. Sloane transmitted a great variety of plants and seeds, which Mr. Ray has described in his History of Plants, and for which he made a proper acknowledgment.

About the year 1705 our author became acquainted with the celebrated Sydenham, who soon contracted so warm an affection for him that he took him into his house, and recommended him in the strongest manner to his patients. He had not been long in London before he was proposed by Dr. Martin Liller as a candidate to be admitted a member of the Royal Society, on the 26th of November 1684; and being approved he was elected on the 21st of January following.

In 1685 he communicated some curiosities to the Society; and in July the same year he was a candidate for the office of their affiiancy secretary, but without success, as he was obliged to give way to the superior interest of his competitor Dr. Halley. On the 12th of April 1687, he was chosen a fellow of the college of physicians in London; and the same year his friend and fellow traveller Dr. Tamarid Robinson, having mentioned to the Society the plant called the flour of the earth, as a remedy newly discovered for the bite of a mad dog, Dr. Sloane acquainted them that this virtue of the plant was to be found in a book called Dr. Grey's Farmacy; and that he knew a man who had cured with it twenty couples of dogs. This observation he made on the 13th of July, and on the 12th of September following he embarked at Portsmouth for Jamaica with the duke of Albemarle, who had been appointed governor of that island. The doctor attended his grace in quality of physician, and arrived at Jamaica on the 15th of December following.

Here a new field was opened for fresh discoveries in natural productions; but the world would have been deprived of the fruits of them, had not our author, by incredible application, converted, as we may say, his minutes into hours. The duke of Albemarle died soon after he landed, and the duchess determined to return to England whenever an answer should be received to the letter she had sent to court on that melancholy occasion. As Dr. Sloane could not think of leaving her grace in her distress, whilst the reit of her retinue were preparing for their departure he improved it in making collections of natural curiosities; so that though his whole stay at Jamaica was not above fifteen months, he brought together such a prodigious number of plants, that on his return to England Mr. Ray was astonished that one man could procure in one island, and in so short a space, so vast a variety.

On his arrival in London he applied himself to the practice of his profession; and soon became so eminent, that he was chosen physician to Christ's Hospital on the 17th of October 1694; and this office he held till the year 1730, when, on account of his great age and infirmities, it found necessary to resign. It is somewhat singular, and redounds much to the Doctor's honour, that though he received the endowments of his office punctually, because he would not lay down a precedent which might hurt his successors, yet he conscientiously applied the money to the relief of those who were the greatest objects of compassion in the hospital, that it might never be said he enriched himself by giving health to the poor. He had been elected secretary to the Royal Society on the 30th of November 1693; and upon this occasion he revived the publication of the Philosophical Transactions, which had been omitted for some time. He continued to be the editor of this work till the year 1712; and the volumes which appeared during that period are monuments of his industry and ingenuity, many of the pieces contained in them being written by himself.

In the mean time he published Catalogus Plantarum que in Insula Jamacia sponte proveniunt, &c. Seu Prodrum Historiae Naturalis pars primo, which he dedicated to the Royal Society and College of Physicians. About the same time he formed the plan of a dictionary, where the poor might be furnished at prime cost with such medicines as their several maladies might require; which he afterwards carried into execution, with the assistance of the president and other members of the college of physicians.

Our author's thirst for natural knowledge seems to have been born with him, so that his cabinet of curiosities may be said to have commenced with his being. He was continually enriching and enlarging it; and the fame which, in the course of a few years, it had acquired, brought every thing that was curious in art or nature to be first offered to him for purchase. These acquisitions, however, increased it but very slowly in comparison of the augmentation it received in 1701 by the death of William Courten, Esq; a gentleman who had employed all his time, and the greater part of his fortune, in collecting rarities, and who bequeathed the whole to Dr. Sloane, on condition of his paying certain debts and legacies with which he had charged it. These terms our author accepted, and he executed the will of the donor with the most scrupulous exactness; on which account some people have said, that he purchased Mr. Courten's curiosities at a dear rate.

In 1707 the first volume of Dr. Sloane's Natural History of Jamaica appeared in folio, though the publication of the second was delayed till 1725. By this very useful as well as magnificent work the materia medica was enriched with a great number of excellent drugs not before known. In 1708 the Doctor was elected a foreign member of the Royal Academy of Sciences at Paris, in the room of Mr. Tchirnhaus; an honour so much the greater, as we were then at war with France, and the queen's express consent was necessary before he could accept it. In proportion as his credit rose among the learned, his practice increased among the people of rank; Queen Anne herself frequently consulted him, and in her last illness was bled by him.

On the advancement of George I. to the throne, that prince, on the 3d of April 1716, created the Doctor a baronet, an hereditary title of honour to which no English physician had before attained; and at the same time made him physician general to the army, in which station he continued till 1727, when he was appointed physician in ordinary to George II. He attended the royal family till his death; and was particularly favoured by Queen Caroline, who placed the greatest confidence in his prescriptions. In the mean time he had been unanimously chosen one of the electors of the college of physicians June 1, 1716, and he was elected president of the same body on September 30, 1719, an office which he held for sixteen years. During
sloane
ing that period he not only gave the highest proofs of
his zeal and assiduity in the discharge of his duty, but
in 1721 made a present to that society of L. 100; and
so far remitted a very considerable debt, which the cor-
poration owed him, as to accept it in such small sums as
were least inconvenient to the state of their affairs. Sir
Hans was no less liberal to other learned bodies. He
had no sooner purchased the manor of Chelsea, than he
gave the company of apothecaries the entire freehold
of their botanical garden there, upon condition only that
they should present yearly to the Royal Society fifty
new plants, till the number should amount to 2000 (a).
He gave besides several other considerable donations for
the improvement of this garden; the situation of which,
on the banks of the Thames, and in the neighbourhood
of the capital, was such as to render it useful in two
respects: First, by producing the most rare medicinal
plants; and, secondly, by serving as an excellent school
for young botanists; an advantage which he himself
had derived from it in the early part of his life.

The death of Sir Isaac Newton, which happened in
1727, made way for the advancement of Sir Hans to
the presidency of the Royal Society. He had been
vice-president, and frequently sat in the chair for that
great man; and by his long connection with this learned
body he had contrived to draw an affection for it,
that he made them a present of an hundred guineas,
caused a curious bust of King Charles II. his founder, to
be erected in the great hall where it met, and, as is
said was very instrumental in procuring Sir Godfrey
Copley's benefaction of a medal of the value of five
guineas, to be annually given as an honorary mark of
distinction to the person who communicates the best ex-
periments to the Society.

On his being raised to the chair, Sir Hans laid aside
all thoughts of further promotion, and applied himself
wholly to the faithful discharge of the duties of the of-
fices which he enjoyed. In this laudable occupation he
employed his time from 1727 to 1740, when, at the
age of fourscore, he formed a resolution of quitting the
service of the public, and of living for himself. With
this view he resigned the presidency of the Royal So-
ciety much against the inclination of that respectable
body, who chose Martin Folkes, Esq.; to succeed him,
and in a public assembly thanked him for the great and
eminent services he had rendered them. In the month
of January 1741, he began to remove his library, and
his cabinet of rarities, from his house in Bloomsbury to
that at Chelsea; and on the 12th of March following,
having settled all his affairs, he retired thither himself, to
enjoy in peaceful tranquillity the remains of a well-spent
life. He did not, however, bury himself in that soli-
tude which excludes men from society. He received
at Chelsea, as he had done in London, the visits of
people of distinction, of all learned foreigners, and of
the royal family, who sometimes did him the honour to
wait on him; but, what was still more to his praise, he
never refused admonition or advice to rich or poor who
came to confult him concerning their health. Not con-
tented with this contracted method of doing good, he
made during his retreat, presented to the public such
useful remedies as success had warranted, during the
course of a long continued practice. Among these is
the efficacious receipt for distempers in the eyes, and
his remedy for the bite of a mad dog.

During the whole course of his life, Sir Hans had
lived with so much temperance, as had preserved him
from feeling the infirmities of old age; but in his goth
year he began to complain of pains, and to be in-
fected of an universal decay. He was often heard to say,
that the approach of death brought no terrors along with
it; that he had long expected the stroke; and that he
was prepared to receive it whenever the great Author
of his being should think fit. After a short illness of
three days, he died on the 11th of January 1752, and
was interred on the 18th at Chelsea, in the same vault
with his lady, the solemnity being attended with the
greatest concourse of people, of all ranks and conditions,
that had ever been seen before on the like occasion.

Sir Hans being extremely solicitous left his cabinet
of curiosities, which he had taken so much pains to col-
lect, should be again disfigured at his death, and being
at the same time unwilling that so large a portion of
his fortune should be left to his children, be bequeathed
it to the public, on condition that L. 20,000 should be
made good by parliament to his family. This sum,
though large in appearance, was scarcely more than the
intrinsic value of the gold and silver medals, the ores
and precious stones that were found in it; for in his
last will we declare, that the first cost of the whole
amounted at least to L. 50,000. Besides his library,
consisting of more than 50,000 volumes, 347 of which
were illustrated with cuts finely engraved and coloured
from nature, there were 3560 manuscripts, and an in-
finitude number of rare and curious works of every kind.
The parliament accepted the legacy, and fulfilled the
conditions.

SLOANEA, in botany: A genus of plants be-

(a) This garden was first established by the company in 1673; and having after that period been stocked by
them with a great variety of plants, for the improvement of Botany, Sir Hans, in order to encourage so service-
able an undertaking, granted to the company the inheritance of it, being part of his estate and manor of Chelsea,
on condition that it should be for ever preserved as a physic garden. As a proof of its being so maintained, he
obliged the company, in consideration of the said grant, to present yearly to the Royal Society, in one of their
weekly meetings, fifty specimens of plants that had grown in the garden the preceding year, and which were all
to be specifically distinct from each other, until the number of two thousand should be completed. This num-
ber was completed in the year 1761. In 1733 the company erected a marble statue of Sir Hans, executed by
Ryburn, which is placed upon a pedestal in the centre of the garden, with a Latin inscription, expressing
his donation, and the design and advantages of it:
Loire into the Seine, though the ground between them rise above 150 feet higher than either of those rivers.

Sluices are made in different ways, according to the use for which they are intended; when they serve for navigation, they are shut with two gates, presenting an angle towards the stream; when they are made near the sea, two pair of gates are made, the one to keep the water out and the other in, as occasion requires; in this case, the gates towards the sea present an angle that way, and the others the contrary way; and the space inclosed by those gates is called the chamber. When sluices are made in the ditches of a fortress, to keep up the water in some parts, instead of gates, shutters are made so as to slide up and down in grooves; and when they are made to raise an inundation, they are then shut by means of square timbers let down in culfès, so as to lie close and firm.

The word *sluice* is formed of the French *eslif*, which Menage derives from the Latin *esula*, found in the Salic law in the same sense. But this is to be restrained to the sluices of mills, &c. for us through serving to raise vessels, they were wholly unknown to the ancients.

SLUR, in music, a mark like the arch of a circle, drawn from one note to another, comprehending two or more notes in the same or different degrees. If the notes are in different degrees, it signifies that they are all to be sung to one syllable; for wind instruments, that they are to be made in one continued breath; and for fringed instruments that are struck with a bow, as a violin, &c. that they are made with one stroke. If the notes are in the same degree, it signifies that it is all one note, to be made as long as the whole notes so connected; and this happens most frequently between the last note of one line and the first of the next; which is particularly called *coception*.

SLUY, a town in Dutch Flanders, opposite the island of Cadsland, with a good harbour, 10 miles north of Bruges. E. Long. 3. 25 N. Lat. 51. 19.

SMACK, a small vessel, commonly rigged as a sloop or hoy, used in the coasting or fishing trade, or as a tender in the king's service.

SMALAND, or EAST GOTHLAND, a province of Sweden, which makes part of Gothland; and is bounded on the north by Olofrottia or East Gothland, on the east by the Baltic Sea, on the south by Schonen and Blekingia, and on the west by Welfrottia or West Gothland. It is about 112 miles in length, and 62 in breadth. Calmar is the capital-town.

SMALKALD, a town of Germany, in Franconia, and in the county of Henneberg: famous for the confederation entered into by the German Protestants against the emperor, commonly called the league of Smalkald. The design of it was to defend their religion and liberties. It was seated on the river Werra, 25 miles south of Erford, and 50 north-west of Hamberg. E. Long. 10. 53. N. Lat. 50. 49. It is subject to the prince of Hesse-Cassel.

SMALLAGE, in botany. See *Afrium*.

SMALT, a kind of glass of a dark blue colour, which when levigated appears of a most beautiful colour; and if it could be made sufficiently fine, would be an excellent succedaneum for ultramarine, as not only resisting all kinds of weather, but even the most violent fires. It is prepared by melting one part of calcined cobalt with two of flint powder, and one of potash.
SMEATON, John, an eminent civil engineer, was born the 28th of May 1724, O. S., at Aulthorpe, near Leeds, in a house built by his grandfather, and where his family have resided ever since.

The strength of his understanding and the originality of his genius appeared at an early age; his playthings were not the playthings of children, but the tools which men employ; and he appeared to have greater entertainment in seeing the men in the neighbourhood work, and asking them questions, than in any thing else. One day he was seen (to the delight of his family) on the top of his father’s barn, fixing up something like a windmill; another time, he attended some men fixing a pump at a neighbouring village, and observing them cut off a piece of bored pipe, he was so lucky as to procure it, and he actually made with it a working pump that raised water. These anecdotes refer to circumstances that happened while he was in petticoats, and felt like before he attained his fifth year.

About his 14th and 15th year, he had made for himself an engine for turning, and made several presents to his friends of boxes in ivory or wood very neatly turned. He forged his iron and steel, and melted his metal; he had tools of every sort for working in wood, ivory, and metals. He had made a lathe, by which he had cut a perpetual firewood in braids, a thing little known at that day, which was the invention of Mr. Henry Hindley of York; with whom Mr. Smeaton became acquainted, and they spent many a night at Mr. Hindley’s house till day-light, conversing on these subjects.

Thus had Mr. Smeaton, by the strength of his genius and indefatigable industry, acquired, at the age of 18, an extensive list of tools, and the art of working in most of the mechanical trades, without the assistance of any master. A part of every day was generally occupied in forming some ingenious piece of mechanism.

Mr. Smeaton’s father was an attorney, and defirous of bringing him up to the same profession, Mr. Smeaton therefore came up to London in 1742, and attended the courts in Westminster hall; but finding (as his common expression was) that the law did not suit the bent of his genius, he wrote a strong memorial to his father on that subject; who, good sense from that moment left Mr. Smeaton to pursue the bent of his genius in his own way.

In 1751 he began a course of experiments to try a machine of his invention to measure a ship’s way at sea, and also made two voyages in company with Dr. Knight to try it, and a compass of his own invention and making, which was made magnetic by Dr. Knight’s artificial magnets: the second voyage was made in the Fortune fleet of war, commanded at that time by Captain Alexander Campbell.

In 1753 he was elected member of the Royal Society; the number of papers published in their Transactions will show the universality of his genius and knowledge. In 1759 he was honoured by an unanimous vote with their gold medal for his paper intitled “An Experimental Inquiry concerning the Natural Powers of Water and Wind to turn Mills, and other Machines depending on a Circular Motion.”

This paper, he says, was the result of experiments made on working models in the years 1752 and 1753, but not communicated to the Society till 1759; before which time he had an opportunity of putting the effect of these experiments into actual practice, in a variety of cafe, and for various purposes, so as to assure the Society he had found them to answer.

In December 1755, the Eddystone lighthouse was burnt down; Mr. Walton, the chief proprietor, and the others, being desirous of rebuilding it in the most substantial manner, inquired of the earl of Macclesfield (then president of the Royal Society) whom he thought the most proper to rebuild it; this Lordship recommended Mr. Smeaton.

Mr. Smeaton undertook the work, and completed it in the summer of 1759. Of this Mr. Smeaton gives an ample description in the volume he published in 1759; that edition has been sold some time ago, and a second is now in the press, under the revisal of his much esteemed friend Mr. Aubert, F. R. S. and governor of the London assurance corporation.

Though Mr. Smeaton completed the building of the Eddystone lighthouse in 1759 (a work that does him so much credit), yet it appears he did not soon get into full business as a civil engineer; for in 1764, while in Yorkshire, he offered himself a candidate for one of the receivers of the Derwentwater estate; and on the 31st of December in that year, he was appointed at a full board of Greenwich Hospital, in a manner highly flattering to himself; when two other positions strongly recommended and powerfully supported were candidates for the employment. In this appointment he was very happy, by the assistance and abilities of his partner Mr. Walton one of the receivers, who taking upon himself the management of the account, left Mr. Smeaton leisure and opportunity to exert his abilities on public works as well as to make many improvements in the mills and in the estates of Greenwich Hospital. By the year 1775 he had so much business as a civil engineer, that he wished to resign this appointment; and would have done it then, had not his friends the late Mr. Stuart the hospital surveyor, and Mr. Ibbetson their secretary, prevailed upon him to continue in the office about two years longer.

Mr. Smeaton having now got into full business as a civil engineer, performed many works of general utility. He made the river Calder navigable; a work that required great skill and judgment, owing to the very impetuous floods in that river: He planned and attended the execution of the great canal in Scotland for conveying the trade of the country either to the Atlantic or German ocean; and having brought it to the place originally intended, he declined a handsome yearly salary in order that he might attend to the multiplicity of his other business.

On the opening of the great arch at London bridge, the excavation around and under the flaring was so considerable, that the bridge was thought to be in great
Mr. Smeaton was a warm friend and admirer of Mr. Holmes, and he had several letters from him, signed with his name, but written and signed by another's pen; the dictation of them showed the strength of his mind had not left him. In one written the 26th of September, after minutely describing his health and feelings, he says, "In confederation of the foregoing, I conclude myself nine-tenths dead; and the greatest favour the Almighty can do me (as I think), will be to complete the other part; but as it is likely to be a lingering illness, it is only in His power to say when that is likely to happen."

Mr. Smeaton had a warmth of expression that might appear to those who did not know him well to border on harshness; but those more intimately acquainted with him, knew it arose from the intense application of his mind, which was always in the pursuit of truth, or engaged in investigating difficult subjects. He would sometimes break out hastily, when any thing was felt that did not tally with his ideas; and he would not give up any thing he argued for, till his mind was convinced by sound reasoning.

In all the social duties of life he was exemplary; i.e., a most affectionate husband, a good father, a warm, zealous, and sincere friend, always ready to assist those he respected, and often before it was pointed out to him in what way he could serve them. He was a lover and encourager of merit wherever he found it; and many men are in a great measure indebted to his affability and advice for their present situation. As a companion, he was always entertaining and instructive; and none could spend any time in his company without improvement.

SMELL, on the organ, is an impression made on the nose by little particles continually exuding from odorous bodies: With regard to the object, it is the figure and disposition of odorous effluvia, which, sticking on the organ, excite the sense of smelling; And with regard to the soul, it is the perception of the impression of the object on the organ, or the affection in the soul resulting therefrom. See ANATOMY, p. 140; and METAPHYSICS.

SMELLING, the act whereby we perceive smells, or whereby we become sensible of odorous bodies, by means of certain effluvia thereof; which, falling on the olfactory organ, briskly enough to have their impulses propagated to the brain, excite a sensation in the soul. The principal organs of smelling are the nostrils and the olfactory nerves; the minute ramifications of which latter are distributed throughout the whole concave of the former. For their descriptions, see ANATOMY.

Smelling is performed by drawing into the nostrils the odorous effluvia floating in the air in inspiration, which strike with such force against the fibrile of the olfactory nerves, which the figure of the nose, and the situation of the little bones, render more susceptible thereto, as to shake them, and give them a vibratory motion; which action, being communicated hence to the common-fenny, occasions an idea of a sweet, or acid, or four, or an aromatic, or a putreous object, &c. The matter in animals, vegetables, fluids, &c. which chiefly affects the sense of smelling, Bierhave observes, is that fibrile substance, inherent in their oily parts, called...
called frilly, because, when this is taken away from the most fragrant bodies, what remains has scarce any smell at all; but this, pored on the most inodorous bodies, gives them a fragrancy.

Wills observes, that brutes have generally the sense of smelling in much greater perfection than man: by this alone they distinguish the qualities of bodies, which could not otherwise be known; hunt out their food at a distance, as hounds and birds of prey; or hide among other substances, as ducks, &c. Man, having other means of judging of his food, &c. did not need so much acuteness in his nose: yet have we inferences of a great deal even in man. In the Histoire des Animaux, we are assured there are negroes that, by their sense of smell alone, can distinguish between the footsteps of a Frenchman and a negro. It is found, that the lamine, where-in the upper part of the nostrils is encased, and which serve to receive the diverticulations of the olfactory nerves, are always longer, and folded up together in greater numbers, as the animal has this sense more acute: the various windings and turnings of these laminae retaining the odoriferous particles.

The sense of smelling may be diminished or destroyed by disease; as by the moisture, dryness, inflammation, or suppuration of the olfactory membrane, the compression of the nerves which supply it, or some fault in the brain itself at their origin. A deafness, or too great a degree of solidity of the small spongy bones of the upper jaw, the caverns of the forehead, &c. may likewise impair this sense; and it may be also injured by a collection of solid matter in these caverns, which is continually exhaled from them, and also by immoderate use of snuff. For the nose abounds with moisture, after gentle evaporation, such things as tend to take that place, and coagulate the thin sharp serum may be applied: as the oil of anise mixed with fine flour, camphor dissolved in oil of almonds, &c. the vapours of amber, frankincense, gum-mastic, and benjamin, may like wise be received into the nose and mouth. For moistening the mucus when it is too dry, some recommend snuff made of the leaves of marjoram, mixed with oil of amber, marjoram, and aniseed; or a purgative of calcined white vitriol, twelve grains of which may be mixed with two ounces of marjoram water and filtrated. The steam of vinegar upon hot iron, and received up the nostrils, is also of use for softening the mucus, removing obstructions, &c. If there be an ulcer in the nose, it ought to be dressed with some emollient ointment, to which, if the pain be very great, a little laudanum may be added. If it be a venereal ulcer, 12 grains of corrosive sublimate may be dissolved in a pint and a half of brandy, a table-spoonful of which may be taken twice a day. The ulcer ought likewise to be washed with it, and the fumes of cinnamar may be received up the nostrils.

If there be reason to suspect that the nerves which supply the organs of smelling are inert, or want stimulating, volatile fumes, or strong snuff, and other things which occasion freezing, may be applied to the nose; the forehead may likewise be anointed with balsam of Peru, to which may be added a little oil of amber.

SMELTING, in metallurgy, the fusion or melting of the ores of metals, in order to separate the metallic part from the earthy, fliny, and other parts. See Metallurgy, Part III.

SMELT, in ornithology. See Margus.

SMILAX, rough bindweed, in botany: A genus of plants belonging to the class of dicot and order of besenaria; and in the natural system ranging under the 11th order, Sarmentacea. The male calyx is hexaphyllous, and there is no corolla; the female calyx is also hexaphyllous, without any corolla: there are three styles, a trilocular berry, and two seeds. There are 18 species: the aspera, excelsa, zoilaica, farfaparilla, china, rotondfolia, laurifolia, tamnoides, carduca, bona nord, herbacea, tetragona, lanceolata, and plendo-china. Of these, the farfaparilla, which affords the farfaparilla root, is the most valuable. This is well described in the London Medical Journal by Dr. Wright, who, during a long residence in Jamaica, made botany his peculiar study.

"This species (says he) has flakes of the thickness of a man's finger; they are jointed, triangular, and beset with crooked spines. The leaves are alternate, smooth and shining on the upper side; on the other side are three nerves or cotyle, with fundry small crooked spines. The flower is yellow, mixed with red. The fruit is a black-berrie, containing several brown seeds.

"Farfaparilla delights in low moist grounds and near the banks of rivers. The roots run superficially under the surface of the ground. The gatherers have only to loosen the foil a little, and to draw out the long fibres with a wooden hook. In this manner they proceed till the whole root is got out. It is then cleared of the mud, dried, and made into bundles.

"The medicinal qualities of farfaparilla are mucilaginous and farinaceous, with a slight degree of acrimony. The taste, however, is so slight as not to be perceived by many; and I am apt to believe that its medicinal powers may fairly be ascribed to its demulcent and farinaceous qualities.

"Since the publication of Sir William Fordyce's paper on Farfaparilla in the Medical Observations and Inquiries, Vol. I. farfaparilla has been in more general ufe than formerly. The planters in Jamaica supply their elates with great quantities of it; and its exhibition has been attended with very happy convequences in the yaws and in venereal affections; as nodes, tophi, and exoftosia; pains of the bones, and carious or cancerous ulcers.

"Sir William Fordyce seems to think farfaparilla a specific in all ftes of lues; but from an attentive and careful observation of its effects in some thousands of cases, I must declare I could place no dependence on farfaparilla alone. But if mercury had formerly been tried, or was used along with farfaparilla, a cure was soon effected. Where the patients had been reduced by pain, disorder, and mercury, I preferred a decoction of farfaparilla, and a table-spoonful of the powder of the same, twice a day, with the greatest successe, in the most deplorable cafes of lues, ill cured yaws, and carious or ill-disposed fore or cancers.

The china, or oriental species of china root, has roundish prickly thorns and red berries, and is a native of China and Japan. The plendo-china, or occidental species, has rounder smooth thorns and black berries, grows wild in Jamaica and Virginia, and bears the colds of our own climate.
These roots have scarce any smell or particular taste: when fresh, they are said to be somewhat acid, but as brought to us they discover, even when long chewed, no other than a slight unctuousness in the mouth. Boiled in water, they impart a reddish colour, and a kind of rapid softness: the decoction when infused yields an irritant, farinaceous, almost insipid mias, amounting to upwards of half the weight of the root. They give a gold yellow tincture to refined spirit, but make no sensible alteration in its taste: on drawing off the spirit from the filtered liquor, there remains an orange-coloured extract, nearly as insipid as that obtained by water, but faintly in half its quantity.

China root is generally supposed to promote perspiration and urine, and by its slight unctuous quality to blunt acrimonious humours. It was first introduced into Europe about the year 1535, with the character of a specific against venereal disorders: the patient was kept warm, a weak decoction of china root was used for common drink, and a stronger decoction taken twice a day in bed to promote a sweat. Such a regimen is doubtless a good auxiliary to mercurial alternatives: but whatever may be its effects in the warmer climates, it is found in this to be itself greatly insufficient. At present the china root is very rarely made use of, having for some time given place to farfaparrilla, which is supposed to be more effectual. Prosper Alpinus informs us, that this root is in great esteem among the Egyptian women for procuring faints and plumpness.

SMITH (Sir Thomas), was born at Wadlen in Eves in 1512. At 14 he was sent to Queen's College, Cambridge, where he distinguished himself so much that he was made Henry VIII. scholar together with John Cheke. He was chosen fellow of his college in 1534, and appointed two years after to read the public Greek lecture. The common mode of reading Greek at that time was very faulty; the fame found it in great esteem among the Egyptian women for procuring faints and plumpness.

SMITH (Edmund), a distinguished English poet, the only son of Mr Neale an eminent merchant, by a daughter of Baron Lechmere, was born in 1668. By his father's death he was left young to the care of Mr Smith, who had married his father's sister, and to whom he was sent at a very tender age to be educated. The father's death he was left young to the care of Mr Smith, who had married his father's sister, and to whom he was sent at a very tender age to be educated. Smith, who was left happy in what he subordinated to armament. In the Kit-cat club he has poured full-bottoms chiefly over night-gowns. If those frames of hair were incommode in a battle, I know nothing (he adds) they were adapted to that can be done in a night-gown.

Smith compiled two large volumes, with proofs of his own plates, for which he asked £50. His finest works are duke Schomberg on horseback; that duke's lion and successor Maynard; the ears of Pembroke, Dorset, and Albemarle; three plates with two figures in each, of young persons or children, in which he shone; William Cowper, Gibbons and his wife; Queen Anne; the duke of Gloucester, a whole length, with a flowerpot; a very curious one of Queen Mary, in a high head, fan, and gloves; the earl of Godolphin; the duchess of Ormond, a whole length, with a black; Sir George Rooke, &c. There is a print by him of James II. with an anchor, but no inscription; which not being finished when the king went away, is so scarce that it is sometimes sold for above a guinea. Smith also performed many historic pieces; as the loves of the gods, from Titian, at Blenheim, in ten plates; Venus landing in a shell, from a picture by Correggio, and many more, of which perhaps the most delicate is the holy family with angels, after Carlo Maratti.

Smith (Dr Adam), the celebrated author of the Inquiry into the Nature and Causes of the Wealth of Nations, was the only son of Adam Smith comptroller of the customs at Kirkaldy, and of Margaret Douglas daughter of Mr Douglas of Strathenry. He was born at Kirkaldy on the 5th June 1723, a few months after the death of his father. His constitution during his infancy was infirm and sickly, and required all the care of his surviving parent. When only three years old he was carried by his mother to Strathenry on a visit to his uncle Mr Douglas; and happening one day to be amusing himself alone at the door of the house, he was stolen by a party of those vagrants who in Scotland are called dullers. Luckily he was missed immediately; and the vagrants purified and overthrown in Leslie wood; and thus Dr Smith was prefered to extend the bounds of science, and reform the commercial policy of Europe.

He received the rudiments of his education in the school of Kirkaldy under David Miller, a teacher of considerable eminence, and whose name deserves to be recorded on account of the great number of eminent men which that infancy produced while under his direction. Dr Smith, even while at school, attracted notice by his passionate attachment to books, and by the extraordinary powers of his memory; while his friendly and generous disposition gained and secured the affection of his schoolfellows. Even then he was remarkable for those habits which remained with him through life, of speaking to himself when alone and of absence in company. He was sent in 1737 to the university of Glasgow, where he remained till 1740, when he went to Balliol college Oxford, as an exhibitor on Snell's foundation. His favourite pursuits while at the university were mathematics and natural philosophy. After his removal to England he frequented himself in translating, particularly from the French, with a view to the improvement of his own style; a practice which he often recommended to all who wished to cultivate the art of composition. It was probably then also that he applied himself with the greatest care to the study of languages, of which, both ancient and modern, his knowledge was uncommonly extensive and accurate.

After seven years residence at Oxford he returned to Kirkaldy, and lived two years with his mother without any fixed plan for his future life. He had been designed for the church of England; but disliking the ecclesiastical profession, he resolved to abandon it altogether, and to limit his ambition to the prospect of obtaining some of those preferments which literary attainments lead in Scotland. In 1748 he fixed his residence in Edinburgh, and for three years read a course of lectures on rhetoric and belles lettres under the patronage of Lord Kaimes. In 1751 he was elected professor of logic in the university of Glasgow, and the year following was removed to the professorship of moral philosophy, vacant by the death of Mr Thomas Craigie the immediate successor of Dr Hutcheson. In this situation he remained 13 years, a period he used frequently to look back to as the most useful part of his life. His lectures on moral philosophy were divided into four parts: The first contained natural theology; in which he considered the proofs of the being and attributes of God, and those truths on which religion is founded: the second comprehended ethics, strictly so called, and consisted chiefly of those doctrines which he afterwards published in his theory of moral sentiments: in the third part he treated more at length of that part of morality called justice; and which, being susceptible of precise and accurate rules, is for that reason capable of a full and accurate explanation: in the last part of his lectures he examined those political regulations which are founded, not upon the principle of justice, but of expediency; and which are calculated to increase the riches, the power, and the prosperity of a state. Under this view he considered the political institutions relating to commerce, to finances, to ecclesiastical and military governments: this contained the substance of his Wealth of Nations. In delivering his lectures he trusted almost entirely to extempore eloquence: his manner was plain and unaffected, and he never failed to interest his hearers. His reputation soon rose very high, and many students resorted to the university merely upon his account.

When his acquaintance with Mr Hume first commenced it was uncertain, but it had ripened into friendship before the year 1752. In 1759 he published his Theory of Moral Sentiments; a work which deservedly extended his reputation: for, though several of its conclusions be ill-founded, it must be allowed by all to be a singular effort of invention, ingenuity, and subtlety. Besides, it contains a great mixture of important truth; and, tho' the author has sometimes been misled, he has had the merit of directing the attention of philosophers to a view of human nature, which had formerly in a great measure escaped their notice. It abounds everywhere with the purest and most elevated maxims concerning the practical conduct of life; and when the subject of his work leads him to address the imagination and the heart, the variety and felicity of his illustrations, the richness and fluency of his eloquence, and the skill with which...
SMITH, which he wins the attention and commands the applause of his reader, leave him among the British moralists without a rival.

Towards the end of 1763 Dr Smith received an invitation from Mr Charles Townend to accompany the Duke of Buccleugh on his travels; and the liberal terms in which this proposal was made induced him to resign his office at Glasgow. He joined the Duke of Buccleugh at London early in the year 1764, and set out with him for the continent in the month of March following. After a stay of about ten days at Paris, they proceeded to Thoulouse, where they fixed their residence for about 18 months; thence they went by a pretty extensive route through the south of France to Geneva, where they passed two months. About Christmas 1765 they returned to Paris, and remained there till October following. The society in which Dr Smith passed these ten months may be conceived in confluence of the recommendation of Mr Hume. Turgot, Quesnay, Necker, D'Alembert, Helvetius, Marmontel, Madame Riccoboni, were among the number of his acquaintances; and some of them he continued ever after to reckon among the number of his friends. In October 1766 the Duke of Buccleugh returned to England.

Dr Smith spent the next ten years of his life with his mother at Kirkaldy, occupied habitually in intense study, but unbending his mind at times in the company of some of his old schoolfellows, who still continued to refire near the place of their birth. In 1776 he published his Inquiry into the Nature and Causes of the Wealth of Nations; a book so universally known, that any panegyric on it would be useless. The variety, importance, and (may we not add) novelty, of the information which it contains; the skill and comprehensiveness of mind displayed in the arrangement; the admirable illustrations with which it abounds; together with a plainness and perspicuity which make it intelligible to all—render it unquestionably the most perfect work which has as yet appeared on the general principles of any branch of legislation.

He spent the next two years of his life in London, where he enjoyed the society of some of the most eminent men of the age; but he removed to Edinburgh in 1778, in consequence of having been appointed, at the request of the Duke of Buccleugh, one of the commissioners of the customs in Scotland. Here he spent the last twelve years of his life in an influence which was more than equal to all his wants. But his studies seemed entirely suspended till the infirmities of old age reminded him, when it was too late, of what he yet owed to the public and to his own fame. The principal materials of the works which he had announced had long ago been collected, and little probably was wanting but a few years of health and retirement to complete them. The death of his mother, who had accompanied him to Edinburgh in 1764, together with that of his bequest, Miss Douglas, in 1768, contrived to frustrate these projects. They had been the objects of his affection for more than 60 years, and in their society he had enjoyed from his infancy all that he ever knew of the endearments of a family. He was now alone and helpless; and though he bore his loss with equanimity, and regained apparently his former cheerfulness, yet his health and strength gradually declined till the period of his death, which happened in July 1790. Some days before his death he ordered all his papers to be burnt except a few carys, which have since been published.

Of the originality and comprehensiveness of his views, the extent, the variety, and the correctness of his information; the inexhaustible fertility of his invention—he has left behind him lasting monuments. To his private worth, the most certain of all testimonies may be found in that confidence, respect, and attachment, which followed him through all the various relations of life. He was habitually absent in conversation, and was apt when he spoke to deliver his ideas in the form of a lecture. He was rarely known to hint a new topic himself, or to appear unprepared upon those topics that were introduced by others. In his external form and appearance there was nothing uncommon. When perfectly at ease, and when warmed with conversation, his gestures were animated and graceful; and in the society of those he loved, his features were often brightened by a smile of inexpressible benignity. In the company of strangers, his tendency to silence, and perhaps still more his coldness of that tendency, rendered his manner somewhat embarrassed; an affect which was probably not a little heightened by those speculative ideas of propriety which his recluse habits tended at once to perfect in his conception, and to diminish his power of realizing.

SMITHIA, in botany: A genus of the decandra order belonging to the diadelphus class of plants; and in the natural method ranking under the 32d order, Papilionaceae. The calyx is monophyllous and bilabiated; the corolla winged; the legumen included in the calyx, with three or four joints, and contain as many seeds, which are smooth, compressed, and kidney-shaped. There is only one species, viz. the thonina.

SMITZ (Gaspard), who, from painting a great number of Magdalen's, was called Magdalen Smith, was a Dutch painter, who came to England soon after the Restoration. For these portraits he was so wretched that he kept, and called his wife. A lady, whom he had taught to draw, took him with her to Ireland, where he painted small portraits in oil, had great business, and high prices. His flowers and fruit were so much admired, that one bunch of grapes sold there for L. 40. In his Magdalen's he generally introduced a thistle on the fore ground. He had several scholars, particularly Maubert, and one Gawdy of Exeter. Yet, notwithstanding his success, he died poor in Ireland in 1707.

SMITHERY, a smith's shop; also the art of a smith, by which iron is wrought into any shape by means of fire, hammering, filing, &c.

SMITING-LINES, in a ship, is a small rope fastened to the mizen-yard-arm, below the deck, and is always furled-up with the mizen-fail, even to the upper end of the yard, and thence it comes down to the poop. Its use is to loofe the mizen-fail Without triking downs the yard, which is easily done, because the mizen-fail is furled up only with rope-yarns, and therefore when this rope is pulled hard, it breaks all the rope yarns, and to the fail falls down of itself. The sailor's phrase is, sul the mizen (whence this rope takes its name), that is, hale by this rope that the fail may fall down.

SMOKE, a dense elastic vapour, arising from burning bodies. As this vapour is extremely disagreeable to the senses, and often prejudicial to the health, many
kind have fallen upon several contrivances to enjoy the benefit of fire, without being annoyed by smoke. The most universal of these contrivances is a tube leading from the chamber in which the fire is kindled to the top of the building, through which the smoke ascends, and is diffused into the atmosphere. These tubes are called chimneys, which, when constructed in a proper manner, carry off the smoke entirely; but, when improperly constructed, they carry off the smoke imperfectly, to the great annoyance of the inhabitants.

As our masons at present seem to have a very imperfect knowledge of the manner in which chimneys ought to be built, we can hardly perform a more acceptable service to the public than to point out the manner in which they ought to be constructed, so as to carry off the smoke entirely; as well as to explain the causes from which the defects so often complained of generally proceed, and the method of removing them.

Those who would be acquainted with this subject should begin by considering on what principle smoke ascends in any chimney. At first many are apt to think that smoke is in its nature, and of itself, specifically lighter than air, and rises in it for the same reason that cork rises in water. These fee no cause why smoke should not rise in the chimney through the room over it as close. Others think there is a power in chimneys to draw up the smoke, and that there are different forms of chimneys which afford more or less of this power.

These amuse themselves with searching for the belt form. The equal dimensions of a funnel in its whole length is not thought artificial enough, and it is made, for fancied reasons, sometimes tapering and narrowing from below upwards, and sometimes the contrary, &c. &c. A simple experiment or two may serve to give more correct ideas. Having lighted a pipe of tobacco, plunge the item to the bottom of a decanter half filled with cold water; then putting a rag over the bowl, blow through it, and make the smoke descend in the item of the pipe, from the end of which it will rise in bubbles through the water; and being thus cooled, will not afterwards rise to go out through the neck of the decanter, but remain spreading itself and resting on the surface of the water. This shows that smoke is really heavier than air, and that it is carried upwards only when attached to or raised upon air that is heated, and thereby raised and rendered specifically lighter than the air in its neighborhood.

Smoke being rarely seen but in company with heated air, and its upward motion being visible, though that of the rarefied air that drives it is not so, has naturally given rise to the error. It is now well known that air is a fluid which has weight as well as others, though about 800 times lighter than water; that heat makes the particles of air recede from each other, and take up more space, so that the same weight of air heated will have more bulk than equal weights of cold air which may surround it; and in that case much rife, being forced upwards by such colder and heavier air, which prevails to get under it and take its place. That air is so rarefied or expanded by heat, may be proved to their comprehension by a lank blown blinder, which laid before a fire, will soon swell, grow light, and burst.

Another experiment may be to take a glass tube about an inch in diameter, 12 inches long, open at both ends, and fixed upright on legs so that it need not be handled, for the hands might warm it. At the end of a quill driven five or six inches of the finest light filament of silk, so that it may be held either above the upper end of the tube or under the lower end, your warm hand being at a distance by the length of the quill. If there were any motion of air through the tube, it would manifest itself by its effect on the quill; but if the tube and the air in it are of the same temperature with the surrounding air, there will be no such motion, whatever may be the form of the tube, whether crooked or straight, narrow below and widening upwards, or the contrary, the air in it will be quietest.

Warm the tube, and you will find as long as it continues warm, a constant current of air entering below and passing up through it till discharged at the top; because the warmth of the tube being communicated to the air it contains, makes it lighter than the air without: which therefore presses in below, forces it upwards, follows and takes its place, and is rarefied in its turn. And, without warming the tube, if you hold under it a knob of hot iron, the air thereby heated will rise and fill the tube, going out at its top; and this motion in the tube will continue as long as the knob remains hot, because the air entering the tube below, is heated and rarefied by passing near and over that knob.

That this motion is produced merely by the difference of specific gravity between the fluid within and that without the tube, and not by any fancied form of the tube itself, may appear by plunging it into water contained in a glass jar a foot deep, through which such motion might be seen. The water within and without the tube being of the same specific gravity, balance each other, and both remain at rest. But take out the tube, stop its bottom with a finger, and fill it with olive oil, which is lighter than water; then floating the top, place it as before, its lower end under water, its top a very little above. As long as you keep the bottom stopped the fluids remain at rest; but the moment it is unstop'd, the heavier enters below, forces up the lighter, and takes its place; and the motion then ceases, merely because the new fluid cannot be successively made lighter, as air may be by a warm tube.

In fact, no form of the funnel of a chimney has any thing in its operation but effect respecting smoke except its height. The longer the funnel, if erec't, the greater its force when filled with heated and rarefied air to draw in below and drive up the smoke, if one may, in compliance with custom, use the expression draw, when in fact it is the superior weight of the surrounding atmosphere that presses to enter the funnel below, and so drives up before it the smoke and warm air it meets with in its passage.

What is it then which makes a smoky chimney, that is, a chimney which, instead of conveying up all the smoke, discharges a part of it into the room, offending the eyes and damaging the furniture.

The causes of this effect may be reduced to nine, differing from each other, and therefore requiring different remedies.

1. Smoky chimneys in a new house are such frequently from mere want of air. The workmanship of the rooms being all good, and jut out of the workman's hands, the joints of the boards of the flooring, and of the pannels of wainscotting, are all true and tight; the more fo as
the walls, perhaps not yet thoroughly dry, preserve a dampness in the air of the room which keeps the wood work dwelled and close. The doors and the failes, too, being worked with truth, shut with exactness, so that the room is as tight as a stuff-box, no passage being left open for air to enter except the key-hole, and even that is sometimes covered by a little dropping shutter. Now if smoke cannot rise but as connected with rarefied air, and a column of such air, suppose it filling the funnel, cannot rise unless other air be admitted to supply its place; and if therefore no current of air enter the opening of the chimney—there is nothing to prevent the smoke from coming out into the room. If the motion upwards of the air in a chimney that is freely supplied, be observed by the rising of the smoke or a feather in it, and it be considered that in the time such feather takes in rising from the fire to the top of the chimney, a column of air equal to the content of the funnel must be discharged, and an equal quantity supplied from below, it will appear absolutely impossible that this operation should go on if the tight room is kept shut; for were there any force capable of drawing constantly so much air out of it, it must soon be exhausted like the receiver of an air-pump; and no animal could live in it. Tho these therefore who flop every crevice in a room to prevent the admission of fresh air, and yet would have their chimney carry up the smoke, require inconsistencies, and expect impossibilities. Yet under this situation it is not uncommon to see the owner of a new house in despair, and ready to sell it for much less than it costs; conceiving it uninhabitable because not a chimney in any one of its rooms will carry off the smoke unless a door or window be left open. Much expense has also been made to alter and amend new chimneys which had really no fault; in one house particularly which Dr. Franklin knew that belonged to a noted man in Wellminister, that expense amounted to no less than L. 200, after his house had been, as he thought, finished and all charges paid. And after all, several of the alterations were ineffectual, for want of understanding the true principles.

Remarks. When you find on trial that opening the door or a window enables the chimney to carry up all the smoke, you may be sure that want of air from without was the cause of its smoking. "I say from without" (adds Dr. Franklin), to guard you against a common mistake of those who may tell you the room is large, contains abundance of air sufficient to supply any chimney, and therefore it cannot be that the chimney wants air. These reasoning are ignorant that the large-ness of a room, if tight, is in this case of small importance, since it cannot with a chimney full of its air without occasioning so much vacuum; which it requires a great force to effect, and could not be borne if effected.

If appearing plainly then, that some of the outward air must be admitted, the question will be, how much is absolutely necessary? for you would avoid admitting more, as being contrary to one of your intentions in having a fire, viz. that of warming your room. To discover this quantity, shut the door gradually while a middling fire is burning, till you find that before it is quite shut the smoke begins to come out into the room; then open it a little till you perceive the smoke comes out no longer. There hold the door, and observe the width of the open crevice between the edge of the door and the rabbit it should shut into. Suppose the distance to be half an inch, and the door eight feet high; you find thence that your room requires an entrance for air equal to a surface of 46 half inches, or 48 square inches, or a passage of 6 inches by 8. This, however, is a large supposition; there being few chimneys that, having a moderate opening and a tolerable height of funnel, will not be satisfied with such a crevice of a quarter of an inch: Dr. Franklin found a square of 6 by 6, or 36 square inches, to be a pretty good medium that will serve for most chimneys. High funnels with small and low openings may indeed be supplied through a less space; because, for reasons that will appear hereafter, the force of levity, if one may so speak, being greater in such funnels, the cool air enters the room with greater velocity, and consequently more enters in the same time. This, however, has its limits; for experience shows, that no increased velocity so occasioned has made the admission of air, through the key-hole equal in quantity to that through an open door, though through the door the current moves slowly, and through the key-hole with great rapidity.

It remains then to be considered, how and where this necessary quantity of air from without is to be admitted so as to be least inconvenient: for if at the door, left too much open, the air thence proceeds directly to the chimney; and in its way comes cold to your back and heels as you sit before your fire. If you keep the door shut, and raise a little the fath of your window, you feel the same inconvenience. Various have been the contrivances to avoid this; such as bringing in fresh air through pipes in the jambs of the chimney, which pointing upwards should blow the smoke up the funnel; opening passages into the funnel above, to let in air for the same purpose. But these produce an effect contrary to that intended: for it is the constant current of air passing from the room through the opening of the chimney into the funnel which prevents the smoke from coming out into the room, if you supply the funnel by other means or in other ways with the air which it wants; and especially if that air be cold, you diminish the force of that current, and the smoke in its efforts to enter the room finds less resistance.

The wanted air must then indispensible be admitted into the room, to supply what goes off through the opening of the chimney. M. Gauger, a very ingenious and intelligent French writer on the subject, proposes with judgment to admit it above the opening of the chimney; and to prevent inconvenience from its coldness, he directs that it may be so made, that it shall pass in its entrance through winding cavities made behind the iron back and sides of the fire-place, and under the iron hearth plate; in which cavities it will be warmed, and even heated, so as to contribute much, instead of cooling, to the warming of the room. This invention is excellent in itself, and may be used with advantage in building new houses; because the chimneys may then be so disposed as to admit conveniently the cold air to enter such passages: but in houses built without such views, the chimneys are often so situated as not to afford that convenience without great and expensive alterations. Easy and cheap methods, though not quite so perfect in themselves, are of more general utility; and such are the following.
In all rooms where there is a fire, the body of air warmed and rarefied before the chimney is continually changing place, and making room for other air that is to be warmed in its turn. Part of it enters and goes up the chimney, and the rest rises and takes place near the ceiling. If the room be lofty, that warm air remains above our heads as long as it continues warm, and we are little benefited by it, because it does not descend until it is cooler. Few can imagine the difference of climate between the upper and lower parts of such a room, who have not tried it by the thermometer, or by going up a ladder till their heads are near the ceiling. It is then among this warm air that the coldness is abated, and its inconvenience diminished so as to become scarcely observable. This may be easily done by drawing down about an inch the upper half of a window; or, if not movable, by cutting such a crevice through its frame; in both which cases it will be well to place a thin pane of glass in one of your father's, set it in a tin frame, giving it two springing angular sides, and then replacing it, with hinges below on which it may be turned to open more or less above. It will then have the appearance of an internal sky-light. By drawing this pane in, more or less, you may admit what air you find necessary. Its position will naturally throw that air up and along the ceiling. This is what is called in France a [illegible]. As this is a German question, the invention is probably of that nation, and takes its name from the frequent asking of that question when it first appeared. In England some have of late years cut a round hole about five inches diameter in a pane of the sash, and placed against it a circular plate of tin hung on an axis, and cut into vanes; which, being separately beat a little oblique, are acted upon by the entering air, so as to force the plate continually round like the vanes of a windmill. This admits the outward air, and by the continual whirling of the vanes, does in some degree diffuse it. The noise only is a little inconvenient.

2. A second cause of the smoking of chimneys is, their openings in the room being too large; that is, too wide, too high, or both. Architects in general have no other ideas of proportion in the opening of a chimney than what relate to symmetry and beauty respecting the dimensions of the room; while its true proportion respecting its function and utility depends on quite other principles; and they might as properly proportion the step in a staircase to the height of the story, instead of the natural elevation of men's legs in mounting. The proportion then to be regarded, is what relates to the height of the funnel. For as the funnels in the different stories of a house are necessarily of different heights or lengths, that from the lowest floor being the highest or longest, and those of the other floors shorter and shorter, till we come to those in the garrets, which are of course the shortest; and the force of draft being, as already said, in proportion to the height of funnel filled with rarefied air, and a current of air from the room into the chimney, sufficient to fill the opening, being necessary to oppose and prevent the smoke from coming out into the room, it follows, that the openings of the longest funnels must be large, and that those of the shorter funnels should be smaller. For if there be a large opening to a chimney that does not draw strongly, the funnel may happen to be furnished with the air which it demands by a partial current entering on one side of the opening, and leaving the other side free of any opposing current, may permit the smoke to issue there into the room. Much too of the force of draft in a funnel depends on the degree of rarefaction in the air it contains, and that depends on the nearness to the fire of its passage in entering the funnel. If it can enter far from the fire on each side or far above the fire, in a wide or high opening, it receives little heat in passing by the fire, and the contents of the funnel are by those means less different in levity from the fire, undisturbing atmosphere, and its force in drawing consequently weaker. Hence if too large an opening be given to chimneys in upper rooms, those rooms will be smoky: On the other hand, if too small openings be given to chimneys in lower rooms, the entering air operating too directly and violently on the fire, and afterwards strengthening the draft as it attends the funnel, will consume the fuel too rapidly.

Remedy. As different circumstances frequently mix themselves in these matters, it is difficult to give precise dimensions for the openings of all chimneys. Our fathers made them generally much too large; we have lessened them; but they are often still of greater dimensions than they should be, the human eye not being easily reconciled to sudden and great changes. If you suspect that your chimney smokes from the too great dimension of its opening, contract it by placing movable boards so as to lower and narrow it gradually till you find the smoke no longer issues into the room. The proportion so found will be that which is proper for that chimney, and you may employ the bricklayer or mason to reduce it accordingly. However, as in building new houses something must be sometimes hazarded, Dr Franklin proposes to make the openings in the lower rooms about 30 inches square and 18 deep, and those in the upper only 18 inches square and not quite so deep; the intermediate ones diminishing in proportion as the height of the funnel is diminished. In the larger openings, billets of two feet long, or half the common length of cordwood, may be burnt conveniently; and for the smaller, such wood may be sawed into thirds. Where coals are the fuel, the grates will be proportioned to the openings. The same depth is nearly necessary to all, the funnels being all made of a size proper to admit a chimney-sweeper. If in large and elegant rooms custom or fancy should require the appearance of a larger chimney, it may be formed of expensive marginal decorations, in marble, &c. But in time perhaps, that which is fittest in the nature of things may come to be thought handiwork.

3. Another cause of smoky chimneys is too short a funnel. This happens necessarily in some cases, as where a chimney
S M O

a chimney is required in a low building; for, if the funnel be raised high above the roof, in order to strengthen its drafts, it is then in danger of being blown down, and crushing the roof in its fall.

Remedies. Contract the opening of the chimney, so as to oblige all the entering air to pass through or very near the fire; whereby it will be more heated and rarified, the funnel itself be more warmed, and its contents have more of what may be called the force of levity, so as to rise strongly and maintain a good draft at the opening.

Or you may in some cases, to advantage, build additional stories over the low building, which will support a high funnel.

If the low building be used as a kitchen, and a contraction of the opening therefore inconvenient, a large one being necessary, at least when there are great dinners for the free management of so many cooking utensils; in such case the best expedient perhaps would be to build two more funnels joining to the first, and having three moderate openings, one to each funnel, instead of one large one. When there is occasion to use but one, the other two may be kept shut by sliding plates, hereafter to be described; and two or all of them may be used together when wanted. This will indeed be an expense, but not an useless one, since your cooks will work with more comfort, fee better than in a smoky kitchen what they are about; your viands will be cleaner drest and not taint of smoke, as is often the case; and to render the effect more certain, a flack of three funnels may be safely built higher above the roof than a single funnel.

The cafe of too short a funnel is more general than would be imagined, and often found where one would not expect it. For it is not uncommon, in ill contrived buildings, instead of having a funnel for each room or fire-place, to bend and turn the funnel of an upper room so as to make it enter the side of another funnel that comes from below. By these means the upper room funnel is made short of course, since its length can only be reckoned from the place where it enters the lower room funnel; and that funnel is also shortened by all the distance between the entrance of the second funnel and the top of the flack: for all that part being readily supplied with air through the second funnel, adds no strength to the draft, especially as that air is cold when there is no fire in the second chimney. The only easy remedy here is, to keep the opening of that funnel shut in which there is no fire.

4. Another very common cause of the smoking of chimneys is, their overpowering one another. For instance, if there be two chimneys in one large room, and you make fires in both of them, the doors and windows close shut, you will find that the greater and stronger fire shall overpower the weaker, from the funnel of which it will draw air down to supply its own demand; which air descending in the weaker funnel, will drive down its smoke, and force it into the room. If, instead of being in one room, the two chimneys be in two different rooms, communicating by a door, the cafe is the same whenever that door is open. In a very tight house, a kitchen chimney on the lowest floor, when it had a great fire in it, has been known to overpower any other chimney in the house, and draw air and smoke into its room as often as the door communicating with the stair-case was opened.

Remedy. Take care that every room have the means of supplying itself from without with the air which its chimney may require, so that no one of them may be obliged to borrow from another, nor under the necessity of lengthening. A variety of these means have been already described.

5. Another cause of smoking is, when the tops of chimneys are commanded by higher buildings, or by a hill, so that the wind blowing over such eminences falls like water over a dam, sometimes almost perpendicularly on the tops of the chimneys that lie in its way, and beats down the smoke contained in them.

To illustrate this, let A (fig. 3.) represent a small building at the side of a great rock B, and the wind coming in the direction CD; when the current of air comes to the point D, being hurried forward with great velocity, it goes a little forward, but soon descends downward, and gradually is reflected more and more inward, as represented by the dotted lines EE, &c. so that, descending downwards upon the top of the chimney A, the smoke is beat back again into the apartments.

It is evident that houses situated near high hills or thick woods will be in some measure expos’d to the same inconvenience; but it is likewise plain, that if a house be situated upon the slope of a hill (as at F, fig. 3.), it will not be in any danger of smoke when the wind blows towards that side of the hill upon which it is situated; for the current of air coming over the house-top in the direction GH, is immediately changed by the slope of the hill to the direction HC, which powerfully draws the smoke upward from the top of the chimney. But it is also evident, that a house in this situation will be liable to smoke when the wind blows from the hill; for the current of air coming downward in the direction CH, will beat downward on the chimney F, and prevent the smoke from ascending with freedom. The effect will be much heightened if the doors and windows are chiefly in the lowermost side of the house.

Remedy. That commonly applied to this case is a turn-cap made of tin or plate iron, covering the chimney above and on three sides, open on one side, turning on a spindle; and which, being guided or governed by a vane always presents its back to the current. This may be generally effectual, though not certain, as there may be cases in which it will not succeed. Raising your funnels if practicable, so as their tops may be higher, or at least equal, with the commanding eminence, is more to be depended on. But the turning cap, being easier and cheaper, should first be tried. "If obliged to build in such a situation, I would choose (says Dr Franklin) to place my doors on the side next the hill, and the backs of my chimneys on the farthest side; for then the column of air falling over the eminence, and of course preffing on that below, and forcing it to enter the doors or wind-inf-arces on that side, would tend to balance the pressure down the chimneys, and leave the funnels more free in the exercise of their functions."

6. There is another case which is the reverse of that last mentioned. It is where the commanding eminence
To explain this figure may be necessary. Suppose a chimney being built whose side AB happens to be exposed to the wind, and forms a kind of dam against its progress. Suppose the wind blowing in the direction EF. The air obstructed by this dam or building AB will, like water waves, pass through it; but finding none, it is beat back with violence, and spreads itself on every side, as is represented by the curved lines. It will therefore force itself down the small chimney C, in order to get through by some door or window open on the other side of the building. And if there be a fire in such chimney, its smoke is of course beat down, and fills the room.

There is but one remedy, which is to raise such a funnel higher than the roof, supporting it if necessary by iron bars. For a turncap in this case has no effect, the dammed up air pressing down through it in whatever position the wind may have placed its opening.

Dr. Franklin mentions a city in which many houses are rendered smoky by this operation. For their kitchens being built behind, and connected by a passage with the houses, and the tops of the kitchen-chimneys lower than the tops of the houses, the whole side of a street when the wind blows against its back forms such a dam as above described; and the wind so obstructed forces down those kitchen-chimneys (especially when they have but weak fires in them) to pass through the passage and house into the street. Kitchen-chimneys so formed and situated have another inconvenience. In summer, if you open your upper room windows for air, a light breeze blowing over your kitchen chimney towards the house, though not strong enough to force down its smoke as before, is sufficient to waft it into your windows, and fill the rooms with it; which, besides the disagreeableness, damages your furniture.

Chimneys, otherwise drawing well, are sometimes made to smoke by the improper and inconvenient situation of a door. When the door and chimney are on the same side of the room, if the door being in the corner is made to open against the wall, which is common, as being there, when open, more out of the way, it follows, that when the door is only opened in part, a current of air rushing in paffes along the wall into and across the opening of the chimney, and flits some of the smoke out into the room. This happens more certainly when the door, is flutting, for then the force of the current is augmented, and becomes very inconvenient to those who, warming themselves by the fire, happen to sit in its way.

The remedy is obvious and easy. Either put an intervening screen from the wall round great part of the fireplace; or, which is perhaps preferable, shift the position of your door, so as it may open the other way, and when open throw the air along the other wall.

A room that has no fire in its chimney is sometimes filled with smoke which is received at the top of its funnel and descends into the room. Funnels without fires have an effect according to their degree of coldness or warmth on the air that happens to be contained in them. The surrounding atmosphere is frequently changing its temperature; but flocks of funnels covered with winds and fun by the house that contains them, retain a more equal temperature. If, after a warm season, the outside air suddenly grows cold, the empty warm funnels begin to draw strongly upward; that is, they rarely admit the air in the chamber, which of course rises, cooler air enters below to supply its place, is rared up in its turn, and rises; and this operation continues till the funnel grows cooler, or the outward air warmer, or both, when the motion ceases. On the other hand, if after a cold season the outward air suddenly grows warm and of course lighter, the air contained in the cool funnels being heavier descends into the room; and the warmer air which enters their tops being cooled in its turn, and made heavier, continues to descend; and this operation goes on till the funnels are warmed by the palling of warm air through them, or the air itself grows cooler. When the temperature of the air and of the funnels is nearly equal, the difference of warmth in the air between day and night is sufficient to produce these currents: the air will begin to ascend the funnels, as the cool of the evening comes on, and this current will continue till perhaps nine or ten o'clock the next morning, when it begins to heat up; and as the heat of the day approaches, it sets downwards, and continues so till towards evening, when it again heats up for some time, and then goes upwards constantly during the night, as before mentioned. Now when smoke issuing from the tops of neighbouring funnels passes over the tops of funnels which are at the time drawing downwards, as they often are in the middle part of the day, such smoke is of necessity drawn into these funnels, and descends with the air into the chamber.

The remedy is to have a sliding plate that will shut perfectly the offending funnel. Dr. Franklin has thus described it: ‘The opening of the chimney is contracted by brick-work faced with marble flaps to about two feet between the jams, and the brick brought down to within about three feet of the hearth. An iron frame is placed just under the bread, and extending quite to the back of the chimney, so that a plate of the same metal may slide horizontally, backwards and forwards in the grooves on each side of the frame. This plate is just so large as to fill the whole space, and shut the chimney entirely when shut quite in, which is convenient when there is no fire. Draw it out, so as to leave between its further edge and the back a space of about two inches; this space is sufficient for the smoke to pass; and so large a part of the funnel being left open by the rest of the plate, the passage of warm air out of the room, up the chimney, is obstructed and retarded; and by those means much cold air is prevented from coming in through crevices, to supply its place. The effect is made manifest three ways. 1. When the fire burns briskly in cold weather, the howling or whistling noise made by the wind, as it enters the room through the crevices, when the chimney is open as usual, ceases as soon as the plate is slid into its proper distance. 2. Opening the door of the room about half an inch, and holding your hand against the opening, near the top of the door, you feel the cold air coming in against your hand, but weakly, if the plate be in. Let another person suddenly draw it out, so as to let the air of the room go up the chimney, with its usual freedom where chimneys are open, and you immediately feel the cold air rushing in strongly. 3. If something be set against the door, just sufficient, when the plate is in, to keep the door nearly shut, by refusing the pressure of the air.
air that would force it open; then, when the plate is drawn out, the door will be forced open by the increased preffure of the outward cold air endeavouring to get in to supply the place of the warm air that now passes out of the room to go up the chimney. In our common open chimneys, half the fuel is wafted, and its effect loft; the air it has warmed being immediately drawn off.

9. Chimneys which generally draw well, do nevertheless sometimes give smoke into the rooms, it being driven down by strong viols passing over the tops of their funnels, though not depending from any commanding eminence. This case is most frequent where the funnel is short and the opening turned from the wind. It is the more grievous, when it happens to be a cold wind that produces the effect, because when you most want your fire you are sometimes obliged to extinguish it. To understand this, it may be considered that the rising light air, to obtain a free issue from the funnel, must pull out of its way or oblige the air that is over it to rise. In a time of calm or of little wind this is done visibly; for we see the smoke that is brought up by that air in a column above the chimney: but when a violent current of air, that is, a strong wind, passes over the top of a chimney, its particles have received so much force, which keeps them in a horizontal direction and follow each other so rapidly, that the rising light air has not strength sufficient to oblige them to quit that direction and move upwards to permit its issue.

Remedies. In Venice, the custom is to open or widen the top of the fine rounding it in the true form of a funnel. In other places the contrary is practised; the tops of the flues being narrowed inwards, so as to form a slit for the issue of the smoke, long as the breadth of the funnel, and only four inches wide. This seems to have been contrived on a supposition that the entry of the wind would thereby be obstructed, and, perhaps it might have been imagined, that the whole force of the rising warm air being condensed, as it were, in the narrow opening, would thereby be strengthened, so as to overcome the refistance of the wind. This, however, did not always succeed; for when the wind was at north-eaft and blew fresh, the smoke was forced down by fits into the room where Dr Franklin commonly sat, so as to oblige him to shift the fire into another. The position of the slit of this funnel was indeed north-eaft and south-west. Perhaps if it had lain across the wind, the effect might have been different. But on this we can give no certainty. It seems a matter proper to be referred to experiment. Possibly a turncap might have been serviceable, but it was not tried.

With all the science, however, that a man shall suppose himself possessed of in this article, he may sometimes meet with cafes that shall puzzle him. "I once lodged (says Dr Franklin) in a house at London, which in a little room had a single chimney and funnel. The opening was very small, yet it did not keep in the smoke, and all attempts to have a fire in this room were fruitless. I could not imagine the reason, till at length observing that the chamber over it, which had no fireplace in it, was always filled with smoke when a fire was kindled below, and that the smoke came through the cracks and crevices of the wainscot; I had the wainscot taken down, and discovered that the funnel which went up behind it had a crack many feet in length, and wide

enough to admit my arm; a breach very dangerous with regard to fire, and occasioned probably by an apparent irregular settling of one side of the house. The air entering this breach freely, destroyed the drawing force of the funnel. The remedy would have been, filling up the breach, or rather rebuilding the funnel: but the landlord rather chose to stop up the chimney."

Another puzzling cafe I met with at a friend's country house near London. His bedroom had a chimney in which he told me, he never could have a fire, for all the smoke came out into the room. I flattered myself I could easily find the cause and prescribe the cure. I had a fire made there, and found it as he said. I opened the door, and perceived it was not want of air. I made a temporary contraction of the opening of the chimney, and found that it was not its being too large that caused the smoke to issue. I went out and looked up at the top of the chimney: Its funnel was joined in the same fork with others; some of them being shorter, that drew very well, and I saw nothing to prevent its doing the same. In fine, after every other examination I could think of, I was obliged to own the insufficiency of my skill. But my friend, who made no pretension to such kind of knowledge, afterwards discovered the cause himself. He got to the top of the funnel by a ladder, and looking down found it filled with twigs and straw cemented by earth and lined with feathers. It seems the house, after being built had stood empty some years before he occupied it; and he concluded that some large birds had taken the advantage of its retired situation to make their nest there. The rubbish, considerable in quantity, being removed, and the funnel cleared, the chimney drew well, and gave satisfaction."

Chimneys whose funnels go up in the north wall of a house, and are exposed to the north winds, are not so apt to draw well as those in a south wall; because when rendered cold by those winds, they draw downwards. Chimneys inclosed in the body of a house are better than those whose funnels are exposed in cold walls.

Chimneys in slots are apt to draw better than separate funnels, because the funnels that have constant fires in them warm the others in some degree that have none.

Smoke-fuck. This ingenious machine is of German extraction; and Meffinger, in his Collecles of Mechaniical Performances, says it is very ancient, being represented in a painting at Nuremberg, which is known to be older than the year 1530.

Its construction is abundantly simple. An upright iron spindle GA (fig. 5.), placed in the narrow part of the kitchen chimney, turns round on two pivots I and L. The upper one H passes through an iron bar, which is built in across the chimney; and the lower pivot I is of tempered steel, and is conical or pointed, reeling in a conical bell-metal socket fixed on another crofs bar. On the upper end of the spindle is a circular gdy G, consisting of 4, 5, 6, or more thin iron plates, fast obliquely on the spindle like the rails on a grindmill, as we shall describe more particularly by and by. Near the lower end of the spindle is a pinion A, which works in the teeth of a contrate or face wheel B, turning on a horizontal axis BC. One pivot of this axis turns in a cock fixed on the crofs bar, which supports the lower end of the upright spindle III, and the other pivot

that the
fly G makes from 12 to 20 turns for one turn of
the
spit.
The
manner of operation of this useful machine
is
easily understood.
The air which contributes to the burning
of the fuel, and passes through the middle of it,
is greatly heated, and expanding prodigiously in bulk,
becomes lighter than the neighbouring air, and is there-
fore pulled by it up the chimney. In like manner, all
the air which comes near the fire is heated, expanded,
becomes lighter, and is driven up the chimney.
It is
called the draught or suction, but would with greater
propriety be termed the drift of the chimney. As
the chimney gradually contracts in its dimensions,
and as the same quantity of heated air passes through
every section of it, it is plain that the rapidity of its
ascent must be greatest in the narrowest place. There the
fly G should be placed, because it will then be exposed
to the strongest current. This air, striking the fly vanes
obliquely, pulls them aside, and thus turns them round
with a considerable force. If the joint of meat is
exactly balanced on the spit, it is plain that the only
resistance to the motion of the fly is that which arises
from the friction of the pivots of the upright spindle,
the friction of the pin and wheel, the friction of the pivots
of the horizontal axis, the friction of the small end of the
spit, and the friction of the chain in the two pulleys.
The whole of this is but a mere trifle. But there is
frequently a considerable superiority in the weight of the
spit on different sides of the fly; that must therefo-
re be a sufficient re-straint in the impulsus of the
ascending air on the vanes of the fly, to over-
come this want of equilibrium occasioned by the unskill-
fulness or negligence of the cook. There is, how-
erver, commonly enough of power when the machine is
properly contrived. The utility of this machine will,
we hope, procure us the indulgence of some of our
readers, while we point out the circumstances on which
its performance depends, and the maxims which should
be followed in its construction.

The upward current of air is the moving power, and
should be increased as much as possible, and applied
in the most advantageous manner. Every thing will in-
crease the current which improves the draught of the
chimney, and figures it from-smoking. A defective
chimney must always have a weak current. For this par-
ticular, therefore, we refer to what has been delivered in
the article

While apposing to the manner of applying this force,
it is evident that the belt construction of a windmill fails
will be nearly the best construction for the fly. Ac-
ting to the usual theory of the impulse of fluids,
It is always of importance to avoid this slipping of the chain by balancing the loaded spit. For this purpose it will be extremely convenient to have what is called a balance fower. Let a part of the spit, immediately adjoining to the pulley, be made round, and let an arm be made to turn on it freely, so that it may be made fast in any position by a screw. Let a leaden ball be made to slide along this arm, with a screw to fasten it at any distance from the spit. When the meat is spitted, lay it on the racks, and the heaviest side will immediately place itself underfoot. Now turn round the balance-fower, so that it may point straight upwards, and make it fast in that position by the screw. Put the leaden ball on it, and slide it inwards or outwards till it exactly balances the heavy side, which will appear by the spit's remaining in any position in which it is put.

The greatest difficulty is to keep the machine in repair. The most confidential part of it, the first mover, the fly, and the pinion and wheel, by which its motion is transmitted to the rest of the machine, are situated in a place of difficult access, and where they are exposed to violent heat and to the smoke and foot. The whole weight of the fly, resting on the lower pivot, must exert a great pressure there, and occasion great friction, even when this pinion is reduced to the smallest size that is compatible with the necessary strength. The pivot must be of hardened steel, tapered, like an obtuse cone, and must turn in a conical socket, also of hardened steel or of bell metal; and this sort of pressure and friction must be continually supplied with oil, which it consumes very quickly. It is not sufficient that it be from time to time smeared with an oiled feather; there must be an iron cup formed round the socket, and kept filled with oil. It is surprising how quickly it disappears: it soon becomes clammy by evaporation, and by the foot which gathers about it. The continued rubbing of the pivot and socket wears them both very fast; and this is increased by hard powders, such as sandy duff, that are hurried up by the rapid current every time that the cook lights the fire. These, getting between the rubbing parts, cause them to grind and wear each other prodigiously. It is a great improvement to invent these rubbing parts. Let the lower end of the spindle be of a considerable thickness, and have a conical hollow nicely drilled in its extremity. Let a blunt pointed conical pin rise up in the middle of the oil-cup, on which the conical hollow of the spindle may rest. Here will be the same steady support, and the same friction as in the other way; but no grinding duff can now lodge between the pivot and its socket: and if this upright pin be screwed up through the bottom of the cup, it may be screwed farther up in proportion as it wears; and thus the upper pivot will never defect its hole, a thing which soon happens in the common way. We can say from experience, that a jack constructed in this way will not require the fifth part of the repairs of one done in the other way.

It is of importance that the whole be so put together as to be easily taken down, in order to sweep the vent, or to be repaired, &c. For this purpose, let the crofs bar which carries the lower end of the straight spindle be placed a little on one side of the perpendicular line from the upper pivot hole. Let the crofs which
The incidents that befell him during his continuance in this capacity served as a foundation for Roderic Random, one of the most entertaining novels in the English tongue. He was present at the siege of Carthage; and in the before-mentioned novel he has given a faithful, though not very pleasing, account of the management of that ill-conducted expedition, which he censures in the warmest terms, and from circumstances which fell under his own particular observation.

His connection with the sea seems not to have been of long continuance; and it is probable that he wrote several pieces before he became known to the public by his capital productions. The first piece we know of with certainty is a Satire in two parts, printed first in the years 1746 and 1747, and reprinted in a Collection of Plays and Poems in 1777. About this period, or some time before, he wrote for Mr Rich an opera intitled Alcist, which has never been performed nor printed.

At the age of 38 he wrote a tragedy intitled The Regicide, founded on the story of the assassination of James I. of Scotland. In the preface to this piece, published by subscription in the year 1749, he bitterly exclaimed against false patrons, and the duplicity of theatrical managers. The warmth and impetuosity of his temper hurried him, on this occasion, into unjust reflections against the late George Lord Lyttleton and Mr Garrick: the character of the former he characterized in the novel of Peregrine Pickle, and he added a burlesque of the monody written by that nobleman on the death of his lady. Against Mr Garrick he made illiberal ill-founded criticisms; and in his novel of Roderic Random gave a very unfair representation of his treatment of him respecting this tragedy. Of this conduct he afterwards repented, and acknowledged his errors; though in the subsequent editions of the novel the passages which were the bulky effusions of disappointment are not omitted.

However, in giving a sketch of the liberal arts in his history of England, he afterwards remarked, "the exhibitions of the stage were improved to the most exquisite entertainment by the talents and management of Garrick, who greatly surpassed all his predecessors of this and perhaps every other nation, in his genius for acting, in the sweetness and variety of his tones, the irresistible magic of his eye, the fire and vivacity of his action, the eloquence of attitude, and the whole pathos of expression."

"Candidates for literary fame appeared even in the higher sphere of life, embellished by the nervous sente and extensive erudition of a Corke; by the delicate talents, the polished muse, and the tender feelings, of a Lyttleton." Not satisfied with this public declaration, he wrote an apology, to Mr Garrick in still stronger terms. With these ample concessions, Mr Garrick was completely satisfied; so that in 1757, when Mr Smollett's comedy of the Refrains, an afterpiece of two acts, was performed at Drury Lane theatre, the latter acknowledged himself highly obliged for the friendly care of Mr Garrick, exalted in preparing it for the stage; and still more for his acting the part of Lafignan in Zara for his benefit, on the sixth instead of the ninth night, to which he was only intitled by the custom of the theatre.

The Adventures of Roderic Random, published in 1748, 2 vols 12mo, a book which still continues to have a most extensive

extensive sale first established the Doctor’s reputation. All the first volume and the beginning of the second appears to consist of real incident and character, the certain good deal heightened and digusted. The Judge his grandfather, Crab and Potion the two apothecaries, and Sir Gregewy were characters well known in that part of the kingdom where the scene was laid. Captains oakum and Whipple, Doctors Mackshane and Morgan, were also said to be real personages; but their names we have either never learned or have new forgotten. A bookbinder and barber long eagerly contended for being shadowed under the name of Strap. The Doctor seems to have enjoyed a peculiar felicity in describing sea characters, particularly the officers and sailors of the navy. His Trinumin, Harchway, and Pipes, are highly finished originals; but what exceeds them all, and perhaps equals any character that has yet been painted by the happiest genius of ancient or modern times, is his Lieutenant Bowling. This is indeed nature itself, original, unique, and of genius.

By the publication of this work the Doctor had acquired so great a reputation, that henceforth a certain degree of success was insured to every thing known or suspected to proceed from his hand. In the course of a few years, the Adventures of Peregrine Pickle appeared; a work of great ingenuity and contrivance in the composition, and in which an uncommon degree of erudition is displayed, particularly in the description of the entertainment given by the Republican Doctor, after the manner of the ancients. Under this preface the late Dr Akinade, author of The Pleasures of Imagination, is supposed to be typified; and it would be difficult to determine whether profound learning or genuine humour predominated most in this episode. Another episode of the Adventures of a Lady of Quality, likewise inferred in this work, contributed greatly to its success, and is indeed admirably executed; the materials, it is said, the lady herself (the celebrated lady Van) furnished.

There were not the only original compositions of this stamp with which the Doctor has favoured the public; Sir James French, and Sir Lawrence Greaves, are still in the list of what may be called running novels, and have gone through several editions; but there is no injustice in placing them in a rank far below the former. No doubt invention, character, composition, and contrivance, are to be found in both; but then situations are described which are hardly possible, and characters are painted which, if not altogether unexampled, are at least incompatible with modern manners; and which ought not to be, as the scenes are laid in modern times.

The last work which we believe the Doctor published was of much the same species, but cut into a different form—The Expedition of Humphry Clinker. It consists of a series of letters, written by different personages to their respective correspondents. He has here carefully avoided the faults which may be justly charged to his two former productions. Here are no extravagant characters or unnatural situations. On the contrary, an admirable knowledge of life and manners is displayed; and most useful lessons are given applicable to interesting but to very common situations.

We know not whether the remark has been made,
health was continuing to decline, and meeting with fresh molestations and disappointments, he went back to Smollett, Italy, where he died in October 21, 1771. He was employed, during the last years of his life, in abridging the Modern Universal History, great part of which he had originally written himself, particularly the histories of France, Italy, and Germany.

He certainly met with many mortifications and disappointments; which, in a letter to Mr Garrick, he thus feelingly expresses: "I am old enough to have seen and observed, that we are all playthings of fortune; and that it depends upon something as insignificant and precarious as the tossing up of a halfpenny, whether a man rises to influence and honours, or continues to his dying day struggling with the difficulties and disgrace of life."

It would be needless to expatiate on the character of a man so well known as Dr Smollet, who has, besides, given so many strictures of his own character and manner of living in his writings, particularly in Humphrey Clinker; where he appears under the appellation of Mr Serf, and has an interview with Mr Bramble; and his manner of living is described in another letter, where young Melford is supposed to dine with him at his house in Chelsea. No doubt he made money by his connections with book-fellers; and he had been a rigid economist, or ended with the gift of retention (an expression of his own), he might have lived and died very independent. However, to do justice to his memory, his difficulties, whatever they were, proceeded not from extravagance or want of economy. He was hospitable, but not ostentatiously so; and his table was plentiful, but not extravagant. No doubt he had his failings; but still it would be difficult to name a man who was so respectable for the qualities of his head, or more amiable for the virtues of his heart.

Since his death a monument has been erected to his memory near Leghorn, on which is inscribed an epitaph written in Latin by his friend Dr Arm-ington, author of The Art of Preserving Health, and many other excellent pieces. An inscription written in Latin was likewise inscribed on a pillar erected to his memory on the banks of the Leven, by one of his relations.

To these memoirs we are extremely sorry to add, that so late as 1785 the widow of Dr Smollet was residing in indigent circumstances at Leghorn. On this account the tragedy of Venice Preferred was acted for her benefit at Edinburgh on the 5th of March, and an excellent prologue spoken on that occasion.

The pieces inserted in this posthumous collection of Dr Smollet's plays and poems are, The Regicide, a tragedy; The Repriël, a comedy; Advice and Reproof, two faires; The Tears of Scotland; Verses on a Young Lady; a Love Elegy, in imitation of Tibullus; two Songs; a Burlesque Ode; Odes to Mirth, to Sleep, to Leven Water, to Blue-eyed Ann, and to Independence.

SMUGGLERS, persons who import or export prohibited goods without paying the duties appointed by the law. The duties of smugglers, it is said, were originally instituted, in order to enable the government to afford protection to trade against pirates; they have since been continued as a branch of the public revenue. As duties
S M U

imposed upon the importation of goods peculiarly raises their price above what they might otherwise have been for, a temptation is presented to import the commodity clandestinely and to evade the duty. Many persons, prompted by the hope of gain, and considering the violation of a positive law of this nature as in no respect criminal (an idea in which they have been encouraged by a great part of the community, who make no scruple to purchase smuggled goods), have engaged in this illicit trade. It was impossible that government could permit this practice, which is highly injurious to the fair trader, as the smuggler is enabled to undersell him, while at the same time he impairs the national revenue, and thus wholly destroys the end for which these duties were appointed. Such penalties are therefore inflicted as it was thought would prevent smuggling.

Many laws have been made with this view. If any goods be shipped or landed without warrant and presence of an officer, the vessel shall be forfeited, and the wharfinger shall forfeit L. 100, and the master or mariner of any ship inward bound shall forfeit the value of the goods; and any carman, porter, or other affilting, shall be committed to gaol, till he find surety of the good behaviour, or until he shall be discharged by the court of exchequer (13 & 14 C. II. c. 11.) If goods be relanded after drawback, the vessel and goods shall be forfeited; and every person concerned therein shall forfeit double the value of the drawback (8 An. c. 13.)

Goods taken in at sea shall be forfeited, and also the vessel into which they are taken; and every person concerned therein shall forfeit treble value (9 G. II. c. 35.) A vessel hovering near the coast shall be forfeited, it under 50 tons burden; and the goods shall also be forfeited, or the value thereof (5. G. III. c. 43.) Persons receiving or buying run goods shall forfeit L. 20 (8 G. c. 18.) A concealer of run goods shall forfeit treble value (8 G. c. 18.) Offering run goods to sale, the same shall be forfeited, and the person to whom they are offered may seize them; and the person offering them shall forfeit treble value (11 G. c. 30.) A porter or other person carrying run goods shall forfeit treble value (9 G. II. c. 35.) Persons armed or disguised carrying run goods shall be guilty of felony, and transported for seven years (8 G. c. 18. 9 G. II. c. 35.)

But the last statute, 19 G. II. c. 34. is for this purpose in vante omium; for it makes all forcible acts of smuggling, carried on in defiance of the laws, or even in disguise to evade them, felony without benefit of clergy: enabling, that if three or more persons shall assist, with fire-arms or other offensive weapons, to affist in the illegal importation or exportation of goods, or in refusing the same after seizure, or in refusing offenders in custody for such offences; or shall pass with such goods in disguise; or shall wound, shoot at, or assault, any officers of the revenue when in the execution of their duty; such persons shall be felons, without the benefit of clergy.

When we consider the nature, and still more the history of mankind, we must allow that the enacting of severe penal laws is not the way to prevent crimes. It was much to be wished that there were no such thing as a political crime; for the generality of men, and especially the lower orders, not differing in the propriety or utility of such laws, consider them as a positive and tyrannical, and never hesitate to violate them when they can do it with impunity. Instead therefore of punishing smugglers, it would be much better to reduce the high duties which have been imposed upon the importation of different sorts of foreign goods, in order to discourage their consumption in Great Britain; because in many cases served only to encourage smuggling; and in all cases have reduced the revenue of the customs below what moderate duties would have afforded. The laying of the Swift, that in the arithmetic of the customs two and two, instead of making four, makes sometimes only one, holds perfectly true with regard to such heavy duties, which never could have been imposed, had not the mercantile system taught us, in many cases, to employ taxation as an instrument, not of revenue, but of monopoly.

The bounties which are sometimes given upon the exportation of home produce and manufactures, and the drawbacks which are paid upon the re-exportation of the greater part of foreign goods, have given occasion to many frauds, and to a species of smuggling more destructive of the public revenue than any other. In order to obtain the bounty or drawback, the goods, it is well known, are sometimes shipped and sent to sea, but soon afterwards clandestinely relanded in some other part of the country.

Heavy duties being imposed upon almost all goods imported, our merchant importers smuggle as much, and make entry of as little as they can. Our merchant-exporters, on the contrary, make entry of more than they export; sometimes out of vanity, and to pass for great dealers in goods which pay no duty; and sometimes to gain a bounty or a drawback. Our exports, in consequence of these different frauds, appear upon the custom-house books greatly to overbalance our imports; to the unspeakable comfort of those politicians who measure the national prosperity by what they call the balance of trade.

S M U, in husbandry, a disease in corn, when the grains, instead of being filled with flour, are full of a blackish powder. See Wheat.

SMYRNA, or ISMI, is preeminent the largest and richest city of Asia Minor, is situated in north latitude 38° 28', and in E. Long. 27° 25' from Greenwich, and about 172 miles west by south of Constantinople. The town extends along the shore about half a mile on a gentle declivity. The houses of the English, French, and Dutch consuls are handsomely situated; these, with most of those occupied by the Christian merchants, are walled on one side by the sea, forming a street named Frank-street, from its being solely inhabited by European Christians. In the year 1753 the whole of this quarter was confiscated by fire; the flocks sustained by this calamity in merchant was estimated at a million and a half of Turkish dollars, or near L. 200,000 Sterling. The port is one of the finest of the Levant, it being able to contain the largest fleet; and indeed there are seldom in it fewer than 100 ships of different nations.

A cable lands at its entrance, and commands all the Payne, which fall in or out. There is likewise an old Grand Canal, near a mile in circumference, which lands ships in the upper part of the city, and, according to tradition,
Smyrna [ 560 ]

Smyrna, was built by the empress Helen; and near it is an ancient structure, said to be the remains of a palace where the Greek council was held when Smyrna was the metropolis of Asia Minor. They also show the ruins of an amphitheatre, where it is said St Polycarp, the first bishop, fought with lions.

This city is about four miles in circumference, and near it is a triangular form; but the side next the mountain is much longer than the other sides. The houses are low, and mostly built with clay-walls, although a continued basar, in which a great part of the mercantile of Europe and Asia is exported, with plenty of provisions; though these are not so cheap as in many other parts of Turkey, on account of the population of the place, and the great resort of foreigners. It is said to contain 15,000 Turks, 10,000 Greeks, 1,800 Jews, 200 Armenian, and 200 Franks. The Turks have nine mosques; two churches belonging to the Greeks; one to the Armenians; and the Jews have eight synagogues. The Romanists have three convents. There is also one of the fathers Della Terra Santa. Here resides an archbishop of the Greek church; a Latin bishop who has a salary from Rome, with the title of bishop of Smyrna in partibus infidelium; and the English and Dutch factories have each their chaplain.

The walks about the town are extremely pleasant, particularly on the west side of Frank street, where there are several little groves of orange and lemon trees, which being always clothed with leaves, blossoms, and fruits, regard several of the fountains at the same time. The vines which cover the little hills about Smyrna afford both a delightful prospect and plenty of grapes, not which good wine is made. These hills are agreeably interspersed with fertile plains, little forests of olives and other fruit-trees, and many pleasure-houses, to which the Franks usually retire during the summer. In the neighbourhood of Smyrna is a great plenty of game and wild-fowl, and particularly deer and wild-hogs. The sea also abounds with a variety of good fish. The European Christians are here allowed all imaginable liberties, and usually clothe themselves after the European manner.

The chief commerce of this city consists in raw silk, silk-bluffs, proverbs, and cotton yarn. However, the unhealthfulness of the situation, and more especially the frequent earthquakes, from which it is said, they are scarcely ever free for two years together, and which have been felt 40 days successively, are an abatement of the pleasure that might otherwise be enjoyed here. A very dreadful one happened in June 1688, which overthrew a great number of the houses; and the rock opening where the cisterns, swallowed it up, and no less than 3000 persons perished in this occurrence.

In the year 1758, to deploring a plague raging here, that feared a sufficient number of the inhabitants survived to gather in the fruits of the earth. In the year 1772, three-fourths of the city were consumed by fire; and 5 years after it was visited by the most dreadful earthquakes, which continued from the 25th of June to the 7th of July; by which successive calamities the city had been so much reduced, that its former consequence is never likely to be restored.

The ladies here wear the oriental dress, consisting of large trowsers or breeches, which reach to the ankle; long veils of rich silk or velvet, lined in winter with costly furs; and round their waist an embroidered zone with clasps of silver or gold. Their hair is platêt, and defended down the back often in great profusion. The girls have sometimes above twenty thick trefoils, besides two or three encircling the head as a coronet, and set off with flowers and plumes of feathers, pearls, or other jewels. They commonly inlet it of a chestnut colour, which is the most desired. Their apparel and carriage are alike antique. It is remarkable that the trowsers are mentioned in a fragment of Sopho as part of the female dress.

Smyrnioum. Alexanders: A genus of plants belonging to the class of pannoniace, and to the order of clipeata; and in the natural syfem ranging under the 45th order, Umbellata. The fruit is oblong and ariated; the petals have a sharp point, and are keel-shaped. There are five species: 1. The perlfoliata, or perlolate alexanders, which is a native of Canda and Italy; 2. The nigrum, or golden alexanders, which is a native of North America; 3. The inconstans; 5. The olfaxum, common alexanders, a native of Britain; the leaves of which are cauline, ter-rate petiolated, and ferrated. It grows on the sea-coast at Dunkens on the borders of Berwickshire North Britain. Since the introduction of celery into the garden, the alexanders is almost forgotten. It was formerly cultivated for salading, and the young shoots or flaks blanched were eaten either raw or stewed. The leaves too were boiled in broths and soups. It is a warlike comfortable plant to a cold weak stomach, and was in much esteem among the monks, as may be inferred by its still being found in great plenty by old abbey walls.

Snaffle, in the manage, is a very slender bit-mouth without any branches, much used in England; the true bridles being reserved for war.

Snail, in zoology. See Helix and Limax.

Snake, in zoology. See Anguis and Serpents.

Method of Preparing Snakes. When the snake is killed, it must first be washed clean, and freed from all filth and naftines; then it is to be put into a glafs of a proper size, the tail first, and afterwards the rest of the body, winding it in spirals ascending circles, and disposing the back which is always the most beautiful, outwardly. A thread connected with a small glass head, is, by the help of a needle, to be passed through the upper jaw from within outwardly, and then through the cork of the bottle, where it must be fastened; by this means the head will be drawn into a natural posture, and the mouth kept open by the head, whereby the teeth, &c. will be discovered: the glass is then to be filled with rum, and the cork sealed down to prevent its exhalation. A label, containing the name and properties of the snake, is then to be affixed to the wax over the cork, and in this manner the snake will make a beautiful appearance, and may be preferred a great number of years; nor will the spirits impair or change the lustr of its colours.
SNAKE-STONES, Ammonites, in natural history, the name of a large genus of fossil shells, very few if any of which are yet known in their recent state, or living either on our own or any other shores; so that it seems wonderful whence so vast a number and variety of them should be brought into subterranean regions. They seem indeed dispersed in great plenty throughout the world, but nowhere are found in greater numbers, beauty, and variety, than in Great Britain.

Mr. Harenberg found prodigious numbers of them on the banks of a river in Germany. He traced this river through its several winding; for many miles, and among a great variety of boulders, corona ammonis, amonites, and coccoliths, of various kinds; he found also great quantities of wood of recent petrifaction, which still preserved plain marks of the axe by which it had been cut from the trees then growing on the shore. The water of this river he found in dry seasons, when its natural springs were not diluted with rains, to be considerably heavier than common water; and many experiments showed him that it contained ferruginous, as well as quantity, in great quantity, whence the petrifications in it appeared the less wonderful, though many of them of recent date.

Of the corona ammonis, or serpent-flones, he there observed more than 30 different species. They lieimmered in a bluish fossil stone, of a soft texture and fatty appearance, in prodigious numbers, and of a great variety of sizes, from the larger known sorts down to such as could not be seen without very accurate inspection or the aid of a microscope. Such as lie in the foifet of these stones are soft like their matrix, and easily crumble to pieces; others are harder. In a piece of this stone, of the bigness of a finger, it is common to find 30 or more of these fossils; and often they are seen only in form of white specks, so minute that their figure cannot be distinguished till examined by the microscope.

They all consist of several volutes, which are different in number in the different species, and their flizes also are extremely various; some very deep with very high ridges between them, others very light; some straight, others crooked; others undulated, and some terminating in dots, tubercles, or cavities, towards the back, and others having tubercles in two or three places. They are all composed of a great number of chambers or cells, in the manner of the scutellus Gracorura, each having a communication with the others, by means of a pipe or siphunculus. There is a small white shell fish of Barbadoes, which seems truly a recent animal of this genus; and in the East Indies there is another also, small and greyish; but the large and beautifully marked ones are found only fossil. They are composed of various fossil bodies, often of quartz flizes, sometimes of the matter of the common pyrites, and of a great variety of other substances; and though they appear usually more flones, yet in some the pearly part of the original flile is preferred in all its beauty. Sometimes also, while the outer substance is of the matter of the pyrites, or other opaque, flony, or mineral matter, the inner cavity is filled with a pure white spar of the common platted texture. This gives a great beauty to the specimen. The corona ammonis, or snake-flones, are found in many parts of England, particularly in Yorkshire, where they are very plentiful in the alun rocks of several fizes.

Vol. XVII.
who endeavour to procure sneezing by external aid. Montaigne, on the contrary, explains this fact in a tone rather cynical. It is singular enough, that so many ridiculous, contradictory, and superstitious opinions, have not abolished those customary civilities which are still preferred equally among high and low; and which only the Anabaptists and Quakers have rejected, because they have renounced professions in every café.

Among the Greeks sneezing was almost always a good omen. It excited marks of tenderness, of respect, and attachment. The genius of Socrates informed him by sneezing, when it was necessary to perform any action. The young Parthenis, hurried on by his passion, resolved to write to Sarpedon an avowal of his love; she sneezes in the most tender and impassioned part of her letter: This is sufficient for her; this incident supplies the place of an answer, and persuades her that Sarpedon is her lover. Penelope, harassed by the vexatious courtship of her suitors, begins to curse them all, and to pour forth vows for the return of Ulysses. Her son Telemachus interrupts her by a loud sneeze. She instantly exults with joy, and regards this sign as an assurance of the approaching return of her husband. Xenophon was haranguing his troops; a soldier sneezed in the moment when he was exhorting them to embrace a dangerous and necessary resolution. The whole army, moved by this preface, determine to pursue the project of their general; and Xenophon orders sacrifices to Jupiter the Preserver.

§ Xenoph. Anab.

This religious reverence for sneezing, so ancient and so universal even in the times of Homer, always excited the curiosity of the Greek philosophers and of the orators. Thales left have spread a tradition, that, after the creation of the world, God made a general law to this purport, that every living man should sneeze but once in his life, and that at the same instant he should render up his soul into the hand of his Creator, without any preceding indiffposition. Jacob obtained an exemption from the common law, and the favour of being informed of his last hour: He sneezed and did not die; and this sign of death was changed into a sign of life. Notice of this was sent to all the princes of the earth; and they ordained, that in future sneezing should be accompanied with forms of blessing, and vows for the persons who sneezed.

Ariflotole remonstrates likewise to the sages of natural religion. He observes, that the brain is the origin of the nerves, of our sentiments, of our sensations, the seat of the soul, the image of the Divinity; that upon all these accounts, the substance of the brain has ever been held in honour; that the first men swore by their head; that they did not touch nor eat the brains of any animal; that it was even a sacred word which they dared not to pronounce. Filled with these ideas, it is not wonderful that they extended their reverence even to sneezing. Such is the opinion of the most ancient and sagacious philosophers of Greece.

According to mythology, the first sign of life Prometheus's artificial man gave was by sneezing. This supposed creator is said to have stolen a portion of the solar rays; and filling them with a phial, which he had made on purpose, sealed it up hermetically. He instantly flies back to his favourite automatons, and opening the phial it holds close to the statute; the rays still retaining all their activity, infatuate themselves through the pores, and set the fantastical man a sneezing. Prometheus, transported with the success of his machine, offers up a sacrifice, with wishes for the preservation of so singular a being. His automatons observed him, remembering his ejaculations, was very careful, on the like occasions, to offer these wishes in behalf of his descendants, who perpetuated it from father to son in all their colonies.

SNIPE, in ornithology. See SCOLOPAX and SNORING.

SNIPE, in medicine, otherwise called feterus, is a found like that of the cerchon, but greater and more manifest.

Many confound these affections, and make them to differ only in place and magnitude, calling by the name of feterus that found or noise which is heard or supposed to be made in the passage between the palate and the nostrils as in those who sleep; that boiling or bubbling noise, which in respiration proceeds from the larynx, or head, or orifice of the alpea arteria, they call cerchon; but if the sound comes from the alpea arteria itself, they will have it called cerchon, that is, as some understand it, a rattling, or as others a stridulous or sneezing roughness of the alpea arteria. In dying persons, the affection is called by the Greeks, apera arteria, which is a roaring or rattling kind of noise, proceeding as it were from a conflict between the breath and the humours in the alpea arteria.

This and such like affections are owing to a weakness of nature, as when the lungs are full of pus or humours; to which purpose we read in the Prognostics of Hippocrates, "it is a bad sign when there is no expectoration, and no discharge from the lungs, but a noise as from an ebullition is heard in the alpea arteria from a plenitude of humour." Expectoration is suppressed either by the vicissitude of the humour, which requires to be discharged, and which adhering to the alpea arteria, and being there agitated by the breath, excites that bubbling noise or feterus; or by an obliteration of the bronchia; or, lastly, by a compulsion of the alpea arteria and throat, whence the passage is thinned, in which the humours being agitated, excite such a kind of noise as before described. Hence Galen calls those who are fyrart-breathed, feterus. That author assigns but two causes of this symptom, which are either the stridulousness of the passage of respiration or redundancy of humours, or both together; but it is necessary to add a third, to wit, the weakness of the faculty, which is the cause of the cerchon in dying persons, where nature is too weak to make discharges.

From what has been said we conclude, that this symptom, or this sort of fervour or ebullition in the throat, is not always mortal, but only when nature is oppressed with the redundancy of humour, in such a manner, that the lungs cannot discharge themselves by spitting; or the passage appointed for the breath (being the alpea arteria) is very much obstructed, upon which account
SNOW, a well-known meteor, formed by the freezing of the vapours in the atmosphere. It differs from hail and hoar-frost, in being as it were crystallized, which they are not. This appears on examining a flake of snow by a magnifying glass; when the whole of it will appear to be composed of fine shining spicula diverging like rays from a centre. As the flakes fall down through the atmosphere, they are continually joined by more of these radiated spicula, and thus increase in bulk like the drops of rain or hailstones. Dr. Grew, in a discourse on the nature of snow, observeth, that many parts thereof are of a regular figure, for the most part flats of six points, and are as perfect and transparent ice as any we see on a pond, &c. Upon each of these points are other collateral points, set at the same angles as the main points themselves: among which there are divers other irregular, which are chiefly broken points, and fragments of the regular ones. Others also, by various winds, seem to have been thawed and frozen again into irreguler clusters; so that it seems as if the whole body of snow were an infinite mass of icicles irregularly figured. That is, a cloud of vapours being gathered into drops, the said drops forthwith with deceit; upon which deceit, meeting with a freezing air as they pass through a colder region, each drop is immediately frozen into an icicle, freezing itself forth into several points; but these fill succeeding their deceit, and meting with some intermitting gales of warmer air, or in their continual waftage to and fro touching upon each other, some of them are a little thawed, blunted, and again frozen into clusters, or en­ tangled so as to fall down in what we call flakes.

The lightness of snow, although it is firm ice, is owing to the excess of its surface, in comparison to the matter contained under it; as gold itself may be extended in surface till it will ride upon the least breath of air.

The whiteness of snow is owing to the small particles into which it is divided; for ice, when pounded, will become equally white. An artificial snow has been made by the following experiment. A tall phial of aquafortis being placed by the fire till it is warm, and filings of pure silver, a few at a time, being put into it; after a brisk ebullition, the silver will dissolve slowly. The phial being then placed in a cold window, as it cools the silver particles will float into crystals, several of which running together will form a flake of snow, which will descend to the bottom of the phial. While they are descending, they represent perfectly a shower of silver snow, and the flakes will lie upon one another at the bottom like real snow upon the ground.

According to Signior Becarina, clouds of snow differ in nothing from clouds of rain, but in the circumstance of cold that freezes them. Both the regular diffusion of the snow, and the regularity of the structure of its parts (particularly some figures of snow or hail which fall about Turin, and which he calls rosette), show that clouds of snow are acted upon by some uniform cause like electricity; and he endeavours to shew how electricity is capable of forming these figures. He was confirmed in his conjectures by observing, that his apparatus for observing the electricity of the atmosphere never failed to be electrified by snow as well as rain. Professor Winthrop sometimes found his apparatus electrified by snow when driven about by the wind, though it had not been affected by it when the snow itself was falling. A more intense electricity, according to Becarina, unites the particles of hail more closely than the more moderate electricity does those of snow, in the same manner as we see that the drops of rain which fall from thunder-clouds are larger than those which fall from others, though the former descend through a less space.

But we are not to consider snow merely as a curious and beautiful phenomenon. The Great Dipenser of universal bounty has so ordered it, that it is eminentlysubservient, as well as all the works of creation, to his beneficent designs. Were we to judge from appearances only, we might imagine, that so far from being useful to the earth, the cold humidity of snow would be detrimental to vegetation. But the experience of all ages affords the contrary. Snow, particularly in those northern regions where the ground is covered with it for several months, fructifies the earth, by guarding the corn or other vegetables from the intense cold of the air, and especially from the cold piercing wind. It has been a vulgar opinion, very generally received, that nitre, as a fertilizer in preference to rain, fertilizes the lands on which it falls more than rain, in consequence of the nitrous salts which it is supposed to acquire by freezing. But it appears from the experiments of Marggraf (a) in the year 1751, that the chemical difference between rain and snow-water is exceedingly small; that the latter is somewhat less nitrous, and contains a somewhat less proportion of earth than the former; but neither of them contain either earth or any kind of salt in any quantity which can be feebly efficacious in promoting vegetation. Allowing, therefore, that nitre is a fertilizer of lands, which many are upon good grounds disposed utterly to deny, yet to very small is the quantity of it contained in snow, that it cannot be supposed to promote the vegetation of plants upon which the snow has fallen. The peculiar agency of snow, as a fertilizer in preference to rain, may admit of a very rational explanation, without recurring to nitrous salts supposed to be contained in it. It may be rationally ascribed to its furnishing a covering to the roots of vegetables, by which they are guarded from the influence of the atmospheric cold, and the internal heat of the earth is prevented from escaping.

The internal parts of the earth, by some principle which

(a) Marggraf collected of the purest snow he could find as much as when melted afforded 100 measures of water, each measure containing 36 ounces. By distilling this quantity he obtained 60 grains, not of nitre but of calcareous earth, with some grains of the acid of sea-fall, impregnated with a nitrous vapour. The same quantity of rain-water collected in the winter months with equal attention, when distilled yielded 100 grains of calcareous earth with some grains of the acid of nitre and sea-fall. The chemical difference therefore between rain and snow is very small.
which we do not understand, is heated uniformly to the 45th degree of Fahrenheit's thermometer. This degree of heat is greater than that in which the watery juices of vegetables freeze, and it is propagated from the inward parts of the earth to the surface, on which the vegetables grow. The atmosphere being variably heated by the action of the sun in different climates, and in the same climate at different seasons, communicates to the surface of the earth and to some distance below it the degree of heat or cold which prevails in itself. Different vegetables are able to preserve life under different degrees of cold, but all of them perish when the cold which reaches their roots is extreme. Providence has therefore, in the coldest climates, provided a covering of snow for the roots of vegetables, by which they are protected from the influence of the atmospheric cold. The snow keeps in the internal heat of the earth, which surrounds the roots of vegetables, and defends them from the cold of the atmosphere.

Snow or ice water is always deprived of its fixed air, which escapes during the process of congelation. Accordingly, as some of the inhabitants of the Alps who use it for their constant drink have enormous wens upon their throats, it has been ascribed to this circumstance. If this were the cause of these wens, it would be easy to remove it by exposing the snow-water to the air for some time. But several eminent physicians have rejected the notion that snow-water is the cause of these wens; for in Greenland, where snow-water is commonly used, the inhabitants are not affected with such swellings: on the other hand, they are common in Sumatra where snow is never seen.

Snow, in sea-affairs, is generally the largest of all two-masted vessels employed by Europeans, and most convenient for navigation.

The sails and rigging on the main-mast and fore-mast of a snow are exactly similar to those on the same masts in a ship; only that there is a small mast behind the main-mast of the former, which carries a sail nearly resembling the mizen of a ship. The foot of this mast is fixed on a block of wood on the quarter-deck abaft the main-mast; and the head of it is attached to the after-top of the main-top. The sail which is called the try-fall is extended from its mast towards the stern of the vessel.

When the fleets of war are rigged as snows, they are furnished with a horse, which answers the purpose of the try-fall, the fore-part of the fall being attached by rings to the said horse, in different places of its height.

Snow-Grotto, an excavation made by the waters on the side of Mount Etna, by making their way under the layers of lava, and by carrying away the bed of pozzolana below them. It occurred to the proprietor, this place was very suitable for a magazine of snow: for in Sicily, at Naples, and particularly at Malta, they are obliged for want of ice to make use of snow for cooling their wine, fierbet, and other liquors, and for making sweetmeats.

This grotto was hired or bought by the knights of Malta, who having neither ice nor snow on the burning rock which they inhabit, have hired several caverns on Etna, into which people whom they employ collect and preserve quantities of snow to be sent to Malta when needed. This grotto has therefore been repaired with

in at the expense of that order; flights of steps are cut into it, as well as two openings from above, by which they throw in the snow, and through which the grotto is enlightened. Above the grotto they have also levelled a piece of ground of considerable extent; this they have inclosed with thick and lofty walls, so that when the winds, which at this elevation blow with great violence, carry the snow from the higher parts of the mountain, and deposits it in this inclosure, it is retained and amassed by the walls. The people then remove it into the grotto through the two openings, and it is there laid up, and preferred in such a manner as to refill the force of the summer heat, as the layers of lava with which the grotto is arched above prevent them from making any impression.

When the season for exporting the snow comes on, it is put into large bags, into which it is pressed as closely as possible; it is then carried by men out of the grotto, and laid upon mules, which convey it to the shore, where small vessels are waiting to carry it away.

But before those lumps of snow are put into bags, they are wrapped in fresh leaves; so that while they are conveyed from the grotto to the shore, the leaves may prevent the rays of the sun from making any impression upon them.

The Sicilians carry on a considerable trade in snow, which affords employment to thousands of mules, horses, and men. They have magazines of it on the summits of their loftiest mountains, from which they distribute it through all their cities, towns, and houses; for every person in the island makes use of snow. They consider the practice of cooling their liquors as absolutely necessary for the preservation of health; and in a climate the heat of which is constantly relaxing the fibres, cooling liquors, by communicating a proper tone to the fibres of the stomach, must greatly strengthen them for the performance of their functions.

In this climate a scarcity of snow is no less dreaded than a scarcity of corn, wine, or oil. We are informed by a gentleman who was at Syracuse in the year 1777, when there was a scarcity of snow, the people of the town learned that a small vessel loaded with that article was paling the coast; without a moment's deliberation they ran in a body to the shore and demanded her cargo; which when the crew refused to deliver up, the Syracusans attacked and took, though with the loss of several men.

Snow-Drop, in botany. See CHIONANTHUS.

SNOWDON-HILL, the name of a mountain in Caernarvonshire in Wales, generally thought to be the highest in Britain; though some have been of opinion that its height is equalled, or even exceeded, by mountains in the Highlands of Scotland. The mountain is surrounded by many others, called in the Welsh language CRIB COCH, CRIBY DIJIFI, LIWADDY BI, Arran, &c.

According to Mr. Pennant, this mountainous tract yields scarcely any corn. Its produce is cattle and sheep; and which, during summer, keep very high in the mountains, followed by their owners with their families, who reside during that season in baronial, or "summer dairies," as the farmers in the Swiss Alps do in their fames. These houses consist of a long low room, with a hole at one end to let out the smoke from the fire which is made beneath. Their furniture is very simple; flues are substituted for floors, and their beds are of

SNO [ 565 ] SNY

Snowdon—

hay, ranged along the sides. They manufacture their own clothes, and dye them with the helix amphibiae and helix parietinus, mosses collected from the rocks. During summer the men pass their time in tending their herds or in making hay, &c., and the women in milling or in making butter and cheese. For their own use they milk both cows and goats, and make cheese of the milk. Their diet consists of milk, cheese, and butter: and their ordinary drink is whey; though they have, by way of reserve, a few bottles of very strong beer, which they use as a cordial when sick. They are people of good understanding, wary, and circumspect; tall, thin, and of strong constitutions. In the winter-time they descend into the fen-dref, or "old dwellings," where they pass their time in inactivity.

The view from the highest peak of Snowdon is very extensive. From it Mr Pennant saw the county of Chelmer, the high hills of Yorkshire, part of the north of England, Scotland, and Ireland; a plain view of the Fjord of Man; and that of Anglesea appeared like a map extended under his feet, with every rivulet visible. Our author took much pains to have this view to advantage; sat up at a farm on the west till about 12, and walked up the whole way. The night was remarkably fine and flurry; towards morning the stars faded away, leaving an interval of darkness, which, however, was soon dispelled by the dawn of day. The body of the sun appeared most distinct, with the roundness of the moon, before it appeared too brilliant to be looked at. The sea, which surrounded the western part of the prospect, appeared gilt with the fun-beams, fir in slender streaks, and at length glowing with redness. The prospect was dilated like the gradual drawing up of a curtain in a theatre; till at last the heat became sufficiently strong to raise the milk from the various lakes, which in a flight of degree obscured the prospect. The shadow of the mountain extended many miles, and showed its bicipitated form; the Wyddef making one head, and Uriq Y Dilfill the other. At this time he counted between 20 and 30 lakes either in Caernarvon or in Meirionethshire. In making another visit, the sky was obscured very soon after he got up. A veil misted the whole circuit of the mountain, and the prospect down was horrible. It gave an idea of numbers of abysmes, concealed by thick smoke furiously circulating around them. Very often a gust of wind made an opening in the clouds, which gave a fine and distinct view of lake and valley. Sometimes they opened in one place, at others in many at once; exhibiting a most strange and perplexing sight of water, fields, rocks, and chains. They then closed again, and every thing was obscured in darkness in a few minutes they would separate again, and repeat the abovementioned scene with infinite variety. From this prospect one Traveller declared with great reluctance; but before he had reached the place where his horses were left, he was overtaken by a thunder storm. The rolling of the thunder-claps, being reiterated by the mountains, was insufferably awful; and after he had mounted, he was in great danger of being swept away by the torrents which poured down in consequence of a very heavy rain.

It is very rare (Mr Pennant observes) that the traveller gets a proper day to ascend this hill; it indeed often appears clear; but by the evident attraction of the clouds by this lofty mountain, it becomes suddenly and unexpectedly enveloped in mist, when the clouds have just before appeared very high and very remote. At times he observed them lower to half their height; and notwithstanding they have been dispersed to the right and left, yet they have met from both sides, and seemed to involve the summit in one great obscurity.

The height of Snowdon was measured, in 1564, by Mr Cawdor, with instruments made by Flamstead: according to his mensuration, the height is 3720 feet; but more modern computations make it only 3560, reckoning from the quay at Caernarvon to the highest peak. The fume that compus this mountain is exceedingly hard. Large coarse crystals, and frequently cubic pyrites, are found. In quantity of water rushes down the sides of Snowdon and the neighbouring mountains, in such that Mr Pennant supposes, if collected into one stream, they would exceed the waters of the Thames.

SNUFF, a powder chiefly made of tobacco, the use of which is too well known to need any description here.

Tobacco is usually the basis of snuff; other matters being only added to give it a more agreeable scent, &c. The kinds of snuff, and their several names, are infinite, and new ones are daily invented; so that it would be difficult, not to say impossible, to give a detail of them. We shall only say, that there are three principal sorts: the first granulated; the second an impalpable powder; and the third the bran, or coarse part remaining after sifting the second sort.

"Every professed, inveterate, and incurable snuff-taker (says Lord Stanhope), at a moderate computation, takes one pinch in ten minutes. Every pinch, with the agreeable ceremony of blowing. Admiring the nose and other incidental circumstances, consumes a minute and a half. One minute and a half out of every ten, allowing 16 hours to a snuff-taking day, amounts to two hours and 24 minutes out of every natural day or one day out of every ten. One day out of every 10 amounts to 36 days and a half in a year. Hence if we suppose the practice to be perished in 40 years, two entire years of the snuff-taker’s life will be dedicated to tickling his nose, and two more to blowing it. The expense of snuff, snuff-boxes, and handkerchiefs, will be the subject of a second essay; in which it will appear, that this luxury encroaches as much on the income of the snuff-taker as it does on his time; and that by a proper application of the time and money thus left to the public, a fund might be constituted for the discharge of the national debt."—See NICOTTIAN.

SNDERS (Francis), a Flemish painter, born at Antwerp in 1579, and bred under his countryman Henry Van Balen. His genius first displayed itself in painting fruit; he afterwards attempted animals, hunting, &c. in which he exceeded all his predecessors. He also painted kitchens, &c. and gave dignity to subjects that seemed incapable of it. He was made painter to Ferdinand and Isabella, archduke, and duchess, and became attached to the house of the cardinal infant of Spain. The king of Spain and the elector Palatine adorned their palaces with paintings by this artist. Rubens, Jordaeus, and Snyders used to co-operate in the enriching of each other’s pictures according to their several
In manufactures where large quantities of it are prepared, soap is made with heat. A lixivium of quicklime and soda is made, but is less concentrated than that above referred to, and only so much that it can sustain a fresh egg. A part of this lixivium is to be even diluted and mixed with an equal weight of oil of olives. The mixture is to put on a gentle fire, and agitated, that the union may be accelerated. When the mixture begins to unite well, the rest of the lixivium is to be added to it; and the whole is to be digested with a gentle heat, till the soap be completely made. A trial is to be made of it, to examine whether the just proportion of oil and alkali has been observed. Good soap of this kind ought to be firm, and very white when cold; not subject to become moist by exposure to air, and entirely miscible with pure water, to which it communicates a milky appearance, but without any drops of oil floating on the surface. When the soap has not these qualities the combination has not been well made, or the quantity of salt or of oil is too great, which faults must be corrected.

In soft or liquid soaps, green or black soaps, cheaper oils are employed, as oil of nuts, of hemp, of flax, &c. These soaps, excepting in confidence, are not essentially different from white soap.

Fixed alcalis are much disposed to unite with oils that are not volatile, both vegetal and animal; since this union can be made even without heat. The compound resulting from this union partakes at the same time of the properties of oil and of alkali; but these properties are modified and tempered by each other, according to the general rule of combinations. Alkali formed into soap has not nearly the same acrimony as when it is pure; it is even deprived of almost all its causticity, and its other saline alkaline properties are almost entirely abolished. The fame of contained in soap is less combustible than when pure, from its union with the alkali, which is an inflammable body. It is miscible, or even soluble, in water, to a certain degree, by means of the alkali. Soap is entirely soluble in spirit of wine; and still better in aquavitæ sharpened by a little alkaline salt, according to an observation of Mr. Geoffroy.

The manufacture of soap in London first began in the year 1524; before which time this city was served with white soap from foreign countries, and with grey soap speckled with white from Bristol, which was sold for a penny a pound; and also with black soap, which sold for a half-penny the pound.

The principal soaps of British manufacture are the soft, the hard, and the ball soap. The soft soap is either white or green. The process of making each of these shall now be described.

Green soft soap. The chief ingredients used in making this are lees drawn from pot-ash and lime, boiled up with tallow and oil. First, the ley of a proper degree of strength (which must be estimated by the weight of the liquor), and tallow, are put into the copper together, and then from the ley boiled, the oil is added; the fire is then damped or stopped up, while the ingredients remain in the copper to unite; when they are united, the copper is again made to boil, being fed or filled with lees as it boils, till there be a sufficient quantity put into it; then it is boiled off and put into caisks. When this soap is first made it appears uniform; but in about a week's time the tallow separates from the oil into those white grains which we see in common soap. Soap thus made would appear yellow, but by a mixture of indigo added at the end of the boiling, it is rendered green, that being the colour which results from the mixture of yellow and blue.

White soap. Of this one sort is made after the same manner as green soft soap, oil alone excepted, which is not used in white. The other sort of white soft soap is made from the lees of ashes of lime boiled up two different times with tallow and alkaIi, a quantity of lees and tallow are put into the copper together, and the boiling is kept with lees as they boil, until the whole is boiled sufficiently; then the lees are separated or discharged from the tallow with part, which part is removed into a tub, and the lees are thrown away; this is called the first half-boil; then the copper is filled again with fresh tallow and lees, and the half-boil of the tub put into the copper a second time, where it is kept boiling with fresh lees and tallow till the soap is produced. It is then put out of the copper into the same sort of caisks as are used for green soft soap.

The common soft soap used about London, generally of a greenish hue, with some white-lumps, is prepared chiefly with tallow: a blackish fort, more common in some other places, is said to be made with whale oil.

Hard soap is made with lees from ashes and tallow, and most commonly boiled twice: the first, called the half-boil, hath the same operation as the first half-boil of soft white soap. Then the copper is charged with fresh lees again, and the half-boil put into it, where it is kept boiling, and fed with lees as it boils, till it grains or is boiled enough; then the ley is discharged from it, and the soap put into a frame to cool and harden.

Common salt is made of for the purpose of graining the soap; for when the oil or tallow has been united with the ley, after a little boiling, a quantity of salt is thrown into the mass, which dissolving readily in water, but not in the oil or tallow, draws out the water in a considerable degree, so that the oil or tallow united with the salt of the ley swins on the top. When the ley is of a proper strength, lees salt is necessary to raise the curd than when it is too weak. It must be observed, that there is no certain time for bringing off a boiling of any of these sorts of soap; it frequently takes up part of two days.

Ball soap, commonly used in the north, is made with lees from ashes and tallow. The lees are put into the copper, and boiled till the watery part is quite gone, and there remains nothing in the copper but a fort of saline matter (the very strength or essence of the ley); to this the tallow is put, and the copper is kept boiling and stirring for above half an hour, in which time
the soap is made; and then it is put out of the copper into tubs or baskets with sheets in them, and immediately (whilst soft) made into balls. It requires near 24 hours in this process to boil away the water part of the ley.

When oil unites with alkali in the formation of soap, it is little altered in the connection of its principles; for it may be separated from the alkali by decomposing soap with any acid, and may be obtained nearly in its original state.

Concerning the decomposition of soap by means of acids, we must observe, first, that all acids, even the weakest vegetable acids, may occasion this decomposition, because every one of them has a greater affinity than oil with fixed alkali. Secondly, these acids, even when united with any base, excepting fixed alkali, are capable of occasioning the same decomposition; whereas all ammonial salts, all salts with bases of earth, and all those with metallic bases, are capable of decomposing soap, in the same manner as disengaged acids are; with this difference, that the oil separated from the fixed alkali, by the acid of these salts, may unite more or less intimately with the substance which was the base of the neutral salt employed for the decomposition.

Soap may also be decomposed by distillation, as Lemery has done. When first exposed to fire, it yields a phlegm called by him a spirit; which nevertheless is neither acid nor alkaline, but some water which enters into the composition of soap. It becomes more and more coloured and empyreumatic as the fire is increased, which shows that it contains the most subtle part of the oil. It seems even to raise along with it, by help of the oil and action of the fire, a small part of the alkali of the soap; for, as the same chemists observe, it occasions a precipitate in a solution of corrosive sublimate.

After this phlegm the oil rises altered, precisely as if it had been distilled from quicklime, that is, empyreumatic, soluble in spirit of wine, at first sufficiently subtle and afterwards thicker. An alkaline residue of coal remains in the retort, containing chiefly of the mineral alkali contained in the soap, and which may be disengaged from the coal by calcination in an open fire, and obtained in its pure state.

Alkaline soaps are very useful in many arts and trades, and particularly in chemistry and medicine. Their principal utility consists in a destructive quality that they receive from their alkali, which, although it is in some measure saturetated with oil, is yet capable of acting upon oily matters, and of rendering them saponaecous and miscible with water. Hence soap is very useful to cleanse any substances from all fat matters with which they happen to be soiled. Soap is therefore daily used for the washing and whitening of linen, for the cleaning of woollen cloths from oil, and for whitening silk and freeing it from the reinous varnish with which it is naturally covered. Pure alkaline liniments being capable of disolving oils more effectually than soap, might be employed for the same purposes; but when this activity is not mitigated by oil, as it is in soap, they are capable of altering, and even of destroying entirely by their cauticity, most substances, especially animal matters, as silk, wool, and others: whereas soap cleanses from oil almost as effectually as pure alkali, without danger of altering or destroying; which renders it very useful.

Soap was imperfectly known to the ancients. It is mentioned by Pliny as made of fat and ashes, and as an invention of the Gauls. Aretaeus and others inform us that the Greeks obtained their knowledge of its medicinal and useful virtues, according to Medical Bergius, are deterrent, resolvent, and aperient, and its saline nature recommended it in jaundice, gout, calculous complaints, and in obstructions of the vescera. The efficacy of soap in the first of these diseases was experienced by Sylvius, and since recommended very generally by various authors who have written on this complaint; and it has also been thought of use in supplying the place of bile in the prime vit. The utility of this medicine in medical cases was inferred chiefly from its supposed power of dissolving biliary concretions; but this medicine has lost much of its reputation in jaundice, for since it is now known that gall-stones have been found in many after death who had been daily taking soap for several months and even years. Of its good effects in urinary calculous affections, we have the testimony of several, especially when dissolved in lime-water, by which its efficacy is considerably increased; for it thus becomes a powerful solvent of mucus, which an ingenious modern author supposes to be the chief agent in the formation of calculi: it is, however, only in the incipient state of the diseafe that their remedies promise effectual benefit; though they generally abate the more violent symptoms where they cannot remove the cause. With Boerhaave soap was a general medicine: for as he attributed most complaints to the vicissitudes of the fluids, he, and most of the Boerhaave school, prescribed it in conjunction with different remedies in gout, rheumatism, and various vesical complaints. Soap is also externally employed as a resolvent, and gives name to several officinal preparations.

From the properties of soap we may know that it must be a very effectual and convenient anti-acid. It absorbs acids as powerfully as pure alkali and absorbs earths, without having the cauticity of the former, and without oppressing the stomach by its weight like the latter.

Lastly, we may perceive that soap must be one of the belt of all antitoxes to foop quickly, and with the least inconvenience, the bad effects of acid corrosive potions, as aquafortis, corrosive sublimate, &c.

Soap imported is subject by 10 Ann. cap. 19. to a British duty of 2d. a pound (over and above former duties); but by 12 Ann. flat. 2. cap. 9. to the further sum of 3d. a pound. And by the same acts, the duty on soap made in the kingdom is 1d. a pound. By 17 G. III. cap. 52. no person within the limits of the head office of excise in London shall be permitted to make any soap unless he occupy a tenement of 10 l. a year, be afeigned, and pay the parifh rates; or elsewhe, unless he be afeigned, and pay to church and poor.

Places of making are to be entered on pain of 50 l. and covers and locks to be provided under a forfeiture of 100 l.; the furnace-door of every utensil used in the manufacture of soap shall be locked by the excise officer, as soon as the fire is damped or drawn out, and fastenings provided, under the penalty of 50 l.; and opening or damaging such fastening incurs a penalty of 100 l. Officers are required to enter and survey at all times, by day or night, and the penalty of obtruding is 20 l. and they may unlock and examine every corpor, &c. between the hours of five in the morning and eleven

S O C

SOCIETY, a number of rational and moral beings, united for their common preservation and happiness.

There are hordes of fishes, herds of quadrupeds, and flocks of birds. But till observation enable us to determine with greater certainty, how far the inferior animals are capable of moral sentiments—whether they are capable of moral sentiments—we cannot with propriety apply to them the term Society. We call cows, and beavers, and several other species of animals, gratarious; but it is hardly good English to say that they are social.

It is only human society, then, that can become the subject of our present investigation. The phenomena which it presents are highly worthy of our notice.

Such are the advantages which each individual evidently derives from living in a social state; and so helpless does any human being appear in a solitary state, that we are naturally led to conclude, that if there ever was a period at which mankind were solitary beings, that period could not be of long duration; for their averting of solitude and love of society would soon induce them to enter into social unions. Such is the opinion which we are led to conceive, when we consider our own condition as members of civilized and enlightened society with that of the brutes around us, or with that of savages in the earlier and ruder periods of social life. When we hear of Indians wandering naked through the woods, delirious of arts, unskilled in agriculture, scarce capable or moral dispositions, void of all religious sentiments, or possessed with the most absurd notions concerning superior powers, and procuring means of subsistence in a manner equally precarious with that of the beasts of prey—we look down with pity on their condition, or turn from it with horror. When we view the order of cultivated society, and consider our institutions, arts, and manners—we rejoice over our superior wisdom and happiness.

Man in a civilized state appears a being of a superior order to man in a savage state; yet some philosophers tell us, that it is only he who, having been educated in society, has been taught to depend upon others, that can be helpless or miserable when placed in a solitary state. They view the savage who exerts himself with intrepidity to supply his wants, or bears them with fortitude, as the greatest hero, and possessing the greatest happiness. And therefore if we agree with them, that the propensities of nature may have prompted men to
enter into social union, though they may have hoped to enjoy superior security and happiness by engaging to protect and support each other, we must conclude that the Author of the universe has designed man to obtain greater dignity and happiness in a savage and solitary than in a social state; and therefore that the dispositions and views which lead us to society are fallacious and inimical to our real interest.

Whatever be the supposed advantages of a solitary state, certain it is that mankind, at the earliest periods, were united in society. Various theories have been formed concerning the circumstances and principles which gave rise to this union; but we have elsewhere shown, that the greater part of them are founded in error; that they suppute the original state of man to have been that of savages; and that such a supposition is contradicted by the most authentic records of antiquity. For though the records of the earlier ages are generally obscure, fabulous, and imperfect; yet happily there is one free from the imperfections of the rest, and of undoubted authenticity, to which we may safely have recourse. This record is the Pentateuch of Moses, which presents us with a genuine account of the origin of man and of society, perfectly consonant to what we have laid down in the article referred to (see Savage).

According to Moses, the first society was that of a husband and wife united in the bonds of marriage; the first government that of a father and husband, the master of his family. Men lived together under the patriarchal form of government while they employed themselves chiefly in tending flocks and herds. Children in such circumstances cannot soon rise to an equality with their parents, where a man's importance depends on his property, not on his abilities. When flocks and herds are the chief articles of property, the son can only obtain these from his father; in general therefore the son must be entirely dependent on the father for the means of subsistence. If the parent during his life befall on his children any part of his property, he may do it on such conditions as shall make their dependence upon him continue till the period of his death. When the community are by this event deprived of their head, instead of continuing in a state of union, and feleecting some one from among themselves whom they may invest with the authority of a parent, they separate into so many distinct tribes, each subjected to the authority of a different lord, the master of the family, and the proprietor of all the flocks and herds belonging to it. Such was the state of the first societies which the narrative of Moses exhibits to our attention.

Those philosophers who have made society, in its various stages between rudeness and refinement, the subject of their speculations, have generally considered mankind, in whatever region of the globe, and under whatever climate, as proceeding uniformly through certain regular gradations from one extreme to the other. They regard them, first, as gaining a precarious subsistence by gathering the spontaneous fruits of the earth, preying on the inhabitants of the waters, if placed on the sea shore, or along the banks of large rivers; or hunting wild beasts, if in a situation where there are to be found in abundance, without foresight or industry to provide for future wants when the present call of appetite is gratified. Next, they say, man rises to the shepherd state, and next to that of husbandmen, when they turn their attention from the management of flocks to the cultivation of the ground. Next, these husbandmen improve their powers, and better their condition, by becoming artisans and merchants; and the beginning of this period is the boundary between barbarity and civilization.

These are the stages through which they who have employed themselves on the natural history of society have generally conducted mankind, for their progress from rudeness to refinement; but they seem to have overlooked the manner in which mankind where at first established on this earth; for the circumstances in which the parents of the human race were originally placed; for the degree of knowledge communicated to them; and for the instruction which they must have been capable of communicating to their posterity. They rather appear to consider the inhabitants of every different region of the globe as aborigines, springing at first from the ground, or dropped on the spot where they inhabit; no less ignorant than infants of the nature and relations of the objects around them, and of the purposes which they may accomplish by the exercise of their organs and faculties.

The absurdity of this theory has been fully demonstrated in another place: and if we agree to receive the Mosaic account of the original establishment of mankind, we shall be led to view the phenomena of social life in a light very different. We must first allow, that though many of the rudest tribes are found in the state of hunters or fishers; yet the hunting or fishing state cannot have invariably been the primary form of society. Notwithstanding the powers with which we are endowed, we are in a great measure the creatures of circumstances. Physical causes exert, though indirectly, a mighty influence in forming the character and directing the exertions of the human race. From the information of Moses we gather, that the first societies of men lived under the patriarchal form of government, and employed themselves in the cultivation of the ground and the management of flocks. And as we know that mankind, being subjected to the influence both of physical and moral causes, are no less liable to degeneracy than capable of improvement; we may easily conceive, that though defending all from the same original pair, and though enlightened with much traditional knowledge relative to the arts of life, the order of society, moral distinctions, and religious obligations; yet as they were gradually, and by various accidents, dispersed over the earth, being removed to situations in which the arts with which they were acquainted could but little avail them, where industry was overpowered, or indolence encouraged by the severity or the profusion of nature, they might degenerate and fall into a condition almost as humble and precarious as that of the brutal tribes. Other moral causes might also concur to debase or elevate the human character in that early period. The particular character of the original settlers in any region, the manner in which they were connected with one another, and the arts which they were best qualified to exercise, with various other causes of a similar nature, would have considerable influence in determining the character of the society.

When laying aside the spirit of theory and system, we set ourselves, with due humility, to trace facts, and to listen to evidence, though our discoveries may be
fewer than we should otherwise fancy them; yet the knowledge which we thus acquire will be more useful and solid, and our speculations more consistent with the spirit of true philosophy. Here, though we learn from the information of the sacred writings, that the first family of mankind was not cruelly exposed in this world, as children whom the inhumanity of their parents induces them to defert; yet we are not, in consequence of admitting this fact, led under any necessity of denying or explaining away any of the other phenomena which occur to our observation when tracing the natural history of society. Tradition may be corrupted; arts and sciences may be lost; the sublimest religious doctrines may be debased into absurdity.

If then we are discerning of surveying society in its rudest form, we must look, not to the earliest period of its existence, but to those districts of the globe where external circumstances concur to drive them to a state of stupidity and wretchedness. Thus in many places of the happy clime of Asia, which a variety of ancient records concur with the sacred writings in representing as the first peopled quarters of the globe, we can trace the form of society backwards beyond the shepherd state. In that state even the bonds which confect society extend not to a wide range of individuals, and men remain for a long period in distinct families; but yet that state is highly favourable to knowledge, to happiness, and to virtue. Again, the torrid and the frozen regions of the earth, though probably peopled at a later period, and by tribes sprung from the same stock—where the shepherds of Asia, have yet exhibited mankind in a much lower state. It is in the parched deserts of Africa and the wilds of America that human beings have been found in a condition approaching the nearest to that of the brutes.

We may therefore with some propriety deter the order of time, and take a view of the different stages through which philosophers have conceived mankind as advancing, beginning with that of rudeness, though we have shown that it cannot have been the first in the progress.

Where the human species are found in the lowest and rudest state, their rational and moral powers are very faintly displayed; but their external senses are acute, and their bodily organs active and vigorous. Hunting and fishing are then their chief employments on which they depend for support. During that portion of their time which is not spent in their pursuits, they are sunk in idleness and indolence. Deficient of foresight, they are routed to active exertion only by the pressure of immediate necessity or the urgent calls of appetite. Accustomed to endure the severity of the elements, and but scantily provided with the means of subsistence, they acquire habits of resignation and fortitude, which are beheld with astonishment by those who enjoy the plenty and indulgence of cultivated life. But in this state of want and depression, when the powers and sensations of every individual are scarce sufficient for his own support, when even the calls of appetite are repressed because they cannot always be gratified, and the more refined passions, which either originate from such as are merely animal, or are intimately connected with them, have not yet been felt—in this state all the milder affections are unknown; or if the breath is at all sensible to their impulsion, it is extremely feeble. Husband and wife, parent and child, brother and brother, are united by the weakest ties. Want and misfortune are not pitied. Why indeed should they, where they cannot be relieved? It is impossible to determine how far beings in this condition can be capable of moral distinctions. One thing certain is, that in no state are the human race entirely incapable of these. If we listen, however, to the relations of respectable travellers, we must admit that human beings have sometimes been found in that abject state where no proper ideas of subordination, government, or distinction of ranks, could be formed. No distinct notions of Deity can be here entertained. Beings in so humble a condition cannot, look through the order of the universe and the harmony of nature to that Eternal Wisdom and Goodness which contrived, and that Almighty Power which brought into existence, the system of things. Of arts they must be almost totally destitute. They may use some instruments for fishing or the chase; but these must be extremely rude and simple. If they be acquainted with any means to shelter them from the inclemency of the elements, both their houses and clothing will be awkward and inconvenient.

But human beings have not often found in so rude a state as this. Even those tribes which we denote in minute savage, are for the most part farther, removed from more animal life. They generally appear united under some species of government, exercising the powers of reason, capable of morality, though that morality be not always very refined; displaying some degree of social virtues, and acting under the influence of religious sentiments. Those who may be considered as but one degree higher in the scale than the rapid and wretched beings, whose condition we have surveyed, are to be found still in the hunting and fishing state; but they are farther advanced towards social life, and are become more sensible to the impulsion of social affection. By unavoidable intercourse in their employments, a few individual hunters or fishers contract a certain degree of fondness for each other's company, and are led to take some part in each other's joys and sorrows; and when the social affections thus generated (see Passion) begin to exert themselves, all the other powers of the mind are at the same time called forth, and the circumstances of the little society are immediately improved. We behold its members in a more comfortable condition, and find reason to view the human character with more complacency and respect. Huts are now built, more commodious clothes are fashioned, implements for the annoyance of wild beasts and even of enemies are contrived; in short, arts, and science, and social order, and religious sentiments, and ceremonies, now make their appearance in the rising society, and serve to characterize it by the particular form which distinguishes each of them. But though social order is no longer unknown nor unobserved, yet the form of government is still extremely simple, and its ties are but loose and feeble. It will perhaps bear some resemblance to the patriarchal; only all its members are on a more equal footing, and at the same time less closely connected than in the shepherd state, to which that form of government seems almost peculiar. The old men are treated with veneration; but the young are not entirely subject to them. They may listen respectfully to their advice; but they do not submit to their arbitrary commands.
commands. Where mankind are in the state of hunters and fishers, where the means of subsistence are precariously acquired, and prudent foresight does not prompt to accumulate much provision for the future, no individual can acquire commensurate wealth. As soon as the son is grown up, he ceases to be dependent on his father, as well as on the society in general. Difference of experience therefore constitutes the only distinction between the young and the old; and if the old have experience, the young have strength and activity. Here, then, neither age nor property can give rise to any striking distinction of ranks. All who have attained to manhood, and are not disabled by unusual deficiency of strength or agility, or by the infirmities of old age, are on equal footing; or if any one poffesses a pre-eminence over the rest, he owes it to superior address or fortitude. The whole tribe deliberate; the old give their advice; each individual of the assembly receives or rejects it at his pleasure (for the whole body think not of exercising any compulsory power over the will of individuals); and he who is most distinguished for strength, address, and valor, leads out the youth of the tribe to the chase or against the enemy. War, which in the former stage did not prevail, as they who were strangers to social sentiments were, at the same time, scarce capable of being enemies, now first begins to depopulate the thinly inhabited regions where those hunters and fishers pursue their prey. They are scattered, possibly in scanty and separate tribes, over an immense tract of country; but they know no medium between the affection which brethren of the same tribe bear to each other and the hatred of enemies. Though thinly scattered over the earth, yet the hunting parties of different tribes will sometimes meet as they range the forests; and when they meet, they will naturally view each other with a jealous eye; for the fuccefs of the one party in the chase may cause the other to be unsuccessful; and while the one snatches the prey, the other must return home to all the pangs of famine. Invertebrate hostility will therefore long prevail among neighbouring tribes in the hunting state.

If we find them not incapable of social order, we may naturally expect that their conduct will be influenced by some sentiments of religion. They have at this period ideas of superior beings. They also practise certain ceremonies to recommend them to those beings; but both their sentiments and ceremonies are superficial and absurd.

We have elsewhere shewn (see Polytheism) how savage tribes have probably degenerated from the pure worship of the one true God to the adoration of a multitude of imaginary divinities in heaven, earth, and hell. We have traced this idolatrous worship from that of the heavenly bodies, through all the gradations of demon-worship, hero-worship, and nature-worship, to that wonderful instance of absurd superstitious which induced the inhabitants of some countries to fall prostrate in adoration before the vilest reptiles. But though we are convinced that the heavenly bodies have by all idolaters been considered as their first and greatest gods, we pretend not that the progress through the other stages of polytheism has been everywhere in the very same order. It is indeed impossible to exhibit under one general view an account of arts, manners, and religious sentiments, which may apply to some certain period in the history of every nation. The characters and circumstances of nations are scarce less various and anomalous than those of individuals. Among many of the American tribes living the ancient inhabitants of the forests of Germany, whole manners have been accurately delineated by the masterly pen of Tacitus, and in some of the islands scattered over the southern ocean, religion, arts, and government, have been found in that state which we have described as characterizing the second stage of social life. But neither can we pretend that all those simple and rude societies have been described by historians and travellers as agreeing precisely in their arts, manners, and religious sentiments; or that the difference of circumstances always enables us to account in a satisfactory manner for the distinction of their characters. There is a variety of facts in the history of the early periods of society, which no ingenuity, no industry however painful, can reduce under general heads. Here, as well as when we attempt to philosophize on the phenomena of the material world, we find reason to conceive that our powers are weak, and our observation confined within a narrow sphere.

But we may now carry our views a little forward, and survey human life as approaching somewhat nearer to the periods of society, in which we have described as exhibiting the phenomena of the material world, we find reason to conceive that our powers are weak, and our observation confined within a narrow sphere. But we may now carry our views a little forward, and survey human life as approaching somewhat nearer to the civilized and enlightened state. As property is acquired, inequality and subordination of ranks necessarily follow; and when men are no longer equal, the many are soon subjected to the will of the few. But what gives rise to these new phenomena is, that after having often suffered from the precariouslyness of the hunting and fishing state, men begin to extend their cares beyond the present moment, and to think of providing some supply for future wants. When they are enabled to provide such a supply, either by pursuing the chase with new eagerness and perseverance, by gathering the spontaneous fruits of the earth, or by breeding tame animals—these acquisitions are at first the property of the whole society, and distributed from a common store to each individual according to his wants. But as various reasons will soon concur to convince the community, that by this mode of distribution, industry and activity are treated with injustice, while negligence and indolence receive more than their due, each individual will in a short time become his own reward, and a community of goods will be abolished. As soon as distinct ideas of property are formed, it must be unequally distributed; and as soon as property is unequally distributed there arises an inequality in ranks. Here we have the origin of the depradation of the female sex in rude ages, of the tyrannical authority exercised by parents over their children, and perhaps of slavery. The women cannot display the same perseverance, or activity, or address, as the men in pursuing the chase. They are therefore left at home; and from that moment are no longer equals, but slaves and dependants, who must subsist by the bounty of the males, and must therefore submit with implicit obedience to all their capricious commands. Even before the era of property, the female sex were viewed as inferiors; but till that period they were not reduced to a state of absolute slavery.

In this period of society new notions are formed of the relative duties. Men now become citizens, masters, and servants; husbands, parents, &c. It is impossible to enumerate all the various modes of government which take place among the tribes who have advanced...

...t to this flage; but on: thing certain is, that the authority of the few over the many is now firft established, and that the rule of property firft introduces inequality of ranks. In one place, we shall perhaps find the community subjectd during this period to the will of a single perfon; in another, power may be lodged in the hands of a number of chiefs; and in a third, every individual may have a voice in creating public officers, and in enfainting laws for the support of public order. But as no code of laws is formed during this period, justice is not very impartially administered, nor are the rights of individuals very faithfully guarded. Many actions, which will afterwards be considered as heinous and immoral, are now considered as praiseworthy or indifferent. This is the age of hero-worship, and of household and tutelary gods; for it is in this flage of society that the invention of arts, which gave rise to that worship, contributes most conspicuously to the public good. War, too, which we consider as beginning first to ravage the earth during the former period, and which is another cause of the dedication of dead men, will still prevail in this age, and be carried on with no less ferocity than before, though in a more systematic form.

The prevalence of war, and the means by which subsistence is procured, cannot but have considerable influence on the character and sentiments of societies and individuals. The hunter and the warrior are characters in many respects different from the shepherd and the husbandman. Such, in point of government, arts, and manners, religious and moral sentiments, were several of the German tribes described by Tacitus; and the Britons whose character has been sketched by the pen of Cæsar: such, too, were the Romans in the early period of their history; such too the inhabitants of Asia Minor about the time of the siege of Troy, as well as the Greeks whom Homer celebrates as the destroyers of the Trojan flate: the northern tribes also, who poured throu' Asia, Africa, and Europe, and overthrew the Roman empire, appear to have been of a nearly similar character. It seems to be a general opinion among those who have directed their attention to the history of society, that, in the scale ascending from the lowest condition of human beings to the most civilized and enlightened state of society, the shepherd state is the next in order above the hunting; and that as mankind improve in knowledge and in moral sentiments, and as the forests are gradually depopulated of their inhabitants, instead of destroying the inferior animals, men become their guardians and protectors. But we cannot unreverently subscribe to this opinion: we believe, that in the shepherd state societies have been sometimes found superior to the most polished tribes of hunters; but upon viewing the annals of mankind in early ages, we observe that there is often no inconsiderable resemblance even between hunters and shepherds in point of the improvement of the rational faculties and the moral sense; and we are therefore led to think, that these two states are sometimes parallel; for instance, several of the American tribes, who still procure their subsistence by hunting, appear to be nearly in the state which we have described as the third stage in the progress of society; and the ancient shepherds of Asia do not appear to have been much more cultivated and refined. We even believe that men have sometimes turned their attention from hunting to agriculture without passing through any intermediate state. Let us remember, that much depends upon local circumstances, and somewhat undoubtedly on original inspiration and traditionary influence. In this period of society the state of the arts well deserves our attention. We shall find, that the shepherds and the hunters are in that respect on a pretty equal footing. Whether we examine the records of ancient history, or view the islands scattered through the South Sea, or range the wilds of America, or survey the snowly valleys of Lapland and the frozen coast of Greenland—still we find the useful arts in this period, though known and cultivated, in a very rude state; and the fine arts, or such as are cultivated merely to please the fancy or to gratify caprice, displaying an odd and fantastic, not a true or natural, taste; yet this is the period in which eloquence shines with the truest luster: all is metaphor or glowing sentiment. Languages are not yet copious; and therefore speech is figurative, expressive, and forcible. The tones and gestures of nature, not being yet laid aside, as they generally are, from regard to decorum, in more polished ages, give a degree of force and expression to the harmonics of the rustic or savage orator, which the most laborious study of the rules of rhetoric and elocution could not enable even a more polished orator to display.

But let us advance a little farther, and contemplate our species in a new light, where they will appear with a greater dignity and amiability of character. Let us view them as husbandmen, artisans, and legislators. Whatever circumstances might turn the attention of any people from hunting to agriculture, or cause the herdman to yoke his oxen for the cultivation of the ground, certain it is that this change in the occupation would produce an happy change on the character and circumstances of men; it would oblige them to exert a more regular and persevering industry. The hunter is like one of those birds that are described as passing the winter in a torpid flate. The shepherd's life is extremely indolent. Neither of these is very favourable to refinement. But different is the condition of the husbandman. His labours proceed each other in regular rotation through the year. Each season with him has its proper employments; he therefore must exert active persevering industry; and in this state we often find the virtues of rude and polished ages united. This is the period where barbarism ends and civilization begins. Nations have existed for ages in the hunting or the shepherd state, fixed as by a kind of stagnation, without advancing farther. But fear the insensibly occur in the history of mankind of those who once reached the state of husbandmen, remaining long in that condition without rising to a more civilized and polished state. Where a people turn their attention to any considerable degree to the objects of agriculture, a distinction of occupations naturally arises among them. The husbandman is so closely employed thro' the several seasons of the year in the labours of the field, that he has no longer leisure to exercise all the rude arts known among his countrymen. He has not time to fashion the instruments of husbandry, to prepare his clothes, to build his house, to manufacture household utensils, or to tend those tame animals which he continues to rear. Those different departments therefore now begin to employ different persons; each of whom dedicates
Society dedicates his whole time and attention to his own occupation. The manufacture of cloth is for a considerable time managed exclusively by the women; butsmiths and joiners arise from among the men. Metals begin now to be considered as valuable materials. The intercourse of mankind is now placed on a new footing. Before, every individual practised all the arts that were known, as far as was necessary for supplying himself with the conveniences of life. Now he confines himself to one or a few of them; and, in order to obtain a necessary supply of the productions of those arts which he does not cultivate himself, he gives in exchange a part of the productions of his own labours. Here we have the origin of commerce.

After continuing perhaps for some time in this state, as arts and distinctions multiply in society, the exchange of one commodity for another is found troublesome and inconvenient. It is ingeniously contrived to adopt a medium of commerce, which being estimated not by its intrinsic value, but by a certain nominal value which it receives from the agreement of the society among whom it is used, serves to render the exchange of property, which is so necessary for the purposes of social life, easy and expedient. Wherever metals have been known, they appear to have been adopted as the medium of commerce as soon as such a medium began to be used: and this is one important purpose for which they serve; but they have still more important uses. Almost all the necessary arts depend on them. Where the metals are known, agriculture practised, and the necessary arts distributed among different orders of artificers—civilization and refinement, if not obstructed by some accidental circumstances, advance with a rapid progress. With regard to the first applying of the precious metals as the medium of commerce, we may observe, that this was probably not accomplished by means of a formal contract. They might be first used as ornaments; and the love of ornament, which prevails among rude as much as among civilized nations, would render every one willing to receive them in exchange for such articles as he could spare. Such might be the change produced on society with regard to the necessary arts by the origin of agriculture. As soon as ornament and amument are thought of the fine arts begin to be cultivated. In their origin therefore they are not long posterior to the necessary and useful arts. They appear long before men reach the comfortable and respectable condition of husbandmen; but so rude is their character at their first origin, that our Didotnii would probably view their productions of that period with unspeakable contempt and disgust. But in the period of society which we now consider, they have acquired to a higher character; yet poetry is now perhaps less generally cultivated than during the shepherd state. Agriculture, considered by itself, is not directly favourable either to refinement of manners or to the fine arts. The conversion of herdsmen is generally supposed to be far more elegant than that of husbandmen; but though the direct and immediate effects of this condition of life be not favourable to the fine arts, yet directly it has a strong tendency to promote their improvement. Its immediate influence is extremely favourable to the necessary and useful arts; and these are not less favourable to the fine arts.
neighbours the Athenians, we behold in their history the natural progress of opinions, arts, and manners. The useful arts are first cultivated with such steady industry, as to raise the community to opulence, and to furnish them with articles for commerce with foreign nations. The useful arts cannot be raised to this height of improvement without leading man to the pursuit of science. Commerce with foreign nations, skill in the useful arts, and a taste for science, mutually aid each other, and confpire to promote the improvement of the fine arts. Hence magnificent buildings, noble statues, paintings expressive of life, action, and passion; and poems in which imagination adds new grace and sublimity to nature, and gives the appearances of social life more irresistible power over the affections of the heart. Hence are moral distinctions more carefully studied, and the rights of every individual and every order in society better understood and more accurately defined. Moral science is generally the first scientific pursuit which strongly attracts the attention of men. Lawgivers appear before geometers and astronomers. Some particular circumstances may cause these sciences to be cultivated at a very early period. In Egypt the overflowing Nile caused geometry to be early cultivated. Causes so less favourable to the study of astronomy, concurred to recommend that science to the attention of the Chaldeans long before they had attained the height of refinement. But, in general, we find, that the laws of morality are understood, and the principles of morals inquired into, before men make any considerable progress in physical science, or even prosecute it with any degree of keenness. Accordingly, when we view the state of literature in this period (for it is now become an object of so much importance as to force itself on our attention), we perceive that poetry, history, and morals, are the branches chiefly cultivated. Arts are generally casual inventions, and long practised before rules and principles on which they are founded assume the form of science. But morality, if considered as an art, is that art in which men have soonest and most constantly occasion to practise. Besides, we are so constituted by the wisdom of nature, that human actions, and the events which befal human beings, have more powerful influence than any other object to engage and fix our attention. Hence we are enabled to explain why morality, and those branches of literature more immediately connected with it, are almost always cultivated in preference to physical science. Though poetry, history, and morals, be purged with no small eagerness and success in that period of society which we now consider, we need not therefore be greatly surprised that natural philosophy is neither very general nor very successfully cultivated. Were we to consider each particular in that happy change which is now produced on the circumstances of mankind, we should be led to a too minute and perhaps unimportant detail. This is the period when human virtue and human abilities shine with most splendour. Radenees, ferocity, and barbarism, are now banished. Luxury has made her appearance; but as yet she is the friend and benefactress of society. Commerce has stimulated and rewarded industry, but has not yet contradicted the heart and debased the character. Wealth is not yet become the sole object of pursuit. The charms of social intercourse are known and relished; but domestic duties are not yet deftuted for public amusements. The female sex acquire new influence, and contribute much to refine and polish the manners of their lords. Religion now assumes a milder and more pleasing form; splendid rites, magnificent temples, pompous sacrifices, and gay festivals, give even superstition an influence favourable to the happiness of mankind. The gloomy notions and barbarous rites of former periods fall into disuse. The system of theology produced in former ages still remains; but only the mild and amiable qualities of the deities are celebrated; and none but the gay, humane, and laughing divinities, are worshipped. Philosophy also teaches men to discard such parts of their religion as are unfriendly to good morals, and have any tendency to call forth or cherish unocial sentiments in the heart. War (for in this period of society enough of causes will arise to arm one nation against another)—war, however, no longer retains its former ferocity; nations no longer strive to extirpate one another; to procure redress for real or imaginary injuries; to humble, not to destroy, is now its object. Prisoners are no longer cut to pieces in cold blood, subjected to horrid and excruciating tortures, or condemned to hopeless slavery. They are ransomed or exchanged; they return to their country, and again fight under its banners. In this period the arts of government are likewise better understood, and practised so as to contribute most to the interests of society. Whether monarchy, or democracy, or aristocracy, be the established form, the rights of individuals and of society are in general respected. The interests of society are so well understood, that the few, in order to preserve their influence over the many, find it necessary to act rather as the faithful servants than the impetuous lords of the public. Though the liberties of a nation in this state be not accurately defined by law, nor their property guaranteed to them by any legal institutions, yet their governors dare not violate their liberties, nor deprive them wantonly of their properties. This is truly the golden age of society: every trace of barbarism is entirely effaced; and vicious luxury has not yet begun to sap the virtue and the happiness of the community. Men live not in idleis indolence; but the industry in which they are engaged is not of such a nature as to overpower their strength or exhaust their spirits. The social affections have now the strongest influence on men's sentiments and conduct.

But human affairs are scarce ever stationary. The degeneracies of mankind are almost always changing, either growing better or worse. Their manners are ever in the same fluctuating state. They either advance towards perfection or degenerate. Scarcely have they attained that happy period in which we have just contemplated them, when they begin to decline till they perhaps fall back into a state nearly as low as that from which we suppos them to have emerged. Instances of this unhappy degeneracy occur more than once in the history of mankind; and we may sketch this short sketch of the history of society by mentioning in what manner this degeneracy takes place. Perhaps, first by speaking, every thing but the simple necessities of life may be denominated luxury: for a long time, however, the welfare of society is best promoted, while its members aspire after something more than the mere necessaries of life. As long as these superfluities are to be obtained only by active and honest exertion; as long as
The period arrives, however, when luxury is no longer serviceable to the interests of nations; when she is no longer a graceful, elegant, active form, but a languid, overgrown, and bloated carcase. It is the love of luxury, which contributed so much to the civilization of society, that now brings on its decline. Arts are cultivated and improved, and commerce extended, till enormous opulence be acquired; the effect of opulence is to increase ideas of new and capricious wants, and to inflame the breast with new desires. Here we have the origin of that selfishness which, operating in conjunction with caprice and the violence of unbridled passions, contributes so much to the corruption of virtuous manners. Selfishness, caprice, indolence, celnamiveness, all join to loosen the bonds of society, to bring on the degeneracy both of the useful and the fine arts, to banish at once the mild and the amiable virtues, to destroy civil order and subordination, and to introduce in their room anarchy or despotism.

Scarcely could we have found an example of the beautiful form of society which we last attempted to describe. Never, at least, has any nation continued long to enjoy such happy circumstances, or to display so amiable and respectable a character. But when we speak of the declining state of society, we have no difficulty in finding instances to which we may refer. History tells us of the Arians, the Egyptians, and the Persians all of them once flourishing nations, but brought down by luxury and a wanton fancy, to degrade their characters, and to introduce in their room anarchy or despotism.

If we suppose the principle of selfishness to be the same, and the arts the same, in all ages, we may account for the gradations between barbarism and refinement; and as the painter who is to exhibit a series of portraits representing the human form in infancy, puerility, youth, and manhood, will not think of delineating all that variety of figures and faces which each of those periods of life affords, and will find himself unable to represent in any single figure all diversities of form and features; so we have not once thought of describing particularly under this article, all the various national characters reducible to any one of those divisions under which we have divided the progress of society, nor have we found it possible to comprehend under one confident view, all the particulars which may be gathered from the remains of antiquity, from the relations of later travellers, and the general records of history concerning the progressive character of mankind in various regions, and under the influence of various accidents and circumstances. This indeed would have even been improper, as all that information appears under other articles in this Work.

SOCIETIES, associations voluntarily formed by a number of individuals for promoting knowledge, industry, or virtue. They may therefore be divided into three classes; societies for promoting science and literature, societies for encouraging and promoting arts and manufactures, and societies for diffusing religion and morality and relieving distresses. Societies belonging to the first class extend their attention to all the sciences and literature in general, or, devote it to one particular science. The same observation may be applied to those which are instituted for improving arts and manufactures. Those of the third class are established, either with a view to prevent crimes, as the Philanthropic Society; or for the diffusion of the Christian religion among unenlightened nations, as the Society for the Propagation of the Gospel in Foreign Parts; or for introducing arts and civilization, along with a knowledge of the Christian religion, as the Sierra Leone company.

The honour of planning and instituting societies for those valuable purposes is due to modern times. A literary association is said to have been formed in the reign of Charlemagne (see Academy); but the plan seems to have been rude and defective. Several others were instituted in Italy in the 16th century; but from the accounts which we have seen of them, they seem to have been far inferior to those which are most flourishing at present. The most enlarged idea of literary societies seems to have originated with the great Lord Bacon, the father of modern philosophy, who recommended to the reigning prince to institute societies of learned men, who should give to the world from time to time a regular account of their researches and discoveries. It was the idea of this great philosopher, that the learned world should be united, as it were, into one immense republic; which, though consisting of many detached states, should hold a strict union and preferre a mutual intelligence with each other, in every thing that regards the common interest. The want of this union and intelligence he laments as one of the chief obstacles to the advancement of science; and, justly considering the institution of public societies, in the different countries of Europe, under the auspices of the sovereign, to be the best remedy for that defect, he has given, in his facile work, the New Atlantis, the delineation of a philosophical society.
Society on the most extended plan, for the improvement of all arts and sciences; a work which, though written in the language, and tinted with the colouring of romance, is full of the noblest philosophic views. The plan of Lord Bacon, which met with little attention from the age in which he lived, was designed to produce its effect in a period not very distant. The scheme of a philosophical colloberry Cowley is acknowledged to have had a powerful influence in procuring the establishment of the Royal Society of London by charter from Charles II.; and Cowley's plan is manifestly copied in almost all its parts from that in the New Atlantis. The institution of the Royal Society of London was soon followed by the establishment of the Royal Academy of Sciences at Paris; and these two have served as models to the philosophical academies of highest reputation in the other kingdoms of Europe.

The experience of ages has shown, that improvements of a public nature are best carried on by societies of liberal and ingenious men, uniting their labours without regard to nation, sect, or party, in one grand pursuit alike interesting to all, whereby mutual prejudices are worn off, and a humane philosophical spirit is cherished. Men united together, and frequently meeting for the purpose of advancing the sciences, the arts, agriculture, manufactures, and commerce, may oftentimes suggest such hints to one another as may be improved to important ends; and such societies, by being the repositories of the observations and discoveries of the learned and ingenious, may from time to time furnish the world with useful publications which might otherwise be lost; for men of ingenuity and modesty may not choose to risk their reputation, by sending abroadapatronized knowledge both serenely and without regard to the invariable and enterprising with pecuniary premiums or honorary rewards.

Societies instituted for promoting knowledge may also be of eminent service, by exciting a spirit of emulation, and by enkindling those sparks of genius which otherwise might for ever have been concealed; and if, when possessed of funds sufficient for the purpose, they reward the exertions of the industrious and enterprising with pecuniary premiums or honorary medals, many important experiments and useful discoveries will be made, from which the public may reap the highest advantages.

Eminent instances of the beneficial effects of such institutions we have in the Royal academy of Sciences at Paris, the Royal Society, and the Society instituted for the Encouragement of Arts, Manufactures, and Commerce, in London, and many others of a similar kind. Hereby a spirit of discovery and improvement has been excited among the ingenious in almost every nation; knowledge of various kinds, and greatly useful to mankind, has taken place of the dry and uninteresting speculations of scholiasts; and bold and erroneous hypotheses has been obliged to give way to demonstrative experiment. In short, since the establishment of these societies, solid learning and philosophy have more increased than they had done for many centuries before.

As to these societies established for promoting industry, religion, and morality, and relieving distress, the design is laudable and excellent, and presents a beautiful picture of the philanthropy of modern times. We are happy to find, from the minutes of some of their proceedings, that their beneficial effects are already conspicuous.

We will now give some account of the most eminent societies; arranging them under the three classes into which we have divided them: I. Religious and Humane Societies. II. Societies for Promoting Science and Literature. III. Societies for Encouraging Arts, Manufactures, &c.

I. Religious and Humane Societies.

1. Society for the Propagation of the Gospel in Foreign Parts was instituted by King William III. in 1701, in order to secure a maintenance for an orthodox clergy, and to make other provisions for propagating the Gospel in the plantations, colonies, and islands beyond the seas. To that end he incorporated the archbishops, several of the bishops, and others of the nobility, gentry, and clergy, to the number of 90, into one body, which, by the name of The Society for the Propagation of the Gospel in Foreign Parts, was to plead and be implored to have perpetual succession, with privilege to purchase L. 2000 a-year inheritance, and citates for lives or years, with other goods and chattels to any value. By its charter the society is authorized to use a common seal; and to meet annually on the third Friday in February for the purpose of choosing a president, vice president, and officers of the year ensuing; and on the third Friday in every month, or oftener if there should be occasion, to transact business, and to depute persons to take subscriptions, and collect money contributed for the purposes aforesaid; and of all moneys received and laid out, it is obliged to give account yearly to the lord-chancellor or keeper, the lord chief-justice of the common-law, and to make other provisions for propagating the canons of the church; and when the new society was formed, they had already transmitted to America and the West Indies L. 800 worth of Bibles, Books of Common Prayer, and tracts of practical religion, besides securing a tolerable maintenance to several clergy-men on this continent. This association still subsists under the denomination of The Society for Propagating Christian Knowledge and has been productive of much good in the cities of London and Westminster; but upon the formation of the new society into which all its original members were incorporated by name, the care which the voluntary association had taken of the colonies devolved of course upon the incorporated society; of which incorporation we believe the object has been sometimes mislaiden, and the labours of its missionaries grossly misrepresented. It has by many been supposed that the society was incorporated for the sole purpose of converting the savages Americans; and it has been much blamed for sending missionaries into provinces where, in the delpicable cant of the complainers, a Gospel-ministry was already established. But an impartial view of the
life and progress of the American provinces, now become independent states, will show the folly and injustice of those complaints.

The English colonies in North America were in the last century formed and first peopled by religious men; who, made uneasy at home by their intolerant brethren, left the old world to enjoy in peace that first and chief prerogative of man, the free worship of God, according to his own conscience. At one time Puritans were driven across the Atlantic by the episcopal church; at another, Churchmen were forced away by the presbyterians just as the revolutions of state threw the civil power into the hands of the one or the other party; and not a few members of the Church of Rome were chased to the wilds of America by the united exertions of both. It has often observed, that people persecuted for their religion become for the most part enthusiastically attached to it; and the conduct of these colonists was in perfect harmony with this observation. Their zeal, inflamed by their violent removal to the other hemisphere, kept religion alive and active among themselves; but their poverty disabled them from supplying fuel to the flame, by making provision for a ministry to instruct their offspring. The consequence was, that the new Christian commonwealth, without the kindly assistance of its mother-country, would have been, in the words of the Roman historian, Res unius statis. Against this danger a timely aid was to be provided by the society; which, as it consisted not of fanatical members, would not intrust the important business of the mission to fanatical preachers, who, though always ready for such spiritual enterprizes, are never qualified to carry them on with success.

It was therefore thought fit to assign a decent maintenance for clergymen of the church of England, who might preach the gospel to their brethren in America; and though these missionaries in general carefully avoided the conduct of those of Rome, whose principal aim is to reduce all churches under submission to the papal tyranny; yet so lately as 1765, did some of the colonies, in which the puritanic spirit of the last century characterized the church established by law, raise a hideous outcry against the society for sending a mission into their quarters, though only for the service of the dispersed members of the Episcopal church residing among them, and for the conversion of those men whom their rigid fanaticism had prejudiced against Christiannity itself.

Indeed the commodity called freethinking, as Bishop Warburton expresses it, was at an early period imprudently by the opulent and fashionable colonists. The celebrated Berkeley, who had resided some years in Rhode Island, and at his return was called upon to preach the anniversary sermon before the society, informs us, that the island where he lived was inhabited by an English colony, consisting chiefly of seafarers of many different denominations; that several of the better sort of the inhabitants of towns were accustomed to assemble themselves regularly on the Lord's day for the performance of divine worship; but that most of those who were dispersed through the colony rivalled some well bred people of other countries, in a thorough indifference for all that is sacred, being equally careless of outward worship and of inward principles. He adds, that the missionaries had done, and were continuing to do, good service in bringing those planters to a serious sense of religion. "I speak it knowingly (says he), that the missionaries of the Gospel, in those provinces which go by the name of New England, sent and supported at the expense of the society, have, by their sobriety of manners, discreet behaviour, and a competent degree of useful knowledge, shown themselves worthy of the choice of those who sent them." We have the honour to be acquainted with some of the missionaries sent at a later period, and have reason to believe that, down to the era of the American revolution, they had the same virtues, and were doing the same good services, which procured to their predecessors this honourable testimony from one of the greatest and the best of men. Surely such a mission deferred not to be evil spoken of by feds of any denomination who believe in Christ; especially as the very charter of incorporation alluded in a reason for missionaries being sent to the colonies, "that by reason of their poverty those colonies were destitute and unprovided of a maintenance for ministers and the public worship of God."

The society, however, was incorporated for other purposes than this. It was obliged by its charter to attempt the conversion of the native Americans and the negro slaves; and we have reason to believe, that, as soon as the spiritual wants of the colonists were decently supplied, it was not inattentive to these glorious objects. Its succés indeed in either pursuit has not been so great as could be wished; but it would be rash and unfair to attribute this failure to the president, vice-president, or other officers of the corporation at home. An erroneous notion, that the being baptized is inconsistent with a state of slavery, rendered the selfish colonists for a long time averse from the conversion of their negroes, and made them throw every obstacle in the way of all who made the attempt; while the difficulties of the Indian mission are such as hardly any clergymen educated in a Protestant country can be supposed able to surmount.

He who hopes to successfully preach the Gospel among a tribe of savage wanderers, must have an ardent zeal and unwearied diligence; appetites subdued to all the difficulties of want; and a mind superior to all the terrors of mortality. These qualities and habits may be acquired in the church of Rome by him who from infancy has been trained up in the severities of some of the monastic orders, and afterwards sent to the college de propaganda fide to be instructed in the languages, and inured to the manners and customs of the barbarous nations whose conversion he is defined to attempt. But in the reformed churches of Britain there are no monastic orders, nor any college de propaganda fide; and yet without the regular preparation, which is to be looked for in such institutions alone, it is not in nature, whatever grace may effect, for any man cheerfully and at the same time fairly to undertake all the accumulated difficulties ever ready to overtake a faithful missionary among savage idolaters. A fanatical zealot will indeed undertake it, though he is totally unqualified for every sober and important work; and a man of ruined fortunes may be pressed into the service, though the impotency of his mind has shown him unable to bear either poverty or riches. The failure of the society therefore in its attempts to convert the American Indians may be attributed, we think, in the first instance,
Propos'd for the better Supplying of Churches in our Foreign Plantations, &c.

Religious and Humane Societies.

Soc, to the want of a college de propaganda for training up young men for the American mission.

Perhaps another cause of this failure may be found in the conduct of the missionaries, who, it is to be presumed, have not always employed in a proper manner even the scanty qualifications which they actually possessed. The Gospel plain and simple as it is, and fitted in its nature for what it was ordained to effect, cannot be understood but by an intellect somewhat raised above that of a savage. Such of the missionaries therefore as began their work with preaching to savage and brutal men, certainly set out at the wrong end; for to make the Gospel understood, and much more to propagate and establish it, those savages should have been first taught the necessary arts of civil life, which, while they improve every bodily accommodation, tend at the same time to enlarge and enlighten the understanding. For want of this previous culture, we doubt not, it hath happened that such of the savages as have been baptised into the faith have so seldom persevered themselves, or been able in any degree to propagate among their tribes the Christianity which they had been taught, and that successful missions have always found it necessary to begin anew the work of conversion.

To one or other of these causes, or to both, may justly be attributed the little progress which reformed Christianity has made among the Indians of North America; and not to any want of zeal, attention, or liberality, in the directors of the society at home. During the dependence of the United States on the mother-country, great part of the society's funds was properly expended in keeping alive a just sense of religion among the Christian colonists from Europe, who had hitherto the first claims upon this best of charities; but now that America has separated herself from Great Britain, and shows that she is able to maintain her independence, and to make ample provision for a regular clergy of her own, the members of the corporation must feel themselves at liberty to bestow greater attention, and to expend more money than they could formerly do, on the conversion of such Indians as have any intercourse with the settlements which Britain still possesses. To a body so respectable, we presume not to offer advice; but we cannot help thinking, with Bishop Berkeley, that the most successful missionaries would be children of Indians, educated in a considerable number together from the age of ten or twelve in a college de propaganda fide, where they should be in no danger of losing their mother-tongue while they were acquiring a competent knowledge of religion, morality, history, practical mathematics, and agriculture. "If there were a yearly supply (says he) of a dozen such missionaries sent abroad into their respective countries, after they had received the degree of master of arts, and been admitted into holy orders, it is hardly to be doubted but that in a little time the world would see good and great effects of their mission."

2. Society in Scotland for propagating Christian Knowledge, was instituted in the beginning of the present century. At that period the condition of the Scotch Highlanders was truly deplorable. Shut up in desolate islands by tempestuous seas, or dispersed over a wide extent of country, intersected by high mountains, rapid rivers, and arms of the sea, without bridges or highways, by which any communication could be kept open either with remote or neighbouring districts, they lived in small detached companies in hamlets or solitary huts. Being thus excluded from intercourse with the more civilized part of the island, they could not enjoy the advantages of trade and manufactures. As their soil was barren and their climate severe, in agriculture no progress was to be expected; and as they were acquainted with no language but Gaelic, in which no books were then written, to possess knowledge was impossible. Their parishes being of great extent, often 30 or 40 miles long and of a proportionable breadth, and sometimes consisting of several islands separated by seas, which are often impassable, a considerable number of the inhabitants was entirely deprived of religious instruction or fell a prey to Pagan emiaries. A single school in such extensive parishes could be of little benefit; yet many parishes were entirely destitute even of this resource: and whereas schools were established, the want of books prevented them from producing the useful effects otherwise to have been expected from them (a). To all this we must add, that they lived in a state of the greatest oppression: For though the Highlands formed a part of the British empire, the blessings of the British constitution had not reached them. The feudal fylem reigned in its utmost rigour; the chieftains exercising the most despotic sway over the inferior Highlanders, whom at their pleasure they deprived of their lives or property (b).

Thus the Highlanders were ignorant, oppressed, and uncivilized; slaves rather than subjects; and either entirely destitute of the advantages of the Christian religion, or unqualified to improve them. Hitherto they had been unhappy and destitute to themselves and dangerous to the state; for they were ready at the call of their chieftains to issue from their mountains, and to turn their arms against their lawful king and his loyal subjects. This character, however, arose from their situation. It was therefore impossible for benevolent minds to contemplate this unhappy situation of their countrymen without feeling a desire to raise them to the dignity of rational beings, and to render them useful as citizens.

Accordingly, in the year 1701, some private gentlemen of the city of Edinburgh, who had formed themselves into a society for the reformation of manners, directed their attention to the Highlands of Scotland, and endeavoured to devise some plan for alleviating the distresses of the inhabitants. The remedy which promised to be most efficacious was, to establish charity schools in different places. But as the exigency was great, it was no easy matter to raise a sufficient fund for this

(a) Even so late as the year 1758, no fewer than 175 parishes, within the bounds of 30 presbyteries, had no parochial school. We are sorry to add, that even in the present enlightened and benevolent age the complaint is not entirely removed.

(b) The feudal system was at length abolished in the year 1748 by the jurisdicition act.
Religious and Humane Societies.

This purpose. They began therefore with what voluntary subscriptions they could procure, hoping afterwards to increase their capital by vacant stipends and public contributions. A memorial with this view was presented to the General Assembly in 1704, which received their approbation; and they accordingly 팔led an act, recommending a general contribution. In 1706 the General Assembly appointed some of their number to inquire more carefully into the state of the Highlands, and the year following appointed a select committee to confer with the gentlemen who had suggested the plan. The result of these conferences was the publication of proposals "for propagating Christian knowledge in the Highlands and islands of Scotland, and in foreign parts of the world." Copies of these proposals, with subscription papers, were distributed through the kingdom; and the contributions having soon amounted to L. 1000, her majesty Queen Anne encouraged this infant society by her royal proclamation, and at the same time issued letters patent under the great seal of Scotland for erecting certain of the subscribers into a corporation; the first nomination of whom was lodged with the lords of council and session.

This corporation held its first meeting on Thursday 3d November 1709. It was attended by several of the nobility, fourteen of the lords of session, many gentlemen of rank, together with most of the ministers of the city of Edinburgh and neighbourhood. A president, secretary, and treasurer, with a committee of fifteen directors, were appointed for the dispatch of business. At their second meeting in January 1710, a scheme of management was formed and approved; in which it was proposed, 1. To erect and maintain schools in such places of Scotland, particularly in the Highlands and islands, as should be found to need them most; in which schools all persons whatsoever should be taught by fit and well qualified schoolmasters, appointed by the society, to read the Holy Scriptures and other pious books; as also to write, and to understand the common rules of arithmetic, with such other things as should be thought suitable to their circumstances. 2. That the schoolmasters should be particularly careful to instruct their scholars in the principles of the Christian reformed religion; and for that end should be obliged to catechise them at least twice a week, and to pray publicly with them twice a day. 3. That not only such as were unable to pay should be taught gratis, but that those whose circumstances required it, should have such farther encouragement as the society should think fit in a conformity with their patent. 4. To name some prudent persons, ministers and others, to be overseers of those schools, who should take care that the schoolmasters do their duty, and that the instructions to be given from time to time by the society or their committee be punctually observed; which overseers should make their report to the society quarterly or half-yearly at farthest. 5. To give suitable encouragement to such ministers or catechists as should be willing to contribute their assistance towards the farther instruction of the scholars remote from church, by not only catechising, but preaching to them; which ministers or catechists should take the same care of the other inhabitants as of the scholars. 6. To extend their endeavours for the advancement of the Christian religion to heathen nations; and for that end to give encouragement to ministers to preach the Gospel among them.

Having thus formed a plan, they immediately proceeded to establish schools in the most useful and economical manner; and as the capital continued to accumulate, the interest was faithfully applied, and the utility of the institution was more extensively diffused.

Until the year 1738 the attention of the society had been wholly directed to the establishment of schools; but their capital being then considerably augmented, they began to extend their views of utility much farther. The grand object of all public associations ought certainly to be the promoting of religion and morality. It must, however, be evident to every man of reflection, that these can neither be propagated nor preserved among a people without agriculture, unaccustomed to commerce and manufactures, and consequently without labour or exertion. Langour and debility of mind must always be the companions of idleness. While the Highlanders roved about with arms in their hands, the latent vigour of their minds must often have been called forth into action; but when their arms were taken away, and themselves confined to a domestic life, where there was nothing to rouse their minds, they must have sunk into indolence and inactivity. All attempts therefore to instruct them in religion and morality, without introducing among them some of the necessary arts of life, would probably have been unavailing. The society accordingly resolved to adopt what appeared to them the most effectual methods of introducing industry among the Highlanders. But as their patent did not extend far enough, they applied to his majesty George II. for an enlargement of their powers; and accordingly obtained a second patent, by which they are empowered, besides fulfilling the purposes of their original patent, to cause such of the children as they shall think fit to be bred to husbandry and houfework, to trades and manufactures, or in such manual occupations as the society shall think proper.

The objects of this second patent the society have not failed to pursue; and though many obstacles and discouragements to their efforts occurred among a rude and barbarous people, yet their perseverance, and the obvious utility of their plans, at length so far overcame the reluctance of the inhabitants, that no less than 94 schools of industry in various parts of the Highlands and islands are now upon their establishment, at which are educated 3360 scholars.

The society, while anxiously endeavouring to diffuse a spirit of industry through the Highlands, were still equally solicitous to promote the knowledge of the Christian religion. As the English language had been the only channel by which knowledge was conveyed to them (a language which, being not used in conversation, was in all respects foreign to them), it was judged requisite that they should have the Scriptures in their vernacular tongue. The society therefore first appointed a translation of the New Testament to be made into Gaelic: A translation was accordingly undertaken by the Rev. Mr Stewart minister of Killin in Perthshire, and printed in 1767, which is said to be executed with much fidelity. Of this work many thousand copies have been distributed in the Highlands. The greater part of the Old Testament has also been translated.
by the Rev. Dr Smith of Campbelton and others, but chiefly by the Rev. Dr Stewart of Luss, by the appointment and at the expense of the society; and as soon as the remaining part can be got ready, the whole will be sold at so low a price as the poor may without difficulty afford. This plan the society have judiciously chosen, in order to prevent discontent and murmuring; effects which the diffusion of the Scriptures ought never to produce; but which could not possibly have been prevented, had the distribution been gratuitous, and of course partial.

For some years past the funds of the society have rapidly accumulated, from the very liberal donations of several individuals.

In consequence of these great additions to their stock, insufficiencies have been thrown out that the society have become so wealthy as to be at a loss for proper objects on which to bestow their increased revenue. If such an opinion be seriously entertained by any one, we must beg him to remember, that the society have erected and endowed no less than 323 schools for religion, the first principles of literature and industry, at the annual expense of L. 3214, 10s. Sterling; and that at these seminaries are educated from 14,000 to 15,000 children; who, but for the means of instruction thus obtained, would in all probability be bred up in ignorance and idleness: That they employ 12 missionary ministers and catechists in remote parts of the Highlands and islands, or among the ignorant Highlanders settled in the great towns of Scotland, at the annual expense of L. 296: That they bestow a burse or pension of L. 15 per annum on each of six students of divinity having the Gaelic language: That they employ two missionary ministers and one schoolmaster among the Oneida and Stockbridge Indians of North America (being the definition of certain legacies bequeathed to them for that purpose), at the annual expense of L. 140. Such is their fixed scheme of annual expenditure, amounting in all to L. 3740, 10s. Sterling—a sum it will be acknowledged of very considerable magnitude. The whole of their incidental expenses arising from the Gaelic translation of the Scripture of the Old Testament; from annuities which they have to pay, in consequence of sums left them as fundatory legacies; from land and house taxes; from enabling candidates for the office of schoolmaster to come to Edinburgh for examination; from furnishing books to poor scholars in their various schools; and from removing schoolmasters from one station to another, is generally about L. 875, which added to the former sum makes the whole annual expense amount to L. 4615, 10s.

If it be inquired at what expense, in the management of it, this extensive and complicated charity is annually conducted, we are authorized to say, that the treasurer, bookholder, and clerk, are allowed each L. 25 per annum, the same salaries which were annexed to these offices from the commencement of the society. The beadle or officer is allowed L. 12 per annum. No salary whatever is enjoyed by any of the other officers of the society. The secretary, comptroller, accountant, and librarian, although subjected, some of them especially, to no small expense of time and labour, have no pecuniary recompense or emolument. Theirs are labours of love, for which they seek and expect no other reward than the confciences of endeavours to promote the best interest of mankind. The whole amount of the expense of managing the business of the society, including the above salaries, and candles, stationery, war, postages, and other incidents, exceeds not at an average L. 115 per annum. From this statement it appears, that hitherto at least the directors have been at no loss for important objects within the proper sphere of their institution on which to bestow their increased funds. They have, it is true, the dispositions of very considerable sums for promoting the objects of the institution; but they are so far from accumulating wealth, that every year their expenditure, notwithstanding the late increase of their capital, exceeds rather than falls short of their income. They have depended upon a kind Providence and a generous public to refund these anticipations of their revenue, and hitherto they have never been disappointed.

Thus has the Society for Propagating Christian Knowledge proceeded for almost a century. It was founded by the pious exertions of a few private individuals, whose names are unknown to the world; and its funds, by faithful and judicious management, as well as by generous contributions, have now become of such magnitude, as to excite the hope that they will be productive of the most valuable effects. The benefits arising from public societies, it is well known, depend entirely upon the management of their directors. If so, the advantages which have accrued from this society intitle it to the praise and gratitude of the nation. While eager to increase the number of schools, the society have not been inattentive to their prosperity. In the year 1771 Mr. Lewis Drummond, a gentleman in whom they placed great confidence, was commissioned by them to visit their schools, and to make an exact report of their state and circumstances. Again, in the year 1795, a commission was granted to the Rev. Dr Kemp, one of the ministers of Edinburgh and secretary to the society, to visit all the schools on their establishment. This laborious and gratifying task he accomplished in the course of four summers with much ability and care, and highly to the satisfaction of the society. At his return he communicated a variety of important information respecting the state of the Highlands and islands, and the means necessary for their improvement in religion, literature, and industry; an abstract of which was published by the society in appendices to the anniversary sermons preached before them in the years 1789, 90, 91, and 92 (c).

(c) It is well known, that the number of Roman Catholics in the Highlands is considerable; but it must give much pleasure to the Protestant reader to be informed, that the ancient maligniant spirit of Popery has in that district given place to mildness and liberality. This is chiefly owing to the gentleman who superintends the priests in that quarter, whose mind is enlightened by science and learning. So far from being hostile to the

Societies

The following table will exhibit at a glance the funds, establishment, and expenditure, of the society, from a few years after its commencement to the present time. Where the number of scholars is not mentioned, the defects may be supplied by taking an average from those years, where a computation has been made. Where the capital is not mentioned, it may easily be made out by considering the salaries as the interest.

Hitherto we have taken no notice of the corresponding board which was established at London so early as the year 1729, to receive subscriptions and lay out sums. That board indeed remained long inactive; but in 1773 its members began to co-operate more cordially with their brethren in Scotland. Since that period an annual sermon has been preached in recommendation of the charity; and the preacher is now selected without any regard to the religious denomination to which he belongs; sometimes from the church of England, sometimes from the church of Scotland, and sometimes from sectaries of different persuasions. The meetings of the corresponding board have been attended by many of the nobility and gentry, who have made great exertions to promote the views of the society. From its present flourishing state therefore, from the indefatigable exertion and laudable zeal of the managers, and from the countenance and support which they have received from persons of the first rank and reputeability in the nation, the benevolent mind may look forward with much confidence and satisfaction to a period not very distant, when its beneficial effects shall be felt not only in the Highlands, but shall be communicated to the rest of the nation. We have been thus particular in our account of the Society for Propagating Christian Knowledge, because we have had access to the most authentic sources of information, and because we know it to be an institution calculated to enlighten and improve a considerable part of the British nation.

3. Society of the Sons of the Clergy, was incorporated by King Charles II. in 1675, by the name of The Governor of the Charity for Relief of the Poor Widows and Children of Clergymen. Societies for Promoting Science and Literature.

I. The Royal Society of London is an academy or body of persons of eminent learning, instituted by Charles II. for the promoting of natural knowledge. The origin of this society is traced by Dr Sprat, its earliest historian, no farther back than to "some space after the end of the civil wars" in the last century. The scene of the first meetings of the learned men who laid the foundation of it, is by him fixed in the university of Oxford at the lodgings of Dr Wilkins warden of Wadham college. But Dr Birch, on the authority of Dr Wallis, one of its earliest and most considerable members, assigns it an earlier origin. According to him, certain persons residing in London about the year 1645, being "inquisitive into natural and the new and experimental philosophy, agreed to meet weekly on a certain day, to discourse upon such subjects, and were known by the title of The Invisible or Philosophical College." In the years 1648 and 1649, the company who formed these meetings were divided, part retiring to Oxford and part remaining in London; but they continued the fame pursuits as when united, corresponding with each other, and giving a mutual account of their respective discoveries. About the year 1650 the greater part of the Oxford society returned to London, and again uniting with their fellow-labourers, met once, if not twice, a week at Gresham college, during term time, till they were scattered by the public disaffections of that year, and the place of their meeting made a quarter for soldiers. On the restoration 1660 their meetings were revived, and attended by a greater concourec of men eminent for their rank and learning. They were at first taken notice of by the king, who having himself a considerable taste for physical science, was pleased to grant them an ample charter, dated the 15th of July 1662, and afterwards a second dated 17th April 1663, by which they were erected into a corpo

To carry into effect these desirable purposes, it is the first business of the society to select from prisons, and from the haunts of vice, profligacy, and beggary, such objects as appear most likely to become obnoxious to the laws, or prejudicial to the community; and, in the execution of this duty, the assistance of the magistrates, the clergy, and all who are interested in the promotion of good morals and good government, is most earnestly requested. For the employment of the children, several houses are supported, at Cambridge Heath, near Hackney, in each of which a master-workman is placed for the purpose of teaching the children some useful trade. The trades already established are those of printer, carpenter, shoemaker, and tailor. The girls are at present educated as domestic servants.

In the year 1791 no less than 70 children were under the protection of this society, among whom were many who had been guilty of various felonies, burglaries, and other crimes. Yet, singular as it may appear, in less than two years those very children became no less remarkable for industry, activity, decency, and obedience, than they formerly were for the contrary vices. Such are the grounds on which the Philanthropic Society now claims the attention and solicits the patronage of the public. If we regard humanity and religion, this institution opens an asylum to the most forlorn and abject of the human race; it befriends the most friends; it saves from the certain and fatal consequences of infamy and vicious courses orphans and deserted children. If we regard national prosperity and the public welfare, it is calculated to increase industry; and it directs that industry into the most useful and necessary channels. If we regard self-interest, its immediate object is to protect our persons from assault and murder, our property from depredation, and our peaceful habitations from the derelicts of midnight incendiaries.

One guinea per annum constitutes a member of the society; and an annual payment of at least two guineas, is a necessary qualification for being elected into the committee.

II. Societies for Promoting Science and Literature.

6. The Philanthropic Society, was instituted in September 1788. It aims at the prevention of crimes, by removing out of the way of evil counsel, and evil company, tho' those children who are, in the present state of things, defined to ruin. It proposes to educate and instruct in some useful trade or occupation the children of convicts or other infant poor who are engaged in vagrant or criminal courses; thus to break the chain of those pernicious confederacies, deprive the wicked of their victims, and by all these means add citizens to the two cafes of the society, their places of meeting.

The society has published an 8vo volume with plates, containing a variety of interesting matter relating to the object of this benevolent institution.

The society was at first composed of members of the learned professions, and at first it was called the "Philanthropic Society," but it was soon afterwards changed to its present name. The society is supported by subscriptions, and the annual subscription is one guinea. The society has a house of correction, where the children are instructed in various trades, and are afterwards placed in the service of respectable families. The society has also a hospital for the care of the sick, and a school for the instruction of the deaf and dumb. The society has a library, and a museum, and a lending library.

The society has also a library, and a museum, and a lending library.

The society has also a library, and a museum, and a lending library.

The society has also a library, and a museum, and a lending library.
Society for Promoting Science and Literature.

...Ruddiman and others, which in 1731 was succeeded by a society instituted for the improvement of medical knowledge. In the year 1731 the celebrated Mac- 

lawr von conceived the idea of enlarging the plan of this society, by extending it to subjects of philosophy and literature. The institution was accordingly new modelled by a printed set of laws and regulations, the number of members was increased, and they were dis-

tinguished from that time by the title of The Society for Improving Arts and Sciences, or more generally by the title of The Philosophical Society of Edinburgh. Its meetings, however, were soon interrupted by the disorders of the country during the rebellion in 1745; and they were not renewed till the year 1752. Soon after this period the first volume of the Transactions of the Philosophical Society of Edinburgh was published under the title of Essays and Observations, Physical and Literary, and was followed by other volumes of acknowledged merit. About the end of the year 1782, in a meeting of the professors of the university of Edinburgh, many of whom were likewise members of the Philosophical Society, and warmly attached to its interests, a scheme was proposed by the Rev. Dr Robertson, principal of the university, for the establishment of a new society on a more extended plan, and after the model of some of the foreign academies. It appeared an expedient measure to solicit the royal patronage to an institution of this nature, which promised to be of national importance, and to request an establishment by charter from the crown. The plan was approved and adopted; and the Philosophical Society, joining its influence as a body inseconding the application from the university, his majesty, as we have already observed, was pleased to incorporate The Royal Society of Edinburgh by charter.

This society consists of ordinary and honorary members; and the honorary places are restricted to persons residing out of Great Britain and Ireland. The election of new members is appointed to be made at two stated general meetings, which are to be held on the fourth Monday of January and the fourth Monday of June. A candidate for the place of an ordinary member must signify by a letter, addressed to one of the members, his wish to be received into the society. He must then be publicly proposed at least a month before the day of election. If the proposal be seconded by two of the members present, his name is to be inserted in the list of candidates, and hung up in the ordinary place of meeting. The election is made by ballot, and is determined in favour of a candidate, if he shall have the votes of two thirds of those present, in a meeting consisting of at least 21 members. The general business of the society is managed by a president, two vice-presidents, with a council of 12, a general secretary, and a treasurer. The officers are chosen by ballot annually on the first Monday of November. All public deeds, whether of a civil or of a literary nature, are transacted by this board, and proceed in the name of the president or vice president.

As it was thought that the members would have a greater inducement to punctual attendance on the meetings of the society, if they had some general intimation of the nature of the subjects which were to be considered, and made the topic of conversation, it was there-
Soc.

Soc. for

Promoting

Science and

Literature.

Soc.

fore resolved to divide the society into two classes, which should meet and deliberate separately. One of these classes is denominated the Physical Clas, and has for its department the sciences of mathematics, natural philosophy, chemistry, medicine, natural history, and whatever relates to the improvement of arts and manufactures. The other is denominated the Literary Clas, and has for its department literature, philology, history, antiquities, and speculative philosophy. Every member is entitled at his admission to intimate which of these classes he wishes to be more particularly associated with; but he is at the same time intimated to attend the meetings of the other class, and to take part in all its proceedings. Each of the classes has four presidents and two secretaries, who officiate by turns. The meetings of the physical class are held on the first Mondays of January, February, March, April, July, August, November, and December; and the meetings of the literary class are held on the third Mondays of January, February, March, April, June, July, November, and December, at 7 o'clock afternoon.

At these meetings the written essays and observations of the members of the society, on their researches, are read publicly, and become the subjects of conversation. The subjects of these essays and observations are announced at a previous meeting, in order to engage the attendance of those members who may be particularly interested in them. The author of each dissertation is likewise desired to furnish the society with an abstract of it, to be read at the next ensuing meeting, when the conversation is renewed with increased advantage, from the knowledge previously acquired of the subject. At the same meetings are exhibited such specimens of natural or artificial curiosities, such remains of antiquity, and such experiments, as are thought worthy of the attention of the society. All objects of natural history presented to the society, are ordered by the charter of the institution to be deposited, on receipt, in the museum of the university of Edinburgh; and all remains of antiquity, public records, or ancient manuscripts, in the library belonging to the faculty of advocates at Edinburgh.

The ordinary members, whose usual residence is in the city of Edinburgh or its immediate neighbourhood, are expected to attend regularly the monthly meetings; and are required to defray, by an annual contribution, the current expenses of the institution. The members who reside at such a distance from Edinburgh, that they cannot enjoy the advantages arising from a regular attendance on the meetings of the society, are not subjected to any contribution for defraying its expenses, but have a right to attend those meetings when occasionally in Edinburgh, and to take part in all their proceedings.

Three volumes of the Transactions of the society have been published, which bear ample testimony to the learning and acuteness of their various authors.

3. Medical Society of London, instituted in the year 1752, on the plan recommended by Lord Bacon (De Augm. Scient. lib. iv. cap. 2.), to revive the hippocratic method of composing narratives of particular cases, in which the nature of the disease, the manner of treating it, and the consequences, are to be specified; to attempt the cure of those diseases which, in his opinion, have been too boldly pronounced incurable; and, lastly, to extend their inquiries after the powers of particular medicines in the cure of particular cases; the collections of this society have been already published under the title of Medical Observations and Inquiries, in several volumes.

4. The Medical Society of Edinburgh was incorporated by royal charter in 1778; but there appears to have been in that city a voluntary association of the same name from the first establishment of a regular school of physic in the university. To the voluntary society the public is indebted for six volumes of curious and useful essays, collected principally by the late Dr Monro from June 1731 to June 1736; but in the year 1739 that society was united to another, as we have already observed, in a former article. The ordinary members of the present medical society are elected by ballot, and three dissententent exclude a candidate; an ordinary member may also be elected an honorary member, who enjoys the privileges of the others, and receives a diploma, but is freed from the obligation of attendance, delivering papers in rotation, &c. to which the ordinary members are subjects; but in this case the votes must be unanimous. The meetings of their society are held every Saturday evening in their own hall, during the winter season, when papers on medical subjects are delivered by the several members in rotation; and four of these are annually elected to fill the chair in rotation, with the title of annual presidents.

5. The Royal Medical Society was instituted in 1776. The members are divided into associates ordinary, limited to 30, honorary to 12, extraordinary to 60, and foreign to 60, and correspondents. This society has published several volumes of Memoirs in 4to.

6. Asiatic Society, an institution planned by the late illustrious Sir William Jones, and actually formed at Calcutta on the 15th of January, 1784, for the purpose of tracing the history, antiquities, arts, sciences, and literature, of the immense continent of Asia. As it was resolved to follow as nearly as possible the plan of the Royal Society of London, of which the king is patron, the patronage of the Asiatic Society was offered to the governor-general and council, as the executive power in the territories of the company. By their acceptance of this offer, Mr Hatfield, as governor-general, appeared among the patrons of the new society; but he seemed in his private station as the first liberal promoter of useful knowledge in Bengal, and especially as the great encourager of Persian and Sanscrit literature, to deserve a particular mark of distinction; he was requested, therefore, to accept the honorary title of president. This was handsomely declined in a letter from Mr Hatfield, in which he requested, 'to yield his pretensions to the gentleman whose genius planned the institution, and who was most capable of conducting it to the attainment of the great and splendid purposes of its formation.' On the receipt of this letter, Sir William Jones was nominated president of the society; and we cannot give the reader a view of the object of the institution in clearer language than that which he employed in his first discourse from the chair.

"It is your design, I conceive (said the president) to take an ample space for your learned investigations, bounding them only by the geographical limits of Asia; so that, considering Hindostan as a centre, and turning your eyes in idea to the north, you have on your right many
S O C

S O C

many important kingdoms in the eastern peninsula, the ancient and wonderful empire of China with all her Tartarian dependencies, and that of Japan, with the cluster of precious islands, in which many singular curiosities have too long been concealed; before you lies that prodigious chain of mountains, which formerly perhaps were a barrier against the violence of the sea, and beyond them the very interesting country of Tibet, and the vast regions of Tartary, from which, as from the Trojan horse of the poet, have issued so many formidable warriors, whose domain has extended at least from the banks of the Ilyus to the mouths of the Ganges: on your left are the beautiful and celebrated provinces of Iran or Persia, the unmeasured and perhaps unmeasurable deserts of Arabia, and the once flourishing kingdom of Yemen, with the pleasant isles that the Arabs have subdued or colonized; and farther westward, the Asiatic dominions of the Turkifh sultans, whose moon seems approaching rapidly to its wane. By this great circumference the field of your useful researches will be inclosed; but since Egypt had unquestionably an old connection with this country, if not with China, since the language and literature of the Abyllinians bear a manifest affinity to those of Asia, since the Arabian arms prevailed along the African coast of the Mediterranean, and even erected a powerful dynasty on the continent of Europe, you may not be displeased occasionally to follow the streams of Asiatic learning a little beyond its natural boundary; and, if it be necessary or convenient that a short name or epithet be given to our society, in order to distinguish it in the world, that of Asiatic appears both classical and proper, whether we consider the place or the object of the institution, and preferable to Oriental, which is in truth a word merely relative, and though commonly used in Europe, conveys no very distinct idea.

"If now it be asked, What are the intended objects of our inquiries within these spacious limits? we answer, Man and Nature; whatever is performed by the one or produced by the other. Human knowledge has been elegantly analyz'd according to the three great faculties of the mind, memory, reason, and imagination, which we constantly find employed in arranging and retaining, comparing and distinguishing, combin'd and diversifying, the ideas, which we receive through our senses, or apperception; hence the three main branches of learning are, History, Science, and Art: the first comprehends either an account of natural productions, or the genuine records of empires and states; the second embraces the whole circle of pure and mixed mathematics, together with ethics and law, as far as they depend on the reasoning faculty; and the third includes all the beauties of imagery and the charms of invention, displayed in modulated language, or represented by colour, figure, or sound.

"Agreeably to this analysis, you will investigate whatever is rare in the stupendous fabric of nature, will correct the geography of Asia by new observations and discoveries; will trace the annals and even traditions of those nations who from time to time have peopled or defolated it; and will bring to light their various forms of government, with their institutions civil and religious; you will examine their improvements and methods in arithmetic and geometry; in trigonometry, mensuration, mechanics, optics, astronomy, and general philosophy; their systems of morality, grammar, rhetoric, and dialectic; their skill in chirurgery and medicine; and their advancement, whatever it may be, in anatomy and chemistry. To this you will add researches into their agriculture, manufactures, trade; and whilst you inquire with pleasure into their music, architecture, painting, and poetry, you will not neglect the inferior arts by which the comforts and even elegancies of social life are supplied or improved. You may observe, that I have omitted their languages, the diversity and difficulty of which are a sad obstacle to the progress of useful knowledge; but I have ever considered languages as the mere instruments of real learning, and think them improperly confounded with learning itself: the attainment of them is, however indispensably necessary; and if to the Persian, Armenian, Turkifh, and Arabic, could be added not only the Shanfrit, the treasures of which we may now hope to see unlocked, but even the Chinefe, Tartarian, Japanese, and the various infori diries, an immense mine would then be open, in which we might labour with equal delight and advantage."

Of this society three volumes of the Transactions have been published, which are replete with information in a high degree curious and important; and we hope that the European world shall soon be favored with another. The much to be lamented death of the accomplished president may indeed damp the spirits of investigation among the members; for to conquer difficulties so great as they must meet with, a portion seems to be necessary of that enthusiasm which accompanied all the pursuits of Sir William Jones; but his successor is a man of great worth and learning, and we trust will use his utmost endeavors to have the plan completed of which Sir William gave the outlines.

5. The American Philosophical Society, held at Philadelphia, was formed in January 1769 by the union of two societies which had formerly subsisted in that city. This society extends its attention to geography, mathematics, natural philosophy, and astronomy; medicine and anatomy; natural history and chemistry; trade and commerce; mechanics and architecture; husbandry and American improvements. Its officers are a president, three vice-presidents, one treasurer, four secretaries, and three curators, who are annually chosen by ballot. The duty of the president, vice-presidents, treasurer, and secretaries, is the same as in other societies. The business of the curators is to take the charge of all specimens of natural productions, whether of the animal, vegetable, or fossil kind; all models of machines and instruments; and all other matters belonging to the society which shall be intrusted to them. The ordinary meetings are held on the first and third Fridays of every month from October to May inclusive. This society was incorporated by charter 15th March 1780; and has published three volumes of its Transactions, containing many ingenious papers on general literature and the sciences, as well as respecting those subjects peculiar to America. It is a delightful prospect to the philosopher to consider, that Asia, Europe, and America, though far separated and divided into a variety of political states, are all three combined to promote the cause of knowledge and truth.

6. A Literary and Philosophical Society of considerable reputation has been lately established at Manchester, under the direction of two presidents, four vice-presidents,
Society for Promoting the Discovery of the Interior Parts of Africa. This society or association first sprang up in the internal districts of Africa, of which so little is at present known, were formed in London by some opulent individuals in 1788; who, strongly impressed with a conviction of the practicability and utility of thus enlarging the fund of human knowledge, determined, if possible, to rescue the age from that stagnation which attaches to its ignorance of so large and so near a portion of the globe. The founders of this society resolved to admit no man a member for a shorter period than three years, during which he must pay annually into the public fund five guineas. After three years, any member, upon giving a year's notice, may withdraw himself from the association. During the first 12 months each of the members was allowed to recommend for the approbation of the society such of his friends as he might think proper to be admitted into it; but since that period we believe all additional members have been elected by a ballot of the association at large. A committee was chosen by ballot to manage the funds of the society, to choose proper persons to be sent on the discovery of the interior parts of Africa, and to carry on the society's correspondence, with express injunctions to disclose no intelligence received from their agents but to the society at large. But a fuller account of the nature of this establishment, and the very happy efforts they have made, may be seen in the superb edition of their proceedings printed in 1790, 4to for their own use; or in the 8vo edition since made public. They soon found two gentlemen, Mr Lucas and Mr Ledyard, who were singularly well qualified for the important mission. The information they have acquired will be found in the above work; with a new map by Mr Rennel, exhibiting the geographical knowledge collected by the African association. Mr Ledyard very unfortunately died during his researches at Cairo.

8. The Society of Antiquaries of London, was founded about the year 1752 by Archbishop Parker, a munificent patron of learned men. For the space of 20 years it flourished in the house of Sir Robert Cotton; in 1759 they resolved to apply to Queen Elizabeth for a charter and a public building where they might hold their meetings; but it is uncertain whether any such application was ever made. In the mean time, the reputation of the society gradually increased, and at length it excited the jealousy of James II. who was afraid lest it should prejudice to canvass the secret transactions of his government. He accordingly dissolved it. But in the beginning of the present century, the Antiquarian Society began to revive; and a number of gentlemen, eminent for their affections to this science, had weekly meetings, in which they examined the antiquities and history of Great Britain preceding the reign of James I. but without excluding any other remarkable antiquities that might be offered to them. From this time the society grew in importance; and in 1750 they unanimously resolved to petition the king for a charter of incorporation. This they obtained the year following, by the influence of the celebrated earl of Hardwicke, then lord-chancellor, and Martin Folkes, Esq; who was then their president. The king declared himself their founder and patron, and empowered them to have a body of officers, and a common seal, and to hold in perpetuity lands, &c., to the yearly value of L. 1000.

The chief object of the inquiries and researches of the society are British antiquities and history; nor, however, wholly excluding those of other countries. It must be acknowledged, that the study of antiquity offers to the curious and inquisitive a large field for research and amusement. The inquirer in this branch furnishes the historian with his best materials, while he distinguishes from the fictions of a bold invention, and ascertains the credibility of facts; and to the philosopher he presents a fruitful source of ingenious speculation, while he points out to him the way of thinking, and the manners of men, under all the varieties of aspect in which they have appeared.

An antiquarian ought to be a man of solid judgment, possessed of learning and science, that he may not be an enthusiastic admirer of every thing that is ancient merely because it is ancient; but be qualified to distinguish between those researches which are valuable and important and those which are trifling and useless. It is from the want of these qualifications that some men have contracted such a blind passion for every thing that is ancient, that they have expatriated themselves to ridicule, and their study to contempt. But if we regard utility we were always to regulate the pursuits of the antiquarian, the shafts of future would no longer be levelled at him; but he would be respected as the man who labours to restore or to preserve such ancient productions as are suited to illuminate religion, philosophy, and history, or to improve the arts of life.

We by no means intend to apply these observations to any particular society of antiquarians; but we throw them out, because we know that an affiduous study of antiquity is apt, like the ardent pursuit of money, to lose light of its original object, and to degenerate into a passion which mingles the mean for the end, and considers perfidious without a regard to utility as enjoyment.

An association similar to that of the Antiquarian Society of London was founded in Edinburgh in 1780, and received the royal charter in 1783.

Besides these literary societies here mentioned, there are a great number more in different parts of Europe, some of which are noticed under the article Academy. Those which are omitted are not omitted on account of any idea of their inferior importance; but either because we have had no access to authentic information; or because they resemble the societies already described so closely, that we could have given nothing but their names.

III. Societies for Encouraging and Promoting Arts, Manufactures, \&c.

1. London Society for the Encouragement of Arts, Manufactures, and Commerces, was instituted in the year 1754 by Lord Folkestone, Lord Romney, Dr Stephen Hales, and a few private gentlemen; but the merit of this institution chiefly belonged to Mr William Shipley,
The office-bearers of this society are a president, 12 vice-presidents, a secretary, and registrar. Their proceedings are regulated by a body, of rules and orders established by the whole society, and printed for the use of the members. All questions and debates are determined by the holding up of hands, or by ballot if required; and no matter can be confirmed without the assent of a majority at two meetings. They invite all the world to propose subjects for encouragement; and whatever is deemed deserving attention, is referred to the consideration of a committee, which, after due inquiry and deliberation, make their report to the whole society, where it is approved, rejected, or altered. A list is printed and published every year of the matters for which they propose to give premiums; which premiums are either sums of money, and those sometimes very considerable ones; or the society's medal in gold or silver, which they consider as the greatest honour they can bestow. All possible care is taken to prevent partiality in the distribution of their premiums, by deferring the claimants' names to be concealed, and by appointing committees (who when they find occasion call to their assistance the most skilful artists) for the strict examination of the real merit of all matters and things brought before them, in conformance of their premiums.

The chief objects of the attention of the Society for the Encouragement of Arts, Manufactures, and Commerce, in the application of their rewards, are ingenuity in the several branches of the polite and liberal arts, useful discoveries, and improvement in agriculture, manufactures, mechanics, and chemistry, or the laying open of any such to the public; and, in general, all such useful inventions, discoveries, or improvements (though not mentioned in the book of premiums), as may appear to have a tendency to the advantage of trade and commerce.

The following are some of the most important regulations of this society. It is required that the matters for which premiums are offered be delivered in without names, or any intimation to whom they belong; that each particular thing be marked in what manner each claimant thinks fit, such claimant sending with it a paper sealed up, having on the outside a corresponding mark, and on the inside the claimant's name and address; and all candidates are to take notice, that no claim for a premium will be attended to, unless the conditions of the advertisement are fully complied with. No papers shall be opened but such as shall gain premiums, unless where it appears to the society absolutely necessary for the determination of the claim; all the referees shall be returned unopened, with the matters to which they belong, if inquired after by the marks within two years; after which time, if not demanded, they shall be publicly burnt unopened at some meeting of the society. All the premiums of this society are designed for that part of Great Britain called England, the dominion of Wales, and the town of Berwick upon Tweed, unless expressly mentioned to the contrary.

No person shall receive any premium, bounty, or encouragement, from the society for any matter for which he has obtained or proposes to obtain a patent. No member of this society shall be a candidate for or intitled to receive any premium, bounty, or reward whatsoever, except the honorary medal of the society.

The respectability of the members who compose it may be seen by perusing the list which generally accompanies their transactions. In the last volume (vol. xii.) it occupies no less than 43 pages. Some idea may be formed of the wealth of this society, by observing that the list of their premiums fills 96 pages and amounts to 250 in number. These consist of gold medals worth from 30 to 50, and in a few instances to 100, guineas; and silver medals valued at 10 guineas.

This society is one of the most important in Great Britain. Much money has been expended by it, and many are the valuable effects of which it has been productive. Among these we reckon not only the discoveries which it has excited, but the institution of other societies on the same principles to which it has given birth; and we do not hesitate to conclude, that future ages will consider the founding of this society as one of the most remarkable epochs in the history of the arts. We contemplate with pleasure the beneficial effects which must result to this nation and to mankind by the diffusion of such institutions; and rejoice in the hope that the active minds of the people of Great Britain, instead of being employed as formerly in controversies about religion, which engender strife, or in discussions concerning the theory of politics, which lead to the adoption of schemes inconsistent with the nature and condition of man, will soon be more generally united into affiliations for promoting useful knowledge and solid improvement, and for alleviating the diffculties of their fellow-creatures.

2. Society instituted at Bath for the Encouragement of Agriculture, Arts, Manufactures, and Commerce. It was founded in the year 1777 by several gentlemen who met at the city of Bath. This scheme met with a very favourable reception both from the wealthy and learned. The wealthy subscribed very liberally, and the learned communicated many important papers. On application to the London and provincial societies instituted for the like purposes, they very politely offered their assistance. Seven volumes of their transactions have already been published, containing valuable experiments and observations, particularly respecting agriculture, which well deserve the attention of all farmers in the kingdom. We have consulted them with much satisfaction on several occasions, and have frequently referred to them in the course of this work; and therefore, with pleasure, embrace the present opportunity of repeating our obligations. We owe the same acknowledgment to the Society for the Improvement of Arts, &c. of London.

3. Society for Working Mines, an association lately formed on the continent of Europe. This institution arose from the accidental meeting of several mineralogists at Sklene near Schenmuntz in Hungary, who were collected in order to examine a new method of amalgamation. Struck with the shackles imposed on mineralogy by monopolizers of new and useful processes, they thought no method so effectual to break them, as forming a society, whose common labours should be directed to fix mining on its solid principles; and whose memoirs, spread
deferving those premiums, in the same manner. By these means they supposed, that there would be a mass of information collected; the interests of individuals would be lost in the general interest; and the one would materially affect the other. Impudence and quackery would, by the same means, be banished from a science, which must be improved by philosophy and experience; and the society, they supposed, would find, in the confidence which they inspired, the reward and the encouragement of their labours. They design, that the memoirs which they publish shall be short and clear; truth must be their basis; and every idle discussion, every foreign digression, must be banished; politics and finance must be avoided, though the discussions may seem to lead towards them; and they oblige themselves to oppose the affectation of brilliance, and the ostentation of empty speculation, when compared with plain, simple, and useful facts.

The object of the society is physical geography; mineralogy founded on chemistry; the management of ore in the different operations which it undergoes; submarine geometry; the history of mining; foundries; and the processes for the extraction of metals from the ores, either by fusion or amalgamation, in every instance applied to practice. The end of this institution is to collect, in the most extensive sense, every thing that can affect the operations of the miner, and to communicate it to the different members, that they may employ it for the public good, in their respective countries. Each member must consider himself as bound to send to the society every thing which will contribute to the end of its institution; to point out, with precision, the several facts and observations; to communicate every experiment which occurs, even the unsuccessful ones, if the relation may seem to be advantageous to the public; to communicate to the society their examination of schemes, and their opinions on questions proposed by it; and to pay annually two ducats (about 18 s. 6 d.) to the direction every Easter. The society, on the other hand, is bound to publish every novelty that shall be communicated to it; to communicate to each member, at the member's expense, the memoirs, designs, models, productions, and every thing connected with the institution; to answer all the necessary demands made, relating in any respect to mining; and to give its opinion on every plan or project communicated through the medium of an honorary member.

The great centre of all intelligence is to be at Zelfenfeld in Hartz, Brunswick; but the society is not fixed to any one spot; for every particular state some practical mineralogist is nominated as director. Among these are the names of Baron Born, M. Pallas, M. Carpenter, M. Prebr, and M. Henkel. Their office is to propose the members; to take care that the views of the society are pursued in the other provinces, where they reside; to answer the requests of the members of their country who are qualified to make them; in case of the death of a director, to choose another; and the majority is to determine where the archives and the strong box is to be placed.

All the eminent mineralogists in Europe are members of this society. It is erected on so liberal and so extensive a plan, that we entertain the highest hopes of its success; and have only to add, that we wish with much to see the study of several other sciences pursued in the same manner.

5. The Society for the Improvement of Naval Architecture, was founded in 1791. The object of it is to encourage every useful invention and discovery relating to naval architecture as far as shall be in their power, both by honorary and pecuniary rewards. They have in view particularly to improve the theories of floating bodies and of the resistance of fluids; to procure draughts and models of different vessels, together with calculations, of their capacity, centre of gravity, tonnage, &c.; to make observations and experiments themselves, and to point out such observations and experiments as appear best calculated to further their designs, and most deserving those premiums which the society can bestow.

But though the improvement of naval architecture in all its branches be certainly the principal object of this institution, yet the society do not by any means intend to confine themselves merely to the form and structure of vessels. Every subordinate and collateral pursuit will claim a share of the attention of the society in proportion to its merits; and whatever may have any tendency to render navigation more safe, salutary, and even pleasant, will not be neglected.

This institution owes its existence to the patriotic disposition and extraordinary attention of Mr Sewel, a private citizen of London, who (though engaged in a line of business totally opposite to all concerns of this kind) has been led, by mere accident, to take such peculiar notice of, and make such observations on, the actual state of naval architecture in his country, as naturally occurred to a man of plain understanding, zealous for the honour and interest of his country, and willing to bestow a portion of that time for the public good, which men of a different description would rather have devoted to their own private advantage. His attention was the more seriously excited, by finding that it was the opinion of some private ship-builders, who, in a debate on the failure of one of our naval engagements, pronounced, that such "would ever be the case while that business (the construction of our ships of war) was not studied as a science, but carried on merely by precedent; that there had not been one improvement in our navy that did not originate with the French, who had naval schools and seminaries for the study of it; and that our ships were not a match for those of that nation either singly or in a fleet, &c. &c."

In a short time the society were enabled to offer very considerable premiums for particular improvements in the construction of our shipping, &c. &c. and also to encourage our philosophers, mathematicians, and mechanics, to make satisfactory experiments, tending to ascertain the laws of resistance of water to foils of different forms, in all varieties of circumstance. On this head the reward is not less than L. 100 pounds or a gold medal. Other premiums of 50, 50, and 20 guineas, according to the importance or difficulty of the particular subje9t or point of investigation, to which the premium offered, for different discoveries, inventions, or improvements. The terms of admission into the society are a subscription of two guineas annually, or twenty guineas for life.

5. Society of Arts of Great Britain, which consists of directors and fellows, was incorporated by charter in 1765, and empowered to purchase and hold lands, not exceeding.
Society, annually elected, are to consist of 24 persons, including the president, vice president, treasurer, and secretary; and it is required that they be either painters, sculptors, architects, or engravers by profession.

6. British Society for Extending the Fisheries and Improving the Sea Coasts of Great Britain, was instituted in 1786. The end and design of this society will best appear from their charter, of which we present an abstract.

The preamble states, "the great want of improvement in fisheries, agriculture, and manufactures, in the Highlands and islands of North Britain; the prevalence of emigration from the want of employment in those parts; the prospect of a new nursery of seamen, by the establishment of fishing towns and villages in that quarter. The act therefore declares, that the persons therein named, and every other person or persons who shall thereafter become proprietors of the joint stock mentioned therein, shall be a distinct and separate body politic and corporate, by the name of The British Society for Extending the Fisheries and Improving the Sea Coasts of this Kingdom: That the said society may raise a capital joint stock not exceeding £150,000, to be applied to purchasing or otherwise acquiring lands and tenements in perpetuity, for the building thereon, and on no other land whatever, free towns, villages, and fishing stations: That the joint stock shall be divided into shares of £50 each: That no one person shall in his own or her name possess more than ten shares, or £500: That the society shall not borrow any sum or sums of money whatsoever: That the sums to be advanced for this undertaking, and the profits arising therefrom, shall be divided proportionally to the sum subscribed; and that no person shall be liable for a larger sum than he or she shall have respectively subscribed: That one or two shares shall intitle to one vote and no more, in person or by proxy, at all meetings of proprietors; three of four shares to two votes; five, six, or seven shares, to three votes; eight or nine shares to four votes; and ten shares to five votes and no more: That more persons than one inclining to hold in their joint names one or more shares shall be intitled to vote, by one of such persons, according to the priority of their names, or by proxy: That bodies corporate shall vote by proxy under their seal: That all persons holding proxies shall be proprietors, and that no one person shall hold more than five votes by proxy: That the affairs of the society shall be managed by a governor, deputy governor, and 13 other directors, to be elected annually on the 25th of March, from among the proprietors of the society, holding at least one full share, by signed lists of their names to be transmitted by the proprietors to the secretary of the society: that five proprietors, not being governor, director, or other officer, shall be in like manner annually elected to audit the accounts of the society: That there shall be one general meeting of the proprietors annually on the 25th of March: That occasional general meetings shall be called on the request of nine or more proprietors: That the general meetings of the proprietors shall make all by-laws and constitutions for the government of the society, and for the good and orderly carrying on of the business of the same: That no matter shall be made of the flock of the society for three years from the 10th of August 1786: That the cash of the society shall be lodged in the bank of England, bank of Scotland, or the royal bank of Scotland: That no director, proprietor, agent, or officer of the society, shall retain any sum or sums of money in his hands beyond the space of 30 days, on any account whatever: That all payments by the society shall be made by drafts on the said banks, under the hands of the governor or deputy-governor, countersigned by the secretary or his deputy and two or more directors: and that the books in which the accounts of the society shall be kept shall be open to all the proprietors.

The institution of this public-spirited society was in a great measure owing to the exertions of the patriotic John Knox; who, in the course of 23 years, traversed and explored the Highlands of Scotland no less than 16 times, and expended several thousand pounds of his own fortune in pursuing his patriotic designs.

Society Isles, a cluster of isles, so named by Captain Cook in 1769. They are situated between the latitudes of 16° 10', and 16° 55', and between the longitudes of 152° 37', and 152° 12'. They are eight in number; namely, Otahiite, Huhaine, Ulitea, Otaha, Bolabola, Maurua, Toobuani, and Tabooyamanoo or Saunders's Island. The soil, productions, people, their language, religion, customs, and manners, are so nearly the same as at Otahiite, that little need be added here on that subject. Nature has been equally bountiful in uncultivated plenty, and the inhabitants are as luxurious and as indolent. A plentiful branch is the emblem of peace, and exchanging names the greatest token of friendship. Their dances are more elegant, their dramatic entertainments have something of plot and confusiveness, and they exhibit temporary occurrences as the objects of praise or satire, so that the origin of ancient comedy may be already discerned among them.

The people of Huhaine are in general router and fiercer than those of Otahiite, and this island is remarkable for its populousness and fertility. Thofe of Ulitea, on the contrary, are smaller and blacker, and much less orderly. Captain Cook put on shore a Capeew at Bolabola, where a ram had been left by the Spaniards; and also an English boar and sow, with two goats, at Ulitea. The valuable animals which have been transported thither from Europe should be suffered to multiply, no part of the world will equal these islands in variety and abundance of refreshments for future navigators.

SOCINIANs, in church-history, a sect of Christian heretics, so called from their founder Fanthus Socinus (see Socinus). They maintain, "That Jesus Christ was a mere man, who had no existence before he was conceived by the Virgin Mary; that the Holy Ghost is no distinct person, but that the Father is truly and properly God. They own, that the name of God is given in the Holy Scriptures to Jesus Christ; but contend, that it is only a deputed title, which, however, invests him with an absolute sovereignty over all created beings, and renders him an object of worship to men and angels. They deny the doctrines of satisfaction and imputed righteousness; and say that Christ only preached the truth to mankind, yet before them in himself an example of heroic virtue, and sealed his doctrines with his blood. Original sin and absolute predestination they esteem scholastic chimneys. They like-
Socinus, the first author of the sect of the Socinians, was born at Sienna in Tuscany in 1525. Being designed by his father for the law, he began early to search for the foundation of that science in the Word of God; and by that study discovered that the Romish religion taught many things contrary to revelation; when being desirous of penetrating farther into the true sense of the Scriptures, he studied Greek, Hebrew, and even Arabic. In 1547 he left Italy, to go and converse with the Protestants; and spent four years in travelling thro' France, England, the Netherlands, Germany, and Poland, and at length settled at Zurich. He by this means became acquainted with the most learned men of his time, who testified by their letters the esteem they had for him; but as he discovered to them his doubts, he was greatly suspected of heresy. He, however, conducted himself with such address, that he lived among the capital enemies of his opinions, without receiving the least injury. He met with some disciples, who heard his instructions with respect; these were Italians who left their native country on account of religion, and wandered about in Germany and Poland. He communicated likewise his sentiments to his relations by his writings, which he caused to be conveyed to them at Sienna. He died at Zurich in 1562. Those who were of sentiments opposite to his, and were personally acquainted with him, confed that his outward behaviour was blameless. He wrote a Paraphrase on the first chapter of St John; and other works are ascribed to him.

Socinus (Faustus), nephew of the preceding, and principal founder of the Socinian sect, was born at Sienna in 1539. The letters which his uncle Lebus wrote to his relations, and which infused into them many seeds of heresy, made an impression upon him; so that, knowing himself not innocent, he fled as well as he could when the inquisition began to persecute that family. He was at Lyons when he heard of his uncle's death, and departed immediately to take possession of his writings. He returned to Tuscany; and made himself so disagreeable to the grand duke, that the charges which he found in that court, and the honourable posts he filled there, hindered him for twelve years from remembering that he had been considered as the person who was to put the last hand to the system of Samothraetian divinity of which his uncle Lebus had made a rough draught. At last he went into Germany in 1574, and paid no regard to the grand Duke's advice to return. He lived three years at Basle, and studied divinity there; and having adopted a set of principles very different from the system of Protestants, he resolved to maintain and propagate them; for which purpose he wrote a treatise De Juse Chrifti Servatore. In 1579 Socinus retired into Poland, and destined to be admitted into the communion of the Unitarians; but as he differed from them in some points, on which he refused to be silent, he met with a repulse. However, he did not cease to write in defence of their churches agaist those who attacked them. At length his book against James Paleologus furnished his enemies with a pretence to exasperate the king of Poland against him but though the mere reading of it was sufficient to refute his accusers, Socinus thought proper to leave Cracow, after having resided there four years. He then lived under the protection of several Polish lords, and married a lady of a good family; but her death which happened in 1587, led him to retire to Germany in 1598, for he met with a thousand insults at Cracow, and was with great difficulty saved from the hands of the rabble. His house was plundered, and he lost his goods; but this loss was not so uneasv to him as that of some manuscripts, which he extremely regretted. To deliver himself from such dangers, he retired to a village about nine miles distant from Cracow, where he spent the remainder of his days at the house of Abrahain Blomilk, a Polish gentleman, and died there in 1634. All Faustus Socinus's works are contained in the two first volumes of the Bibliotheca Fratrum Polonorum.

Socinians, Socemans, or Socmen (Socmani), are such tenants as hold their lands and tenements by socage tenure. See Socage.

Socotora, an island lying between Afa and Arabia Felix; about 50 miles in length, and 22 in breadth. It is particularly noted for its fine aloes, known by the name of Socotrine Aloes. The religion of the natives is a mixture of Mahometanism and Paganism; but they are civil to strangers who call there in their passage to the East Indies. It abounds in fruit and cattle; and they have a king of their own, who is dependent on Arabia.

Socrates, the greatest of the ancient philosophers, was born at Alpece, a village near Athens, in the fourth year of the 77th olympiad. His parents were of low rank; his father Sophronicus being a flauter, and his mother Phænarcus a midwife. Sophronicus
Socrates brought up his son, contrary to his inclination, in his own manual employment; in which Socrates, though his mind was continually aspiring after higher objects, was not unsuccessful; for whilst he was a young man, he is said to have formed statues of the habitable graces, which were allowed a place in the citadel of Athens. Upon the death of his father he was left in such straitened circumstances as laid him under the necessity of excising that art to procure the means of subsistence, though he devoted, at the same time, all the leisure which he could command to the study of philosophy. His difficulties, however, were soon relieved by Crito, a wealthy Athenian; who, remarking his strong propensity to study, and admiring his ingenious dispositions and distinguished abilities, generously took him under his patronage, and instructed him with the instruction of his children. The opportunities which Socrates by this means enjoyed of attending the public lectures of the most eminent philosophers, so far increased his thirst after wisdom, that he determined to relinquish his occupation, and every prospect of emolument which that might afford, in order to devote himself entirely to his favorite studies. Under Anaxagoras and Archelaus he prosecuted the study of nature in the usual manner of the philosophers of the age, and became well acquainted with their doctrines. Prodicus the sophist was his preceptor in eloquence, Euxenus in poetry, Theodorus in geometry, and Damo in music. Alcippus, a woman no less celebrated for her intellectual than her personal accomplishments, whose house was frequented by the most celebrated characters, had also some share in the education of Socrates. Under such preceptors it cannot reasonably be doubted but that he became master of every kind of learning which the age in which he lived could afford; and being blessed with very uncommon talents by nature, he appeared in Athens, under the respectable characters of a good citizen and a true philosopher. Being called upon by his country to take arms in the long and severe struggle between Athens and Sparta, he signified himself at the siege of Potidaea, both by his valor and by the bravery with which his mind and character were combined. During the severity of the Thracian winter, whilst others were clad in furs, he wore only his usual clothing, and walked barefoot upon the ice. In an engagement in which he saw Alcibiades falling down wounded, he advanced to defend him, and saved both him and his arms: and though the price of valor was on this occasion unquestionably due to Socrates, he generously gave his vote that it might be bestowed upon Alcibiades, to encourage his rising merit. He feared in other campaigns with distinguished bravery, and had the happiness on one occasion to save the life of Xenophon, by bearing him, when covered with wounds, out of the reach of the enemy.

It was not till Socrates was upwards of 60 years of age that he undertook to serve his country in any civil office, when he was chosen to represent his own district, in the senate of five hundred. In this office, though he at first exposed himself to some degree of ridicule from the want of experience in the forms of business, he soon convinced his colleagues that he was superior to them all in wisdom and integrity. Whilst they, intimidated by the clamours of the populace, passed an unjust sentence of condemnation upon the commanders, who, after the engagement at the Arginian islands, had been prevented by a storm from paying funeral honours to the dead, Socrates stood forth singly in their defence, and to the last refused to give his suffrage against them, declaring that no force should compel him to act contrary to justice and the laws. Under the subsequent tyranny he never ceased to condemn the oppressive and cruel proceedings of the thirty tyrants; and when his boldness provoked their resentment, so that his life was in hazard, fearing neither treachery nor violence, he still continued to support with undaunted firmness the rights of his fellow-citizens.

Having given these proofs of public virtue both in a military and civil capacity, he wished to do still more for his country. Observing with regret how much the opinions of the Athenian youth were milled and their principles and talents corrupted by philosophers who spent all their time in refined speculations upon nature and the origin of things, and by sophists who taught in their schools the arts of false eloquence and deceitful reasoning; Socrates formed the wise and generous design of instituting a new and more useful method of instruction. He judiciously applied the end of philosophy to be not to make an ostentatious display of superior learning and ability in subtle disquisitions or ingenious conjectures, but to free mankind from the dominion of pernicious prejudices; to correct their vices; inspire them with the love of virtue; and thus conduct them in the path of wisdom to true felicity. He therefore assumed the character of a moral philosopher; and, looking upon the whole city of Athens as his school, and all who were disposed to lend him their attention as his pupils, he feized every occasion of communicating moral wisdom to his fellow citizens. He passed the greater part of his time in public; and the method of instruction which he chiefly made use of, was to propose a series of questions to the person with whom he conversed, in order to lead him to some unforeseen conclusion. He first gained the confidence of his respondent to some obvious truths, and then obliged him to admit others from their relation or resemblance to those to which he had already admitted. Without making use of any direct argument or persuasion, he usually led the person he meant to instruct, to deduce the truth of which he wished to convince him, as a necessary consequence from his own conclusions. He commonly conducted these conferences with such address, as to conceal his design till the respondent had advanced too far to recede. On some occasions he made use of ironical language, that vain men might be caught in their own replies, and be obliged to confess their ignorance. He never assumed the air of a microscope and rigid preceptor, but communicated useful instruction with all the ease and pleasantry of polite conversation. Though eminently furnished with every kind of learning, he preferred moral to speculative wisdom. Convinced that philosophy is valuable, not as it furnishes questions for the schools, but as it provides men with a law of life, he confined his predecessors for spending all their time in abortive researches into nature, and taking no pains to render themselves useful to mankind. His favourite maxim was, Whatever is above us, doth not concern us. He esteemed the value of knowledge by its utility, and recommended the study of geometry, astronomy, and other sciences, only so far as they admit of a practical application to the purposes of human life.
object in all his conferences and discourses was, to lead
men into an acquaintance with themselves; to convince
them of their follies and vices; to inspire them with the
love of virtue; and to furnish them with useful moral
instructions. Cicero might therefore very justly say of
Socrates, that he was the first who called down philo-
sophy from heaven to earth, and introduced her into the
public walks and domestic retirements of men, that she
might instruct them concerning life and manners.

Through the whole of his life this good man discovered
a mind superior to the attractions of wealth and power.
Contrary to the general practice of the preceptors of
his time, he instructed his pupils without receiving from
them any gratuity. He frequently refused rich pre-
sents, which were offered him by Alcibiades and others,
though importantly urged to accept them by this
wife. The chief men of Athens were his rewards;
they sent him in provisions, as they apprehended he
wanted them; he took what his present wants required,
and returned the ref. Observing the numerous articles
of luxury which were exposed to sale in Athens, he ex-
claimed, "How many things are there which I do not
want!" With Socrates, moderation supplied the
place of wealth. In his clothing and food, he consulted
only the demands of nature. He commonly appeared in
a neat but plain cloak, with his feet uncovcred. Though
his table was only supplied with simple fare, he did not
scrope to invite men of superior rank to partake of his
meals; and when his wife, upon some fuch occasion,
expressed her dissatisfaction on being no better pro-
vided, he defired her to give herself no concern; for if
his guests were wise men, they would be contented with
whatever they found at his table; if otherwise, they
were unworthy of notice. Whist others, says he, live
to eat, wise men eat to live.

Though Socrates was exceedingly unfortunate in his
domestic connection, he converted this infelicity into an
occasion of exercising his virtues. Xanthippe, concern-
ing whose ill humour ancient writers relate many amu-
ifying tales, was certainly a woman of a high and unma-
angeable spirit. But Socrates, while he endeavoured
to curb the violence of her temper, improved his own.
When Alcibiades expressed his surprize that his friend
could bear to live in the same house with fo perverse
and quarrelsome a companion, Socrates replied, that
being daily inured to ill humour at home, he was the
better prepared to encounter perverseness and injury
abroad.

In the midst of domestic vexations and public disor-
ders, Socrates retained such an unruffled serenity, as
he was never seen either to leave his own house or to
return home with a disturbed countenance. In acqui-
sing this entire dominion over his passions and appetites,
he had the greater merit, as it was not effected without
a violent struggle against his natural propensities.
Zopyrus, an eminent phyfognomist, declared, that he
discovered in the features of the philosopher evident traces
of many vicious inclinations. The friends of Socrates
who were perfent ridiculed the ignorance of this pre-
tender to extraordinary sagacity. But Socrates himself
ingeniously acknowledged his penetration, and consoled
that he was in his natural disposition prone to Vice, but
that he had subdued his inclinations by the power of
reason and philosophy.

Through the whole of his life Socrates gave himself
up to the guidance of unbiased reason, which is suppo-
sed by some to be all that he meant by the genius or
demon from which he professed to receive instruction.
But this opinion is inconsistent with the accounts given
by his followers of that demon, and even with the lan-
guage in which he spoke of it himself. Plato some-
times calls it his genius, and Apuleius his god; and as
Xenophon attests that it was the belief of his master
that the gods occasionally communicate to men the
knowledge of future events, it is by no means impro-
bable that Socrates admitted, with the generality of his
countrymen, the existence of those intermediate beings
called demons, of one of which he might fancy himself
the peculiar care.

It was one of the maxims of Socrates, "That a wife
man will worship the gods according to the inclinations
of the state to which he belongs." Convinced of the
weakness of the human understanding, and perceiving
that the pride of philosophy had led his predecessors
into futile speculations on the nature and origin of things,
he judged it most consistent with true wisdom to speak
with caution and reverence concerning the divine na-
ture.

The wisdom and the virtues of this great man, whilst
they procured him many followers, created him also
many enemies. The Sophists, whose knavery and igno-
rance he took every opportunity of exposing to public
contempt, became inveterate in their enmity against
him, to foil a reformer, and devise an expenditure, by
which they hoped to check the current of his popularity.
They engaged Aristophanes, the first buffoon of the
age, to write a comedy, in which Socrates should be
the principal character. Aristophanes, pleased with fo
promising an occasion of displaying his own and malig-
nant wit, undertook the task, and produced the comedy
of The Clouds, still extant in his works. In this piece,
Socrates is introduced hanging in a basket in the air,
and thence pouring forth absurdity and prophaneness.
But the philosopher, showing in a crowded theatre
that he was wholly unmoved by this ribaldry, the fate
failed of its effect; and when Aristophanes attempted
the year following to renew the piece with alterations
and additions, the representation was so much discour-
raged, that he was obliged to discontinue it.

From this time Socrates continued for many years to
pursue without interruption his laudable design of in-
structing and reforming his fellow-citizens. At length
however, when the inflexible integrity with which he
had discharged the duty of a senator, and the firmness
with which he had opposed every kind of political cor-
rupion and oppression, had greatly increased the num-
ber of his enemies, clandestine arts were employed to
raise a general prejudice against him. The people were
indultriously reminded, that Critias, who had been one
of the most cruel of the thirty tyrants, and Alcibiades,
who had insulted religion, by defacing the public
images of Mercury, and performing a mock representation
of the Eleusinian mysteries, had in their youth been di-
ciples of Socrates; and the minds of the populace be-
ing thus prepared, a direct accusation was preferred
against him before the supreme court of judicature.
His accusers were Anytus a leather-drier, who had long
entertained a personal enmity against Socrates, for re-
prehending his avarice, in depriving his sons of the
benefits of learning, that they might pursue the gains of
trade; Melitus, a young rhetorician who was capable of undertaking any thing for the sake of gain; and Lycon, who was glad of any opportunity of displaying his talents. The accusation, which was delivered to the senate under the name of Melitus, was this: “Melitus, son of Melitus, of the tribe of Pythos, accused Socrates, son of Sophronicus, of the tribe of Alcpe. Socrates violates the laws, in not acknowledging the gods which the flate acknowledges, and by introducing new divinities. He also violates the laws by corrupting the youth. Be his punishment death.”

This charge was delivered upon oath to the senate; and Crito a friend of Socrates became party to the appearance on the day of trial. Anytus soon afterwards sent a private message to Socrates, affurting him that if he would depart from endeavoring his condud, he would withdraw his accusation. But Socrates refused to comply with so degrading a condition; and with his usual spirit replied, “Whilst I live I will never dignify the truth, nor speak otherwise than my duty requires.”

The interval between the accusation and the trial he spent in philosophical conversations with his friends, choosing to discourse upon any other subject rather than his own situation.

When the day of trial arrived, his accusers appeared in the senate, and attempted to support their charge in three distinct speeches, which strongly marked their respective characters. Plato, who was a young man, and a zealous follower of Socrates, then rose up to address the judges in defense of his master; but whilst he was attempting to apologize for his youth, he was abruptly commanded by the court to sit down. Socrates, however, needed no advocate. Ascending the chair with all the composure of conscious innocence, and with all the dignity of superior merit, he delivered, in a firm and manly tone, an unpremeditated defence of himself, which silenced his opponents, and ought to have convinced his judges. After tracing the progress of the conspiracy which had been raised against him to its true source, the jealousy and resentment of men whom ignorance he had exposed, and whose vices he had ridiculed, and reproved, he distinctly replied to the several charges brought against him by Melitus. To prove that he had not been guilty of impiety towards the gods of his country, he appealed to his frequent practice of attending the public religious festivals. The crime of introducing new divinities, with which he was charged, chiefly as it seems on the ground of the admonitions which he professed to have received from an invisible power, he disclaimed, by pleading that it was no new thing for men to consult the gods and receive instructions from them. To refute the charge of his having been a corrupter to youth, he urged the example which he had uniformly exhibited of justice, moderation, and temperance; the moral spirit and tendency of his discourses; and the effect which had actually been produced by his doctrine upon the manners of the young. Then, disdaining to solicit the mercy of his judges, he called upon them for that justice which their office and their oath obliged them to administer; and professing his faith and confidence in God, resigned himself to their pleasure.

The judges, whose prejudices would not suffer them to pay due attention to this apology, or to examine Vol. XVII.

with impartiality the merits of the cause, immediately declared him guilty of the crimes of which he stood accused. Socrates, in this stage of the trial, had a right to enter his plea against the punishment which the accusers demanded, and instead of the sentence of death, to propose some pecuniary amercement. But he at first peremptorily refused to make any proposal of this kind, imagining that it might be construed into an acknowledgment of guilt; and after that, his conduct merited from the flate reward rather than punishment. At length, however, he was prevailed upon by his friends to offer upon their credit a fine of thirty minae. The judges, notwithstanding, still remained inexorable: they proceeded, without farther delay, to pronounce sentence upon him; and he was condemned to be put to death by the poison of hemlock.

The sentence being passed, he was sent to prison; which, says Seneca, he entered with the same resolution and firmness with which he had opposed the thirty tyrants; and took away all ignominy from the place, which could not be a prison while he was there. He lay in fetters 52 days; and was constantly visited by Crito, Plato, and other friends, with whom he passed the time in dispute after his usual manner. Anxious to save so valuable a life, they urged him to attempt his escape, or at least to permit them to convey him away; and Crito went so far, as to assure him that, by his interest with the jailor, it might be easily accomplished, and to offer him a retreat in Thrasybly; but Socrates rejected the proposal, as a criminal violation of the laws; and asked them, whether there was any place out of Attica which death could not reach.

At length the day arrived when the officers to whose care he was committed delivered to Socrates early in the morning the final order for his execution, and immediately, according to the law, set him at liberty from his bonds. His friends, who came thus early to the prison that they might have an opportunity of conversing with their master through the day, found his wife fitting by him with a child in her arms. Socrates, that the tranquillity of his last moments might not be disturbed by her unavailing lamentations, requested that she might be conducted home. With the most frantic expessions of grief he left the prison. An interring conversation then passed between Socrates and his friends, which chiefly turned upon the immortality of the soul. In the course of this conversation, he expressed his disapprobation of the practice of suicide, and exhorted his friends that his chief support in his present situation was an expectation, though not unmixed with doubts, of a happy existence after death, “It would be inexorable in me (said he) to desiphe death, if I were not persuaded that it will conduct me into the presence of the gods, who are the most righteous governors, and into the society of just and good men: but I derive confidence from the hope that something of man remains after death, and that the condition of good men will then be much better than that of the bad.”

Crito afterwards asking him, in what manner he wished to be buried? Socrates replied, with a smile, “As you please, provided I do not escape out of your hands.” Then, turning to the rest of his friends, he said, “Is it not strange, after all that I have said to convince you that I am going to the society of the hap-
Socrates [594]

Socrates, it seems, that Critias still thinks that this body, which will soon be a lifeless corpse, is Socrates? Let him dispose of my body as he pleases, but let him not at its interment mourn over it as if it were Socrates."

Towards the close of the day he retired into an adjoining apartment to bathe; his friends, in the mean time, expressing to one another their grief at the prospect of losing so excellent a father, and being left to pass the rest of their days in the solitary state of orphans. After a short interval, during which he gave some necessary instructions to his domestics, and took his last leave of his children, the attendant of the prison informed him, that the time for drinking the poison was come. The executioner, though accustomed to such scenes, shed tears as he presented the fatal cup. Socrates received it without change of countenance or the least appearance of perturbation; then offering up a prayer to the gods that they would grant him a peaceful passage into the invisible world, with perfect serenity of soul in the midst of indescribable grief. His friends around him burst into tears. Socrates alone remained unmoved. He upbraided their pusillanimity and entreated them to exercise a manly constancy worthy of the friends of virtue. He continued walking till the chilling operation of the hemlock obliged him to lie down upon his bed. After remaining for a short time silent, he requested Critias (probably in order to refuse a calumny which might prove injurious to his friends; after his decease, not to neglect the offering of a cock which he had vowed to Echecarius. Then, covering himself with his cloak, he expired. Such was the fate of the virtuous Socrates! A story, says Cicero, which I never read without tears.

The friends and disciples of this illustrious teacher of wisdom were deeply afflicted by his death, and attended his funeral with every expression of grief. Apprehensive, however, for their own safety, they soon afterwards privately withdrew from the city, and took up their residence in distant places. Several of them visited the philosopher Euclid of Megara, by whom they were kindly received. No sooner was the unjust condemnation of Socrates known through Greece, than a general indignation was kindled in the minds of good men, who universally regretted that so distinguished an advocate for virtue should have fallen a sacrifice to jealousy and envy. The Athenians themselves, so remarkable for their caprice, who never knew the value of their great men till after their death, soon became sensible of the folly as well as criminality of putting to death the man who had been the chief ornament of their city and of the age, and turned their indignation against his accusers. Melitus was condemned to death; and Anytus, to escape a similar fate, went into voluntary exile. To give a farther proof of the sincerity of their regret, the Athenians for a while interrupted public business; decreed a general mourning; recalled the exiled friends of Socrates; and erected a statue to his memory in one of the most frequented parts of the city. His death happened in the first year of the 96th Olympiad, and in the 70th year of his age.

Socrates left behind him nothing in writing; but his illustrious pupils Xenophon and Plato have in some measure supplied this defect. The Memoirs of Socrates, written by Xenophon, afford, however, a much more accurate idea of the opinions of Socrates, and of his manner of teaching, than the Dialogues of Plato, who everywhere mixes his own conceptions and dictation with the ideas and language of his master. It is related, that when Socrates heard Plato recite his Lytis, he said, "How much does this young man make me say which I never conceived?"

His distinguished character was that of a moral philosopher; and his doctrine concerning God and religion was rather practical than speculative. But he did not neglect to build the structure of religious faith upon the firm foundation of an appeal to natural appearances. He taught, that the Supreme Being, though invisible, is clearly seen in his works; which at once demonstrate his existence and his wise and benevolent providence. He admitted, besides the one Supreme Deity, the existence of beings who perform a middle station between God and man, to whom immediate agency he attributed the ordinary phenomena of nature, and whom he supposed to be particularly concerned in the management of human affairs. Hence he declared it to be the duty of every one, in the performance of religious rites, to follow the customs of his country. At the same time, he taught, that the merit of all religious offerings depends upon the character of the worshipper, and that the gods take pleasure in the sacrifices of none but the truly pious.

Concerning the human soul, the opinion of Socrates, according to Xenophon, was, that it is allied to the Divine Being, not by a participation of essence, but by a similarity of nature; that man excels all other animals in the faculty of reason; and that the existence of good men will be continued after death in a state in which they will receive the reward of their virtue. Although it appears that on this latter topic he was not wholly free from uncertainty, the consolation which he professed to derive from this source in the immediate prospect of death, leaves little room to doubt that he entertained a real expectation of immortality; and there is reason to believe that he was the only philosopher of ancient Greece whose principles admitted of such an expectation (see Metaphysics, Part III. Chap. iv.) Of his moral system, which was in a high degree pure, and founded on the surest principles, the reader will find a short view in our article Moral Philosophy, No. 4.

Socrates was also the name of an ecclesiastical historian of the 5th century, born at Constantinople in the beginning of the reign of Theodosius; he professed the law and pleaded at the bar, whence he obtained the name of Schoebius. He wrote an ecclesiastical history from the year 309, where Eusebius ended, down to 440; and wrote with great exactness and judgment. An edition of Eusebius and Socrates, in Greek and Latin, with notes by Reading, was published at London in 1720.

SODA, the name given by the French chemists to the mineral alkali, which is found native in many parts of the world: it is obtained also from common salt, and from the ashes of the kali, a species of falcidea. See Alkali, No. 7, and Chemistry-Index.

Soda is also a name for a heat in the stomach or heart-burn. See Medicine, No. 275.

SODOM, formerly a town of Palestine in Afiæ, famous in Scripture for the wickedness of its inhabitants, and their destruction by fire from heaven on account of
SODOM

SODOMY, an unnatural crime, so called from the city of Sodom, which was destroyed by fire for the fame. The Levitical law adjudged those guilty of this execrable crime to death; and the civil law affixes the same punishment to it. The law of England makes it felony. There is no statute in Scotland against Sodomym; the libel of the crime is therefore founded on the divine law, and practice makes its punishment to be burned alive.

SODOR, a name always conjoined with Man, in mentioning the bishop of Man's diocese. Concerning the origin and application of this word, very different opinions have been formed by the learned. Buchanan (lib. i. cap. 34.) says, that before his time the name of Sodor was given to a town in the isle of Man. In Gough's edition of Camden's Britannia (vol. iii. p. 701.) it is said, that after the isle of Man was annexed to the crown of England, this appellation was given to a small island within musset-shot of Man, in which the cathedral lands, called by the Norwegians the Holm, and by the inhabitants the Peel. In support of this opinion a charter is quoted A. D. 1505, in which Thomas earl of Derby and lord of Man confirms to Huan Heiketh bishop of Sodor all the lands, &c. anciently belonging to the bishops of Man. "Ecclesiam cathedrali fami Germani in Holm Sodor vel Pole vocatam, ecclesiam funisti Patrioci ibidem, et locum praefatum in quo ecclesiae praevente fite funt." The truth of either, or perhaps of both, these accounts might be allowed; but neither of them are sufficient to account for the constant conjunction of Sodor and Man, in charters, registers, and histories. If Sodor was a small town or island belonging to Man, it cannot be conceived why it is always mentioned before it, or rather why it should be mentioned at all in speaking of a bishop's diocese. To speak of the bishopric of Sodor and Man in this case would be as improper as it would be to call the bishopric of Durham the bishopric of Holy Island and Durham, or the bishopric of Darlington and Durham; the former being a small island and the latter a town belonging to the county and diocese of Durham. Neither of these accounts, therefore, give a satisfactory account of the original conjunction of Sodor and Man.

The isle of Iona was the place where the bishop of the isles resided, the cathedral church of which, it is said, was dedicated to our Saviour, in Greek Soter, hence Soter-nytes, which might be corrupted into Sodoreytes, a name frequently given by Danish writers to the western isles of Scotland. That we may be the more disposed to accede to this Grecian etymology, the advocates for this opinion tell us, that the name Isolamh, which is often applied to this isle, is also of Greek extraction, being derived from Columbia, "a pigeon;" a meaning that exactly corresponds to the Celtic word Colum and the Hebrew word Iona. We must confess, however, that we have very little faith in the conjectures of etymologists, and think that upon no occasion they alone can establish any fact, though when corroborating there is no that certainly tend to confirm and explain them. It is only from historical facts that we can know to what Sodor was applied.

It appears from the history of the Orkneys, compiled by an old Islandic writer, translated and enlarged by Torfeus, that the Ebuddo or Western isles of Scotland were divided into two clusters, Nordureys and Sudereys. The Nordureys, which were separated from the Sude­reys by the point of Ardnamutchan, a promontory in Argyllshire, confided of Muck, Egg, Rum, Canna, Sky, Raay, Barra, South Uist, North Uist, Benbecu­la, and Lewis, including Harris, with a great number of smaller isles. The Sudereys were, Man, Arran, Bute, Cumbra, Avon, Cid, Ila, Colonay, Jura, Scarba, Mull, Iona, Tiree, Coll, Ulva, and other small islands. All thefts, when joined together, and subject to the same prince, made up the kingdom of Man and the isles. In the Norwegian language Sudor and Norder, signifying southern and northern, and oy or ay an isle. When the Ebuddo were under one monarch, the seat of empire was fixed in the Sudereys, and the Nordureys were governed by deputies; hence the former are much oftener mentioned in history than the latter; hence, too, the Sudereys often comprehend the Nordureys, as in our days Scotland is sometimes comprehended under England. Sudereys, or Suder, when anglicized, became Sodor; and all the western isles of Scotland being included in one diocese under the Norwegian princes, the bishop appointed to superintend them was called the bishop of Man and the isles, or the bishop of Sodor and Man. Since Man was conquered by Edward III. it has been separated from the other isles, and its bishops have exercised no jurisdiction over them. Should it now be asked, why then is the bishop of Man still called the bishop of Sodor and Man? we reply, that we have been able to discover no reason; but suppose the appellation to be continued in the same way, as the title king of France, has been kept up by the king of Great Britain, for several centuries after the English were entirely expelled from France.

SOFA, in the ealt, a kind of alcove railed half a foot above the floor of a chamber or other apartment; and used as the place of flate, where victors of distin­ction are received. Among the Turks the whole floor of their flate-rooms is covered with a kind of tapelry, and on the window-side is raised a sofa or sofa, laid with a kind of matsf, covered with a carpet much richer than the other. On this carpet the Turks are seated, both men and women, like the taylors in England, crosf legged, leaning against the wall, which is boldered with velvet, fatin, or other stuff fuitable to the season. Here they eat their meals; only laying a skin of the carpet to serve as a table-cloth, and a round wooden board over all, covered with plates, &c.

SOFALA, Or CEFAEA, a kingdom of Africa, lying on the coast of Mofambique, near Zanguebar. It is bounded on the north by Monomotapa; on the ealt by the Mofambique Sea; on the south by the kingdom of Sabia; and on the west by that of Manica. It contains mines of gold and iron, and a great number of elephants. It is governed by a king, tributary to the Portuguese, who built a fort at the principal town, which is of the fame name, and of great importance for their trade to the East Indies. It is feated in a small island, near the mouth of a river. E. Long. 35° 40'. S. Lat. 20° 20'.

SOTTITA, or Soffita, in architecture, any timber ceiling formed of cros beams of flying cornices, the square compartments or panels of which are enriched.
I was at this place, in the year 1772, that Mr. Eginton invented his expeditious method of copying pictures in oil.
fee. The environs are charming, but, the streets are narrow, and the houses ill-built. The fine cathedral has one of the most considerable chapters in the kingdom; and the bishop, when the archbishop of Rheims was absent, had a right to crown the king. The castle, though ancient, is not that in which the kings of the first race reigned. Soiffons is seated in a very pleasant and fertile valley, on the river Aisne, 30 miles west by north of Rheims, and 60 north east of Paris. E. Long. 3. 24. N. Lat. 49. 23.

SOLEUS, or S. See SoCAGE.

SOLEUS, or S. See SoCAGE.

SOL, in music, the first note on the gamut, ut, re, mi, fa, sol, la. See Gamut.

SOL, or Sou, a French coin made up of copper mixed with a little silver, and is worth upwards of an English halfpenny, or the 23d part of an English shilling. The foI when first struck was equal in value to 12 deniers Tournois, whence it is called denier. A name it still retains, tho' its ancient value be changed; the foil having been formerly augmented by three deniers, and struck with a penceion of a flour-de-lis, to make it current for 15 deniers. Soon after the old foIs were coined over again, and both old and new were indifferently made current for 15 deniers. In the 17th century, the value of the same foIs was raised to 18 deniers. Towards the latter end of the reign of Louis XIV. the foil of 18 deniers was again lowered to 15; and by the late king it was reduced to the original value of 12. What is at present povertiness may perhaps disover.

The Dutch have also two kinds of foil: the one of silver, called felt de gros, and likewise febeling; the other of copper, is called also the foiluer.

SOL, the Sun, in astronomy, astrology, &c. See Astronony, Puffin.

SOL, in chemistry, is gold; thus called from an opinion that this metal is in a particular manner under the influence of the Sun.

SOL, in heraldry, denotes Or, the golden colour in the arms of sovereign princes.

SOLÆUS, or SOLÆUS, in anatomy, one of the extensor muscles of the foot, rising from the upper and hinder parts of the tibia and fibula.

SOLAGAUS, in ornithology. See Pelicanus.

SOLANDRA, in botany: A genus of plants belonging to the class of monogynia, and to the order of polyanthria; and in the natural system arranged under the 28th order, Tricocceae. The calyx is single; the capsule oblong, wreathed, and five celled; the seeds are many, disposed in cells in a double order. The valves after maturity are divaricated, even to the base, and winged inwards by the partition. The only species is the Lobaster. This genus was first named Solandra, in honour of Dr Solander, by Murray in the 14th edition of the Systema Vegetabilis.

SOLANUM, in botany: A genus of the monogynia order, belonging to the class of polyanthria of plants; and in the natural method ranking under the 28th order, Luride. The calyx is inferior; the corolla is rotate, and generally monophylyous; the fruit a berry, bilocular, and containing many small and flat seeds. Of this genus there are 66 species, most of them natives of the East and West Indies. The most remarkable of which are the following.

1. The D. Kamanara, a native of Britain and of Africa. In gardens in the warmer parts of Europe and in all tropic
SOL. [ 598 ] SOL

Solanum, or Tomaten, is cultivated in Jamaica. It is often used boiled as a vegetable along with animal food or butters, and supposed to be aphrodisiac and to cure sterility.

5. Longum. This plant is also herbaceous, but grows much larger than the foregoing. The flowers are blue; and the fruit is six or eight inches long, and proportionally thick. It is boiled and eaten at table as the egg plant.

6. Tuberofum, the common potato. See Potatoes.

SOLAR, something belonging to the Sun. See Astronomy.

SOLANKI. See Astronomy-Index.

SOLDANELLA, in botany: A genus of plants belonging to the class of pantenaria, and order of monogynia; and in the natural system arranged under the 9th order, Precis. The corolla is campanulated; the border being very finely cut into a great many segments. The capule is unilocular, and its apex pédicellate.

SOLDEN, SOLDER, or Solder, a metallic or mineral composition used in foldering or joining together other metals.

Solders are made of gold, silver, copper, tin, bismuth, and lead; usually observin, that in the composition there be some of the metal that is to be foldered mixed with some higher and finer metals. Goldsmiths usually make four kinds of folder, viz. folder of eight, where to seven parts of silver there is one of brass or copper; folder of six, where only a fifth part is copper; folder of four, and folder of three. It is the mixture of copper in the folder that makes rolled plate come always cheaper than flat.

As mixtures of gold with a little copper are found to melt with less heat than pure gold itself, these mixtures serve as folders for gold; two pieces of fine gold are foldered by gold that has a small admixture of copper; and gold alloyed with copper is foldered by such as is alloyed with more copper: the workmen add a little silver as well as copper, and vary the proportions of the two to one another, so as to make the colour of the folder correspond as nearly as may be to that of the piece. A mixture of gold and copper is also a folder for fine copper as well as for fine gold. Gold being particularly disposed to unite with iron, proves an excellent folder for the finer kinds of iron and steel instruments.

The folder used by plumbers is made of two pounds of lead to one of block-tin. Its goodness is tried by melting it, and pouring the bigness of a crown piece on a table; for, if good, there will arise little bright shining stars therein. The folder for copper is made like that of the plumbers; only with copper and tin; and for very nice works, instead of tin, they sometimes use a soldering, a quantity of silver. Solder for tin is made of two-thirds of tin and one of lead, or of equal parts of each; but where the work is anything delicate, as in organ pipes, where the juncture is scarce discernible, it is made of one part of bismuth and three parts of pewter. The pewterers use a kind of folder made with two parts of tin and one of bismuth; this composition melts with the least heat of any of the folders.

Silver folder is that which is made of two parts of silver and one of brass, and used in foldering those metals. Spelter folder is made of one part of brass and two of spelter or zinc, and is used by the braziers and coppersmiths for foldering brass, copper, and iron. This folder is improved by adding to each ounce of it one pennyweight of silver; but as it does not melt without a considerable degree of heat, it cannot be used when it is inconvenient to heat the work red-hot; in which case copper and brass are foldered with silver.

Though spelter folder be much cheaper than silverfolder, yet workmen in many cases prefer the latter. And Mr Boyle informs us, that he has found it to run with but moderate a heat, as not much to endanger the melting of the delicate parts of the work to be foldered; and if well made, this silver folder will lie even upon the ordinary kind itself; and if all those little cavities that may chance to be left in the first operation, which is not easily done without a folder more easily fusible than the first made use of. As to iron, it is sufficient that it be heated to a white heat, and the two extremities, in thisstate, be hammer made together; by which means they become incorporated one with the other.

SOLDERING, the joining and fastening together of two pieces of the same metal, or of two different metals, by the fusion and application of some metallic composition on the extremities of the metals to be joined.

To folder upon silver, brass, or iron: Take silver, five pennyweights: brass, four pennyweights: melt them together for soft folder, which runs soonest. Take silver, five pennyweights: copper, three pennyweights: melt them together for hard folder. Beat the folder thin, and lay it on the place to be foldered, which must be first fitted and bound together with wire as occasion requires; then take borax in powder, and temper it like pap, and lay it upon the folder, letting it dry; then cover it with live coals, and blow, and it will run immediately; take it presently out of the fire, and it is done. It is to be observed, that if any thing is to be foldered in two places, which cannot well be done at one time, you must first folder with the harder folder, and then with the soft; for if it be first done with the soft, it will unfold again before the other is fastened. Let it be observed, that if you would not have your folder run about the piece that is to be foldered, you must rub such places over with chalk.—In the foldering either of gold, silver, copper, or either of the metals above mentioned, there is generally used borax in powder, and sometimes rosin. As to iron, it is sufficient that it be heated red-hot, and the two extremities thus hammered together, by which means they will become incorporated with each other. For the finer kinds of iron and steel instruments, however, gold proves an excellent folder. This metal will diffuse twice or thrice its weight of iron in a degree of heat very far less than that in which iron itself melts; hence if a small plate of gold
as the creature is nourished by means of sea-water; but it is very evident, that if a little salt be fired upon these pipes in a fish taken out of its habitat, it will corrode the joinings of the rings, and often make one or more joints drop off; the creature, to avoid this mischief, arises out of its hole, and throws off the salt, and then retires back again. The use of these pipes to the animal is the same with that of many other pipes of a like kind in other shell-fish; they all serve to take in water: they are only a continuation of the outer membrane of the fish, and serve differently for taking in and throwing out the water, one receiving, and the other discharging it, and either answering equally well to their purpose. See Animal Motion.

This fish was used as food by the ancients; and Athenæus, from Sophron, speaks of it as a great delicacy, and particularly grateful to widows. It is often used as food at present, and is brought up to table fried in eggs.

SOLE, a canton of Switzerland, which holds the 11th rank in the Helvetic confederacy, into which it was admitted in the year 1481. It stretches partly through the plain, and partly along the chains of the Jura, and contains about 50,000 inhabitants. It is 35 miles in length from north to south, and 35 in breadth from east to west. The soil for the most part is exceedingly fertile in corn, and the districts within the Jura abound in excellent pastures. The trade both of the town and canton is of little value, although they are very commodiously situated for an extensive commerce. It is divided into 11 bailiwicks, the inhabitants of which are all Roman Catholics except those of the bailiwick of Buckeggberg, who profess the reformed religion. The sovereign power resides in the great council, which, comprising the senate or little council of 36, consists of 102 members, chosen by the senate in equal proportions from the 11 tribes or companies into which the ancient burgheers are distributed; and, owing to the distinction between the ancient and the new burgheers (the former consisting of only 85 families) the government is a complete anarchy.

SOLEUR, an ancient and extremely neat town of Switzerland, capital of the canton of the same name. It contains about 4000 inhabitants, and is pleasantly seated on the An, which here expands into a noble river. Among the most remarkable objects of curiosity in this town is the new church of St Urs, which was begun in 1752 and finished in 1772. It is a noble edifice of a whith grey stone, drawn from the neighbouring quarries, which admits a polith, and is a species of rude marble. The lower part of the building is of the Corin-than, the upper of the Composite order. The façade, which consists of a portico, surmounted by an elegant tower, presents itself finely at the extremity of the principal street. It cost at least L 80,000, a considerable sum for such a small republic, whose revenue scarcely exceeds L 12,000 a year. Soleure is surrounded by regular stone fortifications, and is 20 miles north-north-east of Bern, 27 south-west of Bâle, and 45 west of Zurich. E. Long. 7. 20. N. Lat. 47. 15.

SOLFAING, in music, the naming or pronouncing of the several notes of a song by the syllables ut, re, mi, fa, sol, la, si, only four are used among us in singing, as
SOL

[Solfera, mi, fa, sol, la]: their office is principally in singing, that by applying them to every note of the scale, it may not only be pronounced with more ease, but chiefly that by them the tones and semitones of the natural scale may be better marked out and distinguished. This design is obtained by the four syllables fa, sol, la, mi. Thus from fa to sol is a tone, also from sol to la, and from la to mi, without distinguishing the greater or less tone; but from la to fa, also from mi to fa, is only a semitone. If these be applied in this order, fa, sol, la, mi, &c. they express the natural series from C; and if that be repeated to a second or third octave, we fee by them how to express all the different orders of tones and semitones in the diatonic scale; and still above mi will stand fa, sol, la, and below it the same inverted fa, sol, la, and one mi is always distant from another an octave; which cannot be said of any of the relics, because after mi ascending come always fa, sol, la, which are repeated invertedly descending.

To conceive the use of this, it is to be remembered, that the first thing in learning to sing, is to make one raise a scale of notes by tones and semitones to an octave, and descend again by the same; and then to rise and fall by greater intervals at a leap, as thirds and fourths, &c. and to do all this by beginning at notes of different pitch. Then those notes are represented by lines and spaces, to which these syllables are applied, and the learners taught to name each line and space thereby, which makes what we call solfáging; the use whereof, is, that while they are learning to tune the degrees and intervals of sound expressed by notes on a line or space, or learning a song to which no words are applied, they may not only do it the better by means of articulate sounds, but chiefly that by knowing the degrees and intervals expressed by those syllables; they may more readily know the places of the semitones, and the true distance of the notes. See the article Solfaterra.

SOLFATERRA, a mountain of Italy in the kingdom of Naples, and Terra di Lavoro. This mountain appears evidently to have been a volcano in ancient times; and the soil is yet so hot, that the workmen employed there in making alum need nothing else besides the heat of the ground for evaporating their liquids. Of this mountain we have the following account by Sir William Hamilton. "Near Afrunti (another mountain, formerly a volcano likewise) rises the Solfaterra, which not only retains its cone and crater, but much of its former heat. In the plain within the crater, smoke issues from many parts, as also from its sides: here, by means of stones and tiles heaped over the crevices, through which the smoke passes, they collect in an awkward manner what they call false armoniac; and from the sand of the plain they extract sulphur and alum. This spot, well attended to, might certainly produce a good revenue, whereas I doubt if they have hitherto ever cleared L. 500 a-year by it. The hollow found produced by throwing a heavy stone on the plain of the crater of the Solfaterra, seems to indicate that it is supported by a fort of arched natural vault; and one is induced to think that there is a pool of water beneath this vault (which boils by the heat of a subterraneous fire still deeper), by the very moist steam that issues from the cracks in the plain of the Solfaterra, which, like that of boiling water, runs off a sword or knife, presented to it, in great drops. On the outside, and at the foot of the cone of the Solfaterra, towards the lake of Agnano, water rushes out of the rocks so hot as to raise the quicksilver in Fahrenheit's thermometer to the degree of boiling water (A); a fact of which I myself was an eye-witness. This place, well worthy the observation of the curious, has been taken little notice of; it is called the Pisciarelli. The common people of Naples have great faith in the efficacy of this water; and make much use of it in all cutaneous disorders, as well as for another disorder that prevails here. It seems to be impregnated chiefly with sulphur and alum. When you approach your ear to the rocks of the Pisciarelli, from whence this water oozes, you hear a horrid boiling noise, which seems to proceed from the huge cauldron that may be supposed to be under the plain of the Solfaterra. On the other side of the Solfaterra, next the sea, there is a rock which has communicated with the sea, till part of it was cut away to make the road to Puzzole; this was undoubtedly a considerable lava, that ran from the Solfaterra when it was an active volcano. Under this rock of lava, which is more than 70 feet high, there is a stratum of pumice and ashes. This ancient lava is about a quarter of a mile broad; you meet with it abruptly before you come in sight of Puzzole, and it finishes as abruptly within about 200 paces of the town. The ancient name of the Solfaterra was Forum Vulcani; a strong proof of its origin from subterraneous fire. The degree of heat that the Solfaterra has preserved for so many ages, seems to have calcined the stones upon its cone and in its crater, as they are very white and crumble easily in the hottest parts. See Chemistry, n° 656.

SOLICITOR, a person employed to take care of and manage suits depending in the courts of law or equity. Solicitors are within the statute to be sworn, and admitted by the judges, before they are allowed to practice in our courts, in like manner as attorneys.

"There is also a great officer of the law, next to the attorney-general, who is styled the king's solicitor-general; who holds his office by patent during the king's pleasure, has the care and concern of managing the king's affairs, and has fees for pleading, besides other fees arising by patents, &c. He attends on the privy-council; and the attorney-general and he were anciently reckoned among the officers of the exchequer; they have their audience, and come within the bar in all other courts." SOLID, in philosophy, a body whose parts are so firmly...
SOL [ 601 ] SOL

SOLICE, a reasoning or discourse which a man holds with himself; or, more properly, according to Pappas, it is a discourse by way of answer to a question that a man propounds to himself.

Soliqquies are become very common on the modern stage: yet nothing can be more artificial, or more unnatural, than an actor's making long speeches to himself, to convey his intentions to the audience. Where such discoveries are necessary to be made, the poet should rather take care to give the dramatic persons such confidants as may necessarily share their inmost thoughts; by which means they will be more naturally conveyed to the audience; yet even this is a shift which an accurate poet would not have occasion for. The following lines of the duke of Buckingham concerning the use and abuse of soliloquies deserve attention:

Soliloquies had need be very few,

Extremely short, and spoke in passion too.

Our lovers talking to themselves, for want

Of others, make the pit their confidant:

Nor is the matter mended, if thus

They trust a friend, only to tell it us.

SOLIMAN II. emperor of the Turks, surnamed the Magnificent, was the only son of Selim I. whom he succeeded in 1520. He was educated in a manner very different from the Ottoman princes in general; for he was instructed in the maxims of politics and the secrets of government. He began his reign by reforming those perils their possessions whom his father had unjustly plundered. He re-established the authority of the tribunals, which was almost annihilated, and bestowed the government of provinces upon none but persons of wealth and probity: “I would have my viceroys (he used to say) resemble those rivers that fertilize the fields through which they pass, not those torrents which sweep everything before them.”

After concluding a truce with Ismael Sophy of Persia, and subduing Gozelii Bey, who had raised a rebellion in Syria, he turned his arms against Europe. Belgrade was taken in 1521, and Rhodes fell into his hands the year following, after an obstinate and enflamable defence. In 1526 he defeated and slew the king of Hungary in the famous battle of Mohatz. Three years after he conquered Buda, and immediately laid siege to Vienna itself. But after continuing 20 days before that city, and assaulting it 20 times, he was obliged to retreat with the loss of 80,000 men. Some time after he was defeated by the Persians, and disappointed of his hopes of taking Malta. He succeeded, however, in dispossessing the Genoese of Chio, an island which had belonged to that republic for more than 200 years.

He died at the age of 76, while he was besieging Szigeth, a town in Hungary, on the 30th August 1566. He was a prince of the first rank, a lover of justice, and vigorous in the execution of it: but he tarnished all his glory by the cruelty of his dispositions. After the battle of Mohatz he ordered 1500 prisoners, most of them gentlemen, to be ranged in a circle, and beheaded in presence of his whole army.

G Soliman
Soliman thought nothing impossible which he commanded: A general having received orders to throw a bridge over the Drave, wrote him, that it was impossible. The sultan sent him a long band of linen with these words written on it: “The emperor Soliman, thy master, orders thee to build a bridge over the Drave in spite of the difficulties thou mayest meet with. He informs thee at the same time, that if the bridge be not finished upon his arrival, he will hang thee with the very linen which informs thee of his will.”

SOLOPUGA, or SOLIPUGA, in natural history, the name given by the Romans to a small venomous insect of the spider-kind, called by the Greeks Solopugus. Both words signify an animal which flies most in the country, and seafons where the sun is most hot. Solinus makes this creature peculiar to Sardinia; but this is contrary to all the accounts given us by the ancients. It is common in Africa and some parts of Europe. Almost all the hot countries produce this venomous little creature. It lies under the sand to seize other insects as they go by, and if it meets with any uncovered part of a man, produces a wound which proves very painful; it is said that the bite is absolutely mortal, but probably this is not true. Solinus writes the word solipuga, and so do many others, erroneously deriving the name from the notion that this animal flies from the sun’s rays, and buries itself in the sand.

SOLIS (Antonio de), an ingenious Spanish writer, of an ancient and illustrious family, born at Placentia in Old Castile, in 1610. He was intended for the law; but his inclination toward poetry prevailed, and he cultivated it with great success. Philip IV. of Spain made him one of his secretaries; and after his death the queen-regent appointed him biographer of the Indies, a place of great profit and honour: his History of the Conquest of Mexico shows that he could not have named a fitter person. He is better known by his history at least abroad, than by his poetry and dramatic writings, though in these he was also distinguished. He turned priest at 57 years of age, and died in 1686.

SOLITARY, that which is remote from the company or commerce of others of the same species.

SOLITARIES, a domination of nuns of St Peter of Alcantara, instituted in 1626, the design of which was to imitate the severe penitent life of that saint. Thus they are to keep a continual silence, never to open their mouths to a stranger; to employ their time wholly in spiritual exercises, and leave their temporal concerns to a number of maids, who have a particular superior in a separate part of the monastery: they always go bare-footed, without sandals; gird themselves with a thick cord, and wear no linens.

SOLO, in the Italian music, is frequently used in pieces consisting of several parts, to mark those that are to perform alone; as fausto fols, violino fols. It is also used for fantas composè for one violin, one German flute, or other instrument, and a bass; thus we say, Corelli’s solo, Geminiani’s solo, &c. When two or three parts play or sing separately from the grand chorus, they are called a dou fols, a tre fols, &c. Solo is sometimes denoted by S.

SOLOMON, the son of David king of Israel, renowned in Scripture for his wisdom, riches, and magnificent temple and other buildings. Towards the end of his life he fulfilled all his former glory by his apathy from God; for which cause vengeance was denounced against his house and nation. He died about 975 B.C.

SOLOMON’S SEAL, in botany; a species of Convallaria.

SOLON, one of the seven wise men of Greece, was born at Salamis, of Athenian parents, who were defended from Codrus. His father leaving little patrimony, he had recourse to merchandise for his subsistence. He had, however, a greater thirst after knowledge and fame than after riches, and made his mercantile voyages subservient to the increase of his intellectual treasures. He very early cultivated the art of poetry, and applied himself to the study of moral and civil wisdom. When the Athenians, tired out with a long and troublesome war with the Megarensians, for the recovery of the isle of Salamis, prohibited any one, under pain of death, to propose the renewal of their claim to that island, Solon thinking the prohibition dishonourable to the state, and finding many of the younger citizens desirous to revive the war, feigned himself mad, and took care to have the report of his insanity spread thro’ the city. In the mean time he composed an elegy adapted to the state of public affairs, which he committed to memory. Everything being thus prepared, he sallied forth into the market-place with the kind of cap on his head which was commonly worn by sick persons, and ascending the herald’s stand, he delivered, to a numerous crowd, his lamentation for the defeat of Salamis. The verses were heard with general applause; and Phidias seconded his advice, and urged the people to renew the war. The decree was immediately repealed; the claim to Salamis was restored; and the conduct of the war was committed to Solon and Pheidias, who, by means of a stratagem, defeated the Megarensians, and recovered Salamis.

His popularity was extended through Greece in consequence of a successful alliance which he formed among the states in defence of the temple at Delphos against the Cyprians. When dissensions had arisen at Athens between the rich creditors and their poor debtors, Solon was created archon, with the united powers of supreme legislator and magistracy. He soon restored harmony between the rich and poor: He cancelled the debts which had proved the occasion of so much oppression; and ordained that in future no creditor should be allowed to seize the body of the debtor for his security: He made a new distribution of the people, instituted new courts of judicature, and framed a judicious code of laws, which afterwards became the basis of the laws of the twelve tables in Rome. Among his criminal laws are many wise and excellent regulations; but the code is necessarily defective with respect to those principles which must be derived from the knowledge of the true God, and of pure morality, as the certain foundations of national happiness. Two of them in particular were very exceptionable; the permission of a voluntary exile to persons that had been guilty of premeditated murder, and the appointment of a less severe punishment for a rape than for seduction. Those who wish to see accurately flated the comparative excellence of the laws of Moses, of Lycurgus, and Solon, may consult Prize Dissertations relative to Natural and Revealed Religion by Teyler’s Theological Society, Vol. IX.

The interview which Solon is said to have had with
SOMERS (John), lord high chancellor of England, was born at Worcester in 1652. He was educated at Oxford, and after wards entered himself at the Middle-Temple, where he studied the law with great vigour. In 1688 he was one of the council for the seven bishops at their trial, and argued with great learning and eloquence against the dispensing power. In the convention which met by the prince of Orange's summons, January 22. 1689, he represented Worcester; and was one of the managers for the House of Commons, at a conference with the House of Lords upon the word abdicated. Soon after the accession of King William and Queen Mary to the throne, he was appointed solicitor-general, and received the honour of knighthood. In 1692 he was made attorney general, and in 1693 advanced to the post of lord keeper of the great seal of England. In 1695 he proposed an expedient to prevent the practice of clipping the coin. In 1697 he was created lord Somers, baron of Aveham, and made lord high chancellor of England. In the beginning of 1706 he was removed from his post of lord chancellor, and the year after was impeached of high crimes and misdemeanors by the House of Commons, of which he was acquitted upon trial by the House of Lords. He then retired to a studious course of life, and was chosen president of the Royal Society. In 1706 he proposed a bill for the regulation of the law; and the same year was one of the principal managers for the union between England and Scotland. In 1708 he was made lord president of the council; from which post he was removed in 1710, upon the change of the ministry. In the latter end of Queen Anne's reign his lordship grew very infirm in his health; which is supposed to be the reason that he held no other post than that at the council-table, after the accession of King George I. He died of an apoplectic fit in 1716. Mr Addition has drawn his character very beautifully in the Freeholder.

SOMERSTHIRE, a county of England, taking its name from Somerton, once the capital, between 50° and 51° 29' north latitude, and between 2° 35' and 59° west longitude. It is bounded on the west by Devonshire, on the south by Dorsetshire, on the north by Bristol Channel or the Severn Sea, on the north-east by a small part of Gloucestershire, and on the east by Wiltshire. It is one of the largest counties in England, extending in length from east to west about 68 miles; in breadth, where broadest, from south to north, about 47; and 240 in circumference. It is divided into 42 hundreds, in which are 3 cities, 32 market towns, 1700 villages, 385 parishes of which 132 are vicarages, containing more than 1,000,000 of acres, and about 300,000 souls. It sends 18 members to Parliament, viz. two for the county, two for Milton, two for Bath, two for Wells, two for Taunton, two for Bridgewater, two for Ilchester, two for Milbourne-port, and two for Minehead.

The air of this country is very mild and wholesome, especially that of the hilly part. The soil in general is exceeding rich, so that single acres very commonly produce forty or fifty bushels of wheat, and there have been instances of some producing sixty of barley. As there is very fine pasture both for sheep and black cattle, it abounds in both, which are as large as those of
SOMERFORD, Lincolnshire, and their flesh of a finer grain. In consequence of this abundance of black cattle, great quantities of cheese are made in it, of which that of Cheddar is thought equal to Parmesan. In the hilly parts are found coal, lead, copper, and lapis calaminaris. Wheat thrives in it as well as in any county of the kingdom. It abounds also in peas, beans, beer, cider, fruit, wild-fowl, and salmon; and its mineral waters are celebrated all over the world.

The riches of this county, both natural and acquired, exceed those of any other in the kingdom, Middlesex and Yorkshire excepted. The woollen manufacture in all its branches is carried on to a very great extent; and in some parts of the county great quantities of linen are made. If to these the produce of various other commodities in which it abounds is added, the amount of the whole must undoubtedly be very great.

Its foreign trade must also be allowed to be very extensive, when it is considered that it has a large trade for sea coal, and poolefs, besides other ports, that of Bristol, a town of the greatest trade in England, next to London.

Besides small streams, it is well watered and supplied with fish by the river Severn, Avon, Parrel, Froome, Ax, Torre, and Tone. Its greatest hills are Mendip, Pouland, and Quantock, of which the first abounds in coal, lead, &c. The rivers Severn and Parrel breed very fine salmon. The chief town is Bristol.

SOMERTON, an ancient town in Somertfethire, from whence the county derives its name. It is 132 miles from London; it has five streets, containing 231 houses, which are mostly built of the blue stone from the quarries in the neighbourhood. It is governed by constables, and has a hall for petty sessions. The market for corn is considerable, and it has several fairs for cattle. The church has not very frequent, an oblong tower with fix bells. N. Lat. 51. 4. W. Long. 1. 53.

SOMNAMBULI, persons who walk in their sleep. See Sleepwalkers.

SOMNER (William), an eminent English antiquary, was born at Canterbury in 1606. His first treatise was 'The Antiquities of Canterbury, which he dedicated to Archibishop Laud. He then applied himself to the study of the Saxon language; and having made himself master of it, he perceived that the old glossary prefixed to Sir Roger Twifden’s edition of the laws of King Henry I. printed in 1644, was faulty in many places; he therefore added to that edition notes and observations valuable for their learning, with a very useful glossary. His Treatise of Gavelkind was finihed about 1648, though not published till 1660. Our author was zealously attached to King Charles I. and in 1648 he published a poem on his sufferings and death. His skill in the Saxon tongue led him to inquire into most of the European languages ancient and modern. He affiled Dugdale and Dodworth in compiling the 'Monasticon Angliae.' His Saxon Dictionary was printed at Oxford in 1659. He died in 1660.

SON, an appellation given to a male child considered in the relation he bears to his parents. See Parent and Pinen Party.

SONATA, in music, a piece or composition, intending to be performed by instruments only; in which sense it stands opposed to cantata, or a piece designed for the voice. See Cantata.

The sonata then, is properly a grand, free, humorous composition, diversified with a great variety of motions and expessions, extraordinary and bold strokes, figures, &c. And all this purely according to the fancy of the composer; who, without confining himself to any general rules of counterpoint, or to any fixed number or measure, gives a loose to his genius, and runs from one mode, measure, &c. to another, as he thinks fit. This species of composition had its rise about the middle of the 17th century; those who have most excelled in it were Baffani and Corelli. We have sonatas of 1, 2, 3, 4, 5, 6, 7, and even 8, parts, but usually they are performed by a single violin, or with two violins, and a thorough bass for the harpsichord; and frequently a more figure bass for the bass viol, &c.

There are a thousand different species of sonatas; but the Italians usually reduce them to two kinds. Sonata de chiasa, that is, sonatas proper for church music, which usually begin with a grave solemn motion, suitable to the dignity and sanctity of the place and the service, after which they strike into a quicker, gayer, and richer manner. These are what they more peculiarly call sonatas. Sonate de camera, or sonatas for the chamber, are properly sonatas of several little pieces, for dancing, only composed to the same tune. They usually begin with a prelude or little sonata, serving as an introduction to all the rest; afterwards come the allemand, pavane, courant, and other serious dances; then jigs, gavottes, minuets, chacons, pasecaillcs, and other gay airs: the whole composed in the same tune or mode.

SONCHUS, sow-thistle, in botany: A genus of plants belonging to the class of fyngeuros, and to the order of polygania equiuls; and in the natural system ranged under the 49th order, Composita. The receptacle is naked; the calyx is imbricated, belling and conical; the down of the feed is simple, feifile, and very soft; the feed is oval and pointed. There are 13 species: the maritimus, palafiris, fruticosus, arvensis, olarcaucus, tenenrims, plumier, alpinus, floridans, fribicus, tatarias, tuberosus, and camenfis. Four of these are native, and rich in Britain.—1. Palafiris, marth fow-thiffe. The feed is erect, from fix to ten feet high, branched and hairy towards the top: the leaves are firm, broad, half pinnated, feiffated, and sharp-pointed; the lower ones fagittate at the base: the flowers are of a deep yellow, large, and dispersed on the tops of the branches: the calyx is rough. It is frequent in marshes, and flowers in July or August.—2. Arvenfis, corn fow-thiffe. The leaves are alternate, runcinate, and heart-shaped at the base; the root creeps under ground; the flem is three or four feet high, and branched at the top. It grows in corn-fields, and flowers in August.—3. Olarcaucus, common fow-thiffe. The flalk is fucculent, piffular, and a cubic high or more; the leaves are broad, embracing the flem, generally deeply finnen, footh or prickly at the edges; the flowers are of a pale yellow, numerous, in a kind of umbel, and terminal; the calyx is smooth. It is frequent in waife places and cultivated grounds.—4. Alpinus, blue-flowered fow-thiffe. The flem is erect, purplish, branched, or fimple, from three to fix feet high: the leaves are large, smooth, and finnen
SONG, in poetry, a little composition, consisting of easy and natural verses, set to a tune in order to be sung. See Poetry, n° 120.

SONG, in music, is applied in general to a single piece of music, whether contrived for the voice or an instrument. See AIR.

Song of Birds, is defined by the honourable Daines Barrington to be a succession of three or more different notes, which are continued without interruption, during the same interval, with a musical bar of four crotchets; the scale of which is an adagio movement, or whilst a pendulum swings four seconds.

It is affirmed, that the notes of birds are no more innate than language in man; and that they depend upon imitation, as far as their organs will enable them to imitate the sounds which they have frequent opportunities of hearing: and their adhering so readily, even in a wild state, to the same song, is owing to the naiiveness attending only to the instruction of the parent bird, whilst they disregard the notes of all others that may perhaps be singing round them.

Birds in a wild state do not commonly sing above two weeks in the year, whereas birds that have plenty of food in a cage sing the greatest part of the year, and we may add, that the female of no species of birds ever sings. This is a wise provision of nature, because her fong would disfigure her nest. In the same manner, we may reasonably account for her inferiority in plumage. The faculty of singing is confined to the cock birds; and accordingly Mr. Hunter, in dissecting birds of several species, found the muscles of the larynx to be stronger in the nightingale than in any other bird of the same fize; and in all those instances, where he dissected both cock and hen, the same muscles were stronger in the cock. To the same purpose, it is an observation as ancient as the time of Pliny, that a capon does not crow.

Some have ascribed the singing of the cock-bird in the spring solely to the motive of pleasing his mate during incubation; others, who allow that it is partly for this end, believe it is partly owing also to another cause, viz. the great abundance of plants and insects in the spring, which, as well as seeds, are the proper food of singing birds at that time of the year.

Mr. Barrington remarks, that there is no instance of any finging bird which exceeds our blackbird in fize; and this, he supposes, may arise from the difficulty of its concealing itself, if it called the attention of its enemies, not only by its bulk, but by the proportionable loudness of its notes. This writer further observes, that some passages of the fong in a few kinds of birds correspond with the intervals of our musical scale, of which the cuckoo is a striking and known instance; but the greater part of their fong cannot be reduced to a musical scale; partly, because the rapidity is often too great, and it is also so uncertain when they may stop, that we cannot reduce the passages to form a musical bar in any time whatever; partly also, because the pitch of most birds is considerably higher than the most thrilling notes of those instruments which have the greatest compass; and principally, because the intervals used by birds are commonly so minute, that we cannot judge of them from the more gross intervals into which we divide our musical octave. This writer apprehends, that all birds sing in the same key; and in order to discover this key, he informs us, that the following notes have been observed in different birds, A, B flat, C, D, F, and G; and therefore E is only wanting to complete the scale; now these intervals, he says, can only be found in the key of F with a sharp third, or that of G with a flat third; and he supposes it to be the latter, because admitting that the first musical notes were learned from birds, those of the cuckoo, which have been most attended to, form a flat third, and most of our compositions are in a flat third, where music is simple, and consists merely of melody. As a further evidence that birds sing always in the same key, it has been found by attending to a nightingale, as well as a robin which was educated under him, that the notes reducible to our intervals of the octave were always precisely the same.

Most people, who have not attended to the notes of birds, suppose, that every species fings expressly the same notes and passages; but this is by no means true; though it is admitted, that there is a general resemblance. Thus the London bird-catchers prefer the fong of the Kentish goldfinches, and Essex chaffinches; and some of the nightingale-fanciers, prefer a Surry bird to those of Middlesex.

Of all finging birds, the fong of the nightingale has been most universally admired; and its superiority (deduced from a caged bird) consists in the following particulars; its ton is much more mellow than that of any other bird, though at the same time, by a proper exertion of its musical powers, it can be very brilliant. Another point of superiority is its continuance of song without a pause, which is sometimes no less than six seconds; and when respiration becomes necessary, it takes it with as much judgment as an opera-singer. The skylark in this particular, as well as in compass and variety, is only second to the nightingale. The nightingale also sings (if the expression may be allowed) with superior judgment and taste. Mr. Barrington has observed, that his nightingale, which was a very capital bird, began softly like the ancient orators; referring its breadth to few certain notes, which by these means had a most alluring effect. This writer adds, that the notes of birds, which are annually imported from Asia, Africa, and America, both singly and in concert, are not to be compared to those of European birds.

The following table, formed by Mr. Barrington, according to the idea of M. de Piles in estimating the merits of painters, is designed to exhibit the comparative merit of the British finging birds; in which 20 is supposed to be the point of absolute perfection.

Nightingale
SONNA, a book of Mahometan traditions, which all the orthodox Mussulmen are required to believe.

SONNERATIA, in botany, a genus of plants belonging to the class of icelandia, and to the order of monagyna. The calyx is cut into six segments; the petals are six; the capsule is multilocular and flocculent; and the seeds contain many hairs. The only species is the acida.

SONNET, in poetry, a composition contained in 14 verses, viz. two stanzas or measures of four verses each, and two of three, the eight first verses being all in three rhymes.

SONNITES, among the Mahometans, an appellation given to the orthodox Mussulmen or true believers; in opposition to the several heretical sects, particularly the Shiites or followers of Ali.

SOOJU, or Soy. See Dolichos.

SOONTABURDAR, in the East Indies; an attendant, who carries a silver bladder in his hand about two or three feet long, and runs before the palanquin. He is inferior to the Chubdar; the property of an Indian newacyr requiring two Soontaburdars for every Chubdar in the train. The Chubdar proclaims the approach of visitors, &c. He generally carries a large silver staff about five feet long in his hands; and among the Nabobs he proclaims their presses aloud as he runs before their palanquins.

SOOT, a volatile matter arising from wood and other fuel along with the smoke; or rather, it is the smoke itself condensed and gathered to the sides of the chimney. Tho' once volatile, however, foot cannot be again resolved into vapour; but, if distilled by a strong fire, yields a volatile alkali and empyreumatic oil, a considerable quantity of fixed matter remaining at the bottom of the distilling vessel. If burnt in an open fire, it flames with a thick smoke, whence other foot is produced. It is used as a material for making sal ammoniac, and as a manure. See Chemistry, No. 796; and Agriculture, No. 20.

SOPHIS, or Sopi, a title given to the emperor of Persia; importing as much as wife, fuge, or philosopher.

The title is by some said to have taken its rise from a young shepherd named Sopi, who attained to the crown of Persia in 1370; others derive it from the sopi or fuges anciently called magi. Vossius gives a different account of the word: sopi, in Arabic, he observes, signifies soud; and he adds, that it was applied by the Turks out of deference to the kings of Persia ever since Ismael's time; because, according to their scheme of religion, he is to wear no other covering on his head but an ordinary red woollen stuff; whence the Persians are also called huzabafise, &c. red-head. But Bochart affirms, that sopi is the original Persian language, signifies one that is pure in his religion, and who prefers the service of God in all things; and derives it from an order of religious called by the same name. The sopi's value themselves on their illustrious extraction. They are defended in a right line from Housfein, second son of Ali, Mahomet's cousin, and Fatima, Mahomet's daughter.

SOPHIS, or Sufis, a kind of order of religious among the Mahometans in Persia, answering to what are otherwise called dervises, and among the Arabs and Indians faquirs. Some will have them called sophis from a kind of coarse cambleet which they wear called fouf from the city Souf in Syria, where it is principally manufactured. The more eminent of those sophis are complimented with the title fobiek, that is, revered, much as in Roman churches the religious are called reverend fathers. Schick sopi, who laid the foundation of the grandeur of the royal house of Persia, was the founder, or rather the refaror of this order: Ismael, who-conquered Persia, was himself a sopi, and greatly valued himself on his being so. He chose all the guards of his person from among the religious of this order; and would have all the great lords of his court sophis. The king of Persia is still grandmaster of the order; and the lords continue to enter into it, though it be now fallen under some contempt.

SOPHISM, in logic a specious argument having the appearance of truth, but leading to falsehood. Sophisms are reduced by Aristotle into eight classes, an arrangement fo just and comprehensive, that it is equally proper in present as in former times. 1. Ignoratio elenchi in which the sophiit seems to determine the question, while he only does it in appearance. Thus the question, 'whether excess of wine be hurtful?' seems to be determined by proving, that wine revives the spirits and gives a man courage: but the principal point is here kept out of sight; for all it may be hurtful to health, to fortune, and reputation. 2. Petitio principii, a begging of the question, or taking for granted that which remains to be proved, as if any one should undertake to prove that the soul is extended through all the parts of the body, because it resides in every member. This is affirming the same thing in different words. 3. Reasoning in a circle; as when the Roman Catholics prove the Scriptures to be the word of God by the authority of the church, and the authority of the church from the Scriptures. 4. Non causa pro causa, or the ascribing of a false cause to any effect. Thus the supposèd principle, that nature abhors a vacuum, was applied to explain the rising of water in a pump before Galilei discovered that it was owing to the preiture of the atmosphère.
In this way the vulgar ascribe accidents to divine vengeance, and the heresies and infidelity of modern times are laid to being owing to learning.

5. **Fallaciam accidentis**, in which the sophist represents what is merely accidental as essential to the nature of the subject. This is nearly allied to the former, and is committed by the Mahometans and Roman Catholics. The Mahometans forbid wine, because it is sometimes the occasion of drunkenness and quarrels; and the Roman Catholics prohibit the reading of the Bible, because it has sometimes promoted heresies. 6. By deducing an universal assertion from what is true only in particular circumstances, and the reverse; thus some even argue, ‘‘translators have committed many errors in copying the Scriptures, therefore they are not to be depended on.’’ 7. By afferting any thing in a compound sense which is only true in a divided sense; so when the Scriptures assure us, that the worth of sinners may be faved, it does not mean that they shall be faved while they remain sinners, but that, if they repent they may be faved. 8. By an abuse of the ambiguity of words. Thus Mr Hume reasons in his Essay on Miracles: ‘‘Experience is our only guide in reasoning concerning matters of fact; now we know from experience, that the laws of nature are fixed and invariable. On the other hand, testimony is variable and often false; therefore from our evidence for the reality of miracles reposes solely on testimony which is variable, and our evidence for the uniformity of the laws of nature is invariable, miracles are not to be believed.’’ The sophistry of this reasoning depends on the ambiguity of the word experience, which in the first proposition signifies the maxims which we form from our own observation and reflection; in the second it is confounded with testimony; for it is by the testimony of others, as well as our own observation, that we learn whether the laws of nature are variable or invariable. The Essay on Miracles may be recommended to those who wish to see more examples of sophistry; as we believe most of the eight species of sophisms which we have mentioned are well illustrated by examples in that essay.

**Sophist**, an appellation assumed in the early periods of Grecian history by those who devoted their time to the study of science. This appellation appearing too arrogant to Pythagoras, he declined it, and wished to be called a philosopher; declaring that, though he could not consider himself as a wise man, he was indeed a lover of wisdom. True wisdom and modesty are generally united. The example of Pythagoras was followed by every man of eminence; while the name sophist was retained only by those who with a pomp of words made a magnificent display of wisdom upon a very flight foundation of knowledge. Those men taught an artificial structure of language, and a false method of reasoning, by which, in argument, the worse might be made to appear the better reason (see Sorism). In Athens they were long held in high repute, and supported, not only by contributions from their pupils, but by a regular salary from the state. They were among the bitterest enemies of the illustrious Socrates, because he embraced every opportunity of exposing to contempt and ridicule their vain pretensions to superior knowledge, and the pernicious influence of their doctrines upon the taste and morals of the Athenian youth.

**Sophistication**, the mixing of any thing with what is not genuine; a practice too common in Sophocles, the making up of medicines for sale; as also among vintners, distillers, and others, who are accused of sophisticating their wines, spirits, oils, &c. by mixing with them cheaper and coarser materials; and in many cafes the cheat is carried on so artfully as to deceive the best judges.

**Sophocles**, the celebrated Greek tragic poet, the son of Sophilus an Athenian, was born at Colon, and educated with great attention. Superior vigour and address in the exercises of the palettr, and skill in music, were the great accomplishments of young men in the states of Greece. In these, Sophocles excelled; nor was he less distinguished by the beauty of his person. He was also instructed in the noblest of all sciences, civil policy and religion; from the first of thefe he derived an unshaken love of his country, which he served in some embassies, and in high military command with Pericles; from the latter he was impressed with a pious reverence for the gods, manifested by the inviolable integrity of his life. But his studies were early devoted to the tragic muse; the spirit of Eschylus lent a fire to his genius, and excited that noble emulation which led him to contend with, and sometimes to bear away the prize from, his great master. He wrote 43 tragedies, of which 7 only have escaped the ravages of time: and having testified his love of his country by refusing to leave it, though invited by many kings; and having enjoyed the uninterrupted esteem and affection of his fellow-citizens, which neither the gallant actions and sublime genius of Eschylus, nor the tender spirit and philosophic virtue of Euripides, could secure to them, he died in the 61st year of his age, about 406 years before Christ. The burial-place of his ancestors was at Decelia, which the Lacedemontians had at that time feized and fortified; but Lyfander, the Spartan chief, permitted the Athenians to inter their deceased poet; and they paid him all the honours due to his love of his country, integrity of life, and high poetic excellence. Eschylus had at once feized the highest post of honour in the field of poetry, his true sublimity, to that eminence his claim could not be disputed. Sophocles had a noble elevation of mind, but tempered with so fine a taste, and so chastened a judgment, that he never passed the bounds of propriety. Under his conduct the tragic muse appeared with the chaste dignity of some noble matron at a religious solemnity; harmony is in her voice, and grace in all her motions. From him the theatre received some additional embellishments; and the drama the introduction of a third speaker, which made it more active and more interesting: but his distinguished excellence is in the judicious disposition of the fable, and so nice a connection and dependance of the parts on each other, that they all agree to make the event not only probable, but even necessary. This is peculiarly admirable in his ‘‘Œdipus King of Thebes,’’ and in this important point he is far superior to every other dramatic writer.

The ingratitude of the children of Sophocles is well known. They wished to become immediate masters of their father’s possessions; and therefore tired of his long life, they accursed him before the Areopagus of infinity. The only defence the poet made was to read his tragedy of Œdipus at Colonos, which he had lately finished; and then he asked his judges, whether the author
SOPHORA, in botany: A genus of plants belonging to the class of *Leguminosae*, and to the order of *Mimosidae*; and in the natural system arranged under the 32d order, *Papilionaceae*. The calyx is quinquedentate and gibbous above; the corolla is papillaceous; the wings being of the same length with the vexillum; the seed is contained in a legumen. There are 16 species; the tetrapetra, microphylla, flavescens, alopecuroides.

SOPHORA, or Sophora, the heath or roan-tree, rises with a regular branching head, twenty or thirty feet high and large umbellate clusters of white flowers at the fides and ends of the branches, succeeded by clusters of fine red berries, ripe in autumn and winter. There is a variety with yellow striped leaves. This species grows wild in many parts of Great Britain in mountainous places, woods, and hedge-rows, often growing to the size of timber; and is admitted into ornamental plantations, for the beauty of its growth, foliage, flowers, and fruit; the latter, in particular, being produced in numerous red large bunches all over the tree, exhibiting a fine appearance in autumn and winter, till devoured by the birds, especially the blackbird and thrush, which are so allure by this fruit as to flock from all parts and feed on it voraciously. In the island of Jura the juice of the berries is employed as an acid for punch. It is probable that this tree was in high esteem with the Druids; for it is more abundant than any other tree in the neighbourhood of those Druidical circles of stones, so common in North Britain. It is still believed by some persons, that a branch of this tree can defend them from enchantment or witchcraft. Even the cattle are supposed to be preferred by it from danger. The dairy-maid drives them to the summer pastures with a rod of the roan-tree, and drives them home again with the same. In Strathpey, we are told, a hoop is made of the wood of this tree on the 1st of May, and all the sheep and lambs are made to pass through it.

2. The *domesfica*, or cultivated service-tree, with eatable fruits, grows with an upright stem, branching 30 or 40 feet high or more, having a brownish bark, and the young shoots in summer covered with a mealy down; pinnate leaves of eight or ten pairs of broad deeply serrated lobes and an odd one, downy underneath, and large umbellate clusters of white flowers at the fides and ends of the branches, succeeded by bunches of large, fleshy, edible red fruits, of various shapes and sizes. This tree is a native of the southern warm parts of Europe, where its fruit is used at table as a dessert, and it is cultivated in the north in many gardens, both as a fruit-tree and as an ornament to diversify hardy plantations.

3. The *hebrida*, or mongrel service-tree of Gothland, grows twenty or thirty feet high; it has half-pinnate leaves, very downy underneath; and clusters of white flowers, succeeded by bunches of round reddish berries in autumn.

SORCERY, or Magic: the power which some persons were formerly supposed to possess of commanding the devil and the infernal spirits by skill in charms and invocations, and of fothing them by fumigations. Sorcery is therefore to be distinguished from witchcraft, an art which was supposed to be practised, not by commanding evil spirits, but by contact with the devil. As an instance of the power of bad smells over demons or evil spirits, we may mention the flight of the evil spirit mentioned in Tobit into the remote parts of Egypt, produced, it is said, by the smell of the burnt liver of a fift. Lilly informs us, that one Evans having raised a spirit at the request of Lord Bothwell and Sir Kenelm Digby, and forgetting a fumigation, the spirit, vexed at the disappointment, pulled him without the circle, and carried him from his house in the Minories into a field near Battersea Caufeway.

King James, in his *Daemonologia*, has given a very full account of the art of sorcery. "Two principal things (says he) cannot well in that errand be wanted:
SOR

[ 609 ]

SOR

holy water (whereby the devil mocks the papists), and some present of a living thing unto him. There are likewise certaine dates and figures that they observe in this purport. These things being all ready and prepared, circles are made, triangular, quadrangular, round, double, or single, according to the forme of the apparition they crave. When the conjured spirit appears, which will not be while after many circumstances, long prayers, and much muttering and murrurings of the conjurers, like a papit priest dispatching a hunting made — how done, I say, he appears, if they have milled one jote of all their rites; or if any of their beasts once fly'd over the circle, through terror of his fearfull apparition, he paires himself at that time, in his owne hand, of that due debt which they ought him, and otherwise would have delayed longer to have paid him: I mean, he carries them with him, body and soul. How the conjurers made triangular or quadrangular circles, his majesty has not informed us, nor does he seem to imagine there was any difficulty in the matter. We are therefore led to suppose, that he learned his mathematics from the same system as Dr. Sacheverell, who, in one of his speeches or sermons, made use of the following simile: "They concur like parallel lines, meeting in one common centre."

Another mode of consulting spirits was by the beryl, by means of a specular or feer; who, to have a complete light, ought to be a pure virgin, a youth who had not known woman, or at least a person of irreproachable life and purity of manners. The method of such consultation is this: The conjurer having repeated the necessary charms and adjurations, with the liany or invocation peculiar to the spirits or angels he wishes to call (for every one has his particular form), the seer looks into a crystal, or beryl, wherein he will see the answer, represented either by types or figures; and sometimes, though very rarely, will hear the angels or spirits speak articulately. Their pronunciation is, as Lilly says, like the Irish, much in the throat. Lilly describes one of these beryles or crystals. It was, he says, as large as an orange, fast in silver, with a croze at the top, and round about engraved the names of the angels Raphael, Gabriel, and Uriel. A delineation of another is engraved in the frontispiece to Anbery's Miscellanies.

These seers or magicians do not always employ their art to do mischief; but, on the contrary, frequently exert it to cure diseases inflicted by witches; to discover thieves; recover stolen goods; to foretell future events, and the state of absent friends. On this account they are frequently called white witches. See Magic, Witchcraft, &c.

Our forefathers were strong believers when they enabed, by statute 33 Hen. VIII. c. 8, all witchcraft and forcery to be felony without benefit of clergy; and again, by statute 1 Jac. I. c. 12, that all persons invoking any evil spirit, or consulting, covincenting with, entertaining, employing, feeding, or rewarding any evil spirit; or taking up dead bodies from their graves to be used in any witchcraft, forcery, charm, or incantation; or killing or otherwise hurting any person by such infernal arts, should be guilty of felony without benefit of clergy, and suffer death. And if any person should attempt by forcery to discover hidden treasure, or to restore stolen goods, or to provoke unlawful love, or to hurt any man or beast, though the same were not effected, he or she shall suffer imprisonement and pillory, for the first offence, and death for the second, and such acts continued in force till lately, to the terror of all the ancient females in the kingdom; and many poor wretches were sacrificed thereby to the prejudice of their neighbours and their own illusions, not a few having by some means or other confessed the fact at the gallows. But all executions for this diabolical crime are now at an end; the legislature having at length followed the wise example of Louis XIV. in France, who thought proper by an edict to restrain the tribunal of justice from receiving informations of witchcraft, and accordingly it is enacted, by statute 9 Geo. II. c. 5, that no prosecution shall for the future be carried on against any person for conjuration, witchcraft forcery, or enchantment; but the misbeloved of persons pretending to use witchcraft, tell fortunes, or discover stolen goods, by skill in the occult sciences, is still deservedly punished with a year's imprisonment, and standing four times in the pillory.

SOREX, the Shrew, in natural history; a genus of animals belonging to the clafs of mammalia, and order of fera. It has two long fore-teeth in the upper jaw, which are divided into two points; in the lower jaw are two or four fore-teeth, the two middle ones, in the latter-case, being shorter than the others. On each side in both jaws are two or more tusks: The grinders are knobbed. The animals of this genus have in general thick clumsy bodies, and five toes on each of their feet; the head resembles that of the mole, being thick at the fore-head, much elongated, and ending in a conical snout, and having very small eyes; in other circumstances of general figure they resemble the murine tribe of quadrupeds. They burrow in the ground, some species living mostly about the sides of waters; and most of them feeding on worms and insects. There are 16 species; of which the most remarkable are

1. The araneus, or field shrew-mouse, with short rounded ears; eyes small, and almost hid in the fur; note long and slender, upper part the longest; head and upper part of the body of a brownish red; belly of a dirty white; length from note to tail, two inches and a half; tail one and a half. Inhabits Europe: lives in old walls and heaps of stones, or holes in the earth; is frequently near hay-ricks, dung-hills, and necessary-houses; lives on corn, insects, and any filth; is often observed rooting in ordure like a hog; from its food, or the places it frequents, has a disagreeable smell; cats will kill, but not eat it; it brings four or five young at a time. The ancient believed it was injurious to cattle; an error now detected. There seems to be an annual mortality of these animals in August, numbers being then found dead in the paths.

2. The fides, or water-shrew, has a long slender note; very minute ears; very small eyes, hid in the fur; colour of the head and upper part of the body black; throat, breast, and belly, of a light as colour; beneath the tail, a triangular dusky spot; much larger than the last; length, from note to tail, three inches and three quarters; tail, two inches. Inhabits Europe: long since known in England, but lost till May 1768, when it was discovered in the fens near Reveley Ab.

Vol. XVII.
bury, Lincolshire; burrows in the banks near the water; is called by the fermen blind-mouse.

3. The minutus, or minute shrew, has a head near as big as the body; very slender nose; broad short naked ears; whiskers reaching to the eyes; eyes small, and capable of being drawn in; hair very fine and shining; grey above, white beneath; no tail; the leaf of quadrupeds, according to Linnaeus. Inhabits Siberia; lives in a net made of lichens, in some moist place beneath the roots of trees; feeds on seeds, digs, runs swiftly, and has the voice of a bat.

4. The tucum, or Mexican shrew, has a sharp nose; small round ears; without fight; two long fore-teeth above and below; thick, fat, and fleshy body; short legs, so that the belly almost touches the ground; long crooked claws; tawny hair; short tail; length, from nose to tail, nine inches. Inhabits Mexico; burrows, and makes such a number of cavities, that travellers can scarcely tread with safety; if it gets out of its hole, does not know how to return, but begins to dig another; grows very round, and is capable of two or three kinds of beans, and other seeds. M. de Buffon thinks it a mouse; but it seems more properly to belong to the genus of frogs.

SORITES, in logic, a species of reasoning in which a great number of propositions are so linked together, that the predicate of the one becomes continually the subject of the next following, till at last a conclusion is formed by bringing together the subject of the first proposition, and the predicate of the last. Such was that merry argument of Themistocles, to prove that his little son under ten years old governed the whole world. Thus: My son governs his brother; his mother me; I the Athenians; the Athenians the Greeks; Greece commands Europe; Europe the whole world; therefore my son commands the whole world. See Logic, p. 96, 97.

SORMING, in Scots law. See Law, No. clxxxvi.

SOREL, in botany, a species of the rutaceae, which grows in pastures and meadows, and is well known. The natives of Lapland boil large quantities of the leaves in water, and mix the juice when cold with the milk of their rein-deers which they esteem an agreeable and wholesome food. The Dutch are said to cultivate this plant for its usefulness in the dyeing of woollen cloths black; and we know that by means of the common broad-leaved Sorel an excellent black colour is, in many places of Scotland, given to woollen stuffs without the aid of coopers. As this mode of dyeing does not in the smallest degree injure the texture of the cloth, which continues to the last soft and silky, without that hardness to the touch which it acquires when dyed black by means of coopers, our readers will probably thank us for the following receipt, with which we have been favoured by a learned phylician.

Let the stuff to be dyed be well washed with soap and water, and afterwards completely dried. Then of the common broad-leaved Sorel boil as much as shall make an acid decoction of sufficient quantity to let the stuff to be dyed lie in it open and easy to be fertil. The greater quantity of Sorel that is used, the better will the colour be; and therefore if the pot or cauldron will not hold enough at once, when part has been sufficiently boiled, it must be taken out and wrung, and a fresh quantity be boiled in the same juice or decoction. When the liquor is made sufficiently acid, strain it from the forrel through a sieve, put the cloth or yarn upon it, and let it boil for two hours, filtering it frequently. If flowings be among the stuff to be dyed, it will be expedient, after they have been an hour in the boiling liquor, to turn them inside out, and in the end of the second hour let the whole be poured into a tub or any other vessel. The pot or cauldron then be washed, and water put into it, with half a pound of logwood chips for every pound of dry yarn or cloth. The logwood and water should boil slowly for four hours; and then the cloth or yarn being wrung from the liquor, and put into the logwood decoction, the whole must be suffered to boil slowly for four hours, stowings, if there be any, being turned inside out at the end of two hours. Of this last decoction there must as of the former be enough to let the cloth lie open and easy to be filled while boiling. At the end of the four hours the cloth must be taken out, and among the boiling liquor, if wanted, pick off or roots, kidneybeans, and other seeds.

WILLIAMSON, in botany. See OXALIS.

Sorrel-Colour, in the manufacture, is a reddish colour, generally thought to be a sign of a good horse.

SORRENTO, a sea-port town of the kingdom of Naples, with an archbishop's see. It is seated in a peninsula, on the bay of Naples, at the foot of a mountain of the same name, 17 miles south-east of Naples. It is the birth-place of Torquato Tasso. E. long. 14. 24. N. lat. 40. 36.

SORTILEGE (Sortilegium), a species of divination performed by means of forrel or lots. The fortes Precessilia, famous in antiquity, consisted in putting a number of letters, or even whole words, into an urn; and then, after shaking them together, they were thrown on the ground; and whatever sentences could be made out from them, constituted the answer of the oracle. To this method of divination succeeded that which has been called the fortes Home-riana and fortes Virgiliiana, a mode of inquiring into futurity, which undoubtedly took its rise from a general custom of the oracular priests of delivering their answers in verse; it continued a long time among the Greeks and Romans; and being from them adopted by the Christians, it was not till after a long succession of centuries that it became exploded. Among the Romans it consisted in opening some celebrated poet at random, and among the Christians the Scriptures, and drawing, from the first passage which presented itself to the eye, a prognostic of what would befal one's self or others, or direction for conduct when under any exigency. There is good evidence that this was one of the vulgar errors; the greatest perfons, philosophers of the best repute, admitted this superstition. Socrates, when in prison, hearing this line of Homer, Within three days I Phthia's shore shall see, immediately
immediately laid, within three days I shall be out of the world; gathering it from the double meaning of the word Plutus, which in Greek is both the name of a country and signifies corruption or death. This prediction, addressed to Achilles, was not easily forgotten, as it was verified.

When this superstitious fear passed from Paganism into Christianity, the Chriftians had two methods of consulting the divine will from the Scriptures; the one, casually, to open the divine writings, and take their direction, as above-mentioned; the other, to go to church with a purpose of receiving, as a declaration of the will of heaven, the words of the Scripture, which were sung or in the infant of one's entrance.

This unwarrantable practice of inquiring into futurity prevailed very generally in England till the beginning of the present century; and sometimes the poems, of Virgil, were consulted for oracular responses. One remarkable instance is that of King Charles I., who being at Oxford during the civil wars, went one day to see the public library, where he was showed, among other books, a Virgil nobly printed and exquisitely bound. The lord Falkland, to divert the king, would have his majesty make a trial of his fortune by the Sortes Virgilianae. Whereupon the king opening the book, the period which happened to come up to this was:

> At bello audaci populi veratus, et armis,
> Finibus extorris, complexa avulsus Iuli,
> Ausiliis implorat; viditque indigna fuorum
> Funera; nec, cum fe sub leges postis unque
> Traditurus, regno aut optata fuce fruatur,
> Sed cadat ante diem, medique inhumanus arena.

Enid. lib. iv.

Yet let a race, untamed and haughty foes,
His peaceful entrance with dire arms oppose;
Opprest with numbers in the unequal field,
His men discouraged, and himself expelled,
Let men for succour fear from place to place,
Torn from his subjects, and his son's embrace:
Fifth let him see his friends in battle slain,
And their untimely fate lament in vain;
And when at length the cruel war shall cease,
On hard conditions may he buy his peace.
Nor let him then enjoy suprême command,
But fall untimely by some hostile hand,
And lie unburied on the barren sand.

Lord Falkland observing that the king was concerned at this accident, would likewise try his own fortune in the same manner, hoping he might fall upon some passage that would have no relation to his fate, and thereby divert the king's thoughts from any impression which the other might have upon him; but the place he stumbled upon was as much fitting to his dying as the omen had been to the king's; being the lamentation of Evander for the untimely death of his son Palæn: for this lord's eldest son, a young man of an amiable character, had been slain in the first battle of Newbury.

We have ourselves known several whose devotion has not always been regulated by judgment; pursue this method of divination; and have generally observed, that the consequence has been despair or presumption. To such we beg leave to recommend one passage in Scripture which will never disappoint them:

> Thou shalt not tempt the Lord thy God.

SOTERIA, in antiquity, sacrifices offered to the gods for delivering a person from danger; as also poetical pieces composed for the same purpose.

SOUBISE, a town of France, in the department of Lower Charente, and late territory of Saintonge. It is situated on the river Charente, 22 miles south of Rochefort, in W. Long. 1° 2. N. Lat. 45° 57'.

SOUÉ, among miners, denotes a passage dug under ground, to convey off waters from mines. See MINES.

SOVEREIGN, in matters of government, is applied to the suprême magistrate or magistrates of an independent government or state; because their authority is only bounded by the laws of God and the laws of the state: such are kings, princes, &c. See PREROGATIVE, &c.

Soveraign Power, or Sovereignty, is the power of making laws; for wherever that power resides, all others must conform to it, and be directed by it, whatever appearance the outward form and administration of the government may put on. For it is at any time in the option of the legislature to alter that form and administration by a new edict or rule, and to put the execution of the laws into whatever hands it pleases: and all the other powers of the state must obey the legislatif power in the execution of their several functions; or else the constitution is at an end.

In the British constitution the law ascribes to the king the Black. attribute of sovereignty; but that is to be understood in Comment. a qualified sense, i.e. as suprême magistrate, not as sole legislator: as the legislative power is vested in the king, lords, and commons, not in any of the three estates alone.

SOUL. See SOUL.

SOUL, the principle of perception, memory, intelligence, and volition, in man; which, since the earliest era of philosophy, has furnished questions of difficult investigation, and materials of keen and important controversy (see Metaphysics, Part III. chap. iii. iv. v.; and Resurrection, n° 42—48.) In the fourth volume of the Memoirs of the Literary and Philosophical Society of Manchester, the reader will find a very valuable paper by Dr. Ferrier, proving, by evidence apparently complete, that every part of the brain has been injured without affecting the act of thought. An abridgment of that memoir would weaken its restoration; which, built on matters of fact and experience, appears to us to have shaken the modern theory of the Materialists from its very foundation.

Soul of Brutes. See BRUTES.

SOUND, in physics, is a term of which it would be preposterous to offer any definition, as it may almost be said to express a simple idea: But when we consider it as a sensation, and fill more when we consider it as a perception, it may not be improper to give a description of it; because this must involve certain relations of external things, and certain trains of events in the material world, which make it a proper object of philosophical discussion. Sound is that primary information which we get of external things by means of the sense of hearing. This, however, does not explain it; for were we in like manner to describe the sense of sight, we should find ourselves obliged to say, that it is the faculty by which we perceive sound. Languages.
are not the invention of philosophers; and we must not expect precision, even in the simplest cases. Our methods of expressing the information given us by our different senses are not familiar, as a philosopher, cautiously constraining language, would make them. We have no word to express the primary or generic object of our sense of seeing; for we believe, that even the vulgar consider light as the medium, but not the object. This is certainly the case (how justly we do not say) with the philosopher. On the other hand, the words smell, found, and perhaps taste, are conceived by most persons as expressing the immediate objects of the senses of smelling, hearing, and tasting. Smell and sound are halitously conceived as separate existences, and as mediums of information, and of intercourse with the odoriferous and sounding bodies; and it is only the very cautious philosopher who distinguishes between the smell which he feels and the perfume which fills the room. To those of the ancients, therefore, who taught that sounds were being wafted through the air, and felt by our ears, shall not, even at this day, be considered as awkward objections. It has required the long, patient, and sagacious consideration of the most penetrating geniuses, from Zeno the Stoic to Sir Isaac Newton, to discover that what we call sound, the immediate external object of the sense of hearing, is nothing but a particular agitation of the parts of surrounding bodies, acting by mechanical impulse on our organs; and that it is not any separate being, nor even a specific quality inherent in any particular thing, by which it can affect the organ, as we suppose with respect to a perfume, but merely a mode of existence competent to every atom of matter. And thus the description which we proposed to give of sound must be description of that state of external contiguous matter which is the cause of sound. It is not therefore preparatory to any theory or set of doctrines on this subject; but, on the contrary, is the sum or refult of them all.

To discover this state of external body by which, without any further intermediaries of substance or of operation, it affects our sensitive faculties, must be considered as a great step in science. It will shew us at least one way by which mind and body may be connected. It is supposed that we have obtained this knowledge with respect to sound. Our senses, therefore, is a very pleasing gratification to the philosophic mind. It is still more important in another view: it has encouraged us to make similar attempts in other cases, and has supplied us with a fact to which an ingenious mind can easily fancy something analogous in many abstruse operations of nature, and thus it enables us to give some sort of explanation of them. Accordingly this use has been most liberally made of the mechanical theory of sound; and there is now fearlessly any phenomenon, either of matter or mind, that has not been explained in a manner somewhat similar. But we are forry to say that these explanations have done no credit to philosophy. They are, for the most part, strongly marked with that precipitate and ill-conceited impatience which has always characterized the investigations conducted solely by ingenious fancy. The consequences of this procedure have been no less fatal to the progress of true knowledge in modern times than in the schools of ancient Greece; and the ethereal philosophers of this age, like the followers of Aristotle of old, have filled ponderous volumes with nonsense and error. It is strange, however, that this should be the effect of a great and a successful step in philosophy: But the fault is in the philosophers, not in the science. Nothing can be more certain than the account which Newton has given of the propagation of a certain class of undulations in an elastic fluid. But this procedure of nature cannot be seen with difficulty and precision by any but well-informed mathematicians. They alone can rest with unhaken confidence on the conclusions legimimately deduced from the Newtonian theorems; and even they can infer success only by treading with the most fenfuous caution the steps of this patient philosopher. But few have done this; and we may venture to say, that not one in ten of those who employ the Newtonian doctrines of elastic undulations for the explanation of other phenomena have taken the trouble, or indeed were able, to go through the steps of the fundamental proposition (Prin. II. 59, &c.) But the general results are so plain, and admit of such imperative illustration, that they are not the atient of the most careless reader; and all imagine that they understand the explanation, and perceive the whole procedure of nature. Emboldened therefore by this successful step in philosophy, they, without hesitation, fancy similar intermediaries in other cases; and as air has been found to be a vehicle for sound, they have supposed that something which they call ether, somewhow-resembling air, is the vehicle of vision. Others have proceeded farther, and have held that ether, or another something like air, is the vehicle of sensation in general, from the organ to the brain: nay, we have got a great volume called A Theory of Man, where all our sensations, emotions, affections, thoughts, and purposes or volitions, are said to be so many vibrations of another something equally unseen, gratuitous and incompetent; and, to crown all, this exalted doctrine, when logically prosecuted, must terminate in the discovery of those vibrations which pervade all others, and which constitute what we have been accustomed to term by the name Dity. Such must be the termination of this philosophy; the only philosophical dissertation on the attributes of the Divine: Being can be nothing else than an accurate description of these vibrations!

This is not a needful and declamatory rhapsody. If the explanation of sound can be legitimately transferred to those other classes of phenomena, these are certain results; and if so, all the discoveries made by Newton are but the glimmerings of the morning, when compared with this meridian splendor. But if, on the other hand, found logic forbids us to make this transference of explanation, we must continue to believe, for a little while longer, that mind is something different from vibrating matter, and that no kind of oscillations will constitute infinite wisdom.

It is of immense importance therefore to understand thoroughly this doctrine of found, that we may see clearly and precisely in what it consists, what are the phenomena of found that are fully explained, what are the data and the assumptions on which the explanations proceed, and what is the general theory in which it terminates. For this, or a fact perfectly similar, must terminate every explanation which we derive from this by analogy, however perfect the analogy may be. This previous knowledge must be completely understood by every.
Sound.

The peron who pretends to explain other phenomena in a similar manner. Then, and not till then, he is able to say what causes of phenomena will admit of the explanation; and, when all this is done, his explanation is still an hypothesis, till he is able to prove, from other indisputable sources, the existence and agency of the same thing analogous to the elastic fluid, from which all is borrowed.

Such considerations would justify us for considering with great attention the nature of sound. But a work like this will not give room for a full discussion; and we must refer our readers to the writers who treat it more at large. Much curious information may be got from the pains-taking authors of the last century; such as Lord Bacon; Kircher; Merfennus; Calerius in his great work De Vos et Audita; Perrault in his Dissertation du Bruit, Mullenbrock in his System of Natural Philosophy, in 3 vols 4to, and in his Effais de Physique; and the writings of the celebrated physiologists of the present age. We also refer to what has been said by us in the article Acoustics.

At present therefore we must content ourselves with giving a short history of the speculations of philosophers on this subject, tracing out the steps by which we have arrived at the knowledge which we have of it. We apprehend this to be of great importance; because it shows us what kind of evidence we have for its truth, and the paths which we must follow if we wish to proceed farther: and we trust that the progress which we have made will appear to be so real, and the object to be attained so alluring to a truly philosophical mind, that men of genius will be incited to exert their utmost efforts to pass the present boundaries of our real progress.

In the infancy of philosophy, sound was held to be a separate existence, something which would be, although no hearing animal existed. This was conceived as wafted through the air to our organ of hearing, which it was supposed to affect in a manner resembling that in which our nostrils are affected when they give us the sensation of smell. It was one of the Platonic speculations, fitted for exciting the intellectual species, which is the immediate object of the soul's contemplation.

Yet, even in those early years of science, there were some, and, in particular, the celebrated founder of the Itoic school, who held that sound, that is, the cause of sound, was only the particular motion of external gross matter, propagated to the ear, and there producing that agitation of the organ by which the soul is immediately affected with the sensation of sound. Zeno, as quoted by Diogenes Laertius*, says, "Hearing is produced by the air which intervenes between the thing sounding and the ear. The air is agitated in a spherical form and moves off in waves, and falls on the ear, in the same manner as the water in a cistern undulates in circles when a stone has been thrown into it." The ancients were not remarkable for precision, either of conception or argument in their discussions, and they were contented with a general and vague view of things. Some followed the Platonic notions, and many the opinion of Zeno, but without any further attempts to give a distinct conception of the explanation, or to compare it with experiment.

But in later times, during the ardent researches in the last century into the phenomena of nature, this became an interesting subject of inquiry. The invention of the air-pump gave the first opportunity of deciding by experiment whether the elastic undulations of air were the cause of sound; and the trial fully established this point; for a bell rung in vacuo gave no sound, and one rung in condensed air gave a very loud one. It was therefore received as a doctrine in general physics that air was the vehicle of sound.

The celebrated Galileo, the parent of mathematical philosophy, discovered the nature of that connection between the lengths of musical cords and the notes which they produced, which had been observed by Pythagoras, or learned by him in his travels in the east, and which he made the foundation of a refined and beautiful science, the theory of music. Galileo showed, that the real connection subsisted between the tones and the vibrations of these cords, and that their different degrees of acuteness corresponded to the different frequency of their vibrations. The very elementary and familiar demonstration which he gave of this connection did not satisfy the curious mathematicians of that inquisitive age, and the mechanical theory of musical cords was prosecuted to a great degree of refinement. In the course of this investigation, it appeared that the cord vibrated in a manner precisely similar to a pendulum vibrating in a cycloid. It must therefore agitate the air contiguous to it in the same manner; and thus there is a particular kind of agitation which the air can receive and maintain, which is very interesting.

Sir Isaac Newton took up this question as worthy of his notice; and endeavored to ascertain with mathematical precision the mechanism of this particular class of undulations, and gave us the fundamental theorems concerning the undulations of elastic fluids, which make the 47, &c. propositions of Book II. of his Principles of Natural Philosophy. They have been (perhaps hastily) considered as giving the fundamental doctrines concerning the propagation of sound. They are therefore given in this work in the article Acoustics; and a variety of facts are narrated in the article Pneumatics to show that such undulations actually obtain in the air of our atmosphere, and are accompanied by a set of phenomena of sound which precisely tally or correspond to all the mechanical circumstances of these undulations. In the mean time, the anatomists and physiologists were busily employed in examining the structure of our organs of hearing. Improved with the validity of this doctrine of aerial undulations being the cause of sound, their researches were always directed with a view to discover those circumstances in the structure of the ear which rendered it an organ susceptible of agitations from this cause; and they discovered many which appeared as contrivances for making it a drum, on which the aerial undulations from without must make very forcible impulsive, so as to produce very sonorous undulations in the air contained in it. Those therefore they considered as the immediate objects of sensation, or the immediate causes of sound.

But some anatomists saw that this would not be a full account of the matter: for after a drum is agitated, it has done all that it can do; it has produced a noise. But a further process goes on in our ear: There is behind the membrane, which is the head of this drum, a curious mechanism, which communicates the agitations of
into the structure. Here they observed a prodigious unfolding of the auditory nerve of the ear, which is curiously distributed through every part of this cavity, lining its sides, hung across it like a curtain, and sending off fibres in every direction, so as to leave hardly a point of it unoccupied. They thought the machinery contained in the drum peculiarly fitted for producing undulations of the air contained in this labyrinth, and that by these agitations of the air the contiguous fibres of the auditory nerve are impelled, and that thus we get the sensation of sound.

The cavity intervening between the external air and this inner chamber appeared to these anatomists to have no other use than to allow a free motion to the flap or little piston that is employed to agitate the air in the labyrinth. This piston condenses upon a very small surface the impulse which it receives from a much larger surface, drained by the malleus on the entry of the tympanum, on purpose to receive the gentle agitations of the external air in the outer canal. This membranous surface could not be agitated, unless completely detached from every thing round it; therefore all animals which have this mechanism have it in a cavity containing only air. But they held, that nature had even taken precautions to prevent this cavity from acting as a drum, by making it of such an irregular rambling form; for it is by no means a cavity of a symmetrical shape, like a vessel, but rather resembles the rambling holes and blebs which are often seen in a piece of bread; scattered through the substance of the cranium, and communicating with each other by small passages. The whole of these cavernules are lined with a fibrous membrane, which still farther unites this cavity for producing sound. This reasoning is specious, but not very conclusive. We might even affirm, that this anfractuous form, with narrow passages, is well fitted for producing noise. If we place the ear close to the small hole in the side of a military drum, we shall hear the first tap of the drumstick like a violent blow. The lining of the cavernule is nervous, and may therefore be strongly affected in the numerous narrow passages between the cells.

While these speculations were going on with respect to the ear of the breathing animals, observations were occasionally made on other animals, such as reptiles, serpents, and fishes, which give undoubted indications of hearing; and many very familiar facts were observed or recollected, where sounds are communicated through or by means of solid bodies, or by water: therefore, without inquiring how or by what kind of mechanism it is brought about, it became a very general belief among physiologists, that all fishes, and perhaps all animals hear, and that water in particular is a vehicle of sound.

In 1767 or 1768 the writer of this article, at the suggestion of the late professor of astronomy in the university of Glasgow, made an experiment in a lake in that neighbourhood, by striking a large hand-bell under water, and heard it very distinctly and strongly when his head was plunged in the water at the distance of more than 1200 feet. Many experiments are mentioned by Kircher and others on the communication of sound through solid bodies, such as masts, yards, and other long beams of dry wood, with similar results. Dr Monro has published a particular account of very curious experiments on the propagation of sound through water in his 'Dissertation on the Physiology of Fishes'; so that it now appears that air is no means the only vehicle of sound.

In 1760 Couturi published his important discovery, that the labyrinth or inner cavity of the ear in animals is completely filled with water. This, after some contest, has been completely demonstrated (see in particular Meckel and de Labyrinthis Auris Contentis, Gentian, 1777), and it seems now to be admitted by all.

This being the case, our notions of the immediate cause of sound must undergo a great revolution, and a new research must be made into the way in which the nerve is affected: for it is not enough that we suppose the undulations of water for those of air in the labyrinth. The well informed mechanician will see at once, that the vivacity of the agitations of the nerve will be greatly increased by this substitution; for if water be perfectly elastic through the whole extent of the undulatory agitation which it receives, the effect will be greater in proportion to its specific gravity; and this is confirmed by an experiment very easily made. Immerse a table-bell in water contained in a large thin glass vessel. Strike it with a hammer. The sound will be heard as if the bell had been immediately struck on the sides of the vessel. The filling of the labyrinth of the ear with water is therefore an additional mark of the wisdom of the Great Artificer. But this is not enough for informing us concerning the ultimate mechanical event in the process of hearing. The manner in which the nerve is exposed to these undulations must be totally different from what was formerly imagined. The filaments and membranes, which have been described by former anatomists, must have been found by them in a state quite unlike to their situation and condition in the living animal. Accordingly the most eminent anatomists of Europe seem at present in great uncertainty as to the state of the nerve, and are keenly occupied in observations to this purpose. The descriptions given by Monro, Scarpa, Camper, Comparetti, and others, are full of most curious discoveries, which make almost a total change in our notions of this subject; and will, we hope, be productive of most valuable information.

Scarpa has discovered that the solid cavity called the labyrinth contains a trefoil expansion of the auditory nerve. One part of it, the cochlea, contains it in a fibrous state, ramified in a most symmetrical manner throughout the whole of the scala media of the lamina spiralis, where it anatomizes with another production of it diffused over the general lining of that cavity. Another department of the nerve, also in a fibrous state, is spread over the external surface of a membranaceous bag.
bag, which nearly fills that part of the vestibule into which the semicircular canals open, and also that orifice which receives the impressions of the stapes. This bag sends off tubular membranaceous ducts, which, in like manner, nearly fill these semicircular canals. A third department of the ear is spread over the external surface of another membranaceous bag, which lies between the coil just now mentioned and the cochlea, but having no communication with either, almost completely filling the remainder of the vestibule. Thus the vestibule and canals seem only a cafe for protecting this sensitive membranaceous vesicle, which is almost, but not altogether, in contact with the osseous case, being separated by a delicate and almost fluid cellular substance. The fibrous expansion of the nerve is not indiscriminately diffused over the surface of these faciculi, but evidently directed to certain foci, where the fibres are concentrated. And this is the last appearance of the fibrous state of the nerve; for when the intake of these faciculi is inspected, no fibres appear, but a pulp judged to be nervous from its similarity to other pulp productions of the brain (adhering to the membranaceous coat, and not separable from it by gently washing it). It is more abundant, that is, of greater thickness, opposite to the external fibrous coat. No organised structure could be discovered in this pulp, but it probably is organised; for, besides this adhering pulp, the water in the faciculi was observed to be clummy or mucous; so that in all probability the vascular or fibrous state of the nerve is succeeded by an interrupted production (perhaps columnar-like balsam, though not cohering); and this at last ends in simple degeneration, symmetrical however, where water and nerve are alternate in every direction.

To these observations of Scarpa, Comaretti adds the curious circumstance that the anterior and posterior semicircular canals in the foramen rotundum, the cylindrical cavity of which is inclosed at both ends by a fine membrane. The membrane which separates it from the cochlea appears to be in a state of variable tension, being drawn up to an umbra by a cartilaginous spoke in its middle, which he thinks adheres to the lamina spiralis, and thus serves to strain the drumhead, as the malacous strains the great membrane known to all.

There is no speculation by the anatomist that this membrane and the different bony cavity, which it incloses, may be considered as the bony cavity, the cause of injury to the organ, seem to conduct us farther into the secrets of nature than anything yet known.

We think that they promise to give us the greatest relief yet made in physiology, viz., to show us the last mechanical fact which occurs in the long train interposed between the external body and the incrustation of our sensitive system. But there is, as yet, great and essential differences in the description given by other celebrated authors. It cannot be otherwise. The containing labyrinth can be laid open to our view in no other way than by destroying it; and its most delicate contents are the first sufferers in the search. They are found in very different situations and conditions by different anatomists, according to their address or their good fortune. Add to this that the natural varieties are very considerable. Factual descriptions will therefore give very different notions of the ultimate action and reaction between the unorganised matter in the labyrinth and the ultimate expansion of the auditory nerve.

We must therefore wait with patience. Since this work of ours was begun, the progress which has been made in many parts of natural science has been great and wonderful; and perhaps before it be completed, we may be furnished with such a collection of facts respecting the structure and the contents of the organ of hearing, as might enable us to give a fuller theory of found than is yet to be found in the writings of philosophers. There seems to be no abatement of ardour in the researches of the physiologists; and they will not remain long ignorant of the truth or mistake in the accounts given by Scarpa and Comaretti. Should the result of our inquiries be what we expect, we should be glad of a proper opportunity of laying it before our readers, together with some disquisition on the nature of hearing. A collection of accurate observations on the structure of the ear would give us principles on which to proceed in explaining the various methods of producing external sounds. The nature of continued sounds might be collected; and would appear, we believe, very different from what it is commonly supposed. Under this head animal voices might be particularly considered, and the elements of human speech properly ascertained. When the production of continued sounds is once firmly to be a thing regulated by principle, it may be systematically treated, and this principle may be ascertained as combined with every mechanical state of body that may be pointed out. This will suggest to us methods of producing four which have not yet been thought of, and may therefore give us sounds with which we are unacquainted. Such an acquisition is not to be despised nor rejected. The inquiries in what we are being and of all our faculties has made it an object of most enchanting utility to the human mind. The Greeks, the most cultivated people who have ever figured on the stage of life, enjoyed the pleasures of music with rapture. Even the poor negro, after toiling a whole day beneath the tropical sun, will go ten miles in the day to dance all night to the simple music of the balafon, and return without sleep to his next day's toil. The penetrating eye of the anatomist has discovered in the human larynx an apparatus evidently contrived for tempering the great movements of the glottis, so as to enable us to produce the intended note with the utmost precision. There is no doubt therefore that the consummation of this art has not thought it unworthy of his attention. We ought therefore to receive with thankfulness this present from our Maker—this laborum dulce iuvens—et indicium worthy the attention of the philosopher to add to this innocent elegance of life. This, however, is not the time to enter upon the subject. From the jarring observations which we have yet made, we could only amuse the curious reader by holding up to his view a specious theory; and we are not so defensive as filling our Work with what is called original matter, as to attempt the attainment of that end by subtilizing fiction for fact and hypothesis for science.

Sound, in geography, denotes in general any fruit or inlet of the sea between two headlands. It is given by way of eminence to the first between Sweden and Denmark.
Sounding.

Denmark, joining the German ocean to the Baltic, being about three miles over. See Denmark and Elyseworth.

SOUNDING, the operation of trying the depth of the sea, and the nature of the bottom, by means of a plummet sunk from a ship to the bottom.

There are two plummets used for this purpose in navigation: one of which is called the hand lead, weighing about 8 or 9 pounds; and the other the deep sea lead, which weighs from 25 to 30 pounds; and both are shaped like the frustum of a cone or pyramid. The former is used in shallow waters, and the latter at a great distance from the shore; particularly on approaching the land after a sea voyage. Accordingly the lines employed for this purpose are called the deep sea lead line, and the hand lead line.

The hand lead line, which is usually 20 fathoms in length, is marked at every two or three fathoms; so that the depth of the water may be ascertained either in the day or night. At the depth of two and three fathoms, there are marks of black leather; at 5 fathoms, there is a white rag; at 7, a red rag; at 10, black leather; at 13, black leather; at 15, a white rag; and at 17, a red ditto.

Sounding with the hand lead, which is called having the lead by feelen, it is generally performed by a man who stands in the main chains to windward. Having the line quite ready to run out without interruption, he holds it nearly at the distance of a fathom from the plummet; and having swung the latter backwards and forwards three or four times, in order to acquire the greater velocity, he swings it round his head, and thence forward as necessary; so that, by the lead's sinking whilst the ship advances, the line may be almost perpendicular when it reaches the bottom. The person sounding then proclaims the depth of the water in a kind of song, resembling the cries of hawkers in a city. Thus if the mark of five fathoms is close to the surface of the water, he calls, 'By the mark five!' and as there is no mark at four, fix, eighth, &c. he estimates those numbers, and calls, 'By the dip four,' &c. If he judges it to be a quarter or an half more than any particular number, he calls, 'And a quarter five!' and a half four,' &c. If he conceives the depth to be three quarters more than a particular number, he calls it a quarter less than the next: thus, at four fathoms and three fourths he calls, 'A quarter less five!' and so on.

The deep sea lead is marked with two knots at 20 fathoms, three at 30, four at 40, and so on to the end. It is also marked with a single knot in the middle of each interval, as at 25, 35, 45 fathoms, &c. To use this lead more effectually at sea, or in deep water on the sea-coast, it is usual previously to bring to the ship, in order to retard her course: the lead is then thrown as far as possible from the ship on the line of her drift, so that, as it sinks, the ship drives more perpendicularly over it. The pilot, feeling the lead strike the bottom, readily discovers the depth of the water by the mark on the line near the surface. The bottom of the lead being well rubbed over with tallow, retains the distinguishing marks of the bottom, as shells, ooze, gravel, &c. which naturally adhere to it.

The depth of the water, and the nature of the ground, which is called the soundings, are carefully marked in the log-book, as well to determine the distance of the place from the shore, as to correct the observations of former pilots.

SOUP, a strong decocation of flax or other substances.

Portable or dry soup is a kind of cake formed by boiling the gelatinous parts of animal substances till the watery parts are evaporated. This species of soup is chiefly used at sea, and has been found of great advantage. The following receipt will show how it is prepared.

Of calves feet take 4; 1 leg of beef 12 lbs.; knuckle of veal 3 lbs.; and leg of mutton 10 lbs. These are to be boiled in a sufficient quantity of water, and the foam taken off as usual; after which the soup is to be separated from the meat by straining and pressing. The meat is then to be boiled a second time in other water, and the two decoctions, being added together, must be kept to cool, in order that the fat may be exactly separated. The soup must then be clarified with five or six whites of eggs, and a sufficient quantity of common salt added. The liquor is then strained through flannel, and evaporated on the water-bath to the consistence of a very thick paste; after which it is spread rather thin upon a smooth stone, then cut into cakes, and lastly dried in a flouve until it is become brittle: these cakes are kept in well closed bottles. The same process may be used to make a portable soup of the flesh of poultry; and aromatic herbs may be used as a flavoring, if thought proper.

These tablets or cakes may be kept four or five years. When intended to be used, the quantity of half an ounce is put into a large glass of boiling water, which is to be covered, and set upon hot ashes for a quarter of an hour, or until the whole is entirely dissolved. It forms an excellent soup, and requires no addition, but a small quantity of salt.

SOUR-CROUTE. See CRUITE.

Sour-Gourd or African Calabosf-tree. See ADANSONIA.

SOUTH (Dr Robert), an eminent divine, was the son of Mr William South a merchant of London, and was born at Hackney near that city in 1631. He studied at Westminster school, and afterwards in Christ's Church College, Oxford. In 1654, he wrote a copy of Latin verses to congratulate Cromwell upon the peace concluded with the Dutch; and the next year a Latin poem, entitled Miscell: Incantata. In 1660 he was elected public orator of the university; and the next year became domestic chaplain to Edward earl of Clarendon, lord-high-chancellor of England. In 1663 he was installed prebendary of Westminister, admitted to the degree of Doctor of divinity, and had a curacy bellowed upon him in Wales by his patron the earl of Clarendon; after whose retirement into France in 1667 he became chaplain to the duke of York. In 1670 he was installed canon of Christ Church in Oxford; and in 1676 attended as chaplain to Laurence Hyde, Esq. ambassador extraordinary to the king of Poland. In 1678 he was presented to the rectory of Iflip in Oxfordshire; and in 1688 rebuilt the chancel of that church, as he afterwards did the rectory-house belonging to it. After the revolution he took the oath of allegiance to king William and queen Mary, though he excused himself from accepting a great dignity in the Church vacated by the personal refusal of that oath. His health began to decline.
SOUTHAMPTON, a sea-port town of Hampshire in England. It is commodiously seated on an arm of the sea; is a place of good trade, and well inhabited. It is surrounded by walls and several watch-towers, and had a strong castle to defend the harbour, now in ruins. It is a corporation and a county of itself, with the title of an earldom, and sends two members to parliament. W. Long. t. 26. N. Lat. 50. 55.

SOUTHERN (Thomas), an eminent dramatic writer, was born at Dublin in 1665, and received his education in the university there. He came young to London to study law; but instead of that devoted himself to poetry and the writing of plays. His Persian Prince, or Loyal Brother, was introduced in 1682, when the Tory interest was triumphant in England; and the character of the loyal brother being intended to compliment James duke of York, he rewarded the author when he came to the throne with a commission in the army. On the Revolution taking place, he retired to his studies, and wrote several plays, from which he is supposed to have derived a very handsome subsistence, being the first who raised the advantage of play-writing to a second and third night. The most finished of all his plays is Oroonoko, or the Royal Slave, which is built on a true story related in one of Mrs Behn’s novels. Mr Southern died in 1746, in the 60th year of his age; the latter part of which he spent in a peaceful felicity, having, by his commission as a soldier, and the profits of his dramatic works, acquired a handsome fortune; and being an exact economist, he improved what fortune he gained to the best advantage. He enjoyed the longest life of all our poets; and died the richest of them, a very few excepted. His plays are printed in two volumes.

SOZOMENUS (Hermonias), an ecclesiastical historian of the 5th century, was born in Bethel, a town of Palestine. He was educated for the law, and became a pleader at Constantinople. He wrote an Abridgment of Ecclesiastical History, in two books, from the ascension of our Saviour to the year 323. This compendium is lost; but a continuation of it in nine books, written at greater length, down to the year 449, is still extant. He seems to have copied Socrates, who wrote a history of the same period. The style of Sozomenus is perhaps more elegant; but in other respects he falls far short of that writer, displaying throughout his whole book an amazing credulity and a superstitious attachment to monks and the monastic life. The
**Spa**

**Spa, a town of Germany, in the circle of Westphalia, and bishopric of Liege, famous for its mineral waters, lies in E. Long. 5° 50. N. Lat. 50° 30. about 21 miles south-east from Liege, and 7 south-west from Lomburg. It is situated at one end of a deep valley on the banks of a small rivulet, and is surmounted on all sides by high mountains. The sides of these mountains next to Spa are rude and uncultivated, presenting a rugged appearance as if shattered by the convulsions of earthquakes; but as they are clothed with tall oaks and abundance of shrubs, the country around forms a wild, romantic, and beautiful landscape. The access to the town is very beautiful. The road winds over the mountains till it descends to their bottom, when it runs along a smooth valley for a mile or a mile and a half.

The town consists of four streets in form of a cross, and contains about 400 inhabitants. Spa has no wealth to boast of. It can scarcely furnish the necessaries of life to its own inhabitants during the winter, and almost all the luxuries which are requisite for the great concourse of affluent visitors during the summer are carried from Liege by women. Its only source of wealth is its mineral waters. No sooner does the warm season commence, than crowds of valetudinarians arrive, as well as many other persons who are attracted solely by the love of amusements, and some from less honourable motives. The inhabitants, who spend seven or eight months of the year without seeing the face of a stranger, wait for the return of this period with impatience. The welcome sound of the carriages brings multitudes from the town, either to gratify their curiosity, or to offer their services in the hopes of securing your employment while you remain at Spa. Immediately after your arrival your name and designation is added to the printed list of the annual visitors; for which you pay a flated sum to the bookseller, who has a patent for this purpose from the prince bishop of Liege. This list not only enables one to know at a glance whether any friends or acquaintance are residing there, but also to distinguish persons of rank and fashion from adventurers, who seldom have the effrontery to infringe their names.

There are two different ways of accommodating the visitors at Spa with lodging and necessaries. People may either lodge at an hotel, where everything is furnished them in a splendid and expensive style; or they may take up their residence in private lodgings, from which they may fend for provisions to a cook’s shop.

Among the people who visit Spa, there are many persons of the first rank and fashion in Europe. Perhaps indeed there is no place in Europe to which so many kings and princes resort; but it is also visited by many self-created nobility, who, under the titles of counts, barons, marquises, and knights, contrive by their addresses and artifices, to prey upon the rich and unexperienced.

The manners established at Spa are conducive both to health and amusements. Every body rises early in the morning, at six o’clock or before it, when a great many horses stand ready saddled for those who choose to drink the Sauveniere or Geronfere waters at a little distance from Spa. After this healthy exercise a part of the company generally breakfast together at Vauxhall, a magnificent and spacious building. At this place a number of card-tables are opened every forenoon, round which many persons assemble and play for stakes to a very considerable amount. A ball too is generally held once a week at Vauxhall, besides two balls at the assembly rooms near the Pouhon in the middle of the town.

The most remarkable waters at Spa are,

1. The Pouhon, situated in the middle of the town; 2. The Sauveniere, a mile and a half from it; 3. Groifbeck, near to the Sauveniere; 4. Tonnelet, situated a little to the left of the road which leads to the Sauveniere; 5. Geronfere, two miles south from Spa; 6. War绍, near to the Tonnelet; 7. Sarts or Nivefet, in the district of Sarts; 8. Cheveron or Bru, in the principality of Blavet; 9. Couve; 10. Beverfe; 11. Sige; 12. Geremont. These four last are near Malmedy.

Dr Brownrigg was the first person who discovered that fire air, or, as it is now generally called, carbonic acid gas, forms a principal ingredient in the composition of the Spa waters, and actually separated a quantity of this elastic fluid, by exposing it to different degrees of heat from 110° to 170° of Fahrenheit. From 20 ounces 7 drams and 14 grains apothecaries weight of the Pouhon water, he obtained 8 ounces 2 drams and 90 grains. Since June 1765, when Dr Brownrigg read a paper on this subject before the Royal Society of London, the waters of Spa have been often analysed, but perhaps by none with more accuracy than by Dr Sibth, who published a book on the chemical and medicinal properties of these waters in 1788. We shall present his analysis of the five principal springs in the following table.

The Pouhon spring rises from the hill to the north of Spa, which consists of argillaceous schists and ferruginous slate. The other fountains rise from the surrounding hills to the south-east, south, west, and north-west of the town; and this ridge of mountains is formed of calcareous earths mixed with siliceous substances. The surface of the mountains is covered with woods, interspersed with large boggy swamps filled with mud and water. The Pouhon is considered as the principal spring at Spa, being impregnated with a greater quantity of iron than any of the rest, and containing more fixed air than any except the Tonnelet. It is from this spring that the Spa water for exportation is bottled; for which the demand is so great, that, according to the best information which Mr. Thicknèse could obtain, the quantity exported amounts to 200,000 or 250,000 bottles annually. This exported water is inferior in its quality to that which is drunk on the spot; for the vessels into which it is collected are injudiciously exposed to the sun, rain, wind, and dust, for several hours before they are corked, by which means a considerable part of its volatile ingredients must be evaporated; for it has been found by experiment, that by exposing it to a gentle heat, air-bubbles ascend in great numbers. It is in its greatest perfection when collected in cold dry weather; it is then pellucid, colourless, and without smell, and almost as light as distilled water. It varies in its heat from 52° or 53° to 67° of Fahrenheit's thermometer.

The Geronflere is a much weaker chalybeate water than the Pouhon; and as it is exceedingly nauseous, and tastes and smells like rotten eggs, it certainly contains some hepatic gas. This is a circumstance which Dr. Ahn seems not to have attended to sufficiently. The Sauviniere water also, when newly taken from the well, smells a little of sulphur. The Grosbeck contains more alkali, and almost as much gas as the Pouhon, and has been celebrated for its good effects in the case of calculous concretions. The Tonnelet contains more gas than any of the rest. So small is the quantity of any effful body held in suspension by the aerial acid in it, and so volatile is the gas, that it begins to pass off very rapidly the moment it is taken out of the well, and in a short time is entirely gone. Dr. Ahn informs us, that in the neighbourhood of this well, the cellars, on any approaching change of weather, are found to contain much fixed air; and the beat prognostic which they have of rain is the avercion which cats shew to be carried into these cellars.

The Spa waters are diuretic, and sometimes purgative. They exhilarate the spirits with an influence much more beneficial than wine or spirituous liquors, and they are more cooling, and allay thirst more efficaciously than common water. They are found beneficial in cases of weaknefs and relaxation, either partial or universal; in nervous disorders; in obstructions of the liver and spleen; in cases where there is obstructions of the bowels and putrefaction; in cases of excessive discharges proceeding from weakness; in the gravel and stone; and in feit cases where a strengthening remedy is wanted. But they are hurtful in confirmed obstructions attended with fever, where there is no free outlet to the matter, as in ulcerations of the lungs. They are also injurious to bilious and plectitic constitutions, when used before the body is cooled by proper evacuations.

**SPA**

**SPACE.** See Metaphysics, Part II. Chap. iv.

**SPACE, in geometry, denotes the area of any figure, or that which fills the interval or distance between the lines that terminate it.

**SPADAIX, in botany, anciently signified the receptacle of the palms. It is now used to express every flower-t stalk that is protruded out of a spatha or sheath.**

**SPAGIRIC ART, a name given by authors to that species of chemistry which works on metals, and is employed in the search of the philosopher's stone.**

**SPHIS, horsemen in the Ottoman army, chiefly raised in Asia. The great strength of the grand seignior's army consists in the janitors, who are the foot, and the spahis, who are the horse.**

**SPAIN, a country of Europe, famous both in ancient and modern history, situated in that large peninsula which forms the south-western part of Europe. It is bounded on the south and east by the Mediterranean sea and straits of Gibraltar, on the north and west by the Bay of Biscay and Atlantic Ocean, on the south-west by Portugal, and on the north-east by the Pyrenees.**

The most ancient name of Spain was *Iberia*, supposed by some to be derived from the *Iberians*, a people inhabiting Mount Caucasus, a colony of whom settled in this country. Others derive it from the Phenician word *Ebra* or *Ibra*, signifying a passage or limit. By the Romans it was called *Spania* or *Hispania*, from the Phenician name *Syphnion*, and this again from *syphon*, a Phenician word signifying a rabbit, because the western part of Spain abounded with those animals.

Spain, as well as the rest of Europe, was probably peopled by the Celts; but the Spanish historians derive the origin of their nation from Tubal the fifth son of Japhet, asserting that Spain had been a monarchy for 2226 years before the coming of the Celts into it. Till the coming of the Carthaginians into Spain, however, nothing certain can be ascertained of the Spaniards; and this happened not long before the commencement of the first Punic war. Their success in reducing the country, and their final expulsion by the Romans, has already been related under the article *Rome* and *Carthage*; we have here, therefore, only, to take notice of the state of Spain under the Roman government, until the Romans were in their turn expelled by the northern barbarians.

At the time of the Roman conquest, Spain, though a great rich country. In the most ancient times, indeed, its country riches were said to have exceeded what is related of the most wealthy country in America. Aristotle assures us, that when the Phenicians first arrived in Spain, they exchanged their naval commodities for such immense quantities of silver, that their ships could neither contain nor fasten its load, though they used it for ballast, and made their anchors and other implements of silver. When the Carthaginians first came to Spain, they found the quantity of silver nothing lessened, since the inhabitants at that time made all their utensils and even ornaments,
mangers, of that precious metal. In the time of the Romans this amazing plenty was very much diminished; however, their gleanings were by no means despible, since in the space of nine years they carried off 111,542 pounds of silver, and 4005 of gold, besides an immense quantity of coin and other things of value. The Spaniards were always remarkable for their bravery, and some of Hannibal's best troops were brought from thence. But as the Romans penetrated farther into the country than the Carthaginians had done, they met with nations whose love of liberty was equal to their valour, and whom the whole strength of their empire was scarce able to subdue. Of these the most formidable were the Numantines, Cantabrians, and Asturians.

In the time of the third Punic war, one Viriathus, a celebrated hunter, and afterwards the captain of a gang of bandits, took upon him the command of some nations who had been in alliance with Carthage, and ventured to oppose the Roman power in that part of Spain called Lusitania, now Portugal. The pretor named Gæcilus, who commanded in those parts, marched against him with 10,000 men, but was defeated and killed, with the loss of 4000 of his troops. The Romans immediately dispatched another pretor with 10,000 foot and 1300 horse; but Viriathus having first cut off a detachment of 4000 of them, engaged the rest in a pitched battle; and having entirely defeated them, reduced great part of the country. Another pretor, who was sent with a new army, met with the same fate; so that, after the destruction of Carthage, the Romans thought proper to send a consul named Quintus Fabius, who defeated the Lusitanians in several battles, and regained two important places which had long been in the hands of the rebels. After the expiration of Fabius's consulship, Viriathus continued the war with his usual success, till the senate thought proper to send against him the consul Q. Cecilius Metellus, an officer of great valour and experience. With him Viriathus did not choose to venture a pitched battle, but contented himself with being on the defensive, in consequence of which the Romans recovered a great many cities, and the whole of Tarraconian Spain was obliged to submit to their yoke. The other consul, named Servilius, did not meet with the same success; his army was defeated in the field and his camp was nearly taken by Viriathus. Notwithstanding the good fortune of Metellus, however, he could not withstand the invades of his countrymen against him, and he was not allowed to finish the war he had begun with so much success. In refection for this he took all imaginable pains to weaken the army under his command; he disbandoned the flower of his troops, exhausted the magazines, let the elephants die, broke in pieces the arrows which had been provided for the Cretan archers, and threw them into a river. Yet, after all, the army which he gave up to his successor Q. Pompeius, consisting of 30,000 foot and 2000 horse, was sufficient to have crushed Viriathus if the general had known how to use it. But, instead of opposing Viriathus with success, the imprudent consul procured much more formidable enemies. The Numantines and Numantians, who had hitherto kept themselves independent, offered very advantageous terms of peace and alliance with Rome; but Pompeius infilled upon their delivering up their arms. Upon this, war was immediately commenced. The consul with great confidence invaded Numantia; but being repulsed with confiderable losses, he fell down before Termantia, where he was attended with still worse successe. The very first day, the Termantines killed 500 of his legions; took a great convoy which was coming to the Roman camp; and having defeated a considerable body of their horse, pushed them from post to post till they came to the edge of a precipice, where they all tumbled down, and were dashed to pieces. In the mean time Servilian, who had been continued in his command with the title of procornful, managed matters so ill, that Viriathus surrounded him on all sides, and obliged him to sue for peace. The terms offered to the Romans were very moderate; being only that Viriathus should keep the country he had at that time possessed, and the Romans remain masters of all the rest. This peace the proconsul was very glad to sign, and afterwards got it signed by the senate and people of Rome.

The next year Q. Pompeius was continued in his command against the Numantines in Further Spain, Q. Servilius Capio, the new consul, had for his province Hither Spain, where Viriathus had established his new state. Pompeius undertook to reduce Numantia by turning aside the stream of the Durus, now the Douro, by which it was supplied with water; but, in attempting this, such numbers of his men were cut off, that, finding himself unable to contend with the enemy, he was glad to make peace with them on much worse terms than they had offered of their own accord. The peace, however, was ratified at Rome; but in the mean time Capio, desirous of showing his prowess against the renowned Viriathus, prevailed upon the Romans to declare war against him without any provocation. As Capio commanded an army greatly superior to the Lusitanians, Viriathus thought proper to sue for peace; but finding that Capio would be satisfied with nothing less than a surrender of the whole country, he resolved to stand his ground. In the mean time, the latter having bribed some of the intimate companions of Viriathus to murder him in his sleep, he by that infamous method put an end to a war which had lasted 14 years, very little to the honour of the republic.

After the death of Viriathus, the Romans with like treachery ordered their new consul Popilius to break the treaty with the Numantines. His infamous conduct met with the reward it deserved; the Numantines falling out, put the whole Roman army to flight with such slaughter, that they were in no condition to adhere during the whole campaign. Mæcianus, who succeeded Popilius, met with still worse success; his great army, consisting of 30,000 men, was utterly defeated by 4000 Numantines, and 20,000 of them killed in the pursuit. The remaining 10,000, with their general, were pent up by the Numantines in such a manner that they could neither advance nor retreat, and would certainly have been all put to the sword or made prisoners, had not the Numantines, with a generosity which their enemies never possessed, offered to let them depart upon condition that a treaty should be concluded with them upon very moderate terms. This the consul very willingily promised, but found himself unable to perform. On the contrary, the people, not satisfied with declaring his treaty null and void, ordered him to be delivered up to the Numantines. The latter refused to accept him.
left he had along with him the 10,000 men whom they had relieved as above related. At last, after the consul had been a whole day before the city, his successor Furius, thinking this a sufficient recompense to the Numantines for breaking the treaty, ordered him to be received again into the camp. However, Furius did not choose to engage with such a desperate and resolute enemy as the Numantines had showed themselves; and the war with them was disconcluded till the year 133 B.C. when Scipio Aemilianus, the destroyer of Carthage, was sent against them. Against this renowned commander the Numantines with all their valour were not able to cope. Scipio, having with the utmost care introduced strict discipline among his troops, and reformed the abuses which his predecessors had suffered in their armies, by degrees brought the Romans to face their enemies, which at his arrival they had absolutely refused to do. Having then ravaged all the country round about the town, it was soon blocked up on all sides, and the inhabitants began to feel the want of provisions. At last they resolved to make one desperate attempt for their liberty, and either to break through their enemies, or perish in the attempt. With this view they marched out in good order by two gates, and fell upon the works of the Romans with the utmost fury. The Romans, unable to stand this desperation shock, were on the point of yielding; but Scipio, hastening to the places attacked, with no fewer than 20,000 men, the unhappy Numantines were at last driven into the city, where they remained for a little longer than the miserables famine. Finding at last, however, that it was altogether impossible to hold out, it was resolved by the majority to submit to the pleasure of the Roman commander. But this resolution was not universally approved. Many shut themselves up in their houses, and died of hunger, while those who had agreed to surrender repented their offer, and setting fire to their houses, perished in the flames with their wives and children, so that not a single Numantine was left alive to grace the triumph of the conqueror of Carthage.

After the destruction of Numantia the whole of Spain submitted to the Roman yoke; and nothing remarkable happened till the times of the Cimbri, when a pretorian army was cut off in Spain by the Lusitanians. From this time nothing remarkable occurs in the history of Spain till the civil war between Marius and Sulla. The latter having crushed the Marian faction, as related under the article Rome, proscribed all those that had sided against him whom he could not immediately destroy. Among these was Sertorius, a man of consummate valour and experience in war. He had by Marius been appointed prator of Spain; and upon the overthrow of Marius, retired to that province. Sulla no sooner heard of his arrival in that country, than he sent thither one Caius Annius with a powerful army to drive him out. As Sertorius had but few troops along with him, he dispatched one Julius Sallinator with a body of 6000 men to guard the passes of the Pyrenees, and to prevent Annius from entering the country. But Sallinator having been treacherously murdered by assassins hired by Annius for that purpose, he no longer met with any obstacle; and Sertorius was obliged to embark for the coasts of Africa with 5000 men, being all he had now remaining. With these he landed in Mauritania; but as his men wereraggling carelessly about,
Metellus; but Sertorius, with an handful of men, accustomed to range about the mountains, to endure hunger and thirst, and live exposed to the inclemencies of the weather, so harassed the Roman army, that Metellus himself began to be quite discouraged. At last, Sertorius, hearing that Metellus had spoken disrespectfully of his courage, challenged his antagonist to end the war by single combat; but Metellus very prudently declined the combat, as being advanced in years; yet this refusal brought upon him the contempt of the unthinking multitude, upon which Metellus resolved to retrieve his reputation by some signal exploit, and therefore laid siege to Lacobriga, a considerable city in those parts. This he hoped to reduce in two days, as there was but one well in the place; but Sertorius, having previously removed all those who could be of no service during the siege, and conveyed 6000 fiths full of water into the city, Metellus continued a long time before it without making any impression. At last, his provisions being almost spent, he sent out Aquinius at the head of 6000 men to procure a new supply; but Sertorius falling unexpectedly upon them, cut in pieces or took the whole detachment; the commander himself being the only man who escaped to carry the news of the disaster; upon which Metellus was obliged to raise the siege with disgrace.

And now Sertorius, having gained some intervals of time in consequence of the many advantages he had obtained over the Romans, began to civilize his new subjects. Their savage and furious manner of fighting he changed for the regular order and discipline of a well-formed army; he bestowed liberally upon them gold and silver to adorn their arms, and by converting familiarly with them, prevailed upon them to lay aside their own dress for the Roman toga. He sent for all the children of the principal people, and placed them in the great city of Oliva, now Huesca, in the kingdom of Arragon, where he appointed them masters to instruct them in the Roman and Greek learning, that they might, as he pretended, be capable of sharing with him the government of the republic. Thus he made them really hostages for the good behaviour of their parents; however, the latter were greatly pleased with the care he took of their children, and all Lusitania were in the highest degree attached to their new sovereign. This attachment he took care to heighten by the power of superstition; for having procured a young hind of a milk-white colour, he made it to tame that it followed him wherever he went; and Sertorius gave out to the ignorant multitude, that this hind was inspired by Diana, and revealed to him the deigns of his enemies, of which he always took care to be well informed by the great numbers of spies he employed.

While Sertorius was thus employed in establishing his authority, the republic of Rome, alarmed at his success, resolved to crush him at all events. Sylla was now dead, and all the eminent generals in Rome solicited this honourable though dangerous employment. After much debate a decree was passed in favour of Pompey the Great, but without recalling Metellus. In the mean time, the troops of one Perpenna, or Perpenna, had, in spite of all that their general could do, abandoned him and taken the oath of allegiance to Sertorius. This was a most signal advantage to Sertorius; for Perpenna commanded an army of 33,000 men, and had come into Spain with a design to settle there as Sertorius had done; but as he was defended from one of the first families in Rome, he thought it below his dignity to serve under any general, however eminent he might be. But the troops of Perpenna were of a different opinion; and therefore declaring that they would serve none but a general who could defend himself, they to a man joined Sertorius; upon which Perpenna himself, finding he could do no better, contented to serve also as a falubrist.

On the arrival of Pompey in Spain, several of the cities which had hitherto continued faithful to Sertorius began to waver; upon which the latter resolved, by some signal exploit, to convince them that Pompey could no more forgo them from his resentment than Metellus. With this view he laid siege to Lauron, now Lirias, a place of considerable strength. Pompey, not doubting but he should be able to raise the siege, marched quite up to the enemy's lines, and found means to inform the garrison that those who besieged them were themselves besieged, and would soon be obliged to retire with loss and disgrace. On hearing this message, "I will teach Sylla's discipline (said Sertorius), that it is the duty of a general to look behind as well as before him." Having thus spoken, he sent orders to a detachment of 6000 men, who lay concealed among the mountains, to come down and fall upon his rear if he should offer to force the lines. Pompey, surprized at their sudden appearance, durst not fire out of his camp; and in the mean time the besieged, despairing of relief, took upon themselves to abandon the city to Pompey of their own accord.

While Sertorius was thus successfully contending with Pompey, his quater Hirtulenus was entirely defeated by Metellus, with the loss of 20,000 men; upon which Sertorius advanced with the utmost expedition to the banks of the Sueco in Tarraconian Spain, with a design to attack Pompey before he could be joined by Metellus. Pompey, on his part, did not decline the combat; but, fearing that Metellus might share the glory of the victory, advanced with the greatest expedition. Sertorius put off the battle till towards the evening; Pompey, though he knew that the night would prove disadvantageous to him, whether vanquished or victorious, because his troops were unacquainted with the country, resolved to venture an engagement, especially as he feared that Metellus might arrive in the mean time, and rob him of part of the glory of conquering fo great a commander. Pompey, who commanded his own right wing, soon obliged Perpenna, who commanded Sertorius's left, to give way. Hereupon Sertorius himself taking upon him the command of that wing, brought back the fugitives to the charge, and obliged Pompey to fly in his turn. In his flight he was overtaken by a gigantic African, who had already lifted up his hand to discharge a blow at him with his broad sword; but Pompey prevented him by cutting off his right hand at one blow. As he still continued his flight, he was wounded and thrown from his horse; so that he would certainly have been taken prisoner, had not the Africans who pursued him quarreled about the rich furniture of his horse. This gave an opportunity to the general to make his escape; so that at length he reached his camp with much difficulty.
ty. But in the mean time Afranius, who commanded the left wing of the Roman army, had entirely defeated the wing which Sertorius had left, and even purified them so close that he entered the camp along with them. Sertorius, returning suddenly, found the Romans baffled by the tenacity of the enemy, when, taking advantage of their situation, he drove them out with great slaughter, and retook his camp. Next day he offered battle a second time to Pompey; but Metellus then coming up with all his forces, he thought proper to decline an engagement with both commanders. In a few days, however, Pompey and Metellus agreed to attack the camp of Sertorius. Metellus attacked Perperna, and Pompey fell upon Sertorius. The event was similar to that of the former battle; Metellus defeated Perperna, and Sertorius routed Pompey. Being then informed of Perperna’s misfortune, he hastened to his relief; rallied the fugitives, and repulsed Metellus in his turn, wounded him with his lance, and would certainly have killed him, had not the Romans, ashamed to leave their general in distress, hastened to his assistance, and renewed the fight with great fury. At last Sertorius was obliged to quit the field, and retire to the mountains. Pompey and Metellus hastened to besiege him; but while they were forming their camp, Sertorius broke through their lines, and escaped into Lusitania. Here he soon raised such a powerful army, that the Roman generals, with their united forces, did not think proper to venture an engagement with him. They could not, however, resist the perpetual attacks of Sertorius, who now drove them from place to place, till he obliged them to separate, the one went into Gaul, and the other to the foot of the Pyrenees.

Thus did this celebrated commander triumph over all the power of the Romans; and there is little doubt but he would have continued to make head against all the other generals whom the republic could have sent; had he not been affailliated at an entertainment by the infamous treachery of Perperna, in 73 B.C., after he had made head against the Roman forces for almost ten years. Pompey was no sooner informed of his death, than, without waiting for any new encouragements, he marched against the traitor, whom he easily defeated and took prisoner; and having cured him to be executed, thus put an end, with very little glory, to a most dangerous war.

Many of the Spanish nations, however, still continued to bear the Roman yoke with great impi petitions; and as the civil wars which took place first between Julius Caesar and Pompey, and afterwards between Octavianus and Antony, diverted the attention of the republic from Spain, by the time that Augustus had become sole master of the Roman empire, they were again in a condition to assert their liberty. The Cantabrians and Asturians were the most powerful and valiant nation at that time in Spain; but, after incredible efforts, they were obliged to lay down their arms, or rather were almost exterminated, by Agrippa, as is related under these articles. From this time the Spaniards continued in quiet submission to the Romans; but on the decline of the empire they were attacked by the northern nations, who put an end to the Roman name in the west. As the inhabitants had by that time entirely left their ancient valour, the Cantabrians met with no resistance but from one another. In the reign of the emperor Honorius, the Vandals, Alans, and Sueviens, entered this country; and having made themselves masters of it, divided the provinces among themselves. In 444 the Romans made one effort more to recover their power in this part of the world; but being utterly defeated by the Sueviens, they had, taking advantage of this good fortune, gathered all to the issue of Sertorius, which lasted till the year 584, when it was utterly overthrown by the Visigoths under Leovigilde. The Gothic princes continued to reign over a considerable part of Spain till the beginning of the 8th century, when their empire was entirely overthrown by the Saracens. During this period, they had entirely expelled the eastern emperors from what they possessed in Spain, and even made considerable conquests in Barbary; but towards the end of the 7th century the Saracens overran all that part of the world with a rapidity which nothing could reftit; and having soon pleased themselves of the Gothic dominions in Barbary, they made a descent upon Spain about the year 711 or 712. The king of the Goths at that time was called Roderic, and by his bad conduct had occasioned great dissatisfaction among his subjects. He therefore determined to put all the issue of a battle, knowing that he could not depend upon the fidelity of his own people if he allowed the enemy time to tamper with them. The two armies met in a plain near Xeres in Andalusia. The Goths began the attack with great fury; but though they fought like men in despair, they were at last defeated with excessive slaughter, and their king himself was supposed to have perished in the battle, being never more heard of.

By this battle the Moors in a short time rendered themselves masters of almost all Spain. The poor remains of the Goths were obliged to retire into the mountaneous parts of Asturias, Burgos, and Bilbao; the inhabitants of Arragon, Catalonia, and Navarre, though they might have made a considerable stand against the enemy, chose for the most part to retire into France. In 718, however, the power of the Goths began again to revive under Don Pelagio or Pelaro, a prince of the royal blood, who headed those that had retired to the mountains after the fatal battle of Xeres. The place where he first laid the foundation of his government was in the Asturias, in the province of Liébana, about nine leagues in length and four in breadth. This is the most inland part of the country, full of mountains, enormously high, and so much fortified by nature, that its inhabitants are capable of resisting almost any number of invaders. Alakor the Saracen governor was no sooner informed of this revival of the Gothic kingdom, than he sent a powerful army, under the command of one Alcaman, to crush Don Pelagio before he had time to establish his power. The king, though his forces were sufficiently numerous (every one of his subjects arrived at man’s estate being a soldier), the Saracens took to the field with such little resolution as not to think proper to venture a general engagement in the open field; but taking post with part of them himself in a cavern in a very high mountain, he concealed the rest among precipices, giving orders to them to fall upon the enemy as soon as they should perceive him attacked by them. These orders were punctually executed, though indeed Don Pelagio himself had repulsed his enemies, but not without a miracle, as the Spanish historians pretend. The slaughter was dreadful; for the troops who lay in ambush joining the fight.
The Moors were not so much disheartened by this defeat, but that they made a second attempt against Don Pelagio. Their success was as bad as ever; the greatest part of their army being cut in pieces or taken; in consequence of which, they left all the Asturias, and never dared to enter the lifts with Pelagio afterwards. Indeed, their bad success had in a great measure taken from them the desire of conquering a country where little or nothing was to be got; and therefore they rather directed their force against France, where they hoped for more plunder. Into this country they poured in prodigious multitudes; but were utterly defeated, in 732, by Charles Martel, with the loss of 300,000 men, as the historians of those times pretend.

Don Pelagio died in 737, and soon after his death such infinite divisions broke out among the Moors, as greatly favoured the increase of the Christian power. In 745 Don Alfonso the Catholic, son-in-law to Pelagio, in conjunction with his brother Froilla, passed the mountains, and fell upon the northern part of Galicia; and meeting with little resistance, he recovered almost the whole of that province in a single campaign. Next year he invaded the plains of Leon and Castile; and before the Moors could assemble any force to oppose him, he reduced Astorgas, Leon, Saldagna, Montes de Oca, Amaya, Avila, and all the country at the foot of the mountains. The year following he pushed his conquests as far as the borders of Portugal, and the next campaign ravaged the country as far as Castile. Being sensible, however, that he was yet unable to defend the flat country which he had conquered, he laid the whole of it waste, obliged the Christians to retire to the mountains, and carried off all the Moors for slaves. Thus secured by a defert frontier, he met with no interruption for some years; during which time, as his kingdom advanced in strength, he allowed his subjects gradually to occupy part of the flat country, and to rebuild Leon and Astorgas, which he had demolished. He died in 757, and was succeeded by his son Don Froilla. In his time Abdelrahman, the khaliff's vice-roy in Spain, threw off the yoke, and rendered himself independent, fixing the seat of his government at Cordova. Thus the infinite divisions among the Moors were composed; yet their success seems to have been little better than before; for, soon after, Froilla encountered the Moors with much success, that 54,000 of them were killed on the spot, and their general taken prisoner. Soon after he built the city of Oviedo, which he made the capital of his dominions, in order to be in a better condition to defend the flat country, which he now determined to people.

In the year 758 the power of the Saracens received another blow by the rie of the kingdom of Navarre. This kingdom, we are told, took its origin from an accidental meeting of gentlemens, to the number of 600, at the tomb of an hermit named John, who had died among the Pyrenees. At this place, where they had met on account of the supposed sanctity of the deceased, they took occasion to converse on the cruelty of the Moors, the miseries to which the country was exposed, and the glory that would result from throwing off their yoke; which, they suppos'd, might easily be done, by reason of the strength of their country. On mature deliberation, the project was approved; one Don Garcia Ximenes was appointed king as being of illustrious birth, and looked upon as a person of great abilities. He recovered Arinta, one of the principal towns of the country, out of the hands of the infidels, and his successor Don Garcia Inigas extended his territories as far as Bisca; however, the Moors still possessed Portugal, Murcia, Andalufia, Valencio, Granada, Tor-tuna, with the interior part of the country as far as the mountains of Caltile and Saragossa. Their internal divisions, which revived after the death of Abdelrahman, contributed greatly to reduce the power of the infidels in general. In 778, Charles the Great being invited by some discontented Moorish governors, entered Spain with two great armies; one passing through Catalonia, and the other through Navarre, where he pushed his conquests as far as the Ebro. On his return he was attacked and defeated by the Moors; though this did not hinder him from keeping possession of all those places he had already reduced. At this time he seems to have been master of Navarre; however, in 851 Count Azner, revolting from Pepin fou to the emperor Louis, again revived the independency of Navarre; but the sovereigns did not assume the title of kings till the time of Don Garcia, who began to reign in 857.

In the mean time, the kingdom founded by Don Pelagio, now called the kingdom of Leon and Oviedo, continued to increase rapidly in strength, and many advantages were gained over the Moors, who having two enemies to contend with, lost ground every day. In 921, however, they gained a great victory over the united forces of Navarre and Leon, by which the whole force of the Christians in Spain must have been entirely broken, had not the victors conducted their affairs so wretchedly, that they suffered themselves to be almost entirely cut out in pieces by the remainds of the Christian army. In short, the Christians became at length far terrible to the Moors, that it is probable they could not long have kept their footing in Spain, had not a great number of the Moors been caused to be killed or made prisoners, and others driven from the country, the victors being thus enabled and incited to proceed with more vigour. In these circumstances, the Moors were now entirely desistive of all heavenly aid they fell upon them with
such fury in the next engagement, that all the valour and conduct of Almanzor could not prevent a defeat. Overcome with flame and despair at this misfortune, he defir'd his followers to shift for themselves, while he himself retired to Medina Celi, and put an end to his life by self-immolation in the year 995.

During this period a new Christian principality appeared in Spain, namely that of Castile, which is now divided into the Old and New Castile. The Old Castile was recovered by Don Rodrigo, son of Don Chell, who appeared in Spain, namely that of Castile. The Old Castile was recovered by Don Rodrigo, son of Don Chell, who

This district soon began to be the object of contention between the kings of Leon and those of Cordova; and as the former were generally victorious, some of the principal Castilian nobility retained their independence under the protection of the Christian kings, even when the power of the Moors was at its greatest height. In 884 we first hear of Don Rodriguez afluming the title of count of Castile, though it does not appear that either his territory or title were given him by the king of Leon. Nevertheless, this monarch having taken upon him to punish some of the Castilian lords as rebels, the inhabitants made a formal remonstrance of their allegiance, and set up a new kind of government. The supreme power was now vested in two persons of quality styled judges; however, this method did not continue to give satisfaction, and the sovereignty was once more vested in a single person. By degrees Castile fell entirely under the power of the kings of Leon and Oviedo; and, in 1035, Don Sanchez bestowed on his eldest son Don Ferdinand, with the title of king; and thus the territories of Castile were first firmly united to those of Leon and Oviedo, and the sovereigns were thenceforth styled kings of Leon and Castile.

Besides all these, another Christian kingdom was set up in Spain about the beginning of the 11th century. This was the kingdom of Aragon. The inhabitants were very brave, and lovers of liberty, so that it is probable they had in some degree maintained their independence even when the power of the Moors was greatest. The history of Aragon, however, during its infancy, is much left unknown than that of any of the others hitherto mentioned. We are only assured, that about the year 1035, Don Sanchez, surnamed the Great, king of Navarre, erected Arragon into a kingdom in favour of his son Don Ramira, and afterwards it became very powerful. At this time, then, we may imagine the continent of Spain divided into two unequal parts by a fright line drawn from east to west, from the coasts of Valencia to a little below the mouth of the Duro. The country north of this belonged to the Christians, who, as yet, had the smallest and least valuable shore, and all the rest to the Moors. In point of wealth and real power, both by land and sea, the Moors were greatly superior; but their continual diffentions greatly weakened them, and every day facilitated the progress of the Christians. Indeed, had either of the parties been united, the other might soon have yielded; for though the Christians did not make war upon each other continually as the Moors did, their mutual feuds were yet sufficient to have ruined them, had their adversaries made the least use of the advantages thus afforded them. But among the Moors almost every city was a kingdom; and as these petty sovereignties supported one another very indifferently, they fell a prey one after another to their enemies. In 1086, the king of Toledo was engaged in a war with the king of Seville, another Moorish potentate; which being observed by Alphonso king of Castile, he also invaded his territory; and in four years made himself master of the city of Toledo, with all the places of importance in its neighbourhood; from thenceforth making Toledo the capital of his dominions. In a short time the whole province of New Castile submitted; and Madrid, the present capital of Spain, fell into the hands of the Christians, being at that time but a small place.

The Moors were so much alarmed at these conquests, that they not only entered into a general confederacy against the Christians, but invited to their assistance Mahomet Ben Joseph the sovereign of Barbary. He accordingly came, attended by an incredible multitude; but was utterly defeated by the Christians in the defiles of the Black Mountain, or Sierra Morena, on the borders of Andalusia. This victory happened on the 16th of July 1212, and the anniversary is still celebrated at Toledo. This victory was not improved; the Christian army immediately dispersed themselves, while the Moors of Andalusia were strengthened by the remains of the African army; yet, instead of being taught, by their past misfortunes, to unite among themselves, their dispositions became worse than ever, and the conquests of the Christians became daily more rapid. In 1236, Don Ferdinand of Castile and Leon took the celebrated city of Cordova, the residence of the first Moorish kings; at the same time that James I. of Arragon dispossessed them of the island of Majorca, and drove them out of Valencia. Two years after, Ferdinand made himself master of Murcia, and took the city of Seville; and in 1303 Ferdinand IV. reduced Gibraltar.

In the time of Edward III. we find England, for the first time, interfering in the affairs of Spain, on the following occasion. In the year 1284 the kingdom of Navarre had been united to that of France by the marriage of Donna Joanna queen of Navarre with Philip the Fair of France. In 1328, however, the kingdoms were again separated, though the sovereigns of Navarre were still related to those of France. In 1350, Charles, surnamed the Wise, ascended the throne of Navarre, and married the daughter of John king of France. Notwithstanding this alliance, and that he himself was related to the royal family of France, he secretly entered into a negotiation with England against the French monarch, and even drew into his schemes the dauphin Charles, afterwards surnamed the Wife. The young prince, however, was soon after made fully sensible of the danger and folly of the connections into which he had entered; and, by way of atonement, promised to facilitate his associates. Accordingly he invited the king of Navarre, and some of the principal nobility of the same family, to a feast at Rouen, where he betrayed them to his father. The most obstinately reduced the king of Navarre and some of the principal nobility of the same family, to a feast at Rouen, where he betrayed them to his father. The most obstinately executed, and the king of Navarre was thrown into prison.

In this extremity, the party of the king of Navarre had recourse to England. The prince of Wales, surnamed the
of that time, whom Charles had the discernment to choose as the instrument of his victories. He also settled the affairs of Brittany, by acknowledging the title of Montfort, and receiving homage for his dominions. But much was yet to be done. On the conclusion of the peace of Bretigny, the many military adventurers who had followed the fortunes of Edward, being dispersed into the several provinces, and possest of strong holds, refused to lay down their arms, or relinquish a course of life to which they were now accustomed, and which alone they could earn a subsistence. They associated themselves with the banditti, who were already injured to the habits of rapine and violence; and, under the name of companies and compagnies, became a terror to all the peaceable inhabitants.

Some English and Gascon gentlemen of character were not ashamed to take the command of these ruffians, whose number amounted to near 40,000, and who bore the appearance of regular armies rather than bands of robbers. As Charles was not able by power to redress so enormous a grievance, he was led by necessity, as well as by the turn of his character, to correct it by policy; to discover some method of discharging into foreign countries this dangerous and intestine evil; and an occasion now offered.

Alphonso XI. king of Castile, who took the city of Reign of Algiersa from the Moors, after a famous siege of two years, during which artillery are said first to have been used by the besieged, had been succeeded by his son Peter I., named the Cruel; a prince equally pernicious, debauched, and bloody. He began his reign with the murder of his father's mistresses Leonora de Guzman; his nobles fell every day the victims of his severity; he put to death his cousin and one of his natural brothers, from groundless jealousy; and he castrated his queen Blanche de Bourbon, of the blood of France, to be thrown into prison, and afterwards poisoned, that he might enjoy in quiet the embraces of Mary de Padella, with whom he was violently enamoured.

Henry count of Trastamara, the king's natural brother, alarmed at the fate of his family, and distracting his own, took arms against the tyrant; but having failed in the attempt, he fled to France, where he found the minds of men much inflamed against Peter, on account of the murder of the French princes. He asked permission of Charles to enlist the compagnies in his service, parties employed to lead them into Castile against his brother. The French king, charmed with the project, employed du Guefcclin in negotiating with the leaders of these banditti. The treaty was soon concluded; and du Guefcclin having completed his levies, led the army first to Avignon, where the Pope then resided, and demanded, sword in hand, abolition for his ruffian soldiers, who had been excommunicated, and the sum of 200,000 livres for their subsistence. The first was readily promised him; but some difficulty being made with regard to the second, du Guefcclin replied, "My fellows, I believe, may make a shift to do without your abolution, but the money is absolutely necessary." His Holiness then extorted from the inhabitants of the city and its neighbourhood the sum of 100,000 livres, and offered it to du Guefcclin. "It is not my purpose (cried that generous warrior) to oppress the innocent people. The pope and his cardinals can spare me double the sum from their own pockets. I therefore inflict that,"
Spain. 

"...this money be restored to the owners; and if I hear they are defrauded of it, I will myself return from the other side of the Pyrenees, and oblige you to make them restitution." The pope found the necessity of submitting, and paid from his own treasury the sum demanded.

A body of experienced and hardy soldiers, conducted by fo able a general, easily prevailed over the king of Castile, whose subjects were ready to join the enemy against their oppressor. Peter fled from his dominions, took shelter in Guienne, and craved refuge in a principality of Aquitaine. The prince promised his assistance to the deposed monarch; and having obtained his father's consent, he levied an army, and set out on his enterprise.

The first loss which Henry of Trastamara suffered from the intrusion of the king of Wales, was the recall of the companies from his service; and so much reverence did they pay to the name of Edward, that great numbers of them immediately withdrew from Spain, and infiltrated under his standard. Henry, however, beloved by his new subjects, and supported by the king of Wales, was able to meet the enemy with an army of 100,000 men, three times the number of those commanded by the Black Prince; yet du Guelfelin, and all his experienced officers, advised him to delay a decisive action; so high was their opinion of the valour and conduct of the English hero! But Henry, trusting to his numbers, ventured to give Edward battle on the banks of the Ebro, between Najar and Navarette, where the French and Spaniards were defeated, with the loss of above 20,000 men, and du Guelfelin and other officers of distinction taken prisoners. All Castile submitted to the victor; Peter was restored to the throne, and Edward returned to Guienne with his usual glory; having not only overcome the greatest general of his age, but restrained the most blood-thirsty tyrant from executing vengeance on his prisoners.

This gallant warrior had soon reason to repent of his connections with a man like Peter, lost to all sense of virtue and honour. The ungrateful monster refused the stipulated pay to the English forces. Edward abandoned him; he treated his subjects with the utmost barbarity; their animosity was roused against him; and du Guelfelin, having obtained his ransom, returned to Castile with the count of Trastamara, and some forces levied anew in France. They were joined by the Spanish malcontents; and having no longer the Black Prince to encounter, they gained a complete victory over Peter in the neighbourhood of Toledo. The tyrant now took refuge in a castle, where he was soon after besieged by the victors and taken prisoner in endeavouring to make his escape. He was conducted to his brother Henry; against whom he is said to have rushed in a transport of rage, disarmed as he was. Henry flew him with his own hand, in retribution of his cruelties; and, though a bailiff, was placed on the throne of Castile, which he transmitted to his polity.

After the death of Peter the Cruel, nothing remarkable happened in Spain for almost a whole century; but the debaucheries of Henry IV. of Castile routed the retribution of his nobles, and produced a most singular in

This prince, surnamed the Impotent, though continually surrounded with women, began his unhappy reign in 1454. He was totally enervated by his pleasures; and every thing in his court confined to set the Castilians an example of the most abject flattery and most abandoned licentiousness. The queen, a daughter of Portugal, lived as openly with her parasites and her gallants as the king did with his minions and his mistresses. Pleasure was the only object, and effeminacy the only recommendation to favour; the affairs of the state went every day into disorder; till the nobility, with the archbishop of Toledo at their head, combining against the weak and flagitious administration of Henry, arrested to themselves, as one of the privileges of their order, the right of trying and passing sentence on their sovereign, which they executed in a manner unprecedented in history.

All the malecontent nobility were summoned to meet without the walls of the city: an image, representing Peter, the king, was seated on a throne, clad in royal robes, with a crown on its head, a sceptre in its hand, and the sword of justice by its side. The accusation against Henry was read, and the sentence of deposition pronounced, in presence of a numerous assembly. At the close of the first article of the charge, the archbishop of Toledo advanced, and tore the crown from the head of the image; at the close of the second, the Conde de Placentia snatched the sword of justice from its side; at the close of the third, the Conde de Benavente wrenched the sceptre from its hand; and at the close of the last, Don Diego Lopez de Stuniaga tumbled it headlong from the throne. At the same instant, Don Alphonso, Henry's brother, a boy of about twelve years of age, was proclaimed king of Castile and Leon in his stead.

This extraordinary proceeding was followed by a civil war, which did not cease till some time after the death of the young prince, on whom the nobles had bestowed the kingdom. The archbishop and his party then continued to carry on war in the name of Isabella the king's sister, to whom they gave the title of Infanta; and Henry could not extricate himself out of these troubles, nor remain quiet upon his throne till he had signed one of the most humiliating treaties ever extorted from a sovereign; he acknowledged his sister Isabella, the only lawful heir of his kingdom, in prejudice to the rights of his reputed daughter Joan, whom the malecontents affirmed to be the offspring of an adulterous commerce between the queen and Don la Cueva. The grand object of the malecontent party now was the marriage of the princes Isabella, upon which, it was evident, the security of the crown and the happiness of the people must in a great measure depend. The alliance was sought by several princes: the king of Portugal offered her his hand; the king of France demanded her for his brother, and the king of Arragon for his son Ferdinand. The malecontents very wisely preferred the Arragonian prince, and Isabella prudently made the same choice: articles were drawn up; and Arragon, they were privately married by the archbishop of Toledo.

of of war. Joan retired into a convent; and the death of Henry left a...w Ferdinand; to be

common under the influence, and, as sovereigns, highly worthy of imitation. They were zealous and ambitious; naturally disposed to turn their eyes to that fertile territory, and to think of increasing their hereditary dominions, by expelling the enemies of Christianity, and extending its doctrines.

Anything confpored to favour their project: the Moorish kingdom was a prey to civil wars; when Ferdinand, having obtained the bull of Sixtus IV. authorizing a crusade, put himself at the head of his troops, and entered Granada. He continued the war with rapid success: Isabella attended him in several expeditions; and they were both in great danger at the siege of Malaga, an important city, which was defended with great courage, and taken in 1487. Baza was reduced in 1489, after the loss of 20,000 men. Guadix and Almeria were delivered up to them by the Moorish king Al宗教el, who had first deserted his brother Alboacen, and afterwards been chafed from his capital by his nephew Abdali. That prince engaged in the service of Ferdinand and Isabella; who, after reducing every other place of eminence, undertook the siege of Granada. Abdali made a gallant defence; but all communication with the country being cut off, and all hopes of relief at an end, he capitulated, after a siege of eight months, on condition that he should enjoy the revenue of certain places in the fertile mountains of Alpujarras; that the inhabitants should retain the undisputed possession of their houses, goods, and inheritances; the use of their laws, and the free exercise of their religion. Thus ended the empire of the Arabs in Spain, after it had continued about 800 years. They introduced the arts and sciences into Europe at a time when it was lost in darkens; they possessed many of the luxuries of life, when they were not even known among the neighbouring nations; and they seem to have given birth to that romantic gallantry which so eminently prevailed in the ages of chivalry, and which, blending itself with the veneration of the northern nations for the softer sex, is particularly distinguished ancient from modern man.
The conquest of Granada was followed by the expulsion, or rather the pillage and punishment, of the Jews, who had engrossed all the wealth and commerce of Spain. The inquisition exhausted its rage against these unhappy people, many of whom pretended to embrace Christianity, in order to preserve their property. About the same time their Catholic majesties concluded an alliance with the emperor Maximilian, and a treaty of marriage for their daughter Joan with his son Philip, archduke of Austria and sovereign of the Netherlands. About this time also the contract was concluded with Christopher Columbus for the discovery of new countries; and the counties of Roussillon and Cerdaigne were agreed to be restored by Charles VIII. of France, before his expedition into Italy. The discovery of America was soon followed by extensive conquests in that quarter, as is related under the articles Mexico, Peru, Chile, &c., which tended to raise the Spanish monarchy above any other in Europe.

On the death of Isabella, which happened in 1506, Philip archduke of Austria came to Castile in order to take possession of that kingdom as heir to his mother-in-law; but he dying in a short time after, his son Charles V. afterwards emperor of Germany, became heir to the crown of Spain. His father at his death left the king of France governor to the young prince, and Ferdinand at his death left cardinal Ximenes regent of Castile, till the arrival of his grandson. This man, whose character is no less singular than illustrious, who united the abilities of a great statesman with the object devoted of a superfluous monk, and the magnificence of a prince minister with the severity of a mendicant, maintained order and tranquility in Spain, notwithstanding the discontent of a turbulent and high-minded nobility. When they disputed his right to the regency, he coolly showed them the testament of Ferdinand, and the ratification of that deed by Charles; but these not satisfying them, and argument proving ineffectual, he led them insensibly towards a balcony, whence they had a view of a large body of troops under arms, and a formidable train of artillery. "Behold (said the cardinal) the powers which I have received from my Catholic majesty: by these I govern Castile; and will govern it, till the King, your master and mine, shall come to take possession of his kingdom." A declaration so bold and determined silenced all opposition; and Ximenes maintained his authority till the arrival of Charles in 1517.

The young king was received with universal acclamations of joy; but Ximenes found little cause to rejoice. He was fized with a violent disorder, supposed to be the effect of poison; and when he recovered, Charles, prejudiced against him by the Spanish grandees and his Flemish courtiers, slighted his advice, and allowed him every day to sink into neglect. The cardinal did not bear this treatment with his usual fortitude and spirit. He expected a more grateful return from a prince to whom he delivered a kingdom more flourishing than it had been in any former age, and authority more extensive and better established than the most illustrious of his ancestors had ever possessed. Confident of his own integrity and merit, he could not therefore refrain from giving vent, at times, to indignation and complaint. He lamented the fate of his country, and foretold the calamities to which it would be exposed from the influence, the rapaciousness, and the ignorance of strangers. But in the mean time, he received a letter from the king, dismissing him from his councils, under pretext of easing his age of that burden which he had so long and so ably sustained. This letter proved fatal to the minister; for he expired in a few hours after reading it.

While Charles was taking possession of the throne of Spain, in consequence of the death of one grandfather, another was endeavouring to obtain for him the imperial crown. With this view Maximilian assembled a diet at Augsburg, where he cultivated the favour of the electors by many acts of beneficence in order to engage them to choose that young prince as his successor. But Maximilian himself never having been crowned by the pope, a ceremony deemed essential in that age, as well as in the preceding, he was considered only as king of the Romans, or emperor elect; and no example occurred in the history of any person being chosen successor to a king of the Romans, the German, always tenacious of their forms, obstinately refused to confer upon Charles a dignity for which their constitution knew no name.

But though Maximilian could not prevail upon the German electors to choose his grandson of Spain king of the Romans, he had disposed their minds in favour of that prince; and other circumstances, on the death of the emperor, conspired to the exaltation of Charles. The imperial crown had so long continued in the Austrian line, that it began to be considered as hereditary in that family; and Germany, torn by religious disputes, stood in need of a powerful emperor, not only to preserve its own internal tranquility, but also to protect it against the victorious arms of the Turks, who under Selim I. threatened the liberties of Europe. This fierce and rapid conqueror had already subdued the Mamelukes, and made himself master of Egypt and Syria. The power of Charles appeared necessary to oppose that of Selim. The extensive dominions of the house of Austria, which gave him an interest in the preservation of Germany; the rich sovereignty of the Netherlands and Franche Comte; the extensive possessions of the great and warlike kingdom of Spain, together with that of Naples and Sicily, all united to hold him up to the first dignity among Christian princes; and the new world seemed only to be called into existence that its treasures might enable him to defend Christendom against the infidels. Such was the language of his partisans.

Francis I. however, no sooner received intelligence of the death of Maximilian, than he declared himself a candidate for the empire; and with no less confidence of success than Charles. He trusted to his superior years and experience; his great reputation in arms; and it was further urged in his favour, that the impetuosity of the French cavalry added to the firmness of the German infantry, would prove irresistible, and not only the sufficient under a war-like emperor, to set limits to the ambition of Selim, but to break entirely the Ottoman power, and prevent it from ever becoming dangerous again to Germany.

Both claims were plausible. The dominions of Fran-
The candidates had hitherto been fairly and openly suitors to the hand of Henry, who, by his talents and accomplishments, had risen from one of the lowest conditions in life to the highest employment in church and state, enjoyed a greater degree of power and dignity than any English subject ever possessed, and governed the haughty, prepu­matous, and untractable spirit of Henry, with absolute authority. Francis was equally well acquainted with the character of Henry and of his minister. He had successfully flattered Wolsey's pride by honouring him with particular marks of his confidence, and belittling upon the pope's legate the surname of Pope, Tutor, and Governor; and he had obtained the restitution of Tournay, by adding a pension to those respectful titles. He now solicited an interview with the king of England near Calais; in hopes of being able, by familiar conversation, to attach him to his friendship and interest, while he gratified the cardinal's vanity, by affording him an opportunity of displaying his magnificence in the presence of two courts, and of discovering to the two nations his influence over their monarchs. Charles dreaded the effects of this projected interview between two gallant princes, whose hearts were no less susceptible of friendship than their manners were of inspiring it. Finding it impossible, however, to prevent a visit, in which the vanity of all parties was so much concerned, he endeavored to defeat its purpose, and to pre-occupy the adoption of the English monarch, and of his minister, by an act of complaisance still more flattering and more uncommon. Relying wholly upon Henry's generosity for his safety, he landed at Dover, in his way from Spain to the Low Countries. The king of England, who was on his way to France, charmed with such an influence of confidence, hastened to receive his royal guest; and Charles, during his short stay, had the address not only to give Henry favourable impressions of his character and intentions, but to detach Wolsey entirely from the interest of Francis. The tiara had attracted the eye of that ambitious prelate; and as the emperor knew that the papacy was the sole point of elevation, beyond his present greatness, at which he could aspire, he made him an offer of his interest on the first vacancy.

The day of Charles's departure, Henry went over to Calais with his whole court, in order to meet Francis. Their interview was in an open plain between Guines and Ardes; where the two kings and their attendants displayed their magnificence with such emulation and prodigal expense, as procured it the name of the Field of the Cloth of Gold. Here Henry erected a spacious house of wood and canvas, framed in London, on which, under the figure of an English archer, was the following motto: "He prevails whom I favour," alluding to his own political situation, as holding in his hands...
hands the balance of power among the potencies of Europe. Feats of chivalry however, parties of galleantry, and such exercises as were in that age reckoned manly or elegant, rather than serious business, occupied the two courts during the time that they continued together, which was 18 days.

After taking leave of this scene of dissipation, the king of England paid a visit to the emperor and Margaret of Savoy at Gravelines, and engaged them to go along with him to Calais; where the artful and politic Charles completed the impression which he had begun to make on Henry and his favourite, and wafted all the friendship to which the frank and generous nature of Francis had given birth. He renewed his assurances of affilling Wolsey in obtaining the papacy; and he put him in present possession of the revenues belonging to the fees of Badajoz and Palencia in Spain. He flattered Henry's pride, by convincing him of his own importance, and of the judgements of the motto which he had chosen; offering to submit to his sole arbitration any difference that might arise between him and Francis.

This important point being secured, Charles repaired to Aix-la-Chapelle, where he was solemnly invested with the crown and sceptre of Charlemagne, in presence of a more splendid and numerous assembly than had appeared on any former inauguration. About the same time Solyman the Magnificent, one of the moft accomplished, enterprising, and victorious of the Turkish princes, and a confiant and formidable rival to the emperor, ascended the Ottoman throne.

The first act of Charles's administration was to appoint a diet of the empire, to be held at Worms, in order to concert with the princes proper measures for checking the progress of those new and dangerous opinions which threatened to disturb the peace of Germany, and to overturn the religion of their ancestors. The opinions propagated by Luther and his followers were here meant. But all his efforts for that purpose were insufficient, as is related under the articles Luther and Reformation.

In 1521, the Spaniards, dissatisfied with the departure of their sovereign, whose election to the empire they forewad would interfere with the administration of his own kingdom, and incensed at theavarice of the Flemings, to whom the direction of public affairs had been committed since the death of cardinal Ximenes, several grandees, in order to shake off this opprobrium, entered into an association, to which they gave the name of the Sanfta Familia; and the sword was appealed to as the means of redress. This seemed to Francis a favourable juncture for reuniting the family of John d'Albert in the kingdom of Navarre. Charles was at a distance from that part of his dominions, and the troops usually stationed there had been called away to quell the commotions in Spain. A French army, under Andrew de Foix, speedily conquered Navarre; but that young and inexperienced nobleman, pushed on by military ardour ventured to enter Castle. The Spaniards, though divided among themselves, united against a foreign enemy, routed his forces, took him prisoner, and recovered Navarre in a shorter time than he had spent in subduing it.

Hostilities thus begun in one quarter, between the rival monarchs, soon spread to another. The king of France encouraged the duke of Bouillon to make war against the emperor, and to invade Luxembourg. Charles, after, humbling the duke, attempted to enter France; but was repelled and worsted before Messieres by the famous chevalier Bayard, distinguished among his contemporaries by the appellation of The knight without fear and without reproach; and who united the talents of a great general to the punctilious honour and romantic gallantry of the heroes of chivalry. Francis broke into the Low Countries, where, by an excess of caution, an error not natural to him, he lost an opportunity of cutting off his whole imperial army; and, what was of still more consequence, he disfigured the coalable Bourbon, by giving the command of the van to the duke of Alençon.

During these operations in the field, an unsuccessful congress was held at Calais, under the mediation of Henry VIII. It served only to exasperate the parties which it was intended to reconcile. A league was soon after concluded, by the intrigues of Wolsey, between the pope, Henry, and Charles, against France. Leo had already entered into a separate league with the emperor, and the French were fast losing ground in Italy.

The influence and exactions of Marefial de Lautrec, governor of Milan, had totally alienated the affections of the Milanese from France. They resolved to expel the troops of that nation, and put themselves under the government of Francis Sforza, brother to Maximum, their late duke. In this resolution, they were encouraged by the pope, who excommunicated Lautrec, and took into his pay a considerable body of Swifs. The papal army, commanded by Prosper Colonna, an experienced general, was joined by supplies from Germany and Naples: while Lautrec, neglected by his court, and defeated by the Swifs in its pay, was unable to make head against the enemy. The city of Milan was betrayed by the inhabitants to the confederates; Parma and Placentia were united to the ecclesiastical state; and of their conquests in Lombardy, only the town of Cremona, the castle of Milan, and a few inconsiderable forts, remained in the hands of the French.

Leo X. received the accounts of this rapid success with such transports of joy, as are said to have brought on a fever, which occasioned his death. The spirit of the confederacy was broken, and its operations suspended by this accident. The Swifs were recalled; some other mercenaries disbanded for want of pay; and only the Spaniards, and a few Germans in the emperor's service, remained to defend the duchy of Milan. But Lautrec, who with the remnant of his army had taken shelter in the Venetian territories, delitute both of men and money, was unable to improve this favourable opportunity as he wished. All his efforts were rendered ineffectual by the vigilance and ability of Colonna and his associates.

Meantime much discord prevailed in the concave. Wolsey's name, notwithstanding all the emperor's magnificent promises, was scarcely mentioned there. Julio de Medici, Leo's nephew, thought himself sure of the election; when, by an unexpected turn of fortune, Cardinal Adrian of Utrecht, Charles's preceptor, who at that time governed Spain in the emperor's name, was unanimously raised to the papacy, to the astonishment of all Europe and the great disgust of the Italians.

Francis,
France, roused by the rising consequence of his rival, resolved to exert himself with fresh vigour, in order to outstrip him in his late conquests in Lombardy. Lautrec received a supply of money, and a reinforcement of 10,000 Swifs. With this reinforcement he was enabled to go more offensively, and even to advance within a few miles of the city of Milan; when money again failing him, and the Swifs growing mutinous, he was obliged to attack the imperialists in their camp at Bicocca, where he was repulsed with great slaughter, having lost his bravest officers and best troops. Such of the Swifs as survived set out immediately for their own country; and Lautrec, despairing of being able to keep the field, retired into France. Genoa, which still remained subject to Francis, and made it easy to execute any scheme for the recovery of Milan, was soon after taken by Colonna: the authority of the emperor and his faction was everywhere established in Italy. The citadel of Cremona was the sole fortress which remained in the hands of the French. The submission of France for such a succession of misfortunes was augmented by the unexpected arrival of an English herald, who in the name of his sovereign declared war against France. The courage of this excellent prince, however, did not forsake him; but his treasury was exhausted by expensive pleasures, no less than by hostile enterprises; he assembled a confederate army, and put his kingdom in a posture of defence for resisting this new enemy, without abandoning any of the schemes which he was forming against the emperor. He was surprized, but not alarmed, at such a denunciation.

Meanwhile Charles, willing to draw as much advantage as possible from so powerful an ally, paid a second visit to the court of England in his way to Spain, where his presence was become necessary. His success exceeded his most sanguine expectations. He not only gained the entire friendship of Henry, who publicly ratified the treaty of Bruges; but disarmed the resentment of Wolsey, by affuring him of the pacy on Adrian's death; an event seemingly not distant, by reason of his age and enormities. In consequence of these negotiations an English army invaded France, under the command of the earl of Surrey; who, at the end of the campaign, was obliged to retire, with his forces greatly reduced, without being able to make himself master of one place within the French frontier. Charles was more fortunate in Spain: he soon quelled the tumults which had theretofore arisen in his absence.

While the Christian princes were thus waiting each other's strength, Solyman the Magnificent entered Hungary, and made himself master of Belgrade, reckoned the chief barrier of that kingdom against the Turkish power. Encouraged by this successe, he turned his victorious arms against the Island of Rhodes, at that time the seat of the knights of St John of Jerusalem; and though every prince in that age acknowledged Rhodes to be the great bulwark of Christendom in the east, so violent was their animosity against each other, that they suffered Solyman without disturbance to carry on his operations against that city and island. Lisle Adam, the grandmaster, made a gallant defence; but, after incredible efforts of courage, patience, and military conduct, during a siege of six months, he was obliged to surrender the place, having obtained an honourable capitulation from the sultan, who admired and respected his heroic qualities (See Rhodes and Malta). Charles and Francis were equally afield of having occasioned such a loss to Christendom by their contests; and the emperor, by way of reparation, granted to the knights of St John the small island of Malta, where they fixed their residence, and continued long to retain their ancient spirit, though much diminished in power and splendor.

Adrian VI, though the creature of the emperor, and devoted to his interest, endeavoured to assume the impartiality which became the common father of Christendom, and laboured to reconcile the contending princes, that they might unite in a league against Solyman, whose conquest of Rhodes rendered him more formidable than ever to Europe. The Italian fleets were no less defirous of peace than the pope: and so much regard was paid by the hostile powers to the exhortations of their holiness, and to a bull which he issued, requiring all Christian princes to content to a truce for three years, that the imperial, the French, and the English ambassadors at Rome, were empowered to treat of that matter; but while they waited their time in fruitless negotiation, their masters were continuing their preparations for war; and other negotiations soon took place. The confederacy against France became more formidable than ever.

The Venetians, who had hitherto adhered to the Austrian interest, formed engagements with the emperor confederate for securing Francis Sforza in the possession of the duchy of Milan; and the pope, from a perfusion that the ambition of the French monarch was the only obstacle to peace, acceded to the same alliance. The Florentines, the dukes of Ferrara and Mantua, and all the Italian powers, followed this example. Francis was left without a single ally, to resist the efforts of a multitude of enemies, whose armies everywhere threatened, and whose territories encompassed his dominions. The emperor in person menaced France with an invasion on the side of Guienne; the forces of England and the Netherlands hovered over Picardy, and a numerous body of Germans was preparing to ravage Burgundy.

The dread of so many and such powerful adversaries, it was thought, would have obliged Francis to keep wholly on the defensive, or at least have prevented him from entertaining any thoughts of marching into Italy. But before his enemies were able to strike a blow, Francis had assembled a great army, with which he hoped to disconcert all the emperor's schemes, by marching it in person into Italy; and this bold measure, the more formidable because unexpected, could scarcely have failed of the desired effect, had it been immediately carried into execution. But the discovery of a domestic conspiracy, which threatened the destruction of his kingdom, obliged Francis to stop short at Lyons.

Charles duke of Bourbon, lord high constable of France, was a prince of the most shining merit: his great talents equally fitted him for the council or the field, while his eminent services to the crown intitled him to its first favour. But unhappily Louise duchesse of Angouleme, the king's mother, had contrived a violent aversion against the house of Bourbon, and had taught her son, over whom she had acquired an absolute ascendancy, to view all the favourite's actions with a jealous eye. After repeated afronts he retired from court, and
and began to listen to the advances of the emperor's ministers. Meantime the duchess of Bourbon died; and as the confable was no less amiable than accomplished, the duchess of Angoulême, still susceptible of the tender passions, formed the scheme of marrying him. But Bourbon, who might have expected every thing to which an ambitious mind can aspire, from the doting fondness of a woman who governed her son and the kingdom, incapable of imitating Louïsa in her sudden transition from hate to love, or of meanly counteringpassion for one who had so long pursued him with unprovoked malice, rejected the match with disdain and turned the proposal into ridicule. At one defpifed, and insulted by the man whom love only could have made her ceased to persecute, Louïsa was filled with all the rage of disappointed woman; she resolved to ruin, since she could not marry, Bourbon. For this purpose the commenced an iniquitous suit against him; and by the chicanery of chancellor du Prat, the confable was stripped of his whole family-estate. Driven to despair by so many injuries, he entered into a secret correspondence with the emperor and the king of England; and he proposed, as soon as Francis should have crossed the Alps, to raise an insurrection among his numerous vassals, and introduce foreign enemies into the heart of France.

Happily Francis got intimation of this conspiracy before he left the kingdom; but not being sufficiently convinced of the Conflable's guilt, he suffered so dangerous a foe to escape; and Bourbon entering into the emperor's service, employed all the force of his enterprising genius, and his great talents for war, to the prejudice of his prince and his native country.

In consequence of the discovery of this plot, and the escape of the powerful conspirator, Francis relinquished his intention of leading his army in person into Italy. He was ignorant how far the infection had spread among his subjects, and afraid that his absence might encourage them to make some desperate attempt in favour of a man so much beloved. He did not, however, suspect that the Malines, on whose account the Milanese were in arms, were an army of 30,000 men, under the command of admiral Bonnivet. Colonna, who was entrusted with the defence of that duchy, was in no condition to defend such a force; and the city of Milan, on which the whole territory depends, must have fallen into the hands of the French, had not Bonnivet, who poiffessed none of the talents of a general, waited his time in trivial enterprises, till the inhabitants recovered from their confternation. The imperial army was reinforced; Colonna died; and Lannoy, viccry of Naples, succeeded him in the command; but the chief direction of military operations was committed to Bourbon and the marquis de Pefcara, the greatest generals of their age. Bonnivet, desirous of troops to oppose this new enemy and still more of the talents which could render him a match for its leaders, after various movements and encounters, was reduced to the necessity of attempting a retreat into France. He was followed by the imperial generals, and routed at Biagrafia, where the famous chevalier Bayard was killed.

The emperor and his allies were less successful in their attempts upon France. They were baffled in every quarter; and Francis, though stripped of his Italian dominions, might still have enjoyed in safety the glory of having defended his native kingdom against one half of Europe, and have bid defiance to all his enemies; but understanding that the king of England, discouraged by his former fruitless enterprises, and diffused with the emperor, was making no preparations Francis determined for any attempt on France, his ancient armdour feized him for the conquest of Milan, and he determined, notwithstanding the advanced season, to march into Italy.

The French army no sooner appeared in Piedmont, than the whole Milanese was thrown into confternation. The capital opened its gates. The forces of the emperor and Sforza retired to Lodi; and had Francis been so fortunate as to pursue them, they must have abandoned that poft, and been totally dispersed; but his evil genius led him to besiege Pavia, a town of confiderable strength, well garrisoned, and defended by Antonio de Leyva, one of the bravest officers in the Spanish service; before which place he was defeated and taken prisoner on the twenty-fourth day of February 1574.

The captivity of Francis filled all Europe with alarm. Almost the whole French army was cut off; Milan was immediately abandoned; and in a few weeks not a Frenchman was left in Italy. The power of the emperor, and still more his ambition, became an object of universal terror; and revolutions were everywhere taken to fet bounds to it. Meanwhile Francis, deeply impreffed with a sense of his misfortune, wrote to his mother Louïsa, whom he had left regent of the kingdom, the following short but expressive letter: "All, Madam, is lost but honour." The fame courier that carried this letter, carried also dispatches to Charles; who received the news of the signal and unexpected success which had crowned his arms with the most hypocritical moderation. He would not suffer any public rejoicing to be made on account of it; and laid, he only valued it, as it would prove the occasion of restoring peace to Christendom. Louïsa, however, did not trußt to those appearances; if the could not preserve what was yet left, the determined at least that nothing should be lost through the negligence or weakness. Instead of giving herself up to such lamentations as were natural to a woman so remarkable for maternal tenderness; she discocered all the foresight, and exerted all the activity of a confummate politician. She took every possible measure for putting the kingdom in a posture of defence, while she employed all her address to appease the resentment and to gain the friendship of England; and a ray of comfort from that quarter soon broke in upon the French affairs.

Though Henry VIII. had not entered into the war against France from any concerted political views, he had always retained some imperfect idea of that balance of power which it was necessary to maintain between Charles and Francis; and the preservation of which he boasted to be his peculiar office. By his alliance with the emperor, he hoped to recover some part of those territories on the continent which had belonged to his ancestors; and therefore willingly contributed to give him the ascendency above his rival; but having never dreamt of any event to decisive and fatal as the victory at Pavia, which seemed not only to have broken him, but to have annihilated the power of Francis, he now became sensible of his own danger, as well as that of all Europe, from the loss of a proper counterpoise to the power of Charles.
Charles. Instead of taking advantage of the disaffected condition of France, Henry therefore determined to afflict her in her present calamities. Some disputes also had taken place between him and Charles, and still more between Charles and Wolsey. The elevation of the 'lueror, breaft,

HenryVIII. between Charles and Wolsey. The elevation of the cardinal of Medici to St Peter's chair, on the death of Adrian, under the name of Clement VII, had made the English minister sensible of the influence of the emperor's promises, while it extinguished all his hopes of the papacy; and he resolved on revenge. Charles, too, had still supported the appearance of moderation which he assumed, when first informed of his good fortune; that he had already changed his usual style to Henry; and instead of writing to him with his own hand, and subscribing himself "your affectionate son and cousin," he dictated his letters to a secretary, and simply subscribed himself "Charles." Influenced by all these motives, together with the glory of raising a fallen enemy, Henry listened to the flattering submissions of Louis; entered into a defensive alliance with her as regent of France, and engaged to use his fleet offices in order to procure the deliverance of her son from a state of captivity.

Meanwhile Francis was rigorously confined; and severe conditions being proposed to him as the price of his liberty, he drew his dagger, and, pointing it at his breast, cried, "Twere better that a king should die thus! His hand was with-held: and flattering himself, when he grew cool, that such propositions could not come directly from Charles, he defined that he might be removed to Spain, where the emperor then refided. His request was complied with; but he languished long before he obtained a sight of his conqueror. At last he was favoured with a visit; and the emperor dreading a general combination against him, or that Francis, as he threatened, might, in the obstinacy of his heart, reign his crown to the dauphin, agreed to abate somewhat of his former demands. A treaty was accordingly concluded at Madrid; in consequence of which Francis obtained his liberty. The chief article of this treaty was, that Burgundy should be restored to Charles as the rightful inheritance of his ancestors, and that Francis's two eldest sons should be immediately delivered up as hostages for the performance of the conditions stipulated. The exchange of the captive monarch for his children was made on the borders between France and Spain. The moment that Francis entered his own dominions, he mounted a Turkish horse, and putting it to its speed, waved his hand, and cried aloud several times, "I am yet a king! I am yet a king!"

Francis never meant to execute the treaty of Madrid; but he had even left a protest in the hands of notaries before he signed it, that his consent should be considered as an involuntary deed, and be deemed null and void. Accordingly, as soon as he arrived in France, he assembled the states of Burgundy, who protested against the article relative to their province; and Francis coldly replied to the imperial ambassadors, who urged the immediate execution of the treaty, that he would religiously perform the articles relative to himself, but, in those affecting the French monarchy, he must be directed by the sense of the nation. He made the highest acknowledgments to the king of England for his friendly interpolation, and offered to be entirely guided by his counsellors. Charles and his ministers saw that they were over-reached in those very arts of negotiation in which they so much excelled, while the Italian states observed with pleasure, that Francis was resolved not to execute a treaty which they considered as dangerous to the liberties of Europe. Clement abdicated him from the oath which he had taken at Madrid; and the kings of France and England, the Pope, the Swiss, the Venetians, the Florentines, and the duke of Milan, entered into an alliance, to which they gave the name of the Holy League, because his Holiness was at the head of it, in order to oblige the emperor to deliver up Francis's two sons on the payment of a reasonable ransom, and to re-establish Sforza in the quiet possession of the Milanese.

In consequence of this league, the confederate army took the field, and Italy once more became the scene of war. But Francis, who it was thought would have inflamed spirit and vigour into the whole body, had gone through such a scene of disasters, that he was become diffident of himself, distrustful of his fortune, and desirous of tranquillity. He flattered himself, that the dread alone of such a confederacy would induce Charles to listen to what was equitable, and therefore neglected to send due reinforcements to his allies in Italy. Meanwhile the duke of Bourbon, who commanded the Imperialists, had made himself master of the whole Milanese of which the emperor had promised him the investiture; and his troops beginning to mutiny for want of pay, he led them to Rome, and promised to enrich them with the spoils of that city. He was as good as his word; for though he himself was slain in planting a scaling-ladder against the walls, his followers, rather encouraged than discouraged by his death, mounted to the assault with the utmost ardour, animated by the greatness of the prize, and, entering the city sword in hand, plundered it for several days.

Never did Rome in any age suffer so many calamities, not even from the Barbarians, by whom she was cruelly often subdued, the Huns, Vandals, or Goths, as now. Plundered, from the subjects of a Chilian and Catholic monarch. Whatever was respectable in modesty, or sacred in religion, seemed only the more to provoke the rage of the soldiery. Virgins suffered violation in the arms of their parents, and upon those altars to which they had fled for safety. Venerable prelates, after enduring every indignity and every torture, were thrown into dungeons, and menaced with the most cruel death, in order to make them reveal their secret treasures. Clement himself, who had neglected to make his escape in time, was taken prisoner, and found that the sturdiness of his character could neither procure him liberty nor respect. He was confined till he should pay an enormous ransom imposed by the victorious army, and surrender to the emperor all the places of strength belonging to the church.

Charles received the news of this extraordinary event with equal surprize and pleasure; but in order to contrive how to reap the joy from his Spanish subjects, who were filled with horror at the insult offered to the sovereign pontiff, and to lessen the indignation of the rest of Europe, he expressed the most profound sorrow for the success of his arms. He put himself and his court into mourning; stopped the rejoicings for the birth of his son Philip, and ordered prayers to be put up in all the churches of Spain for the recovery of his pope's liberty, which

Spain.

France actuated by Henry VIII.
which he could immediately have procured by a letter to his generals.

The concern expressed by Henry and Francis for the calamity of their ally was more than felt. Alarm at the progress of the imperial arms, they had, even before the taking of Rome, entered into a closer alliance, and agreed to invade the Low Countries with a powerful army; but no sooner did they hear of the Pope's captivity, than they changed, by a new treaty, the scene of the projected war from the Netherlands to Italy, and resolved to take the most vigorous measures for restoring him to liberty. Henry, however, contributed only money. A French army entered Italy, under the command of Marshal Lautrec; Clement obtained his freedom; and war was for a time carried on by the confederates with success; but the death of Lautrec, and the revolt of Andrea Doria, a Genoese admiral in the service of France, entirely changed the face of affairs. The French army was utterly ruined; and Francis, discouraged and almost exhausted by so many unsuccessful enterprises, began to think of peace, and of obtaining the release of his sons by conciliating them, not by the terror of his arm.

At the same time Charles, not withstanding the advantages he had gained, had many reasons to wish for an accommodation. Sultan Soliman having over-run Hungary, was ready to break in upon the Austrian territories with the whole force of the East; and the progress of the Reformation in Germany threatened the tranquillity of the empire. In consequence of this situation of affairs, though pride made both parties conceal their real sentiments, two ladies were permitted to restore peace to Europe. Margaret of Austria, Charles's aunt, and Louisa, Francis's mother, met in 1529 at Cambray, and settled the terms of accommodation between the French king and the emperor. Francis agreed to pay two millions of crowns as a ransom of his two sons, to resign the sovereignty of Flanders and Artois, and to forego all his Italian claims; and Charles ceased to demand the restitution of Burgundy.

All the steps of this negotiation had been communicated to the king of England; and Henry was, on that occasion, so generous to his friend and ally Francis, that he sent him an acquittal of near fix hundred thousand crowns, in order to enable him to fulfill his agreement with Charles. But Francis's Italian confederates were left satisfied with the treaty of Cambray. They were almost wholly abandoned to the will of the emperor; and seemed to have no other means of security left but his equity and moderation. Of these, from his past conduct, they had not formed the most advantageous idea. But Charles's present circumstances, more especially in regard to the Turks, obliged him to behave with a generosity inconsistent with his character. The Florentines alone, whom he reduced under the dominion of the family of Medici, had reason to complain of his severity. Sforza obtained the investiture of Milan and his pardon; and every other power experienced the liberty of the conqueror.

After having received the imperial crown from the hands of the Pope at Bologna, Charles proceeded on his journey to Germany, where his presence was become highly necessary; for although the conduct and valour of his brother Ferdinand, on whom he had conferred the hereditary dominions of the house of Austria, and who had been elected king of Hungary, had obliged Soliman to retire with infamy and loss, his return was to be feared, and the disorders of religion were daily increasing; an account of which, and of the emperor's transactions with the Protestants, is given under the article Reformation.

Charles having exerted himself as much as he could against the reformers, undertook his first expedition against the piratical states of Africa. Barbary, or that part of the African continent lying along the coast of the Mediterranean sea, was then nearly in the same condition which it is at present. Morocco, Algiers, and Tunis, were its principal states; and the two last were nests of pirates. Barbarooff, a famous Contad, had succeeded his brother in the kingdom of Algiers, which he had formerly allotted him to usurp. He regulated with much prudence the interior police of his kingdom, carried on his piracies with great vigour, and extended his conquests on the continent of Africa; but perceiving that the natives submitted to his government with impatience, and fearing that his continual depredations would one day draw upon him a general combination of the Christian powers, he put his dominions under the protection of the grand signor. Soliman, flattered by such an act of submission, and charmed with the boldness of the man, offered him the command of the Turkish fleet. Proud of this distinction, Barbarooff repaired to Constantinople, and made use of his influence with the sultan to extend his own dominion. Partly by force, partly by treachery, he usurped the kingdom of Tunis; and being now possessed of greater power, he carried on his depredations against the Christian states with more destructive violence than ever.

Daily complaints of the piracies and ravages committed by the galleys of Barbarooff were brought to the emperor by his subjects, both in Spain and Italy; and all Christendom seemed to look up to him, as its greatest and most fortunate prince, for relief from this new and odious species of oppression. At the same time Muley Hafcen, the exiled king of Tunis, finding none of the African princes able or willing to support him in recovering his throne, applied to Charles for assistance against the usurper. Equally desirous of delivering his dominions from the dangerous neighbourhood of Barbarooff, of appearing as the protector of an unfortunate prince, and of acquiring the glory annexed in that age to every expedition against the Mahometans, the emperor readily concluded a treaty with Muley Hafcen, and set sail for Tunis with a formidable armament. The Gofletta, a sea-port town, fortified with 300 pieces of cannon, was taken, together with all Barbarooff's fleet; he was defeated in a pitched battle, and 10,000 Christian slaves, having knocked off their fetters, and made themselves masters of the citadel, Tunis was at length pre-empted, and paring to surrender. But while Charles was negotiating the inhabi-tants cruelly unfaithful to the condition, his troops fearing that they would be deprived of the bootky which they had expected, broke suddenly into the town, and pillaged and maffacred without distinction. Thirty thousand persons perished by the sword, and 10,000 were made prisoners. The sceptre was restored to Muley Hafcen, on condition that he should acknowledge himself a vaflal of the crown of Spain, put into the emperor's hand all the fortified sea ports in the kingdom of Tunis, and
Francis, though unsupported by any ally, commanded his army to advance towards the frontiers of Italy, under pretence of chastising the duke of Milan for a breach of the law of nations, in putting to death his ambassador. The operations of war, however, soon took a new direction. Instead of marching directly to the Milanese, Francis commenced hostilities against the duke of Savoy, with whom he had cause to be dissatisfied, and on whom he had some claims; and before the end of the campaign, that feeble prince saw himself stripped of all his dominions, except the provinces of Piedmont. To complete his misfortunes, the city of Geneva, the sovereignty of which he claimed, and where the reformed opinions had already got footing, threw off his yoke; and its revolt drew along with it the loss of Savoy of the adjacent territory. Geneva was then an imperial city, and has ever since remained entirely free.

In this extremity the duke of Savoy saw no resource but in the emperor's protection; and as his misfortunes were chiefly occasioned by his attachment to the imperial interest, he had a title to immediate aid. But Charles, who was just returned from his African expedition, was not able to lend him the necessary support. His treasury was entirely drained, and he was obliged to disband his army till he could raise new supplies. Mean time the death of Sforza duke of Milan entirely changed the nature of the war, and afforded the emperor full leisure to prepare for action. The French monarch's pretext for taking up arms was at once cast aside; but as the duke died without issue, all Francis's rights to the duchy of Milan, which he had yielded only to Sforza and his descendants, returned to him in full force. He instantly renewed his claim to it; and if he had ordered his army immediately to advance, he might have made himself master of it. But he unfortunately wasted his time in fruitless negotiations, while his more politic rival took possession of the duchy as a vacant fief of the empire; and though Charles seemed still to admit the equity of Francis's claim, he delayed granting the investiture under various pretences, and was secretly taking every possible measure to prevent him from regaining footing in Italy.

During the time gained in this manner Charles had recruited his finances, and of course his armies; and finding himself in a condition for war, he at last threw off the mask under which he had so long concealed his designs from the court of France. Entering Rome with great pomp, he pronounced before the pope and cardinals, assembled in full curiosity, a violent invective against Francis, by way of reply to his propositions concerning the investiture of Milan. Yet Francis, by an abundant account of the misfortunes of his unaccountable late ally, continued to negotiate, as if it had been still possible to terminate their differences in an amicable manner; and Charles, finding him too eager to run into the snare, favored the deception, and, by seeming to listen to his proposals, gained yet more time for the execution of his ambitious projects.

If misfortunes had rendered Francis too diffident, Charles attempted to subvert the French monarchy; for, he considered it as an insaluble event. Having chafed the forces of his rival out of Piedmont and Savoy, he pushed forward at the head of 50,000 men, contrary to the advice of his most experienced ministers and generals, to invade the southern provinces of France; while other two armies were ordered to enter the one on the side of Picardy, the other on the side of Champagne. He thought it impossible that Francis could resist so many unexpected attacks on such different quarters; but he found himself mistaken.

The French monarch fixed upon the most effectual plan...
plan for defeating the invasion of a powerful enemy; and he prudently persevered in following it, though contrary to his own natural temper and to the genius of his people. He determined to remain altogether upon the defensive, and to deprive the enemy of sublimity by laying walle the country before them. The execution of this plan was committed to the mariscal Montmorency its author, a man happily fitted for such a trust by the inflexible severity of his disposition. He made choice of a strong camp, under the walls of Avignon, at the confluence of the Rhone and Durance, where he assembled a considerable army; while the king, with another body of troops, encamped at Valence, higher up the Rhone. Marfelles and Arles were the only towns he thought it necessary to defend; and each of these he furnished with a numerous garrison of his belt troops. The inhabitants of the other towns were compelled to abandon their habitations; the fortifications of such places as might have afforded shelter to the enemy were thrown down; coin, forage, and provisions of every kind, were carried off or destroyed; the mills and ovens were ruined, and the wells filled up or rendered useless. This devastation extended from the Alps to Marfelles, and from the sea to the confines of Dauphiné; so that the emperor, when he arrived with the van of his army on the confines of Provence, instead of that rich and populous country which he expected to enter, beheld nothing but one vast and desert solitude. He did not, however, despair of success, though he saw that he would have many difficulties to encounter; and as an encouragement to his officers, he made them liberal promises of lands and honours in France. But all the land which any of them obtained was a grave, and their master lost much honour by this rash and precipitate enterprise. After unsuccessfully inveting Marfelles and Arles, after attempting in vain to draw Montmorency from his camp at Avignon, and not daring to attack it, Charles having spent two inglorious months in Provence, and lost one half of his troops by disease or by famine, was under the necessity of ordering a retreat; and though he was some time in motion before the enemy suspected his intention, it was conducted with so much precipitation and disorder, as to deprive the name of a flight, since the light troops of France turned it into a perfect rout. The invasion of Picardy was not more successful: the imperial forces were obliged to retire without effecting any conquest of importance.

Charles had no sooner concluded the shattered remains of his army to the frontiers of Milan, than he set out for Genoa; and unwilling to expose himself to the scorn of the Italians after such a reverse of fortune, he embarked directly for Spain.

Meanwhile Francis gave himself up to that vain resentment which had formerly disgraced the prosperity of his rival. They had frequently, in the course of their quarrels, given each other the lie, and mutual challenges had been sent; which, though productive of no serious consequences between the parties, had a powerful tendency to encourage the pernicious practice of duelling. Charles, in his inquisitive proneness at Rome, had publicly accused Francis of perfidy and breach of faith; Francis now exceeded Charles in the indecency of his accusations. The Dauphin dying suddenly, his death was imputed to poison: Montecuculi his cup-bearer was put to the rack; and that unhappy nobleman, in the agonies of torture, accused the emperor's generals Gonzagar de Leyva, of intriguing him to the dastardly act. The emperor himself was insulted; nay, this entertained confederation, and some obscure hints, were considered as incontestable proofs of his guilt; though it was evident to all mankind, that neither Charles nor his generals could have any inducement to perpetrate such a crime, as Francis was still in the vigour of life himself, and had two sons before the dauphin, grown up to a good age.

But the incensed monarch's resentment did not stop here. Francis was not satisfied with endeavouring to blacken the character of his rival by an ambiguous testimony which led to the most injurious suppositions, and upon which the most cruel confusions had been put; he was willing to add rebellion to murder. For this purpose he went to the parliament of Paris; where being feated with the usual solemnities, the advocate-general appeared, and accused Charles of Austria (so he affected to call the emperor) of having violated the treaty of Cambray, by which he was freed from the homage due to the crown of France for the counties of Artois and Flanders; adding, that this treaty being now void, he was full to be considered as a vassal of France, and consequently had been guilty of rebellion in taking arms against his sovereign. The charge was disdained, and Charles was summoned to appear before the parliament of Paris at a day fixed. The term to appear expired; and no person appearing in the emperor's name, at Paris, the parliament gave judgment, and Charles of Austria had forfeited, by rebellion and contumacy, the counties of Flanders and Artois, and declared those fiefs reunited to the crown of France.

Francis, soon after this vain display of his animosity, marched into the Low Countries, as if he had intended to execute the sentence pronounced by his parliament; but such perfusion of arms took place, through the intervention of the queens of France and Hungary, before any thing of consequence was effected: and this cessation, which was followed by a truce, concluded at Nice, through the mediation of the reigning pontiff Paul III. of the family of Farnese, a man of a venerable character and pacific disposition.

Each of these rival princes had strong reasons to incline them to peace. The finances of both were exhausted; and the emperor, the most powerful of the two, was deeply im pressed with the dread of the Turkish arms, which Francis had drawn upon him by a league with Solyman. In consequence of this league, Barbarossa with a great fleet appeared upon the coast of Naples; filled that kingdom with consternation; landed without resistance near Taranto; obliged Caltro, a place of some strength, to surrender; plundered the adjacent country; and was taking measures for securing and extending his conquests, when the unexpected arrival of Doria, the famous Genoese admiral, together with the pope's galleys and a squadron of the Venetian fleet, made it prudent for him to retire. The sultan's forces also invaded Hungary, where Mahomet the Turkish general, after gaining several inferior advantages, defeated the Germans in a great battle at Effik on the Drave. Happily for Charles and Europe it was not in Francis's power at this juncture either to join the Turks or to

Violent animosity between him and Francis.
emblem an army strong enough to penetrate into the Milanese. The emperor, however, was sensible that he could not long retain the efforts of two such powerful confederates; nor expect that the same fortunate circumstances would concur a second time in his favor; he therefore thought it necessary, both for his safety and reputation, to give his consent to a truce. Francis, indeed, rather to run the risk of disobliging his new ally the sultan, than to draw on his head the stigma and disrepute, by obstinately obstructing the re-establishment of tranquillity, and contributing to the agrandizement of the infidels.

These considerations inclined the contending monarchs to listen to the arguments of the holy father; but he found it impossible to bring about a final accommodation between them, each inflexibly perceiving in affording his own claims. Nor could he prevail on them to see one another, though both came to the place of rendezvous: for great was the remains of distrust and rancour, or such the difficulty of adjusting the ceremonial! Yet, improbable as it may seem, a few days after signing the truce, the emperor, in his passage to Barcelona, being driven on the coast of Provence, Francis invited him to come ashore; frankly visited him on board his galley, and was received and entertained with the warmest demonstrations of esteem and affection.

Charles, with an equal degree of confidence, paid the king next day a visit at Aigues-mortes; where these two hostile rivals and vindictive enemies, who had acceded each other of every kind of beneficence, conversing together with all the cordiality of brothers, seemed to vie with each other in expressions of respect and friendship.

Besides the glory of having restored tranquillity to Europe, the pope gained a point of much confluence to his family. He obtained for his grandsons, Marguer of Althia, the emperor's natural daughter, formerly wife of Alexander de Medici, whom Charles had raised to the supreme power in Florence. Lorenzo de Medici, the kinman and intimate companion of Alexander, had affiliated him by one of the blackest treasons recorded in history. Under pretence of having secured an assent with a lady of the highest rank and great beauty, he drew him into a secret apartment of his house, and there stabbed him as he lay carelessly on a couch, expecting the embrace of the lovely fair, whom he had often solicited in vain. Lorenzo, however, did not reap the fruits of his crime; for though some of his countrymen extolled him as a third Brutus, and endeavoured to seize this occasion for recovering their liberties, the government of Florence passed into the hands of Cofmo II. another kinman of Alexander. Cofmo was defirous of marrying the widow of his predecessor; but the emperor chose rather to oblige the pope, by betowing his daughter upon Ottavio Farnese, son of the duke of Parma.

Charles had soon farther cause to be sensible of his obligations to the holy father for bringing about the treaty of Nice. His troops everywhere mutinied and wanted of pay, and the ability of his generals only could have prevented a total revolt. He had depended, as his chief resource for discharging the arrears due to his soldiers, upon the subsidies which he expected from his Castilian subjects. For this purpose he assembled the Cortes of Castile at Toledo; and having represented to them the great expence of his military operations, he proposed to levy such supplies as the present exigency of affairs demanded, by a general excise on commodities; but the Spaniards, who already felt themselves oppress'd by a load of taxes unknown to their ancestors, and who had often complained that their country was taxed to drain of its wealth and inhabitants, in order to provide, as they supposed, the imperial army with money, the states general were resolved to oppose the impost; and, on this account, one city more, viz. Valencia, was added to the number of those which had been already summed up.

The emperor's son, finding his father preoccupied with the numerous business of his dominions, and the parliaments of the universities still full of crimes committed by the trained bands, in order to procure a passage through France, it was immediately granted him; and Charles, to whom every moment was precious, set out, notwithstanding the remonstrances of his藩 council and the fears of his Spanish subjects, with a large
small but splendid train of 100 persons. He was met on the frontiers of France by the dauphin and the duke of Orleans, who offered to go into Spain, and remain there as hostages, till he should reach his own dominions; but Charles replied, that the king's honour was sufficient for his safety, and prosecuted his journey without any other security. The king entertained him with the utmost magnificence at Paris, and the two young princes did not take leave of him till he entered the Low Countries; yet he still found means to evade his promise, and Francis continued to believe him sincere.

The citizens of Ghent, alarmed at the approach of the emperor, who was joined by three armies, sent ambassadors to implore his mercy, and offered to throw open their gates. Charles only condescended to reply, "That he would appear among them as a sovereign and a judge, with the sceptre and the sword." He accordingly entered the place of his nativity on the anniversary of his birth; and instead of that lenity which might have been expected, exhibited an awful example of his severity. Twenty-six of the principal citizens were put to death; a greater number were banished; the city was declared to have forfeited its privileges; a new system of laws and political administration was prescribed; and a large fine was imposed on the inhabitants, in order to deprive the enemy of creating a cabal, together with an annual tax for the support of a garrison. They were not only despoiled of their ancient immunities, but made to pay, like conquered people, for the means of perpetuating their own slavery.

Having thus re-established his authority in the Low Countries, and being now under no necessity of continuing that scene of falsehood and dissimulation with which he had ammired the French monarch, Charles began gradually to throw aside the veil under which he had concealed his intentions with respect to the Malines, and at last peremptorily refused to give up a territory of such value, or voluntarily to make such a liberal addition to the strength of an enemy by diminishing his own power. He even denied that he had ever made any promise which could bind him to an action so fool's, and so contrary to his own interest.

This transaction exposed the king of France to as much scorn as it did the emperor to censure. The credulous simplicity of Francis seemed to merit no other return, than experiencing too often the duplicity and arts of his rival. He remonstrated, however, and exclaimed as if this had been the first circumstance in which the emperor had deceived him. The insult offered to his understanding affected him even more sensibly than the injury done to his interest; and he discovered such resentiment as made it obvious that he would feize on the first opportunity of revenge; and that a new war would soon defolate the European continent.

Meanwhile Charles was obliged to turn his attention towards the affairs of Germany. The Protestants having in vain demanded a general council, prevailed on him earnestly to appoint a conference between a select number of divines of each party, in order to examine the points in dispute. For this purpose a diet was assembled at Ratisbon: and such a conference, notwithstanding the opposition of the pope, was held with great solemnity in the presence of the emperor. But the divines chosen to manage the controversy, though men of learning and moderation, were only able to settle a few speculative opinions, all points relative to worship and jurisdiction serving to inflame the minds of the disputants. Charles, therefore, finding his endeavours to bring about an accommodation ineffectual, and being impatient to close the diet, prevailed on a majority of the members to approve of the following edict of reecess; viz. that the articles concerning which the divines had agreed, should be held as points decided; that those about which they had differed, should be referred to the determination of a general council, or if that could not be obtained, to a national synod; and should it prove impracticable also to assemble a synod of Germany, that a general diet of the empire should be called within 18 months, in order to give final judgment on the whole controversy; that, in the mean time, no innovations should be attempted, nor any endeavours employed to gain profelytes.

This diet gave great offence to the pope. The bare mention of allowing a diet, composed chiefly of laymen, to pass judgment in regard to articles of faith, appeared to him no less criminal and profane than the worst of those heresies which the emperor seemed so zealous to suppress. The Protestants also were dissatisfied with it, as it considerably abridged the liberty which they at that time enjoyed. They murmured loudly against it; and Charles, unwilling to leave any seeds of discontent in the empire, granted them a private declaration, exempting them from whatever they thought injurious or oppressive in the reecess, and affecting them to the full possession of all their former privileges.

The situation of the emperor's affairs at this juncture made these extraordinary concessions necessary. He forebore a rupture with France to be unavoidable, and he was alarmed at the rapid progress of the Turks in Hungary. A great revolution had happened in that kingdom. John Zapoly Scappus, by the abstinence of Solymans, had wrested from the king of the Romans a considerable part of the country. John died, and left an infant son. Ferdinand attempted to take advantage of the minority, in order to repel himself of the whole kingdom; but his ambition was disappointed by the adivity and address of George Martinuzzi, bishop of Waradin, who shared the regency with the queen. Sensible that he was unable to oppose the king of the Romans in the field, Martinuzzi satisfied himself with holding out the fortified towns, all of which he provided with every thing necessary for defence; and at the same time he sent ambassadors to Solymans, befeeching him to extend towards the son that imperial protection which had so generously maintained the father on his throne. Ferdinand used his utmost endeavours to thwart this negotiation, and even meanly offered to hold the Hungarian crown on the fame ignominious condition by which John had held it, that of paying tribute to the Porte. But the sultan saw such advantages from engaging the interest of the young king, that he instantly marched into Hungary; and the Germans, having formed the siege of Buda, were defeated with great slaughter before that city. Solymans, however, instead of becoming the protector of the infant sovereign whom he had relieved, made use of this success to extend his own dominions: he sent the queen and her son into Transylvania, which province he allotted them, and added Hungary to the Ottoman empire.

Happily.
Happily for the Protestants, Charles received intelligence of this revolution soon after the diet at Ratisbon; and by the concessions which he made, he obtained such liberal supplies, both of men and money, as left him under little anxiety about the security of Germany. He therefore hastened to join his fleet and army in Italy, in order to carry into execution a great and favourite enterprise which he had concerted against Algiers; though it would certainly have been more convenient with his dignity to have conducted the whole force of the empire against Solymam, the common enemy of Christendom, who was ready to enter his Austrian dominions. But many reasons induced Charles to prefer the African expedition: he wanted strength, or at least money to combat the Turks in so distant a country as Hungary; and the glory which he had formerly acquired in Barbary led him to hope for the like success, while the cries of his Spanish subjects routed him to take vengeance on their ravagers. But the unfortunate event of this expedition has already been related under the article Algiers, No. 14-20.

The loss which the emperor suffered in this calamitous expedition encouraged the king of France to begin hostilities, on which he had been for some time resolved; and an action dishonourable to civil society furnished him with too good a pretext for taking arms. The marquis del Guaito, governor of the Milanese, having got intelligence of the motions and destination of two ambassadors, Roncin and Fergòlo, whom Francis had dispatched, the one to the Ottoman Porte, the other to the republic of Venice; knowing how much his master wished to discover the intentions of the French monarch, and of what consequence it was to retard the execution of his measures, he employed some soldiers belonging to the garrison of Pavia to lie in wait for the ambassadors as they failed down the Po, who murdered them and most of their attendants, and seized their papers. Francis immediately demanded reparation for this barbarous outrage; and as Charles endeavoured to put him off with an evasive answer, he appealed to all the courts of Europe, setting forth the heinoufness of the injury, the iniquity of the emperor in disregarding his just request, and the necessity of vengeance. But Charles, who was a more profound negotiator, defeated in a great measure the effects of these representations: he secured the fidelity of the Protestant princes in Germany, by granting them new concessions; and he engaged the king of England to espouse his cause, under pretence of defending Europe against the Infidels; while Francis was only able to form an alliance with the kings of Denmark and Sweden (who for the first time interled themselves in the quarrels of the more potent monarchs of the fourth), and to renew his treaty with Solymam, which drew on him the indignation of Christendom.

But the activity of Francis supplied all the defects of his negotiation. Five armies were soon ready to take the field, under different generals, and with different designations. Nor was Charles wanting in his preparations. He and Henry a second time made an ideal division of the kingdom of France. But as the hostilities which followed terminated in nothing decisive, and were distinguished by no remarkable event, except the battle of Cerifoles (gained by count d'Enguicien over the imperialists, in which 10,000 of the emperor's best troops fell), at last Francis and Charles, mutually tired of harrying each other, concluded at Crepsey a treaty of peace, in which the king of England was not mentioned; and from being implacable enemies, became elated at once more, to appearance, cordial friends, and even allies by the ties of blood.

The chief articles of this treaty were, that all the conquests which either party had made since the peace of Nies should be restored; that the emperor should give in marriage to the duke of Orleans, either his own eld-er daughter, with the Low Countries, or the second daughter of his brother Ferdinand, with the investiture of the Milanese; that Francis should renounce all pretensions to the kingdom of Naples, as well as to the sovereignty of Flanders and Artois, and Charles give up his claim to the duchy of Burgundy; and that both should unite in making war against the Turks.

The emperor was chiefly induced to grant conditions so advantageous to France, by a design of humbling the Protestant princes in Germany. With the papal jurisdiction, he foresaw they would endeavour to throw off the imperial authority; and he determined to make his zeal for the former a pretence for enforcing and extending the latter. However, the death of the duke of Orleans before the consummation of his marriage disentangled the emperor from the most troublesome stipulation in the treaty of Crepsey; and the French monarch, being still engaged in hostilities with England, was unable to obtain any reparation for the loss which he suffered by this unforeseen event. These hostilities, like those between Charles and Francis, terminated in nothing decisive. Equally tired of a struggle attended with no glory or advantage to either, the contending princes concluded, at Campe, near Ardies, a treaty of peace; in which it was stipulated, that France should pay the arrears due by former treaties to England. But these arrears did not exceed one-third of the sums expended by Henry on his military operations; and Francis being in no condition to discharge them, Boulogne (a chargeable pledge) was left in the hands of the English as a security for the debt.

In consequence of the emperor's resolution to humble the Protestant princes, he concluded a dishonourable obliged to conclude a disadvantageous peace with the Turks and Infidels, and was forced to pay tribute for that part of Hungary which he still possessed; whilst the sultan enjoyed the imperial and undisturbed possession of all the rest. At the same time he entered into a league with pope Paul III. for the extirpation of heresy; but in reality, with a view to oppress the liberties of Germany. Here, however, his ambition met with a severe check; for though he was successful at first, he was compelled in 1552 to conclude a peace with the Protestants on their own terms; as has been related under the article Reformation, No. 26-32.

By the peace concluded on this occasion the emperor attempted to recover the barrier of the empire on that quarter; and therefore, soon after put himself at the head of an army, in order to recover these three bishoprics. In order to conceal the destination of his army, he gave out, that he intended to lead it into Hungary, to second Maurice in his operations against the Infidels; and as that pretext failed him, when he began to advance towards the Rhine, he propagated a report that he was marching
first to chastise Albert of Brandenburgh, who had refused to be included in the treaty of Paffan, and whose cruel exactions in that part of Germany called loudly for redress.

The French, however, were not deceived by these arts. Henry immediately guessed the true object of Charles's armament, and resolved to defend his conquests with vigour. The defence of Metz, against which it was foreseen the whole weight of the war would be concentrated, was committed to Francis of Lorraine, duke of Guise, who possessed in an eminent degree all the qualities that render men great in military command. He repaired with joy to the dangerous station; and many of the French nobility, and even princes of the blood, eager to distin­guish themselves under such a leader, entered Metz as volunteers. The city was of great extent, ill fortified, and the suburbs large. For all these defects the duke endeavoured to provide a remedy. He repaired the old fortifications with all possible expedition, labouring with his own hands; the officers imitated his example; and the soldiers, thus encouraged, cheerfully submitted to the most severe toils; he erected new works, and he levelled the suburbs with the ground. At the same time he filled the magazines with provisions and military stores, compelled all useless persons to leave the place, and laid waste the neighbouring country; yet such were his popular talents, as well as his arts of acquiring an ascendant over the minds of men, that the citizens not only refrained from murmuring, but seconded him with no less ardour than the soldiers in all his operations—in the ruin of their edifices, and in the havoc of their public and private buildings.

Meanwhile the emperor continued his march towards Lorraine, at the head of 60,000 men. On his approach Albert of Brandenburgh, whose army did not exceed 20,000, withdrew into that principality, as if he intended to join the French king; and Charles, notwithstanding the advanced season, it being towards the end of October, laid siege to Metz, contrary to the advice of his most experienced officers.

The attention of both the besiegers and the besieged was turned for some time towards the motions of Albert, who still hovered in the neighbourhood, undetermined which side to take, though resolved to fell his service. Charles at last came up to his price, and he joined the imperial army. The emperor now flattered himself that nothing could resist his force; but he found himself deceived. After a siege of almost 60 days, during which he had attempted all that was thought possible for art or valour to effect, and had lost upwards of 30,000 men by the inclemency of the weather, difficulties, or the frowning of the enemy, he was obliged to abandon the enterprise.

When the French fell out to attack the enemy’s rear, the imperial camp was filled with the sick and wounded, with the dead and dying. All the roads by which the army retired were strewn with the same miserable objects; and, having made an effort beyond their strength to escape, and not being able to proceed, were left to perish without assistance. Happily that, and all the kind offices which their friends had not the power to perform, they received from their enemies. The duke of Guise ordered them all to be taken care of, and supplied with every necessary; he appointed physicians to attend, and directed what treatment was proper for the sick and wounded, and what refreshments for the feeble; and such as recovered he sent home, under an escort of soldiers, and with money to bear their charges. By these acts of humanity, less common in that age, the duke of Guise completed that heroic character which he had justly acquired by his brave and successful defence of Metz.

The emperor’s misfortunes were not confined to Ger­many. During his residence at Villach, he had been obliged to borrow 200,000 crowns of Cosimo de’ Me­dicis; and so low was his credit, that he was obliged to put Cosimo in possession of the principality of Pumbino as a security for that inconsiderable sum; by which means he lost the footing he had hitherto maintained in Tuscany. Much about the same time he lost Siena. The citizens, who had long enjoyed a republican government, rose against the Spanish garrison, which they had admitted as a check upon the tyranny of the nobility, but which they found was meant to enslave them; forgetting their domestic animosities, they recalled the exiled nobles; they demolished the citadel, and put themselves under the protection of France.

To these unfortunate events one still more fatal had almost succeeded. The severe administration of the viceroy of Naples had filled that kingdom with murmuring and dissatisfaction. The prince of Salerno, the head of the malcontents, fled to the court of France. The French monarch, after the example of his father, applied to the grand signior; and Solyman, at that time highly incensed against the house of Austria on account of the proceedings in Hungary, sent a powerful fleet into the Mediterranean, under the command of the corsair Dragut, an officer trained up under Barba­roff, and scarce inferior to his master in courage, talents, or in good fortune. Dragut appeared on the coast of Calabria at the time appointed; but not being joined by the French fleet according to concert, he returned to Constantinople, after plundering and burning several places, and filling Naples with confusion.

Highly mortified by so many disasters, Charles retired into the Low Countries, breathing vengeance against France: and here the war was carried on with considerable vigour. Impatient to efface the stain which his military reputation had received before Metz, Charles laid siege to Terouan; and the fortifications being in di­srepair, that important place was carried by assault. Hes­tin also was invested, and carried in the same manner. The king of France was too late in assembling his forces to afford relief to either of these places; and the emperor afterwards cautiously avoided an engagement.

The imperial arms were less successful in Italy: The vic­eroy of Naples failed in an attempt to recover Sienna; and the French not only established themselves more firmly in Tuscany, but conquered part of the island of Corfu. Nor did the affairs of the house of Austria go on better in Hungary during the course of this year. Isabella and her fiancé appeared once more in Transylvania, at a time when the people were ready for revolt, in order to revenge the death of Martinozzi, whose loss they had severely felt. Some noblemen of eminence declared in favour of the young king; and the bashaw of Belgrade, by Solyman’s order, expelling his caufes,
in opposition to Ferdinand, Castaldo, the Austrian general, was obliged to abandon Transylvania to Isabella and the Turks.

In order to counterbalance these and other losses, the emperor, in 1544, concerted a marriage between his son Philip and Mary of England, in hopes of adding that kingdom to his other dominions. Meanwhile the war between Henry and Charles was carried on with various successes in the Low Countries, and in Italy much to the disadvantage of France. The French, under the command of Strozzi, were defeated in the battle of Merciano; Sienna was reduced by Medicino, the Florentine general, after a siege of ten months; and the gallant Siene was subjected to the Spanish yoke. Much about the same time a plot was formed by the Franciscans, but happily discovered before it could be carried into execution, to betray Metz to the Turks. Meanwhile the emperor Charles had formed a plan of religious pacification agreed upon at Passau and referred to the consideration of the next meeting of the Germanic body. During the negotiation of this treaty, an event happened which astonished all Europe, and confirmed the fears of the wisest politicians.

The emperor Charles V., though no more than 56, an age when objects of ambition operate with full force on the mind, and are generally pursued with the greatest ardour, had for some time formed the resolution of resigning his hereditary dominions to his son Philip. He now determined to put it in execution. Various have been the opinions of historians concerning a resolution so singular and unexpected; but the most probable seem to be, the disappointments which Charles had met with in his ambitious hopes, and the daily decline of his health. He had early in life been attacked with the gout; and the fits were now become so frequent and severe, that not only the vigour of his constitution was broken, but the faculties of his mind were severely impaired. He therefore judged it more decent to conceal his infirmities in some solitude, than to expose them any longer to the public eye; and as he was unwilling to forfeit the fame, or lose the acquisitions of his better years, by attempting to guide the reins of government when he was no longer able to hold them with steadiness, he determined to seek in the tranquillity of retirement, that happiness which he had in vain pursued amidst the tumults of war and the intrigues of state.

In consequence of this resolution, Charles, who had already ceded to his son Philip the kingdom of Naples and the duchy of Milan, assembled the states of the Low Countries at Brussels; and seating himself for the last time in the chair of state, he explained to his subjects the reasons of his resignation, and solemnly declared his authority upon Philip. He recounted with dignity, but without ostentation, all the great things which he had undertaken and performed since the commencement of his administration. "I have dedicated observed he), from the 17th year of my age, all my thoughts and attention to public objects, sparing no portion of my time for the indulgence of ease, and very little for the enjoyment of private pleasure. Either in a pacific or hostile manner, I have visited Germany nine times, Spain six times, France four times, Italy seven times, the Low Countries ten times, England twice, Africa as often; and while my health permitted me to discharge the duty of a sovereign, and the vigour of my constitution was equal in any degree to the arduous office of governing such extensive dominions, I never shunned labour, nor repined under fatigue; but now, when my health is broken, and my vigour exhausted by the rage of an incurable distemper, my growing infirmities admonish me to retire; nor am I to fond of reigning, as to retain the sceptre in an impotent hand, which is no longer able to protect my subjects. Instead of a sovereign worn out with diseases (continued he), and scarce half alive, I give you one in the prime of life, already accustomed to govern, and who adds to the vigour of youth all the attention and sagacity of mature years." Then turning towards Philip, who fell on his knees, and kissed his father's hand, "It is in your power (said Charles), by a wife and virtuous administration, to justify the extraordinary proof which I give this day of my paternal affection, and to demonstrate that you are worthy of the extraordinary confidence which I repose in you. Persevere (added he) an inviolable regard for religion; maintain the Catholic faith in its purity; let the laws of your country be sacred in your eyes; encroach not on the rights of your people; and if the time should ever come when you shall wish to enjoy the tranquillity of private life, may you have a son to whom you can resign your sceptre with as much satisfaction as I give up mine to you." A few weeks after, he resigned to Philip the sovereignty of Spain and America, reserving nothing to himself out of all these vast possessions but an annual pension of 100,000 crowns.

Charles was now impatient to embark for Spain, where he had fixed on a place of retreat; but by the advice of his physicians, he put off his voyage for some months, on account of the severity of the season; and, by yielding to their judgment, he had the satisfaction before he left the Low Countries of taking a considerable step towards a peace with France. This he ardently longed for; not only on his son's account, whose administration he wished to commence in quietness, but that he might have the glory, when quitting the world, of restoring to Europe that tranquillity which his ambition had banished out of it almost from the time that he assumed the reins of government.

The great bar to such a pacification, on the part of France, was the treaty which Henry had concluded with the Pope; and the emperor's claims were too numerous to hope for adjusting them suddenly. A truce of five years was therefore proposed by Charles; during which term, without discarding their respective pretensions, each should retain what was in his possession; and Henry, through the perfunation of the con-fident Montmorency, who represented the imprudence of sacrificing the true interests of his kingdom to the rash engagements that he had come under with Paul, authorized his ambassadors to sign at Vaucelles a treaty, which
which would inflame to him for so considerable a period the important conquest which he had made on the German frontier, together with the greater part of the duke of Savoy's dominions.

The Pope, when informed of this transaction, was no less filled with terror and astonishment than rage and indignation. But he took equal care to conceal his fear and his anger. He affected to approve highly of the truce; and he offered his mediation, as the common father of Christendom, in order to bring about a definitive peace. Under this pretence, he appointed cardinal Ribuso his nuncio to the court of Brussel, and his nephew cardinal Caraffa to that of Paris. The public instructions of both were the same; but Caraffa, besides these, received a private commission, to spare neither intrigues, promises, nor bribes, in order to induce the French monarch to renounce the truce and renew his engagements with the holy see. He flattered Henry with the conquest of Naples; he gained by his addresses the Guises, the queen, and even the famous Diana of Poitiers, the king's mistresses; and they easily fayed the king himself, who already leaned to that side towards which they wished to incline him. All Montmorency's prudent remonstrances were disregarded; the nuncio (by powers from Rome) absolved Henry from his oath of truce; and that weak prince signed a new treaty with the Pope; which rekindled with fresh violence the flames of war, both in Italy and the Low Countries.

No sooner was Paul made acquainted with the success of this negotiation than he proceeded to the most indelicatc extortions against Philip. He ordered the Spanish ambassador to be imprisoned; he excommunicated the Colonnas, because of their attachment to the imperial house; and he considered Philip as guilty of high treason, and to have forfeited his right to the kingdom of Naples, which he was supposed to hold of the holy see, for afterward affording them a retreat in his dominions.

Alarmed at a quarrel with the Pope, whom he had been taught to regard with the most superstitious reverence, as the viceroy of Christ and the common father of Christendom, Philip tried every gentle method before he made use of force. He even consulted some Spanish divines on the lawfulness of taking arms against a person so sacred. They decided in his favour; and Paul continuing inexorable, the duke of Alva, to whom the negotiations as well as the war had been committed, entered the ecclesiastical state at the head of 10,000 veterans, and carried terror to the gates of Rome.

The haughty pontiff, though still inflexible and undaunted in himself, was forced to give way to the fears of the cardinals, and a truce was concluded for 40 days. Mean time the duke of Guise arriving with a supply of 20,000 French troops, Paul became more arrogant than ever, and banished all thoughts from his mind but those of war and revenge. The duke of Guise, however, who had precipitated his country into this war, chiefly from a desire of gaining a field where he might display his own talents, was able to perform nothing in Italy worthy of his former fame. He was obliged to abandon the siege of Civetella; he could not bring the duke of Alva to a general engagement; his army perished by diseases; and the Pope neglected to furnish the necessary reinforcements. He begged to be recalled; and France stood in need of his abilities.

Philip, though willing to have avoided a rupture, was no sooner informed that Henry had violated the truce of Vaucelles, than he determined to act with such vigour, as should convince Europe that his father had not erred in resigning to him the reins of government. He immediately assembled in the Low Countries a body of 50,000 men, and obtained a supply of 10,000 from England, which he had engaged in his quarrel; and as he was not ambitious of military fame, he gave the command of his army to Emanuel Philibert duke of Savoy, one of the greatest generals of that warlike age.

The duke of Savoy kept the enemy for some time in suspense with regard to his destination; at last he seemed to threaten Champagne; towards which the French drew all their troops; then turning suddenly to the right, he advanced by rapid marches into Picardy, and laid siege to St Quintin. It was deemed in those times a town of considerable strength; but the fortifications had been much neglected, and the garrison did not amount to a fifth part of the number requisite for its defence: it must therefore have surrendered in a few days, if the admiral de Coligny had not taken the garrison out of the town. This he effected in spite of the enemy, breaking through their main body. The place, however, was closely invested; and the capable Montmorency, anxious to extricate his nephew out of that perilous situation, in which his zeal for the public had engaged him, as well as to save a town of such importance, rashly advanced to its relief with forces one half inferior to those of the enemy. His army was cut in pieces, and he himself made prisoner.

The cautious temper of Philip on this occasion saved France from devastation, if not ruin. The duke of Savoy proposed to overlook all inferior objects, and marches speedily to Paris, which, in its present condition, he could not have failed to make himself master of; but Philip, afraid of the consequences of such a bold enterprise, desired him to continue the siege of St Quintin, in order to secure a safe retreat in case of any disfavourable event. The town, long and gallantly defended by Coligny, was at last taken by storm; but not till France was in a state of defence.

Philip was now sensible that he had lost an opportunity which could never be recalled, of disturbing his enemy, and contented himself with reducing Horn and Cateau; which petty towns, together with St Quintin, were the sole fruits of one of the most decisive victories gained in the 16th century. The Catholic king, however, continued in high exaltation on account of his successes; and as all his passions were tinged with superstitious ardour, he vowed to build a church, a monastery, and a palace, in honour of St Laurence, on the day theie were +

The Lilly which dictated the vow dictated the building. It was so formed as to resemble a gridiron—on which culinary instrument, according to the legendary tale,
St. Lawrence had suffered martyrdom. Such is the origin of the famous clerical near Madrid, the royal residence of the kings of Spain.

The first account of that fatal blow which France had received at St. Quintin, was carried to Rome by the courtier whom Henry had sent to recall the duke of Guise. Paul remonstrated warmly against the departure of the French army; but Guise's orders were peremptory. The arrogant pontiff therefore found it necessary to accommodate his conduct to the exigency of his affairs, and to employ the mediation of the Venetians, and of Cosimo de Medici, in order to obtain peace. The first overtures of this nature were eagerly listened to by the Catholic king, who still doubted the justice of his cause, and considered it as his greatest misfortune to be obliged to contend with the Pope. Paul agreed to renounce his league with France; and Philip stipulated on his part, that the duke of Alva should repair in person to Rome, and after asking pardon of the holy father in his own name and in that of his master, for having invaded the territory of the church, should receive abjuration from that crime. Thus Paul, thro' his presumptuous timidity of Philip, not only furnished an unpromising war without any detriment to the apostolical see, but saw his conqueror humbled at his feet, and to excessive war the veneration of the Spaniards in that age for the papal character, that the duke of Alva, the proudest man perhaps of his time, and accustomed from his infancy to converse with princes, acknowledged, that when he approached Paul, he was so much overawed, that his voice failed, and his presence of mind forsook him.

But though this war, which at its commencement threatened mighty revolutions, was terminated without occasioning any alteration in those states which were its immediate object, it produced effects of considerable consequence in other parts of Italy. In order to detach Othoavio Farneze, duke of Parma, from the French interests, Philip restored to him the city of Piacenza and its territory, which had been seized by Charles V., and he granted to Cosimo de Medici the inviolability of Siena, as an equivalent for the sums due to him. By these treaties, the balance of power among the Italian states was restored to its former equality, and even Alva, from his infancy to converse with princes, acknowledged, that when he approached Paul, he was so much overawed, that his voice failed, and his presence of mind forsook him.

The French, who left Rome the same day that his adversary the duke of Alva made his humiliating submission to the Pope, was received in France as the guardian angel of the kingdom. He was appointed lieutenant-general in chief, with a jurisdiction unlimited; and, eager to justify the extraordinary confidence which the king had reposed in him, as well as to perform something suitable to the high expectations of his countrymen, he undertook in winter the siege of Calais. Having taken that place, he next invested Thionville in the duchy of Luxembourg, one of the strongest towns on the frontiers of the Netherlands; and forced it to capitulate after a siege of three weeks. But

the advantages on this quarter were more than balanced by an event which happened in another part of the Low Countries. The mareschal de Termes governor of Calais, who had penetrated into Flanders and taken Dunkirk, was totally routed near Gravelines, and taken prisoner by count Egmont. This disaster obliged the duke of Guise to relinquish all his other schemes, and hasten towards the frontiers of Picardy, that he might oppose the progress of the enemy.

The eyes of all France were now turned towards the Duke of Guise, as the only general on whose arms victory always attended, and in whose conduct as well as good fortune they could confide in every danger. His strength was nearly equal to the duke of Savoy's, each commanding at the distance of a few about 40,000 men. They encamped at the distance of a few leagues one from another; and the French and Spanish monarchs having joined their respective armies, it was expected that, after the vicissitudes of war, a decisive battle would at last determine which of the rivals should take the ascendant for the future in the affairs of Europe. But both monarchs, as if by agreement, stood on the defensive; neither of them discovering any inclination, though each had it in his power, to ret the decision of a point of such importance on the issue of a single battle.

During this state of inaction, peace began to be mentioned in each camp, and both Henry and Philip discovered an equal disposition to listen to any overture that tended to re-establish it. The private inclinations of both kings concurred with their political interests and the wishes of their people. Philip languished to return to Spain, the place of his nativity; and peace only could enable him, either with decency or safety, to quit the Low Countries.

Henry was now desirous of being freed from the avocations of war, that he might have leisure to turn the whole force of his government towards suppressing the opinions of the reformers, which were spreading with such rapidity in Paris and the other great towns, that they began to grow formidable to the established church. Court-intrigues confined with these public and avowed motives to hale the negociation, and the abbey of Ceremamp was fixed on as the place of concert.

While Henry was making these advances towards a treaty which restored tranquility to Europe, Charles V., whose ambition had so long disturbed it, but who had been for some time dead to the world, ended his days in the monastery of St. Julius in Etremadura, which he had chosen as the place of his retreat, as is particularly related under the article Charles V.

After the death of Charles, the kingdom of Spain soon lost great part of its consequence. Though Charles had used all his interest to get his son Philip elected emperor of Germany, he had been totally disapproved; and thus the grandeur of Philip II. never equalled that of his father. His dominions were also considerably abridged by his tyrannical behaviour in the Netherlands.

In consequence of this, the United Provinces revoked; and after a long and bloody war obtained their liberty. The United Provinces. In this quarrel Elizabeth of England took part against Philip, which brought on a war with Spain. The great losses he sustained in these wars expatriated the kingdom of both men and goods, notwithstanding the great sums imported from America. Indeed, the discovery and conquest of that country hath much impoverished, instead,

Spain—the most considerable are the Ebro, formerly Iterus, Guadalquivir, and the Ebro; Guadalupe, or Bethis, Segura, and Xucar.

Religion.

The Spaniards are zealous Romanists. Nowhere is there more pomp, farce, and parade, in what regards religion; and nowhere less true Christianity. Their zeal and their superstitious excess of that of any other Roman Catholic country, unless perhaps we should except Portugal. Nowhere did the inquisition reign with greater terror; there being no subject who was not liable to be professed by the holy office, as it is called; however, the powers of that tribunal are now greatly diminished even in Spain. There are eight archbishops in Spain, even in America, and one in Asia at Manila; each of which has his suffragan bishops. The archbishop of Toledo is primate, chancellor of Castile, and, by virtue of his office, privy councilor. He is said to have a revenue of 100,000. Sterling per annum, or more. The king nominates all archbishops and bishops; and since 1754, all small benefices are also in his gift. He has also lately obtained a power to tax ecclesiastical possessions, according to his pleasure and the exigency of affairs. Though the rest of the nation is poor, the clergy are immensely rich, and their revenues of all kinds very great. Most of the towns and estates belong to them, and are exempt from all public burdens; yet their avarice is inextinguishable, especially that of the mendicant friars, though they profess poverty. Their commerce, which is free from all duties and imposts, is also a rich fund to them. Though the Spaniards are naturally men of wit and of an elevated genius, yet little progress in the sciences is to be expected from them, while the clergy use their utmost efforts to keep them in ignorance, branding all literary researches with the name of heresy, and inveighing against the feats of the muses as the schools of hell, where the devil teaches forcery. There are 32 universities, and several academies, in Spain; but so constituted, and under such restrictions, that they can never attain to any measure of true learning. There are few printing-houses in Spain; and most of the books in that language are published in other countries.

Trade and manufactures.

In regard to trade and manufactures, the Spaniards are far from making such a figure as might be expected. Most of the laborious work in their husbandry, manufactures, and handicrafts, is performed by the French, especially in the two Castiles and the midland provinces, the natives being either too lazy or too proud to flock to such employments. By the means, the French usually return with large fortunes to their own country. The chief manufactures of Spain are those of silk, wool, iron, copper, and other hardwares; but the fall far short of the flourishing condition to which they might be brought; hence a great part of the treasures of America go to the foreign merchants, who supply them with goods for that part of the world. However, it is certain, that Spain, since it hath had princes of the house of Bourbon upon the throne, hath improved its revenues, increased its forces by sea and land, and applied itself more than it did before to manufactures and husbandry; having shaken off, in some measure, that ill indolent disposition which rendered it so contemptible in the eyes of other nations; but it will be a long time before they will be able to supply the wants of their own country, and those of America, in any great degree. Spain is extremely well situated for trade: but most of its produce is exported by foreigners, except what is carried to the Indies; and even with regard to that trade, they are little better than factors to the English, French, Dutch, and Italians. Smugglers, which was formerly carried to a great height, is now in a great measure suppressed. Since the year 1750, the exportation of silver hath been allowed on the payment of 3 per cent. From 1735 almost to 1776, the flota and galleons were discontinued, and the trade to America carried on in regifter-ships, which any merchant might send, on permission obtained from the council of the Indies; but then the flota and galleons were restored. The Aviso-ships are two vessels which carry quicksilver on the king's account to Vera Cruz. There is a company which has an exclusive Grant for trading to the Caraccas; and another for trading to Porto Rico, the Bay of Honduras, the province of Guatemala and Honduras; but the Spanish part of the latter, it is said, hath been lately ceded to the French. One ship, and sometimes two, sail annually from Manila in the island of Luzon, one of the Philippines, for Acapulco in Mexico; her cargo, which belongs to the convents, consists of the principal commodities of that part of the world; but the return from Acapulco is for the most part made in money, and amounts to a vast sum, as appeared from the treasure found on board the Acapulco ship taken by Lord Anson. In return for the manufactures sent to America, the Spaniards receive gold, silver, cochineal, indigo, the coca or chocolate nut, logwood and other dyeing woods, sugar, tobacco, snuff, and other productions of that part of the world; supplying most part of Europe and Asia with the silver which they bring from thence in their galleons. In the time of the Moors and Goths, this kingdom was exceedingly populous. It is said to have then contained between twenty and thirty millions; whereas now it does not contain above nine: and this, among other causes, is owing to the pride and laziness of the inhabitants, want of manufactures and good regulations, neglect of the mines and agriculture, the expulsion of the Moors, the peopling of America, heavy taxes, the great number of convents, excessive venery, and the consequent infecundity of both sexes. Their debauchery and sterility are partly occasioned by their way of living; for they make great use of spices, and drink a great deal of chocolate, and strong wine mixed with brandy. The cauets assigned for the want of people in Spain will account in some measure for its poverty; notwithstanding it is computed that it receives one year with another, letting aside other sums, above 26 millions of pieces of eight, in registered gold and silver. As most of the manufactures that are sent to America are furnished by Britain, France, Italy, and Holland; a great part of the treasure brought home by the galleons is paid to the merchants of those nations.

The constitution of Spain is at present an absolute, hereditary monarchy, where the females inherit in default of the males. The king, in his title, enumerates vermilion.

The king, in his title, enumerates vermilion.

most of the provinces and particular parts of the dominions he has been or is possessed of. In speaking of him, he is commonly called his Catholic Majesty, or the Catholic King. The hereditary prince is commonly styled Prince of Asturias, and the other royal children Infants. The kings of Spain are never crowned; they seem
The general history of Spain proves how great an influence the Cortes had in former times in the most important affairs of government; such as war or peace, and the levying of taxes. But during a long course of years they have not been assembled, except for the sake of form; and the sovereigns, without violence, or formally rejecting their intervention, have found means to elude their authority. They promulgate from the throne certain ordinances under the name of Pragmatics, the preamble of which give us to understand, that they claim the same authority as if they had been published in the assembly of the Cortes; who are never convoked but at the accession of a new monarch, to administer to him an oath in the name of the Cortes representative of all the deputies of the kingdom. The two first clauses represent the nobility; the prelates sit in the name of the clergy; and the cities, which depute one of their magistrates, represent the people.* Except on the above-mentioned occasion, the Cortes of the whole kingdom have been assembled but twice during the present century, and only once upon public business, in the year 1713, when Philip V. convoked them to give their approbation to the Pragmatic Sanction, which changed the order of succession to the throne. They are still confounded, for the sake of form, in certain cases; but then, the members of which they are composed correspond with each other without assembling. At their breaking up in 1713, it was regulated, that they should be represented by a permanent committee, whose office it should be to watch over the administration of that part of the taxes known by the name of Millones, and which had been granted under Philip II., with the formal consent of the Cortes, upon certain conditions, which the monarch swore to observe. They retained the administration of these impôts until the year 1718, when cardinal Alberoni, whole ardent and imperious genius was irritated at such shackles, transferred it to the hands of the sovereign. From that time, the assemblies of the deputies of the kingdom have received no more of the revenues of the state than is necessary to pay the salaries and defray the expenses of the members. There are eight in number, and are chosen in the following manner: All the provinces of Castile unite to nominate six; Catalonia and Majorca appoint one; and the regencies of Valencia and Aragon elect the eighth. These deputies hold their places six years, at the end of which a new election takes place in the same manner. As a relic of their ancient rights, they still retain the privilege of being, by virtue of their places, members of the council of finances, by which the sovereign communicates to the nation the necessity of levying any new tax; and the approbation they are supposed to give to the royal resolution, is a shadow of the content of the Cortes, without which taxes could not formerly be either levied or augmented. But it is easy to perceive, how feeble this rampart of liberty must be, which is only formed of a small number of citizens, who possess little real power; are under the control of government, from which they expect favours and preferences; and who, after all, represent the most numerous indeed, but least respected, part of the nation. The provinces of Biscay and Navarre, which have assemblies and particular privileges, fend also, on certain occasions, deputies to the throne; but they do not make a part of the body of the deputies of the kingdom, and their constituents fix at pleasure the object and duration of the temporary mission.

The administration of Spain is divided into fixed principal departments. The minister for foreign affairs is in many respects the dwelling minister, and receives, as a mark of distinction, the title of secretary of state. The minister of war has but a circumscribed authority. He is president of the council of war, which is rather a tribunal than a board of administration; but the inspectors of the infantry, and those of the cavalry, dragoons, and provincial regiments, draw up a statement of whatever relates to the corps of which they have the direction; and the minister at war has only to present the memorial they give in to the king. The marine minister has no associates. The chiefs of the three departments of Ferrol, Carthagena, and Cadiz, and inspectors of the marine, are named by the king, on the representation of the minister; but the marine ordinances prepared by him alone, require only the function of the king. The minister of the finances should properly be under the inspection of the superintendent-general of that department; but these two offices were some time since united, and will probably be continued; for the separation of them would multiply, without necessity, the spnings of government, and signify nothing; but the minister of finance requires that they should be simplified as much as permanent forms of those sacred bulwarks of justice and property, will admit.

The higher nobility consist of counts, marquises, and dukes. The grandees, who have precedence of all others, next the king and princes of the blood, are named out of these. They have the privilege of being covered in the king's presence, who styles them in his letters Illustrious; and in speaking to them or of them, their Eminencies: but there are others besides the grandees who are covered in the king's presence; as cardinals, nuncios, archbishops, the grand prior of Castile and the grand prior of Malta, the generals of the orders of St. Dominie and St. Francis, ambassadors of crowned heads, the knights of the golden fleece, and of the three military orders of St. James, Claretta, and Alcantara, when the king allows them at their respective chapters in quality of grandmaster. No grandee can be apprehended for any crime but by the express order of the king; and they have many other privileges besides these. The inferior nobility style themselves Cavalleros and Hidalgos.

Of the orders in Spain, that of the golden fleece, is the
the principal: which was instituted in 1430 by Philip the good duke of Burgundy, and is common now to the kings of Spain and the house of Austria. The order of St Jagc de Campotelli was instituted in the year 1175 by Ferdinand II. king of Leon. The order of Calatrava was founded by Sancho III. of Castile. The order of Alcantara owes its institution to Ferdinand II. king of Leon. The three last orders have large commanderies or estates annexed to them. The matters of them were once so powerful, that they disputed the king's authority over them; whereupon the king procured them matters to be conferred on himself by the Pepe, that they might no longer assume an independence of the state. The knights of these three orders are esteem'd noblemen.

In the last century, the revenues of Spain amounted to 32 or 33 millions of livres; but afterwards they were so reduced, that they did not exceed seven or eight millions. At present, the revenues of the crown arising in Spain are computed at five millions Sterling per annum, besides what arises from America. The silver mines there are inexhaustible; and of the produce of these a fifth belongs to the king. The taxes in Spain are numerous and heavy. The land forces, in time of peace, are computed at about 80,000: and in time of war, must be much more numerous. Their navy at present cannot be ascertained.

The language of this country, especially that spoken in Castile, which is by far the purest, approaches the nearest to the Latin of any language in Europe, mixed with Arabic words and terminations introduced by the Moors. In some provinces, the vulgar tongue is a dialect of the old French, or rather Gallicon, which is little understood in the others. In Bisay, the language is said to be a dialect of the Gothic or Celtic, and to have some analogy with the Welsh and Irish. As to what regards the character of the Spaniards, they do not want either an inclination or capacity for the sciences; but have hardly an opportunity of acquiring any true learning or knowledge, at least in their schools and universities. They are admired for their ferocity, confiancy, gravity, patience in adversity, and loyalty. They are also said to be true to their word, great enemies to lying, and so nice and jealous in point of honour, that they will fight at nothing or any thing that is call upon it. Among their vices and defects are reckoned their pride and contempt of foreigners, their indolence, laziness, lust, bigotry, and credulity in believing the feigned miracles and legends of their saints. They are also said to be extremely passionate, jealous, and vindictive; and are noted, above any other European nation, for defpising and neglecting agriculture, arts, and manufactures.

We will here subjoin some directions for travelling in Spain by Mr. Townsend, a late respectable traveller; as they will enable the reader to form a more distinct notion of the state of that country than he could obtain from general description.

To travel commodiously in Spain, a man should have a good constitution, two good servants, letters of credit for the principal cities, and a proper introduction to the best families, both of the native inhabitants and of foreigners settled in the country.

The language will be easily acquired.

His servants should be Spaniards and from the art of cooking, and with the superior art of providing for the journey; which implies a perfect knowledge of the country through which he is to pass, that he may secure a flock of wine, bread, and meat, in places where these excel, and such a flock as may be sufficient to carry him through the districts in which these are not to be obtained. For himself, his servants, and his baggage, he should purchase three strong mules, able to support the load which is to be put upon them. In his baggage he should have fleeces, a mattress, a blanket, and a quilt, a tablecloth, knives, forks, and spoons, with a copper vessel sufficiently capacious to boil his meat. This should be furnished with a cover and lock. Each of the servants should have a gun slung by the side of his mule. To travel as an economist in Spain, a man must be contented to take his chance for conveyance, and either go by the poll, wherever it is established; or join with officers, going to their various stations; to hire a coach, or quietly reign himself to a calash, a calasina, a horse, a mule, or a burrico. This last is the most convenient for the purpose of crossing the country, or of wandering among the mountains. If he is to traverse any district infested by banditti, it will be safe for him to go by the common carriers, in which case he will be mounted on a good mule, and take the place which would have been occupied by some bale of goods. Any one, who is fond of botany, for short excursions, will make choice of a burrico. This is always to be had when, as in some villages, neither horse nor mule are to be obtained. I have used this honourable appellation for the most patient of all animals, because I would not shock the delicacy of a young traveller, by telling him, at his first setting out, that he may sometimes find himself under the necessity of riding upon an ass. He must, however, know, for his consolation, that an ass does not appear so contemptible in Spain as in the colder regions of the north.

The best time for him to begin this expedition is in autumn, when he may go by Bayonne, Burgos, Valldolid, and Segovia, hailing to the court at St Ildefonso. Here he is to procure letters for the chief cities in Spain. On these will depend the whole pleasure of his excursion. During the winter he may see all the south of Spain, Toledo, Cordova, Seville, Cadiz, Gibraltar, Malaga, Granada, Carthagena, Murcia, Alicant, Valencia, and Barcelona. Returning by Zaragoza to Aranjuez in the spring, he may follow the Merino flock to the mountains of the north, whilst the country, on which he has turned his back, is rendered unfit for travelling, by the dissolving heat, by want of provisions, and by malignant fevers. This season will be best employed in Galicia, the Afturias, and the provinces of Bisay, taking Salamanca and Leon in the way.

New Spain. See Mexico.

SPALATRO, or SPALATO, a rich, populous, and thriving town of the republic of Venice, capital of Venetian Dalmatia, with a good harbour and an archbishop's see. Here are the ruins of the palace of Dicollan, of which the late Mr. Robert Adam published in 1764 a splendid account, enriched with 71 foine plates. In 1794, Spalato was nearly depopulated by the plague. It is strong in situation, being built on a peninsula, which is joined to Terra Firma by a neck of land half a mile over. It is seated on the Gulf of Venice, 35 miles south—
SPAN, or the running or dropping of water, containing a large number of plants belonging to the class of monocots, and to the order of triandra; and in the natural system ranged under the 3d order, Calamaria. The amentum of the

Vol. XVII.
male flower is roundish, the calyx is triphyllous, and there is no corolla. The amentum of the female flower resembles that of the male. The stigma is bifid; the fruit is a dry berry containing one seed. There are two species, the erectum and natans, both of them natives of Great Britain and Ireland. 1. The Erectum, great bur-reed, has a stem two or three feet high, erect, firm, and branched; the lower leaves are triangular, the upper ones plain. The male heads are much smaller than the female. This species flowers in July, and is frequent on the banks of rivers and lakes and near stagnant waters. 2. The Natans, floating or little bur-reed, has a stalk about two feet long. The leaves float, are about a foot long, one fourth of an inch wide at the base, and one-eighth in the middle, and end in a point. The male spherules are generally three, and all sessile; the female are commonly three, the two lower being supported on peduncles, the uppermost sessile. It flowers in July, and grows in pools and lakes, but is rare.

SPARMANNIA, in botany; a genus of plants belonging to the class of Polyandria, and to the order of Monogyna. The corolla consists of four petals, and bent back; the nectaria are numerous, and swell a little; the calyx is quadrphyllous; the capsule is angulated, quinquelocular and exinated. There is only one species, the Africana.

SPARTA, or LacEdemon, the capital of the country of Laconia in Greece, an ancient and most renowned state, the inhabitants of which have been in all ages celebrated for the singularity of their laws and characters. The history of Sparta for many ages is entirely fabulous; and the authentic accounts commence only with the celebrated lawgiver Lycurgus, who flourished about 870 B.C. See the article Lycurgus.

After his death, the first important transact which we find mentioned in the Spartan history is the Messenian war, which commenced in the year 752 B.C. and ended in the total reduction of the Messenian territory, as related under the article Messenia. During this period, according to some authors, a great change took place in the government of Sparta. This was the creation of the ephory, which is ascribed to one of the kings named Thespis. This man perceiving that there was a necessity for leaving magistrates to execute the laws, when the kings were obliged to be in the field, appointed the magistrates abovementioned, who afterwards made so great a figure in the state (see Ephors). One great privilege of the ephor was, that they did not rise up at the presence of the kings, as all other magistrates did: another was, that the kings offended against the laws, the ephori took cognizance of the offence, and inflicted a suitable punishment. From the first election of the ephori, the year was denominated, as at Athens, from the first election of the archons.

The conquest of Messenia gave Sparta the superiority over the rest of the states, excepting only that of Athens, which for a long time continued to be a very troublesome rival; but the contests between these two rival states have been so fully related under the article Athens, that nothing more is requisite to be added in this place.—In the time of the Persian war, Leonidas the Spartan king distinguished himself in such a manner, as to become the admiration not only of that but of every succeeding age. It being resolved in a general council to defend the straits of Thermopylae against the Persians, 7000 foot were put under the command of Leonidas, of whom, however, only 300 were Spartans. Leonidas did not think it practicable to defend the pass against such multitudes as the Persian king commanded, and therefore privately told his friends, that his design was to devote himself to death for his country.

Xerxes advancing near the straits, was strangely surprised to find that the Greeks were resolved to dispute his passage; for he had always flattered himself, that on his approach they would betake themselves to flight, and not attempt to oppose his innumerable forces. However, Xerxes still entertaining some hopes of their flight, waited four days without undertaking anything, on purpose to give them time to retreat. During this time, he used his utmost endeavours to gain and corrupt Leonidas, promising to make him master of all Greece if he would come over to his interest. His offers being rejected with contempt and indignation, the king ordered him by an herald to deliver up his arms. Leonidas, in a style and with a spirit truly laconical, answered, "Come, therefore, and take them." Xerxes, at this reply, transported with rage, commanded the Medes and Ciffians to march against them, take them all alive, and bring them to him in fetters. The Medes, not able to stand the shock of the Greeks, soon betook themselves to flight; and in their room Hydras was ordered to advance with that body which was called Immortal, and consisted of 10,000 chosen men; but when these came to close with the Greeks, they succeeded no better than the Medes and Ciffians, being obliged to retire with great slaughter. The next day the Persians, reflecting on the small number of their enemies, and supposing so many of them to be wounded that they could not possibly maintain a second fight, resolved to make another attempt; but could not by any efforts make the Greeks give way; on the contrary, they were themselves put to a shameful flight. The valour of the Greeks exerted itself on this occasion in a manner so extraordinary, that Xerxes is said to have three times leaped from his throne, exasperating the entire distraction of his army.

Xerxes having lost all hopes of forcing his way through troops that were determined to conquer or die, was extremely perplexed and doubtful what measures he should take in this posture of affairs; when one Epialtes, in expectation of a great reward, came to him, and discovered a secret passage to the top of the hill over which overlooked and commanded the Spartan forces. The king immediately ordered Hydras thither with his select body of 10,000 Persians; who marching all night, arrived at break of day, and possessed themselves of that advantageous post. The Phocians, who defended this pass, being overpowered by the enemy's numbers, retired with precipitation to the very top of the mountain, prepared to die gallantly. But Hydras, neglecting to pursue them, marched down the mountain with all possible expedition, in order to attack those who defended the straits in the rear. Leonidas being now apprised that it was impossible to bear up against the enemy, obliged the rest of his allies to retire; but he stood himself, with the Thebians, Thessals, and 300 Laced.
Lacedemonians, all resolved to die with their leader; who being told by the oracle, that either Sparta should be destroyed or the king lose his life, determined without the least hesitation to sacrifice himself for his country. The Thebans indeed remained against their inclination, being detained by Leonidas as hostages; for they were justified to favour the Persians. The Thebans, with their leader Demophilus, could not by any means be prevailed upon to abandon Leonidas and the Spartans. The augur Megistias, who had foretold the event of this enterprise, being pressed by Leonidas to retire, sent home his only son; but remained himself, and died by Leonidas. Those who did not feed themselves with any hopes of conquering or escaping, but looked upon Thermopylae as their graves; and when Leonidas, exhorting them to take some nourishment, said, that they should all fight together with Pluto, with one accord they set up a shout of joy, as if they had been invited to a banquet.

Xerxes, after pouring out a libation at the rising of the sun, began to move with the whole body of his army, as he had been advised by Epialtes. Upon their approach, Leonidas advanced to the broadest part of the passage, and fell upon the enemy with such unexpected courage and resolution, that the Persian officers were obliged to stand behind the divisions they commanded, in order to prevent the flight of the men. Great numbers of the enemy falling into the sea, were drowned, others were trampled under foot by their own men, and a great many killed by the Greeks; who knowing they could not avoid death upon the arrival of those who were advancing to fail upon their rear, exerted their utmost efforts. In this action fell the brave Leonidas; which Abrocomes and Hyperanthe, two of the brothers of Xerxes, observing, advanced with great resolution to seize his body, and carry it in triumph to Xerxes. But the Lacedemonians, more eager to defend it than their own lives, repulsed the enemy four times, killed both the brothers of Xerxes, with many other commanders of distinction, and rescued the body of their beloved general out of the enemy’s hands. But in the mean time, the army that was led by the treacherous Epialtes, advancing to attack their rear, they retired to the narrow place of the passage, and drawing all together except the Thebans, posted themselves on a rising ground. In this place they made head against the Persians, who poured upon them in all fidel, till at length, not vanquished, but opposed and overwhelmed by numbers, they all fell, except one who escaped to Sparta, where he was treated as a coward and traitor to his country; but afterwards made a glorious redemption in the battle of Plataea, where he distinguished himself in an extraordinary manner. Some time after, a magnificent monument was reared at Thermopylae, in honour of those brave defenders of Greece, with two inscriptions: the one general, and relating to all those who died on this occasion, importing, that the Greeks of Peloponnesus, to the number only of 4000, made head against the Persian army, confenting of 3,000,000. The other related to the Spartans in particular, and was composed by the poet Bion. (to this purpose, “On the passage, and acquaint the Spartans that we died here in obedience to their just commands.”) At those tombs a funeral oration was yearly pronounced in honour of the dead heroes, and public games performed with great solemnity, wherein none but the Lacedemonians and Thebians had any share, to show that they alone were concerned in the glorious defence of Thermopylae.

At the end of the 77th Olympiad, a most dreadful earthquake happened at Sparta, in which, according to Diodorus, 20,000 persons lost their lives; and Plutarch tells us, that only five houses were left standing in the whole city. On this occasion the Helotes or slaves, whom the Spartans had all along treated with the utmost cruelty, attempted to revenge themselves, by taking up arms, and marching directly to the ruins of the city, in hope of cutting off at once those who had escaped from the earthquake. But in this they were prevented by the prudence of the Spartan king Archidamus; for he, observing that the citizens were more desirous of preserving their effects than taking care of their own lives, caused an alarm to be sounded, as if he had known that an enemy was at hand. On this the citizens armed themselves in haste with such weapons as they could come at; and having marched a little way from the city, met the Helotes, whom they soon compelled to retire. The latter, however, knowing that they had now no mercy to expect from those who had already treated them with such cruelty, resolved to defend themselves to the last. Having therefore seized a sea-port town in Mellenia, they from thence made such incursions into the Spartan territories, that they compelled those imperious masters to ask assistance from the Athenians. This was immediately granted; but when the Spartans saw that the skill of the Athenians in besieging towns was much greater than their own, they became jealous, and diftrusted their allies, telling them, that they had now no farther occasion for their services. On this the Athenians left them in disgust; and as the Helotes and Messenians did not choose to come to an engagement with a Spartan army in the field, but took shelter in their fortified places, the war was protracted for ten years and upwards. At last the Helotes were reduced to their former misery; and the Messenians were obliged to leave Peloponnesus, on pain of being made slaves also. These poor people were then received by the Athenians, who granted them Naupactus for their residence, and afterwards brought them back to a part of their own country, from whence in the course of the Peloponnesian war they had driven the Spartans.

In the year 431 B.C. the Peloponnesian war commenced; of which a full account has been given under the article ATTICA, P. 116-165. It ended most unfortunately for the Athenians; their city being taken and dismantled, as related in the article above-mentioned. Thus were the Spartans raised to the highest pitch of glory; and, in the reign of Agesilas, they seemed to be on the point of subverting the Persian empire, as related under the article PERSIA, P. 34. But here their good fortune and their views of empire were suddenly checked. Agesilas had carried on the war in Asia with the greatest success; and as he would hear to no terms of accommodation, a Persian general named Tissaphernes, having first attempted in vain to bribe the king, dispatched Timocrates the Rhodian, with 500 archers into Greece, in order to try whether he could there meet with any persons less incorruptible than the Spartan monarch. This agent found many who inclined to accept his offers; particularly in Thebes, Co.
of the Spartan army in vain. At sea they were defeated by Timoleon the son of Conon; and by land the battle of Leuctra put an end to the superiority which Sparta had held over Greece for near 500 years. Of Sparta entirely.

After this dreadful defeat, the Spartans had occasion to exert all their courage and resolution. The women and nearest relations of those who were killed in battle, instead of spending their time in lamentations, shook each other by the hand, while the relations of the rest who had escaped from the battle hid themselves among the women; or if they were obliged to go abroad, they appeared in tattered clothes, with their arms folded, and their eyes fixed on the ground. It was a law among the Spartans, that such as fled from battle should be degraded from their honours, should be contrained to appear in garments patched with divers colours, to wear their beards half-shaven, and to suffer any to beat them who pleased, without resistance. At present, however, this law was dispensed with; and Agestias by his prudent conduct kept up the spirits of the people, at the same time that by his skill in military affairs he checked the progress of the enemy. Yet, during the lifetime of Epaminondas the Theban general, the war went on greatly to the disadvantage of the Spartans; but he being killed at the battle of Mantinea, all parties became quickly desirous of peace. Agestias did not long survive; and with him, we may say, perished the glory of Sparta. Soon after this all the states of Greece fell under the power of Alexander the Great; and the Spartans, as well as the rest, having become corrupt, and lost their martial spirit, became a prey to domestic tyrants, and to foreign invaders. They maintained their ground, however, with great resolution against the celebrated Pyrrhus king of Epirus; whom they repulsed for three days successively, though not without assistance from one of the captains of Antigonus. Soon after this one of the kings of Sparta named Agis, perceiving the universal degeneracy that had taken place, made an attempt to reform the laws and discipline of Lycourgas, by which he supposed the state would be restored to its former glory. But though at first he met with some appearance of success, he was in a short time tried and condemned by the ephori as a traitor to his country. Cleomenes, however, who ascended the throne in 216 B.C. accomplished the reformation which Agis had attempted in vain. He suppressed the ephori; cancelled all debts; divided the lands equally, as they had been in the time of Lycourgas; and put an end to the luxury which prevailed among the citizens. But at last he was overborne by the number of enemies which surrounded him; and being defeated in battle by Antigonus, he fled to Egypt, where he put an end to his own life. With him perished every hope of retrieving the affairs of Sparta: the city for the present fell into the hands of Antigonus; after which a succession of tyrants took place; till at last all disturbances were ended by the Romans, who reduced Macedon and Greece to provinces of their empire, as has been related under other articles.

It remains now only to say something concerning the character, manners, and customs of the Spartans, which, as they were founded on the laws of Lycourgas, may best be learned from a view of these laws.

The institutions of Lycourgas were divided into 12 tables.
A man of his tribe looked upon the infant; and if they perceived its limbs straight, and thought it had a who-e-some look, then they returned it to its parents to be educated; otherwise it was thrown into a deep cavern at the foot of the mountain Taygetus. This law seems to have had one very good effect, viz. making women very careful, when they were with child, of either eating, drinking, or exercising, to expect: it made them also excellent nurses; for which they were in the highest respect throughout Greece. Strangers were not allowed to reside long in the city, that they might not corrupt the Spartans by teaching them new customs. Citizens were also forbidden to travel, for the same reason, unless the good of the state required it. Such as were not bred up in their youth according to the law, were not allowed the liberty of the city, because they held it unreasonable, that one who had not submitted to the laws in his youth should receive the benefit of them when a man. They never preferred any stranger to a public office; but if at any time they had occasion for a person not born a Spartan, they first made him a citizen, and then preferred him.

IV. Celibacy in men was infamous, and punished in a most extraordinary manner; for the old bachelor was and married, to walk naked, in the depth of winter, through the market-place: while he did this, he was obliged to sing a song in disparagement of himself; and he had none of the honours paid him which otherwise belonged to old age, it being held unreasonable, that the youth should venerate him who was resolved to leave none of his progeny behind him, to revile them when they grew old in their turn. The time of marriage was also fixed; and if a man did not marry when he was of full age, he was liable to an action; as were such also as married above or below themselves. Such as had three children had great immunities; such as had four were free from all taxes whatsoever. Virgins were married without portions; because neither wanted to hinder a man, nor riches induce him, to marry contrary to his inclinations. When a marriage was agreed on, the husband committed a kind of rape upon his bride. Husbands went for a long time, secretly and by stealth, to the beds of their wives, that their love might not be quickly and easily extinguished. Husbands were allowed to lend their wives, but the kings were forbid to take this liberty. Some other laws of the like nature there were, which as they were evidently against modesty, so they were from producing the end for which Lycurgus designed them; since, though the men of Sparta were generally remarkable for their virtue, the Spartan women were as generally decorous for their boldness and contempt of decency.

V. It was the care of Lycurgus, that, from their education, the Lacedemonians should be inured to their conquer their appetites: for this reason he directed, that nurses should accustom their children to spare meals, and now and then to fasting; that they should carry them, when 2 or 3 years old, to those who should examine their education, and who should carefully observe whether they were able to be in the dark alone, and whether they had got over all other follies and weaknesses incident to children. He directed, that children of all ranks should be brought up in the same way; and that none should be more favoured in food than another, that they might not, even in their

tables. The first comprehended such of the Spartan laws as regarded religion. The statues of all the gods and goddesses were represented in armour, even to Venus herself; the reason of which was, that the people might conceive a military life the most noble and honourable, and not attribute, as other nations did, floth and luxury to the gods. As to sacrifices, they conceived of things of very small value; for which Lycurgus himself gave this reason. That want might never hinder them from worshipping the gods. They were forbidden to make long or rash prayers to the heavenly powers, and were enjoined to ask no more than that they might live honestly and discharge their duty. Graves were permitted to be made within the bounds of the city, contrary to the custom of most of the Greek nations; nay, they buried close by their temples, that all degrees of people might be made familiar with death, and not conceive it such a dreadful thing as it was generally esteemed elsewhere: on the same account, the touching of dead bodies, or afflicting at funerals, made none unclean, but were held to be as innocent and honourable duties as any other. There was nothing thrown into the grave with the dead body; magnificent sepulchres were forbidden; neither was there so much as an inscription, however plain or modest, permitted. Tears, sighs, outcries, were not allowed in public, because they were thought dishonourable in Spartans, whom their lawgiver would have to bear all things with equanimity. Mourning was limited to 11 days; on the 13th the mourner sacrificed to Ceres, and threw aside his weeds. In favour of such as were slain in the wars, however, and of women who devoted themselves to a religious life, there was an exception allowed as to the rules before-mentioned; for such had a short and decent incision on their tombs. When a number of Spartans fell in battle, at a distance from their country, many of them were buried together under one common tomb; but if they fell on the frontiers of their own state, then their bodies were carefully carried back to Sparta, and interred in their family-sepulchres.

II. Lycurgus divided all the country of Laconia into 30,000 equal shares: the city of Sparta he divided into 5000, as some say; into 6000, as others say; and, as a third party will have it, into 4500. The intent of the legislator was, that property should be equally divided among his citizens, so that none might be powerful enough to oppress his fellows, or any be in such necessity, as to be therefrom in danger of corruption. With the same view he forbade the buying or selling these possessions. If a stranger acquired a right to any of these shares, he might quietly enjoy it, provided he submitted to the laws of the republic. The city of Sparta was unwalled; Lycurgus trusting it rather to the virtue of its citizens than to the art of masons. As to the houses, they were very plain; for their ceilings could only be wrought by the axe, and their gates and doors only by the law; and their utensils were to be of a like flample, that luxury might have no influence among them. If a stranger acquired a right to any of these shares, he might quietly enjoy it, provided he submitted to the laws of the republic. The city of Sparta was unwalled; Lycurgus trusting it rather to the virtue of its citizens than to the art of masons. As to the houses, they were very plain; for their ceilings could only be wrought by the axe, and their gates and doors only by the law; and their utensils were to be of a like flample, that luxury might have no influence among them. If a stranger acquired a right to any of these shares, he might quietly enjoy it, provided he submitted to the laws of the republic. The city of Sparta was unwalled; Lycurgus trusting it rather to the virtue of its citizens than to the art of masons. As to the houses, they were very plain; for their ceilings could only be wrought by the axe, and their gates and doors only by the law; and their utensils were to be of a like flample, that luxury might have no influence among them.
infancy, perceive any difference between poverty and riches, but consider each other as equals, and even as brethren, to whom the same portions were alligned, and who, through the course of their life, were to fare alike: the youths alone were allowed to eat flesh; older men ate their black broth and pulse; the lads slept together in chambers, and after a manner somewhat resembling that still in use in Turkey for the Janizaries; their beds, in the summer, were very hard, being composed of the reeds plucked by the hand from the banks of the Eurotas; in winter their beds were softer, but by no means downy, or fit to indulge immoderate sleep. They ate altogether in public; and in case any abstained from coming to the tables, they were fined. It was crowns when they were about the latter. In the field, however, their fumptuary laws did not take place so strictly as in the city; for when they went to war, they were purple habits; they put on crowns when they were about to engage the enemy; they had also rings, but they were of iron; which metal was most esteemed by this nation. Young women wore their veils or jerkins only to their knees, or, as some think, not quite so low; a custom which both Greek and Roman authors confene as indecent. Gold, precious stones, and other costly ornaments, were permitted only to common women; which permission was the strongest prohibition to women of virtue, or who affected to be thought virtuous. Virgins went abroad without veils, with which married women, on the contrary, were always covered. In certain public exercises, in which girls were admitted as well as boys, they were both obliged to perform naked. Plutarch apologizes for this custom, urging, that there could be no danger from nakedness to the morals of youth whose minds were fortified and habituated to virtue. One of Lycurgus’s principal views in his inquisitions, was to eradicate the very seeds of civil disention in his republic. Hence proceeded the equal division of estates injed by him; hence the contempt of wealth, and the neglect of other distinctions, as particularly birth, he considering the people of his whole state as one great family; distinctions which, in other commonwealths, frequently produce tumults and confusions that shake their very foundation.

VI. Though the Spartans were always free, yet it was this restraint, that they were subaltern to their own laws, which bound them as strictly in the city as soldiers, in other states, were bound by the rules of war in the camp. In the first place, strict obedience to their superiors was the great thing required in Sparta. This they looked upon as the very basis of government; without which neither laws nor magistrates availed much. Old age was an indubitable title to honour in Sparta; to the old men the youth rose up whenever they came into any public place; they gave way to them when they met them in the streets, and were stelent whenever their elders spoke. As all children were looked upon as the children of the state, so all the old men had the authority of parents; they reprehended whatever they saw amiss, not only in their own, but in other people’s children; and by this method Lycurgus provided, that as youth are everywhere apt to offend, they might be nowhere without a monitor. The laws went still further: if an old man was present where a young one committed a fault, and did not reprove him, he was punished equally with the delinquent. Amongst the youths there was one of their own body, or at most two years older than the rest, who was styled iros: he had the same authority to question all their actions, to look strictly to their behaviour, and to make them amends; neither were their punishments light, but, on the contrary, very severe; whereby the youth were made hardy, and accustomed to bear stripes and rough usage. Silence was a thing highly commended at Sparta, where modesty was held to be a most becoming virtue in young people; nor was it restrained only to their words and actions, but to their very looks and gestures; Lycurgus having particularly directed, that they should look forward, or on the ground, and that they should always keep their hands within their robes. A stupid inconsiderate person, one who would not listen to instruction, but was careless of whatever the world might say of him, the Lacedemonians treated as a scandal to human nature; with such an one they would not converse, but threw him off as a rotten branch and worthless member of society.

VIII. The plainness of their manners, and their being so very much addicted to war, made the Lacedemonians
monians left fond of the sciences than the rest of the
Greeks. A soldier was the only reputable profession
in Sparta; a mechanic or husbandman was thought a
low fellow. The reason of this was, that they imagi-
ned professions which required much labour, some con-
stant posture, being continually in the house, or always
about a fire, weakened the body and deprested
the mind: whereas a man brought up hardly, was equally
fit to attend the service of the republic in time of
peace, and to fight its battles when engaged in war.
Such occupations as were necessary to be followed for
the benefit of the whole, as husbandry, agriculture,
and the like, were left to their slaves the Helots; but
for curious arts, and such as served only to luxury, they
would not so much as suffer them to be introduced in
their city; in consequence of which, rhetoricians, au-
gurs, bankers, and dealers in money, were shut out:
The Spartans admitted not any of the theatrical diver-
sions among them; they would not bear the representa-
tion of evil even to produce good; but other kinds of
poetry were admitted, provided the magistrates had the
perusal of pieces before they were handed to
the public.

Above all things, they affected brevity of speech,
and accustomed their children, from their very infancy,
ever to express themselves in more words than were
strictly necessary; whence a concise and sententious orati-
ory is to this day styled Laconic. In writing they used
the same conciseness; of which we have a signal instance
in a letter of Archidamus to the Eleans, when he un-
derstood that they had some thoughts of affailing the
Arcadians. It ran thus: "Archidamus to the Eleans:
It is good to be quiet." And therefore Epaminondas,
thought that he had reason to glory in having forced
the Spartans to abandon their monosyllables, and to
lengthen their discourse.

The greatest part of their education consisted in gi-
ving their youth right ideas of men and things: the
iron or master propounded questions, and either commend-
ed the answers that were made him, or reproved such
as answered weakly. In these questions, all matters,
either of a trivial or abstruse nature, were equally avoid-
ed; and they were confined to such points as were of
the highest importance in civil life; such as, Who was
the best man in the city? Wherein lay the merit of
such an action? and, Whether this or that hero's fame
was well-founded? Harmlefs raffery was greatly en-
couraged; and this, joined to their short manner of
speaking, rendered laconic replies universally admired.

Music was much encouraged; but in this, as in other
things, they adhered to that which had been in favour
with their ancestors; nay, they were so fixed therein,
that they would not permit their slaves to learn either
the tune or the words of their most admired odes; or,
which is all one, they would not permit them to sing
them if they had learned them. Though the youth of
the male sex were much cherishead and beloved, as those
that were to build up and continue the future glory of
the state, yet in Sparta it was a virtuous and modest af-
ection, untinged with that fenuality which was so
scandalous at Athens. The good e€:fects of this part of
Lycurgus's institutions were seen in the union that
reigned among his citizens; and which was so extra-
ordinary, that even in cafes of competition, it was hardly
known that rivals bore ill-will to each other; but,
on the contrary, their love to the same person bega$ a
secondary friendship among themselves, and united
them in all things which might be for the benefit of
the person beloved.

Some authors have accused this great lawgiver of en-
couraging theft in his institutions; which, they say,
was not held scandalous among the Spartans, if it were
so dexterously managed as that the person was not de-
dected in it. But this is certain, and seems to be a
strong contradiction of the heinous charge, that when a
theft was discovered, it was punished with the utmost
severity: a person even suspected of it would endure
the heaviest punishments rather than acknowledge it,
and be branded with so base a crime.

IX. The exercitcs instituted by law fall under the Exercitcs
ninth table. In thefe all the Greeks were extremely
careful, but the Lacedemonians in a degree beyond
the rest; for if a youth, by his corpulence, or any
other means, became unfit for these exercitcs, he under-
went public contempt at least, if not banishment.—
Hunting was the usual diversion of their children; nay,
it was made a part of their education, because it had a
tendency to strengthen their limbs, and to render
those who practised it fupple and fleet: they likewise
bred up dogs for hunting with great care. They had
a kind of public dances, in which they exceedingly
delighted, and which were common alike to virgins and
young men; indeed, in all their sports, girls were allowed
to divert themselves with the youth; infomuch
that, at darting, throwing the quoit, pitching the
bar, and such-like robust diverfions, the women were as
dexterous as the men. For the manifest oddity of this
proceeding, Lycurgus assigned no other reason than
that he fought to render women, as well as men, strong
and healthy, that the children they brought forth might
be fo too. Violent exercitcs, and a laborious kind of
life, were only enjoined the youth; for when they were
grown up to men's estate, that is, were upwards of 30
years old, they were exempted from all kinds of labour,
and employed themselves wholly either in affairs of state
or in war. They had a method of whippmg, at a cer-
tain time, young men in the temple of Diana, and about
her altar; which, however palliated, was certainly
unnatural and cruel. It was esteemed a great honour
to fulfill these flagellations without weeping, groan-
ing, or showing any fenfe of pain; and the sight of
this was so strong in these young minds, that they
were very frequently suffered death without shedding a tear
or breathing a figh. A defire of overcoming all the
weakness of human nature, and thereby rendering his
Spartans not only superior to their neighbours, but to
their species, runs through many of the institutions of
Lycurgus; which principle, if well attended to, thor-
oughly explains them; and without attending to which,
it is impossible to give any account of them at all.

X. Gold and silver were, by the confiderations of
Lycurgus, made of no value in Sparta. He was so ze-
ulous of the danger of riches, that he made the
very possession of them venal; but as there was no
living without some sort of money, that is, some common
measure or standard of the worth of things, he direc-
ed an iron coinage, whereby the Spartans were sup-
plied with the useful money, and at the fame time had
no temptation to covetousnes afforded them; for a very
small sum was sufficient to load a couple of horses; and

a great
a great one must have been kept in a barn or warehouse. The coming in of all foreign money was also prohibited, that corruption might not enter under the name of commerce. The most ancient method of dealing, viz. by barter, or exchange of one commodity for another, was preferred by law in Sparta long after it had been out of date everywhere else. Interest was a thing forbidden in the Spartan commonwealth; where they had also a law against alienation of lands, accepting presents from foreigners, even without the limits of their own country, and when their authority and character might well seem to excuse them.

X. Such of the laws of Sparta as related to courts of justice may be brought under the 11th table. Thirty years must have passed over the head of him who had a right to concern himself in judicial proceedings. Young men were thought unfit for them; and it was even held indecent, and did report, for a man to have any fondness for law-suits, or to be baffling himself at the tribunals, when he had no affairs there of his own. By these rules Lycurgus thought to shut out litigiousness, and to prevent that multiplicity of suits which is always scandalous in a state. As young people were not permitted to inquire about the laws of other countries, and as they were hindered from hearing judicial proceedings in their courts, so they were likewise forbidden to ask any questions about, or to endeavour to discover, the reasons of the laws by which themselves were governed. Obedience was their duty; and to that alone they would have them kept. Men of abandoned characters, or who were notoriously of ill fame, lost all right of giving their votes in respect of public affairs, or of speaking in public assemblies; for they would not believe that an ill man in private life could mean his country better than he did his neighbour.

XI. Till a man was 30 years old, he was not capable of serving in the army, as the best authors agree; though some think that the military age is not well ascertained by ancient writers. They were forbidden to march to any time before the full-moon; the reason of which law is very hard to be disbelieved, if indeed it had any reason at all, or was not rather founded on some superstitious opinion, that this was a more lucky conjunction than any other. They were likewise forbidden to fight often against the same enemy; which was one of the wisest maxims in the political system of Lycurgus: and Ageiilaulus, by offending against it, destroyed the power of his country, and lost her that authority which for many ages the maintained over the rest of Greece; for, by continually warring against the Thebans, to whom he had an inveterate hatred, he at last beat them into the knowledge of the art of war, and enabled them, under the command of Epaminondas, to maintain for a time the principality of Greece. Maritime affairs they were forbidden to meddle with, though the necessity of things compelled them, in process of time, to transgress this institution, and by degrees to transfer to themselves the dominion of the sea as well as of the land: but, after the Peloponnesian war, they again neglected naval affairs, from a persuasion that the sea was a fortress, and to the exterior, as they never fortified Sparta, they were not ready to undertake sieges: fighting in the field was their proper province, and, while they could overcome their enemies there, they rightly conceived that nothing could hurt them at home. In time of war, they relaxed somewhat of their strict manner of living, in which they were singular. The true reason for this was, in all probability, that war might be less burdensome to them; for, as we have more than once observed, a strong desire to render them bold and warlike was the reigning passion of their legislator. They were forbidden to remain long encamped in the same place, as well to hinder their being surprized, as that they might be more troublesome to their enemies, by wailing every corner of their country. They kept all night in their armour; but their outguards were not allowed their shields, that, being unprovided of defence, they might not dare to sleep. In all expeditions they were careful in the performance of religious rites: and, after their evening meal was over, the folders sung together hymns to their gods. When they were about to engage, the king sacrificed to the muses, that, by their assistance, they might be enabled to perform deeds worthy of being recorded to late times. Then the army advanced in order to the sound of flutes, which played the hymn of Castor. The king himself sung the pean, which was the signal to charge. This was done with all the solemnity imaginable; and the folders were fated either to die or conquer: indeed they had no other choice; for if they fled they were infamous, and in danger of being slain, even by their own mothers, for disgracing their families. In this consisted all the excellency of the Spartan women, who, if possible, exceeded in bravery the men, never lamenting over husbands or sons, if they died honourably in the field: but deploring the flame brought on their house, if either the one or the other escaped by flight. The throwing away a shield also induced infamy; and, with respect to this, mothers, when they embraced their departing sons, were wont to caution them, that they should either return armed as they were, or be brought back to when they were dead: for, as we have observed, such as were slain in battle were nevertheless buried in their own country. When they made their enemies fly, they pursued no longer than till victory was certain; because they would seem to fight rather for the honour of conquering, than of putting their enemies to death. According to their excellent rules of war, they were bound not to spoil the dead bodies of their enemies; but in process of time, this, and indeed many other of their most excellent regulations, fell into desuetude. He who overcame by stratagem, offered up an ox to Mars; whereas he who conquered by force, offered up only a cock; the former being esteemed more manly than the latter. After 40 years service, a man was, by law, no longer required to go into the field; and consequently, if the military age was 30, the Spartans were not held invalids till they were 70.

SPARTIUS (Elius), a Latin historian, who wrote the lives of Adrian, Caracalla, and four other Roman emperors. He lived under the reign of Diocleian, about the year 296.

SPARTIUM, Broom, in botany: A genus of plants belonging to the class of Dendrophlebia, and order of Dendrophylem, and in the natural system arranged under the family Papilionaceae. The stigma is longitudinal and woolly above: the filaments adhere to the germen. The calyx is produced downwards. There are 16 species,
The common broom is used for a variety of purposes. It has been of great benefit sometimes in dropical complaints. The manner in which Dr Cullen administered it was this: He ordered half an ounce of fresh broom tops to be boiled in a pound of water till one half of the water was evaporated. He then gave two table-spoonfuls of the decoction every hour till it operated both upon the bowel and urine. By repeating these doses every day, or every second day, he says some dropsy have been cured. Dr Mead relates, that a dropical patient, who had taken the usual remedies, and been tapped three times without effect, was cured by taking half a pint of the decoction of green broom tops, with a spoonful of whole malt and beer morning and evening.

An infusion of the seeds drunk freely (says Mr Withering) has been known to produce similar effects; but whoever expects these effects to follow in every dropical case, will be greatly deceived. I knew them succeed in one case that was truly deplorable; but out of the great number of cafes in which the medicine had a fair trial, this proved a single instance.

The flower buds are in some countries pickled, and eaten as capers; and the seeds have been used as a bad substitute for coffee. The branches are used for making beets, and tanning leather. They are also used instead of thatch to cover sheep-folds. The old wood furnishes the cabinet-maker with beautiful materials for varnishing. The tender branches are in some places mixed with hops for brewing, and the macerated bark may be manufactured into cloth.

The junceum, or Spanish broom, grows naturally in the southern provinces of France, as well as other parts of the south of Europe. It grows in the poorest soils, on the steepest declivities of the hills in a fliny soil, where hardly any other plant could vegetate. In a few years it makes a vigorous shrub; infinuating its roots between the interstices of the stones, it binds the soil, and retains the small portion of vegetable earth scattered over the hills, which is worn away by the annual rains. It is most easily raised from seed, which is usually sown in January, after the ground has received a slight dressing.

This shrub serves two useful purposes. Its branches yield a thread of which linen is made, and in winter support sheep and goats.

In manufacturing thread from broom, the youngest plants are cut in the month of August, or after harvest, and gathered together in bundles, which at first are laid in the sun to dry: they are then beaten with a piece of wood, washed in a river or pond, and left to steep in the water for about four hours. The bundles thus prepared are taken to a little distance from the water, and laid in a hollow place made for them, where they are covered with fern or straw, and remain thus to steep for eight or nine days; during which time, all that is necessary, is to throw a little water once a-day on the heap, without uncovering the broom. After this, the bundles are well washed, the green rind of the plant or epidermis comes off, and the fibrous part remains; each bundle is then beaten with a wooden hammer upon a stone, to detach all the threads, which are, at the same time carefully drawn to the extremity of the branches. After this operation, the faggots are untied, and spread upon stones or rocks till they are dry. The twigs must not be peeled till they are perfectly dry; they are then dressed with the comb, and the threads are separated according to their fineness, and spun upon a wheel.

The linen made of this thread serves various purposes in rural economy. The coarsest is employed in making sacks and other strong cloths for carrying grain or feeds. Of the finest is made bed, table, and bed linen. The peafants in several places use no other, for they are unacquainted with the culture of hemp or flax, their soil being too dry and too barren for raising them. The cloth made with the thread of the broom is very useful; it is as soft as that made of hemp; and it would perhaps look as well as that made of flax if it was more carefully spun. It becomes white in proportion as it is steeped. The price of the finest thread, when it is fold, which seldom happens, is generally about a shilling a pound.

The other use to which this broom is applied, is to maintain sheep and goats during winter. In the mountains of Lower Languedoc these animals have no other food from November to April, except the leaves of trees preferred. The branches of this broom therefore are a resource the more precious, that it is the only fresh nourishment which at that season the flocks can procure, and they prefer it at all times to every other plant. In fine weather the sheep are led out to feed on the broom, where it grows; but in bad weather the shepherds cut the branches, and bring them to the sheep-folds. There is, however, an inconvenience attending the continued use of this food. It generally produces inflammation in the urinary passages. But this inconvenience is easily removed by cooling drink, or a change of food, or by mixing the broom with something else.

It is perhaps needless to add, that it differs much from the broom that is common everywhere in the north of Europe, though this too, in many places, is used for food to cattle. Both of them produce flowers that are very much resorted to by bees, as they contain a great quantity of honey juice. And this should be another inducement to the cultivation of the Spanish broom.

SPARUS, Gilt-head, in natural history, a genus of animals belonging to the class of Pisces, and the order of Atherinid. The fore-teeth and dog-teeth are very strong; the grinders are obtuse and thick set; the lips are folded over; there are five rays in the gill membrane; and the opercula are scaly; the body is compressed; the lateral line is crooked behind; and the pectoral fins are roundish.

Gmelin enumerates 33 species, of which only three are found in the British seas, the pegasus, auratus, and dentatus. 1. The pegasus, or sea-bream, is of a reddish colour. The skin forms a finus at the roots of the dorsal and anal fins. The body is broad; the back and belly ridged. There is only one dorsal fin. 2. The auratus, or gilt-bream. The head and sides of it are gilt, and there is a golden spot between the eyes shaped like a half moon; there is also a black purple spot on the gills; and it weighs from eight lb. to ten lb. It is one
of the pijes saxatilis; or fish that haunts deep waters on bold rocky shores. They feed chiefly on shell-fish, which they comminate with their teeth before they swallow; the teeth of this genus in particular being adapted for that purpose: the grinders are flat and strong, like those of certain quadrupeds: besides which there are certain bones in the lower part of the mouth that affist in grinding their food. They are but a coarse fish: they were known to the Romans, who did not esteem them unless they were fed with Lucerne oysters, as Martial informs us,

Non omnis laudem pretiumque Auxilium meretur,
Sed qui folus erit concha Lucinae cibus.

Lib. xiii. Ep. 90.

3. The dentatus, toothed sea-bream, is black above, and of a silvery appearance below. The eyes and gills are very large. There are nine rows of teeth in the lower jaw, and one in the upper.

In the account of Captain Cook's voyage published by Mr Forster, we are informed, that the gillheads are sometimes poisonous, owing to their feeding on certain species of the raja, which have an extremely acrid and stimulating property.

SPASM, a convulsion. See Medicine, n° 278.

SPATHA, in botany, a sheath; a species of calyx which burits lengthwise, and protrudes a stalk supporting one or more flowers, which commonly have no perianthium or flower-cup.

SPATHACAEAE (from spatha, "a sheath"), the name of the ninth order in Linnaeus's Fragments of a Natural Method consisting of plants whose flowers are protruded from a spatha or sheath. See Botany, p. 458.

SPATHELLA, in botany; a genus of plants belonging to the class of pentandria, and to the order of trignia. The calyx is pentaphyllous; the petals are five; the capsule is three-edged and trilocular; the seeds solitary. There is only one species, the simplicis, which is a native of Jamaica, and was introduced into the botanical gardens of Britain in 1778 by Dr. Wright, late of Jamaica.

SPEAKER, in commerce, the several pieces of gold, silver, copper, &c. which having passed their full preparation and coinage, are current in public. See Money.

SPECIFIC, in philosophy, that which is peculiar to any thing, and distinguishing it from all others.

SPECIFICS, in medicine. By species is not meant so much as in all patients produce salutary effects. Such medicines are not to be expected, because the operations and effects of remedies are not formally inherent in them, but depend upon the mutual action and reaction of the body and medicine upon each other; hence the various effects of the same medicine in the same kind of disorder in different patients, and in the same patient at different times. By specific medicines we understand such medicines as are more insalubrious than any other in any particular disorder.

SPECIES, in logic, a relative term, expressing an idea which is comprised under some general one called a genus. See Logic, n° 68.

not regulate or prevent; but we know very few indeed that can make any sensible change in this weight without the addition or ablation of other matter. Even taking it to the summit of a high mountain, or from the equator to the polar region, will make no change in its weight as it is ascertained by the balance, because there is the same real diminution of weight in the pounds and ounces used in the examination.

Notwithstanding the unavoidable change which heat and cold make in the bulk of bodies, and the permanent varieties of the same kind of matter which are caused by different circumstances of growth, texture, &c., all kinds of matter have a certain constancy in the density of their particles, and therefore in the weight of a given bulk. Thus the purity of gold, and its degree of adulteration, may be inferred from its weight, as being purer in proportion as it is more dense. The density, therefore, of different kinds of tangible matter becomes characteristic of the kind, and a test of its purity; it marks a particular appearance in which matter exists, and may therefore be called, with propriety, Specific.

But this density cannot be directly observed. It is not by comparing the distances between the atoms of matter in gold and in water that we say the first is 19 times denser than the last, and that an inch of gold contains 19 times as many material atoms as an inch of water; we reckon on the equal gravitation of every atom of matter whether of gold or of water; therefore the weight of any body becomes the indication of its material density, and the weight of a given bulk becomes specific of that kind of matter, marking its kind, and even ascertaining its purity in this form.

It is evident that, in order to make this comparison of general use, the standard must be familiarly known, and must be very uniform of its density, and the comparison of bulk and density must be easy and accurate. The most obvious method would be to form, with all nicety, a piece of the standard matter of some convenient bulk, and to weigh it very exactly, and keep a note of its weight; then, to make the comparison of any other substance, it must be made into a mass of the same specific bulk, and weighed with equal care; and the most convenient way of expressing the specific gravity would be to consider the weight of the standard as unity, and then the number expressing the specific gravity is the number of times that the weight of the standard is contained in that of the other substance. This comparison is most easily and accurately made in fluids. We have only to make a vessel of known dimensions equal to that of the standard which we employ, and to weigh it when empty, and then when filled with the fluid. Nay, the most difficult part of the process, the making a vessel of the precise dimensions of the standard, may be avoided, by using some fluid substance for a standard. Any vessel will then do; and we may ensure very great accuracy by using a vessel with a slender neck, such as a phial or matra; for when this is filled to a certain mark in the neck, any error in the estimation by the eye will bear a very small proportion to the whole. The weight of the standard fluid which fills it to this mark being carefully ascertained, is kept in remembrance. The specific gravity of any other fluid is had by weighing the contents of this vessel when filled with it, and dividing the weight by the weight of the standard. The quotient is the specific gravity of the fluid. But in all other cases this is a very difficult problem: it requires very nice hands, and an accurate eye, to make two bodies of the same bulk. An error of one hundredth part in the linear dimensions of a solid body makes an error of a 30th part in its bulk; and bodies of irregular shapes and friable substance, such as the ores of metals, cannot be brought into convenient and exact dimensions for measurement.

From all these inconveniences and difficulties we are freed by the celebrated Archimedes, who, from the principles of hydraulics discovered or established by him, deduced the accurate and easy method which is now universally practiced for ascertaining the specific gravity and density of bodies. (See Archimedes and Hydraulics, etc.) Instead of measuring the bulk of the body by that of the displaced fluid (which would have been impossible for Archimedes to do with any thing like the necessary precision), we have only to observe the loss of weight sustained by the solid. This can be done with great ease and accuracy. Whatever may be the bulk of the body, this loss of weight is the weight of an equal bulk of the fluid; and we obtain the specific gravity of the body by simply dividing its whole weight by the weight lost: the quotient is the specific gravity when this fluid is taken for the standard, even though we should not know the absolute weight of any given bulk of this standard. It also gives us an easy and accurate method of ascertaining even this fundamental point. We have only to form any solid body into an exact cube, sphere, or prism, of known dimensions, and observe what weight it loses when immersed in this standard fluid. This is the weight of the same bulk of the standard to be kept in remembrance; and thus we obtain, by the by, a most easy and accurate method for measuring the bulk or solid contents of any body, however irregular its shape may be. We have only to see how much weight it loses in this standard fluid; we can compute what quantity of the standard fluid will have this weight. Thus should we find that a quantity of sand, or a furnace bulk, loses 250 ounces when immersed in pure water, we learn by this that the solid measure of every grain of the sand, or of every twig and prickle of the furnace, when added into one fathom, amounts to the fourth part of a cubic foot, or to 432 cubic inches.

To all these advantages of the Archimedean method of ascertaining the specific gravity of bodies, derived from his hydraulical doctrines and discoveries, we may add, that the immediate standard of comparison, namely, water, is, of all the substances that we know, the fittest for the purpose of an universal standard of reference. In its ordinary natural state it is sufficiently confant and uniform in its weight for every examination where the utmost mathematical accuracy is not wanted; all its variations arise from impurities, from which it may at times be separated by the simple process of distillation; and we have every reason to think that when pure, its density, when of the same temperature, is invariable.

Water is therefore universally taken for the unit of that scale on which we measure the specific gravity of bodies, and its weight is called 1. The specific gravity of any other body is the real weight in pounds and ounces, when of the bulk of one pound or one ounce of water. It is therefore of the first importance, in all
difficulties respecting the specific gravity of bodies, to have the specific weight of some known bulk of pure water. We have taken some pains to examine, and compare the experiments on this subject, and shall endeavour to ascertain this point with the precision which it deserves. We shall reduce all to the English cubic foot and avoirdupois ounce of the Exchequer standard, on account of a very convenient circumstance peculiar to this unit, viz., that a cubic foot contains almost precisely a thousand ounces of pure water, so that the specific gravity of bodies expresses the number of such ounces contained in a cubic foot.

We begin with a trial made before the house of commons in 1696 by Mr Everard. He weighed 21456 cubic inches of water by a balance, which turned feebly with 6 grains, when there were 30 pounds in each scale. The weights employed were the troy weights, in the deposit of the Court of Exchequer, which are still preserved, and have been most scrupulously examined and compared with each other. The weight was 1131 ounces 14 penny weights. This wants just 1 grain of a thousand avoirdupois ounces for 1728 cubic inches, or a cubic foot; and it would have amounted to that weight had it been a degree or two colder. The temperature indeed is not mentioned; but as the trial was made in a comfortable room, we may presume the temperature to have been about 55° of Fahrenheit's thermometer. The dimensions of the vessel were as accurate as the nice hand of Mr Abraham Sharp, Mr Flamsteed's assistant at Greenwich, could execute, and it was made by the Exchequer standard of length.

This is confirmed by the naturalists of Europe as a very accurate standard experiment, and it is confirmed by many others both private and public. The standards of weight and capacity employed in the experiment are all in existence, and publicly known, by the report of the Royal Society to parliament in 1742, and by the report of a committee of the house of commons in 1748. This gives it a superiority over all the measures which have come to our knowledge.

The first experiment, made with proper attention, that we meet with, is by the celebrated Snellius, about the year 1659, and related in his Eratosthenes Batavus. He weighed a Rhinland cubic foot of distilled water, and found it 6270 Amsterdam pounds. If this was the ordinary weight of the hopes, containing 7626 English troy grains, the English cubic foot must be 62 pounds 9 ounces, only one ounce more than Everard's experiment. If it was the Minto pound, the weight was 62 pounds 6 ounces. The only other trials which can come into competition with Mr Everard's are some made by the Academy of Sciences at Paris. Picart, in 1691, found the Paris cubic foot of the water of the fountain d'Arcueil to weigh 69,588 pounds poids de Paris. Du Hamel obtained the very same refult; but Mr Monges, in 1783, says that filtered rain-water of the temperature 12° (Reaumur) weighs 69,3792. Both these measures are considerably below Mr Everard's, which is 63; 5, the former giving 63,083, and the letter 61,888. M. Lavater finds the Paris cubic foot at 76 pounds, which makes the English foot 62,47. But there is an inconsistency among them which makes the comparison impossible. Some changes were made in 1688, by royal authority, in the national standards, both of length and weight; and the academicians are exceedingly puzzled to this day in reconciling the differences, and cannot even ascertain with perfect accuracy the linear measures which were employed in their most boasted geometrical operations.

Such variations in the measurements made by persons of reputation for judgment and accuracy engaged the writer of this article some years ago to attempt another. A vessel was made of a cylindrical form, as being more easily executed with accuracy, whose height and diameter were 8 inches, taken from a most accurate copy of the Exchequer standard. It was weighed in distilled water of the temperature 56° several times without varying 2 grains, and left 42885 grains. This gives for the cubic foot 99874 ounces, deficient from Mr Everard's an ounce and a quarter; a difference which may be expected, since Mr Everard used the New River water without distillation.

We hope that these observations will not be thought superfluous in a matter of such continual reference, in the most interesting questions both to the philosopher and the man of business; and that the determination which we have given will be considered as sufficiently authenticated.

Let us, therefore, for the future take water for the standard, and suppose that, when of the ordinary temperature of summer, and in its state of greatest natural purity, viz. in clean rain or snow, an English cubic foot of it weighs a thousand avoirdupois ounces of 4375 troy grains each. Divide the weight of any body by the weight of an equal bulk of water, the quotient is the specific gravity of that body; and if the three first figures of the decimal be accounted integers, the quotient is the number of avoirdupois ounces in a cubic foot of the body. Thus the specific gravity of the very finest gold which the refiner can produce is 19365, and a cubic foot of it weighs 19565 ounces.

But an important remark must be made here. All bodies of homogeneous or unorganized texture expand by heat, and contract by cooling. The expansion and contraction by the same change of temperature is very different in different bodies. Thus water, when heated from 60° to 100°, increases its volume nearly \( \frac{1}{39} \) of its bulk, and mercury only \( \frac{1}{27} \), and many substances much less. Hence it follows, that an experiment determines the specific gravity only in that very temperature in which the bodies are examined. It will therefore be proper always to note this temperature; and it will be convenient to adopt some very useful temperature for such trials in general; perhaps about 64° of Fahrenheit's thermometer is as convenient as any.

It may always be procured in these climates without inconvenience. A temperature near to freezing would have some advantages, because water changes its bulk very little between the temperature 32° and 45°. But this temperature cannot always be obtained. It will much conduce to the facility of the comparison to know the variation which heat produces on pure water.

The following table, taken from the observations of Dr Blagden and Mr Gilpín (Phil. Trans. 1792) will answer this purpose.

Those gentlemen observed the expansion of water to be very anomalous between 32° and 45°. This is distinctly seen during the gradual cooling of water to the point of freezing. It contracts for a while, and then suddenly expands. But we seldom have occasion to measure specific gravities in such temperatures.

The reader is now sufficiently acquainted with the principles of this hydrostatical method of determining the specific gravity of bodies, and can judge of the propriety of the forms which may be proposed for the experiment.

The specific gravity of a fluid may be determined either by filling with it a vessel with a narrow neck, or by weighing a solid body that is immersed in it. It is hard to say which is the best way. The last is not subject to any error in filling, because we may suspend the solid by a fine wire, which will not displace any sensible quantity of the fluid; and if the solid is but a little heavier than the fluid, the balance being loaded only with the excess, will be very sensible to the smallest want of equilibrium. But this advantage is perhaps compensated by an obstruction to the motion of the fluid up or down in the fluid, arising from viscosity. When the weight in the opposite scale is yet too small, we slowly add more, and at last grain by grain, which gradually brings the beam to the level. When it is exactly level, the weight in the scale is somewhat too great; for it not only balances the preponderance of the solid, but also the viscosity of the fluid. But we may get rid of this error. Add a small quantity more; this will bring the beam over to the other side. Now put as much into the scale on the same side with the solid; this will not restore the beam to its level. We must add more till this be accomplished; and this addition is the measure of the viscosity of the fluid, and must be subtracted from the weight that was in the other scale when the beam came first to a level. This effect of viscosity is not inappreciable, with nice a paratus, even in the purest water, and in many fluids it is very considerable—and, what is worse, it is very changeable. It is greatly diminished by heat; and this is an additional reason for making those trials in pretty warm temperatures. But for fluids of which the viscosity is considerable, this method is by no means proper; and we must take the other, and weigh them in a vessel with a narrow neck.

Mercury must also be treated in this way, because we have no solid that will stick in it but gold and platinum.

It is not so easy as one would imagine to fill a vessel precisely to the same degree upon every trial. But if we do not operate on too small quantities, the unavoidable error may be made altogether insignificant, by having the neck of the vessel very small. If the vessel hold a pound of water, and the neck do not exceed a quarter of an inch (and it will not greatly retard the operation to have it half this size), the examinator must be very careful indeed to err one part in two thousand, and this is perhaps as near as we can come with a balance. We must always recollect that the capacity of the vessel changes by heat, and we must know this variation, and take it into the account. But it is affectation to regard (as Mr. Hamberg would make us believe that he did) the dilution of the vessel by the presence of the fluid. His experiments of this kind have by no means the confidence with each other that should convince us that he did not commit much greater errors than what arose from dilution.

In examining either solids or fluids, we must be careful to free their surface, or that of the vessel in which the fluid is to be weighed, from air, which frequently adheres to it in a peculiar manner, and, by forming a bubble, increases the apparent bulk of the solid, or diminishes the capacity of the vessel. The greatest part of what appears or those occasions seems to have ex­filed in the fluid in a state of chemical union, and to be set at liberty by the superior attraction of the fluid for the contiguous solid body. These air bubbles must be carefully brushed off by hand. All greasy matters must be cleared off for the same reason: they prevent the fluid from coming into contact.

We must be no less careful that no water is imbibed by the solid, which would increase its weight without increasing its bulk. In some cases, however, a very long maceration and imbition is necessary. Thus, in examining the specific gravity of the fibrous part of vegetables, we should err exceedingly if we imagined it as small as appears at first. We believe that in most plants it is at least as great as water, for after long maceration they sink in it.

It is almost needless to say that the nicest and most sensible balances are necessary for this examination. Bal­ances are even constructed on purpose, and fitted with several pieces of apparatus, which make the examination easy and neat. We have described (see Balance) Mr. Gravesande's as one of the most convenient of any. His contrivance for observing the fractions of a grain is extremely ingenious and expedient, especially for detecting the effect of viscosity.

The hydrometer, or acconmoter, is another instrument for ascertaining the specific gravity of fluids. This very pretty instrument is the invention of a lady, as eminent for intellectual accomplishments as she was admired for her beauty. Hypatia, the learned daughter of the celebrated mathematician Theon of Alexandria, became so eminent for her mathematical knowledge, that she was made public professor of the science in the first school in the world. She wrote a commentary on the works of Apollonius and of Diogenes and composed Astronomical Tables; all of which are lost. These rare.
Specific Gravity.

accomplices, however, could not save her from the fury of the fanatics of Alexandria, who cut her in pieces for having taken an offensive part in a dispute between the governor and patriarch.—We have described some of the most approved of these instruments in the article HYDROMETER, and shall in this place make a few observations on the principles of their construction, not as they are usually made, accommodated to the examination of particular liquors, but as indicators of pure specific gravity. And we must premise, that this would, for many reasons, be the best way of constructing them. The very ingenious contrivances for accommodating them to particular purposes are unavoidably attended with many sources of error, both in their adjustment by the maker and in their use; and all that is gained by a very expensive instrument is the saving the trouble of inspecting a table. A simple scale of specific gravity would expose to no error in construction, because all the weights but one, or all the points of the scale but one, are to be obtained by calculation, which is incomparably more exact than any manual operation, and the table can always be more exact than any complex observation. But a still greater advantage is, that the instruments would by this means be fitted for examining all liquids whatever, whereas at present they are almost useless for any but the one for which they are constructed.

Hydrometers are of two kinds. The most simple and the most delicate are called a substitute for the hydrostatical balance. They consist of a ball (or rather an egg or pear-shaped vessel, with moves more easily through the fluid) A (fig. 1.) having a foot projecting down from it, terminated by another ball B, and a slender stalk or wire above, carrying a little dish C. The whole is made so light as to float in the lightest fluid we are acquainted with; such as vitriolic or muriatic aether, whose specific gravity is only 0.73. This number should be marked on the dish, indicating that this is the specific gravity of the fluid in which the instrument floats, referring to the point D of the stem. The ball B is made heavy, and the foot is of the same length, so that the instrument may have stability, and swim erect, even if considerably loaded above; and, for saving reason, must be made very round, otherwise it will lean to a side. When put into a heavier liquor, its buoyancy will cause it to float with a part of the ball above the surface. Weights are now put into the scale C till the instrument sink to D. The weight put into the scale, added to the weight of the instrument, is the weight of the displaced fluid. This compared with the weight of the whole when the instrument is swimming in pure water, gives the specific gravity of the fluid. All trouble of calculation may be avoided by marking the weights with such numbers as shall indicate the specific gravity at once. Thus having loaded the instrument so as to sink it to D in pure water, call the whole weight 1000; then weigh the instrument itself, and say, "as the weight when swimming in water is to its present weight, so is 1000 to a 4th proportional." This is the specific gravity of the liquor which would float the unloaded instrument. Suppose this to be 730. The hydrometer would float in muriatic aether, and this should be marked on the scale. Now make a set of small weights, and mark them not by their weights in grains, but in such units that 270 of them shall be equal to the weight which is the instrument for pure water.

Suppose that, in order to float this instrument in a certain brandy, there are required 186 in these small weights. This added to 730 gives 916 for the specific gravity, and shows it to be precisely excise proof spirit. Nine weights, viz. 256, 128, 64, 32, 16, 8, 4, 2, 1, will suffice for all liquors from ather to the strongest worts. And that the trouble in changing the weights may be greatly lessened, let a few circles a, b, c, d, e, be marked on the top of a ball. When we see it float unloaded at the article C for instance, we know it will require at least 128 to sink it to D on the stem.

If the weights to be added above are considerable, it raises the centre of gravity so much, that a small want of equilibrium, by laying the weights on one side, will produce a great inclination of the instrument, which is unsightly. Instead of making them loose weights, it is proper to make them round plates, with a small hole in the middle, to go on a pin in the middle of the scale. This will keep the instrument always upright. But unless the hydrometer is of a considerable size, it can hardly be made so as to extend from the lightest to the heaviest fluid which we may have occasion to examine, even though we except mercury. Some of the mineral acids are considerably more than twice the weight of aether. When there is such a load at top, the hydrometer is very apt to oververt, and inclines with the smallest want of equilibrium. Great size is inconvenient even to the philosopher, because it is not always in his power to operate on a quantity of fluid sufficient to float the instrument. Therefore two, or perhaps three, are necessary for general examination. One may reach from water to ather; another may serve for all liquors of a specific gravity between 1 and 1 1/4; and a third, for the mineral acids, may reach from this to 2. If each of these be about two solid inches in capacity, we may easily and expeditiously determine the specific gravity within one ten thousandth part of the truth; and this is precision enough for most purposes of science or business.

The chief questions are, 1. To ascertain the specific gravity of an unknown fluid. This needs no farther explanation. 2. To ascertain the proportion of two fluids which are known to be in a mixture. This is done by discovering the specific gravity of the mixture by means of the hydrometer, and then deducing the proportion from a comparison of this with the specific gravities of the ingredients.

In this mode of examination the bulk is always the same; for the hydrometer, is immersed in the different fluids to the same depth. Now if an inch, for example, of this bulk is made up of the heaviest fluid, there is an inch wanting of the lightest; and the change made in the weight of the mixture is the difference between the weight of an inch of the heaviest and of an inch of the lightest ingredient. The number of inches therefore of the heaviest fluid is proportional to the addition made to the weight of the mixture. Therefore let B and b be the bulks of the heaviest and lightest fluids in the bulk p of the mixture; and let D, d, and p be the densities, or the weights, or the specific gravities (for they are in one ratio).
The specific gravity of the heavy fluid, the light fluid, and the mixture (their bulk being that of the hydrometer). We have $\frac{\beta}{\alpha} = \frac{B}{D} = \frac{b}{d}$. The addition which would have been made to the bulk if the lightest fluid were changed entirely for the heaviest, would be $D - d$; and the change which is really made is $\beta$. Therefore $\frac{\beta}{\alpha} = \frac{B}{D} = \frac{d - d'}{D - d}$.

For similar reasons we should have $\frac{\beta}{\alpha} = \frac{B}{D} = \frac{d}{D - d}$; or, in words, "the difference between the specific gravities of the two fluids, to the difference between the specific gravities of the mixture and of the lightest fluid, as the bulk of the whole to the bulk of the heaviest fluid contained in the mixture." and "the difference of the specific gravities of the mixture and of the heaviest fluid, as the bulk of the whole to that of the lightest fluid contained in the mixture." This is the form in which the ordinary balances of life require the answer to be expressed, because we generally reckon the quantity of liquids by bulk, in gallons, pints, quarts. But it would have been equally easy to have obtained the answer in pounds and ounces; or it may be had from their bulks, since we know their specific gravities.

The hydrometer more commonly used is the ancient form, a hardened glass tube, nominally cylindrical or conical, made ready by an addition $D$, below it the like, but having a long stem $C$ above. It is so loaded that it sinks to the top $F$ of the stem in the lightest of all the fluids which we propose to measure with it, and to sink only to $C$ in the heaviest. In a fluid of intermediate specific gravity it will sink to some point between $C$ and $F$.

In this form of the hydrometer the weight is always the same; and the information given by the instrument is that of different bulks with equal weight. Because the instrument sinks till the bulk of the displaced fluid equals its own weight, and the additions to the displaced fluid are all made by the stem, it is evident that equal bulks of the stem indicate equal additions of volume. Thus the stem becomes a scale of bulks to the same weight.

The only form in which the stem can be made with sufficient accuracy is cylindrical or prismatical. Such a stem may be made in the most accurate manner by drawing, that is, passing it through a hole made in a hardened steel plate. If such a stem be divided into equal parts, it becomes a scale of bulks in arithmetical proportion. This is the easiest and most natural division of the scale, but it will not indicate densities, specific gravities, or weights of the same bulk in arithmetical proportion. The specific gravity is as the weight divided by the bulk. Now a series of divisors (the bulks), in arithmetical progression, applied to the same dividend (the bulk and weight of the hydrometer as it floats in water), will not give a series of quotients (the specific gravities) in arithmetical progression: they will be in what is called harmonic progression, their differences continually diminishing. This will appear even when physically considered. When the hydrometer sinks a tenth of an inch near the top of the stem, it displaces one tenth of an inch of a light fluid, compared with that displaced by it when it is floating with all the stem above the surface. In order therefore that the divisions of the stem may indicate equal changes of specific gravity, they must be in a series of harmonic progressions increasing. The point at which the instrument floats in pure water should be marked 1000, and those above it 999, 998, 997, &c.; and those below the water mark must be numbered 1001, 1002, 1003, &c. Such a scale will be a very apposite picture of the densities of fluids, for the density or vicinity of the divisions will be precisely similar to the density of the fluids. Each interval is a bulk of fluid of the same weight. If the whole instrument were drawn into wire of the size of the stem, the length from the water mark would be 1000.

Such are the rules by which the scale must be divided. But there must be some points of it determined by experiment, and it will be proper to take them as remote from each other as possible. For this purpose let the instrument be accurately marked at the point where it stands, in two fluids, differing as much in specific gravity as the instrument will admit. Let it also be marked where it stands in water. Then determine with the utmost precision the specific gravities of these fluids, and put their values at the corresponding points of the scale. Then the intermediate points of the scale must be computed for the different intervening specific gravities, or it must be divided from a pattern scale of harmonic progressions in a way well known to the mathematical instrument-makers. If the specific gravities have been accurately determined, the value 1000 will be found to fall precisely in the water mark. If we attempt the division entirely by experiment, by marking a number of fluids of different specific gravities, and marking the stem as it stands in them, we shall find the divisions turn out very anomalous. This is however the way usually practised; and there are few hydrometers, even from the best makers, that hold true to a single division or two. Yet the method by computation is not more troublesome; and one scale of harmonic progressions will serve to divide every stem that offers. We may make use of a scale of equal parts for the stem, with the assistance of two little tables. One of these contains the specific gravities in harmonic progression, corresponding to the arithmetical scale of bulks on the stem of the hydrometer; the other contains the divisions and fractions of a division of the scale of bulks, which correspond to an arithmetical scale of specific gravities. We believe this to be the best method of all. The scale of equal parts on the stem is so easily made, and the little table is so easily inspected, that it has every advantage of accuracy and dispatch, and it gives, by the way, an amusing view of the relations of the bulks and densities.

We have hitherto supposed a scale extending from the lightest to the heaviest fluid. But unless it be of a very inconvenient length, the divisions must be very minute. Moreover, when the bulk of the stem bears a great proportion to that of the body, the instrument does not swim steadily; it is therefore proper to limit the range of the instrument in the same manner as those of the first kind. A range from the density of water to that of water may be very well executed in an instrument of very moderate size, and two others will do for all the heavier liquors; or an equal range in any other densities as may suit the usual occupations of the experimenter.

To avoid the inconveniences of a hydrometer with a very long and slender stem, or the necessity of having a series of them, a third fort has been contrived, in which
which the principle of both are combined. Suppose a hydrometer with a stem, whose bulk is \( \frac{1}{4} \) th of that of the ball, and that it sinks in ether to the top of the stem, it is evident that in a fluid which is \( \frac{1}{4} \) th heavier, the whole stem will emerge; for the bulk of the displaced fluid is now \( \frac{1}{4} \) th of the whole stem, and the weight is the same as before, and therefore the specific gravity is \( \frac{1}{4} \) th greater.

Thus we have obtained a hydrometer which will indicate, by means of divisions marked on the stem, all specific gravities from 0.73 to 0.803; for 0.803 is \( \frac{1}{4} \) th greater than 0.73. These divisions must be made in harmonic progression, as before directed for an entire scale, placing 0.73 at the top of the stem and 0.803 at the bottom.

When it floats at the lowest division, a weight may be put on the top of the stem, which will again sink it to the top. This weight must evidently be 0.073, or \( \frac{1}{4} \) th of the weight of the fluid displaced by the unloaded instrument. The hydrometer, thus loaded, indicates the same specific gravity, by the top of the stem, that the unloaded instrument indicates by the lowest division.

Therefore, when loaded, it will indicate another series of specific gravities, from 0.803 to 0.8833 (=0.803 + 0.0803), and will float in a liquor of the specific gravity 0.8833 with the whole stem above the surface.

In like manner, if we take off this weight, and put on 0.0803, it will sink the hydrometer to the top of the stem; and with this new weight it will float the hydrometer, thus loaded, to the top of the stem, and so on, using a series of weights, graduated in harmonic progression, until the whole range of the scale is divided into any number of equal parts.

This is a very commodious form of the instrument, and is now in very general use for examining spirituous liquors, worts, ales, brines, and many such articles of commerce. But the divisions of the scale are generally adapted to the questions which naturally occur in the business. Thus, in the commerce of strong liquors, it is usual to indicate the article by the quantity of spirit of a certain strength which the liquor contains. This we have accustomed to call proof spirit, and it is such that a wine gallon weighs 7 pounds 12 ounces; and it is by this strength that the excise duties are levied. Therefore the divisions on the scale, and the weights which connect the successive repetitions of the scale, are made to express at once the number of gallons or parts of a gallon of proof spirits contained in a gallon of the liquor. Such instruments save all trouble of calculation to the exciseman or dealer; but they limit the use of a very delicate and expensive instrument to a very narrow employment. It would be much better to adhere to the expression either of specific gravity or of bulk, and then a very small table, which could be compiled in the smallest cafe for the instrument, might render it applicable to every kind of fluid.

The reader cannot but have observed that the successive weights, by which the short scale of the instru-

ment is extended to a great range of specific gravities, do not increase by equal quantities. Each difference is the weight of the liquor displaced by the graduated item of the instrument when it is sunk to the top of the scale. It is a determined aliquot part of the whole weight of the instrument so loaded; (in our example it is always \( \frac{1}{4} \) th of it). It increases therefore in the same proportion with the preceding weight of the loaded instrument. In short, both the successive additions, and the whole weights of the loaded instrument, are quantities in geometrical progression; and, in like manner, the divisions on the scale, if they correspond to equal differences of specific gravity, must also be unequal.—

This is not sufficiently attended to by the makers; and they commit an error here, which is very considerable when the whole range of the instrument is great. For the value of one division of the scale, when the largest weight is on, is as much greater than its value, when the instrument is not loaded at all, as the full loaded instrument is heavier than the instrument unloaded. No manner whatever of dividing the scale will correspond to equal differences of specific gravity through the whole range with different weights; but if the divisions are made to indicate equal proportions of gravity when the instrument is used without a weight, they will indicate equal proportions throughout. This is evident from what we have just now saying; for the proportion of the specific gravities corresponding to any two immediately succeeding weights is always the same.

The best way, therefore, of constructing the instrument, so that the same divisions of the scale may be accurate in all its successive repetitions with the different weights, is to make these divisions in geometrical progression. The corresponding specific gravities will also be in geometric proportion. These being all inscribed in a table, we obtain them with no more trouble than by inspecting the scale which usually accompanies the hydrometer. This table is of the most easy construction; for the ratio of the successive bulks and specific gravities being all equal, the differences of the logarithms are equal.

This will be illustrated by applying it to the example already given of a hydrometer extending from 0.73 to 0.88393 with three weights. This gives four repetitions of the scale on the stem. Suppose this scale divided into ten parts, we have 40 specific gravities. Let these be indicated by the numbers 0, 1, 2, 3, &c. to 40. The mark 0 is affixed to the top of the stem, and the divisions downwards are marked 1, 2, 3, &c. the lowest being 10. These divisions are easily determined. The stem, which we may suppose 5 inches long, was supposed to be \( \frac{1}{4} \) th of the capa 10 of the ball. It may therefore be considered as the extremity of a rod of 11 times its length, or 55 inches; and we must find nine mean proportionals between 50 and 55 inches. Subtract each of these from 55 inches, and the remaining are the differences of the points of division from 0, the top of the scale. The smallest weight is marked 10, the next 20, and the third 30. If the instrument loaded with the weight 20 sinks in some liquor to the mark 7, it indicates the specific gravity 27, that is, the 27th of 40 mean proportionals between 0.73 and 1.068793, or 0.94442. To obtain all these intermediate specific gravities, we have only to subtract 0.863529, the logarithm
S P E  [ 665 ]  S P E  

Specific Gravity. 

Logarithm of 0.73, from that of 1.068793, viz. 0.288037, and take 0.0041393, the 40th part of the difference. Multiply this by 1, 2, 3, &c. and add the logarithm of 0.73 to each of the products. These sums are the logarithms of the specific gravities required. These will be found to proceed so equally, that they may be interpolated to any number of intermediate parts without the smallest sensible error. Therefore the item may be divided into a hundred parts very sensibly to the eye (each being nearly the 20th of an inch), and 400 degrees of specific gravity obtained within the range, which is as near as we can examine this matter by any hydrometer. Thus the specific gravities corresponding to 26, 27, 28, 29, are as follow:

Nay, the trouble of inspecting a table may be avoided, by forming on a scale the logarithms of the numbers between 7300 and 1068793, and placing along side of it a scale of the same length divided into 400 equal parts, numbered from 0 to 400. Then, looking for the mark shown by the hydrometer on this scale of equal parts, we see opposite to it the specific gravity.

We have been thus particular in the illustration of this mode of construction, because it is really a beautiful and commodious instrument, which may be of great use both to the naturalist and to the man of business.

A table may be comprised in 20 octavo pages, which will contain the specific gravities of every fluid which can intertend either, and answer every question relative to their admixture with as much precision as the observations can be made. We therefore recommend it to our readers, and we recommend the very example which we have given as one of the most convenient. The instrument need not exceed eight inches in length, and may be contained in a pocket case of 2 inches broad and as many deep, which will also contain the scale, a thermometer, and even the table for applying it to all fluids which have been examined.

It is unfortunate that no graduated hydrometer can be made so easily for the examination of the corrosive mineral acids (a). These must be made of glass, and we cannot depend on the accurate cylindrical form of any glass item. But if any such can be procured, the construction is the same. The divided scale may either be on thin paper pasted on the inside of the item, or it may be printed on the item itself from a plate, with ink made of a metallic cake, which will attach itself to the glass with a very moderate heat. We would recommend common white enamel, or aréline glass, as the fittest material for the whole instrument; and the ink used, in taking the impression of the scale, may be the same that is used for the low-priced printing on Delft ware pottery. First form the scale on the item. Then, having measured the solid contents of the graduated part as exactly as possible, and determined on the general shape of the ball and counterpoise below, calculate its size, so that it may be a little less than ten times that of the item. The glass-blower can copy this very nearly, and join it to the item. Then make two brass or other liquids, which shall have specific gravities in the ratios 1 to 10. Load the instrument so that it may float to the lightest. Then, put into the heaviest, it should rise to to. If it does not rise to high, the immersed part is too small. Let the glass blower enlarge the ball of the counterpoise a little. Repeat this trial till it be exact. Nothing now remains but to form the weights.

And here we observe, that when the instrument is to have a very great range, as for examining all flates of the vitriolic acid, it has a chance of being very tottering when loaded with the greatest weight on the top of so long a scale. To avoid this, Mr Quin and others have added some of their weights below.

But this will not suit the present construction, because it will alter the proportion between the bulbs of the item and immersed part. Therefore let these weights consist of cylinders of metal small enough to go into the item, and let them be soldered to the end of long wires, which will let them go to the bottom, and leave a small hook or ring at top. These can lie alongside of the instrument in its case. This is indeed the best construction for every hydrometer, because it makes it incomparably more steady. The instrument is poise from a small float or mercury. But it will be much better to do it with Newton's fusible metal (three parts of tin, five parts of lead, and eight parts of bismuth) in coarse filings. When the exact quantity has been put in, the instrument may be set in a vessel of oil, and this kept on the fire till all is completely melted. It soon freezes again, and remains fast. If this metal is not to be had, let a few bits of sealing-wax be added to the mercury or float, to make up the counterpoise. When heated, it will float a-top, and when it freezes again it will keep all fast. Thus we shall make a very complete and cheap instrument.

There is yet another method of examining the specific gravities of fluids, first proposed by Dr Wilfon, late professor of astronomy in the university of Glasgow. This is by a series of small glass bubbles, differing equally, or according to some rule, from each other in specific gravity, and each marked with its proper number. When these are thrown into a fluid which is to be examined, all those which are heavier than the fluid will fall to the bottom. Then holding the vessel in the hand, or near a fire or candle, the fluid expands, and one of the floating bubbles begins to sink. Its specific gravity, therefore, was either equal to, or a little less than, that of the fluid; and the degree of the thermometer, when it began to sink, will inform us how much it was deficient, if we know the law of expansion of the liquor. Sets of these bubbles fitted for the examination of spirituous liquors, with a little treacle showing the manner of using them, and calculating by the thermometer, are made by Mr Brown, an ingenious artist of Glasgow, and are often used by the dealers in spirits, being found both accurate and expeditious.

Also, though a bubble or two should be broken, the strength of spirits may easily be had by means of the remainder, unless two or three in immediate succession be

(a) It would be worth while to try copper enameled.
contains many experiments on this subject, with mixtures of gold and silver, of other metals, and of various fluids, examined by the hydrostatical balance of Mr. Boyle. Dr. Hooke made a prodigious number, chiefly on articles of commerce, which were unfortunately lost in the fire of London.

It was soon found, however, that Lord Bacon's conjecture had been well founded, and that bodies changed their densities very sensibly in many cases. In general, it was found that bodies which had a strong chemical affinity increased in density, and that their admission was accompanied with heat.

By this discovery it is manifest that Archimedes had not solved the problem of detecting the quantity of silver mixed with the gold in King Hiero's crown, and that the physical solution of it requires experiments made on all the kinds of matter that are mixed together.

We do not find that this has been done to this day, although we may affirm that there are few questions of more importance. It is a very curious fact in chemistry, and it would be most desirable to be able to reduce it to some general laws: For instance, to ascertain what is the proportion of two ingredients which produces the greatest change of density. This is important in the science of physics, because it gives us considerable information as to the mode of action of those natural powers or forces by which the particles of tangible matter are united.

If this introspection, concentration, penetration, or by whatever name it be called, were a mere reception of the particles of one substance into the interfaces of those of another, it is evident that the greatest concentration would be observed when a small quantity of the recipient is mixed with, or disseminated through, a great quantity of the other. It is thus that a small quantity of fine sand will be received into the interfaces of a quantity of small shot, and will increase the weight of the bagful without increasing its bulk. The case is nowise different when a piece of freestone has grown heavier by imbibing or absorbing a quantity of water.

In more than a certain quantity of sand has been added to the small shot, it is no longer concealed. In like manner, various quantities of water may combine with a mass of clay, and increase its size and weight alike. All this is very conceivable, occasioning no difficulty.

But this is not the case in any of the mixtures we are now considering. In all these, the first additions of either of the two substances produce but an incon siderable change of general density; and it is in general most remarkable, whether it be condensation or rarefaction, when the two ingredients are nearly of equal bulks. We can illustrate even this difference, by reflecting on the imbibition of water by vegetable bodies, such as timber. Some kinds of wood have their weight much more increased than their bulk; other kinds of wood are more enlarged in bulk than in weight. The like happens in grains. This is curious, and flows in the most unquestionable manner that the particles of bodies are not in contact, but are kept together by forces which act at a distance. For this distance between the centres of the particles is most evidently susceptible of variation; and this variation is occasioned by the introduction of another substance, which, by acting on the particles by attraction or repulsion, diminishes or increases their mutual actions, and makes new distances necessary.
necessary for bringing all things again into equilibrium. We refer the curious reader to the ingenious theory of the Abbé B. Vocchi for an excellent illustration of this subject. (Theor. Phil. Nat. 5 de Solutione Chemica). This question is no less important to the man of business. Till we know the condensation of these metals by mixing them, we cannot tell the quantity of alloy in gold and silver by means of their specific gravity; nor can we tell the quantity of pure alcohol in any spirituous liquor, or that of the valuable falt in any solution of it. For want of this knowledge, the dealers in gold and silver are obliged to have recourse to the tedious and difficult test of the alloy, which cannot be made in all places or by all men. It is therefore much to be wished, that some persons would initiate a series of experiments in the most interesting cases: for it must be observed, that this change of density is not always a small matter; it is sometimes very considerable and paradoxical. A remarkable instance may be given of it in the mixture of brass and tin for bells, great guns, optical spectacles, &c. The specific gravity of cast brass is nearly 8.006, and that of tin is nearly 7.363. If two parts of brass be mixed with one of tin, the specific gravity is 8.917; whereas, if each had retained its former bulk, the specific gravity would have been only 7.793 (\(\frac{2 \times 8.006 + 7.363}{3}\)). A mixture of equal parts should have the specific gravity 7.684; but it is 8.441. A mixture of two parts tin with one part brass, instead of being 7.577, is 8.027.

In all these cases there is a great increase of specific gravity, and consequently a great condensation of parts or contraction of bulk. The first mixture of eight cubic inches of brass, for instance, with four cubic inches of tin, does not produce 12 cubic inches of bell-metal, but only 10½, nearly, having shrunk \(\frac{1}{5}\). It would appear that the diminution of the brass's particles are most affected, or perhaps it is the brass that receives the tin into its pores; for we find that the condensations in these mixtures are nearly proportional to the quantities of the brass in the mixtures. It is remarkable that this mixture with the lightest of all metals has made a composition more heavy and dense than brass can be made by any hammering.
It is to be remarked, that the condensation is greatest when $16^1_2$ ounces of alcohol have been added to 20 of water, and the condensation is $\frac{\text{Sp. Grav}_{\text{observed}}}{\text{Sp. Grav}_{\text{calculated}}}$, or nearly $\frac{1}{3}$ of the computed density. Since the specific gravity of alcohol is 0.825, it is evident that $16^1_2$ ounces of alcohol and 20 ounces of water have equal bulks. So that the condensation is greatest when the substances are mixed in equal volumes; and 18 gallons of alcohol mixed with 18 gallons of water will produce not 36 gallons of spirits, but 35 only.

We may also observe, that this is the mixture to which the revenue-laws refer, declaring it to be one to which appeal may always be made under proof, and to weigh 7 pounds creases by the continual addition of an equal volume of one ingredient, and 20 for the other for the purposes of science or of trade. The regularity of the progression is so great, that in the column which we have examined, viz. that for temperature $69^0$, the greatest anomaly does not amount to one part in 10,000. The form of the series is also very judiciously chosen for the purposes of science. It would perhaps have been more directly illustrative had the proportions of the ingredients been stated in bulks, which are more immediately connected with density. But the author has adopted a very cogent reason for his choice, viz. that the proportion of bulks varied by a change of temperature, because the water and spirits follow different laws in their expansion by heat.

This is a proper opportunity for taking notice of a mistake which is very generally made in the conclusions drawn from experiments of this kind. Equal additions of the spirit or water produce a series of specific gravities, which decrease or increase by differences continually diminishing. Hence it is inferred that there is a contradiction of bulk. Even Dr Lewis, one of the most accomplished naturalists, advances this position, in a dissertation on the pot-ah of America; and it considerably affects his method for estimating the strength of the pot-ahs. But that it is a mistake, appears plainly from this, that although we add for ever equal quantities of the spirits, we shall never produce a mixture which has as small a specific gravity as alcohol. Therefore the series of succedaneous gravities must approximate to this without end, like the ordinates of a hyperbolic curve referred to its asymptote.

That this may appear in the most general terms, let $w$ represent the weight of the constant quantity of water in the mixture, and let $a$ be the weight of the small addition of spirits. Also let $w$ represent the bulk of this quantity of water, and $b$ the bulk of the small addition of alcohol. The weight of the mixture is $w+a$, and its bulk is $w+b$, and its specific gravity is $\frac{w+a}{w+b}$.

If we now add a second equal quantity of spirits, the weight will be $w+2a$, and if the spirit retains its density unchanged, the bulk will be $w+2b$, and the specific gravity is $\frac{w+2a}{w+2b}$; and after any number $m$ of such equal additions of spirits, the specific gravity will be $\frac{w+ma}{w+mb}$. Divide the numerator of this fraction by its denominator, and the quotient or specific gravity will be $1 + \frac{m \times \frac{a-b}{w+mb}}{w+mb}$. This consists of the constant part $1$, and the variable part $\frac{m(a-b)}{w+mb}$. We need attend only to this part. If its denominator were constant, it is plain that the succedaneous specific gravities would have equal differences, each being $\frac{a-b}{w+mb}$, because $m$ increases by the continual addition of an unit, and $a-b$ is a constant quantity. But the denominator $w+mb$ continually increases, and therefore the value of the fraction $\frac{a-b}{w+mb}$ continually diminishes.

Therefore the gradual diminution of the increments or decrements of specific gravity, by equal additions of one ingredient to a constant measure of the other, is not of itself an indication of a change of density of either of the ingredients; nor proves that in very diluted mixtures a greater proportion of one ingredient is absorbed or lodged in the interfaces of the other, as is generally imagined. This must be ascertained by comparing each specific gravity with the gravity expressed by $1 + \frac{w+ma(a-b)}{w+mb}$.

This series of specific gravities resembles such a numerical series as the following, 1, 1.156; 1.163; 1.169; &c. the terms of which also consist of the constant integer 1, and the decimal fractions 0.156; 0.163; 0.169; &c. The fraction $\frac{m(a-b)}{w+mb}$ expresses this decimal part. Call this $d$, or make $d = \frac{m(a-b)}{w+mb}$.

This will give us $b = \frac{ma-wd}{m(1+d)}$. Now $a$ is the weight of the added ingredient, and $d$ is the variable part or the specific gravity observed; and thus we learn whether...
either of the ingredients, suffers any change. We shall have occasion by and by to resume the consideration of this question, which is of the first moment in the theory of specific gravities, and has great influence in many transactions of commerce.

This series of specific gravities is not so well fitted for commercial transactions. In the usual question is, how many gallons of alcohol is there in a cask, or some number of gallons of spirit? and it is more directly answered by means of a table, formed by mixing the ingredients in aliquot parts of one confiant bulk. The following table, contrived from the experiments of Mr Brifon of the academy of Paris, and published in the Memoirs for 1769, is therefore inferred.

</table>

In this table the whole quantity of spirituous liquor is always the same. The first column is the number of measures (gallons, pints, inches, &c.) of water in the mixture; and column 2d gives the measures of alcohol. Column 3d is the specific gravity which was observed by Mr Brifon. Column 4th is the specific gravity which would have been observed if the spirits, or water, or both, had retained their specific density unchanged. And the 5th column marks the augmentation of specific gravity or density in parts of 10,000. A 6th column is added, showing the bulk of the 16 cubic measures of the two ingredients. Each measure may be conceived as the 16th part of 10,000, or 625; and we may suppose them cubic inches, pints, gallons, or any solid measure.

This table fearfully differs from Sir Charles Blagden's; and the very small difference that may be observed, arises from Mr Brifon's having used an alcohol not so completely rectified. Its specific gravity is 0,8371, whereas the other was only 0,8250.

Here it appears more distinctly that the condensation is greatest when the two ingredients are of equal bulk.

Perhaps this series of specific gravities is as declarative as the other, whether or not there is a change of density induced on either of the ingredients. The whole bulk being always the same, it is plain that the successive equal additions to one of the ingredients is a successive equal abridgment of the other. The change produced, therefore, in the weight of the whole, is the difference between the weight of the ingredient which is taken out and the weight of the equal measure of the other which supplies its place. Therefore, if neither ingredient changes its density by mixture, the weights of the mixtures will be in arithmetical progression. If they are not, there is a variation of density in one or both the ingredients.

We see this very clearly in the mixtures of water and alcohol. The first specific gravity differs from the second by 0,56, and the last differs from the preceding by no more than 81. Had it not required much changes, the common difference would have been 0,25.

We observe also, that the augmentation of specific gravity, by the successive addition of a measure of water, grows less and less till 12 measures of water is mixed with 4 of alcohol, when the augmentation is only 58, and then it increas again to 81.

It also appears, that the addition of one measure of water to a quantity of alcohol produces a greater change of density than the mixture of one measure of alcohol to a quantity of water. Hence some conclude, that the water disappears by being lodged in the interstices of the spirit. But it is more agreeable to the just theory notions which we can form of the internal constitution of tangible bodies to suppose that the particles of water diminish the distances between the particles of alcohol by their strong attractions, and that this diminution (exceedingly minute in itself) becomes sensible on account of the great number of particles whose distances are thus diminished. This is merely a probability founded on this, that it would require much greater diminution of distances if it was the particles of water which had their distances thus diminished. But the greater probability is, that the condensation takes place in both.

We have been so particular in our consideration of this mixture, because the law of variation of density has, in this instance, been ascertained with such precision by the elaborate examination of Sir Charles Blagden, so that it may serve as an example of what happens in almost every mixture of bodies. It merits a fuller discussion, because it is intimately connected with the action of the corpuscular forces; and an exact knowledge of the variations of distance between the particles will go far to ascertain the law of action of these forces. But the limits of a Work like this will not permit us to dwell longer on this subject. We proceed therefore to give another useful table.

The vitriolic or sulphuric acid is of extensive use in manufactures under the name of oil of vitriol. Its value depends entirely on the pure ingredient, and the water is merely a vehicle for the acid. This, being much denser than water, affects its specific gravity, and thus gives us a method of ascertaining its strength.

The strongest oil of vitriol that can be easily manufactured contains 612,4 grains of dry acid, united with 387,5 grains of water, which cannot be separated from it by distillation, making 1000 grains of oil of vitriol. Its specific gravity in this state is 1,877.

The following table shows its specific gravity at the temperature 55°, when diluted by the successive addition of parts of water by weight.

Specific Gravity.
The proportions of the aeriform ingredients of the muriatic acid are so very variable, and so little under our command, that we cannot frame tables of its specific gravity which would enable us to judge of its strength.

It is a general property of these acids, that they are more expansible by heat as they are more concentrated.

There is another class of fluids which it would be of great consequence to reduce to some rules with respect to specific gravity, namely, the solutions of salts, gums, and resins. It is interesting to the philosopher to know in what manner salts are contained in these watery solutions, and to discover the relation between their strength and density; and to the man of business it would be a most desirable thing to have a criterion of the quantity of salt in any brine, or of extraneous matter in a decoction. It would be equally desirable to those who are to purchase them as to those who manufacture or employ them. Perhaps we might after all arrive in this way the value of figar, depending on the quantity of sweetening matter, which it contains; a thing which at present relies on the vague determination of the eye or palate. It would therefore be doing a great service to the public, if some intelligent person would undertake a train of experiments with this view. Accuracy alone is required; and it may be left to the philosophers to compare the facts, and draw the consequences respecting the internal arrangement of the particles.

One circumstance in the solution of salts is very general; and we are inclined, for serious reasons, to think it universal: this is a diminution of bulk. This indeed in some cases is inconsiderable. Sedative salt, for instance, hardly shows any diminution, and might be considered as an exception, were it not the salt at present relies on the vague determination of the eye or palate. This circumstance, and some considerations connected with our notions of this kind of solution, dispose us to think that this salt differs in contradiction from others only in degree, and that there is some, though it was not feasible, in the experiment hitherto made.

These experiments, indeed, have not been numerous. Those of Mr. Achard of Berlin, and of Dr. Richard Watfon of Cambridge, are perhaps the only ones of which we have a descriptive narration, by which we can judge of the validity of the inferences drawn from them. The subject is not susceptible of much accuracy; for salts in their solid form are seldom free from cavities and fibrous interstices, which do not admit the water on their first immersion, and thereby appear of greater bulk when we attempt to measure their specific gravity by weighing them in fluids which do not disolve them, such as spirits of turpentine. They also attach to themselves, with considerable tenacity, a quantity of atmospheric air, which merely adheres, but makes no part of their composition. This escapes in the act of solution, being yet at liberty by the stronger affinity of the water. Sal gern, however, and a few others, may be very accurately measured; and in these instances the degree of contraction is very constant.

The following experiments of Dr. Watfon appear to us the most instructive as to this circumstance. A glass vessel was used, having a slender cylindrical neck, and holding 67 ounces of pure water when filled to a certain

There is not the same uniformity in the densities of this acid in its different states of dilution. This seems owing to the variable proportion of the deleterious and vital air which compose this acid. It is more dense in proportion as it contains more of the latter ingredient.
tain mark. The neck above this mark had a scale of equal parts pasted on it. It was filled to the mark with water. Twenty-four pennyweights of salt were thrown into it as speedily as possible, and the bulk of the salt was measured by the elevation of the water. Every thing was attended to which could retard the immediate solution, that the error arising from the solution of the first particles, before the rest could be put in, might be as small as possible; and in order that both the absolute bulk and its variations might be obtained by some known scale, 24 pennyweights of water were put in. This raised the surface 58 parts of the scale. Now we know exactly the bulk of 24 pennyweights of pure water. It is 2,275 cubic inches; and thus we obtain every thing in absolute measures: And by comparing the bulk of each salt, both at its first immersion and after its complete solution, we obtain its specific gravity, and the change made on it in passing from a solid to a fluid form. The following table is an abstract of these experiments. The first column of numbers is the elevation of the surface immediately after immersion; the second gives the elevation when the salt is completely dissolved; and the third and fourth columns are the specific gravities of the salts in these two states.

</table>

The inspection of this list naturally suggests two states of the case as particularly interrelating to the philosopher studying the theory of solution. The first state is when the laximum approaches to saturation. In the very point of saturation any addition of salt retains its bulk unchanged. In diluted brines, we shall see that the density of the fluid salt is greater, and gradually diminishes as we add more salt. It is an important question, whether this diminution goes on continually, till the fluid density of the salt is the same with its solid density? or, whether there is an abrupt passage from some degree of the one to the fixed degree of the other, as we observe in the freezing of iron, the setting of tallow, and some other inclusions?

The other interesting state is that of extreme dilution, when the differences between the successive densities bear a great proportion to the densities themselves, and thus enable the mathematician to ascertain with some precision the variations of the particles, in consequence of a variation of distance between the particles. The sketch of an investigation of this important question given by Boscowich, in his Theory of Natural Philosophy, is very promising, and should incite the philosophical chemist to the study. The first thing to be done is to compare the law of specific gravity; that is, the relation between the specific gravity and quantity of salt held in solution.

Willing to make this work as useful as possible, we have searched for experiments, and trains of experiments, on the density of the many brines which make important articles of commerce; but we were mortified by the candor of the information, and disappointed in our hopes of being able to combine the detached observations, suited to the immediate views of our authors, in such a manner as to deduce from them scales (as they may be called) of their strength. We rarely found these detached observations attended with circumstances which would connect them with others; and there was frequently such a discrepancy, may opposition, in series or experiments made for ascertaining the relation between the density and the strength, that we could not obtain general principles which enable us to construct tables of strength a priori.

Mr Lambert, one of the first mathematicians and philosophers of Europe, in a dissertation in the Berlin Memoirs (1762), gives a narration of experiments on the brines of common salt, from which he deduces a very great condensation, which he attributes to an absorption in the weak brines of the salt, or a condensation of its particles in the interfaces of the particles of water. Mr Achard of the same academy, in 1785, gives a very great list of experiments on the brines of various brines, made in a different way, which threw no such introduction; and Dr Watton, formerly professor of chemist at Cambridge, and now bishop of Landaff, thinks this confirmed by experiments which he narrates in his Chemical Essays. We feel great reason for hesitating our assent to either side, and do not think the experiments decisive. We incline to Mr Lambert’s opinion; for this reason, that in the successive dilutions of oil of vitriol and aquafortis there is a most evident and remarkable condensation. Now what are these but brines, of which we have not been able to get the saline ingredient in a separate form? The experiments of Mr Achard and Dr Watton were made in such a way that a single grain in the measurement bore too great a proportion to the whole change of specific gravity. At the same time, some of Dr Watton’s are so simple in their nature that it is very difficult to withhold the assent.

In this state of uncertainty, in a subject which seems to us to be of public importance, we thought it our duty to undertake a train of experiments to which recourse may always be had. Works like this are seldom considered as sources of original information; and it is thought sufficient when the knowledge...
ledge already diffused is judiciously compiled. But a due respect for the public, and gratitude for the very honourable reception hitherto given to our labours, induce us to exert ourselves with honest zeal to merit the continuance of public favour. We assure our readers that the experiments were made with care, and on quantities sufficiently large to make the unavoidable irregularities in such cases quite insignificant. The law of density was ascertained in each substance in two ways. We dissolved different portions of salt in the same quantity of water, and examined the specific gravity of the brine by weighing it in a vessel with a narrow neck. The portions of salt were each of them one-eighth of what might be considered a nearly saturated solution of the temperature 55°. We did not make the brine stronger, that there might be no risk of a precipitation in form of crystals. We considered the specific gravities as the ordinates of a curve, of which the abscissae were the numbers of ounces of dry salt contained in a cubic foot of the brine. Having thus obtained eight ordinates corresponding to 1, 2, 3, 4, 5, 6, 7, and 8 portions of salt, the ordinates or specific gravities for every other proportion of salt were had by the usual methods of interpolation.

The other method was, by first making a brine nearly saturated, in which the proportion of salt and water was exactly determined. We then took out one-eighth of the brine, and filled up the vessel with water, taking care that the mixture should be complete; for which purpose, besides agitation, the diluted brine was allowed to remain 24 hours before weighing. Taking out one-eighth of the brine also takes out one eighth of the salt; so that the proportion of salt and water in the diluted brine was known. It was now weighed, and thus we determined the specific gravity for a new proportion of salt and water.

We then took out one-seventh of the brine. It is evident that this takes out one-seventh of the original quantity of salt; an abstraction equal to the former. We filled the vessel with water with the same precautions; and in the same manner we proceeded till there remained only one-eighth of the original quantity of salt.

The specific gravities by these two methods agreed extremely well. In the very deliquescing saltes the first method exhibited some small irregularities, arising from the unequal quantities of water which they had imbibed from the atmosphere. We therefore confined most of the experiments made with diluted brines.

That the reader may judge of the authority of the tables which we shall infer, we submit to his inspection one series of experiments.

Two thousand one hundred and eighty-eight grains of very pure and dry (but not decrepitated) common salt, prepared in large crystals, were dissolved in 6562 grains of distilled water of the temperature 55°. A small matrafi with a narrow neck, which held 4200 grains of distilled water, was filled with this brine. Its contents weighed 5027 grains. Now 6562 + 2185 = 5027 : 125675. Therefore the bottle of brine contained 125675 grains of salt dissolved in 377045 grains of water. Its specific gravity is \( \frac{5027}{2185} \), or 1.196905; and a cubic foot of brine weighs 11969 ounces avoirdupois. Alto 5027 : 125675:

Thus, by repeated abstraction of brine, so as always to take out the fifth of the salt contained in one constant bulk, we have obtained a brine consisting of 157 grains of salt united with 4313, or 1475 grains of water. Its specific gravity is \( \frac{513}{4200} \), or 1.196905, and a cubic foot of its weight 1028 ounces, and contains 37.76 ounces of dry salt. In like manner may the specific gravity, the weight of a cubic foot, and the salt it contains, be estimated for the intermediate brines.

When these eight quantities of salt contained in a cubic foot are made the abscissae, and the weights of the cubic foot of brine are the corresponding ordinates, the curve
Specific curve will be found to be extremely regular, resembling a hyperbolic arch whose asymptote makes an angle of 30° with the axis. Ordinates were then interpolated analytically for every 10 ounces of contained salt, and thus the table was constructed. We did not, however, re-interpret it on one figure alone; but made others, in which 1/9 of the salt was repeatedly abstracted. They agreed, in some cases of common salt, with great exactness, and in some others there were some very considerable irregularities.

To show the authority of the tables of strength was by no means our only motive for giving an example of the process. It may be of use as a pattern for similar experiments. But, besides, it is very instructive. We see, in the first place, that there is a very sensible change of density in one or both of the ingredients. For the series is of that nature (as we have formerly explained), that if the ingredients retained their densities in every proportion of mixture, the specific gravities would have been in arithmetical progression; whereas we see that their differences continually diminish as the brines grow more dense. We can form some notion of this by comparing the different brines. Thus in the first brine, weighing 5027 grains, there are 3770 grains of water in a vessel holding 4200. If the density of the water remains the same, there is left for the salt only as much space as would hold 430 grains of water. In this space are lodged 1257 grains of salt, and its specific gravity, in its liquid form, is 1257/4200 = 1.9097 very nearly. But in the 8th brine the quantity of water is 4156, the space left for 157 grains of salt is only the bulk of 44 grains of water, and the density of the salt is 157/430 = 3.638, considerably greater than before. This induced us to continue the dilution of the brine as follows, beginning with the 8th brine.

| 157 | 2| 4313 | 8th brine. | 785 | 21565 | 21565 | 21056 |
| 785 | | | |
| 785 | 2| 4262 | 9th brine. | 597 | 2131 | 2131 | 2102 |
| 397 | 2| 4233 | 10th brine. | 21165 | 21165 | 2102 |
| | | | | 198 | 4218 | 11th brine. |

This last brine contains 4198.4 grains of water, leaving only the bulk of 1.8 grains of water to contain 19.8 of salt, so that the salt is ten times denser than water. This will make the strength 242.5 instead of 210 indicated by the specific gravity. But we do not pretend to measure the densities with accuracy in these diluted brines. It is evident from the process that a single grain of excess or defect in taking out the brine and replacing it with water has a sensible proportion to the whole variation. But we see with sufficient evidence, that from the strength to the weak brine the space left for the portion of salt is continually diminishing. In the first dilution 232 grains of water were added to fill up the vessel; but 1/9 of its contents of pure water is only 325; so that there is a diminution of 1/9 grains of the space occupied by the remaining salt. The subsequent additions were 606.7, 706.5, 857, 1054.5, 1405.3, 2105.5, 2102, instead of 600, 700, 840, 1050, 1400, 2100, 2100. Nothing can more plainly show the condensation in general, though we do not learn whether it happens in one or both of the ingredients; nor do the experiments show with sufficient accuracy the progression of this diminution. The excesses of the added water being only six or seven grains, we cannot expect a nice repartition. When the brine is taken out, the upper part of the vessel remains lined with a briny film containing a portion of salt and water, perhaps equal or superior to the differences. Had our time permitted, we should have examined this matter with ferupulous attention, using a vessel with a still narrower neck, and in each dilution abstracting one half of the brine. The curve, whose abscissae and ordinates represent the weight of the contained salt and the weight of a constant bulk of the brine, exhibits the belt and most synoptical view of the law of condensation, because the position of the tangent in any point, or the value of the symbol dy, always shows the rate at which the specific gravity increases or diminishes. We are inclined to think that the curve in all cases is of the hyperbolic kind, and complete; that is, having the tangent perpendicular to the axis at the beginning of the curve. The mathematical reader will easily guess the physical notions which incline us to this opinion; and will also see that it is hardly possible to discover this experimentally, because the mistake of a single grain in the very small ordinates will change the position of the tangent many degrees. It was for this reason that we thought it useless to prosecute the dilution any further. But we think that it may be prosecuted much further in Dr Watfon's or Mr Achard's method, viz. by dissolving equal weights of salt in two vessels, of very different capacities, having tubular necks, in which the change of bulk may be very accurately observed. We can only conclude, that the condensation is greatest in the strongest brines, and probably attains its maximum when the quantities of true saline matter and water are nearly equal, as in the case of vitriolic acid, &c.

We consider these experiments as abundantly sufficient for deciding the question "Whether the salt can be received into the pores of the water, or the water into the pores of the salt, so as to increase its weight without increasing its bulk?" and we must grant that it may. We do not mean that it is simply lodged in the pores as sand is lodged in the interstices of small flint; but the two together occupy less room than when separate. The experiments of Mr Achard were insufficient for a decision, because made on so small a quantity as 600 grains of salt. Dr Watfon's experiments have, for the most part, the same defect. Some of them, however, are of great value in this question, and are very fit for alter-
containing the specific gravity of dissolving salts. In one of them (not particularly narrated) he found that a quantity of dissolved salt occupied the same bulk in two very different states of dilution. We cannot pretend to reconcile this with our experiments. We have given these as they stood; and we think them conclusive, because they were so numerous and so perfectly consistent with each other; and their result is so general, that we have not found an exception. Common salt is by no means the most remarkable instance of condensation. Vegetable alkali, sal ammoniac, and some others, exhibit much greater condensation.

We thought this a proper opportunity of considering this question, which is intimately connected with the principles of chemical solution, and was not perhaps considered in sufficient detail under the article Chemistry. We learn from it in general, that the quantities of salt in brines increase at some greater rate than their specific gravities. This difference is in many cases of sensible importance in a commercial view. Thus an alkaline lixivium for the purpose of bleaching or soap-making, whose specific gravity is 1,234, or exceeds that of water by 234, contains 361 ounces of salt in a cubic foot; a ley, which exceeds the weight of water twice as much, or 468 ounces per cubic foot, contains 777 ounces of salt, which exceeds the double of 361 by 55 ounces more than 7 per cent. Hence we learn, that hydrometers for discovering the strength of brines, having equal divisions on a cylindrical item, are very erroneous; for even if the increments of specific gravity were proportional to the quantities of salt in a gallon of brine, the divisions at the bottom of the item ought to be smaller than those above.

The construction of the following table of strengths from the above narrated series of brines is sufficiently obvious. Column 1st is the specific gravity as discovered by the balance or hydrometer, and also is the number of ounces in a cubic foot of the brine. Col. 2d is the ounces of the dry salt contained in it.

</table>

The table differs considerably from Mr. Lamhert's. The quantities of salt corresponding to any specific gravity are about 5/6th less than in his table. But the reader will see that they correspond with the series of experiments above narrated; and there were but a few of many which all corresponded within an hundredth part. The cause of the difference seems to be, that most kinds of common salt contain magnesium salts, which contain a very great proportion of water necessary for their crystallization. The salt which we used was of the purest kind, but such as may be had from every salt works, by Lord Dundonald's very easy process, viz. by passing through it a saturated solution boiling hot, which carries off with it about 3ths of all the bitter salts. Our aim being to ascertain the quantities of pure salt, and to learn by the by its relation to water in respect of density, we thought it necessary to use the purest salt. We also dried it for several days in a stove, so that it contained no water not absolutely necessary for its crystallization. An ounce of such salt will communicate a greater specific gravity to water than an ounce of a salt that is less pure, or that contains extraneous water.

The specific gravity 1,060 is that of ordinary pickles, which are estimated as to strength by floating an egg.

We cannot raise the specific gravity higher than 1,206 by simply dissolving salt in cold water. But it will become much denser, and will even attain the specific gravity 1,240 by boiling, so that a vessel which held 3006 grains of distilled water held 4329 of this brine. This was evaporated to dryness, and there were obtained 1344 grains of salt. By this was computed the number interpolated between 310 and 320 in the table. We have however raised the specific gravity to 1,217, by putting in no more salt than was necessary for this density, and using heat. It then cooled down to 60° without quitting any salt; but if a few grains of salt be thrown into this brine, it will quickly deposit a great deal more, and its density will decrease to 1,206. We find this to hold in all salts; and it is a very instructive fact in the theory of crystallization; it resembles the effect which a magnet produces upon iron filings in its neighbourhood. It makes them temporary magnets, and causes them to arrange themselves as if they had been really made permanent magnets. Just as a crystal already formed dips the root to crystallize. We imagine that this analogy is complete, and that the forces are similar in both cases.

The above table is computed for the temperature 50°; but in other temperatures the strength will be different on two accounts, viz. the expansion of the brine and the dissolving power of the water. Water expands about 40 parts in 1000 when heated from 60° to 212°. Saturated brine expands about 48 parts, or 4/5th more than water; and this excess of expansion is nearly proportional to the quantity of salt in the brine. If therefore any circumstance should oblige us to examine a brine in a temperature much above 60°, allowance should be made for this. Thus, should the specific gravity of brine of the temperature 130° (which is nearly half way between 60 and 212) be 1,140, we must increase it by 20 (half of 40); and having found the strength 240 corresponding to this corrected specific gravity, we must correct it again by adding 1 to the specific gravity for every 43 ounces of salt.
But a much greater and more uncertain correction is necessary in account of the variation of the dissolving power of water by heat. This indeed is very small in the case of sea-salt in comparison with other salts. We presume that our readers are apprised of this peculiarity of sea-salt, that it dissolves nearly in equal quantities in hot or in cold water. But although water of the temperature 60 will not dissolve more than 320 or 325 ounces of the purest and dryest sea-salt, it will take up above 20 ounces more by boiling on it. When thus saturated to the utmost, and allowed to cool, it does not quit any of it till it is far cooled, viz. near to 60°. It then deposits this redundant salt, and holds the rest till it is just going to freeze, when it lets it go in the infant of freezing. If evaporated in the flame in which it continues to hold the salt, it will yield above 400 ounces per cubic foot of brine, in good crystals, but rather overcharged with water. And since in this flame the cubic foot of brine weighs about 1220 ounces, it follows, that 820 ounces of water will, by boiling, dissolve 400 of crystallized salt.

The table shows how much any brine must be boiled down in order to grain. Having observed its specific gravity, find in the table the quantity of salt corresponding. Call this \( x \). Then, since a boiling hot grainings or saturated solution contains 340 ounces in the cubic foot of brine, say \( 340 : \frac{1000}{x} = x : \frac{1000}{340} \). This is the bulk to which every cubic foot (valued at \( 1000 \)) must be boiled down. Thus suppose the brine has the specific gravity 1109. It holds 160 ounces per foot, and we must boil it down to \( 1000 \times 160 \) or 471; that is, we must boil off \( \frac{1000}{340} \) of every cubic foot or gallon.

These remarks are of importance in the manufacture of common salt; they enable us to appreciate the value of salt springs, and to know how far it may be profitably to engage in the manufacture. For the doctrine of latent heat affords us, that in order to boil off a certain quantity of water, a certain quantity of heat is indispensably necessary. After the most judicious application of this heat, the consumption of fuel may be too expensive.

The specific gravity of sea-water in these climates does not exceed 1.021, or the cubic foot weighs 1030 ounces, and it contains about 41 ounces of salt. The brine-pits in England are vastly richer; but in many parts of the world brines are boiled for salt which do not contain above 10 or 20 ounces in the cubic foot.

In buying salt by weight, it is of importance to know the degree of humidity. A salt will appear pretty dry (if free from magnesia salts) though moistened with 1 per cent. of water; and it is found that incipient humidity exposes it much to farther deliquescence. A much smaller degree of humidity may be discovered by the specific gravity of a brine made with a few ounces of the salt. And the inspection of the table informs us that the brine should be weak; for the differences of specific gravity go on diminishing in the stronger brines: 300 ounces of dry salt dissolved in 807 ounces of water should give the specific gravity 1197. Suppose it be but 1190, the quantity of salt corresponding is only 290; but when mixed with 897 ounces of water, the weight is 1197, although the weight or the cubic foot is only 1190. There is therefore more than a cubic foot of the brine, and there is as much salt as will make more than a cubic foot of the weight 1190. There is 290 \( \times 1197 \), or 291. ounces, 1190

and there is 8½ ounces of water attached to the salt.

The various informations which we have pointed out as deducible from a knowledge of the specific gravity of the brines of common salt, will serve to suggest several advantages of the knowledge of this circumstance in other brines. We shall not here reform them, but simply give another table or two of such as are most interesting. Of those alkaline leys are the chief, being of extensive use in bleaching, soap-making, glass-making, &c.

We therefore made a very strong ley of the purest vegetable alkali that is ever used in the manufactories, not thinking it necessary, or even proper, to take it in its state of utmost purity, as obtained from cubic nitre and the like. We took salt of tartar from the apothecary, perfectly dry, of which 3983 grains were dissolved in 3540 grains of distilled water, and after agitation for several days, and then standing to deposit sediment, the clear ley was decanted. It was again agitated; because, when of this strength, it becomes, in a very short time, rarer above and denser at the bottom. A flask containing 4200 grains of water held 6165 of this ley when of the temperature 55°. Its specific gravity was therefore 1,407,8, and the 6165 grains of ley contained 3264 grains of salt. We examined its specific gravity in different flutes of dilution, till we came to a brine containing 51 grains of salt, and 4189 grains of water, and the contents of the flask weighed 4240 grains: its specific gravity was therefore 1,0097. In this train of experiments the progression was most regular and satisfactory; so that when we constructed the curve of specific gravities geometrically, none of the points deviated from a most regular curve. It was considerably more incur- vated near its commencement than the curve for sea-salt indicating a much greater condensation in the diluted brines. We think that the following table, constructed in the same manner as that for common salt, may be depended on as very exact.

We see the same augmentation of the density of the salt in the diluted brines here as in the case of common salt. Thus a brine, of which the cubic foot weighs 1.482 ounces, or which has the specific gravity 1.482, contains 800 ounces of dry alkali and 682 of water. Therefore, if we suppose the density of the water unchanged, there remains the bulk of 318 ounces of water to receive 840 ounces of salt: its density is therefore $\frac{318}{800} = 0.4$ nearly. But in the brine whose weight per foot is only 1.016 there are 20 ounces of salt, and therefore 996 of water; and there is only four ounce-measures of water, that is, the bulk of four ounces of water, to receive 20 ounces of salt. Its specific gravity therefore is $\frac{20}{4} = 5$, almost twice as great as in the strong brine. Accordingly Mr. Achard is disposed to admit the abstraction (as it is carelessly termed) in the case of salt tart. But it is a general (we think an universal) fact in the solution of salts. It must be carefully distinguished from the first contraction of bulk which salts undergo in passing from a solid to a fluid form. The contraction now under consideration is analogous to the contraction of oil of vitriol when diluted with water; for oil of vitriol must be considered as a very strong brine which we cannot dephlegmate by distillation, and therefore cannot obtain the dry saline ingredient in a separate form, so as to observe its solid density, and say how much it contracts in first becoming fluid. The way of conceiving the first contraction in the act of solution as a lodging of the particles of the one ingredient on the interfaces of the other, "en les fe lieant en augmentant le poids sans afféter le volume de la saumure," as Eiller and Lambert express themselves, is impossible here, when both are fluids. Indeed it is but a flowery way of thinking in either case, and should be avoided, because inadvertent persons are apt to use a physical principle which is merely a mode of speech.

We learn from the table, that a hydrometer with equivalent divisions on a cylindrical or prismatical stem is still more erroneous than in the brines of common salt.

We learn from the experiments of Kirwan, Lavoisier, and others, that dry salt of tartar contains about 3/4 of its weight of fixed air. In many applications of this salt to the purposes of manufacture, this ingredient is of no use. In soap it is hurtful, and must be abstracted by lime. Soap-maker's ley consists of the pure alkaline salt dissolved in water. It is therefore of importance to ascertain its quantity by means of the specific gravity of the brine. For this purpose, we took a ley of salt tartar whose specific gravity was 1.20417, containing 314 oz. of mild alkali in a cubic foot of ley, and we rendered it nearly caustic by lime. The specific gravity was then 1.1897. This is a very unexpected result. Nothing is employed with more success than quicklime for dephlegmating any watery fluid. We should rather have expected an increase of specific gravity by the abstraction of some of the water of the menhirium, and perhaps the water of the crysballization, and the aerial part of the salt. But we must ascribe this to the great density in which the fixed air exists in the mild alkali.

It is unnecessary to give similar tables for all the salts, unless we were writing a dissertation on the theory of their solution. We shall only observe, that we examined with particular attention salt ammoniac, because Mr. Achard, who denies what is called the abstraction of salts, finds himself obliged to allow something like it in this salt. It does not, however, differ from those of which we have given an account in detail in any other respect than this, that the changes of fluid density are much less than in others (instead of being greater, as Achard's experiments seem to indicate) in all brines of moderate strength. But in the very weak brines there is indeed a remarkable difference; and if we have not committed an error in our examination, the addition of one part of salt ammoniac to 64 of water occupies less room than the water alone. We think that we have met with this as an accidental remark by some author, whose work we do not recollect. But we do not choose to rest too much on our form of the experiment in such weak brines. The following mixtures will abundantly serve for contrasting the table of its strength: Sal ammoniac = 960 grains was dissolved in 3566 grains of water, making a brine of 4466 grains. A phial which held 1600 grains of water held 1698 of this brine. It contained $\frac{1698 \times 960}{4466}$, or 365 grains of salt. The specific gravity was $\frac{1698}{1600} = 1.061$, and the cubic foot weighed 1698 ounces. It also contained $\frac{1601 \times 265}{1698}$, or 228 ounces of salt. By repeated abstraction of brine, and replacing with water, we had the following series:

</table>

This series is extremely regular, and the progress of density may be confidently deduced from it.

From the whole of this disquisition on the relation between the specific gravities of brines and the quantities of salt contained, we see in general that it may be ascribed, with a useful degree of precision, from the density or specific gravity of saturated solutions. We therefore conclude with a list of the specific gravities of several saturated solutions, made with great care by the bishop of Landaff.—The temperature was $42^\circ$. The first numerical column is the density of saturated brine, and the next is the density of a brine containing 12 parts (by weight) of water and one of salt. From this may be inferred the quantity in the saturated solution, and from this again may be inferred the quantity corresponding to inferior densities.

SPECTACLES, in dioptrics, a machine consisting of two lenses set in silver, horn, &c. to affit the defects of the organ of sight. Old people, and others who have flat eyes, use convex spectacles, which cause the rays of light to converge so as to meet upon the retina: whereas myopes, or short sighted people, use concave lenses for spectacles, which cause the rays to diverge, and prevent their meeting ere they reach the retina.

See Optics, n° 73.

Ocular SPECTRA, images presented to the eye after removing them from a bright object, or closing them. When any one has long and attentively looked at a bright object, as at the setting sun, on closing his eyes, or removing them, an image, which resembles in form the object he was attending to, continues some time to be visible. This appearance in the eye we shall call the ocular spectrum of that object.

These ocular spectra are of four kinds: 1st. Such as are owing to a less sensibility of a defined part of the retina or spectra from the defect of sensibility. 2d. Such as are owing to a greater sensibility of a defined part of the retina, or spectra from excess of sensibility. 3d. Such as resemble their object in its colour as well as form: which may be termed direct ocular spectra. 4th. Such as are of a colour contrary to that of the object, which may be termed reverse ocular spectra.

SPECTRE, an apparition, something made preternaturally visible to human sight, whether the ghosts of dead men or beings superior to man.

A belief that supernatural beings sometimes make themselves visible, and that the dead sometimes revisit the living, has prevailed among most nations, especially in the rudest ages of society. It was common among the Jews, among the Greeks, and among the Romans, as we find from the Scriptures, and from the poems of Homer and Virgil. Celestial appearances were indeed often exhibited to the Jews, that the origin of their belief is not difficult to be explained. The Divine Being manifested himself to each of the Patriarchs by some sensible sign, generally by a flame of fire, as he did in Moses. Under this semblance also did he appear to the Israelites during their absence in the desert, and after they had obtained a settlement in the land of Canaan. Nor did they believe that heavenly beings, as they were admitted a sensible appearance: They believed that deceased men also sometimes revisited this world. When Saul went to consult the witch at Endor, he asked her to bring up the person whom he should name unto her; a proof that he considered his demand as easy to be performed, and therefore that he probably acted under the influence of popular opinion. The same opinions had been generally entertained at a much earlier period; for necromancy and witchcraft, the arts by which the dead were supposed to be raised, had been prohibited while the Israelites were in the wilderness, and yet untainted with the vices of the Canaanites. They must therefore have derived them from Egypt, the cradle of superstition, as well as of the arts and sciences.

Among the Greeks and Romans the apparition of spectres was generally believed. On innumerable occasions the gods are said to have discovered themselves to the eyes of mortals, to have held conferences, and to have intercepted their aid. The ghosts of the dead, too, are said to have appeared. When Aeneas, amidst the distraction and confusion of his mind in flying from the destruction of Troy, had lost his wife by the way, he returned in search of her. Her shade appeared to him (for the herself had been slain) with the same aspect as before, but her figure was larger. She endeavored to allay the grief of her unhappy husband, by ascribing her death to the appointment of the gods, and by foretelling the illustrious honours which yet awaited him. But when Aeneas attempted to clasp her in his arms, the phantom immediately vanished into air. From this story we may observe, that the ancients believed that the umbras or shades, retained nearly the same appearance after death as before; that they had so far the resemblance of a body as to be visible that they could think and speak as formerly, but could not be touched. This description applies equally well to those shades which had passed the river Styx, and taken up their residence in the infernal regions. Such were the shades of Dido, of Deiphobus, and all those which Aeneas met with in his journey through the subterraneous world.

It appears from the writings of modern travellers who have visited rude and savage nations, that the belief of spectres is no less common among them. Mr. Bruce tells us, that the priests of the Nile affirmed, that he had more than once seen the spirit of the river in the form of an old man with a white beard. Among the Mahometans the doctrine of spectres seems to be reduced to a regular system, by the accounts which they give of genii. Whoever has read the Arabian Nights' Entertainments must have furnished his memory with a thousand instances of this kind. Their opinions concerning genii seem to be a corrupted mixture of the doctrines of the Jews and ancient Persians. In Christian countries, too, notwithstanding the additional light which their religion has spread, and the great improvement in the sciences to which it has been subservient, the belief of ghosts and apparitions is very general, especially among the lower ranks. They believe that evil spirits sometimes make their appearance in order to terrify wicked men, especially those who have committed murder. They suppose that the spirits of dead men affirms a corporeal appearance, hover about church yards and the houses of the deceased, or haunt the places where murderers have been committed. (See Ghost.) In some places it is believed that beings have been seen bearing a perfect resemblance to men alive. In the Highlands of Scotland, what is called the second sight is still believed by many (see Second Sight); viz. that future events are foretold by certain individuals by means of spectral representation.

So general has the belief of spectres been, that this circumstance alone may be thought by some sufficient to prove that it must have its foundation in human nature, or must rest upon rational evidence. When any doctrine has been universally received by all nations, by generations living several thousand years from one another, and by people in all the different stages of society, there is certainly the strongest presumption to conclude that such a doctrine has its foundations in reason, and in truth. In this way we argue in favour of the existence of a God, concerning moral distinction, and the doctrine of a future state: and certainly so far we argue well. But if the same argument be applied to idolatry, or sacrifice, or to apparitions, we shall find that it is applied improperly. Idolatry was very general among ancient nations; it was the offering of sacrifices,
So was polytheism; but they were by no means universal. Should we allow, for the sake of shortening the argument, that all ancient nations were polytheists and idolaters, and preferred oblations to their imaginary deities, all that could be concluded from this concession is, that they fell into these mistakes from their ignorance, and from the rude state of society, from which their imperfect knowledge of theology and moral philosophy was never able to rescue them. These erroneous notions held before the brightens of the Christian system; while the doctrines of the existence of God, of moral distinction, and of a future state, have been more thoroughly confirmed and ascertained. The same thing may be said of the belief of spirits. However generally it has been adopted in the first stages of society, or by civilized nations who had made but little progress in the study of divine things, it has been rejected, we may say invariably, wherever theology and philosophy have gone hand in hand.

As all popular and long established opinions are objects of curiosity and research for the philosopher, we think the belief of spirits worthy of some attention even in this light. It will therefore, we hope, give some satisfaction to the philosophical reader to see a short account of the sources or principles from which this belief is derived. But as the belief of spirits is connected with other opinions which appear to us highly injurious to religion; opinions which have been supported by many learned men, and which are still believed by some men of literary education—it will also be proper, in the first place, to consider the evidence on which this belief rests, in which we must consider both their probability and credibility.

In the present investigation we mean to set aside altogether the celestial appearances recorded in Scripture, as being founded on unquestionable evidence, and perfectly agreeable to those rules by which the Deity acts in the usual course of his Providence. The Israelites, during the existence of their state, were immediately under the authority of God, not only as the moral governor of the world, but as the King of Israel. In the infancy of the world, while men were rude and unenlightened, and entirely under the influence of idolatry, many revelations were necessary to preserve in their minds pure ideas of the nature of God, and of the worship due to Him. They were necessary also to pave the way for that illustrious dispensation which the Lord Jesus came from Heaven to diffuse over the world. Every celestial appearance recorded in Scripture was exhibited for some wise and important purpose, which must be apparent to every person who considers these appearances with attention. But when the Scriptures were written and published, and the Christian religion fully established, revelation ceased, and miracles and heavenly manifestations were no longer requisite. What credit then ought we to give to those marvellous stories related in ancient authors concerning prodigies in the heavens, and the apparition of angels both good and bad?

It is not pretended that any of those prodigies and appearances were exhibited for purposes equally great and important with those which are described in Scripture: And can we suppose that the all-wise Governor of the World would permit his angels to render themselves visible to the eye of man for no purpose at all, or for a purpose which might have been equally well accomplished without their interposition? Would this be consistent with perfect wisdom, or would it be consistent even with the excellence and superiority of understanding which we are taught to ascribe to these elevated beings? The whole will of God is revealed to us in the Scriptures; what further use for the visible interposition of angels? It may be objected, Are they not all ministering spirits sent forth to minister for them who shall be heirs of salvation? We answer, That angels may animate and support good men by an invisible interposition. But the Apostle is not speaking of celestial spirits. The word p
ta

And if God has given no commission to his angels to deliver to men since the publication of the Christian religion, is there any probability that he would give any commission or any licence to evil spirits? It will be said, that this doctrine is clearly taught in the New Testament, in these words, "The devil goeth about as a roaring lion seeking whom he may devour." We will not avail ourselves of the interpretation of some, who say that the word devil, which in the Greek language signifies an adversary, or slanderer, refers here to some human being, who was a violent enemy of the Christians. All that can be deduced from these words, upon the supposition that they refer to a malignant spirit, is merely that he goeth about seducing men to vice. But it is not by assuming a hideous form, and presenting himself to the midnight traveller, that such a purpose is to be accomplished. A spirit may probably have direct access to our minds without the intervention of any thing corporeal; and by exciting our passions may plunge us into vice, which is the only object such a being is supposed to have in view. None of the marvellous stories which we have heard concerning the apparition of evil spirits lead us to conclude that they appear to entice men to commit crimes. We never heard of any evil spirits that required men to steal, to perpetrate robbery or murder. They only appeared to terrify some crazy timid individuals, who have whims and fancies enough of their own to agitate their minds, though no supernatural vision should ever appear to them. It is not convenient, therefore, with the character of God, and what he has revealed to us of his will, to believe that he would commission good angels, or permit evil angels, to appear to men since the propagation of the Gospel, or indeed at any former period of the world, unless some great and mighty purpose was to be fulfilled. It is not convenient with what we know of the nature of good or bad angels to suppose, that though permission were granted them occasionally to show themselves to men, that they would appear in that way which story-tellers describe.

It is equally improbable that the spirits of the dead who have removed from this world should again be permitted to visit it. At death men undergo as great, perhaps a greater change, than when they came first into the light of the sun. Is it not therefore as improbable that a man should return in a visible corporeal form
There is one strong objection against the probability of spectres, which is sufficient to prove that they are not intelligent creatures; or at least that they possess so small a degree of intelligence, that they are unqualified to act with prudence, to propage any end to themselves, or use the proper means to accomplish that end. Ghosts often appear in order to discover some crime that has been committed: but they never appear to a magistrate, or person in authority, but to some ignorant clown, who has no power to live in the place where the crime was perpetrated; to some person who has no connection with the affair at all, and who in general is the most improper in the world for making the discovery. For instance, in Glanville's *Saduceus triumplatus* (a book written in the last century by a chaplain of Charles II. in support of the common opinions respecting witchcraft and apparitions), we have the following story: "James Haddock, a farmer, was married to Eleanor Welsh, by whom he had a son. After the death of Haddock, his wife married one Davis; and both agreed to defraud the son by the former marriage of a lease bequeathed to him by his father. Upon this the ghost of Haddock appeared to one Francis Taverner the servant of Lord Chichele, and directed him to go to Eleanor Welsh, and to inform her that it was the will of her former husband that their son should enjoy the lease. Taverner did not at first execute this commission; but he was continually haunted by the apparition in the most hideous shapes, which even threatened to tear him in pieces, till at last he delivered the message. Now, had this spectre had the least common sense, it would have appeared first to Eleanor Welsh and her husband Davis, and threatened them into compliance at once, and not have kept poor Taverner in such constant disquietude, who had no concern in the matter."

Another very odd circumstance respecting apparitions in general must not be omitted, which is, that they have no power to speak till they are addressed. In the 27th of Glanville's Relations we read of an old woman that appeared often to David Hunter, a neat-herd, at the house of the Bishop of Down and Connor. Whenever she appeared, he found himself obliged to follow her; and for three quarters of a year poor David spent the whole of almost every night in scampering up and down through the woods after this old woman. How long this extraordinary employment might have continued, it is impossible to guess, had not David's violent fatigue made him one night exclaim, "Lord bless me! would I were dead!—shall I never be delivered from this misery!" On which the phantom replied, "Lord bless me too! It was happy you spoke first, for till then I had no power to speak though I have followed you so long." Then she gave him a message to her two sons, though David told her he remembered nothing about her. David, it seems, neglected to deliver the message; at which the old beldam was so much provoked, that she returned and hit him a hearty blow on the shoulder, which made him cry out, and then spoke to her. Now if she could not speak till David addressed her, why might she not have applied this oratorical medicine the first time she appeared to him? It would have saved both herself and him many a weary journey; and certainly David would much rather have had even half a dozen of blows from her choppy fists than have wanted so many nights sleep. To complete the story, we must add, that when David's wife found it impossible to keep him from following the troublesome visitor, the trudged after him, but never was gratified with a fight of the enchantress. David's little dog too was a dutiful attendant on his master during his pilgrimage.

It is remarked by Glanville, that ghosts are generally very eager to be gone. Indeed they are often so much so, that they do not stay to tell their errand. One would be induced from this, as well as the circumstances already mentioned, to think that they are the stupidest and dullest of the dead that assume the appearance of ghosts; unless we adopt the ingenious solution of Glanville, "That it is a very hard and painful thing for them to force their thin and tenuous bodies into a visible confinement; that their bodies must needs be exceedingly compressed; and that therefore they must be in haste to be delivered from the unnatural pressur[e]."

With respect to the evidence in favour of spectres, if examined ever so slightly, it will be found very destructive. They only appear to one person at a time; they are seen only in the night; they are visible only to ignorant, illiterate, and credulous persons, and never project themselves before men of education and learning. That spectres only appear to one person at a time, even though there are more in company, is an objection against the credibility of their appearance quite insurmountable. How is it possible that two men of eyesight equally good, directing their eyes to the same spot, should not see so large an object as that of a man or woman at a small distance equally well? Some will tell us that a mist is cast over the eyes of the one, while the view of the other is free from obstruction. But how is this to be proved? and besides what purpose would it serve? Ghosts have seldom any secrets to disclose; they might be proclaimed to a multitude with as much propriety as confined to one person. Shall we be told, that the spectre has the power of becoming visible to some, and of remaining invisible to others? This cannot be allowed without adopting opinions destructive to revealed religion; for it would be a miracle, and we cannot be persuaded, without evidence, that God would empower any inferior being to control at pleasure the wise laws which he has ordained for governing the world. To him who is of a different opinion, we would
would recommend Farmer on Miracles; a book in which this question is fully examined.

Spectres appear only in the night. But why should they flum the light of the sun? Thofe mischievous ghoids that Osnville mentions might indeed have fome reason to choose midnight for the execution of their pranks, as they would be more feafily detected in open day. Such was the roome, with drummer; that haunted Mr Mompeffon's houfe, who beat his drum all night, threw the old gentlewoman's clothes about the room, hid her Bible in the arks, plucked the clothes off the bed, and amufed himfelf with tolling about Mr Mompiffon's fhoes. But why fhould a grave ferior ghost appear at midnight? Might it not deliver its meffage with as much cafe and more fuccefs in the day-time? In the day-time it would not be as excite as much fear; it would be leften to the public rather than attenion; and did it choose to exhibit itself before a number of witneffes, its grievances would be more feafily redreffed, because more pertons would interef themselves in feeing juftice done to the injured ghoid.

Spectres not only choofe the moft improper time, but the moft improper pertons. To render the testimony of any perfon credible, he muft not only be a man of veracity, but he muft have fufficient abillity to judge of the subjeft to which he is to bear witnefl. It is not on the evidence of an ignornnt ignornnt perfon, who has more fancy and fear than judgment, that we are to reft our belief of what is fuperflurual. It is alfo worthy of remark, that we have never heard of a ghost appearing to any perfon who did not previously believe their efiidence. A man muft be prejudiced in favour of this opinion, or he will never fee a ghost. But fenible men know, that he who has been accoutemod to hear frightful stories of ghosts and appearances gliding thro' a church-yard, or haunting fome particular place, can scarcely pas through a church-yard or haunted spot without conjuring up in his imagination the hideous phantoms which he has been accoutemod to afsoicate with fuch places. If it a strange, then, that an ignornnt man, with a mind uncultivated and uninformed, with all the prejudices of the curfery about him, fhould imagine he fees ghosts in thofe places where he believes they hover, especially in the dead hour of midnight, when, with the flightefl aid of the imagination, a cow may be turned into a monifhor phantom, and the refleftion of the beams of the moon from a little water be converted into a ghoid with a winding-sheet? But why fhould apparitions fhun men of understanding and learning? Why fhould learning be formidable to them (A)? It was not fo with the celestial meffenagers men- tioned in the Scriptures: they appeared to the patriarchs and prophets, and the miracles there recorded were performed in the moft public places, being the eyes of Rabbins, of Scribes, and Pharifees. Indeed this circumftance is fufficient to defroy the evidence of fpectres. They have never been feen by any but men of weak or diftempered minds, or by men who have previously believed in them.

Having now confidered the evidence on which the belief of fpectres rests, we will endeavour to give fome account of the foundation of it. To trace an opinion that has prevailed generally in the world to its fource, is a labour not unworthy of the philofopher, even tho' the opinion be falle. It is alfo gratifying to detect the caufes of error; it is no lefs useful; for in order to refute error, it is often fufficient to point out the fources from which it has sprung. To reach the origin of the belief of fpectres is not more difficult than to account for idolatry or polytheifm. In the infant state of the intellectual powers every thing is confidered as poifefling life and intelligence. The child beats the floor over which he has fallen with the fame raffion that he would treat his companion: The young girl talks to her doll as if it understood her: The favages ascribe every change which they obferve on the face of nature to the action of fome animated being. As knowledge advances, they fingle out thofe beings which seem to produce the moft striking effecls, arrange them into fome kind of order, and divide the government of the world among them. Unable, at the fame time, to conceive any notion of a pure spirit, they imagine thofe divinities are corporeal beings. This is the foundation of idolatry. The belief of fpectres is but another step. That thofe animated corporeal beings, to whom they addrefs their prayers, and who prefide over the world, fhould on particular occasions display themselves to the human eye, is what they muft be previously disposed to expect. Hence the numberlefs appearances of the heaven gods, of the Perifian and Mahometan genei. The belief

(A) The celebrated historian De Thou had a very singular adventure at Saumur, in the year 1598. One night, having retired to rep very much fatigued, while he was enjoying a found fleep, he felt a very extraordinary weight upon his feet, which, having made him turn suddenly, fell down and awakened him. At firft he imagined that it had been only a dream, but hearing foon after fome noise in his chamber, he drew aside the curtains, and faw, by help of the moonlight, which at that time fhone very bright, a large white figure walking up and down, and at the fame time obferved upon a chair fome rags, which he thought belonged to thieves who had come to rob him. The figure then approached his bed, he had the courage to ask it what it was. "I am (fay'd it) the Queen of Heaven." Had fuch a figure appeared to any credulous ignornnt man in the dead of night and made fuch a speech, would he not have trembled with fear, and have frightened the whole neighbourhood with a marvellous defcription of it? But De Thou had too much understanding to be fo imposed upon. Upon hearing the words which dropped from the figure, he immediately concluded that it was fome mad woman, got up, called his fervants, and ordered them to turn her out of doors; after which he returned to bed and fell afleep. Next morning he found that he had not been deceived in his conjecture, and that having forgot to shut his door, this female figure had escaped from her keepers, and entered his apartment. The brave Schomberg, to whom De Thou related his adventure fome days after, confefled that in fuch a cafe he would not have fown fo much courage. The king afo, who was informed of it by Schomberg, made the fame acknowledge-
belief of ghosts may be easily deduced from the opinions entertained respecting a future state. These opinions are founded on that essential doctrine of natural religion, that there is another world in which men shall exist when death has removed them hence. This doctrine has been universally received both by savage and civilized nations; but, as might be expected, men have formed very different sentiments concerning the nature of a future state, of the situation and employments of departed spirits, according to the degree of knowledge which they possessed. But the general opinion in ancient and rude nations was, that departed spirits retained the same external appearance, the same passions and principles as before. Nothing therefore was more natural than the opinion, that they might occasionally revisit this world, from an anxious desire to alleviate the sufferings of those beloved friends and relations whom they had left behind them, or to communicate from the unseen world what might be important to their welfare. Upon such an errand did Creusa appear to Atreus. The apparition of the ghosts of murderers is easily explained upon the same general principles. The remorse and horror of mind which the murderer feels are supposed to haunt him in the other world; and to render his situation intolerable (especially if the murder was never detected and punished), till he return and give information against himself. In this way, then, we think it highly probable the belief of spectres has originated. But many other causes concur to confirm and propagate this belief. These are, imperfect visions united with fear, dreams, opium, diseases, drunkenness, and artifice.

1. Indistinct visions are one source of apparitions, especially when the mind is under the influence of fear. It is well known, that the sense of seeing conveys no idea of distance till improved by experience and observation; and how we come at length to distinguish objects at a distance from those that are near, has been explained in another place (see Metaphysics, n° 50).

In the day-time we seldom commit mistakes, because we know the object at which we look; but at night, when we see objects obscurely, and know not what they are, we have no distinct idea either of their distances or of their magnitude. We may mistake a bull that is near us for a tree at a distance; or if the imagination be under the influence of fear, it will easily convert it into a gigantic figure. "It is generally asserted (says Buffon) that these figures exist only in the imagination; yet they may have a real existence in the eye; for whenever we have no other mode of judging of an unknown object but by the angle it forms in the eye, its magnitude will uniformly increase in proportion to its propinquity. If it appears, when at the distance of 20 or 30 paces, to be only a few feet high, its height, when within two or three feet of the eye, will be many fathoms. An object of this kind must naturally excite terror and alarm in the spectator, till he approaches and recognizes it by actual feeling; for the moment a man knows an object, the gigantic appearance it assumed in the eye infinitely diminishes, and its apparent magnitude is reduced to its real dimensions. But if, instead of approaching such an object, the spectator flies from it, he can have no other idea of it but from the image which it formed in his eye; and, in this case, he may affirm with truth that he saw an object terrible in its aspect, and enormous in its size. Thus the notions concerning spectres is founded in nature, and depend not, as some philosophers affirm, upon the imagination alone."

In addition to these observations of Buffon, we may take notice, that objects are always magnified in a fog, so that when a fog happens in the night-time, objects may be magnified to an enormous size. But, at any rate, whether there be fog in the night or not, there is such a great analogy between darkness and a fog, that if the latter deceive us with respect to the size of objects, the former will also deceive us. The writer of this article was passing the Frith of Forth at Queensberry, near Edinburgh, one morning which was extremely foggy. Though the water be only two miles broad, the boat did not get within sight of the southern shore till it approached very near it. He then saw to his great surprise a large perpendicular rock, where he knew the shore was low and almost flat. As the boat advanced a little nearer, the rock seemed to split perpendicularly into portions, which separated at a little distance from one another. He next saw these perpendicular divisions move; and upon approaching a little nearer, found it was a number of people standing on the beach, waiting the arrival of the ferry-boat.

2. Dreams are another fertile source of apparitions. It is well known to every person, that while the mind is under the influence of a dream it considers it as much a reality as it does any particular action while awake. Now if a person of a weak superstitious mind should have a very lively dream, which interests his passions, particularly the passion of fear, it may make a deep impression, that he may be firmly convinced that he has actually seen with his eyes what has only passed before his imagination (See Apparition) (n). We shall here tell a story, by way of illustration which we have received on unquestionable authority. An East Indian captain had an honest faithful servant named John, for whom he had a great regard. John died, if we recollect right, on a voyage from England to the East Indies during a French war. As the ship approached the place of its destination the captain had a dream, in which John appeared to him, and earnestly besought him not to fail to the port for which he was bound, as it was in the hands of the French. The captain, though not addicted to superstition, thought it prudent to follow this admonition; and after landing at a different port, he was informed that the place to which he had intended to fly was, according to the information of the dream, captured by the French. On the voyage home, the captain had a second dream, in which John again appeared to him, and gave him notice.

---

(n) When the thoughts are much troubled, and when a person sleeps without the circumstances of going to bed, or putting off his clothes, as when he nods in his chair, it is very difficult, as Hobbes remarks, to distinguish a dream from a reality. On the contrary, he that compacts himself to sleep, in case of any uncouth or absurd fancy, easily suspeets it to have been a dream.—Leviathan, par. i. c. 1.
Spectre. nifice that he should soon die, and that the ship should be taken in the mouth of the Channel by the French. Next morning the captain called his first mate, told him his dream, which he believed was prophetic, and delivered his papers, that he might take proper care of them after his decease. Everything happened exactly as the dream had foretold; the captain died, and the vessel was taken by a French man of war in the mouth of the Channel. This dream, wonderful as it appears, is easily explained. In the voyage out to India, nothing was more natural than that the captain should sometimes be thinking, that amidst the various chances of war, the port to which he was bound might be taken; perhaps it was a place of confluence, which the French might be eager to possess. The captain being accustomed to resolve these thoughts in the day-time, they would naturally return at night; the regret which caused them, was therefore, was immediately reported through the neighbourhood; all were alarmed, and looked around them with solicitude for the detection of the murder which they supposed to have been committed; and it was not long till a discovery seemed actually to be made. It was reported, that a gentleman, who had relations at no great distance, and had been residing in the West Indies, had lately arrived with a considerable fortune; that he had lodged in an inn about three miles off; and that he had afterwards been seen entering a house in the village where the widow lived, from which he had never returned. It was next affirmed, that a tradesman passing the church-yard about twelve at midnight had seen four men carry a dead corpse into that cemetery. These three facts being joined together seemed perfectly to agree and to confirm one another, and all believed some horrible murder had been committed. The relations of the gentleman thought they were called upon to make inquiry into the truth of these allegations; they accordingly came first to the church-yard, where, in company with the sexton, they examined all the graves with great care, in order to discover whether any of them had been lately dug, or had the appearance of containing more than one coffin. But this search was to no purpose, for no alteration had been made upon the graves. It was next reported that the murdered man had been buried in a plantation about a mile distant from the village. As the alarm was now very general, a number of the inhabitants proposèd of their own accord to explore it. They accordingly spread themselves over the wood, and searched it with care, but no grave nor new dug earth was found. The writer of this article, who was then a boy at school, was along with them. The matter did not rest here: The person who was said to have seen four men carry a dead corpse into the church-yard at midnight was summoned to appear before a meeting of the justices of the peace. Upon examination he denied any knowledge of the affair, but referred the court to another person from whom he had received his information. This person was examined, and the result was the same as the former. In short, one person had heard it from another, who had received it from a third, who had heard it from a fourth; but it had received a little embellishment from every person who repeated...
repeated it. It turned out to be the same with Smollet's story of the three black crows, which some body was said to have vomited.

Upon inquiry at the inn where the Wilt Indian gentleman had lodged, no such gentleman had been seen there. It was found afterwards he had never left the Wilt ladies. Still, however, the veracity of the widow was not disputed; and some dark and secret transaction was suspected. But the whole affair was at length explained by discovering that she was somewhat deranged by melancholy. And the cries which she had at first imagined she had heard were afterwards imitated by some rogueish person, who was highly amused with spreading terror among the credulous.

5. Drunkenness also has the power of creating spectres. Its natural effect in most cases is to derange the understanding, to throw it off its guard, and to give full scope to that passion which has a natural disposition to gain an ascendency; and sometimes it excites passions which fearfully seem to exist at any other time. It makes some men licentious, some furious, some all behaviour and kindred, some from being cowards it renders undaunted; and some from being frightened, it seduces to flight. It seldom, if ever, excites fear; and therefore it may be thought strange that men should imagine they see ghosts while intoxicated. But it must be remarked, that the ghost which the drunkard sees, he fears not with the same alarm and terror as men who are sober. He is not afraid of them. He has the courage to converse with them, and even to fight with them, if they give him provocation. A man returning home intoxicated, affirmed that he had met with the devil; and that after a severe encounter he had vanquished him and brought him to the ground, to which he had nailed him fast by driving his staff through his body. Next morning the staff was found stuck with great violence into a heap of turfs!

6. Many apparitions of spectres have no other origin than the artifices of the waggish or self-interested. Dr Plot, in his Natural History of Oxfordshire, relates a marvellous story, which will illustrate this affection. Soon after the murder of King Charles I a commission was appointed to survey the king's house at Woodstock, with the manor, park, woods, and other demesnes that to that manor belonging; and one Collins, under a feigned name, hired himself as secretary to the commissioners, who, upon the 13th of October 1649, met, and took up their residence in the king's own rooms. His majesty's bed-chamber they made their kitchen, the council hall their pantry, and the presence chamber was the place where they sat for the dispatch of business. His majesty's dining-room they made their wood-yard, and floored it with the wood of the famous royal-oak from the High Park, which, that nothing might be left with the name of king about it, they had dug up by the roots, and split and bundled up for faggots for their firing. Things being thus prepared, they sat on the 16th of the same month for the dispatch of business; and in the midst of their first debate there entered a large black dog (as they thought), which made a dreadful howling, overturned two or three of their chairs, and then crept under a bed and vanished. This gave them the greater surprize, as the doors were kept constantly locked, so that no real dog could get in or out. The next day their surprize was increased, when, sitting at dinner in a lower room, they heard plainly the noise of persons walking over their heads, though they well knew the doors were all locked, and there could be no body there. Presently after they heard also all the wood of the king's oak brought by parcels from the dining-room, and thrown with great violence into the presence chamber; as also all the chairs, stools, tables, and other furniture, forcibly hurled about the room; their papers, containing the minutes of their transactions, were torn, and the ink-glass broken. When all this noise had ceased, Giles Sharp, their secretary, proposed to enter first into these rooms; and in presence of the commissioners, from whom he received the key, he opened the doors, and found the wood spread about the room, the chairs tossed about and broken, the papers torn, the ink-glass broken (as has been said), but not the least track of any human creature, nor the least reason to suspect one, as the doors were all fast, and the keys in the custody of the commissioners. It was therefore unanimously agreed, that the power who did this mischief must have entered the room at the key-hole. The night following, Sharp their secretary, with two of the commissioners servants, as they were in bed in the same room, which room was contiguous to that where the commissioners lay, had their bed's feet lifted up so much higher than their heads, that they expected to have their necks broken, and then they were let fall at once with so much violence as shook the whole house, and more than ever terrified the commissioners. On the night of the 19th, as all were in bed in the same room for greater safety, and lights burning by them, the candles in an infant went out with a fulphurous smell, and that moment many trenches of wood were hurled about the room, which next morning were found to be the fame their honours had eaten on the day before, which were all removed from the pantry, though not a lock was found opened in the whole house. The next night they fell fared worse; the candles went out as before, the curtains of their honours' beds were rattled to and fro with great violence; their honours received many cruel blows and bruises, by eight great pewter-dishes and a number of wooden trenches being thrown on their beds, which being heaved off, were heard rolling about the room, though in the morning none of these were to be seen. This night likewise they were alarmed with the tumbling down of oaken billets about their beds, and other frightful noises; but all was clear in the morning, as if no such thing happened. The next night the keeper of the king's house and his dog lay in the commissioners room, and then they had no disturbance. But on the night of the 22d, though the dog lay in the room as before, yet the candles went out, a number of brick-bats fell from the chimney into the room, the dog howled piteously, their bed clothes were all stripped off, and their terror increased. On the 24th they thought all the wood of the king's oak was violently thrown down by their bed-fides; they counted 64 billets that fell, and some hit and shook the beds in which they lay; but in the morning none were found there, nor had the door been opened where the wood was kept. The next night the candles were put out, the curtains rattled, and a dreadful crack like thunder was heard; and one of the servants running in haste, thinking his master was killed, found three dozen of trenches laid smoothly under the quilt by him. But all this was nothing to what succeeded afterwards: The
2dly, about midnight, the candles went out, something walked majestically through the room, and opened and shut the windows; great stones were thrown violently into the room, some of which fell on the beds, others on the floor; and at about a quarter after one a noise was heard as of forty cannon discharged together, and again repeated at about eight minutes distance. This alarmed and raised all the neighbourhood, who coming into their honoured room, gathered up the great stones, fourscore in number, and laid them in the corner of a field, where, in Dr Plot's time, who reports this story, they were to be seen. This noise, like the discharge of cannon, was heard through all the country for 16 miles round. During these noises, which were heard in both rooms together, the commemorators and their servants gave one another over for lost, and cried out for help; and Giles Sharp, snatching up a sword, had well nigh killed one of their honourables, mistaking him for the spirit, as he came in his skirt from his own room to theirs. While they were together, the noise was continued, and part of the tiling of the house was stript off, and all the windows of an upper room were taken away with it. On the 30th at midnight some thing walked into the chamber treading like a bear; it walked many times about, then threw the warming-pan violently on the floor; at the same time a large quantity of broken glass, accompanied with great stones and hollow bones, came pouring into the room with uncommon force. Thrice were all found in the morning to the astonishment and terror of the commemorators, who were yet determined to go on with their business. But on the 1st of November the most dreadful scene of all ensued: candles in every part of the room were lighted up, and a great fire made; at midnight, the candles all yet burning, a noise like the burfting of a cannon was heard in the room, and the burning billets were tossed about by it even into their honourables' beds; who called Giles and his companions to their relief, otherwise the house had been burnt to the ground; about an hour after the candles went out as usual, the crack as if many cannon was heard, and many pailsfuls of green finking water were thrown upon their honourables' beds; great stones were also thrown in as before, the bed curtains and bedheads torn and broken, the windows shattered, and the whole neighbourhood alarmed with the most dreadful noises; nay, the very rabbits, foxes, and hares, that were abroad that night in the warren were so terrified, that they fled for fear and left their ferrets behind them. One of their honourables this night spoke and, in the name of God, asked what it was, and why it disturbed them so? No answer was given to this; but the noise ceased for a while, when the spirit came again; and, as they all agreed, brought with it seven deaths worse than itself. One of the servants now lighted a large candle, and set it in the door-way between the two chambers, to see what paffed, and as he watched it, he plainly saw a hoof striking the candle and candlestick into the middle of the room, and afterwards making three scapes over the fluff, scraped it out. Upon this the same person was so bold as to draw a sword; but he had scarce got it out when he felt another invisible hand holding it too, and pulling it from him; and at length prevailing, struck him so violently on the head with the pummel, that he fell down for dead with the blow. At this instant was heard another burst like the discharge of the broadside of a ship of war, and at about a minute or two's distance each no less than 19 more such; these shook the house violently, that they expected every moment it would fall upon their heads. The neighbours, on this, as has been said, being all alarmed, flocked to the house in great numbers, and all joined in prayer and psalm-singing; during which the noise still continued in the other rooms, and the discharge of cannons was heard as from without; though no visible agent was seen to discharge them. But what was the most alarming of all, and put an end to their proceedings effectually, happened the next day as they were all at dinner, when a paper, in which they had signed a mutual agreement to reserve a part of the premises out of the general survey, and afterwards to share it equally amongst them-selves, (which paper they had hid for the present under the earth in a pot in one corner of the room, and in which an orange-tree grew,) was confumed in a wonderful manner, by the earth's taking fire with which the pot was filled, and burning violently with a blue flame, and an intolerable fench; so that they were all driven out of the house, to which they could never be again prevailed upon to return.

This wonderful contrivance was all the invention of the memorable Joseph Collins of Oxford, otherwise called *Fanny Fen*, who having hired himself as secretary, under the name of Giles Sharp, by knowing the private traps belonging to the house, and the help of *pullus fulminans* and other chemical preparations, and letting his fellow-servants into the scheme, carried on the deceit without discovery to the very last; infomuch that the late Dr Plot, in his *Natural History*, relates the whole for fact, and concludes in this grave manner, "That though tricks have been often played in affairs of this kind, many of the things above related are not reconcilable with jugglery; such as the loud noises, beyond the power of man to make without such instruments as were not there; the tearing and breaking the beds; the throwing about the fire; the hoof treading out the candle; and the striving for the sword, and the blow the man received from the pummel of it."

**SPE**

*SPECULARIS LAPIIS*, in natural history, a genus of talcs, composed of large plates visibly separate, and of extreme thinness; and each filel again separated into a number of plates still finer. (See TALC.) Of this genus there are three species: 1. The white shining specularis, with large and broad leaves, commonly called *王者 and *Mylonite glass; its lamellae, or leaves, are extremely thin, elastic, and transparent; it makes not the least effervescence with aquafortis, and is not easily calcined in the fire. It is imported in great quantities; the miniature-painters cover their pictures with it; the lantern-makers sometimes use it instead of horn; and minute objects are usually preferred between two plates of it, for examination by the microscope. 2. The bright brown specularis, with broad leaves; a very valuable species, though inferior to the former. 3. The purple bright specularis, with broad leaves, which is the most elegant of all the talcs, and not less beautifully transparent than the first kind.

**SPECULATIVE**, something relating to the theory of some art or science, in contradistinction to practical.

**SPECULUM** for reflecting telescopes, is made of a kind of white copper consisting of 32 parts fine.
red copper, 1 of brass, 15 of grain-tin, and 3 of white arsenic. The process given by the late J. Edwards, who was rewarded by the Board of Longitude for disclosing it to the public, was published in the Nautical Almanack for 1787, and is as follows: Melt the copper in a large crucible, employing some black flux, composed of two parts of tartar and one of nitre; when melted, add to it the brass and the silver. Let the pure tin be melted in another crucible, also with some black flux. Take them both from the fire, and pour the melted tin into the fused mass in the large crucible. Stir the whole well with a dry spatula of birch, and pour off the fused metal immediately into a large quantity of cold water. The sudden chill of the water will cause the fluid metal to divide into an infinite number of small particles, which will cool instantly.

2. If the copper be completely saturated, the fracture of one piece of this mixed metal will appear bright, and of a glossy look, resembling the face of pure quicksilver. But if it is of a brown reddish colour, it wants a little more tin. To ascertain the required proportion, melt a small quantity, known by weight, of the mixed metal, with a known very small part of tin; and, if necessary, repeat the trial with different doses, till the fracture of the new mixture looks as already described. Having now ascertained the necessary addition of tin that is required, proceed to the last melting of the whole metal, together with the additional proportional dose of tin; fuse the whole, observing the same cautions as before; and you will find that the mixture will melt with a much less heat than that for the first fusion. Have ready as many ounces of white arsenic in coarse powder as there are pounds in the weight of the metal; wrap up the arsenic in a small paper, and put it, with a pair of tongs, into the crucible; stir it well with the spatula, retaining the breath to avoid the arsenic fumes or vapours (which however are not found to be hurtful to the lungs) till they disappear; take the crucible off the fire, clear away the dross from the top of the metal, pour in about one ounce of powdered rosin, with as much nitre, in order to give the metal a clean surface, and pour out the metal into the moulded flasks.

3. The speculum should be moulded with the concave surface downwards, and many small holes should be made through the sand upwards, to discharge the air. The moulding sand from Highgate near London, used by the founders, is as good as any for casting these metallic mirrors. The call metal should be taken out from the sand of the flasks whilst it is hot, or else it may happen to crack if left to cool within. See Telescope.

Speculum, a looking glass or mirror, capable of reflecting the rays of the sun.

Speculum, in surgery, an instrument for dilating a wound, or the like, in order to examine it attentively. See Surgery.

SPECHT, in general, the art or act of expressing a person's thoughts by means of articulate sounds, which we call words. See Language, Grammar, Reading, and Oratory, part iv.

Speed (John), an eminent English historian, was born at Farringdon, in Cheshire, in 1542. He was by profession a taylor, and rector of the company of merchant-tailors in the city of London. In 1606, he published his Theatre of Great Britain, which was afterwards reprinted in folio, under the title of the Theatre of Empire of Great Britain. His Genealogies of the Empires were first bound up with the Bible in 1615, when the first edition of the present translation was printed. In 1614 appeared his History of Great Britain, which has since been translated into Latin; and in 1616 he published his Cloud of Witness, in octavo. He lived in marriage 57 years with his wife, by whom he had twelve sons and five daughters; and died in 1629. He was interred in the church of St. Giles's, Cripplegate, London, where a monument was erected to his memory.

Speedwell, in botany. See VERONICA.

SPELL, a charm consisting of some words of occult power, generally attended with some ceremony. In order to explain it, we will produce a few examples. On St Agnes's night, 21st of January, take a row of pins, and pull out every one, one after another, saying a Pater-noster on flicking a pin in your sleeve, and you will dream of him or her you shall marry.

Another method to see a future spouse in a dream. Gred's Provincial Glory.

The party inquiring must lie in a different county from that in which he commonly resides, and on going to bed must knit the left garter over the right legged stocking, letting the other garter and stocking alone; and as he rehearses the following verses, at every comma knit a knot:

This knot I knit,
To know the thing I know not yet;
That I may see
The man (woman) that shall my husband (wife) be;
How he goes, and what he wears,
And what he does all days and years.

Accordingly, in a dream, he will appear with the insignia of his trade or profession.

Another, performed by charming the moon, thus:

At the first appearance of the new moon, immediately after the new year's day, (though some say any other new moon is as good), go out in the evening, and stand over the spurs of a gate or fiddle, and, looking on the moon, repeat the following lines:

All hail to the moon! all hail to thee!
I prithee, good moon, reveal to me
This night who my husband (wife) must be.

Immediately after you must go to bed, when you will dream of the person defined for your future husband or wife.

SPELLING, in grammar, that part of orthography which teaches the true manner of reducing words into their syllables.

All words are either simple or compound, as fly, flys; done, done; and the rules for dividing each must be such as are derived from the analogy of language in general, or from the established custom of speaking; which, for the English language, are reduced to the following rules: 1. A consonant between two vowels must be joined with the letter in spelling, as nature, ve-rily, ge-norous; except, however, the letter s which is joined to the first, as in flex-er, ex-er, &c. and compound words, as in spen, un-afed, &c.

2. A double consonant must be divided, as in letter, man-ner, &c.

3. Those consonants which can begin a word must not be parted in spelling, as in de-fran, fran-chie. 
Speelman re-prove, di-fined; however, this rule is found some-
times to fail; for though gn begins a word, as great,
gnate, &c. yet it must be divided in spelling, as in cog-
nomines, ma-tigu-y, &c. 4. Those consonants which
cannot begin a word must be divided, as td in faldom, tl
in multitudes, mp in tem-ple; rd in arc-ent; but in final
syllables there are exceptions, as tl in title, frit, am-
dle, &c. 5. When two vowels come together, and are
both of them distinctly founded, they must be separated
in spelling, as in co-eval, nu-tural, &c. 6. The gram-
matical terminations or endings must be separated in
spelling, as ed in wing-ed, ed-fi in de-li-ver-ed, ing
in bearing, ance in de-li-ver-ance, &c. 7. Compound
words must be resolved into their simple or component
words, as upon, in-to, ne-ver-the-less, not with-fling,
&c.

SPELMAN (Sir Henry), an eminent English anti-
quarian, was descended from an ancient family, and
born at Cengham, near Lynn in Norfolk, about the
year 1561. He was knighted by King James I. who
had a particular esteem for him on account of his known
capacity for business; and he employed him several
times in Ireland on public affairs. When he was
about 50 years of age, he went to reside in London;
where falling into a dispute to which his own genius had
always inclined him, he collected all such books and
MSS. as concerned the subject of antiquities, either fo-
 reign or domestic. In 1626, he published the first part
of his well-known Glossary, which he never carried be-
 yond the letter L; because, as some have suggested, he
had said things under "Magna charta," and "Maxi-
mum coniinium," that could not then have appeared
without giving offence. Upon his death all his papers
 came into the hands of his son Sir John Spelman, a gen-
tleman who had abilities to have completed his father's
design, if death had not prevented him. The second
part was afterwards published by Sir William Dugdale;
but with all the marks of a century unfinished perfor-
amce. The next work he entered upon was an edition
of the English Councils, of which he published the first
volume about two years before his death, leaving the
second volume as well as his Glossary, to be pub-
lished by Sir William Dugdale. Sir Henry wrote
several other things, all relating to ancient laws and
customs, and died in 1641. His Pothumous Works
were published in folio, 1698, under the inspection of
Mr. Giffen, afterwards bishop of London.

vindicated. To this excellent work was afterwards added, A Discourse concerning vulgar prophecies, wherein the vanity of receiving them as the certain indications of any future event is expos’d; and some marks of dissimulation between true and pretended prophets are laid down. 3. A Latin Dissertation concerning Utiris and Thommini. 4. His famous treatise De legibus Helvorum rutilibus et earum rationibus. The intention of this book, as he informs us himself, was to vindicate the Deity from the imputation of acting from arbitrary and fantastical motives. It has been highly and justly esteemed both for the elegance of style and the uncommon erudition and found sense which it displays. It has, however, (that part of it particularly which endeavours to deduce some of the Jewish ceremonies from the practices of their heathen neighbours,) alarmed many persons, as if such a doctrine, if it could be proved, would derogate from the Divine wisdom, and undermine revelation. But this is so far from being the case, that Dr. Spencer’s attempt, whether successful or not, does not deserve the gratitude of Christians, because it has a tendency to throw light on an important and difficult subject.

SPENSER (Edmund), the poet, was born in London in the year 1552, and descended from an ancient family of the Spencers in Northamptonshire. All we know concerning his education is, that he was admitted a fizar of Pembroke-hall in Cambridge, and matriculated in 1569. At this time began his intimacy with Mr. Gabriel Harvey, a man of genius and a poet. In 1576, having completed his degrees in arts, he left the university, as it is conjectured, for want of subsistence, and retired to the north of England. Here he had the misfortune to become enamoured of his Rosalind, who, after flattering his passion for a time, at length preferred his happier rival. Spenser continued in the country till the year 1578, when at the persuasion of his friend Mr. Harvey he removed to London, where that gentleman introduced him to Mr. Sidney (afterwards Sir Philip Sidney). Concerning his first introduction to Sir Philip, there is indeed a different story, which was first told by the writer of his life, prefixed to his works in 1679, and transferred by Hughes, Cibber, and several others; which, nevertheless, is certainly not true. The purport of it is, that Spenser, being unknown to this Macenas of the age, went to Leicester house, and sent in the 9th canto of the first book of the Fairy Queen; that, on reading part of it, Sir Philip ordered his reward to give the bearer 50l. or on reading a little farther 50l. more; then 200l. bidding him to make haste and pay the money, lest he should give the poet his whole estate. The story tells prettily enough; but it is very certain, that the Fairy Queen was begun long after his acquaintance with Sir Philip. By this universal patron of geniuses, however, he was prefented to queen Elizabeth, who honoured him with the place of poet-laurat. About this time he finished his Shepherd’s Calendar, which was first printed in 1579; and in the following year, being recommended by his patron to the earl of Leicelcer, he went to Ireland as secretary to the lord Grey of Wilton, then appointed lord-lieutenant of that kingdom. Lord Grey was recalled in 1582, and with him Spenser returned to London, where he continued till after the death of Sir Philip Sidney in 1586; a loss which he bewailed to the end of his life. The following year, our poet, having obtained a royal grant of 3000 acres of forfeited lands in the county of Cork in Ireland, set out for that kingdom, took possession of his estate, and fixed his residence in the castle of Kilcolman, which had belonged to the earl of Desmond. In this retirement he resumed his great work of the Fairy Queen; and continued in Ireland till, being visited by his old friend Sir Walter Raleigh in 1589, he came over with him to England, but returned to Ireland the year following, where he fell in love with a country girl, and married her. Soon after his marriage, he paid another visit to his native country, where we also find him in 1596. In the following year he returned once more to Kilcolman; but on the rebellion of Lord Tyrone, who ravaged the whole county of Cork, he was obliged to fly for safety with his family to England, where, in the year 1599, he died in extreme poverty (a). He was buried in Westminster Abbey, according to his request, near Chaucer. A monument was erected to his memory by Ann countess of Dorset. We know but little of his character as a man; as a poet, considering the age in which he lived, he deserves our utmost veneration. He wrote various pieces besides those abovementioned. His whole works, with his life by Hughes, were published in six volumes 12mo, in 1715 and 1750.

SPERGULA, SPURREY, in botany: A genus of plants belonging to the class of decandria, and the order of pennigina; and in the natural system arranged under the 22d order, carophyllae. The calyx is pentaphyllous; the petals five, and undivided; the capsule oval, unilocular, and containing five valves. There are five species, the arvenfis, nodulata, pentandra, laticina, and figninode: all of which are British: 1. The arvenfis, corn spurrey, has linear narrowed leaves, from eight to twenty in a whir. The flowers are small, white, and terminal. It is frequent in corn-fields. In Holland it is cultivated as food for cattle, and has the advantage of growing on the very poorest soils; but does not afford a great deal of food. Poultry are fond of the seeds; and the inhabitants of Finland and Norway make bread of them when their crops of corn fail. Horses, sheep, goats, and swine, eat it. Cows refuse it.

2. The nodulata, knotted spurrey. Several stalks arise from one root, sometimes reclining and sometimes erect, and from three to five inches high. The leaves are smooth, of a fine green, narrow, pointed, and opposite. The flowers are white, terminal, with yellow anther.

3. Pentandra, small spurrey. The leaves are very narrow, and grow in whirs at the joints. The seeds are black with a white circle. It flowers in July.

4. Laticina, larch-leaved spurrey. Several stalks arise.

(a) This is Camden’s account, and it has been generally believed; but Mr. Malone, the last editor of Shakespeare’s works, by examining the patent roll, 53 Eliz. p. 3, has discovered, that in February 1590, Spenser obtained from Queen Elizabeth an annuity or pension of L. 50 during his life; a sum equivalent to L. 200 at present.
Spermaceti, a whitish, unctuous, flaky substance, prepared from oil, but chiefly from the brains of a species of whale called physeter macrocephalus.

The method of preparing spermaceti is kept a secret; but the process is said to be this: The brains being taken out of the animal, are then, as some say, melted over a gentle fire, poured into moulds, and when cold melted again; and this process is continued till they are purified. Others say, that after being pressed and drained they are more thoroughly purified by steeping them in a ley of alkaline salt and quicklime. The brains are then washed, and cut into thin flakes or fine white flakes; soft and transparent, having a fragrant smell if not carefully washed, and cut into thin flakes or fine white flakes; soft and transparent, melting in the form of an oil or by the dulness of the colour. Whence it is said to be this: The brains being the nitrous acid and unites by the process discovered, is of use in medicine.

Spermaceti, in anatomy, something belonging to the sperm or seed.

Speusippus, an Athenian philosopher, the nephew and successor of Plato. Contrary to the practice of Plato, Speusippus required from his pupils a Eratosthenian charity. He placed statues of the graces in the school which Plato had built. On account of his informaftion of health, he was commonly carried to and from the academy in a vehicle. On his way thither he one day met Diogenes, and saluted him; the Eratosthenian philosopher refused to return the salute, and told him, that such a feeble wretch ought to be ashamed to live; to which Speusippus replied, that he lived not in his limbs, but in his mind. At length, being wholly incapacitated, by a paralytic stroke, for the duties of the chair, he resigned it to Xenocrates. He is said to have been of a violent temper, fond of pleasures, and exceedingly avaricious. Speusippus wrote many philosophical works, which are now lost, but which Aristotle thought sufficiently valuable to purchase at the expense of three talents. From the few fragments which remain of his philosophy, it appears that he adhered very strictly to the doctrine of his master.

Spey, a river of Scotland, rising from a lake of the same name in Badenoch, and, after a serpentine course of 70 miles, passes by Ruthven's castle, and falls into the German sea at Garnoch near Elgin. Mr Pennant tells us, that the Spey is a dangerous neighbour to Cattle Gordon, overflowing frequently in a dreadful manner, as appears by its ravages far beyond its banks. The bed of the river is wide and full of gravel, and the channel very shifting. In 1746 the Duke of Cumberland passed this river at Belles church, near Cattle Gordon, when the channel was so deep as to take an officer, from whom...
SPHACELUS, in surgery and medicine, an absolute
and perpetual corruption or death of the parts.

SHEERANTHUS, in botany: A genus of plants
belonging to the class of Crypogamia and order of
Myricaceae. The anthers are globose; the mouth entire
dosed by an operculum; the calyptra is wanting. There
are three species, the Paludost, Alpinum, and
to an order of Polygama, *Egregera;* and in the natural
fyls arranged under the 49th order, *Composita.* Each partial
calyx contains eight florets; the florets are tubulated, the
female being feerely distinguishable. The receptacle is
scaly; and thereis no papus. The species are three,
the indius, africanus, and chinenfis.

SPHAGNUM, bog-moss, in botany: A genus of
plants belonging to the class of Cryptogamia and order of
Musci. The anthers are globose; the mouth entire
dosed by an operculum; the calyptra is wanting. There
are three species, the Paludost, Alpinum, and
in the natural ylms arranged under the
order, *Composita.* Each partial
calyx contains eight florets; the florets are tubulated, the
female being feerely distinguishable. The receptacle is
scaly; and thereis no papus. The species are three,
the indius, africanus, and chinenfis.

Spheroid, in geometry, a solid approaching to
the figure of a sphere. It is generated by the entire
revolution of a semi-ellipsoid about its axis. When
the revolution is made round the largest axis, the spheroid
is called prolate; and when round the shortest, oblate.
This last is the figure of the earth, and probably of all
the planets.

SPHEX, Ichneumon Wasp, or Spaviz: a gen-
us of insects belonging to the order of Hymenoptera.
The mouth is armed with entire jaws, but contains no
tongue; the mandibles are horny, crooked, dentated;
the lip horny, the apex membranaceous. The palpi
or feelers are four. The antennae have from 10 to 16
joints. The wings of both sexes are extended without
folds, and laid horizontally on the back. The sting is
hard, and concealed within the abdomen. There are
97 species, of which two only are natives of Britain
and Ireland, the viatica and cibritidae. 2. The viatica
is black; the antennae are short and thick; the three first
segments of the abdomen red-brown; the pedicle is
short; the length half an inch. 3. The cibritidae is
black, with yellow ringlets on the abdomen; the anten-
nae are short, and turned backwards: the fore-legs are
broad, with an appendix like a shield.

The manner of living is different in the various
species, and so is the general form of the body and their
haunts; but though the method of life be utterly dif-
ferent, yet the name manners appear innate and inherent
in all. They agree in being the fiercest of all flies;
they will attack insects much larger than themselves,
and this whether they be defenceless or armed, as they
are provided with a sting. The strength in all this fa-
vage kind is great; their jaws are hard and sharp, and
in their sting lies a poison suddenly fatal to the crea-
tures with whom they engage. The savage strives har-
dily on the animal he attacks, and gives a stroke of
amazing force; after which he falls down as if himself
were killed, but it is to reef from his fatigue, and en-
joy his victory. He keeps a steady eye on the crea-
ture he has struck till it dies, which happens in a few
minutes, and then drags it to the nest to feed the
young. The number of other insects they destroy is
fearsome to be conceived; the mouth of their cave is like
that of a giant in the days of yore, strewed with the
remains of prey. The eyes, the filament that serves as
a brain, and a small part of the contents of the body,
are all the savage eats, and he will kill 50 for a meal.

SPHINCTER, in anatomy, a term applied to a
kind of circular muscles, or muscles in form of rings,
which serve to close and draw up several orifices of the
body, and prevent the excretion of the contents.

SPHINX (fab. hist.), a monster which had the
head and breasts of a woman, the body of a dog, the tail
of a serpent, the wings of a bird, the paws of a lion, and
an human voice. It sprang from the sson of Ortho-

Vol. xvii.
The Sphinx, or of Typhon with Echidna. The Sphinx had been sent into the neighbourhood of Thebes by Juno, who wished to punish the family of Cadmus, which she perfecuted with immortal hatred, and it laid this part of Boea contiguous continual alarms, by proposing enigmas and devouring the inhabitants if unable to explain them. In the midst of their conflagration the Thebans were told by the oracle, that the sphinx would destroy herself as soon as one of the enigmas she proposed was explained. In this enigma she wished to know what animal walked on four legs in the morning, two at noon, and three in the evening. Upon this Creon king of Thebes promised his crown and his sister Jocasta in marriage to him who could deliver his country from the monster by a successful explanation of the enigma. It was at last happily explained by Oedipus, who observed, that man walked on his hands and feet when young; or in the morning of life, at the noon of life he walked erect; and in the evening of his days he supported his infirmities upon a stick. (Vid. Oedipus.) The sphinx no sooner heard this explanation than she dashed her head against a rock, and immediately expired. Some mythologists with to unriddle the fabulous traditions about the sphinx, by the supposition that one of the daughters of Cadmus, or Lains, infested the country of Thebes by her continual depredations, because she had been refused a part of her father’s possessions. The lion’s paw expressed, as they observe, her cruelty, the body of the dog her lasciviousness, her enigmas the phæres she laid for strangers and travellers, and her wings the dispatch she used in her expeditions.

Among the Egyptians the sphinx was the symbol of religion, by reason of the obscurity of its mysteries; and on the same account the Romans placed a sphinx in the pronaos or porch of their temples. Sphinxes were used by the Egyptians to show the beginning of the water’s rising in the Nile: with this view, as it had the head of a woman and body of a lion, it signified that the Nile began to swell in the months of July and August, when the sun passes through the signs of Leo and Virgo. There are several of these still to be seen; one in particular, near the pyramids, much spoken of by the ancients; being of a prodigious size, and cut out of the rock; the head and neck appear only at present, the rest of the body being hid in the sand. This, according to Thevenot, is 26 feet high, and 15 feet from the ear to the chin: but Pliny affures us, the head was no less than 102 feet in circumference, and 62 feet high from the belly, and that the body was 143 feet long, and was thought to be the phœnix of king Amasis.

The learned Mr. Bryant* observes, that the sphinx seems to have been originally a valltf rock of different fitrate; which, from a shapeless mass, the Egyptians fashioned into an object of beauty and veneration. The Egyptians used this figure in their building; from them the Greeks derived it, and afterwards improved it into an elegant ornament. It is also frequently used in modern architecture.

It is proper to observe, that the sphinx of the Egyptians is said in the Asiatic Researches † to have been found in India. Colonel Pearce was told by Murari Pandit, a man of learning among the Hindoos, that the sphinx there called fanga is to appear at the end of the world, and as soon as he is born will prey on an elephant: he is therefore figured seizing an elephant in his claws; and the elephant is made small, to show that the fanga, even a moment after his birth, will be very large in proportion to it. But in opposition to this account positively by Murari Pandit the late Sir William Jones, the learned and illustrious president of the Asiatic Society, was afeured by several Brahmons, that the figure taken for a sphinx was a representation of a lion seizing a young elephant. This point therefore requires farther investigation.

**Sphinx, Hawk-Moth, in natural history; a genus of insects belonging to the order of lepidoptera. The antennæ are shaped somewhat like a prism, and are more slender at each end than at the middle. The tongue is generally throt out: the two palpi are bent back, and the wings deflexed. There are about 165 species already discovered, of which ten are found in Great Britain and Ireland.**

1. The occlu (2) eyed willow hawk-moth. There is no trunk; the wings are indented. Above, 3d wings dark and light-brown, marbled; 2d, red, with a large yellow-black eye. Beneath, a large red triangle from the base of the 1st wings. The breadth one inch and an half. Caterpillar smooth, green, and oblique white lines on the sides, and a posterior horn. The eggs are green. It lives on willows. 2. Populis, poplar-hawk-moth. The wings are scalloped, bluish grey, and waved with dark lines. On the first wings a long white spot, and the base of the 2d red-brown. Wings revered. Length one inch. A long spiral trunk caterpillar green, smooth, with oblique white spots, and a posterior horn. It lives on poplars and willows. 3. This lime hawk-moth. No trunk; the wings are scalloped: the antennæ are white on the under side, yellow on the upper. Above, 1st wings grey-brown, with two irregular large green spots; 2d, wings orange. Beneath greenish grey. Caterpillar green, faggreeen, with a posterior horn. 4. Convulvulus, unicorn, or bindweed hawk-moth. The antennæ are long and thick; the trunk very long and spiral. Above, body marked with black and red belts; wings entire, brown-grey, with black zigzag transverse lines. The breadth three inches. Caterpillar smooth, green, with a posterior horn. 5. Lysigoras, privet hawk-moth. The antennæ are long, thick, and brown. Trunk long, spiral. 1st wings two inches long, narrow, entire, brown; 2d, short, red, with black bars. The abdomen is red, with black vings. Caterpillar smooth, yellow-green, with a posterior horn. 6. Aurotops, jessamine hawk-moth. The wings are entire: the trunk long, spiral. Above, 1st wings brown, clouded with grey and yellow, and a yellowish spot in the centre; 2d, yellow, with two waved transverse stripes. The abdomen is yellow, with seven black-brown belts. The thorax marked like a Death’s-head. Length two inches. Caterpillar very large, yellow, with five green and orange oblique belts, and a posterior horn. 7. Eferon, elephant-moth. The wings are angular, entire. Above, 1st wings fringed transversely with red and green; 2d, black at the base, and red outwards. The body red and green. Caterpillar smooth brown and yellow, with a posterior horn, and a frill like a hog. It lives on vines, convolvulus, &c. 8. Stellatarum, large bee moth. The antennæ are thick towards the ends, brown.
The trunk is spiral; the wings are short and entire; the body is thick, brown, and hairy. First wings are brown, waved; 2d, red-brown. It resembles a large bee. Caterpillar smooth, with a posterior blue horn, tnt with red. It lives on psilium. 9. **Tipuliformia**, small bee moth. The thorax is yellow beneath: the wings are short, with black veins. The abdomen black, bearded, yellow at the extremity. Caterpillar on the lonicera. 10. **Fipendula**, burnet moth. The antennae, legs, and body, are black. Second wings red, with a greenish border. First wings bluish green, with fix red spots, in pairs. Length eight lines. Caterpillar yellow, with black spots. It lives on gran$.

The name *fibinx* is given to this genus on account of the singular attitudes of their caterpillars, who apply the hinder part of their body to a branch of a tree, holding the rest of it erect, like the fabulous sphinx. Most of them spin their cod under ground, making them up with small parcels of earth and grains of corn interwoven with threads. The sphinges fly either early in the morning, or after sunset in the evening. They fly heavily and sluggishly, often emitting a kind of smoke. Success; and these, it succeeded to admiration, even when the sick did not void worms.

I have of late, previous to the use of the Indian pink, given a vomit, when the circumstances of the cafe permitted it; and I have found this method answer so well, that I think a vomit should never be omitted. I have known half a dram of this root purge as briskly as the same quantity of rhubarb; at other times I have known it, though given in large quantities, produce no effect upon the belly: in such cases, it becomes necessary to add a grain or two of sweet mercury, or some grains of rhubarb; but it is to be observed, that the same happy effects did not follow its use in this way, as when it was purgative without addition. The addition, however, of the purgative renders its use safe, and removes all danger of convulsions of the eyes although neither *ol. ruta, fibinæ*, or any other nervous substance, is given along with it. It is, in general, safer to give it in large doses than in small; for, from the latter, more frequently the giddiness, dimness of the sight, and convulsions, &c. follow; whereas, from large doses, I have not known any other effect than its proving emetic or violently cathartic. To a child of two years of age, who had been taking 10 grains of the root twice a-day, without having any other effect than making her dull and giddy, I prescribed 22 grains morning and evening, which purged her briskly, and brought away five large worms. After some months an increased dose had the same good effects. I prefer the root to the other parts of the plant; of which, when properly dried, I gave from 12 to 60 or 70 grains in phiallets. In infusion, it may be given to the quantity of two, three, or four grains, twice a-day. I have found that, by keeping, the plant loses its virtue in part; for 40 grains of the root which has not been gathered above two months, will operate as strongly as 60 which has been kept for 15 months.”

In Dr Garden’s subsequent letters, addressed to Dr Hope, in the years 1764 and 1766, the efficacy of this root in worm cafes is further confirmed; and he observes, that the root keeps better than he at first thought (having lately used it several years old with great success). In what he calls continued or remitting low worm fevers, he found its efficacy promoted by the addition of rad. fetentor cing. SPICE, any kind of aromatic drug that has hot and pungent qualities: such as pepper, nutmeg, ginger, cinnamon, cloves, &c.
SPIRAL, in anatomy, the name of several muscles, &c. of the spine.

SPINARIA, in botany. See Euonymus.

SPINARIS, in botany. See Anatomia, p. 30.

SPINE, in botany. See Spina.

SPINELLO, a Tuscan painter, of great repute in his time. He painted a picture of the fallen angels, in which he drew so horrible a picture of Lucifer, that it frightened him so much as to affect his senses ever after. He flourished about the year 1580.

SPINET, or Spinnet, a musical instrument ranked in the second or third place among harmonious instruments. It consists of a chest or belly made of the most porous and resonant wood to be found, and a table of fir glued on slips of wood called furniers, which bear on the sides. On the table is raised two little prominences, or bridges, wherein are placed so many pins as there are chords or strings to the instrument. It is played on by two ranges of continued keys, the former range being the order of the diatonic scale, and that behind the order of the artificial notes or semitones. The keys are so many flat pieces of wood, which, touched and pressed down at the end, make the other raise a jack which strike and found the strings by means of the end of a crow's quill, wherewith it is armed. The 30 first strings are of brass, the other more delicate ones of steel or iron-wire; they are all stretched over the two bridges already mentioned. The figure of the spinet is a long square or parallelogram; some call it a harp couched, and the harp an inverted spinet. See the article Harp.

This instrument is generally tuned by the ear, which method of the practical musicians is founded on a supposition that the ear is a perfect judge of an octave and a fifth. The general rule is to begin at a certain note, as C, taken towards the middle of the instrument, and tuning all the octaves up and down, and also the fifths, reckoning seven semitones to each fifth, by which means the whole is tuned. Sometimes to the common or fundamental play of the spinet is added another similar one in unison, and a third in octave to the first, to make the harmony the fuller; they are either played separately or together by means of a fly: these are called double or triple spinets; sometimes a play of violins is added, by means of a bow, or a few wheels parallel to the keys, which press the strings and make the found last as long as the musician pleases, and heighten and soften them more or less, as they are more or less pressed. The harpsichord is a kind of spinet, only with another disposition of the keys (see the article Harpsichord). The instrument takes its name from the small quill ends which touch the strings, resembling spines or thorns.

SPINIFEX, in botany; a genus of plants belonging to the class of Polygonum and order of Monocotyledones. The herbaceous flowers have a calyx with bivalved biflorous glumes, the valves being parallel to the rachis; the corolla is bivalved and awoolly; there are three stamina and two styles. In the male flowers the calyx is common with the hermaphrodite; the corolla and stamina are similar. There is only one species, the squarrosus.

SPINNING, in commerce, the art or art of reducing flax, hemp, wool, hair, or other matters, into thread. Spinning is either performed on the wheel, or with a diatass and spindle, or with other machines proper
spinning

proper for several kinds of working. Hemp, flax, nettle-thread, and other like vegetable matters, are to be wetted in spinning: silks, wools, &c. are spun dry, and do not need water; yet there is a way of spinning or reeling silk as it comes off the cafes or balls, where hot and even boiling water is to be used (see Silk).

The vast variety, and the importance of those branches of the manufactures which are produced from cotton, wool, and flax, spin into yarn, together with the cheapness of provisions, and the low price of labour in many foreign countries, which are rivals in trade, have occasioned many attempts in Britain to render spinning more easy, cheap, and expeditious, for which see Cotton Spinning and Cotton Mills.

These contrivances have in some parts of Scotland been applied to the spinning of flax; but a very considerable improvement has lately been made by Mr. Antis of Fowlsheugh near Leeds of the common spinning wheel. It is well known, that hitherto much time has been lost by stopping the wheel in order to shift the thread from one flake to the flyer to another; but in Mr. Antis's wheel the bobbin is made to move backwards and forwards so as to prevent the necessity of this perpetual interruption, as well as to obviate the danger of breaking the thread and losing the end. This is effected by the axis of the great wheel being extended through the pillar next the spinner, and formed into a pinion of one leaf A, which turns with a wheel B, seven inches diameter, having on its periphery 97 teeth; so that 97 revolutions of the great wheel cause one of the lesser wheel. On this lesser wheel is fixed a ring of wire C C C C; which, being supported on fix pegs, stands obliquely to the wheel itself, touching it at one part, and projecting nearly three quarters of an inch at the opposite one; near the side of this wheel is an upright lever C, about 15 inches long, moving on a centre three inches from its lower extremity, and connected at the top to a sliding bar D; from which rises an upright piece of brass E, which working in the notch of a pulley drives the bobbin F backward and forward, according to the oblique wire forces a pin G in or out, as the wheel moves round. To regulate and adjust the alternate motion, a weight H hangs by a line to the sliding bar, and passing over a pulley I rises and falls as the bobbin advances or recedes, and tends constantly to keep the pin in contact with the wire. It is evident, from this description, that one flake only is wanted to the flyer; which, being placed near the extremity K, the thread passing through it is by the motion of the bobbin laid regularly thereon. For this invention the Society for the Encouragement of Arts, &c. gave the author a premium of twenty guineas.

SPINOUS CAULIS, in botany; a stem covered with strong woody prickles, whose roots are not superficial, but proceeding from the body of the stem. When applied to a leaf, spinaeae folianae, it indicates the margin running out into rigid points or prickles quod marginem esset in avulsum duxerat, rigida praegerata.

SPINOUS, in botany. See Spinosus.

Spinosus Fluitus, such as have one of the rays of the back fins running out into thorns or prickles, as the perch, &c.

SPINOZA (Benedict), was born at Amsterdum the 24th November 1632. His father was a Jew of Portuguese extraction, by profession a merchant. After being taught Latin by a physician, he applied himself for many years to the study of theology, and afterwards devoted himself entirely to philosophy. He began very early to be dissatisfied with the Jewish religion; and as his temper was open, he did not conceal his doubts from the synagogue. The Jews, it is said, offered to tolerate his infidelity, and even promised him a pension of a thousand dollars per annum, if he would remain in their society, and continue outwardly to prostitute their ceremonies. But if this offer was really made, he rejected it, perhaps from his aversion to hypocrisy, or rather because he could not endure the restraint which it would have imposed. He also refused the legacy of a very considerable fortune, to the prejudice of the natural heirs; and he learned the art of polishing glasses for spectacles, that he might subsist independently of every one.

He would probably have continued in the synagogue for some time longer, if it had not been for an accident. As he was returning home one evening from the theatre, he was stabbed by a Jew: the wound was fatal; but the attempt naturally led Spinoza to conclude that the Jews had formed the design of afflicting him.

After leaving the synagogue, he became a Christian, and frequented the churches of the Lutherans and Calvinists. He now devoted himself more than ever to his favourite philosophical speculations; and finding himself frequently interrupted by the visits of his friends, he left Amsterdam, and settled at the Hague, where he often continued for three months together without ever sparing from his lodgings. During his residence in that city, his tastes, who was a Lutheran, asked him one day if he could be saved while she continued in her religion? "Yes (replied Spinoza), provided you join to your religion a peaceful and virtuous life." From this answer it has been concluded that he was a Christian in appearance only, while in reality he regarded all religions as indifferent. But this conclusion would be too severe, even if the woman had been a Mahometan.

His Thesaurus Theologiopoliticus which was published about that time, is a better proof of his sincerity than a thousand such conclusions; for this book contains all those doctrines in embryo which were afterwards unfolded in his Opera Politica, and which are generally considered as a system of atheism.

His fame, which had now spread far and wide, obliged him sometimes to interrupt his philosophical researches. Learned men visited him from all quarters. While the prince of Condé commanded the French army in Utrecht, he interested Spinoza to visit him; and though he was absent when the philosopher arrived, he returned immediately, and spent a considerable time with him in conversation. The Elector Palatine offered to make Spinoza professor of philosophy at Heidelberg; which, however, he declined.

He died of a consumption at the Hague on the 21st February 1677, at the age of 45. He left a peremptory contradiction to his opponents. He was temperate, liberal, and remarkably disinterested; he was inoffensive, affable, and friendly. His conversation was agreeable and instructive, and never deviated from the noblest propriety.

The only edition of the works of Spinoza that we have seen is in two volumes small 4to; the former of which
SPI

which was printed at Hamburg in the year 1670, and the latter we know not where, in 1677, a few months after his death. In the *Tractatus Theologico-politicus,* already mentioned, he treats of prophecy and prophets; and of the call of the Hebrews, whom he affirms to have been distinguished from other nations only by the admirable form of their government, and the fitness of their laws for long preserving their political state. He is likewise of opinion, or at least pretends to be so, that God may, in what we call a supernatural way, have given political institutes to other nations as well as to the Hebrews, who were, he saith, at no time a peculiar people to the Supreme Lord of heaven and earth; for, according to him, all history, sacred and profane, testifies that every nation was blessed with the light of prophecy. That light indeed, if his notions of it be just, was of very little value. He labours to prove, that the prophets were distinguished from other men only by their piety and virtue; that their revelations depended wholly on their imaginations and the dispositions of their minds; that they were often grossly ignorant and highly prejudiced; that the speculative opinions of one prophet are seldom in unison with those of another; and that their writings are valuable to us only by the prudence and piety of the authors. He then proceeds to treat of the divine law and of miracles; and endeavours to prove that no miracle, in the proper sense of the word, can have been at any time performed; because every thing happens by a necessity of nature, the result of the divine decrees, which are from all eternity necessary to themselves. He acknowledges, that in the Scriptures, which he professes to admit as true history, miracles are often mentioned; but he says that they were only singular events which the sacred historians imagined to be miraculous; and he then gives some very extraordinary rules for interpreting the books of the Old and New Testaments where they treat of miracles, or appear to foretell future events. See our articles Miracle and Prophecy.

Having thus divulged the Scriptures of every thing characteristic of a revelation from heaven, he next calls in question their authenticity. He affirms, in contradiction to the common opinion, that the Pentateuch and all the other historical books must have been written by one man; and that man, he thinks, could not have flourished at a period earlier than that of Ezra. The ground of this opinion are unwarranted and the talents of Spinoza; for that he had talents is uncontroversible. His principal objection to the authenticity of the Pentateuch is, that Moses is made to speak of himself in the third person, and to talk of the Canaanites being then in the land; and because he finds in his writings, as well as in the books of Joshua, Judges, Ruth, Samuel, &c. places designated by names which he supposes they had not in the early ages of which these books contain the history, he concludes that these writings must be one compilation from ancient records made at a very late period; more especially as the author often speaks of things of great antiquity relating to this day. The books of Esther, Ezra, Nehemiah, and Chronicles, must have been compiled, he thinks, under the Maccabees; and he seems to consider as of equal value with them the story of Tobit, and the other two apocryphal treatises intitled the Wisdom of Solomon and Ecclesiasticus.

These specious cavils, worthy only of some modern freethinkers, being useless, in the opinion of Bishop Warburton, is not sufficient to carry them even to the confines of rational doubt, we have sufficiently obviated in another place (see Scripture, no 8-—11.) Spinoza urges them against the other books of the Old Testament. The prophecies of Isaiah, Jeremiah, Ezekiel, Daniel, Hosea, and Jonah, are, as we have them, only fragments, he says, of the writings of those men compiled by the Pharisees under the second temple from ancient and voluminous records.

In the midst of this dogmatical scepticism, if we may use such a phrase, he bears such a testimony to the last chapters of the book of Daniel, as we should not have looked for in the writings either of a Jew or of a Deist. After detailing the various hypotheses which in his time were held respecting the author and the intention of the book of Job; in which, he says, Bionus is called Satan, he proceeds in these words: ' Transeo ad Daemonum librum, hic fine dubbio ex cap. 6. plius Danielis scripto continuo. Unde autem premio septem capita tuerint, necio,' thus admitting the *Tracts* of the seventy weeks. The canon of the Pharisaic sect, who wished to exclude from it the books of Proverbs, Ecclesiastes, and Ecclesi, as they had actually excluded others of equal value; but the three books in question were interred by the influence of two of the rabbins of greater wisdom and integrity than the rest. That so paradoxical a writer, who had been originally a Jew, and was now almost a Deist, should have treated the New Testament with as little ceremonial as the Old, will not surprise the intelligent reader. He begins his remarks, however, with affirming, that no man can peruse the Christian Scriptures, and not acknowledge the apocryphal books to have been prophets; but he thinks that their mode of prophesying was altogether different from that which prevailed under the Mosaic dispensation; and that the gift, whatever it was, forsook them the instant they left off preaching, as their writings, he says, have no connection or human compositions. This distinction between Christian and Jewish prophecy is the more wonderful, that he founds it principally on the diffimilarity of style visible in the writings of the Old and New Testaments; though, in his second chapter, which treats of the style of the Jewish prophets, he says expressly, 'Stylus deinde propheticus pro eloquentia cujusque prophetie variat, prophetic enim Exegetis et Amofoi non sunt, ut ille Eiaze, Nahumbei, eleganti, sed rude orto scripta.' That the Hebrew scholar may be convinced of the truth of this remark he recommends to him to study diligently the writings of these prophets, and to consider the occasions on which their prophecies were uttered: 'Quem si omnia recte perpenditur (fays he) facile ostendit, Deumnullum habere fylum peculiarem divend, sed tantum pro eruditum, et capacitate prophetarum daten us effer elegantem, compendiofum, feverum, rude, prolixum, et obscurum.' Another objection brought by Spinoza against the prophecies of the New Testament arises from the authors of them having been at
This volume contains a collection of philosophical and religious writings, primarily focused on the nature of God and His relationship with humanity.

[695]

**S P I**

at all times masters of themselves. This, says he, was peculiarly the case of St Paul, who often confirms his doctrine by reasoning, which the Jewish prophets never condescended to do, as it would have submitted their dogmas to the examination of private judgment. Yet, with singular inconsistency, he affirms that the Jewish prophets could not know that the impurities made on their imaginations proceeded from God, but by a given them, which by their own reason or judgment they knew would never be vouchsafed to an impious or a wicked man.

After these very free remarks on the Scriptures of the Old and New Testaments, he naturally enough expresses a suspicion, that by those who consider the Bible as the epistle of God sent from heaven to men, he will be thought to have fanned against the Holy Ghost by vilifying his dicta. This leads him to inquire in what sense the Scriptures are the word of God; and he gravely determines them to be so only as they actually contribute to make men more virtuous and holy. It is not enough that they are calculated to improve virtue and holiness: for should the words of the languages in which they are written acquire in process of time a signification different from what they had originally; should mankind lose all knowledge of these languages; or even should they agree to neglect the books, whether from ignorance or from wilfulness—these books would cease to be the word of God, and become nothing better than wafeful paper and ink; just as the two tables, which Moses broke on observing the idolatry of his countrymen, were not the covenant between Jehovah and the Israelites, but merely two pieces of stone! The Scriptures, however, are the word of God, because they teach the true religion of God above all mankind to lose all knowledge of these languages; or even transferendi fundamentum iidem ad omnia abscutte decreviTe quod omnia praetare tenetur, quamdui rex, five nobles, five populus humam, quam accepere, potestatem, que juris transferendi fundamentum fult, conferiant; nec his plura addere opus est. We heartily agree with him, *p. 181*. This to that precious conclusion it is needful to add a single word.

The *Ethica* are divided into five parts, which treat in order, de *Deo*; de *natura et origine mentis*; de *origine et natura affectuum*; de *serviti humanae fius de affectuum viribus*; de *potentia intellectus*; *fius de libertate humana*. As the author professes to tread in the footsteps of the geometers, and to deduce all his conclusions by rigid demonstration from a few *evident* truths, he introduces his work, after the manner of Euclid with a collection of definitions and axioms. These are couched in terms generally ambiguous; and therefore the reader will do well to consider attentively, in what sense, if in any, they can be admitted; for it will not be found easy to grant his premises, and at the same time refute his conclusions. His definition of substance, for instance, is so expressed as to admit of two senses; in one of which it is just, whilst in the other it is the parent of the most impious absurdity. We shall give it in his own words; “Per substantiam intelligi id, quod in se est, et per se concipitur, hoc est id, cujus conceptus non indiget conceptu alterius rei, a quo formari debeat.” If by this he meant, that a substance is that which we can conceive by itself without attending to any thing else, or thinking of its formation, the definition, we believe, will be admitted by every reflecting mind as sufficiently distinguishing the thing defined from an attribute, which, he says, is that which we perceive of a substance, and which we certainly cannot conceive as existing by itself. Thus the writer of this article can shut his eyes and contemplate in idea the small 4to volume now before
fore him, without attending to any thing else, or thinking of its paradoxical author, or even of the Great Being who created the matter both of him and of it; but he cannot for an instant contemplate the yellow colour of its vellum boards without thinking of triple extension, or, in other words, of body. The book therefore is a substance, because conceivable by itself; the colour is an attribute or quality, because it cannot be conceived by itself, but necessarily leads to the conception of something else. But if Spinoza's meaning be, that nothing is a substance but what is conceived as existing from eternity, independent of every thing as a cause, his definition cannot be admitted: for every man conceives that which in himself thinks, and wills, and is conscious, as a substance, at the same time that he has the best evidence possible that he existed not as a conscious, thinking, and active being, from eternity.

His fourth axiom is thus expressed: "Effecus cognitio est cognitionis causa dependent, et tandem iniviolata," and his fifth, "Quae nihil commune cum se invivum habent, etiam per se invicem intelligi non possunt, quin conceptus unus alterius conceptum non involuit." The former of these propositions, so far from being false-evident, is not even true; and the latter is capable of two tenors very different from each other. That every effect proceeds from a cause, is indeed an axiom; but surely we may know the effect accurately, though we be ignorant of the particular cause from which it proceeds (see PHILOSOPHY, n. 36; and PHYSICS, n. 91, &c.) nor does the knowledge of the one by any means involve the knowledge of the other. If different things have nothing in common, it is indeed true that the knowledge of one of them will not give us an adequate conception of the other; but it will in many cases compel us to believe, that the other exists or has existed. A parcel of gunpowder lying at rest has nothing in common with the velocity of a cannon-ball; yet when we know that a ball has been driven with velocity from a cannon, we infer with certainty that there has been a parcel of powder at rest in the chamber of that cannon.

It is upon such ambiguous definitions and axioms as these that Spinoza has raised his pretended demonstrations, that one substance cannot produce another; that every substance must necessarily be infinite; that no substance exists or can be conceived besides God; and that extended substance or body is one of the infinite attributes of God. We shall not waste our own time or the reader's with a formal confutation of these impious absurdities. We trust they are sufficiently contained in the other articles of this work (see METAPHYSICS, Part III. PROVIDENCE, and THEOLOGY, Part I.) and whoever wishes for a more particular examination of the author's principles, may find it in Dr Clarke's Demonstration of the Being and Attributes of God. The truth, however, is, that no man will need the aid of that eminent metaphysician to discover the fallacy of the reasoning by which they are attempted to be proved, if he adds any one precise meaning to the definitions and axioms, and adhere to that meaning steadily thro' the whole process of the pretended demonstrations.

By way of apology for this jargon, it has been lately said, that "Spinoza takes the word substance in its most simple and perfect sense; which is necessary, as he writes mathematically, and proposes a simple idea as the foundation of his theory. What is the proper signification of a substance? Is it not that which stands alone, which has the cause of its existence within itself? I wish that this simple meaning of the word could be universally admitted in philosophy. Strictly speaking, no worldly thing is a substance; since all mutually depend on each other, and finally on God, who, in this exalted sense, is the only substance. The word modification founds harf and improper, and therefore it cannot be expected to gain a place in philosophy; but if the school of Leibnitz may term matter the appearance of substance, why may not Spinoza be allowed a bolder term? Worldly substances are kept in union by divine power, as it was by divine power that they had existence. They represent also, if you please, modified appearances of divine power; each according to the situation, the time, and the organs, in and with which it appears. The phrase used by Spinoza is concise, and it gives an unity and simplicity to his whole system, however strange it may found in our ears."

From this account of Spinozism, one who had never looked into the works of the author would be led to suppose that his system is the same with that of Berkeley; which, denying the existence of material substance, attributes all our perceptions of what we call the qualities of body to the immediate agency of the Deity on our minds (see METAPHYSICS, Part II. Chap. 3.) But Spinoza's doctrine is very different. According to him, bodies are either attributes or affections of God; and as he says there is but one extended substance, he affirms that substance to be indivisible, and employs a long scholium to prove that those are mistaken who suppose it finite and not essential to the Deity. That we do not misrepresent his sentiments, the learned reader will be convinced by the two following definitions, with which he introduces that part of his ethics which treats of the nature and origin of mind.

1. "Ier corpus intellectum, qui Dei effentiam, quaternam, ut res extensa consideratur, certo et determinato modo exsistit."

2. "Ad effentiam aliquas rei id pertinere dico, quo dato res necessario positur, et quo sublato necessario tollitur; vel id, fine quo res, et vice versa, quod fine re nec effe nec concepi potest." In conformity with these definitions, he attempts to prove that God is an extended as well as a thinking substance; that as vii. i. a thinking substance he is the cause of the idea of a Part 2. circle, and as an extended substance of the circle itself; and that the minds of men are not substances, but certain modifications of the divine attribute; or, as he sometimes expresses it, "Quod hominum mentis auctore conititum, eis idea rei singularis aude existentes." Hence, he says, it follows that the human mind is a part of the intellect of the infinite God; so that when we speak of the human mind perceiving this or that, we can only mean that God, not as he is infinite, but as he appears in the human mind or constitutes its essence, has this or that idea; and when we speak of God's having this or that idea, we must conceive of Him not only as constituting the human mind, but as, together with it, having the idea of something else (a). Another place he tells us, that the human mind is nothing but the idea which

(a) Hine sequitur mentem humanam partem esse infiniti intellectus Dei; ac proinde cum dicimus, mentem humanam
Part l.

Prop. vii. Dei tulle, which God has of the human body as actually existing; that this idea of the body, and the body itself, are one and the same thing; and that thinking and extended substances are in reality but one and the same substance, which is sometimes comprehended under one attribute of the Deity, and sometimes under another 

If this impious jargon be not Atheism, or as it has been sometimes called Pantheism, we know not what it is (see Pars. ii.). According to Spinoza, there is but one substance, which is extended, infinite, and indivisible. That substance indeed he calls God; but he labours to prove that it is corporeal; that there is no difference between mind and matter; that both are attributes of the Deity variously considered; that the human soul is a part of the intellect of God; that the same soul is nothing but the idea of the human body; that this idea of the body, and the body itself, are one and the same thing; that God could not exist, or be conceived, were the visible universe annihilated; and therefore that the visible universe is either the one substance, or at least an essential attribute or modification of that substance. He sometimes indeed speaks of the power of this substance; but when he comes to explain himself, we find that by power he means nothing but blind necessity; and though he frequently talks of the will of God, he seems to make use of the word without meaning. This we think evident from the appendix: to his 36th proposition, in which are to be found in other systems. The passions are divided many precepts of practical wisdom, as well as some judicious rules for conducting philosophical investigation; and we only regret, that the reader must wade to them through pages of fatalism, scepticism, and palpable contradictions. His Compendium Grammaticum Linguae Latinae, though left imperfect, appears to have shown much merit, that it is to be wished he had fulfilled his intention of writing a philosophical grammar of that language, instead of wasting his time on abstruse speculations, which though they seem not to have been injurious to his own virtue, are certainly not calculated to promote the virtue of others, or to increase the sum of human happiness.

SPIREA, in botany: A genus of plants belonging to the class of icaranteria, and to the order of pentagynia; and in the natural system arranged under the 26th order, Pomaceae. The calyx is quinquefolium; there are five petals; and the capsule is polyperspermous. There are 18 species; of which two only are British, the Filipendula and ulmaria. 1. The filipendula,dropwort, has pinnated leaves; the leaflets are serrated; the stalk is herbaceous, with a foot and a half high, terminated with a lovely umbel of white flowers, often tinged with red. The petals are generally six, and the segments of the calyx are reflexed: the stamens are 30 or more; the germina i 2 or upwards. It grows in mountainous pastures. 2. The ulmaria, meadow-sweet. The leaves have only two or three pair of pinne, with a few smaller ones intermixed; the extreme one being larger than the rest, and divided into three lobes. The calyx is red; the petals white, and the number of capules from six to ten twisted in a spiral. The tuberous pea, like roots of the filipendula dried and reduced to powder, have been used instead of bread in times of scarcity. Hogs are very fond of these roots. Cows, goats, sheep, and swine, eat the plant; but hares refuse it. The flowers of the ulmaria have a fragrant scent, which rises in distillation. The whole plant indeed is extremely fragrant, so that the common people of Sweden burn their floors with it on holydays. It has also an altringent quality, and has been found useful in dysenteries, ruptures, and in tanning of leather.

SPIRAL, in geometry, a curve line of the circular kind, which in its progress recedes from its centre.

SPIRE, in architecture, was used by the ancients for the base of a column, and sometimes for the square or tore; but among the moderns it denotes a figure that continually diminishes as it ascends, whether conically or pyramidal.

SPIRIT, in metaphysics, an incorporeal being or intelligence;
SPIRIT, in chemistry and pharmacy, a name applied to every volatile liquid which is not insipid like phlegm or water; and hence the distillation into acid, alkaline, and vinous spirits. See Pharmacy-Index.

SPIRIT of Wine. See Chemistry-Index, Distillation, and Pharmacy-Index.

SPIRITS, or Animal Spirits. See Anatomy, Part V. n° 136, and Physiology, n° 183.

SPIRITUAL, in general, something belonging to or pertaining of the nature of spirit. See Spirit.

SPIRITUOUS LIQUORS have in all nations been considered as a proper subject of heavy taxation for the support of the state. This has naturally occasioned a nice examination of their strength. It having been at last found that this was intimately connected with the specific gravity, this has been examined with the most scrupulous attention to every circumstance which could affect it, so that the duties might be exactly proportioned to the quantity of spirit in any strong liquor, independent on every other circumstance of flavour or taste, or other valued quality. The chemist at last found that the basis of all strong liquors is the same, produced by the vinous fermentation of pure saccharine matter dissolved in water. He also found, that whether this vegetable salt be taken as it is spontaneously formed in the juices of plants and fruits, or as it may be formed or extracted from farinaceous fruits and roots by a certain part of the process of vegetation, it produces the same ardent spirit, which has always the same density in every mixture with water. The minute portions of aromatic oils, which are in some degree inseparable from it, and give it a different flavour according to the substance from which it was obtained, are not found to have any sensible effect on its density or specific gravity. This seems a very completely established in consequence of the unceasing attempts of the manufacturers to lessen the duties payable on their goods by mixtures of other substances, which would increase their density without making them less palatable. The vigilance of the revenue officers was no less employed to detect every such contrivance. In short, it is now an acknowledged point, that the specific gravity is an accurate test of the strength.

But though this is true in general, we cannot derive much benefit from it, unless we know the precise relation between the strength and the density of a spirituous liquor. Do they increase pari passu, or by what law are they connected? It was natural to expect that equal additions of ardent spirits or alcohol to a given quantity of water would produce equal diminutions of density. Areometers were accordingly made on this principle above 200 years ago, as may be seen in the works of Gaspur Schottus, Sturmus, Agricola, and other old authors. But when mathematical physics became more generally known, this was easily discovered to be erroneous; and it was shown (we think first by Mr Boyle) that equal additions to the specific gravity would be produced by successively taking out of any vessel a certain measure of alcohol and replacing it with an equal measure of water. This was the most convenient discovery for all parties, because then the duties payable on a cask of spirits would be in the exact proportion of the diminution of its density. But it was soon found by those who were appointed guardians of the revenue that this conclusion was erroneous, and that a mixture which appeared by this rule to contain 35 gallons of alcohol, did really contain 35. This they found by actually making such a mixture: 18 gallons of alcohol mixed with 18 of water produced only 35 gallons of spirits. The revenue officers, finding that this conclusion was most remarkable in mixtures of equal parts of water and the strongest spirits which could then be procured, determined to levy the duties by this mixture; because, whether the spirituous liquor was stronger or weaker than this, it would appear, by its specific gravity, rather stronger than it really was. This sagacious observation, and the simplicity of the composition, which could at all times be made for comparison, seem to be the reasons for the excise officers selecting this mode of estimating the strength and levying the duties. A mixture of nearly equal measures of water and alcohol is called proof spirit, and pays a certain duty per gallon; and the strength of a spirituous liquor is estimated by the gallons, not of alcohol, but of proof spirit which the cask contains. But because it might be difficult to procure at all times this proof spirit for comparison, such a mixture was made by order of the board of excise; and it was found, that when six gallons of it was mixed with one gallon of water, a wine gallon of the mixture weighed 7 pounds 13 ounces avoirdupois. The board therefore declared, that the spirituous liquor of which the gallon weighed 7 pounds 13 ounces should be reckoned 1 to 6 or 1 in 7 under proof. This is but an awkward and complex formula; it was in order to suit matters to a mode of examination which had by time obtained the sanction of the board. Mr Clarke, an ingenious artificer of that time, had made a hydrometer incomparably more exact than any other, and constructed on mathematical principles, fit for computation. This had a set of weights corresponding to the additions of water or proof spirit, and the mixture 1 to 6 or 1 in 7 was the only one which weighed an exact number of ounces per gallon without a fraction.

This binds the excise law; and Clark's hydrometer is still the instrument of authority, although others have been since constructed by Dicas Quin, and others, which are much more ingenious and convenient. The mathematician who examines Dicas's hydrometer, with its sliding scale, by which it is adjusted to the different temperatures, and points out the condenstations, will perceive a beautiful and sagacious combination of quantities, which he will find it difficult to bring under any analytical form. Perhaps Quin's may have some preference in respect of convenience; but facile inverti addes. Mr Dicas's was original.

As naturalists became more accustomed to exact observation in every topic of inquiry, the composition which obtains in the mixture of different substances became more familiarly known. This evidently affects the present question; and both the excise and the distillers are interested in its accurate decision. This occasioned an application to the Royal Society; and a most scrupulous examination of the strength of spirituous liquors was made by Sir Charles Blagden and Mr Gilpin, of which they have given a particular account in the Philosophical Transactions for 1790 and 1792.

We have taken notice of this in the article Specific Gravity.
Spirits of Gravity, mentioning such circumstances of the results obtained in the analysis of spirits, as suited our purposes of physical discussion. At present we give the general result in the table of specific gravity, as peculiarly belonging tospirits of spirits, affording the most exact account of their density in every state of dilution of alcohol with water. And as the relation between the proportion of ingredients and the density is peculiar to every substance, so that scarcely any inference can be made from one to another, the reader will consider the tables here given as characteristic with respect to alcohol. In all solutions of salts we found that the condensation increases continually with the dilution, whereas it is greatest when equal bulk of water and alcohol are mixed: yet we do not consider this as an exception; for it is certain, that in the strong est brine the saline ingredient bears a small proportion to the water—and when we mix two solutions, the condensation is greatest when they are nearly equal in bulk. But we think ourselves entitled to infer, that alcohol is not a dilution of a substance in a quantity of water; but that water, in a certain proportion, not very distant from which we can produce by slow distillation, is an ingredient of alcohol, or is one of its constituents, and not merely a vehicle or menstruum. We therefore imagine that proof spirit contains nearly equal bulk of water and ardent spirits.

The great difficulty in this examination arose from the very dissimilar expansions of water and alcohol by heat. This determined Sir Charles Blagden to estimate the proportions of ingredients by weight, and made it absolutely necessary to give a scale of specific gravity and strength for every temperature. For it must be remarked, that the question (whether in commerce or philosophy) always is, "How many gallons of alcohol and of water, taken just now and mixed together, will produce a hundred gallons of the spirit we are examining?" The proportion of these two will be different according to the temperature of both. As many mixtures therefore must have been made in each proportion as there were temperatures considered; but by taking the ingredients by weight, and examining the density of the compound in one temperature, it is then heated and cooled, and its change of density observed. Calculation then can tell us the change in the proportion of the bulk or numbers of gallons in the mixture, by means of a previous table showing the expansions of water and of alcohol.

The alcohol selected for this examination had the specific gravity 0.825. This is not the purest that can be procured; some was produced of 0.816, of 0.814, and 0.813 both obtained from rum, from brandy, and from malt spirit. We are informed that Dr Black has obtained it of the specific gravity 0.8 by digesting alcohol with fixed ammoniac (muriatic acid united with lime) made very dry. It dephlegmates alcohol very powerfully without decomposing it, which always happens when we use caustic alkalis. Alcohol of 0.825 was chosen because expressed by a number of easy management in computation.

The examination commenced by ascertaining the expansions of water and alcohol. The temperature 60° of Fahrenheit's scale was selected for the general temperature of comparison, being easily attainable even in cold weather, and allowing the examiner to operate at ease. The first and last compartments of the tables contain the weights and specific gravities of alcohol and water from every fifth degree of heat from 25° to 100°. From these we have constructed the following tables of expansion. The bulk of 100,000 ounces, pounds, or other weight of water and of alcohol of the temperature 60°, occupies the bulk expressed in the table for every other temperature. Water could not be easily or usefully examined when the temperature 30°, because it is with great difficulty kept fluid in that temperature. It is very remarkable, that when it can be kept, it expands instead of contracting; while cooling down from 35° or thereabouts, and as it approaches to 32°, it expands rapidly. We observe the same thing in the crystallization of Glauber salt, martial vitriol, and some others, which contain much water in their crystals. We observe, on the other hand, a remarkable contraction in the zeolite just before its beginning to swell into bubbles by a red heat.

</table>

This being premised, the examination was conducted in the following manner. It was determined to mix 100 parts by weight of pure alcohol with five, ten, fifteen, twenty, parts of distilled water, till they were compounded in equal quantities, and then to mix 100 parts of distilled water with 95, 90, 85, 80, &c. parts of alcohol, till they were mixed in the proportion of 100 to 5. Thus a series of mixtures would be obtained, extending from pure alcohol to pure water. This series would be such, that the examinations would be most frequent in the cafes most usual in the commerce of strong liquors. A set of phials, fitted with ground stoppers, were provided, of sizes fit to hold the intended mixtures. These mixtures were made by suspending the phial to the arm of a very nice balance, in the opposite scale of which (besides the counterpoise of the phial) there was placed the weight 100. Spirit was then poured into the phial till it exactly balanced the weight 100. The weight for the water to be added was then put into the opposite scale, and water was poured into the phial by means of a slender glass funnel, by small quantities at a time, and the phial frequently agitated to promote the mixture. When the additional weight was exactly balanced, the phial was taken off, its stopper put in, and leather tied over it, and it was set by, for at least a month, that the mixture and the whole process...
The method was followed in the mixtures where the water was predominant.

When the ingredients of these mixtures were judged to have completely incorporated, their specific gravity was examined by weighing with the most scrupulous precision the contents of a vessel which held 2925 grains of water, of the temperature 50°. The balance was so exceedingly sensitive, that the 50th part of a grain greatly deranged its position when loaded with the scales and their contents. It was constructed by Mr. Ramfden, and some account of its exquisite sensibility may be seen in the Journal de Physique, vol. xxi. This quantity of materials was therefore thought abundantly sufficient for ascertaining the density of the liquor. It is needless to detail the precautions which were taken for having the contents of the weighing bottle brought to the precise temperature proper for the experiment. They were such as every person conversant with such things is accustomed to take—The bottle had a slender neck, and being put on a lathe, a mark was made round it with a diamond. The bottle was filled till the bottom of the hollow surface of the fluid was in the plane of this mark; and to judge of the accuracy attainable in filling the bottle, the operation was several times repeated and the contents weighed, without the difference of a 25th of a grain in 2925. The only source of error which was to be guarded against was air-bubbles adhering to the inside of the bottle, or moisture condensing (in the experiments with low temperatures) on the outside. Both of these were attended to as much as possible.

This method of determining the specific gravity was preferred to the usual method, observing the weight lost by a lump of glass when suspended in water; for Mr. Gilpin had been enabled, by means of this nice balance, to discover, even in pure water and in alcohol, want of perfect fluidity. Something like viscidity rendered the motion of a lump of glass through the liquor sensibly sluggish, so that when the balance was brought to a level, there was not a perfect equilibrium of weights: (See what we have said of this matter in Specific Gravity). Mr. Gilpin also tried the ingenious instrument proposed for such experiments by Mr. Ramfden, and described by him in a pamphlet on this very subject; and he found the anomalies of experiment much greater than in this method by weighing.—Indeed the regular progression of weights to be seen in the annexed tables is an unquestionable proof of the sufficiency of the method; and it has the evident advantage of all other methods in point of simplicity and practicability without any uncommon apparatus. Any person possessed of a good ordinary balance and a set of exact weights may examine all questions of this kind, by weighing pure water and the liquor which he may have occasion to examine in a common 6 or 8 ounce phial. For this reason, it is recommended (in preference to all hydrometers) to the board of excise to provide this simple apparatus in every principal office.

Every experiment was made at least three times; and the mean result (which never differed one grain from the extreme) was taken.

From these experiments the annexed tables were constructed. The first is the simple abstract of the experiments, containing the weights of the contents of the bottle of every mixture. The second contains the specific gravities deduced from them. We have said that the experiments appear surprisingly accurate. This we say on the authority of the regular progression of the specific gravity in any of the horizontal rows. In the series, for instance, for the temperature 50°, the greatest anomaly is in the mixture of 50 parts of spirit with 100 of water. The specific gravity is 0·59804, wanting 3 or 4 of the regular progression. This does not amount to 1 in 18000.

(Continued)
SPIRITOUS LIQUORS. 

We formerly observed, that the series of mixtures chosen by Sir Charles Blagden, for the advantages attending it in making the experiments, was not suited for solving the questions which commonly occur in the spirit business. He accordingly suggests the propriety of forming tables in a convenient series from the data furnished by these experiments, indicating the proportion of ingredients contained in some constant weight or bulk.

To facilitate the construction of such tables, it is necessary to consider the subject in the most general manner. Therefore let \( x \) represent the constant number 100. Let \( \omega \) and \( \tau \) represent the quantities of water and spirit by weight in any mixture; that is, the pounds, ounces, or grains of each. Let \( x \) represent the quantity per cent. of spirits also by weight; that is, the number of pounds of spirits contained in 100 pounds of the mixture; and let \( y \) be its quantity per cent. in gallons, or the number of gallons contained in 100 gallons of the unmixed ingredients. Let \( m \) be the bulk of a pound of spirit of any given temperature, the bulk of a pound of water of the same temperature being accounted 1.

Then \( \omega + \tau \) is the weight of any mixture, and \( \omega + m \tau \) is its bulk.

We have the following proportions: 1. \( \omega + \tau = a \); \( x \), and \( x = \frac{a s}{\omega + \tau} \) (Equation 1st); and hence \( s \) may be found when \( x \) the per centage in weight is given, for 

\[
(\omega + \tau = \omega x a - x)
\]

Equation 2.

2. \( \omega + m \tau = m y \); and \( y = \frac{m y}{\omega + m \tau} \) (Equation 3d); and \( s \) may be found when \( y \), the per centage in gallons, is given: for \( s = \frac{m y}{a - y} \) (Equation 4th).

The usual questions which can be solved from these experiments are:

1. To ascertain the quantity of spirits per cent. in bulk, from observation of the specific gravity, or to tell how many gallons of spirit are in 100 gallons of mixture.

Look for the specific gravity in the table, and at the head of the column will be found the \( \omega \) and \( s \) corresponding. If the specific specific gravity observed is not in the tables, the \( s \) must be found by interpolation. And here it is proper to remark, that taking the simple proportional parts of specific gravity will not be sufficiently exact, especially near the beginning or the end of the table, because the densities corresponding to the series of mixtures do not change uniformly. We must have recourse to the general rules of interpolation, by means of first and second differences or be provided with a subsidiary table of differences. A good deal of practice in computations of this kind suggested the following method of making such interpolations with great dispatch and abundant accuracy. On a plate of wood, or metal, or stiff cardboard, draw a line EF (fig. 3.) as a scale of equal parts, representing the leading or equable arithmetical series of any table. (In the present case EF is the scale on which \( s \) is computed.) Through every point of division draw the perpendiculars BA, EC, FD, &c. Make one of them AB more conspicuous than the rest, and differing from the others also in such a fort, that the eye shall readily catch their distance from the principal line AB. Let CPL be a thin slip of whalebone, of uniform breadth and thickness, also divided into equal parts properly distinguishable. Lastly, let there be a pin P fixed near the middle of the principal line AB.

Now suppose that a value of \( s \) is to be interpolated by means of an observed specific gravity not in the table. Look for the nearest to it, and note its distance from the preceding and the following. Let these be \( \phi \) and \( \psi \) on the flexible scale. Also take notice of the lines \( K \) to \( H \), whose distances from \( A \) are equal to the constant difference between the successive values of \( S \), or to any easily estimated multiple of it (as in the present case we have taken \( 10 \) and \( 10 \), instead of \( 5 \) and \( 5 \), the running difference of Sir Charles Blagden's table). Then, leaning the middle point P of the whalebone on the pin P in the board, bend it, and place it slantwise till the points K and H fall somewhere on the two parallels \( K \) and \( H \). No matter how oblique the position of the whalebone is. It will bend in such a manner that its different points of division (representing different specific gravities) will fall on the parallels which represent the corresponding values of \( S \). We can say that all this may be done in less than half a minute, and less time than is necessary for bending a table of proportional parts, and not the tenth part of that necessary for interpolating by second differences. Yet it is exact enough (if of the size of a duodecimo page) for interpolating three decimal places.

This is ten times more exact than the present case requires. To return from this digression.

Having thus found \( S \) in the table, we get \( x \) or \( y \) by the equations \( \frac{a - S}{\omega + \tau} = x \), and \( \frac{m y}{\omega + m \tau} = y \).

But here a material circumstance occurs. The weight of alcohol \( \tau \), and its per centage \( x \), was rightly determined by the specific gravity, because it was interpolated between two values, which were experimentally connected with this specific gravity. But in making the transition from \( x \) to \( y \), we only give the per centage in gallons before mixture, but not the number of gallons of alcohol contained in an hundred gallons of mixed liquor. For when we have taken \( \omega - \tau \) and \( y \) instead of \( \omega \) and \( s \), they will indeed make a similar compound when mixed, because the proportion of their ingredients is the same. But they will not make 100 gallons of this compound, because there is a shrinking or condensation by mixture, and the specific gravity by which we interpolated \( s \) is the physical or real specific gravity corresponding to \( \omega \) and \( s \); while \( \frac{\omega + \tau}{\omega x m} \), the specific gravity implied in the value of \( y \), is the mathematical density independent on this condensation. Since therefore \( y \), together with \( \omega - \tau \), make less than 100 gallons of the compound, there must in 100 gallons of it be more alcohol than is expressed by \( y \).

Let \( G \) be the mathematical specific gravity \( (\omega + \tau) \), and \( g \) the physical or real observed specific gravity (which we cannot express algebraically); and let \( \omega \) be the gallons of alcohol really contained in 100 gallons of the compound. The bulk being inversely as the density or specific gravity, it is evident that the bulk
SPIRITUOUS LIQUORS.

...bulk of the compound must be to 100 gallons as g to G. And since we want to make it fill up to 100 gallons, we must increase it in the proportion of G to g. And because this augmentation must be of the same strength with this contracted liquor, both ingredients must be increased in the proportion of G to g, and we must have $G = y \times z$ and $z = x \times \frac{G}{y}$. Now, instead of $y$, write $\frac{a - m s}{w + m s}$, and instead of $z$ write $\frac{w + m s}{w + s}$, which are respectively equal to this. This gives us $z = g \times \frac{w + m s}{w + s} \times \frac{m s}{w + s} = g a \times \frac{m s}{w + s}$.

All this will be illustrated by an example.

Suppose that we have observed the specific gravity of a spirituous liquor of the temperature 65° to be 0.94128. Looking into Sir Charles Blagden's table, we find the gravities 0.94018 and 0.94296, and the $s$ corresponding to them is 80 and 75, the water in each mixture being 100. By interpolation we obtain the $s$ corresponding to 0.94128, viz. 79. At this temperature $m = \frac{1}{0.925} = 1.0825$, and $m = 94.54545$. Therefore $z = 0.94128 \times 100 \times 94.54545 = 49.997$, or 49.99 gallons as nearly 50.

We have seen even persons not unacquainted with subjects of this kind puzzled by this sort of paradox. $z$ is said to be the per cent of spirit in the compound. The compound has the same proportion of ingredients when made up to 100 gallons as before, when $y$ was said to be its per cent, and yet $y$ and $z$ are not the same. The fact is, that although $z$ is the number of gallons of alcohol really contained in 100 gallons of the compound, and this alcohol is in the same proportion as before to the water, this proportion is not that of 50 to 50: for if the ingredients were separated again, there would be 50 gallons of alcohol and 52,876 of water.

The proportion of the ingredients in their separable state is had by the 3d Equation $y = a \frac{m s}{w + m s}$, which is equivalent to $G a \frac{m s}{w + s}$. For the present example $y$ will be found 45,599, and $a - y$, or the water per cent. 51,401, making 100 gallons of unmixed ingredients. We see then that there has been added 1,398 gallons of alcohol; and since both ingredients are augmented in the proportion of $G$ to $g$, there have also been added 1,478 of water, and the whole addition for making up the 100 gallons of compound is 2,876 gallons; and if the ingredients of the compound were separate, they would amount to 102,876 gallons. This might have been found at the first, by the proportion, $G : g = 100 : 1$ (The addition.)

The next question which usually occurs in business is to find what density will result from any proposed mixture per gallon. This question is solved by means of the equation $m(a - y) = s$. In this examination it will be most convenient to make $w = a$. If the value of $z$ found in this manner falls on a value in the table, we have the specific gravity by inspection. If not, we must interpolate.

N. B. The value of $m$, which is employed in these reductions, varies with the temperature. It is always obtained by dividing the specific gravity of alcohol of that temperature by the specific gravity of water of the same temperature. The quotient is the real specific gravity of alcohol for that temperature. Both of these are to be had in the first and last compartments of Sir Charles Blagden's table.

These operations for particular cases give the answers to particular occasional questions. By applying them to all the numbers in the table, tables may be constructed for solving every question by inspection.

There is another question which occurs most frequently in the excise transactions, and also in all compositions of spirituous liquors, viz. What strength will result from a mixture of two compounds of known strength, or mixing any compound with water? To solve questions of this kind by the table so often quoted, we must add into one sum the water per gallon of the different liquors. In like manner, take the sum of the spirits, and say, as the sum of the waters is to that of the alcohol, so is to $s$; and operate with $a$ and $s$ as before.

Analogous to this is the question of the duties. These are levied on proof spirit; that is, a certain duty is charged on a gallon of proof spirit; and the gauger's business is to discover how many gallons of proof spirit there is in any compound. The specification of proof spirit in our excise laws is exceedingly obtuse and complex. A gallon weighing 7 pounds 13 ounces (at 55°) is accounted 1 to 6 under proof. The gallon of water contains 584.76 grains, and this spirit is 54.888. Its density therefore is 0.93324 at 55°, or (as may be inferred from the table) 0.9335 at 60°. This density corresponds to a mixture of 100 grains of water with 93.457 of alcohol. If this be supposed to result from the mixture of 6 gallons of alcohol with 1 of water (as is supposed by the designation of 1 to 6 under proof), the gallon of proof spirits consists of 100 parts of spirits by weight, mixed with 75 parts of water. Such a spirit will have the density 0.9162 nearly.

This being premised, in order to find the gallons of proof spirits in any mixture, find the quantity of alcohol by weight, and then say, as 100 to 75, so is the alcohol in the compound to the proof spirit that may be made of it, and for which the duties must be paid.

We have considered this subject at some length, because it is of great importance in the spirit trade to have these circumstances ascertained with precision; and because the specific gravity is the only sure criterion that can be had of the strength. Firing of gunpowder, or producing a certain bubble by shaking, are very vague tests; whereas, by the specific gravity, we can very securely ascertain the strength within one part in 500, as will presently appear.

Sir Charles Blagden, or Mr. Gilpin, have published* a philosophical work copious set of tables, calculated from these valuttable experiments. In these computations are made for 2794 every unit of the hundred, and for every degree of the thermometer. But these tables are still not in the most commodious form for business. Mr. John Wilson, an ingenious gentleman residing at Dundee, has just publid
lified at Edinburgh tables somewhat similar, founded on the same experiments. Both of these tables show the quantities by measure corresponding to every unit by weight of Sir Charles Blagden's experiments, and for every degree of temperature. They also show the per centage of alcohol, and the condensation or the quantity lost by mixture. But as they both retain the original series of parts by weight, which is very ununiform, the spirit traders will find considerable difficulty in making use of them. Retaining this series also caues all the per centage numbers (which are the only interrising ones to the reader) to be fractional, and no answer can be had without a double interpolation.

We have therefore calculated a table in the form in which it must be most useful and acceptable to those who are engaged in the spirit trade, showing at once the specific gravity which results from any proportion of admixture in hundredth parts of the whole. This answers immediately the chief objections in the terms in which they are usually conceived and propsoed. The two first or leading columns show the proportion in gallons, pints, or other cubic measures, of the mixture, the whole quantity being always 100. The second column shows the corresponding specific gravity : so that we can either find the proportion of the ingredients by the observed specific gravity, or find the gravity resulting from any proportion of the ingredients. A third column shows how much the hundred measures of the two ingredients fall short of making an hundred measures of the compound. A simple proportion, which can be done without the pen, will determine what part of this deficiency must be made up by spirit. The use of this table must now be so familiar to the reader's mind, that we need not give further instructions about it.

This is followed by another similar table, giving an immediate answer to the most usual question, "How many measures of alcohol are there really contained in 100 measures? This is also accompanied by a column of condensation. It would have been somewhat more elegant, had the specific gravities in this table made the equable series and leading column. But we did not advert to this till we had computed the table, and the labour was too great to be repeated for slight reasons. The tables are only for the temperature 60°. To this the spirituous liquors can always be brought in these climates; and in cases where we cannot, a moment's inspection of Sir Charles Blagden's table will point out very nearly (or exactly, by a short computation) the necessary corrections.

</table>

Vol. XVII.
"In the first table, of which the sole intention is to point out the proportion of ingredients, the specific gravities are computed only to four places, which will always give the answer true to the tenth part. In the last, which is more immediately interesting to the merchant in his transactions with the excise office, the computation is carried one place further.

The consideration of the first of these two tables will furnish some useful information to the reader who is interested in the philosophy of chemical mixture, and who endeavours to investigate the nature of those forces which connect the particles of tangible matter. These vary with the distance of the particle; and therefore the law of their action, like that of universal gravitation, is to be discovered by measuring their sensible effects at their various distances. Their change of distance is seen in the change of density or specific gravity.

Did the individual densities of the water and spirit remain unchanged by mixture, the specific gravity would change by equal differences in the series of mixtures on which this table is constructed; for the bulk being always the same, the change of specific gravity must be the difference between the weight of the gallon of water which is added and that of the gallon of spirit which is taken out. The whole difference of the specific gravities of spirits and water being 1,750 parts in 10,000, the augmentation by each successive change of a measure of spirit for a measure of water would be the 100th part of this, or 17.5. But, by taking the successive differences of density, as they occur in the table, we see that they are vastly greater in the first additions of water, being then about 25; after which they gradually diminish to the medium quantity 14.4, when water and spirits are mixed in nearly equal bulk. The differences of specific gravity fill diminish, and are reduced to 9, when about 75 parts of water are mixed with 25 of spirit. The differences now increase again; and the last, when 99 parts of water are mixed with 1 part of spirit, the difference from the specific gravity of pure water is above 14.

The mechanical effect, therefore, of the addition of a measure of water to a great quantity of spirit is greater than the similar effect of the addition of a measure of spirits to a great quantity of water. What we call mechanical effect is the local motion, the change of distance of the particles, that the corporeal forces may again be in equilibrium. Observe, too, that this change is greater than in the proportion of the distance of the particles.
SPIRITUOUS LIQUORS.

SPIRITIIOUS LIQUORS. for the density of water is to that of spirits nearly as 6 to 5, and the changes of specific gravity are nearly as 6 to 5.

We also see that the changing cafe, which produces the absolute condensation of each ingredient, ceases to operate when 75 parts of water have been mixed with 25 parts of alcohol: for the variation of specific gravity, from diminishing comes now to increase 1; and therefore, in this particular state of composition, is equal. Things are now in the same state as if we were mixing two fluids which did not act on each other, but were mutually disseminated, and whose specific gravities are nearly as 5 to 10; for the variation 9 of specific gravity may be considered as the 100th part of the whole difference, in the same manner as 17,5 would have been had water and alcohol sustained no contraction.

The imagination is greatly added in the contemplation of geometrical quantity by exhibiting it in its own form. Specific gravity, being an expression of density (a notion purely geometrical), admits of this illustration.

Therefore let AB (fig. 4) represent the bulk of any mixture of water and alcohol. The specific gravity of water may be represented by a line such a length, that AB shall be the difference between the gravities of alcohol and water. Suppose it extended upwards towards a, till B is to A as 10,000 to 8250. It will suit our purpose better to represent it by a parallelogram a B F e, of any breadth BF. In this case the difference of the specific gravities of alcohol and water will be expressed by the parallelogram ABFE. If there were no change produced in the density of one or both ingredients, the specific gravity of the compound would increase as this parallelogram does, and A E H G would be the augmentation corresponding to the mixture of the quantity A G of alcohol with the quantity G B of water, and so of other mixtures. But, to express the augmentation of density as it really obtains, we must do it by some curvilinear area D A B C H D, which varies at the rate determined by Sir Charles Blagden's experiments. This area must be precisely equal to the rectangle A B F E. It must then be fall without it in some places, and be deficient in others. Let D M, H K, C be the curves which correspond with these experiments. It is evident to the mathematical reader, that the ordinates L M, G H, I K, &c. of this curve are in the ultimate ratio of the differences of the observed specific gravities. If A = a, = b, &c. are each = 5, the little spaces A = a + D, a + b + d, &c. will be precisely equal to the differences of the specific gravities 0,8250; 0,8375; 0,8163 &c. corresponding to the different mixtures of water and alcohol. The curve cuts the side of the parallelogram in K, where the ordinate G K expresses the mean variation of density 0,00175. I K is the smallest variation. The concretion may be expressed by drawing a curve d m G k f parallel to DM, making D d = AE. The concretion is now represented by the spaces comprehended between this last curve and the abscissa A G B, reckoning those negative which lie on the other side of it. This shows us, not only that the concretion is greatest in the mixture A G X B, but also that in mixing such a compound with another A I X B, there is a rarefaction. Another curve A N P O B may be drawn, of which the ordinates L N, P G, I O, &c. are proportional to the areas A L m d, A G m D,
SPO [ 708 ] SPO

Splenic-wort. See Asplenium.

 SPLENETIC, a person afflicted with an obstrualion of the spleen.

 Spleen, or spleen, among farriers, a callous indolent excrescence, breeding on the flank-bone of horses. See Farrery, sect. xxvi.

Splecing, in the sea-language, is the untwisting the ends of two cables or ropes, and working the several brands into one another by a fold, so that they become as strong as if they were but one rope.

SPOILS, whatever is taken from the enemy in time of war. Among the ancient Greeks, the spoils were divided among the whole army; only the general's share was largest: but among the Romans, the spoils belonged to the republic.

Spleetto, a duchy of Italy, bounded on the north by the Marquirate of Ancona and duchy of Urbino, on the east by Farther Abruzzo, on the south by Sabina and the patrimony of St. Peter, and on the west by Orvietano and Perugino. It is about 35 miles in length and 40 in breadth. It was anciently a part of Umbria, and now belongs to the Pope. — The name of the capital city is also Spelletto. It was formerly a large place, but in 1703 was ruined by an earthquake; from whence it has never recovered itself.

Spleolation, in ecclesiastical law, is an injury done by one clerk or incumbent to another, in taking the fruits of his benefice without any right thereunto, but under a pretended title. It is remedied by a decree to account for the profits so taken. This injury, when the jus patronatus, or right of advowson, doth not come in debate is cognizable in the spiritual court: as if a patron first presents A to a benefice, who is infallibly and indisputably thereto; and then, upon presence of a vacancy, the same patron presents B to the same living, and he also obtains infallibility and introduction. Now if A disputes the fact of the vacancy, then that clerk who is kept out of the profits of the living, whichever it be, may sue the other in the spiritual court for spoilation, or taking the profits of his benefice. And it shall there be tried, whether the living were or were not vacant; upon which the validity of the second clerk's pretensions must depend. But if the right of patronage comes at all into dispute, as if one patron preferred A, and another patron preferred B, there the ecclesiastical court hath no cognizance, provided the titles fixed for amount to a fourth part of the value of the living, but may be prohibited at the instance of the patron by the king's writ of indiciavit. So also if a clerk, without any colour of title, ejects another from his parsonage, this injury must be redressed in the temporal courts; for it depends upon no question determinable by the spiritual law (as plurality of benefices or no plurality, vacancy or no vacancy), but is merely a civil injury.

SPONDIAE, Brasilius or Jamaica Plum, in botany; a genus of plants belonging to the class of Decandria, and order of Pentagynia. The calyx is quinquodentate. The corolla pentapetalous. The fruit contains a quinquilocular kernel. There are only two species, the mombin and myrobalanus, which appear so much confounded in the descriptions of different botanists, that we do not venture to present them to our readers.

SPONGIA, Sponge, in natural history; a genus of animals belonging to the class of Vermes, and order of Zoophyta. It is fixed, flexible, and very torpid, growing in a variety of forms, composed either of reticulated fibres, or masses of small spines interwoven together and clothed with a living gelatinous flesh, full of small mouths or holes on its surface, by which it sucks in and throws out the water. Fifty species have already been discovered, of which no belong to the British coasts.

1. Osculata, or branched sponge, is delicately soft and very much branched; the branches are a little compressed, grow erect, and often united together. They have rows of cells on each margin, that project a little. This species is of a pale yellow colour, from five to ten inches high. The fibres are reticulated, and the flesh or gelatinous part is tender, that when it is taken out of the water it soon dries away. It is very common round the sea-coast of Britain and Ireland. This description will be better understood by Plate ccclxxi.

2. Cristata, or cockcomb sponge, is flat, erect, and soft, growing in the shape of cock's combs, with rows of little holes along the tops, which project a little. It abounds on the rocks to the eastward of Hastings in Sussex, where it may be seen at low-water. It is commonly about three inches long, and two inches high, and of a pale yellow colour. When put into a glass vessel of sea-water, it has been observed to suck in and squirt out the water through little mouths along the tops, giving evident signs of life.

3. Stuposa, tow-sponge, or downy branched sponge, is soft like tow, with round branches, and covered with fine pointed hairs. It is of a pale yellow colour, and about three inches high. It is frequently thrown on the shore at Hastings in Sussex. Fig. 2. represents this sponge; but it is so closely covered with a fine down, that the numerous small holes in its surface are not discernible.

4. Dichotoma, dichotomous or forked sponge, is stiff, branched, with round, upright, elastic branches, covered with minute hairs. It is found on the coast of Norway, and also, according to Berkshout, on the Cornish and Yorkshire coasts. It is of a pale yellow colour, and full of very minute pores, guarded by minute spines. Fig. 3.

5. Ursus.
SPONGES.

Fig. 1

Fig. 2

Plate CCCCLXXV.
5. *Ureca* or *tomentosa*, flinging sponge, or crumb of bread sponge, is of many forms, full of pores, very brittle and soft, and interwoven with very minute spines. It is full of small protruberances, wib a hole in each, by which it sucks in and throws out the water. It is very common on the British coast, and is frequently seen surrounding fucules. It is found also on the shores of North America, Africa, and in the East Indies. When newly taken out of the sea, it is of a bright orange colour, and full of gelatinous flesh; but when dry, it becomes whitish, and when broken has the appearance of crumb of bread. If rubbed on the hand, it will raise blisters; and if dried in an oven, its power of slinging is much increased, especially that variety of it which is found on the sea-coal of North America.

6. *Palmata*, palmed sponge, is like a hand with fingers a little divided at the top. The mouths are a little prominent, and irregularly disposed on the surface. It is found on the beach at Brighthelmstone. It is of a reddish colour, inclining to yellow, and of the same soft wooly texture with the *fpongia oculata*, fig. 3. The palmate sponge, is like a hand with the fpongia oculata, fig. 3.

7. *Coronula*, corona sponge, is very small, consisting of a single tube surrounded at top by a crown of little spines. The tube is open at the top. The rays that compose the little crown are of a bright, shining pearl colour; the body is of a pale yellow. It has been found in the harbour of Emsworth, between Sussex and Hampshire.

8. *Bolysides*, grape sponge, is very tender and branched, as if in bunches: the bunches are hollow, and are made up of oblong oval figures having the appearance of grapes; and each bunch is open at top. This species is of a bright, shining colour. The openings at the top are evidently the mouths by which the animal imbibles and discharges moisture. When the surface is very much magnified, it appears covered with little masses of triple, equidistant, shining spines.

10. *Fusitellla*, river sponge, is green, erect, brittle, and irregularly disposed in numerous branches. It abounds in many parts of Europe, in the fresh rivers of Russia and England, but particularly in the river Thames. It scarcely exhibits any symptoms of life, is of a filthy smell: its pores or mouths are sometimes filled with green gelatinous globules. It differs very little from the *lacunis*.

So early as the days of Arilotile sponges were supposed to possess animal life; the persons employed in collecting them having observed them shrink when torn from the rocks, thus exhibiting symptoms of senfation. The same opinion prevailed in the time of Pliny: But no attention was paid to this subject till Count Marigli examined them, and declared them vegetables. Dr Peyronell, in a paper which he sent to the Royal Society in the year 1752, and in a second in 1757, affirmed they were not vegetables, but the production of animals; and has accordingly described the animals, and the species which they performed in making the sponges. Mr Ellis, in the year 1762, was at great pains to difcover these animals. For this purpose he difsected the spongia urens, and was surprized to find a great number of small worms of the genus of nereis or sea-cololopendra, which had pierced their way through the soft substance of the sponge in quest of a safe retreat. That this was really the case, he was fully affured of, by inspecting a number of specimens of the same frt of sponge, just frefh from the sea. He put them into a glafs filled with sea-water; and then, instead of seeing any of the little animals which Dr Peyronell described, he observed the papillae or small holes with which the papillae are surrounded contract and dilate themselves. He examined another variety of the same species of sponge, and plainly perceived the small tubes inspire and expire the water. He therefore concluded, that the sponge is an animal, and that the ends or openings of the branched tubes are the mouths by which it receives its nourishment, and discharges its excrements.

Sponsors, among Christians, are those persons who, in the office of baptism, answer or are sureties for the persons baptized.

Sponnotaneous, a term applied to such motions of the body and operations of the mind as we perform of ourselves without any contraint.

Spon. bill, in ornithology. See Platæas.

Sponning, in the sea language, is said of a ship, which being under fail in a storm at sea, is unable to bear it, and consequently forced to go right before the wind.

Sporades, among ancient astronomers, a name given to such stars as were not included in any constellation.

Sporadic diseases, among physicians, are such as feize particular persons at any time or season, and in any place; in which sense they are distinguished from epidemical and endemical diseases.

Spots, in astronomy, certain places of the sun's or moon's disk, observed to be either more bright or dark than the rest; and accordingly called *faculae et maculae*. See Astronom. Index.

Spotswood (John), archbishop of St Andrew's in Scotland, was descended from the lairds of Spotswood in the Merse, and was born in the year 1555. He was educated in the university of Glasgow, and succeeded his father in the parsonage of Calder, but in 1618, he entered into the archbishopric of Glasgow, where he found there was not 1001. Sterling of yearly revenue left; yet such was his care for his successors, that he greatly improved it, and much to the satisfaction of his diocese. After having filled this see 13 years, he was raised to that of St Andrew's in 1635, and made primate and metropolitian of all Scotland. He presided in several assemblies for restoring the ancient discipline, and bringing the church of Scotland to some sort of uniformity with that of England. He continued in high esteem with King James I., but was he left valued by king Charles I., who was crowned by him in 1633, in the abbey church of Holyroodhouse. In 1635, upon the death of the earl of Kinnoul chancellor of Scotland, our primate was advanced to that post; but had scarcely held it four years, when the confusions beginning in Scotland, he was obliged to retire into England, and being broken with age, grief, and licks, died at London in 1639.
SPRAT (Dr Thomas), bishop of Rochester, was born in 1626. He had his education at Oxford, and after the Restoration entered into holy orders. He became fellow of the Royal Society; chaplain to George duke of Buckingham, and chaplain in ordinary to king Charles II. In 1667 he published the History of the Royal Society, and a Life of Mr Cowley; who, by his last will, left to his care his printed works and MSS., which were accordingly published by him. In 1668 he was intailed prebendary of Wellsminster; in 1680, was appointed canon of Windsor; in 1683, dean of Wellsminster; and in 1684, consecrated to the bishopric of Rochester. He was clerk of the closet to king James II.; in 1685, was made dean of the chapel royal; and the year following, was appointed one of the commissioners for ecclesiastical affairs. In 1692 his lordship, with several other persons, was charged with treason by two men, who drew up an accusation, in which they whose names were subjoined declared their resolution to restore king James; to seize the princes of Orange, dead or alive; and to be ready with 30,000 men to meet king James when he should land. To this they put the name of Sancroft, Sprat, Marlborough, Salisbury, and others. The bishop was arrested, and kept at a messenger's, under a strict guard, for eleven days. His house was searched, and his papers seized, among which nothing was found of a treasonable appearance, except one memorandum, in the following words: Thorough-bred doctrine. Being asked at his examination the meaning of the words, he said that, about 20 years before, curiosity had led him to hear Daniel Burges preach; and that being struck with his account of a certain kind of doctrine, which he said entered at one ear and passing through the head went out at the other, he had inserted the memorandum in his table-book, that he might not lose the substance of so strange a sermon. His innocence being proved, he was set at liberty, when he published an account of his examination and deliverance; which made such an impression upon him, that he commemorated it through life by an annual day of thanksgiving. He lived to the 70th year of his age, and died May 20, 1713. His works, besides a few poems of little value, are, "The History of the Royal Society!; "The Life of Cowley!; "The Answer to Sorbere; "The History of the Rye-house Plot; "The Relation of his own Examination;" and a volume of Sermons." Dr Johnston says, "I have heard it observed, with great judgness, that every book is of a different kind, and that each has its definite and characteristical excellence."

SPRAY, in ichtyology. See CLupea.

SPRAY, the sprinkling of the sea, which is driven from the top of a wave in stormy weather. It differs from spoor drift, as being only blown occasionally from the broken surface of a high wave; whereas the latter continues to fly horizontally along the sea, without intermission, during the excess of a tempest or hurricane.

SPRING, in natural history, a fountain or source of water rising out of the ground. Many have been the conjectures of philosophers concerning the origin of fountains, and great pains have been taken both by the members of the Royal Society and those of the Academy of Sciences at Paris, in order to ascertain the true cause of it. It was Aristotle's opinion, and held by most of the ancient philosophers after him, that the air contained in the caverns of the earth, being condensed by cold near its surface, was thereby changed into water; and that it made its way through, where it could find a passage. But we have no experience of any such tranmutation of air into water.

Those who imagine that fountains owe their origin to waters brought from the sea by subterraneous ducts, give a tolerable account how they lose their fountains by percolation as they pass through the earth; but they find great difficulty in explaining by what power the water rises above the level of the sea to near the tops of mountains, where springs generally abound; it being contrary to the laws of hydrostatics, that a fluid should rise in a tube above the level of its source. However, they have found two ways whereby they suppose they can extricate themselves from this difficulty. The one is that of Des Cartes, who imagines, that after the water is become fresh by percolation, it is raised out of the caverns of the earth in vapour towards its surface; where meeting with rocks near the tops of mountains in the form of arches or vaults, it sticks to them, and runs down their sides, (like water in an alembic), till it meets with proper receptacles, from which it supplies the fountains. Now this is a mere hypothesis, without foundation or probability: for, in the first place, we know of no internal heat of the earth to cause such evaporation; or if that were allowed, yet it is quite incredible that there should be any caverns so smooth and void of protruberances as to answer the ends of an alembic, in collecting and condensing the vapours together in every place where fountains are. There are others (as Varenus, &c.) who suppose that the water may rise through the pores of the earth, as through capillary tubes by attraction. But hereby they show, that they are quite unacquainted with what relates to the motion of a fluid through such tubes: for when a capillary tube opens into a cavity at its upper end, or grows larger and larger, so as to cease to be capillary at that end, the water will not ascend through that tube into the cavity, or beyond where the tube is capillary; because that part of the periphery of the cavity, which is partly above the surface of the water and partly below it, is not of the capillary kind. Nay, if the cavity is continually supplied with water, it will be attracted into the capillary tube, and run down it as through a funnel, if the lower end is immerged in the same fluid, as in this case it is supposed to be.

It has been a generally received opinion, and much espoused by Mariotte (a diligent observer of nature), that the rise of springs is owing to the rains and melted snow. According to him, the rain-water which falls upon the hills and mountains, penetrating the surface, meets with clay or rocks contiguous to each other; along which it runs, without being able to penetrate them, till, being got to the bottom of the mountain, or to a considerable distance from the top, it breaks out of the ground, and forms springs.

In order to examine this opinion, Mr Perrault, De la Hire, and D. Sideleau, endeavoured to make an estimate
estimate of the quantity of rain and snow that falls in the space of a year, to see whether it would be sufficient to afford a quantity of water equal to that which is annually discharged into the sea by the rivers. The result of their inquiries was, that the quantity of rain and snow which fell in a year into a cylindrical vessel would fill it (if secured from evaporating) to the height of about nineteen inches. Which quantity D. Sideleau showed was not sufficient to supply the rivers; for that those of England, Ireland, and Spain, discharge a greater quantity of water annually, than the rain, according to that experiment, is able to supply. Besides which, another observation was made by them at the same time, viz. that the quantity of water raised in vapour, one year with another, amounted to about thirty-two inches, which is thirteen more than falls in rain: a water which was absolutely necessary, to supply the water of fountains, and many of the seas; to nourish the crops of the land, and is the fund of all those springs which break out on the south side of the Carpathian mountains, and on the north side of the Alpes, which is one continued chain of mountains from Switzerland to the Black Sea.

Thus one part of the vapours which are blown on the land is returned by the rivers into the sea from whence it came. Another part falls into the sea before it reaches the land; and this is the reason why the rivers do not return so much water into the Mediterranean as is raised in vapours. A third part falls on the low lands, where it affords nourishment to plants; yet it does not reft there, but is again exhaled in vapour by the action of the sun, and is either carried by the winds to the sea to fall in rain or dew there, or else to the mountains to become the sources of springs.

However, it is not to be supposed that all fountains are owing to one and the same cause; but that some proceed from rain and melted snow, which, subsiding through...
through the surface of the earth, makes its way into certain cavities, and thence issues out in the form of springs; because the waters of several are found to increase and diminish in proportion to the rain which falls: that others again, especially such as are hot, and spring near the sea-shore, owe their origin to sea-water percolated through the earth; and some to both these causes: though without doubt most of them, and especially such as spring near the tops of high mountains, receive their water from vapours, as before explained.

This reasoning of Dr Halley's is confirmed by more recent observations and discoveries. It is now found, that though water is a tolerable conductor of the electric fluid, dry earth is an electric \textit{par fe}, consequently the dry land must always be in an electrified state compared with the ocean, unless in such particular cases as are mentioned under the article \textit{Earthquake}, n° 82. It is also well known, that such bodies as are in an electrified state, whether \textit{plus} or \textit{minus}, will attract vapour, or other light substanctes that come near them. Hence the vapours that are raised from the ocean must necessarily have a tendency to approach the land in great quantity, even without the assistance of the wind, though this last must undoubtedly contribute greatly towards the same purpose, as Dr Halley justly observes. In like manner, the higher grounds are always in a more electrified state than the lower ones; and hence the vapours having once left the ocean and approached the shore, are attracted by the high mountains; of which Mr Pennant gives an instance in Snowdon. Hence we may see the reason why springs are so common in the neighbourhood of mountains, they being fo advantageously formed in every respect for collecting and condensing the vapours into water.

The heat of springs is generally the same with the mean temperature of the atmosphere. The mean temperature of the south of England is \(48^\circ\); in Scotland, near Edinburgh, it is \(45^\circ\); in the north of Ireland it is \(48^\circ\), and on the south coast about \(51^\circ\). At Upsal, in Sweden, it is \(43^\circ\), and in Paris \(53^\circ\). According to accurate experiments made by eminent philosophers, the heat of the springs in these different countries corresponds with the medium temperature. We have not heard that similar experiments have been made in other countries, or we should have been careful to collect them. We do not, however, doubt but they have been made in most countries of Europe; yet we suspect little attention has been paid to this subject within the tropical regions.

Though this coincidence of the heat of springs with the mean temperature of the climate where they flow, seems to be a general fact, yet it admits of many exceptions. In many parts of the world there are springs which not only exceed the mean temperature, but even the throggest meridian heat ever known in the torrid regions. The following table will give a distinct notion of the degrees of heat which different springs have been found to possess, according to the experiments of philosophers. It is necessary to remark, that experiments made upon the same springs, made by different persons, vary a little from one another, which may be owing to many accidents easily accounted for. Where this is the case, we shall mention both the lowest and highest degree of heat which has been ascribed to the same spring, according to Fahrenheit's thermometer.

In cold countries, where congelation takes place, the heat of the earth is considerably above the freezing point, and continues fo through the whole year. From experiments that have been made in mines and deep pits, it appears that this heat is uniform and stationary at a certain depth. But as the heat of these springs far exceeds the common heat of the internal parts of the earth, it must be occasioned by causes peculiar to certain places; but what these causes are it is no easy matter to determine. We are certain, indeed, that hot springs receive their heat from some subterranean cause; but it is a matter of difficulty to investigate how this heat is produced and preferred. Theories, however, have been formed on this subject. The subterranean heat has been ascribed to the electrical fluid, and to a great body of fire in the centre of the earth; but we suspect that the nature of the electrical fluid and its effects are not sufficiently understood. As to the supposition that the heat of springs is owing to a central fire, it is too hypothetical to require any refutation. From what then does this heat originate, and whence is the fuel which has produced it for so many ages? To enable us to answer these questions with precision, more information is necessary than we have hitherto obtained respecting the structure of the internal parts of the earth. It is peculiarly requisite that we should be made acquainted with the fossils which are most common in those places where hot springs abound. We should then perhaps discover that hot springs always pass thro' bodies of a combustible nature. It is well known to chemists, that when water is mixed with the vitriolic acid, a degree of heat is produced superior to that of boiling water. It is also an established fact, that when water meets with pyrites, that is, a mixture of sulphur and iron, a violent inflammation takes place. If, therefore, we could prove that these materials exist in the strata from which hot springs are derived, we should be enabled to give a satisfactory account of this curious phenomenon. As some apology for this supposition, we may add, that most of the hot springs mentioned above have been found by analysts to be impregnated with sulphur, and some of them with iron. It must, however, be acknowledged, that the hot springs of Iceland, which are \(212^\circ\), the heat of boiling water, according to an accurate German analysis of their contents by the ingenious Dr Black, and Switzerland, were neither found to contain iron nor sulphur. It will therefore, perhaps, be necessary that we should wait with patience, and continue to collect facts, till the sciences of chemistry and mineralogy shall be so far advanced as to enable us to form a permanent theory on this subject.

Springs are of different kinds. Some are \textit{perennial}, or

\begin{table}[h]
\begin{tabular}{|l|}
\hline
\textit{Gray's Letters from Germany,}\n\hline
\end{tabular}
\end{table}
or continue to flow during the whole year; others flow only during the rainy seasons; some ebb and flow. At Torbay there is one of this kind, which ebbs and flows in two branches every hour. There is another near Corio in Italy, which ebbed and flowed three times a day in the time of Pliny, and continues to do so still. A spring near Henly sometimes flows for two years together, and then dries up for an equal period. The cause of this is explained under the article Hydrostatics, No. 26. For the ingredients found in springs, see Mineral Waters, and Water.

Spring, in mechanics, denotes a thin piece of tempered iron, or other elastic substance, which being wound up serves to put machines in motion by its elasticity, or endeavours to unbend itself; such is the spring of a watch, clock, or the like.

Spring, Ver, in oemography, denotes one of the feasons of the year; commencing, in the northern parts of the world, on the day the sun enters the first degree of Aries, which is about the 10th day of March, and ending when the sun leaves Gemini; or, more strictly and generally, the spring begins on the day when the distance of the sun’s meridian altitude from the zenith, begins to increase, is at a medium between the greatest and least. The end of the spring coincides with the beginning of summer. See Summer.

Spring Tide. See Astronomy-Index, and Tide.

During Springs. See Burning Springs.

Springer, or Spring-Boat, in zoology, See Capra.

Spirit, a small boom or pole which crosses the fall of a boat diagonally, from the mast to the upper hindmost corner of the fall, which is used to extend and elevate; the lower end of the spirit rests in a fork of a wreath or collar called the fnouton, which encircles the mast in that place.

Spritsail. See Sail and Ship.

Sprit-Mast-Top-sail. See Sail and Ship.

Spruce-tree. See Pinus.

Spruce-Beer, a cheap and wholesome liquor, which is thus made: Take of water 16 gallons, and boil the half of it. Put the water thus boiled, while in full heat, to the requisite cold part, which should be previously put into a barrel or other vessel; then add 16 pounds of treacle or molasses, with a few table spoonsfuls of the essence of spruce, stirring the whole together; add half a pint of yeast, and keep it in a temperate situation, with the bunghole open, for two days, till the fermentation be abated. Then close it up or bottle it off, and it will be fit for being drunk in a few days afterwards. In North America, and perhaps in other countries, where the black and white spruce is abundant, instead of adding the essence of the spruce at the same time with the molasses, they make a decoction of the leaves and small branches of these trees, and find the liquor equally good. It is a powerful antiscorbutic, and may prove very useful in long sea voyages.

Spunge, or Sponge. See Spongia.

Spunging, in gunnery, the cleaning of the inside of a gun with a spunge, or in order to prevent any sparks of fire from remaining in it, which would endanger the life of him that should load it again.

Spun-yarn, among sailors, is a kind of line made from rope yarn, and used for seizing or fastening things together.

Vol. XVII.
1. _Squalus._ Squale, greater dog-fish, or spotted shark, is distinguished by large nostrils, which are covered by a lobe and worm-shaped flap, or by the position of the anal fin, which is at an equal distance from the anus and tail. The body is spotted, the head is small, with a short snout; the eyes are oblong; the mouth is large and oblong, armed with three rows of teeth; the tongue is cartilaginous; the anus is before the middle of the body; the first dorsal fin is behind the ventral fins; the other, which is left, is almost opposite the anal fin; the caudal fin is narrow and marginated. This species is found in almost every sea, is about four feet long, extremely voracious, generally feeding on fishes, and is long lived. The skin, which is spotted like a leopard's, is used when dried for various purposes.

2. _Caninus._ Greater dog-fish, or spotted shark, is about seven feet long, and weighs 500 lbs. The head is elongated on each side; the fore part is bent back, and converges both above and below. At the extremities of the elongated part are the eyes, which are large, prominent, and directed downwards; the iris is of a golden colour; the mouth is arched, and near the beginning of the trunk. It has a horrible appearance from the teeth, which are arranged in three or four rows, and are broad, pointed, and serrated on both sides. The tongue is thick, broad, and like a man's. The trunk is long and tapering: the fins are semicircular on the margin, and black at the base; the ventral fins are separate; the anal and posterior dorsal fins are small; the anterior dorsal fin is large, and near the head; the caudal is long — This species inhabits the Mediterranean Sea and the Indian Ocean. It is one of the most voracious of the whole tribe. See fig. 2.

3. _Carcharias._ Smaller dog-fish, has a large head; the pupil of the eyes is black; the iris white; the snout is of a bright hue; the mouth, which is large, is situated between the nostrils, and is armed with four rows of teeth, serrated with three points bent inwards; those in the middle between the two mandibles are longer than the rest. The tongue is broad and smooth; the spiracles are five; the back is tapering and yellowish; the sides are somewhat compressed; the tail longer than the body, and the caudal fin is narrow and marginated; the anterior anal and dorsal fins are behind the ventral; the posterior dorsal fin is opposite to the anal. It inhabits the Mediterranean, Northern, and Indian Ocean, and is two or three feet long.

4. _Stellarius._ Greater eat-fish. The head is marked with points; the abdominal fins are united and sharp at the apex; the dorsal fins extend almost to the tail; the skin is reddish, marked with black spots of different sizes, and is of a dirty ash colour below. It is from two to six feet long; resembles the caninus, but distinguished by larger and fewer spots, by a snout somewhat longer, a tail somewhat shorter, and nostrils almost flat. It brings forth 19 or 20 young at a time. It inhabits the European seas, living chiefly on shell fish, molluscs, and other small fishes. The dorsal fins are equal; the anterior one being behind the middle of the body, and the posterior one being a little behind the anal.

5. _Tigrinus._ Tiger, is about 15 feet long; the body is long, of unequal thickness, black, interpersed with white spots and spots, irregularly and transversely. — The head is large; the mouth low and transverse, the upper jaw having two cusp; the upper lip is thick and prominent; there are five spiracles on each side, the two last being united so as to give the appearance only of four; the mandibles are armed with very small pointed teeth; the tongue is short and thick; the eyes small and oblong; the pupil azure; the iris black. The abdomen is broad; the pectoral fins are broad, and rounded at the extremity. The anterior dorsal fin is opposite to the ventral fins, and the posterior dorsal fin to the anal. The tail is compressed on both sides, and the fin which terminates it is hollow. The tigrinus is found in the Indian Ocean, and lives chiefly on shell fish. See Plate CCCCLXXVI. fig. 1.

6. _Zygus._ A marteau, or balance-fish, is frequently six feet long, and weighs 500 lbs. The head is elongated on each side; the fore part is bent back, and converges both above and below. At the extremities of the elongated part are the eyes, which are large, prominent, and directed downwards; the iris is of a golden colour; the mouth is arched, and near the beginning of the trunk. It has a horrible appearance from the teeth, which are arranged in three or four rows, and are broad, pointed, and serrated on both sides. The tongue is thick, broad, and like a man's. The trunk is long and tapering: the fins are semicircular on the margin, and black at the base; the ventral fins are separate; the anal and posterior dorsal fins are small; the anterior dorsal fin is large, and near the head; the caudal is long — This species inhabits the Mediterranean Sea and the Indian Ocean. It is one of the most voracious of the whole tribe. See fig. 2.

8. _Fusus._ Or sea-fox, is most remarkable for the great length of its tail, the body being about seven feet and the tail six feet long. The head is short and conical; the eyes are large; the jaws are armed in a dreadful manner with three rows of triangular, compressed, and pointed teeth; the tongue is blunt; the lateral line is straight. The anterior dorsal fin is placed about the middle of the back; the posterior, which consists of two-pointed lobes, is opposite to the anal fin; the ventral fins are very near one another; the anal is acuminate; the inferior lobe of the tail is about a foot long; the upper, which is shaped like a sheythe, is five times longer. This species inhabits the Mediterranean, the coasts of Scotland, and England. It is covered with small scales; its back is ash-coloured, belly whitish. It is extremely voracious. The ancients styled this fish _alveus_, and _valpes_, from its fuddled cunning. They believed, that when it had the misfortune to have taken a bait, it swallowed the hook till it got at the cord, which it bit off, and so escaped.

6. _Glauus._ Or blue shark, is about seven feet long. The colour of the back is a fine blue; the belly a silver white; the head is flat; the eyes small and roundish; the teeth are almost triangular, elongated, and pointed, but not serrated. The anus is very near the tail; the anterior dorsal fin is situated before the ventral fins, about the middle of the body, and is almost triangular; the posterior dorsal fin is equal to the anal fin, and is placed nearer the tail; the pectoral fins are large, long, and marginated; and the ventral are blue above and white below; the caudal is blue, divided into two lobes, of which the superior is much longer than the inferior lobe. This species is frequent in every sea, and is fierce, but not very destructive in the northern seas.

10. The _maximus_, bulking shark, or the fun-fish of the Irish. This species has been long known to the inhabitants of the south, and east of Ireland, and Scotland, and those of Cornwall, and Anglesea; but having never been considered in any other than a commercial view, is described by no English writer except Mr. Pennant; and, what is worse, mistaken for and confounded with the _Squalus._
that our English writers call the sun-fish. The Irish

and Welsh give it the same name, from its lying as if to

sun itself on the surface of the water; and for the same

reason Mr. Pennant calls it the basking shark. It was

long taken for a species of whale, till Mr. Pennant

pointed out the branchial orifices on the sides, and the

perpendicular fins of the tail. These are migratory

sharks, or at least it is but in a certain number of years

that they are seen in multitudes on the Welsh seas, though

in most summers a single, and perhaps a strayed fish

appears.

They inhabit the northern seas, even as high as the

arctic circle. They visited the bays of Caernarvonshire

and Anglesea in vast flocks in the summers of

1756 and a few succeeding years, continuing there

only the hot months; for they quit the coast about

Michaelmas, as if cold weather was disagreeable to

them. Some old people say they recollected the same

sort of fishes in vast numbers about 1700. They appear

in the Frith of Clyde, and among the Hebrides, in the

month of June, in small droves of seven or eight, but often in pairs. They

continue in those seas till the latter end of July, when

they disappear.

They have nothing of the fierce and voracious nature

of the shark kind, and are so tame as to suffer them-

selves to be stroked; they generally lie motionless on

the surface, commonly on their bellies, but sometimes,

like tired swimmers, on their backs. Their food feeds

on confit entirely of sea plants, no remains of fish

being ever discovered in the stomachs of numbers

that were cut up, except some green stuff, the half digested

parts of algae, and the like. Linnaeus says it feeds on

medusse.

At certain times, they are seen sporting on the

waves, and leaping with vast agility several feet out of

the water. They swim very deliberately, with the
dorsal fins above water. Their length is from three
to twelve yards, and sometimes even longer. Their

form is rather flender, like others of the shark kind.

The upper jaw is much longer than the lower, and

blunt at the end. The tail is very large, and the upper

part remarkably longer than the lower. The

colour of the upper part of the body is a deep leaden

—the belly white. The skin is rough like flag-rue,

but less so on the belly than the back. In the

mouth, towards the throat, is a very short sort of

whale-bone. The

whalebone. The

mouth is placed far beneath; for which reason

these, as well as the rest of the kind, are said to be

obliged to turn on their backs to seize their prey;

which is an observation as ancient as the days of Pliny.
The eyes are large; the back broad, flat, and shorter

than that of other sharks. The tail is of a semilunar

form, but the upper part is longer than the lower. It

has vast strength in the tail, and can strike with great

force; so that the sailors at once cut it off with an

axe as soon as they draw one on board. The pectoral

fins are very large, which enables it to swim with great

swiftness. The colour of the whole body and fins is a

light ash. The ancients were acquainted with this fish;

and Oppian gives a long and entertaining account of

its capture. Their flesh is sometimes eaten, but is esteemed

course and rank. — They are the dread of the

sailors in all hot climates, where they constantly attend the

ships in expectation of what may drop overboard: a

man that has that misfortune perishes without redemption;

they have been seen to dart at him like gudgeons

at a worm. A matter of a Guinea ship informed Mr.

Pennant, that a rage of suicide prevailed among his

new-bought slaves, from a notion the unhappy creatures

had, that after death they should be restored again to

their families, friends, and country. To convince them

at least that they should not reanimate their bodies, he

ordered one of their corpses to be tied by the heels to

a rope and lowered into the sea; and though it was drawn

up again as fast as the united force of the crew could

be exerted, yet in that short space the sharks had devoured

every part but the feet, which were secured at the end of the cord.

Swimmers very often perish by them; sometimes

they
they lose an arm or leg, and sometimes are bit quite
so under, serving but for two morsels for this ravenous
animal; a melancholy tale of this kind is related in a
West-India ballad, preferred in Dr Percy's Relics of
ancient English Poetry.

This species inhabits the abyss of the ocean, and
only appears on the surface when allure by "prey. It
is the most voracious of all animals, not even it is said
sparing its own offspring, and often swallowing its prey
entire. At the famous naval battle of the 12th of Ap-

April 1782, when the Caesar, one of the French ships of
the line, was set on fire, the sailors threw themselves into
the sea. Sir Charles Douglas observed great num-
bers of these sharks, which lay between the French and
British fleets, infamity feiz on the unhappy victims.
He several times saw two of them disputing about their
prey, each seizing a leg, and at length disappearing,
dragging the body along with them. Notwithstanding
the continued roar of artillery, he heard distinctly the
cries of these unhappy men.

12. Pristis fecis, or saw-fish, is sometimes 15 feet
long, smooth, black on the upper parts, black
coloured on the sides, and white underneath. The head is flat
and conical; the beak or snout projecting from the nose
is about five feet long, covered with a coruscating skin,
and armed on each side, generally with 14 long, strong,
and sharp-pointed teeth; but the number varies with
age. The teeth are granulated; the eyes large, the
iris of a golden colour, and the spiracles five. The an-
terior dorsal fin corresponds to those of the belly; the
posterior is situated in the middle, between the former
and apex of the tail; the pectoral fins are broad and
long; the caudal is shorter than in the other species. It
inhabits all the seas from Greenland to Brazil; and is
found also in the Indian Ocean. It is harmless.

13. Sphyrna, sphyra, or picked dog-fish, takes its name
from a strong and sharp spine placed just before each of
the back fins, distinguthing it at once from the rest
of the British sharks. The nose is long, and extends
greatly beyond the mouth, but is blunt at the end.
The teeth are disposed in two rows, are small and sharp,
and bend from the middle of each jaw towards the cor-
ers of the mouth. The back is of a brownish all-co-
our; the belly white.—It grows to the weight of
about 20 pounds. This species swarms on the coasts
of Scotland, where it is taken, split, and dried; and is
a food among the common people. It forms a sort of
inland commerce, being carried on women's backs 14
or 16 miles up the country, and sold or exchanged for
necessaries.

14. Squatlus, angel-fish, is from six to eight feet
long, has a large head; teeth broad at their base, but
flender and very sharp above, and disposed in five rows
all round the jaws. Like those of all sharks, they are
capable of being raised or depressed by means of mu-
cles unijning them to the jaws, not being lodged in fok-
cets as the teeth of cetaceous fiue are. The back is of
a pale all-colour, and very rough; along the middle is
a prickly tuberculated line; the belly is white and
smooth. The pectoral fins are very large, and extend
horizontally from the body to a great distance; they
have some resemblance to wings, whence its name. The
ventral fins are placed in the same manner, and the
double penis is placed in them; which forms another
character of the males in this genus.

This is the fish which connects the genus of rays and
sharks, partaking something of the character of both;
yet is an exception to each in the situation of the
mouth, which is placed at the extremity of the head.
It is a fish not frequent on most British coasts, where
it prowls about for prey like others of the kind. It is
extremely voracious; and, like the ray, feeds on floun-
ders and flat fiue, which keep at the bottom of the
water. It is extremely fierce, and dangerous to be
approached. Mr Pennant mentions a fisherman whole
leg was terribly torn by a large one of this species,
which lay within his nets in shallow water, and which
he went to lay hold of incuriously. The aspect of
these, as well as the rest of the genus, have much mal-
ignity in them: their eyes are oblong, and placed
lengthwise in their head, sunk in it, and overhung by
the skin, and seem fuller of malice and than fire.
Their skin is very rough; the ancients made use of it,
to polish wood and ivory, as we do at present that of
the greater dog-fish. The flesh is now but little esteem-
ed on account of its coarsefes and rankness; yet Ar-
cheleatus (as quoted by Athenæus, p. 319.), speak-
ing of the fish of Miletus, gives this the first place, in
respect to delicacy, of the whole cartilaginous tribe.
They grow to a great size; being sometimes near an
hundred weight.

Sharks are seldom destructive in the temperate re-
gions; it is in the torrid zone that their ravages are
most frequent. In the west Indies accidents happen
from them almost every day.

"During the American war in 1780, while the Pal-
las frigate was lying in Kinglyton harbour, a young
North American jumped overboard one evening to
make his escape, and perished by a shark in a shocking
manner.

"He had been captured in a small vessel, left all his
property, and was detained by compulsion in the Eng-
lish navy, to serve in a depredatory war against his
country. But he, animated with that spirit which per-
vaded every bosom in America, resolved, as soon as he
arrived at some port, to release himself from the morti-
ying state of employing his life against his country,
which, as he said when dying, he was happy to lay
down, as he could not employ it against his enemies.

"He plunged into the water; the Pallas was a quarter
of a mile from the shore. A shark perceived him, and
followed him, very quietly, till he came to a state of
rest, near the shore; where, as he was hanging by a
rope, that moored a vessel to a wharf, larcely out of
his depth, the shark seized his right leg, and stripped
the flesh entirely away from the bones, and took the foot
off at the ankle. He still kept his hold, and called to
the people in the vessel near him, who were flanding
on the deck and saw the affair. The shark then feiz his
other leg, which the man by his struggling disengaged,
from his teeth, but with the flesh cut through down to
the bone, into a multitude of narrow slips. The people
in the vessel threw billets of wood into the water, and
frightened the shark away. The young man was
brought on shore. Dr Mofley was called to him; but
he had lost so much blood before any assistence could
be given him, that he expired before the mangled limbs
could be taken off.

"A few weeks before this accident happened, a shark,
of 14 feet in length, was caught in the harbour; and
Squaws. on being opened, the entire head of a man was found in his stomach. The scalp, and flesh of the face, were macerated to a soft pulpy substance; which, on being touched, separated entirely from the bones. The bones were somewhat softened, and the features lost their

The following extraordinary instance of intrepidity and friendship is well worth recording. It is given on the authority of Mr Hughes, who published a natural history of Barbadoes. About the latter end of Queen Anne’s wars, captain John Beanis, commander of the York Merchant, arrived at Barbadoes from England. Having disembarked the last part of his lading, which was coals, the sailors, who had been employed in that dirty work, ventured into the sea to wash themselves; there they had not been long before one on board espied a large shark making toward them, and gave them notice of their danger; upon which they swam back, and all reached the boat except one: him the officer overtook almost within reach of the oars, and gripping him by the small of his back, soon cut him alunder, and as soon swallowed the lower part of his body; the remaining part was taken up and carried on board, where a comrade swallowed the upper part of his body; the deceased had been long distinguished by a reciprocal discharge of all such endearing offices as implied a union and sympathy of souls. When he saw the revered trunk of his friend, it was with an horror and emotion too great for words to paint. During this affecting scene, the insatiable shark was seen traversing the bloody surface in search of the remainder of his prey; the rest of the crew thought themselves happy in being on board, he alone unhappy, that he was not within reach of the devourer. Fired at the sight, and vowing that he would make the devourer disgorge, or be swallowed himself in the same grave, he plunges into the deep, armed with a sharp-pointed knife. The shark no sooner saw him, but he made furiously towards him; both equally eager, the one of his prey, the other of revenge. The moment the shark opened his rapacious jaws, his adversary dexterously diving, and grappling him with his left hand somewhat below the upper fins, successfully employed his knife in his right hand, giving him repeated flaps in the belly; the enraged shark, after many unavailing efforts, finding himself overmatched in his own element, endeavoured to desegage himself, sometimes plunging to the bottom, then mad with pain, rearing his uncouth form, now flained with his own streaming blood, above the foaming waves. The crews of the surrounding vessels saw the unequal combat, uncertain from which of the combatants the streams of blood issued; till at length the shark, much weakened by the loss of blood, made towards the shore, and with him his conqueror; who, flushed with an assurance of victory, pushed his foe with reddened ardour, and, by the help of an ebbing tide, dragged him on shore, ripped up his bowels, and united and buried the fevered carcase of his friend.

"It is evident (says Dr Mofley, to whose valuable work we are indebted for the story of the American related above), that digestion in these animals is not performed by triturations, nor by the muscular action of the stomach; though nature furnished them with a stomach of wonderful force and thickness, and far exceeding that of any other creature. Whatever their force of digestion is, it has no effect upon their young ones, which always retreat into their stomachs in time Squamaria of danger.

"That digestion is not performed by heat in fish, is equally evident. Being on the Banks of Newfoundland in August 1782, I opened many cod-fish, and ripped up their stomachs full as they came alive out of the water; in which were generally found small oysters, muscles, cockles, and crabs, as well as small fishes of their own and other species. The coldness of the stomach of these fishes is far greater than the temperature of the water out of which they are taken; or of any other part of the fish, or of any other substance of animated nature I ever felt. On wrapping one of them round my hand, immediately on being taken out of the fish, it caused so much aching and numbness that I could not endure it long."

Squamosa, in botany. See Lathrea.

Squamous, in anatomy, a name given to the furrows or false futures of the skull, because composed of squamae, or scales like those of fishes.

Square, in geometry, a quadrilateral figure both equilateral and equangular. See Geometry.

Square Root. See Algebra, Part I. Chap. iv. and Arithmetic, no. 33. and 34.

Hollow Square, in the military art, a body of foot drawn up with an empty space in the middle, for the colours, drums, and baggage; faced and covered by the pikes every way, to keep off the horse.

Squares, among mechanics, an instrument consisting of two rules or branches, fastened perpendicularly at one end of their extremities, so as to form a right angle. It is of great use in the description and mensuration of right angles, and laying down perpendiculars.

Square Rigged, an epithet applied to a ship whose yards are very long. It is also used in contradistinction to all vessels whose fails are extended by stays or lateen-yards, or by booms and gaffes; the usual situation of which is nearly in the plane of the keel; and hence.

Square-Sail, is a sail extended to a yard which hangs parallel to the horizon, as distinguished from the other sails which are extended by booms and stays placed obliquely. This sail is only used in fair winds, or to foul under a tempered wind. In the former case, it is furnished with a large additional part called the boom, which is then attached to its bottom, and removed when it is necessary to scud. See Scudding.

Squatina. See Squaleus.

Squill, in botany. See Scilla.

Squilla, the name of a species of cancer. See Cancer.

Squinting. See Medicine, no. 533.

Squirrel, in zoology. See Sciurus.

Stabbing, in law. The offence of mortally stabbing another, though done upon sudden provocation, is punished as murder; the benefit of clergy being taken away from it by statute. (See Murder). For by 1a. I. e. 8, when one thrusts or stabs another, not then having a weapon drawn, or who hath not then felt broken the party stabbing, so that he dies thereof within six months after, the offender shall not have the benefit of clergy, though he did it not of malice aforethought. This statute was made on account of the frequent quarrels and stabings with short daggers between the Scotch and the English, at the acce...
STA

STADTHOLDER, the principal magistrate or governor of the Seven United Provinces, until this office was abolished by the republican influence of France; but as the prince of Orange is at this time in alliance with Great Britain, our readers will probably not be ill pleased with a short account of his several powers and claims. To render that account the more intelligible, we shall trace the office of Stadtholder from its origin.

The Seven Provinces of the Low Countries were long governed by princes invested with the sovereignty, though limited in their powers, and under various titles; as Counts of Holland, Dukes of Gelder, Bishop of Utrecht, &c. When these countries fell to the princes of the house of Burgundy, and afterwards to those of Austria, who had many other dominions, the absence of the sovereign was supplied by a stadtholder or governor, vested with very ample powers. These stadtholders or lieutenants had the administration of the government, and presided in the courts of justice, whose jurisdiction was not at that time confined merely to the trial of causes, but extended to affairs of state. The stadtholders wore allegiance to the princes at their inauguration, jointly with the states of the provinces they governed. They likewise took an oath to the states, by which they promised to maintain their fundamental laws and privileges.

It was upon this footing that William the Fifth, prince of Orange, was made governor and lieutenant-general of Holland, Zeeland, and Utrecht, by Philip the Second, upon his leaving the Low Countries to go into Spain. The troubles beginning soon after, this prince found means to bring about an union, in 1576, between Holland and Zeeland; the states of which two provinces put into his hands, as far as was in their power, the sovereign authority (for so long time as they should remain in war and under arms), upon the same footing as Holland had intrusted him with in the year before. In 1581 the same authority was again renewed to him by Holland, as it was soon after by Zeeland likewise; and in 1584, being already elected count of Holland, upon certain conditions he would have been formally invested with the sovereignty, had not a wrench, hired and employed by the court of Spain, put an end to his life by a horrid assassination.

In the preamble of the instruments by which the states in 1581 conferred the sovereign authority upon prince William the Fifth, we find these remarkable words, which are there set down as fundamental rules: "That all republics and communities ought to preserve, maintain, and fortify themselves by unanimity; which being impossible to be kept up always among so many
Stadtholders, &c., many members, often differing in inclinations and sentiments, is consequently necessary that the government should be placed in the hands of one single chief magistrate." Many good politicians, and the greatest part of the inhabitants of these provinces, have, since the establishment of the republic, looked upon the stadtholder as an essential part of its constitution; nor has it been without a stadtholder but twice, that is to say, from the end of 1650 to 1672, and again from March 1702 till April 1747. The provinces of Friesland and Groningen, with Ommeland, have always had a stadtholder without interruption; their instructions, which are now no longer in force, may be seen in Alzema; but formerly the powers of the stadtholder of these provinces were confined within narrower bounds, and till William the Fourth there was no stadtholder of the seven provinces together.

The stadtholder cannot declare war nor make peace, but he has, in quality of captain-general of the union, the command in chief of all the forces of the state (A); and military persons are obliged to obey him in everything that concerns the service. He is not limited by instructions, but he has the important power of giving out orders for the march of troops, and the disposition of all matters relative to them. He not only directs their marches, but provides for the garrisons, and changes them at pleasure. All military edicts and regulations come from him alone; he constitutes and authorizes the high council of war of the United Provinces, and as captain-general of every province, disposes of all military officers, as far as the rank of colonel inclusively. The higher posts, such as those of veld-marshals, generals, lieutenant-generals, major-generals, are given by the states-general, who choose the persons recommended by his highness. He makes the governors, commandants, &c. of towns and strong places of the republic, and of the barrier. The persons nominated present their instruments of appointment to their high mightinesses, who provide them with commissions. The states-general have likewise great regard to the recommendation of the prince stadtholder in the disposition of those civil employments which are in their gift.

The power of the stadtholder as high-admiral, extends to everything that concerns the naval force of the republic, and to all the other affairs that are here within the jurisdiction of the admiralty. He presides at those boards either in person or by his representatives; and as chief of them all in general, and of every one in particular, he has power to make their orders and instructions be observed by themselves and others. He holds the polls of lieutenant-admiral, vice-admiral, and rear-admiral, who command under him; and he makes likewise post-capitains.

The stadtholder grants likewise letters of grace, pardon, and abolition, as well for the crime called Comunis Debita, as for military offences. In Holland and Zealand these letters are made out for crimes of the first fort, in the name of the states, with the advice of his stadtholder highness. In military offences he consults the high council of war, and upon the communia debita he takes the advice of the courts of justice, of the counsellors, committees of the provinces, of the council of state, and the tribunals of justice in the respective towns, according to the nature of the case.

In the provinces of Holland and Zealand, the stadtholder elects the magistrates of the towns annually, out of a double number that are returned to him by the towns themselves.

When any of these offices become vacant, which, at the time there was no governor, were in the disposal of the states of Holland, or as formerly in that of the chamber of accounts, the stadtholder has his choice of two, or, in some cases, of three candidates, named by their noble and great mightiness. He chooses likewise the counsellors, inspectors of the dykes of Rynland, Dellland, and Schoeland, out of three persons presented to him by the boards of the counsellors inspectors; which boards are of very ancient establishment in Holland.

His highness presides in the courts of Holland, and in the courts of justice of the other provinces; and his name is placed at the head of the proclamations and acts, called in Dutch Mandamenten, or Proclamaten van Justiz. In Overijssel and in the province of Utrecht the posseffors of seels hold of the prince stadtholder. He is supreme curator of the universities of Guelder, Friesland, and Groningen; grand forester and grand vreur in Guelder, in Holland, and other places. In the province of Utrecht, his highness, by virtue of the regulation of 1674, disposes of the provostships and other benefices which remain to the chapters, as also of the canonical prebends that fall in the months which were formerly the papal months.

By the first article of the council of state of the United Provinces, the stadtholder is the first member of it, and has a right of voting there, with an appointment of 25,000 guilders a year. He affiis also as often as he thinks fit for the service of the state, at the deliberations of the states general, to make propositions to them, and sometimes also at the conferences which the deputies of their high mightinesses hold in their different committees, in consequence of their standing orders. He likewise affis at the assemblies of the states of each particular province, and at that of the counsellor's committees. In Guelder, Holland, and Utrecht, his highness has a share of the sovereignty, as chief of president of the body of nobles; and in Zeeland, where he professes the marquisate of Veer and Flushing, as first noble, and representing the whole nobility. In his absence he has in Zeeland his representatives, who have the first place and the first voice in all the councils, and the first of whom is always first deputy from the province to the assembly of their high mightinesses.

In 1749 the prince stadtholder was created by the

(A) In time of war, however, the states have always named deputies for the army, to accompany the stadholders in the field, and to serve them as counsellors in all their enterprises, particularly in the most important affairs, such as giving battle, or undertaking a siege, &c. This was always practised till the accession of king William the Third to the crown of Great Britain, and after his death was continued with regard to the general in chief of the army of the republic. In 1747 and 1748 there were likewise deputies with the army, but with more limited power.
of Scotland" are marked. The prince enjoyed this prerogative in Zealand from the time of his elevation to the stadtholderate.

The revenues of the stadtholderate of the seven United Provinces are reckoned (including the 25,000 guilders which the prince enjoys annually as the first member of the council of state, and what he has from the India company's dividends) to amount to 500,000 guilders a year. As captain-general of the union, his serene highness has 240,000 guilders per annum, besides 24,000 from Friesland, and 12,000 from Groningen, in quality of captain-general of these provinces. In times of war the state allows extraordinary sums to the captain-general for the expense of every campaign.

To all these powers and privileges the prince of Orange had a legal and constitutional right; but he has been divided of them by the late revolution, and the government of that country modelled on the plan of the French republic, by whose armies chiefly the revolution was effected.

STHHELINA, in botany: A genus of plants belonging to the class of fingen-asii, and order of polygamia equilibria; and in the natural system arranged under the 46th order, Composita. The receptacle is paleaceous, the calyx very short; the pappus is branched, and the anthers clefted.

STAFF, an instrument ordinarily used to rest on in walking. The staff is also frequently used as a kind of natural weapon both of offence and defence; and for several other purposes.

STAFF, a light pole erected in different parts of a ship, whereon to hold and display the colours.

The principal of these is reared immediately over the mainmast, to display the ensign; another is fixed on the bowsprit, to extend the yard; three more are erected at the three main heads, or formed by their upper ends, to show the flag or pendant of the respective squadron or division to which the ship is appropriated. See Ensign, Mast, Jack, and Pendant.

STAFF, in military matters, consists of a quarter-master-general, adjutant-general, and majors of brigade. The staff properly exists only in time of war. See Quarter Master General, &c.

Regimental Staff, consists in the adjutant, quarter-master, chaplain, surgeon, &c.

Staff, in music, five lines, on which, with the intermediate spaces, the notes of a song or piece of music are marked.

Fore-Staff. See Fore-Staff.

STAFFA, one of the Hebrides or Western Islands of Scotland, remarkable for its basaltic pillars. It was visited by Sir Joseph Banks, who communicated the following account of it to Mr Pennant.

"The little island of Staffa lies on the west coast of Mull, about three leagues north-east from Iona, or 1-
Stratum above the pillar, 61 6 Staff
Stratum below the pillar, 17 1 Staff
Height of the pillar, 59 0 Sh.
Stratum above, 51 1 Staff
Stratum below the pillar, 19 3 Sh.
Height of the pillar, 55 1 Sh.
Stratum above, 54 7 Sh.

The stratum above the pillars, which is here mentioned, is uniformly the same, consisting of numberless small pillars, bending and inclining in all directions, sometimes so irregularly that the stones can only be made to have an inclination to assume a columnar form; in others more regular, but never breaking into or disturbing the stratum of large pillars, whose tops everywhere keep an uniform and regular line.

Proceeding now along the shore round the north end of the island, you arrive at Our na Searce, or the Corvorant's Cave. Here the stratum under the pillars is lifted up very high; the pillars above it are considerably less than those at the north-west end of the island, but still very considerable. Beyond is a bay, which cuts deep into the island, rendering it in that place not more than a quarter of a mile over. On the sides of this bay, especially beyond a little valley, which almost cuts the island into two, are the slates of pillars, but small; however, having a stratum between them exactly the same as that above them, formed of innumerable little pillars, shaken out of their places, and leaning in all directions.

Having passed this bay, the pillars totally cease; the rock is of a dark-brown stone, and no signs of regularity occur till you have passed round the south-east end of the island (a space almost as large as that occupied by the pillars), which you meet again on the west side, beginning to form themselves irregularly, as if the stratum had an inclination to that form, and soon arrive at the bending pillars where I began.

The stone of which the pillars are formed, is a coarse kind of basalt, very much resembling the Giant's Causeway in Ireland, though none of them are near so neat as the specimens of the latter which I have seen at the British Museum; owing chiefly to the colour, which in ours is a dirty brown, in the Irish a fine black; indeed the whole production seems very much to resemble the Giant's Causeway.

STAFFORD, the county town of Staffordshire, in W. Long. 2° 0′, N. Lat. 55°. It stands on the river Sow, has two parish-churches, a fine square market-place, and a flourishing cloth manufacture. It sends two members to parliament, and is 135 miles from London.

STAFFORDSHIRE, a county of England, bounded on the south by Worcestershire, by Cheshire and Derbyshire on the north, by Warwickshire and Derbyshire on the east, and Shropshire and Cheshire on the west. The length is reckoned 62 miles, the breadth 53, and the circumference 180. It contains 5 hundreds, 150 parishes, 810,000 acres, and 18 market towns. The air, except in the parts that are called the Moorlands, and Woodlands, and about the mines, is very good, especially upon the hills, where it is accounted very good.
natural text
STAMINA, in the animal body, are defined to be those simple original parts which existed first in the embryo or even in the seed; and by whose distinction, augmentation, and accretion by additional juices, the animal body at its utmost bulk is supposed to be formed.

STAMP-DUTIES, a branch of the perpetual revenue. See REVENUE.

In Great Britain there is a tax imposed upon all parchment and paper, wherein any legal proceedings or private instruments of almost any nature whatsoever are written; and also upon licences for retailing wines, of all denominations; upon all almanacs, newspapers, advertisements, cards, dice, &c. These imposts are very various; being higher or lower, not so much according to the value of the property transferred, as according to the nature of the deed. The highest do not exceed six pounds upon every sheet of paper or skin of parchment; and these high duties fall chiefly upon grants from the crown, and upon certain law proceedings, without any regard to the value of the subject.

There are in Great Britain no duties on the registration of deeds or writings, except the fees of the officers who keep the registers; and these are seldom more than a reasonable recompense for their labour. The crown derives no revenue from them.

The stamp-duties constitute a tax which, though in some instances it may be heavily felt, by greatly increasing the expense of all mercantile as well as legal proceedings, yet (if moderately imposed) is of service to the public in general, by authenticating instruments, and rendering it much more difficult than formerly to forge deeds of any standing; since, as the officers of this branch of the revenue vary their stamps frequently, by marks perceptible to none but themselves, a man that would forge a deed of King William's time, must know and be able to counterfeit the stamp of that date also.

In France and some other countries the duty is laid on the contract itself, not on the instrument in which it is contained; as also in England (besides the stamps on the indentures), a tax is laid, by statute 8 Ann. c. 9, on every apprentice-fee; of 6 d. in the pound if it be 50 l. or under, and 1 s. in the pound if a greater sum: but this tends to draw the subject into a thousand nice disquisitions and disputes concerning the nature of his contract, and whether taxable or not; in which the farmers of the revenue are sure to have the advantage. The general method in England answers the purposes of the state as well, and confults the ease of the subject much better. The first institution of the stamp-duties was by statute 5 and 6 W. and M. c. 21. and they have since, in many instances, been increased to five times their original amount.

STAMINA, in botany, are those upright filaments which, on opening a flower, we find within the corolla surrounding the pistillum. According to Linnæus, they are the male organs of generation, whose office it is to prepare the pollen. Each filament consists of two distinct parts, viz. the filamentum and the anthera.

STANDARD, in war, a sort of banner or flag, bore
STANHOPE

borne as a signal for the joining together of the several troops belonging to the same body.

STANDARD, in commerce, the original of a weight, measure, or coin, committed to the keeping of a magistrate, or deposited in some public place, to regulate, adjust, and try the weights used by particular persons in traffic. See MONEY.

STANHOPE (Philip Dormer, earl of Chesterfield), was born in 1695, and educated in Trinity-hall, Cambridge; which place he left in 1714, when, by his own account, he was an absolute pendule. In this character he went abroad, where a familiarity with good company soon convinced him he was totally mithaken in almost all his notions: and an attentive study of the air, manner, and address of people of fashion, soon polished a man whose predominant desire was to please; and who, as it afterwards appeared, valued external accomplishments beyond any other human acquirement. While Lord Stanhope, he got an early feat of satisfaction for himself with books and his pen; in particular, he raised the esteem of the states-general. While Lord Stanhope, he got an early seat in parliament; and in 1722, succeeded to his father's estate and titles. In 1728, and in 1745, he was appointed ambassador extraordinary and pleni potentiary to Holland: which high character he supported with the greatest dignity; serving his own country, and gaining the esteem of the states-general. Upon his return from Holland, he was sent Lord-lieutenant of Ireland; and during his administration there, gave general satisfaction to all parties. He left Dublin in 1746, and in October succeeded the earl of Harrington as secretary of state, in which post he officiated until February 6th 1748. Being seized with a deafness in 1752 that incapacitated him for the pleasures of society, he from that time led a private and retired life, amusing himself with books and his pen; in particular, he engaged largely as a volunteer in a periodical miscellaneous paper called The World, in which his contributions have a distinguished degree of excellence. He died in 1773, leaving a character for wit and abilities that had few equals. He distinguished himself by his eloquence in parliament on many important occasions; of which we have a characteristic instance, of his own relating. He was an active promoter of the bill for altering the style; on which occasion, as he himself writes in one of his letters to his son, he made to eloquent a speech in the house, that every one was pleased, and said he had made the whole very clear to them; "when (says he), God knows, I had not even attempted it. I could just as soon have talked Celtic or Schlovonian to them, as astronomy; and they would have understood me full as well." Lord Macclesfield, one of the greatest mathematicians in Europe, and who had a principal hand in framing the bill, spoke afterwards, with all the clearness that a thorough knowledge of the subject could dictate; but not having a flow of words equal to Lord Chesterfield, the latter gained the applause from the former, to the equal credit of the speaker and the auditors. The high character Lord Chesterfield supported during life, received no small injury soon after his death, from a fuller display of it by his own hand. He left no issue by his lady, but had a natural son, Philip Stanhope, Esq; whose education was for many years a close object of his attention, and who was afterwards envoy extraordinary at the court of Dresden, but died before him. When Lord Chesterfield died, Mr Stanhope's widow published a course of letters, written by the father to the son, filled with instructions suitable to the different gradations of the young man's life to whom they were addressed. These letters contain many fine observations on mankind, and rules of conduct: but it is observable that he lays a greater stress on exterior accomplishments and address, than on intellectual qualifications and sincerity; and allows greater latitude to fashionable pleasures than good morals will justify, especially in paternal instruction. Hence it is that a celebrated writer, and of man, Dr Johnson somewhat different from those of the polite earl of Chesterfield, is said to have observed of these letters that "they inculcate only the morals of a whore, with the manners of a dancing-master."

STANHOPE (Dr George), an eminent divine, was born at Hereford in Derbyshire, in the year 1660. His father was rector of that place, vicar of St Margaret's church in Leicester, and chaplain to the earls of Chesterfield and Clare. His grandfather Dr George Stanhope was chaplain to James I. and Charles I.; had the chancellorship of York, where he was also a canon residentiary, held a prebend, and was rector of Woldrake in that county. He was for his loyalty driven from his home with eleven children; and died in 1644. Our author was sent to school, first at Uppingham in Rutland, then at Leicester; afterwards removed to Eaton; and thence chosen to King's college in Cambridge, in the place of W. Cleaver. He took the degree of B. A. in 1681; M. A. 1683; was elected one of the syndics for the university of Cambridge, in the busines of Albam Francis, 1687; minister of Quoi near Cambridge, and vice-proctor, 1683; was that year preferred to the rectory of Tring in Hertfordshire, which after some time he quitted. He was in 1689 prefented to the vicarage of Lewinham in Kent by Lord Dartmouth, to whom he had been chaplain, and tutor to his son. He was also appointed chaplain to King William and Queen Mary, and continued to enjoy that honour under Queen Anne. He commenced D. D. July 5th 1697, performing all the offices required to that degree publicly and with great applause. He was made vicar of Deptford in 1703; succeeded Dr Hooper as dean of Canterbury the same year; and was three choosen provoker of the lower house of convocation. His uncommon diligence and industry, added by his excellent parts, enriched him with a large stock of polite, solid, and useful learning. His discourses from the pulpit were equally pleasing and profitable; a beautiful intermixture of the clearest reasoning with the purest diction, attended with all the graces of a just elocution. The good Christian, the solid divine, and the fine gentleman, in him were happily united. His conversation was polite and delicate, grave without precineness, facetious without levity. His piety was real and rational, his charity great and universal, fruitful in acts of mercy, and in all good works. He died March 18th 1728, aged 68 years; and was buried in the chancel of the church at Lewinham. The dean was twice married: 1. to Olivia Cotton, by whom he had one son and four daughters. His second lady, who was heir to Sir Charles Wager, survived him, dying October 16th 1735, aged about 54. One of the dean's daughters was married to a son of bishop Burnet. Bishop Moore of Ely died the day before Queen Anne; who, it has been said, designed our dean for that
STANISLAUS (Leczinski), king of Poland, was born at Leopold the 20th of October 1677. His father was a Polish nobleman, distinguished by his rank and the important offices which he held, but still more by his firmness and courage. Stanislaus was sent ambassador in 1704 by the assembly of Warfaw, to Charles XII. of Sweden, who had conquered Poland. He was at that time 27 years old, was general of Great Poland, and had been ambassador extraordinary to the Grand Signior in 1699. Charles was so delighted with the frankness and sincerity of his deportment, and with the firmness and sweetness which appeared in his countenance, that he offered him the crown of Poland, and ordered him to be crowned at Warfaw in 1705. He accompanied Charles XII. into Saxony, where a treaty was concluded with King Augustus in 1704, by which that prince renounced the crown, and acknowledged Stanislaus king of Poland. The new monarch remained in Saxony with Charles till 1707, when they returned into Poland and attacked the Russians, who were obliged to evacuate that kingdom in 1708. But Charles being defeated by Peter the Great in 1709, Augustus returned into Poland, and being assisted by a Russian army, obliged Stanislaus to retire first into Sweden, and afterwards into Turkey. Soon after he took up his residence at Weitzenburg, a town in Alface. Augustus dispatched Sum his envoy to France to complain of this; but the duke of Orleans, who was then regent, returned this answer: "Tell your king, that France has always been the asylum of unhappy princes." Stanislaus lived in obscurity till 1725, when Louis XV. espoused the princess Mary his daughter. Upon the death of King Augustus in 1730, he returned to Poland in hopes of reuniting the throne of that kingdom. A large party declared for him; but his competitor the young elector of Saxony, being supported by the Emperor Charles VI. and the Empress of Russia, was chosen king, though the majority was against him. Stanislaus, to which Stanislaus had retired, was quickly taken, and the unfortunate prince made his escape in disguise with great difficulty. After hearing that a price was set upon his head by the Russians. When peace was concluded in 1736 between the Emperor and France, it was agreed that Stanislaus should abdicate the throne, but that he should be acknowledged king of Poland and grand duke of Lithuania, and continue to heare the titles during life; that all his effects and those of the queen his spouse should be restored; that an annuity should be declared in Poland for all that was past, and that every person should be restored to his possessions, rights, and privileges: that the elector of Saxony should be acknowledged king of Poland by all the powers which acceded to the treaty: that Stanislaus should be put in peaceable possession of the dukedoms of Lorraine and Bar; but that immediately after his death these dukedoms should be united for ever to the crown of France. Stanislaus succeeded a race of princes in Lorraine, who were beloved and regretted; and his subjects found their ancient sovereigns revived in him. He reigned then the pleasure which he had so long denied, the pleasure of making men happy. He adorned his new subjects with embellishments, and had useful establishments; he founded colleges and built hospitals. He was engaged in these noble employments, when an accident occasioned his death. His night-gown caught fire and burnt him so severely before it could be extinguished, that he was seized with a fever, and died the 23d of February 1766. His death occasioned a public mourning: the tears of his subjects indeed were the best eulogium upon this prince. In his youth he had accustomed himself to fatigue, and had thereby strengthened his mind as well as his constitution. He lay always upon a kind of mattress, and seldom required any service from his domestics. He was temperate, liberal, adored by his vassals and perhaps the only nobleman in Poland who had any friends. He was in Lorraine what he had been in his own country, gentle, amiable, companionable, treating his subjects as equals, participating their sorrows and alleviating their misfortunes. He resembled completely the picture of a philosopher which he himself has drawn. "The true philosopher (said he) ought to be free from prejudices, and to know the value of reason; he ought neither to think the higher ranks of life of more value than they are, nor to treat the lower orders of mankind with greater contempt than they deserve; he ought to enjoy pleasures without being a slave to them, riches without being attached to them, honours without pride or vanity: he ought to support disgrace without either fearing or counting them; he ought to reckon what he possesses sufficient for him, and regard what he has not as useless: he ought to be equal in every fortune, always tranquil, always gay; he ought to love order, and observe it in all his actions: he ought to be severe to himself, but indulgent to others: he ought to be frank and ingenuous without rudeness, polite without falsehood, complaisant without baseness; he ought to have the courage to disregard every kind of glory, and to reckon as nothing even philosophy itself." Such was Stanislaus in every situation. His temper was affectionate.
STANNARIES, the mines and works where tin is dug and purified; as in Cornwall, Devonshire, &c.

STANNARY courts, in Devonshire and Cornwall, for the administration of justice among the tinners therein. They are held before the lord-warden and his substitutes, in virtue of a privilege granted to the elytra, and feet being always present. They are held before the lord-warden; and thence to the privy-council of the prince of Wales, as duke of Cornwall, when he hath had livery or investiture of the same. And from thence the appeal lies to the king himself, in the last resort.

STANNUM, tin. See Chemistry-Index, and Tin.

STANZA, in poetry, a number of lines regularly adjusted to each other; so much of a poem as contains every variation of measure or relation of rhyme used in that poem.

STAPHYLEA, bladder-nut, in botany: A genus of plants belonging to the class of pentandria, and order of trignia; and in the natural system arranged under the 23d order, tribulata. The calyx is quinquelobate. There are five petals. The capsules are three, inflated and joined together by a longitudinal future. The seeds are two, and are globose with a beak. There are two species, the pinnata and trifolia. The pinnata, or bladder-nut tree, is a tall shrub or tree. The leaves are pinnate; the pinne are generally five, oblong, pointed, and notched round the edges. The flowers are white, and grow in whips on long pendulous footstalks. This plant flowers in June, and is frequent in hedges about Pantefrad and in Kent. The trifolia, or three-leaved bladder-nut, is a native of Virginia.

STAPHYLINUS, a genus of animals belonging to the class of insecta, and order of coleoptera. The antennae are moniliform; the feelers four in number; the elytra are not above half the length of the abdomen; the wings are folded up and concealed under the elytra; the head or extremity of the abdomen is single, is provided with two long vehicles which the insect can shoot out or draw back at pleasure. Gmelin enumerates 117 species, of which five only are natives of Great Britain; the murinus, maxillarius, rufus, riparius, chryomelinus. 1. Marinus. The head is depressed. The colour is grey, clouded with black. The length is fix lines. It lives among horde-dung. 2. The maxillarius is black, with ash-coloured stripes, and jaws as long as the head. It inhabits the woods. 3. Rufus is of an orange-colour; but the posterior part of the elytra and abdomen is black, as are also the thighs at their base. 4. Riparius is of a reddish brown colour; but the elytra are azure-coloured; and the head, antennae, and two last rings of the abdomen, are black. It is frequent on the banks of rivers in Europe. 5. Chryomelinus is black; the thorax, elytra, and feet being tinctuous. It is found in the north of Europe.

The insects have a peculiarity to be met with in almost every species of this genus, which is, that they frequently turn up their tail, or extremity of the abdomen, especially if you chance to touch them; in which case the tail is seen to rise immediately, as if the insect meant to defend itself by stinging. Yet that is not the place where the insect's offensive weapons are situated. Its tail has no sting, but in recompense it bites and pinches strongly with its jaws; and care must be taken, especially in laying hold of the larger species. Their jaws are strong, shoot out beyond the head, and are subervient to the animal in seizing and destroying
its prey. It feeds on all other insects it can catch: even frequently two flaphylini of the same species bite and tear each other. Though this insect has very small elytra, yet its wings are large; but they are curiously folded up, and concealed under the elytra. The insect unfolds and expands them when he chooses to fly, which he does very lightly. Among the small species of this genus, there are several whole colours are lively and singularly intermingled.

Some of them are found upon flowers, but they chiefly inhabit the dung of cows. Their larve, which resemble them so much as to be scarce distinguishable, live in damp places under ground. They are by some called _Rove beetles._

STAPLE, primarily signifies a public place or market, whither merchants, &c. are obliged to bring their goods to be bought by the people; as the Greve, or the places along the Seine, for sale of wines and corn, at Paris, whither the merchants of other parts are obliged to bring those commodities.

Formerly, the merchants of England were obliged to carry their wool, cloth, lead, and other like staple commodities of that realm, in order to expoe them by wholesale; and these staples were appointed to be constantly kept at York, Lincoln, Newcastle upon Tyne, Norwich, Welfiminster, Canterbury, Chichester, Winchester, Exeter, and Britofl; in each whereof a public mart was appointed to be kept, and each of them had a court of the mayor of the staple, for deciding differences, held according to the law-merchant, in a summary way.

STAR, in astronomy, a general name for all the heavenly bodies, which, like so many brilliant fluids, are dispersed throughout the whole heavens. The stars are distinguished, from the phenomena of their motion, &c. into fixed, and erratic or wandering stars; these last are again distinguished into the greater luminaries, viz. the sun and moon; the planets, or wandering stars, properly so called; and the comets; which have been all fully considered and explained under the article _Astronomy._ As to the fixed stars, they are so called, because they seem to be fixed, or perfectly at rest, and consequently appear always at the same distance from each other.

_Falling Stars_, in meteorology, fiery meteors which dart through the sky in form of a star. See _Meteor._

_Twinkling of the Stars._ See _Optics_, n° 21. et seq.

_STAR_, is also a badge of honour, worn by the knights of the garter, bath, and thistle. See _Garter._

_STAR of Bethlehem_, in botany. See _Ornithogalum._

_Court of Star-chambers._ (camera jellata), a famous, or rather infamous, English tribunal, said to have been so called either from a Saxon word signifying to _flour_ or govern; or from its punishing the _crimen jellionatis_, or cofenage; or because the room wherein it sat, the old council-chamber of the palace of Welfininster, (Lamb. 148,) which is now converted into the lottery-office, and forms the easterm side of New Palace-yard, was full of windows; or, (to which Sir Edward Coke, 4. Inst. 66. accedes), because _happily_ the roof thereof was at the first garnished with gilded _stars_. As all these are merely conjectures, (for no _stars_ are now in the roof, nor are any said to have remained there so late as the reign of queen Elizabeth), it may be allowable to propose another conjectural etymology, as plausible perhaps as any of them. It is well known, that, before the banishment of the Jews ederward I. their con-

1. For in process of time, when the meaning of the words _flares_ or _flars_, from a corruption of the Hebrew word _shfar_, a covenant. (_Tovey's Angl. Judic. P. 256._ pierced by Hoveden, were commanded to be enrolled and deposited in chests under three keys in certain places; one, and the most considerable, of which was in the king's exchequer at Welfiminster: and no _star_ was allowed to be valid, unless it were found in some of the said repositories. (_Memor. in Sac. P. 6. Edw. I._ prefixed to Maynard's year-book of Edw. II. fol. 8. Madox hist. excl. c. vii. § 45, 6.) The room at the exchequer, where the chests containing these _stars_ were kept, was probably called the _star-chamber_; and, when the Jews were expelled the kingdom, was applied to the use of the king's council, sitting in their judicial capacity.

To confirm this, the first time the _star-chamber_ is mentioned in any record, it is said to have been situated near the receipt of the exchequer at Welfiminster: (the king's council, his chancellor, treasurer, justices, and other fages, were assembled en la chambre des effeulles pour la recepice al Welfiminster. Clau. 41 Edw. III. m. 13.) For in process of time, when the meaning of the Jewish _flars_ were forgotten, the word _star-chamber_ was naturally rendered in law French, _la chambre des effeulles_, and in law Latin _camera jellata_; which continued to be the style in Latin till the dissolution of that court.

This was a court of very ancient original; but now-modelled by statutes 3 Hen. VII. c. 1. and 21 Hen. VIII. c. 20. confounding of divers lords spiritual and temporal, being privy councilours, together with two judges of the courts of common-law, without the intervention of any jury. Their jurisdiction extended legally over riots, perjury, misbehaviour of sheriffs, and other notorious misdemeanours, contrary to the laws of the land. Yet this was afterwards (as lord Clarendon informs us) stretched "to the affenting of all proclamations and orders of state; to the vindicating of illegal commissions and grants of monopolies; holding for honourable that which pleased, and for jilt that which profited; and becoming both a court of law to determine civil rights, and a court of revenue to enrich the treasury: the council-table by proclamations enjoining to the people that which was not enjoined by the laws, and prohibiting that which was not prohibited; and the _star-chamber_, which confided of the fame persons in different rooms, confounding the breach and disobedience to those proclamations by very great fines, imprisonments, and corporal severities; so that any disrepeet to any acts of state, or to the perons of state-men, was in no time more penal, and the foundations of right never more in danger to be destroyed." For which reasons, it was finally abolished by statute 16 Car. I. c. 10. to the general joy of the whole nation. See _King's Bench._ There is in the Britifh MuJum (Harl. MSS. Vol. I. n° 126.) a very full, methodical, and accurate account of the constitution and course of this court, compiled by William Hudson of Gray's Inn, an eminent practitioner therein. A short account of the same, with copics...
copies of all its processes, may also be found in 18 Rym.

STARCH, the right side of the ship when the eye of the spectator is directed forward.

STARCH, a gelatinous substance frequently found in fields, and supposed by the vulgar to have been produced from the meteor called a falling-star: but, in reality, is the half-digested food of herons, sea-mews, and the like birds; for these birds have been found, when newly shot, to disgorge a substance of the same kind.

STARCH, in natural history, a name given to certain extraneous foUill stones, in form of short, and commonly somewhat crooked, columns composed of several joints, each resembling the figure of a radiated star, with a greater or smaller number of rays in the different species: they are usually found of about an inch in length, and of the thickness of a goose-quill. Some of them have five angles or rays, and others only four; and in some the angles are equidistant, while in others they are irregularly so: in some also they are short and blunt, while in others they are long, narrow, and pointed; and some have their angles very short and obtuse. The several joints in the same specimen are usually all of the same thickness; this, however, is not always the case: but in some they are larger at one end, and in others at the middle, than in any other part of the body; and some species, have one of the rays bifid, so as to resemble the appearance of a fix rayed kind.

STARCH, in botany. See CENTAUREA.

STARCH, in botany. See ASTER.

STARCH, a secula or sediment, found at the bottom of vessels wherein wheat has been steeped in water, of which secula, after separating the bran from it, by passing it through sieves, they form a kind of loaves, which being dried in the sun or an oven, is afterwards cut into little pieces, and so sold. The best starch, is white, soft, and tender, and easily broken into powder. Such as require fine starch, do not content themselves, like the starchmen, with refuse wheat, but use the finest grain. The process is as follows: The grain, being well cleaned, is put to ferment in vessels full of water, which they expose to the sun while in its greatest heat; changing the water twice a day, for the space of eight or twelve days, according to the season. When the grain begins easily under the finger, they judge it sufficiently fermented. The fermentation perfected, and the grain thus softened, it is put, hand by hand, into a canvas-bag, to separate the flour from the husks, which is done by rubbing and beating it on a plank laid across the mouth of an empty vessel that is to receive the flour.

As the vessels are filled with this liquid flour, there is seen swimming at top a reddish water, which is to be carefully scummed off from time to time, and clean water is to be put in its place, which, after stirring the whole together, is also to be strained through a cloth or sieve, and what is left behind put into the vessel with new water, and exposed to the sun for some time. As the sediment thickens at the bottom, they drain off the water four or five times, by inclining the vessel, but without pausing it through the sieve. What remains at bottom is the starch, which they cut in pieces to get out, and leave it to dry in the sun. When dry, it is laid up for use.

STARK (Dr William), known to the public by a volume containing Clinical and Anatomical Observations, with some curious Experiments on Diet, was born at Manchester in the month of July 1740; but the family from which he sprang was Scotch, and respectable for its antiquity. His grandfather John Stark of Killermont was a covenantor; and having appeared in arms against his sovereign at the battle of Bothwell bridge in the year 1579, became obnoxious to the government, and to conceal himself, withdrew into Ireland. There is reason to believe that he had not imbibed either the extravagant zeal or the savage manners of the political and religious party to which he adhered; for after residing a few years in the country which he had chosen for the scene of his banishment, he married Elizabeth daughter of Thomas Stewart Esq; of Balydron in the north of Ireland; who, being descended of the noble family of Galloway, would not probably have matched his daughter to such an exile as a ruthless fanatic of the last century. By this lady Mr Stark had several children; and his second son Thomas, who settled at Manchester as a wholesale linen-draper, and married Margaret Stirling, daughter of William Stirling, Esq; of Northwood side, in the neighbourhood of Glasgow, was the father of the subject of this article. Another of his sons, the reverend John Stark, was minister of Lecropt in Perthshire; and it was under the care, of this gentleman that our author received the rudiments of his education, which, when we consider the character of the master, and reflect on the relation between him and his pupil, we may presume was calculated to form the mind of Dr Stark with those virtuous principles which influenced his conduct through life.

From Lecropt young Stark was sent to the university of Glasgow, where, under the tuition of the Doctors Smith and Black, with other eminent masters, he learned the rudiments of science, and acquired that mathematical accuracy, that logical precision, and that contempt of hypotheses, with which he prosecuted all his future studies. Having chosen physic for his profession, he removed from the university of Glasgow to that of Edinburgh, where he was soon distinguished, and honoured with the friendship of the late Dr Cullen; a man who was not more eminently conspicuous for the superiority of his own genius, than quick-sighted in perceiving, and liberal in encouraging, genius in his pupils. Having finished his studies at Edinburgh, though he took there no degree, Mr Stark, in the year 1765, went to London, and devoted himself entirely to the study of physic and the elements of surgery; and looking upon anatomy as one of the principal pillars of these arts, he endeavoured to complete with Dr Hunter what he had begun with Dr Monro; and under their two eminent professors he appears to have acquired a high degree of anatomical knowledge. He likewise entered himself about this time a pupil at St George's hospital; for being diffugled, as he often confessed, with the inaccuracy or want of candour observable in the generality of pratical writers, he determined to obtain an acquaintance with diseases at a better school and from an able master; and to have from his own experience a standard, by which he might judge of the experience...
In the year 1767 Mr Stark went abroad and obtained the degree of M. D. in the university of Leyden, publishing an inaugural dissertation on the dysesterny. On his return to London, he recommended his studies at the hospital; and when Dr Black was called to the chemical chair in Edinburgh, which he has long filled with so much honour to himself and credit to the university, Dr Stark was solicited by several members of the university of Glasgow to fland a candidate for their professorship of the theory and practice of physic, rendered vacant by Dr Black’s removal to Edinburgh. This however Dr Stark declined, being influenced by the advice of his English friends, who wished to detain him in London, and having likewise some prospects of an appointment in the hospital.

In the mean time he had commenced (1769) a series of experiments on diet, which he was encouraged to undertake by Sir John Pringle and Dr Franklin, whose friendship he enjoyed, and from whom he received many hints respecting both the plan and its execution. These experiments, or rather the imprudent zeal with which he attempted them, proved in the opinion of his friends, fatal to himself; for he began them on the 1st of July 1769 in perfect health and vigour, and from that day, though his health varied, it was seldom if ever good, till the 23d of February 1770, when he died, after suffering much uneasiness. His friend and biographer Dr Smyth thinks, that other caufrs, particularly chagrinn and disappointment had no small share in hastening his death; and as the Doctor was intimately acquainted with his character and disposition, his opinion is probably well-founded, though the pernicious effects of the experiments are visible in Dr Stark’s own journal. When he entered upon them, the weight of his body was 12 stone 3 lb. avoirdupois, which in a very few days was reduced to 11 stone 10 lb. 8 oz: and though some kinds of food increas’d it, by much the greater part of what he resisted had an contrary effect, and it continued on the whole to decrease till the day of his death. This indeed can excite no wonder. Though the professed object of his experiments was to prove that a pleasant and varied diet is equally conducive to health with a more strict and simple one, most of the diles which he ate during these experiments were neither pleasant nor simple, but compounds, such as every famach must nauseate. He began with bread and water; from which he proceeded to bread, water, and sugar; then to bread, water, and oil of olives; then to bread and water with...
naked stem about six inches high. The radical leaves are like grass. The flowers are terminal, pale red, with a round head, and not very large. The plant flowers in July or August, and grows in meadows near the sea.

2. Limonium, sea-lavender. The stem is naked, branched, and about a foot high. The radical leaves are long, pointed, and grow on the top of the branches. It grows on the coast of South Britain.

3. Reticulata, matted sea-lavender. This species is also found on the sea coast of South Britain.

**Statics**, a term which the modern improvements in knowledge have made it necessary to introduce into physico mathematical science. It was found convenient to distribute the doctrines of universal mechanics into two classes, which required both a different mode of consideration and different principles of reasoning.

Till the time of Archimedes little science of this kind was possessed by the ancients, from whom we have received the first rudiments. His investigations of the centre of gravity, and his theory of the lever, are the foundations of our knowledge of common mechanics, and his theory of the equilibrium of floating bodies contains the greatest part of our hydrostatical knowledge. But it was as yet limited to the simplest cases; and there were in which Archimedes was ignorant, or was mistaken. The marquis Guido Ubaldi, in 1578, published his theory of mechanics, in which the doctrines of Archimedes were well explained and considerably augmented. Stevinus, the celebrated Dutch engineer, published about 20 years after an excellent system of mechanics, containing the chief principles which now form the science of equilibrium among solid bodies. In particular, he gave the theory of inclined planes, which was unknown to the ancients, though it is of the very first importance in almost every machine. He even states in the most explicit terms the principle afterwards made the foundation of the whole of mechanics, and published as a valuable discovery by Varignon, viz. that three forces, whose directions and intensities are as the sides of a triangle, balance each other. His theory of the pressure of fluids, or hydrostatics, is so easily conceivable, including every thing that is now received as a leading principle in the science. When we consider the ignorance, even of the most learned, of that age in mechanical or physico mathematical knowledge, we must consider those performances as the works of a great genius, and we regret that they are too little known, being lost in a crowd of good writings on these subjects which appeared soon after.

Hitherto the attention had been turned entirely to equilibrium, and the circumstances necessary for producing it. Mechanicians indeed saw, that the energy of a machine might be somehow measured by the force which could be opposed or overcome by its intervention; but they did not remark, that the force which prevented its motion, did so more than prevent it, was an exact measure of its energy, because it was in immediate equilibrio with the pressure exerted by that part of the machine with which it was connected. If this opposed force was less, or the force acting at the extremity of the machine was greater, the mechanicians knew that the machine would move, and that work would be performed; but what would be the rate of its motion or its performance they hardly pretended to conjecture. They had not studied the motion of moving forces, nor conceived what was done when a motion was communicated.

The great Galileo opened a new field of speculation in his work on Local Motion. He there considers a change of motion as the indication and exact and adequate measure of a moving force; and he considers every kind of pressure as competent to the production of such changes. He contented himself with the application of this principle to the motion of bodies by the action of gravity, and gave the theory of projectiles, which remains to this day without change, and only improved by considering the changes which are produced in it by the resistance of the air.

Sir Isaac Newton took up this subject nearly as Galileo had left it. For, if we except the theory of the centrifugal forces arising from rotation, and the theory of pendulums, published by Huygens, hardly anything had been added to the science of motion. Newton considered the subject in its utmost extent; and in his mathematical principles of natural philosophy he considers every conceivable variation of moving force, and determines the motion resulting from its action. His first application of these doctrines was to explain the celestial motions; and the magnificence of this subject caused it to occupy for a while the whole attention of the mathematicians. But the same work contained propositions equally conducive to the improvement of common mechanics, and to the complete understanding of the mechanical actions of bodies. Philosophers began to make these applications also. They saw that every kind of work which is to be performed by a machine may be considered abstractedly as a retarding force; that the impulse of water or wind, which are employed as moving powers, act by means of preijures which they exert on the impelled point of the machine; and that the machine itself may be considered as an assemblage of bodies moveable in certain limited circumstances, with determined directions and proportions of velocity. From all these considerations resulted a general abstract condition of a body acted on by known powers. And they found, that after all conditions of equilibrium were satisfied, their remains a surplus of moving force. They could now state the motion which will ensue the new resistance which this will excite, the additional power which this will absorb; and they at last determined a new kind of equilibrium, not thought of by the ancient mechanicians, between the resistance to the machine performing work and the moving power, which exactly balance each other, and is indicated, not by the refb, but by the uniform motion of the machine. In like manner, the mathematician was enabled to calculate that precise motion of water which would completely absorb, or, in the new language, balance the superiority of preijure by which water is forced through a sluice, a pipe, or canal, with a constant velocity.

Thus the general doctrines of motion came to be considered in two points of view, according as they balanced each other in a state of rest or of uniform motion. These two ways of considering the same subject required both different principles and a different manner of reasoning. The first has been named Statics, as expressing...
preparing that rest which is the test of this kind of equilibrium. The second has been called Dynamics or Universal Mechanics, because the different kinds of motion are characteristic of the powers or forces which produce them. A knowledge of both is indispensably necessary for acquiring any useful practical knowledge of machines: and it was ignorance of the doctrines of accelerated and retarded motions which made the progress of practical mechanical knowledge so very slow and imperfect. The mechanics, even of the moderns, before Galileo, went no further than to flate the proportion of the power and resistence which would be balanced by the intervention of a given machine, or the proportion of the parts of a machine by which two known forces may balance each other. This view of the matter introduced a principle, which even Galileo considered as a mechanical axiom, viz. that what is gained in force by means of a machine is exactly compensated by the additional time which it obliges us to employ. This is false in every instance, and not only prevents improvement in the construction of machines, but leads us into erroneous maxims of construction. The true principles of dynamics teach us, that there is a certain proportion of the machine, dependent on the kind and proportion of the power and resistence, which enables the machine to perform the greatest possible work.

It is highly proper therefore to keep separate these two ways of considering machines, that both may be improved to the utmost, and then to blend them together in every practical discussion.

Statics therefore is preparatory to the proper study of mechanics; but it does not hence derive all its importance. It is the sole foundation of many useful parts of knowledge. This will be best seen by a brief enumeration.

1. It comprehends all the doctrines of the excitement and propagation of pressure through the parts of solid bodies, by which the energies of machines are produced. A pressure is exerted on the impelled point of a machine, such as the float-boards or buckets of a mill-wheel. This excites a pressure at the pivots of its axle, which act on the points of support. This must be understood, both as to direction and intensity, that it may be effectually reftored. A pressure is also excited at the acting tooth of the cog wheel on the same axle, by which it urges round another wheel, exciting similar pressures on its pivots and on the acting tooth perhaps of a third wheel. Thus a pressure is ultimately excited in the working point of the machine, perhaps a wiper, which lifts a heavy flameur, to let it fall again on some matter to be bounded. Now statics teaches us the intensities and directions of all those pressures, and therefore how much remains at the working point of the machine unbalanced by resistence.

2. It comprehends every circumstance which influences the stability of heavy bodies; the investigation and properties of the centre of gravity; the theory of the construction of arches, vaults, and domes; the attitudes of animals.

3. The strength of materials, and the principles of construction, so as to make the proper adjustment of strength and strain in every part of a machine, edifice, or structure of any kind. Statics therefore furnishes us with what may be called a theory of carpentry, and gives us proper instructions for framing floors, roofs, centres, etc.

4. Statics comprehends the whole doctrine of the pressure of fluids, whether liquid or aeriform, whether arising from their weight or from any external action. Hence we derive our knowledge of the stability of ships, or their power of maintaining themselves in a position nearly upright, in opposition to the action of the wind on their sails. We learn on what circumstances of figure and flowage this quality depends, and what will augment or diminish it.

Very complete examples will be given in the remaining part of this work of the advantages of this separate consideration of the condition of a machine at rest and in working motion; and in what yet remains to be delivered of the hydraulic doctrines in our account of Water Works: in general, will be perceived the propriety of flating apart the equilibrium which is indicated by the uniform motion of the fluid. The observations too which we have to make on the strength of the materials employed in our edifices or mechanical structures, will be examples of the investigation of those powers, pressures, or strains, which are excited in all their parts.

STATISTICS, a word lately introduced to express a view or survey of any kingdom, county, or parish. A Statistical view of Germany was published in 1790 by Mr. B. Clarke; giving an account of the imperial and territorial constitutions, forms of government, legislation, administration of justice, and of the ecclesiastical state; with a sketch of the character and genius of the Germans; a short inquiry into the state of their trade and commerce; and giving a distinct view of the dominions, extent, number of inhabitants to a square mile; chief towns, with their size and population; revenues, expenses, debts, and military strength of each state. In Prussia, in Saxony, Sardinia, and Tuscany, attempts have also been made to draw up statistical accounts; but they were done rather with a view of a tertaining the present state of those countries, than as the means of future improvement.

A grand and extensive work of this kind, founded on a judicious plan, conducted by the most patriotic and enlightened men, and drawn up from the communications of the whole body of the clergy, was undertaken in Scotland in the year 1790 by Sir John Sinclair of Ulbster, one of the most useful members of his country. Many praises are heaped upon genius and learning; but to genius and learning no applause is due, except when exerted for the benefit of mankind: but gratitude and praise is due to him whose talents shine only in great undertakings, whose happiness seems to consist in patriotic exertions, and whose judgment is uniformly approved by his successes. A work of this kind, so important in its object, so comprehensible in its range, so judicious in its plan, and drawn up by more than 900 men of literary education, many of them men of great genius and learning, must be of immense value. Sixteen volumes otavc are already published; and it is supposed that the work will be completed in two or three additional volumes.

The great object of this work is to give an accurate view of the state of the country, its agriculture, its manufacture, and its commerce; the means of improvement, of which they are respectively capable; the amount of the population of a state, and the causes of its increase or
fciences, viz. political or statitical philosophy; that is, the science, which, in preference to every other, ought to be held in reverence. No science can furnish, to any mind capable of receiving useful information, so much real entertainment; none can yield such important hints, for the improvement of agriculture, for the extension of commercial industry, for regulating the conduct of individuals, or for extending the prosperity of the state; none can tend so much to promote the general happiness of the species.

STATIUS (Publius Papinius), a celebrated Latin poet of the 1st century, was born at Naples, and was the son of Statius, a native of Epirus, who went to Rome to teach poetry and eloquence, and had Domitian for his scholar. Statius the poet also obtained the favour and friendship of that prince; and dedicated to him his Thebais and Achilles; the first is twelve books, and the last in two. He died at Naples about the year 100. Besides the above poems, there are also full extant his Syllus, in five books; the style of which is purer, more agreeable, and more natural, than that of his Thebais and Achilles.

STATUARY, a branch of sculpture, employed in the making of statues. See Sculpture and the next article.

Statuary is one of those arts wherein the ancients surpassed the moderns; and indeed it was much more popular, and more cultivated, among the former than the latter. It is disputed between statuary and painting, which of the two is the most difficult and the most arduous.

Statuary is also used for the artist who makes statues. Phidias was the greatest statuary among the ancients, and Michael Angelo among the moderns.

STATE, is defined to be a piece of sculpture in full relief, representing a human figure. Dacier more scientifically defines statue a representation, in high relief and in metal, of some person distinguished by his birth, merit, or great actions, placed as an ornament in a fine building, or exposed in a public place, to preserve the memory of his worth. In Greece one of the highest honours to which a citizen could aspire was to obtain a statue.

Statues are formed with the chisel, of several matters, as stone, marble, plaster, &c. They are also cast of various kinds of metal, particularly gold, silver, brass, and lead. For the method of casting statues, see the article Founder of Statues.

Statues are usually distinguished into four general kinds. The first are those less than the life; of which kind we have several statues of great men, of kings, and of gods themselves. The second are those equal to the life; in which manner it was that the ancients, at the public expense, used to make statues of personages eminent for virtue, learning, or the services they had done. The third are those that exceed the life; among which those that surpassed the life once and a half were for kings and emperors; and those double the life, for heroes. The fourth kind were those that exceeded the life twice, thrice, and even more, and were called colossal. See Colossus.

Every statue resembling the person whom it is intended to represent, is called statua eiconia. Statues acquire various other denominations. Thus, allegorical statue is that which, under a human figure, or other symbol,
3. and when the hounds of the main-mast: the fore top-gallant stay comes to the outer end of the jib-boom; and the main-top-gallant stay is extended to the head of the fore-top-mast.

St. r. S. a fort of triangular fall extended upon a stay. See Sail.

STEAM, is the name given in our language to the Definition, visible moist vapour which arises from all bodies which contain juices easily expelled from them by heats not sufficient for their combustion. Thus we find, the steam of boiling water, of malt, of a tan-bed, &c. It is distinguished from smoke by its not having been produced by combustion, by not containing any foot, and by its being condensible by cold into water, oil, inflammable spirits, or liquids composed of these.

We fee it rise in great abundance from bodies when they are heated, forming a white cloud, which diffuses itself and disappears at no very great distance from the body from which it was produced. In this case the surrounding air is found loaded with the water or other juices which seem to have produced it, and the steam seems to be completely soluble in air, as falt is in water, composing while thus united a transparent elastic fluid.

But in order to its appearance in the form of an apparent white cloud, the mixture with or diffamation in air seems absolutely necessary. If a tea-kettle boils violently, so that the steam is formed at the spout in great abundance, it may be observed, that the visible cloud is not formed at the very mouth of the spout, but at a small distance before it, and that the vapour is perfectly transparent at its first emission. This is rendered still more evident by fitting to the spout of the tea-kettle a glass pipe of any length, and of as large a diameter as we please. The steam is produced as copiously as without this pipe, but the vapour is transparent through the whole length of the pipe. Nay, if this pipe communicate with a glass vessel terminating in another pipe, and if the vessel be kept sufficiently hot, the steam will be as abundantly produced at the mouth of this second pipe as before, and the vessel will be quite transparent. The visibility therefore of the matter which constitutes the steam is accidental or extraneous circumstance, and requires the admixture with air; yet this quality again leaves it when united with air by solution. It appears therefore to require a diffimation in air. The appearances are quite agreeable to this notion: for we know that one perfectly transparent body, when minutely divided and diffused among the parts of another transparent body, but not dissolved in it, makes a mass which is visible. Thus oil beat up with water makes a white opaque mass.

In the mean time, as steam is produced, the water is again gradually wafted in the tea-kettle, and will soon be totally expended, if we continue it on the fire. It is reasonable therefore to suppose, that this steam is nothing but water changed by heat into an aerial or elastic form. If so, we should expect that the privation of this heat would give it in the form of water again. Accordingly this is fully verified by experiment; for if the pipe luted to the spout of the tea-kettle be surrounded with cold water, no steam will issue, but water will continually trickle from it in drops; and if the process be conducted with the proper precautions, the water which we thus obtain from the pipe will be found...
equal in quantity to that which disappears from the teakettle. This is evidently the common process for distilling; and the whole appearances may be explained by saying, that the water is converted by heat into an elastic vapour, and that this, meeting with colder air, imparts to it the heat which it carried off as it arose from the heated water, and being deprived of its heat it is again water. The particles of this water being vastly more remote from each other than when they were in the teakettle, and thus being diffused in the air, become visible, by reflecting light from their anterior and posterior surfaces, in the same manner as a transparent salt becomes visible when reduced to a fine powder. This diffused water being presented to the air in a very extended surface, is quickly dissolved by it, as poured salt is in water, and again becomes a transparent fluid, but of a different nature from what it was before, being no longer convertible into water by depriving it of its heat.

Accordingly this opinion, or something very like it, has been long entertained. Mülchenbroek expressly says, that the water in the form of vapour carries off with it all the heat which is continually thrown in by the fuel. But Dr Black was the first who attended minutely to the whole phenomena, and enabled us to form distinct notions of the subject. He had discovered that it was not sufficient for converting ice into water that it be raised to that temperature in which it can no longer remain in the form of ice. A piece of ice of the temperature 32° of Fahrenheit's thermometer will remain a very long while in air of the temperature 50° before it be all melted, remaining all the while of the temperature 32°, and therefore continually absorbing heat from the surrounding air. By comparing the time in which the ice had its temperature changed from 28° to 32° with the subsequent time of its complete liquefaction, he found that it absorbed about 150 or 140 times as much heat as would raise its temperature one degree; and he found that one pound of ice, when mixed with one pound of water 140 degrees warmer, was just melted, but without rising in its temperature above 32°. Hence he justly concluded, that water differed from ice of the same temperature by containing, as a constituent ingredient, a great quantity of fire, or of the cause of heat, united with it in such a way as not to quit it for another colder body, and therefore so as not to go into the liquor of the thermometer and expand it. Considered therefore as the possible cause of heat, it was latent, which Dr Black expressed by the abbreviated term latent heat. If any more heat was added to the water it was not latent, but would readily quit it for the thermometer, and, by expanding the thermometer, would show what is the degree of this redundant heat, while fluidity alone is the indication of the combined and latent heat.

Dr Black, in like manner, concluded, that in order to convert water into an elastic vapour, it was necessary, not only to increase its combined heat till its temperature is 212°, in which state it is just ready to become elastic; but also to pour into it a great quantity of fire, or the cause of heat, which combines with every particle of it, so as to make it repel, or to recede from, its adjoining particles, and thus to make it a particle of an elastic fluid. He supposed that this additional heat might be combined with it, so as not to quit it for the thermometer; and therefore so as to be in a latent state, having elastic fluidity for its sole indication.

This opinion was very confined with the phenomenon of boiling off a quantity of water. The application of heat to it causes it gradually to rise in its temperature till it reaches the temperature 212°. It then begins to send off elastic vapour, and is slowly expended in this way, continuing all the while of the same temperature. The steam also is of no higher temperature, as appears by holding a thermometer in it. We must conclude that this steam contains all the heat which is expended in its formation. Accordingly the scaling power of steam is well known; but it is extremely difficult to obtain precise measures of the quantity of heat absorbed by water during its conversion into steam. Dr Black endeavoured to ascertain this point, by comparing the time of raising its temperature a certain number of degrees with the time of boiling it off by the same external heat; and he found that the heat latent in steam, which balanced the pressure of the atmosphere, was not less than 800 degrees. He also directed Dr Irvine of Glasgow to the form of an experiment for measuring the heat actually extracted from such steam during its condensation in the refrigeratory of a still, which was found to be not less than 774 degrees.

Dr Black was afterwards informed by Mr Watt, that a course of experiments, which he had made in each of these ways with great precision, determined the latent heat of steam under the ordinary pressure of the atmosphere to be about 948 or 950 degrees. Mr Watt also found that water would distil with great ease in vacuo when the temperature 70°; and that in this case the latent heat of the steam is not less than 1200 or 1300 degrees; and a train of experiments, which he had made by distilling in different temperatures, made him conclude that the sum of the sensible and latent heats is a constant quantity. This is a curious and not an improbable circumstance; but we have no information of the particulars of these experiments. The conclusion evidently presupposes a knowledge of that particular temperature in which the water has no heat; but this is a point which is still fab judice.

This conversion of liquids (for is not confined to water, but obtains also in ardent spirits, oils, mercury, &c.) is the cause of their boiling. The heat is applied to the bottom and sides of the vessel, and gradually accumulates in the fluid, in a sensible state, uncombined, tie and ready to quit it and enter into any body that is colder, and to diffuse itself between them. Thus it enters into the fluid of a thermometer, expands it, and thus gives us the indication of the degree in which it has been accumulated in the water; for the thermometer swells as long as it continues to absorb sensible heat from the water; and when the sensible heat in both is in equilibrio, in a proportion depending on the nature of the two fluids, the thermometer rises no more, because it absorbs no more heat or fire from the water; for the particles of water which are, in immediate contact with the bottom, are now (by this gradual expansion of liquidity) at such distance from each other, that their laws of attraction for each other and for heat are totally changed. Each particle either no longer attracts, or perhaps it repels its, adjoining particle, and now accumulates round itself a great number of the particles of heat.
heat, and forms a particle of elastic fluid, so related to the adjoining new formed particles, as to repel them to a distance at least a hundred times greater than their distances in the state of water. Thus a mass of elastic vapour of sensible magnitude is formed. Being at least ten thousand times lighter than an equal bulk of water, it must rise up through it, as a cork would do, in form of a transparent ball or bubble, and getting to the top, it disdissipates, filling the upper part of the vessel with vapour or steam. Observe, that during its passage up through the water, it is not changed or condensed; for the surrounding water is already so hot that the sensible or uncombined heat in it, is in equilibrio with that in the vapour, and therefore it is not disposed to absorb any of that heat which is combined as an ingredient of this vapour, and gives it its elasticity. For this reason, it happens that water will not boil till its whole mass be heated up to 212°; for if the upper part be colder, it robs the rising bubble of that heat which is necessary for its elasticity, so that it immediately collapses again, and the surface of the water remains still. This may be perceived by holding water in a Florence flask over a lamp or chafier. It will be observed, some time before the real ebullition, that some bubbles are formed at the bottom, and get up a very little way, and then disappear. The distances which they reach before collapsing increase as the water continues to warm farther up the mass, till at last it breaks out into boiling. If the handle of a tea-kettle be grasped with the hand, a tremor will be felt for some little time before boiling, arising from the little sucussions which are produced by the collapsing of the bubbles of vapour. This is much more violent, and is really a remarkable phenomenon, if we suddenly plunge a lamp of red hot iron into a vessel of cold water, taking care that no red part be near the surface. If the hand be now applied to the side of the vessel, a most violent tremor is felt, and sometimes strong thumps: these arise from the collapsing of very large bubbles. If the upper part of the iron be too hot, it warms the surrounding water so much, that the bubbles from below come up through it uncondened, and produce ebullition without this success. The great resemblance of this tremor to the feeling which we have during the shock of an earthquake has led many to suppose that these last are produced in the same way, (See Earthquake, no. 88—98;) and by their hypothesis, notwithstanding the objections which we have elsewhere flated to it, is by no means unfeasible.

It is owing to a similar cause that violent thumps are the noise sometimes felt on the bottom of a tea-kettle, especially one observed in the boiling of a tea-kettle excited on the bottom with a stony concretion. This sometimes is detached in little scales. When one of these is detached, adhering by one end to the bottom, the water gets between them in a thin film. Here it may be heated considerably above the boiling temperature, and it suddenly rises up in a large bubble, which collapses immediately. A smooth filling lying on the bottom will produce this appearance very violently, or a thimble with the mouth down.

In order to make water boil, the fire must be applied to the bottom or sides of the vessel. If the heat be applied at the top of the water, it will wake away without boiling; for the superficial particles are first supplied with the heat necessary for rendering them elastic, and they fly off without agitating the rest of the vessel.

Since this disengagement of vapour is the effect of its elasticity, and since this elasticity is a determinate degree of pressure when the temperature is given, it follows, that fluids cannot boil till the elasticity of the vapour overcomes the pressure of the incumbent fluid and of the atmosphere. Therefore, when this pressure is removed or diminished, the fluids must sooner overcome what remains, and boil at a lower temperature. Accordingly it is observed that water will boil in an exhausted receiver, when the heat of the human body. If two glass balls A and B (fig. 1.) be connected by a slender tube, and one of them be filled with water (a small opening or pipe being left at top of the other), and this be made to boil, the vapour produced from it will drive all the air out of the other, and will at last come out itself, producing steam at the mouth of the pipe. When the ball B is observed to be occupied by transparent vapour, we may conclude that the air is completely expelled. Now shut the pipe by flicking it into a piece of tallow or bees-wax; the vapour in B will soon condense, and there will be a vacuum. The flame of a lamp and blow-pipe being directed to the little pipe, will cause it immediately to close and feel hermetically. We now have a pretty instrument or toy called a Polish Glass. Grasp the ball A in the hollow of the hand; the heat of the hand will immediately expand the bubble.

(A) We explained the opaque and cloudy appearance of steam, by saying that the vapour is condensed by coming into contact with the cooler air. There is something in the form of this cloud which is very inexplicable. The particles of it are sometimes very distinguishable by the eye; but they have not the smart tar like brilliany of very small drops of water, but give the fainter reflection of a very thin film or vehicle like a soap-bubble. If we attend also to their motion, we see them descending very slowly in comparison with the descent of a solid drop; and this vesicular constitution is established beyond a doubt by looking at a candle through a cloud of steam. It is then surrounded by a faint halo with tenuous colours, precisely such as we can demonstrate by optical laws to belong to a collection of vehicles, but totally different from the halo which would be produced by a collection of solid drops. It is very difficult to conceive how these vehicles can be formed of watery particles, each of which was surrounded with many particles of fire, now communicated to the air, and how each of these vehicles shall include within it a body of air, but we cannot refuse the fact. We know, that if, while indeed oil is boiling or nearly boiling, the surface be obliquely struck with the ladle, it will be dashed into a prodigious number of exceedingly small vehicles, which will float about in the air for a long while. Mr Saussure was (we think) the first who distinctly observed this vesicular form of mils and clouds; and he makes considerable use of it in explaining several phenomena of the atmosphere.
of vapour which may be in it, and this vapour will
drive the water into B, and then will blow up through
it for a long while, keeping it in a state of violent
ebullition, as long as there remains a drop or film of water
in A. But care must be taken that B is all the while
kept cold, that it may condense the vapour as fast as it
rises through the water. Touching B with the hand,
or breathing warm on it, will immediately stop the
ebullition in it. When the water in A has thus been diffi-
ipated, grasp B in the hand; the water will be driven in
to A, and the ebullition will take place there as it did
in B. Putting one of the balls into the mouth will
make the ebullition more violent in the other, and the
one in the mouth will feel very cold. This is a pretty
illustration of the rapid abstraction of the heat by the
particles of water which are thus converted into elasic
vapour. We have seen this little toy suspended by the
middle of the tube like a balance, and thus placed in
the inside of a window, having two holes a and b cut
in the pane, in such a situation that when A is full of
water and preponderates, B is opposite to the hole b.
Whenever the room became sufficiently warm, the
vapour was formed in A, and immediately drove the
water into B, which was kept cool by the air coming in
to the room through the hole b. By this means B was
made to preponderate in its turn, and A was then op-
posite to the hole a, and the process was now repeated
in the opposite direction; and this amusement continued
as long as the room was warm enough.

We know that liquors differ exceedingly in the tem-
perature necessary for their ebullition. This forms the
great chemical distinction between volatile and fixed
bodies. But the difference of temperature in which
they boil, or are converted into permanently elasic
vapour, under the pressure of the atmosphere, is not a certain
measure of their differences of volatility. The natural
boiling point of a body is that in which it will be con-
verted into elasic vapour under no pressure, or in vacuo.
The boiling point in the open air depends on the law of
the elaticity of the vapour in relation to its heat. A
fluid A may be less volatile, that is, may require more
heat to make it boil in vacuo, than a fluid B. But if
the elaticity of the vapour of B, A be more increased by
an increase of temperature than that of the vapour of
B, A may boil at as low, or even at a lower tempera-
ture, in the open air, than B does; for the increased
elaticity of the vapour of A may sooner overcome the
pressure of the atmosphere. Few experiments have been
made on the relation between the temperature and the
elaticity of different vapours. So long ago as the year
1765, we had occasion to examine the boiling points of
all such liquors as we could manage in an air-pump;
that is, such as did not produce vapours which defgroyed
the valves and the leathers of the piston; and we
thought that the experiments gave us reason to conclu-
sion that the elaticity of all the vapours was affected by
heat nearly in the same degree. For we found that the dif-
ference between their boiling points in the air and in
vacuo was nearly the same in all, namely, about 120 de-
grees of Fahrenheit's thermometer. It is exceedingly
difficult to make experiments of this kind: The va-
pours are so condensible, and change their elaticity so
prodigiously by a trifling change of temperature, that
it is almost impossible to examine this point with pre-
cision. It is, however, as we shall see by and by, a sub-
ject of considerable practical importance in the mechanic
arts; and an accurate knowledge of the relation would
be of great use also to the distiller; and it would be
no less important to discover the relation of their elatic-
ty and density, by examining their comprepressibility, in
the same manner as we have ascertained the relation in
the case of what we call aeriel fluids, that is, such as we
have never observed in the form of liquids or solids,
except in consequence of their union with each other or
with other bodies. In the article Pneumatics we
noticed of it as something like a natural law,
that all these airs, or gases as they are now called, had their
elaticity very nearly, if not exactly proportional to their
density. This appears from the experiments of Achard,
of Fontana, and others, on vital air, inflammable air,
fixed air, and some others. It gives us some preump-
tion to suppose that it holds in all elasic vapours what-
ever, and that it is connected with their elaticity; and
it renders it somewhat probable that they are all elasic,
only because the cause of heat (the matter of fire if you
will) is elasic, and that their law of elaticity, in respect
density, is the same with that of fire. But it must
be observed, that although we thus assign the elaticity
of fire as the immediate cause of the elaticity of vapours,
in the same way, and on the same grounds, that we as-
scribe the fluidity of brine to the fluidity of the water
which holds the solid salt in solution; it does not follow
that this is owing, as is commonly supposed, to a repul-
sion or tendency to recede from each other exerted by
the particles of fire. We are as much entitled to infer
a repulsion of unlimited extent between the particles of
water; for we see that by its means a single particle of
sea-salt becomes diffeminated through the whole of a
very large vessel. If water had not been a visible and
palpable fluidity, and the salt only had been visible
and palpable, we might have formed a similar notion of
chemical solution. But we, on the contrary, have
considered the quaquaversal motion or expansion of the
salt as a diffemination among the particles of water; and
we have ascribed it to the strong attraction of the atoms
of salt for the atoms of water, and the attraction of
the salt for itself, making that each atom of salt
accumulates round itself a multitude of watery atoms,
and by so doing must recede from the other like atoms.
Nay, we farther see, that by forces which we
naturally consider as attractions, an expansion may be
produced of the whole mass, which will act against ex-
ternal mechanical forces. It is thus that wood swells
with almost insuperable force by imbising moisture;
it is thus that a sponge immebered in water becomes
really an elastic comprensible body, resembling a blown
bladder; and there are appearances which warrant us
to apply this mode of conception to elasic fluids.—
When air is suddenly compressed, a thermometer in-
cluded in it shows a rise of temperature; that is, an
appearance of heat now redundant which was former-
ly combined. The heat seems to be squeezed out as the
water from the sponge.

Accordingly this opinion, that the elaticity of steam
Aerated and other vapours is owing merely to the attraction for
fire, and the consequent diffemination of their particle,
attraction, through the whole mass of fire, has been entertained
by many naturalists, and it has been ascribed entirely to Perly,
attraction. We by no means pretend to decide; but we
think the analogy by far too strong to be found any

confident opinion on it. The aim is to solve phenomena by attraction only, as if it were of more easy conception than repulsion. Considered merely as facts, they are quite on a par. The appearances of nature in which we observe actual recesses of the parts of body from each other, are as distinct, and as frequent and familiar, as the appearances of actual approach. And if we attempt to go farther in our contemplation, and to conceive the way and the forces by which either the approximations or recesses of the atoms are produced, we must acknowledge that we have no conception of the matter; and we can only say, that there is a cause of these motions, and we call it a force, as in every case of the production of motion. We call it attraction or repulsion; and we have it to consider as a fact or a recess. But the analogy here is not only light, but imperfect, and fails most in these cases which are most simple, and where we should expect it to be most complete. We can squeeze water out of a sponge, and mix the air, true, or out of a piece of green wood; but when the white of an egg, the tremella, or some gums, swell to a hundred times their dry dimensions by imbuing water, we cannot squeeze out a particle. If fluidity (for the reasoning must equally apply to this as to vaporous fluids) be owing to an accumulation of the extended matter of fire, which gradually expanded the solid by its very minute additions; and if the accumulation round a particle of ice, which is necessary for making it a particle of water, be so great in comparison of what gives it the expansion of one degree, as experiment obliges us to conclude—it seems an inevitable consequence that all fluids should be many times rarer than the solids from which they were produced. But we know that the difference is trilling in all cases, and in some (water, for instance,) it is so small that the solid is rarer than the fluid. Many other arguments (each of them perhaps of little weight when taken alone, but which are all systematically connected) concur in rendering it much more probable that the matter of fire, in causing elasticity, acts immediately by its own elasticity, which we cannot conceive in any other way than as a mutual tendency in its particles to recede from each other; and we doubt not but that, if it could be obtained alone, we should find it an elastic fluid like air. We even think that there are cases in which it is observed in this state. The elastic force of gunpowder is very much beyond the elasticity of all the vapours which are produced in its deflagration, each of them being expanded as much as we can reasonably suppose by the great heat to which they are exposed. The writer of this article exploded some gunpowder mixed with a considerable portion of finely powdered quartz, and another parcel mixed with fine filings of copper. The elasticity was measured by the penetration of the ball which was discharged, and was great in the degree now mentioned. The experiment was so conducted, that much of the quartz and copper was collected; none of the quartz had been melted, and some of the copper was not melted. The heat, therefore, could not be such as to explain the elasticity by expansion of the vapours; and it became not improbable that fire was acting here as a detached chemical fluid by its own elasticity. But to return to our subject.

There is one circumstance in which we think our own experiments show a remarkable difference (at least in degree) between the condensible and incondensible vapours. It is well known, that when air is very suddenly expanded, cold is produced, and heat when it is suddenly condensed. When making experiments with the hopes of discovering the connection between the great difference between the condensible and incondensible and incomprehensible gaseous vapours; probably we may expect to expand into five times its bulk, we observed the depression of a large and sensible air thermometer to be at least four or five times greater than in a similar expansion of common air of the same temperature. The chemical reader will readily see reasons for expecting, on the contrary, a smaller alteration of temperature, both on account of the much greater rarity of the fluid, and on account of a partial condensation of its water, and the consequent disengagements of combined heat. This difference in the quantity of fire which is combined in the vapours and gaseous air is so considerable as to authorize us to suppose that there is some difference in the chemical constitution of vapours and gaseous air, and that the connection between the specific boses of the vapours and the fire which it contains is not the same in air, for instance as in the vapour of boiling water; and this difference may be the reason why the one is easily condensible by cold, while the other has never been exhibited in a liquid or solid form, except by means of its chemical union with other substances. In this particular instance we know that there is an essential difference—that in vital or atmospheric air there is not only a predigious quantity of fire which is not in the vapour of water, but that it also contains light, or the caufe of light, in a combined state. This is equally evident by the great diffusion of Mr. Cavendish of the combined gaseous air. Here we are taught that water (and consequently its vapour) consists of air from which the light and greatest part of the fire have been separated. And the subsequent discoveries of the celebrated Lavoisier shew, that almost all the condensible gases with which we are acquainted consist either of airs which have already lost much of their fire (and perhaps light too), or of waters in which we have no evidence of fire or light being combined in this manner.

This consideration may go far in explaining this difference in the condensibility of these different species of aerial fluids, the gaseous and the gaseous; and it is with this qualification only that we are disposed to allow that all bodies are condensible into liquids or solids by abrading the heat. In order that vital air may become liquid or solid, we hold that it is not sufficient that a body be presented to it which shall simply abract its heat. This would only abract its uncombined fire—but another, and much larger portion remains chemically combined by means of light. A chemical affinity must be brought into action which may abract, not the fire from the oxygen (to speak in the language of Mr. Lavoisier,) but the oxygen from the fire and light. And our production is not the detached basins of air, but detached heat and light, and the formation of an oxyd of some kind.

To prosecute the chemical consideration of Steam farther than these general observations, which are applicable to all, would be almost to write a treatise of chemistry, and would be a repetition of many things which have been treated of in sufficient detail in other articles.
Steam.

As fluids boil under the preface of the vapour which ascends from them, the conclusion mentioned in No. 14, is only a gross approximation.

Account of experiments to determine the relation between the temperature of the vapour and its elasticity.

A very different process was necessary for ascertaining the elasticity of the steam in lower temperatures, and consequently under smaller pressures than that of the atmosphere. The glass syphon SGF was now fixed into its hole in the lid of the cistern. The water was made to boil smartly for some time, and the steam issued copiously both at the valve and at the syphon. The lower
lower end of the syphon was now imersed into a broad faucer of mercury, and the lamp instantly removed, and every thing was allowed to grow cold. By this the steam was gradually condensed, and the mercury rose in the syphon, without sensibly sinking in the faucer. The valve and all the joints were smeared with a thick clammy cement, composed of oil, tallow, and rosin, which effectually prevented all ingress of air. The weather was clear and frosty, the barometer standing at 29,84, and the thermometer in the veffel at 42°. The mercury in the syphon stood at 29,7, or somewhat higher, thus showing a very complete condensation. The whole veffel was surrounded with pounded ice, of the temperature 32°. This made no sensible change in the height of the mercury. A mark was now made at the surface of the mercury. One observer was stationed at the thermometer, with instructions to call out as the thermometer reached the divisions 42, 47, 52, 57, and so on by every five degrees till it should attain the boiling heat. Another observer noted the descents for every fifth degree, becaufe they exceeded each other fo faft. Every 10th was judged sufficient to establish the law of variation. The first column of the table contains the temperature, and the second the descent (in inches) of the mercury from the mark 29,84.

This form of the experiment is much more susceptible of accuracy than the other, and the measures of elafiity are more to be depended on. In repeating the experiment, they were found much more constant; whereas, in the former method, differences occurred of two inches and upwards.

We may now connect the two sets of experiments into one table, by adding to the numbers in this last table the constant height, 29,9, which was the height of the mercury in the barometer during the last set of observations.

Four or five numbers at the top of the column of elafiities are not fo accurate as the others, becaufe the mercury passed pretty quick through thefe points. But the progress was extremely regular through the remaining points, fo that the elafiities correponding to temperatures above 70° may be considered as very accurately ascertained.

Not being altogether satisfied with the method employed for measuring the elafiity in temperatures above that of boiling water, a better form of experiment was adopted. (Indeed it was the want of other apparatus which made it necessary to employ the former). A glaas tube was procured of the form represented in fig. 3, having a little ciftern L, from the top and bottom of which proceeded the syphons K and MN. The ciftern contained mercury, and the tube MN was of a flender bore, and was about fix feet two inches long. The end K was firmly fixed in the third hole of the lid, and the long leg of the syphon was furnished with a scale of inches, and firmly fastened to an upright post.

The lamp was now applied at such a distance from the veffel as to warm it slowly, and make the water boil, the steam escaping for some time through the safety valve. A heavy weight was then suspended on the steel yard; such as it was known that the syphon would support, and at the fame time, such as would not allow the steam to force the mercury out of the long tube. The thermometer began immediately to rise, as also the mercury in the tube MN. Their correspondent fations are marked in the following table:

...
In the memoirs of the Royal Academy of Berlin for 1792, there is an account of some experiments made by Mr. Achard on the elastic force of团队, from the temperature 32° to 112°. They agree extremely well with those mentioned here, rarely differing more than two or three tenths of an inch. He also examined the elasticity of the vapour produced from alcohol, and found that when the elasticity was equal to that of the vapour of water, the temperature was about 35° lower. Thus, when the elasticity of both was measured by 28.1 inches of mercury, the temperature of the watery vapour was 209°, and that of the spirituous vapour was 174°. When the elasticity was 18.5, the temperature of the water was 189.5, and that of the alcohol 154.6. When the elasticity was 11.05, the water was 168°, and the alcohol 134°.4. Observing the difference between the temperatures of equally elastic vapours of water and alcohol not to be constant, but gradually to diminish, in Mr. Achard's experiments, along with the elasticity, it became interesting to discover whether and at what temperature this difference would vanish altogether. Experiments were accordingly made by the writer of this article, similar to those made with water. They were not made with the same scrupulous care, nor repeated as they deserved, but they furnished rather an unexpected result. The following table will give the reader a distinct notion of them:

We say that the result was unexpected; for as the natural boiling point seemed by former experiments to be in all fluids about 120° or more below their boiling point in the ordinary pressure of the atmosphere, it was reasonable to expect that the temperature at which they ceased to emit sensibly elastic team would have some relation to their temperatures when emitting team of any determinate elasticity. Now as the vapour of alcohol of elasticity 50 has its temperature about 36° lower than the temperature of water equally elastic, it was to be expected that the temperature at which it ceased to be sensibly affected would be several degrees lower than 32°. It is evident, however, that this is not the case. But this is a point that deserves more attention, because it is closely connected with the chemical relation between the element (if such there be) of fire and the bodies into whose composition it seems to enter as a constituent part. What is the temperature 32°, to make it peculiarly connected with elasticity? It is a temperature assumed by us for our own convenience, on account of the familiarity of water in our experiments. Either, we know, boils in a temperature far below this, as appears from Dr. Cullen's experiments narrated in the Effays Physical and Literary of Edinburgh. On the faith of former experiments, we may be pretty certain that it will boil in vacuo at the temperature 14°, because in the air it boils at 106°. Therefore we may be certain, that the team or vapour of ether, when the temperature 32°, will be very sensibly elastic. Indeed Mr. Lavoisier says, that if it be exposed in an exhausted receiver in winter, its vapour will support mercury at the height of 10 inches. A series of experiments on this vapour similar to those above, would be very instructive. We even wish that those on alcohol were more carefully repeated. If we draw a curve line, of which the abscissa is the line of temperatures, and the ordinates are the corresponding heights of the mercury in these experiments on water and alcohol, we shall observe that although they both sensibly coincide at 32°, and have the abscissa for their common tangent, a very small error of observation may be the cause of this, and the curve which expresses the elasticity of spirituous vapour may really interface the other, and go backwards considerably beyond 32°.

This range of experiments gives rise to some curious and important reflections. We now see that no particular temperature is necessary for water affixing the form of permanently elastic vapour; and that it is highly probable that it assumes this form even at the temperature 32°; only its elasticity is too small to afford us any sensible measure. It is well known that ice evaporates (see experiments to this purpose by Mr. Wilson in the Philosophical Transactions, when a piece of polished metal covered with hoar-frost became perfectly clear by exposing it to a dry frosty wind).

Even mercury evaporates, or is converted into elastic vapour, when all external pressure is removed. The dim film which may frequently be observed in the upper part of a barometer which stands near a stream of air, is found to be small globules of mercury sticking to the inside of the tube. They may be seen by the help of a magnifying glass, and are the best test of a well made barometer. They will be entirely removed by causing the mercury to rise along the tube. It will lick them all up. They consist of mercury which had evaporated in the void space, and was afterwards condensed by the cold glass. But the elasticity is too small to occasion a sensible depression of the column, even when considerably warmed by a candle.

Many philosophers accordingly imagine, that spontaneous evaporation in low temperatures is produced in this way. But we cannot be of this opinion, and must still think that this kind of evaporation is produced by the cold and the dissolving power of the air. When moist air is suddenly rarefied, there is always a precipitation of water. This is most distinctly seen when we work an air-pump briskly. A mist is produced, which we see plainly fall to the bottom of the receiver. But by this new doctrine the very contrary should happen, because the tendency of water to appear in the elastic form is promoted by removing the external pressure; and we really imagine that more of it now actually becomes simple elastic watery vapour. But the mist or precipitation shows incontrovertibly, that there had been a previous solution. Solution is performed by forces which act in the way of attraction; or, to express it more safely, solutions are accompanied by the mutual approaches of the particles of the meniscus and solvent: all such tendencies are observed to increase by a diminution of distance. Hence it must follow, that the air of double density will diffuse more than twice as much water. Therefore when we suddenly rarefy saturated air (even though...
its heat should not diminish) some water must be let go. What may be its quantity we know not; but it may be more than what would now become elastic by this diminution of surrounding pressure; and it is not unlikely but this may have some effect in producing the vehicles which we found so difficult to explain. These may be filled with pure watery vapour, and be floating in a fluid composed of water dissolved in air. An experiment of Fontana's seems to put this matter out of doubt. A distilling apparatus $\Delta B$ (fig. 4.) was so contrived, that the heat was applied above the surface of the water in the alembic $\Delta$. This was done by inclining it in another vessel $CC$, filled with hot water. In the receiver $B$ there was a sort of barmometer $D$, with an open cistern, in order to see what pressure there was on the surface of the fluid. While the receiver and alembic contained air, the heat applied at $A$ produced no sensible distillation during several hours: But on opening a cock $E$ in the receiver at its bottom, and making the water in the alembic to boil, steam was produced which soon expelled all the air, and followed it through the cock. The cock was now shut, and the whole allowed to grow cold by removing the fire, and applying cold water to the alembic. The barometer fell to a level nearly. Then warm water was allowed to get into the outer vessel $CC$. The barometer rose a little, and the distillation went on briskly without the smallest ebullition in the alembic. The conclusion is obvious: while there was air in the receiver and communicating pipe, the distillation proceeded entirely by the dissolving power of this air. Above the water in the alembic it was quickly saturated; and this saturation proceeded slowly along the still air in the communicating pipe, and at last might take place thro' the whole of the receiver. The sides of the receiver being kept cold, should condense part of the water dissolved in the air in contact with them, and this should trickle down the sides and be collected. But any person who has observed how long a crystal of blue vitriol will lie at the bottom of a glass of still water before the tinge will reach the surface, will see that it must be next to impossible for distillation to go on in these circumstances; and accordingly none was observed. But when the upper part of the apparatus was filled with pure watery vapour, it was supplied from the alembic as fast as it was condensed in the receiver, just as in the pale glass.

Another inference which may be drawn from these experiments is, that Nature seems to affect a certain law in the dilatation of aeriform fluids by heat. They seem to be dilatable nearly in proportion of their present dilatation. For if we suppose that the vapours resemble air, in having their elasticity in any given temperature proportional to their density, we must suppose that if steam of the elasticity $50$, that is, supporting 50 inches of mercury, were subjected to a pressure of 30 inches, it would expand into twice its present bulk. The augmentation of elasticity therefore is the measure of the bulk into which it would expand in order to acquire its former elasticity. Taking the increase of elasticity therefore as a measure of the bulk into which it would expand under one constant pressure, we see that equal increments of temperature produce nearly equal multiplications of bulk. Thus if a certain diminution of temperature diminishes its bulk

$$\frac{4}{5}$$

another equal diminution of temperature will diminish this new bulk $$\frac{4}{5}$$ very nearly. Thus in our experiments, the temperatures 110°, 130°, 170°, 200°, 230°, are in arithmetical progression, having equal differences; and we see that the corresponding elasticities $2, 2.5, 5, 15, 11, 05, 22, 64, 44, 7$, are very nearly in the continued proportion of 1 to 2. The elasticity corresponding to the temperature 260 deviates considerably from this law, which would give 88 or 89 instead of 80; and the deviation increases in the higher temperatures. But still we see that there is a considerable approximation to this law; and it will frequently assist us to recollect, that whatever be the present temperature, an increase of 30 degrees doubles the elasticity and the bulk of watery vapour.

This is sufficiently exact for most practical purposes. Thus an engineer finds that the injection cools the cylinder of a steam engine to 192°. It therefore leaves a steam whose elasticity is $\frac{4}{5}$ of its full elasticity, $= 18$ inches $\gamma$. But it is better at all times to have recourse to the table. Observe, too, that in the lower temperatures, i.e. below 110°, this increment of temperature does more than double the elasticity.

This law obtains more remarkably in the incorratable vapours; such as vital air, atmospheric air, fixed air, &c. all of which have also their elasticity proportional to their bulk inversely; and perhaps the deviation from the law in liquids is connected with their chemical difference of constitution. If the bulk were always augmented in the same proportion by equal augmentations of temperature, the elasticities would be accurately represented by the ordinates of a logarithmic curve, of which the temperatures are the corresponding abscissae; and we might contrive such a scale for our thermometers, that the temperatures would be the common logarithms of the elasticities, or of the bulbs having equal elasticity; or, with our present scale, we may find such a multiplier $m$ for the number $x$ of degrees of our thermometer (above that temperature where the elasticity is equal to unity), that this multiple shall be the common logarithm of the elasticity $y$; so that $m \times x = \log y$.

But our experiments are not sufficiently accurate for determining the temperature where the elasticity is measured by 1 inch; because in these temperatures the elasticities vary by exceedingly small quantities. But if we take 11.04 for the unit of elasticity, and number our temperature from 170°, and make $m = 0.010035$, we shall find the product $m \times x$ to be very nearly the logarithm of the elasticity. The deviations, however, from this law, are too great to make this equation of any use. But it is very practicable to frame an equation which shall correspond with the experiments to any degree of accuracy; and it has been done for air in a translation of General Roy's Measurement of the Bafe at Eloumflough Heath into French by Mr Prony. It is as follows: Let $x$ be the degrees of Reaumur's ther-
And is considerably approximated to in the augmentation of the bulk or elasticity of elastic vapours; that is, it is a fact that a given increment of temperature makes nearly the same proportional augmentation of bulk and elasticity. This gives us some notion of the manner in which the supposed expanding cause produces the effect. When vapour of the bulk 4 is expanded into a bulk 5 by addition of 10 degrees of sensible heat, a certain quantity of fire goes into it, and is accumulated round each particle, in such a manner that the temperature of each, which formerly was m, is now m + 10. Let it now receive another equal augmentation of temperature. This is now m + 20, and the bulk is \(\frac{5 \times 5}{4}\), or 6\(\frac{1}{4}\). The absolute quantity of fire which has entered is greater than the former, both on account of the greater augmentation of space and the greater temperature. Consequently if this vapour be compressed into the bulk 5, there must be heat or fire in it which is not necessary for the temperature m + 20, far less for the temperature m + 10. It must therefore emerge, and be dispensed to enter a thermometer which has already the temperature m + 20; that is, the vapour must grow hotter by compulsion; not by freeing out the heat, like water out of a sponge, but because the law of attraction for heat is deranged. It would be a very valuable acquisition to our knowledge to learn with precision the quantity of sensible heat produced in this way; but no satisfactory experiments have yet been made. M. Lavoisier, with his chemical friends and colleagues, were busily employed in this inquiry; but the wickedness of their countrymen has deprived the world of this and many other important additions which we might have expected from this celebrated and unfortunate philosopher. He had made, in conjunction with M. de La Place, a numerous train of accurate and expensive experiments for measuring the quantity of latent or combined heat in elastic vapours. This is evidently a very important point to the distiller and practical chemist. This heat must all come from the fuel; and it is greatly worth while to know whether any saving may be made of this article. Thus we know that distillation will go on either under the pressure of the air, or in an alembic and receiver from which the air has been expelled by steam; and we know that this last may be conducted in a very low temperature, even not exceeding that of the human body. But it is uncertain whether this may not employ even a greater quantity of fuel, as well as occasion a great expense of time. We are disposed to think, that when there is no air in the apparatus, and when the condensation can be speedily performed, the proportion of fuel expended to the fluid which comes over will diminish continually as the heat, and consequently the density of the steam, is augmented; because in this case the quantity of combined heat must be left. In the mean time, we earnestly recommend the trial of this mode of distillation in vessels cleared of air. It is undoubtedly of great advantage to be able to work with smaller fires; and it would secure us against all accidents of blowing off the head of the still, often attended with terrible consequences.

We must not conclude this article without taking notice of some natural phenomena which seem to owe their origin to the action of elastic steam.

We have already taken notice of the resemblance of the tremors and convulsions observed in the flocks of many earthquakes to those which may be felt in a vessel where water is made to boil internally, while the breaking out of the ebullition is shifted by the cold of the upper parts; and we have likewise stated the objections which are usually made to this theory of earthquakes. We may perhaps resume the subject under the article Volcano; but in the mean time we do not hesitate to say, that the wonderful appearances of the Geyser spring in Iceland (see Huer; and Iceland, m. 53–5) are undoubtedly produced by the expansion of steam in ignited caverns. Of these appearances we suppose the whole train to be produced as follows.

A cavern may be supposed of a shape analogous to CBDEF (fig. 5.), having a perpendicular funnel AB issuing from a depressed part of the roof. The part ACDE may be lower than the rest, remote, and red-hot. Such places we know to be frequent in Iceland. Water may be continually trickling into the part CD. It will fall by the force of gravity upon the face of the red soil, and then trickle slowly forward. As soon as any gets into contact with an ignited part, it expands into elastic steam, and is partly condensed by the cool sides of the cavern, which gradually warms, till it condenses no more. This produces

(b) We earnestly recommend this subject to the consideration of the philosophers. The laws which regulate the formation of elastic vapour, or the general phenomena which it exhibits, give us that link which connects chemistry with mechanical philosophy. Here we see chemical affinities and mechanical forces set in immediate opposition to each other, and the one made the indication, characteristic, and measure of the other. We have not the least doubt that they make but one science the Science of Universal Mechanics; nor do we despair of seeing the phenomena of solution, precipitation, crystallization, fermentation, nay animal and vegetable secretion and assimilation, successfully investigated, as cases of local motion, and explained by the agency of central forces. Something of this kind, and that not inconsiderable, was done when Dr. Cullen first showed how the double affinities might be illustrated by the affinities of numbers. Dr. Black gave to this hint (for it was little more) that elegant precision which characterizes all his views. Mr. Kirwan has greatly promoted this study by his numerous and ingenious examples of its application; and the most valuable passages of the writings of Mr. Lavoisier, are those where he traces with logical precision the balancing of force which appear in the chemical phenomena. It is from the similar balancing and consequent measurements, which may be observed and obtained in the present case, that we are to hope for admission into this abstruse and unbounded science of contemplation. We have another link equally interesting and promising, viz. the production of heat by friction. This also highly deserves the consideration of the mathematical philosopher.
production of steam hinders not in the smallest degree the trickling of more water into $F$, and the continual production of more steam. This now preys on the surface of the water in $C D$, and causes it to rise gradually in the funnel $B A$; but slowly, because its cold surface is condensing an immense quantity of steam. We may easily suppose that the water trickles further into $F$ than it is expended in the production of steam; so that it reaches further into the ignited part, and may even fall in a stream into some deeper pit highly ignited. It will now produce steam in vast abundance, and of prodigious elasticity; and at once pulls up the water through the funnel in a solid jet, and to a great height. This must continue till the surface of the water links to $B D$. If the lower end of the funnel have any inequalities or notches, as is most likely, the steam will get admission along with the water, which in this particular place is boiling hot, being superficial, and will get to the mouth of the funnel, while water is still pressed in below. At last the steam gets in at $B$ on all sides; and as it is converging to $B$, along the surface of the water, with prodigious velocity it sweeps along with it much water, and blows it up through the funnel with great force. When this is over, the remaining steam blows out unmixed with water, growing weaker as it is expelled, till the bottom of the funnel is again stopped by the water increasing in the cavern $C B D$. All the phenomena above ground are perfectly conformable to the necessary consequences of this very probable construction of the cavern. The feeling of being lifted up, immediately before the jet, in all probability is owing to a real heaving up of the whole roof of the cavern by the first expansion of the great body of steam. We had an accurate description of the phenomena from persons well qualified to judge of these matters who visited these celebrated springs in 1789.

**Steam-Engine**, is the name of a machine which derives its moving power from the elasticity and condensibility of the steam of boiling water. It is the most valuable present which the arts of life have ever received from the philosopher. The mariner’s compass, the telescope, gunpowder, and other most useful and convenient to human weakness and ingenuity, were the productions of chance, and we do not exactly know to whom we are indebted for them; but the steam-engine was, in the very beginning, the result of reflection, and the production of a very ingenious mind; and every improvement it has received, and every alteration in its construction and principles, were also the results of philosophical study.

The steam-engine was beyond all doubt invented by the marquis of Worcester during the reign of Cha. II. This nobleman published in 1663 a small book intitled *A Century of Inventions*, giving some obscure and enigmatical account of an hundred discoveries or contrivances of his own, which he extols as of great importance to the public. He appears to have been a person of much knowledge and great ingenuity: but his description or accounts of these inventions seem not so much intended to instruct the public, as rather to amuse; and his encomiums on their utility and importance are to a great degree extravagant, resembling more the puff of an advertising tradesman than the patriotic communications of a gentleman. The marquis of Worcester was indeed a projector, and very important in his applications for public encouragement. His account, however, of the steam-engine, although by no means fit to give us any distinct notions of its structure and operation, is exact as far as it goes, agreeing precisely with what we now know of the subject. It is No. 68. of his inventions. His words are as follow: “This admirable method which I propose of raising water by the force of fire has no bounds if the vessels be strong enough: for I have taken a cannon, and having filled it with shot, and that up its muzzle and touch-hole, and exposed it to the fire for 24 hours, it burst with a great explosion. Having afterwards discovered a method of fortifying vessels internally, and combined them in such a way that they filled and acted alternately, I have made the water spout in an uninterrupted stream 40 feet high; and one vessel of rarefied water raised 40 of cold water. The person who conducted the operation had nothing to do but turn two cocks; so that one vessel of water being consumed, another begins to force, and then to fill itself with cold water, and so on in succession.”

It does not appear that the noble inventor could ever interest the public by these accounts. His character as reduced to a projector, and the many failures which perfections of this produce by Captain Savary.

But first we must consider the public by these accounts. His character as reduced to a projector, and the many failures which perfections of this produce by Captain Savary.

The steam-engine invented by the Marquis of Worcester.

**Steam-Engine**
them in close vessels, which he called digesters, so as to acquire a great degree of heat. For it must be observed in this place, that it had been discovered long before (in 1684) by Dr Hooke, the most inquisitive experimental philosopher of that inquisitive age, that water could not be made to acquire above a certain temperature in the open air; and that as soon as it begins to boil, its temperature remains fixed, and an increase of heat only produces a more violent ebullition, and more rapid walk. But Papin's experiments made the elastic power of steam very familiar to him; and when he left England and settled as professor of mathematics at Marburg, he made many awkward attempts to employ this force in mechanics, and even for raining water. It appears that he had made experiments with this view in 1698, by order of Charles Landgrave of Hesse. For this reason the French affect to consider him as the inventor of the steam-engine. He indeed published some account of his invention in 1697; but he acknowledges that Captain Savary had also, and without any communication with him, invented the same thing. Whoever will take the trouble of looking at the defcription which he has given of these inventions, which are to be seen in the Athenaeum Lipsianus, and in Leupold's Theatrum Machinarum, will see that they are not much awkward, absurd, and impracticable. His conceptions of natural operations were always vague and imperfect, and he was neither philosopher nor mechanician.

We are thus anxious about the claim of those gentlemen, because a most respectable French author, Mr Boffut, says in his Hydrodynamique, that the first notion of the steam-engine was certainly owing to Dr Papin, who had not only invented the digester, but had in 1695 published a little performance describing a machine for raining water, in which the pistons are moved by the vapour of boiling water alternately dilated and condensed. Now the fact is, that Papin's first publication was in 1697, and his piston is nothing more than a floater on the surface of the water, to prevent the waste of steam by condensation; and the return of the piston is not produced, as in the steam engine, by the condensation of the steam, but by admitting the air and a column of water to press it back into its place. The whole contrivance is so awkward, and so unlike any distinct notions of the subject, that it cannot do credit to any person. We may add, that much about the same time Mr Amontons contrived a very ingenious but intricate machine, which he called a fire-wheel. It consisted of a number of buckets placed in the circumference of a wheel, and communicating with each other by very intricate circular passages. One part of this circumference was exposed to the heat of a furnace, and another to the steam or cident of cold water. The communications were so disposed, that the steam produced in the buckets on one side of the wheel drove the water into buckets on the other side, so that one side of the wheel was always much heavier than the other; and it must therefore turn round, and may execute some work. The death of the inventor, and the intricacy of the machine, caused it to be neglected. Another member of the French academy of sciences (Mr Deflandres) also presented to the academy a project of a steam-wheel, where the impulsive force of the vapour was employed; but it met with no encouragement.

The English engineers had by this time so much improved Savary's first invention, that it supplanted all others. We have therefore no hesitation in giving the honour of the first and complete invention to the marquis of Worcester; and we are not disposed to refuse Captain Savary's claim to originality as to the construction of the machine, and even think it probable that his own experiments made him see the whole independent of the marquis's account.

Captain Savary's engine, as improved and simplified by himself, is as follows.

A (fig. 6.) represents a strong copper boiler properly built up in a furnace. There proceeds from its top a large steam-pipe B, which enters into the top of another strong vessel called the receiver. This pipe has a cock C called the steam-cock. In the bottom of the receiver is a pipe F, which communicates with the rising pipe KGH. The lower end of this pipe is immersed in the water of the pit well, and its upper part opens into the cistern into which the water is to be delivered. Immediately below the pipe of communication F there is a valve H, opening when pressed from below, and shutting when pressed downwards. A similar valve is placed at I, immediately above the pipe of communication. Lastly, there is a pipe ED which branches off from the rising pipe, and enters into the top of the receiver. This pipe has a cock D called the injection-cock. The mouth of the pipe ED has a nozzle F pierced with small holes, pointing from a centre in every direction. The keys of the two cocks C and D are united, and the handle g is called the regulator.

Let the regulator be so placed that the steam-cock C is open and the injection-cock D is shut; put water into the boiler A, and make it boil strongly. The steam coming from it will enter the receiver, and gradually warm it, much steam being condensed in producing this effect. When it has been warmed so as to condense no more, the steam proceeds into the rising pipe; the valve G remains shut by its weight; the steam lifts the valve I, and gets into the rising pipe, and gradually warms it. When the workman feels this to be the case, or hears the rattling of the valve I, he immediately turns the steam-cock so as to shut it, the injection-cock full remaining shut (at least we may suppose this for the present). The apparatus must now cool, and the steam in the receiver collapses into water. There is nothing now to balance the pressure of the atmosphere; the valve I remains shut by its weight; but the air incumbent on the water in the pit presses up this water through the admission-pipe H G, and causes it to lift the valve G, and flow into the receiver R, and fill it to the top, if not more than 20 or 25 feet above the surface of the pit water.

The steam-cock is now open. The steam which, during the cooling of the receiver, has been accumulating in the boiler, and acquiring a great elasticity by the action of the fire, now rushes in with great violence, and, pressing on the surface of the water in the receiver, causes it to shut the valve G and open the valve I by its weight alone, and it now flows into the rising pipe, and would stand on a level if the elasticity of the steam were no more than what would balance the atmospheric pressure. But it is much more than this, and therefore it presses the water out of the receiver into the rising pipe,
Steam Engine.

pipe, and will even cause it to come out at K, if the elasticity of the steam is sufficiently great. In order to ensure this, the boiler has another pipe in its top, covered with a safety-valve V, which is kept down by a weight W suspended on a stay-yard L M. This weight is so adjusted that its pressure on the safety-valve is somewhat greater than the pressure of a column of water V k as high as the point of discharge K. The fire is so regulated that the steam is always issuing a little by the loaded valve V. The workman keeps the steam-valve open till he hears the valve rattle. This tells him that the water is all forced out of the receiver, and that the steam is now following it. He immediately turns the regulator which shuts the steam-cock, and now, for the first time, opens the injection-cock. The cold water trickles at first through the holes of the nozzle f, and falling down through the stem, begins to condense it; and then its elasticity being less than the pressure of the water in the pipe K E D f, the cold water spouts in all directions through the nozzle, and, quick as thought, produces a complete condensation.

The valve G now opens again by the pressure of the atmosphere on the water of the pit, and the receiver is soon filled with cold water. The injection-cock is now shut, and the steam-cock opened, and the whole operation is now repeated; and so on continuously.

This is the simple account of the process, and will serve to give the reader an introductory notion of the operation; but a more minute attention must be paid to many particulars before we can see the properties and defects of this ingenious machine.

The water is driven along the rising pipe by the elasticity of the steam. This must in the boiler, and every part of the machine, exert a pressure on every square inch of the vessels equal to that of the upright column of water. Suppose the water to be raised 100 feet, about 25 of this may be done in the suction-pipe; that is, the upper part of the receiver may be about 25 feet above the surface of the pit-water. The remaining 75 must be done by forcing, and every square inch of the boiler will be squeezed out by a pressure of more than 30 pounds. This very moderate height therefore requires very strong vessels; and the Marquis of Worcester is well aware of the danger of their bursting. A copper boiler of six feet diameter must be 3 feet of an inch thick to be in equilibrio with this pressure; and the folded joint will not be able to withstand it, especially in the high temperature to which the water must be heated in order to produce steam of sufficient elasticity. By consulting the table of the elasticity of steam deduced from our experiments mentioned in the preceding article, we see that this temperature must be at least 280° of Fahrenheit's thermometer. In this heat soft folder is just ready to melt, and has no tenacity; even spelter folder is considerably weakened by it. Accordingly, in a machine erected by Captain Savary at York Buildings in London, the workman having loaded the safety-valve a little more than usual to make the engine work more briskly, the boiler burst with a dreadful explosion, and blew up the furnace and adjoining parts of the building as if it had been gunpowder. Mr. Savary succeeded pretty well in raising moderate quantities of water to small heights, but could make nothing of deep mines. Many attempts were made, on the Marquis's principle, to strengthen the vessels from within by radiated bars and by hoops, but in vain. Very small boilers or evaporators were then tried, kept red hot, or nearly so, and supplied with a tender stream of water trickling into them; but this afforded no opportunity of making a collection of steam during the refrigeration of the receiver, so as to have a magazine of steam in readiness for the next forcing operation; and the working of such machines was always an employment of great danger and anxiety.

The only situation in which this machine could be employed with perfect safety, and with some effect, was where the whole lift did not exceed 30 or 35 feet. In this case the greatest part of it was performed by the suction-pipe, and a very manageable pressure was sufficient for the rest. Several machines of this kind were erected in England about the beginning of the century. A very large one was erected at a colliery in the south of France. Here the water was to be raised no more than 18 feet. The receiver was capacious, and it was occasionally supplied with steam from a small salt-pan constructed purposely with a cover. The entry of the steam into the receiver merely allowed the water to run out of it by a large valve, which was opened by the hand, and the condensation was produced by the help of a small forcing pump also worked by the hand. In particular a situation as this (and many such may occur in the endless variety of human wants), this is a very powerful engine; and having few moving and rubbing parts, it must be of great durability. This circumstance has occasioned much attention to be given to this first form of the engine, even long after it was supplanted by those of a much better construction. A very ingenious attempt was made very lately to adapt this construction to the uses of the miners. The whole depth of the pit was divided into lifts of 15 feet, in the same manner as is frequently done in pump-machines. In each of these was a suction pipe 14 feet long, having above it a small receiver like K, about a foot high, and its capacity somewhat greater than that of the pipe. This receiver had a valve at the head of the suction-pipe, and another opening outwards into the little cistern, into which the next suction-pipe above dipped to take in water. Each of these receivers sent up a pipe from its top, which all met in the cover of a large vessel above ground, which was of double the capacity of all the receivers and pipes. This vessel was close on all sides. Another vessel of equal capacity was placed immediately above it, with a pipe from its bottom passing through the cover of the lower vessel and reaching near to the bottom. This upper vessel communicates with the boiler, and constitutes the receiver of the steam-engine. The operation is as follows: The lower vessel is full of water. Steam is admitted into the upper vessel, which expels the air by a valve, and fills the vessel. It is then condensed by cold water. The pressure of the arm sphere would cause it to enter by all the suction-pipes of the different lifts, and pres on the surface of the water in the lower receiver, and force it into the upper one. But because each suction-pipe dips in a cistern of water, the air presses this water before it, raises it in each of the little receivers which it fills, and allows the spring of the air (which was formerly in them, but which now presses into the lower receiver) to force the water out of the lower receiver into the
upper one. When this has been completed, the steam is again admitted into the upper receiver. This allows the water to run back into the lower receiver, and the air returns into the small receivers in the pit, and allows the water to run out of each into its proper cistern. By this means the water of each pipe has been raised 15 feet. The operation may thus be repeated continually.

The contrivance is ingenious, and similar to some which are to be met with in the hydraulic works of Schottus, Sturmius, and other German writers. But the operation must be exceedingly slow; and we imagine that the expense of steam must be great, because it must fill a very large and very cold vessel, which must walsen a great portion of it by condensation. We see by some late publications of the very ingenious Mr. Blackey, that he is still attempting to maintain the reputation of this machine by some contrivance of this kind; but we imagine that it will be inefficient, except in some very particular situations.

For the great defect of the machine even when we can secure it against all risk of bursting, is the prodigious waste of steam, and consequently of fuel. Daily experience shows, that a few scattered drops of cold water is sufficient for producing an almost instantaneous condensation of a great quantity of steam. Therefore, when the steam is admitted into the receiver of Savary's engine, and comes into contact with the cold top and cold water, it is condensed with great rapidity; and the water does not begin to boil till its surface has become so hot that it condenses no more steam. It may now begin to yield the pressure of the incumbent steam; but as soon as it defends a little, more of the cold surface of the receiver comes into contact with the steam, and condenses more of it, and the water can defend no farther till this addition of cold surface is heated up to the state of evaporation. This rapid condensation goes on all the while the water is defending. By some experiments frequently repeated by the writer of this article, it appears that no less than $\frac{1}{4}$ ths of the whole steam is uselessly condensed in this manner, and not more than $\frac{1}{4}$ th is employed in allowing the water to defend by its own weight; and he has reason to think that the portion thus waisted will be considerably greater, if the steam be employed to force the water out of the receiver to any considerable height.

Observe, too, that all this waste must be repeated in every succeeding stroke; for the whole receiver must be cooled again in order to fill itself with water.

Many attempts have been made to diminish this waste, but all to little purpose, because the very filling of the receiver with cold water occasions its fides to condense a prodigious quantity of steam in the succeeding stroke. Mr. Blackey has attempted to lessen this by using two receivers. In the first water was cold; and into this only the steam was admitted. This oil paled to and fro between the two receivers, and never touched the water except in a small surface. But this hardly produced a sensible diminution of the waste: for it must now be observed, that there is a necessity for the first cylinder's being cooled to a considerable degree below the boiling point; otherwise, though it will condense much steam, and allow the water to rise into the receiver, there will be a great diminution of the height of fution, unless the vessel be much cooled. This appears plainly by inspecting the table of elasticity. Thus, if the vessel be cooled no lower than $150^\circ$, we should lose one half of the pressure of the atmosphere; if cooled to 150, we should still lose $\frac{1}{4}$ th. The inspection of this table is of great use for understanding and improving this noble machine; and without a constant recollection of the elasticity of steam corresponding to its actual heat, we shall never have a notion of the niceties of its operation.

The rapidity with which the steam is condensed is the above all astonishing. Experiments have been made on steam-vessels of six feet in diameter and seven feet high; and it has been found, that about four ounces of water are evaporated and converted into water, as warm as the human body, will produce a complete condensation in less than a second; that is, will produce all the condensation that it is capable of producing, leaving an elasticity about $\frac{1}{8}$ of the elasticity of the air. In another experiment with the same steam vessel, no cold water was allowed to get into it, but it was made to communicate by a long pipe four inches in diameter with another vessel immerged in cold water. The condensation was so rapid that the time could not be measured: it certainly did not exceed half a second. Now this condensation was performed by a very trifling surface of contact. Perhaps some may explain it a little in this way: When a mass of steam, in immediate contact with the cold water, is condensed, it leaves a void, into which the adorning steam instantly expands; and by this very expansion its capacity for heat is increased, or it grows cold, that is, abstracts the heat from the steam situated immediately beyond it. And in this expansion and refrigeration it is itself partly condensed or converted into water, and leaves a void, into which the circumjacent steam immediately expands, and produces the same effect on the steam beyond it. And thus it may happen that the abstraction of a small quantity of heat from an inconceivable mass of steam may produce a condensation which may be very extensive. Did we know the change made in the capacity of steam for heat by a given change of bulk, we should be able to tell exactly what would be the effect of this local actual condensation. But experiment: has not as yet given us any precise notions on this subject. We think that this rapid condensation to a great distance by a very moderate actual abstraction of heat is a proof that the capacity of steam for heat is prodigiously increased by expansion. We say a very moderate actual abstraction of heat, because very little heat is necessary to raise four ounces of blood-warm water to a boiling temperature, which will unfit it for condensing steam. The remarkable phenomenon of snow and ice produced in the Hungarian machine, when the air condensed in the receiver is allowed to blow over the cock (see Paronymy), flows this to be the case in moist air, that is, in air holding water in a state of chemical solution. We see something very like it in a thunder-storm. A small black cloud sometimes appears in a particular spot, and in a very few seconds spreads over many hundred acres of sky, that is, a precipitation of water goes on with that rapid diffusion. We imagine that this increase of capacity or demand for heat, and the condensation that must ensue if this demand is not supplied, is much more remarkable in pure watery vapours, and that this is a capital distinction of their constitution from vapours dissolvcd in air.
The reader must now be so well acquainted with what
patties in the steam-vent, and with the exterior retus
from it, as readily to comprehend the propriety of the
changes which we shall now describe as having been
made in the construction and principle of the steam
engine.

At all places in England the tin-mines of Cornwall
flood molt in need of hydraulic aiditude; and Mr Savary
was much engaged in projects for draining them by
his steam-engine. This made its construction and
principles well known among the machinists and engi-
neers of that neighbourhood. Among these were a
Mr Newcomen, an ironmonger or blacksmith, and Mr
Cawley a glazier at Dartmouth in Devonshire, who had
dabbled much with this machine. Newcomen was a
person of some reading, and was in particular
acquainted with the works, writings, and projects of his
countryman Dr Hooke. There are to be found among
Hooke's papers, in the possession of the Royal Society,
some notes of observations for the use of Newcomen and
his countryman. On Papin's boasted method of transmitting
to a great distance the action of a mill by means of pipes,
Papin's project was to employ the mill to work two air-
pumps of great diameter. The cylinders of these pumps
were to communicate by means of pipes with equal cy-
linders furnished with piltons, in the neighbourhood of
a diftant mine. These piltons were to be connected,
by means of levers, with the piston-rods of the mine.
Therefore, when the piston of the air-pump at the mill
was drawn up by the mill, the corresponding piston at
the side of the mine would be pressed down by the at-
mosphere, and thus would raise the piston-rod in the
mine. This made its appearance, and became known in his neighbourhood. Among these were a
Mr Newcomen, an ironmonger or blacksmith, and Mr
Cawley a glazier at Dartmouth in Devonshire, who had
dabbled much with this machine. Newcomen was a
person of some reading, and was in particular
acquainted with the works, writings, and projects of his
countryman Dr Hooke. There are to be found among
Hooke's papers, in the possession of the Royal Society,
some notes of observations for the use of Newcomen and
His countryman. On Papin's boasted method of transmitting
to a great distance the action of a mill by means of pipes,
Papin's project was to employ the mill to work two air-
pumps of great diameter. The cylinders of these pumps
were to communicate by means of pipes with equal cy-
linders furnished with piltons, in the neighbourhood of
a distant mine. These piltons were to be connected,
by means of levers, with the piston-rods of the mine.
Therefore, when the piston of the air-pump at the mill
was drawn up by the mill, the corresponding piston at
the side of the mine would be pressed down by the at-
mosphere, and thus would raise the piston-rod in the
mine, and draw the water. It would appear from these
notes, that Dr Hooke had diffused Mr Newcomen
from erecting a machine on this principle, of which he
had expounded the fallacy in several discourses before
the Royal Society. One passage is remarkable. "Could
he (meaning Papin) make a speedy vacuum under your
second piston, your work is done."

It is highly probable that, in the course of this spe-
culation, it occurred to Mr Newcomen that the vac-
um he so much wanted might be produced by steam,
and that this gave rise to his new principle and construc-
tion of the steam-engine. The specific defideratum was
in Newcomen's mind; and therefore, when Savary's en-
gine appeared, and became known in his neighbourhood
many years after, he would readily catch at the help
which it promised.

Savary however claims the invention as his own;
but Switzer, who was personally acquainted with both,
is positive that Newcomen was the inventor. By his
principles (as a quaker) being averse from contention,
he was contented to share the honour and the profits
with Savary, whose acquaintance at court enabled him to
procure the patent in 1705, in which all the three were
associated. Paffes has done justice to the modest in-
venter, and the machine is universally called Newco-
men's Engine. Its principle and mode of operation
may be clearly conceived as follows.

Let A (fig. 7.) represent a great boiler properly
built in a furnace. At a small height above it is a
cylinder CBBC of metal, bored very truly and smooth-
ly. The boiler communicates with this cylinder by
means of the throat or steam-pipe MQ. The lower
aperture of this pipe is shut by the plate N, which is
ground very flat, so as to apply very accurately to
the whole circumference of the office. This plate is
called the regulator or steam-cock, and it turns hori-
zontally round an axis b which passes through the top
of the boiler, and is nicely fitted to the socket, like the
key of a cock, by grinding. The upper end of this axis
is furnished with a handle t.

A piston P is suspended in this cylinder, and made
quite tight by a packing of leather or felt rope, well fill-
ded with tallow; and for greater security, a small quan-
tity of water is kept above the piston. The piston and
rod PD is suspended by a chain which is fixed to the upper
extremity F of the arched head FD of the great lever
or working beam HK, which turns on the gudgeon O.
There is a similar arched head FD at the other
end of the beam. To its upper extremity E is fixed a
chain carrying the pump rod XL, which raises the water
from the mine. The load on this end of the beam is
made to exceed considerably the weight of the piston P
at the other extremity.

At some small height above the top of the cylinder
is a cistern W called the injection cistern. From
this descends the injection pipe ZSR, which enters
the cylinder through its bottom, and terminates in a
small hole R, or sometimes in a nozzle pierced with
many smaller holes diverging from a centre in all di-
rections. This pipe has at a cock called the injection
cock, fitted with a handle V.

At the opposite side of the cylinder, a little below its
bottom, there is a lateral pipe, turning upwards at the
extremity, and there covered by a clack-valve f, called
the safety-valve, which has a little dial round it to hold water for keeping it airtight.

There proceeds also from the bottom of the cylinder
a pipe deg b (passing behind the boiler), of which the
lower end is turned upwards, and is covered with a valve
b. This part is immersed in a cistern of water Y, called
the hot well, and the pipe itself is called the
eduction pipe. Lastly, the boiler is furnished with a
safety-valve called the puppet clack (which is not
represented in this sketch for want of room), in the same
manner as Savary's engine. This valve is generally loaded
with one or two pounds on the square inch, so that
it allows the steam to escape when its elasticity is 16th
greater than that of common air. Thus all risk of
bursting the boiler is avoided, and the prejudice towards
very moderate; so also is the heat. For, by inspect-
ing the table of vaporous elasticity, we see that the
heat corresponding to 32 inches of elasticity is only
about 216° of Fahrenheit's thermometer.

There are all the essential parts of the engine, and
are here drawn in the most simple form, till our knowl-
dge of their particular offices shall show the prop-
erty of the peculiar forms which are given to them.
Let us now see how the machine is put in motion, and
what is the nature of its work.

The water in the boiler being supposed to be in a
state of strong ebullition, and the steam rising by the
machine a safety-valve, let us consider the machine in a state of
motion, and the nature of the work.

The retelling position or attitude of the machine must be
such as appears in this sketch, the pump rods propor-
tionating, and the great piston being drawn up to the top
of the cylinder. Now open the steam cock by turning the
handle T of the regulator. The steam from the
pelling force would be continually diminished, because the capacity of the cylinder is diminished by the defect of the piston, and the air in it is continually becoming more dense and elastic. The piston would stop at a certain height, where the elasticity of the included air, together with the load at E, would balance the atmospheric pressure on the piston. But when the contents of the cylinder are pure vapour, and the continued stream of injected cold water keeps down its temperature to the same pitch as at the beginning, the elasticity of the remaining steam can never increase by the defect of the piston, nor exceed what corresponds to this temperature. The impelling or accelerating force therefore remains the same, and the defect of the piston will be uniformly accelerated, if there is not an increase of refilience arising from the nature of the work performed by the other end of the beam. This circumstance will come under consideration afterwards, and we need not attend to it at present. It is enough for our present purpose to state, that if the cylinder has been completely purified of common air before the steam-cock was shut, and if none has entered since, the piston will descend to the very bottom of the cylinder. And this may be frequently observed in a good steam-engine where every part is air-tight. It sometimes happens, by the pit pump drawing air, or some part of the communication between the two straws giving way, that the piston comes down with such violence as to knock out the bottom of the cylinder with the blow.

The only observation which remains to be made is that the motion of the piston in descending is, that it does not begin at the instant the injection is made. The beginning of the descent of the outer end of the working beam, and it must remain there till the difference between the elasticity of the steam below it and the pressure of the atmosphere made.

There must therefore be a small space of time between the beginning of the condensation and the beginning of the motion. This is very small, not exceeding the third or the fourth part of a second; but it may be very distinctly observed by an attentive spectator. He will see, that the instant the injection-cock is opened, the cylinder will instantly rise upwards a little by the pressure of the air on its bottom. Its whole weight is not nearly equal to this pressure; and instead of its being necessary to support it by a strong floor, we must keep it down by strong struts loaded by heavy walls. It is usual to frame these struts into the goits which carry the axis of the working-beam, and are therefore loaded with the whole strain of the machine. This rising of the cylinder shows the instantaneous commencement of the condensation; and it is not till after this has been distinctly observed that the piston is seen to start, and begin to descend.

When the manager sees the piston as low as he thinks proper, he shuts the injection-cock, and opens the steam-cock. The steam has been accumulating above that filled the water in the boiler during the whole time of the piston's descent, and is now rushing violently through the puppet clack. The moment therefore that the steam-cock is opened, it rushes violently into the cylinder, having an elasticity greater than that of the air. It therefore immediately opens the diffusing valve, and allows (at least) the water which had come in by the former injection, and what arose from the condensation of it, to immediately rush in, and fly all over the surface of the cylinder, will mix with the air. Much of it will be condensed by the cold surface of the cylinder and piston, and the water produced from it will trickle down the sides, and run off by the eduction-pipe. This condensation and waste of steam will continue till the whole cylinder and piston are made as hot as boiling water. When this happens, the steam will begin to open the diffusing valve, and diffuse through the pipe; slowly at first, and very cloudy, being mixed with much air. The blast at D will grow stronger by degrees, and more transparent, having already carried off the greatest part of the common air which filled the cylinder. We supposed that the water was boiling briskly, so that the steam was diffusing through the safety-valve which is in the top of the boiler, and through every crevice. The opening of the steam-cock puts an end to this at once, and it has sometimes happened that the cold cylinder absorbs the steam from the boiler with such astonishing rapidity, that the pressure of the atmosphere has become greater than the bottom of the boiler. We may here mention an accident of which we were witnesses, which also shows the immense rapidity of the condensation. The boiler was in a state of fire at the side of the engine-house; a scoop of snow from the top of the house fell down and broke through the roof of the shed, and was scattered over the head of the boiler, which was of an oblong or oval shape. In an instant the sides of it were squeezed together by the pressure of the atmosphere.

When the manager of the engine perceives that not only the blast at the diffusing valve is strong and steady, but that the boiler is now full of steam with a proper strength, appearing by the renewal of the discharge at the safety-valve, he shuts the steam-cock, and opens the injection-cock S by turning its handle V. The pressure of the column of water in the injection-pipe ZS immediately forces some water through the stopper R. This coming in contact with the pure vapour which now fills the cylinder, condenses it, and thus makes a partial void, into which the more dilatant steam immediately expands, and by expanding collapses (as has been already observed). What remains in the cylinder can no longer balance the atmospheric pressure on the surface of the water in the injection-cylinder, and therefore the water spouts rapidly through the hole R by the joint action of the column ZS and the unbalanced pressure of the atmosphere; at the same time the lifting valve f and the eduction valve b are shut by the unbalanced pressure of the atmosphere. The velocity of the injection water must therefore rapidly increase, and the jet will dash (if figural) against the bottom of the piston, and be scattered through the whole capacity of the cylinder. In a very short space of time, therefore, the condensation of the steam becomes universal, and the elasticity of what remains is almost nothing. The whole pressure of the atmosphere is exerted upon the surface of the piston, while there is hardly any on its under side. Therefore, if the load on the outer end E of the working beam is inferior to this pressure, it must yield to it. The piston P must descend, and the pump piston L must ascend, bringing along with it the water of the mine, and the motion must continue till the great piston reaches the bottom of the cylinder; for it is not like the motion which would take place in a cylinder of air rarefied to the same degree. In this last case, the im-
Steam-Engine.

fed steam, to descend by its own weight through the eduction pipe d e g b to open the valve h, and to run out into the hot well. And we must easily see that this water is boiling hot; for while lying in the bottom of the cylinder, it will condense steam till it acquires this temperature, and therefore cannot run down till it condenses no more. There is still a waite of steam at its first admission, in order to heat the inside of the cylinder and the injected water to the boiling temperature: but the space being small, and the whole being already very warm, this is very soon done; and when things are properly contrived, little more steam is wanted than what will warm the cylinder; for the eduction-pipe receives the injection water even during the descent of the piston, and it is therefore removed pretty much out of the way of the steam.

This first puff of the entering steam is of great service: it drives out of the cylinder the vapour which it finds there. This is seldom pure watery vapour: all water contains a quantity of air in a state of chemical union. The union is but feeble, and a boiling heat is sufficient for disengaging the greatest part of it by increasing its elasticity. It may also be disengaged by simply removing the external pressure of the atmosphere. This is clearly seen when we expose a glass of water in an exhausted receiver. Therefore the small space below the piston contains watery vapour mixed with all the air which had been disengaged from the water in the boiler by ebullition and all that was separated from the injection water by the diminution of external pressures. All this is blown out of the cylinder by the first puff of steam. We may observe in this place, that waters differ exceedingly in the quantity of air which they hold in a state of solution. All spring water contains much of it; and water newly brought up from deep mines contains a great deal more, because the solution was aided in these situations by great pressures. Such waters sparkle when poured into a glass.

It is therefore of great consequence to the good performance of a steam-engine to use water containing little air, both in the boiler and in the injection-cylinder. The water of running brooks is preferable to all others, and the freer it is from any saline impregnation it generally contains less air. Such engines as are so fortunately situated that they are obliged to employ the very water which they have brought up from great depths, are found greatly inferior in their performance to others. The air collected below the piston greatly diminishes the accelerating force, and the expulsion of such a quantity requires a long continued blast of the bell steam at the beginning of every stroke. It is advisable to keep such water in a large shallow pond for a long while before using it.

Let us now consider the state of the piston. It is evident that it will start or begin to rise the moment the steam-cock is opened; for at that instant the excess of atmospheric pressure, by which it was kept down in opposition to the preponderancy of the outer end of the beam, is diminished. The piston is therefore dragged upwards, and it will rise even although the steam which is admitted be not so elastic as common air. Suppose the mercury in the barometer to stand at 30 inches, and that the preponderancy at the outer end of the beam in fifth of the pressure of the air on the piston, the piston will not rise if the elasticity of the beam is not equal to \( \frac{30}{5} \); that is, to 6 inches nearly; but if it is just this quantity, the piston will rise as fast as this steam can be supplied through the steam-pipe, and the velocity of its ascent depends entirely on the velocity of this supply. This observation is of great importance; and it does not seem to have occurred to the mathematicians, who have paid much attention to the mechanism, and the motion of this engine. In the mean time, we may clearly see that the entry of the steam depends chiefly on the counter weight at E; for suppose there was none, steam no stronger than air would not enter the cylinder at all; and if the beam be stronger, it will enter only by the excess of its strength. Writers on the steam-engine (and even some of great reputation) familiarly speak of the steam giving the piston a push: but this is far from being possible. During the rise of the piston the shutting valve is never observed to blow; and we have not heard any well attested accounts of the piston-chains ever being blackened by the upward preasure of the steam, even at the very beginning of the stroke. During the rising of the piston the steam is (according to the common conception and manner of speaking) "fueled in," in the same way that air is sucked into a common fire-engine or pump when we draw up the piston; for in the steam engine the piston is really drawn up by the counter weight. It is still more sucked in, and requires a more copious supply, for another reason. As the piston descended only in consequence of the inside of the cylinder's being sufficiently cooled to condense the steam, this cooled surface must again be presented to the steam during the rise of the piston, and must condense steam a second time. The piston cannot ride another inch till the part of the cylinder which the piston has already emptied has been warmed up to the boiling point, and steam must be expended in this warming. The inner surface of the cylinder is not only of the heat of boiling water while the piston rides, but is also perfectly dry; for the film of water left on it by the ascending piston must be completely evaporated, otherwise it will be condensing steam. That the quantity thus wafted is considerable, appears by the experiments of Mr. Blyton. He found that five pints of water were boiled off in a minute, and produced 16 strokes of an engine whose cylinder contained 113 gallons of 282 inches each; and he thence concluded that steam was 2885 times rarer than water. But in no experiment made with scrupulous care on the expansion of boiling water does it appear that the density of steam exceeds \( \frac{1}{16,000} \) that of the density of water. Dufaguliers says that it is above 14,000 times rarer than water. We have frequently attempted to measure the weight of steam which filled a very light vessel, which held 12,600 grains of water, and found it always less than one grain ½; that we have no doubt of its being much more than 10,000 times rarer than water. This being the case, we may safely supposit the number of gallons of steam, instead of being 16 times 113, were nearly five times as much; and that only ¼th were employed in allowing the piston to rise, and the remaining ¾th were employed to warm the cylinder.

The moving force during the ascent of the piston must be considered as resulting chiefly, if not solely, from the preponderating weight of the piston-rods. The office of this is to return the steam-piston to the top.
top of the cylinder, where it may again be pressed down by the air, and make another working stroke by raising the pump rods. But the counter-weight at E has another service to perform in this use of the engine; namely, to return the pump pistons into their places at the bottom of their respective working barrels, in order that they also may make a working stroke. This requires force independent of the friction and inertia of the moving parts; for each piston must be pushed down through the water in the barrel, which must rise through the piston with a velocity whose proportion to the velocity of the piston is the same with that of the bulk of the water through which the water rises through the piston. It is enough at present to mention this in general terms: we shall consider it more particularly afterwards, when we come to calculate the performance of the engine, and to deduce from our acquired knowledge maxims of construction and improvement.

From this general consideration of the ascent of the piston, we may see that the motion differs greatly from the descent. It can hardly be supposed to accelerate, even if the steam in the cylinder were in a moment annihilated. For the resistance to the descent of the piston is the same with the weight of the column of water, which would cause it to flow through the box of the pump piston with the velocity with which it really rises through it, and must therefore increase as the square of that velocity increases; that is, as the square of the velocity of the piston increases. Independent of friction, therefore, the velocity of descent through the water must soon become a maximum, and the motion become uniform. We shall see by and by, that in such a pump as is generally used this will happen in less than the tenth part of a second. The friction of the pump will diminish this velocity a little, and retard the time of its attainment uniformity. But, on the other hand, the supply of steam which is necessary for this motion, being susceptible of no acceleration from its previous motion, and depending entirely on the briskness of the ebullition, an almost instantaneous stop is put to acceleration.

Accordingly, any person who observes with attention the working of a steam-engine, will see that the rise of the piston and descent of the pump-rods is extremely uniform, whereas the working stroke is very sensibly accelerated. Before quitting this part of the subject, and left it should afterwards escape our recollection, we may observe that the counter weight is different during the two motions of the pump-rods. While the machine is making a working stroke, it is lifting not only the column of water in the pump, but the absolute weight of the pistons and piston-rods also: but while the pump-rods are descending, there is a diminution of the counter weight by the weight of water; the immersion of the rod in water. The wooden rods which are generally used, soaked in water, and joined by iron straps, are heavier, and but a little heavier than water, and they are generally about one-third of the bulk of the water in the pumps.

These two motions complete the period of the operation; and the whole may be repeated by shutting the steam cock and opening the injection-cock whenever the piston has attained the proper height. We have been very minute in our attention to the different circumstances, that the reader may have a distinct notion of the state of the moving forces in every period of the operation. It is by no means sufficient that we know in general that the injection of cold water makes a void which allows the air to press down the piston, and that the readmission of the steam allows the piston to rise again. This lumping and steady way of viewing it has long prevented even the philosopher from seeing the defects of the construction, and the methods of removing them.

We now see the great difference between Savary's Difference and Newcomen's engine in respect of principle. Savary's was really an engine which raised water by the force of steam; but Newcomen's raised water entirely by the pressure of the atmosphere, and steam is employed merely as the most expedient method of producing a void, into which the atmospheric pressure may impel the first water of his machine. The efficacy of the steam is not the first mover.

We see also the great superiority of this new machine. We have no need of steam of great and dangerous power, and we operate by means of very moderate heat, and consequently with much smaller quantities of fuel; and there is no bounds to the power of this machine. How deep forever a mine may be, a cylinder may be employed of such dimensions that the pressure of the air on its piston may exceed in any degree the weight of the column of water to be raised. And lastly, this form of the machine renders it applicable to almost every mechanical purpose; because a skilful mechanic can readily find a method of converting the reciprocating motion of the working beam into a motion of any kind which may suit his purpose. Savary's engine could hardly admit of such an immediate application, and seems almost restricted to raising water.

Inventions improve by degrees. This engine was gradually first offered to the public in 1705. But many difficulties occurred in the execution, which were removed one by one; and it was not till 1712 that the engine seemed to give confidence in its efficacy. The most exact and unremitting attention of the manager was required to the precise moment of opening and shutting the cocks; and neglect might frequently be ruinous, by beating out the bottom of the cylinder, or allowing the piston to be wholly drawn out of it. Stops were contrived to prevent both of these accidents; then springs were used to connect the handles of the cocks with the beam, so that they should be turned whenever it was in certain positions. Thence were gradually changed and improved into detents and catches of different shapes; at last, in 1717, Mr. Beighton, a very ingenious and well informed artist, simplified the whole of these subordinate movements, and brought the machine into the form in which it has continued, without the smallest material change, to the present day. We shall now describe one of their improved engines, copying almost exactly the drawings and description given by Boffit in his Hydrodynamique; these being by far the most accurate and perspicuous of any that have been published.

Fig. 8. no. 1. is a perspectival view of the boiler cylinder, and all the parts necessary for turning the cocks. Fig. 8. no. 2. is a vertical section of the same; and the same pieces of both are marked with the same letters of reference.
The rod $X$ of the piston $P$ is suspended from the arch of the working-beam, as was represented in the preceding sketch (fig. 7). An upright bar of timber FG is also seen hanging by a chain. This is suspended from a concentric arch of the beam, as may be seen also in the sketch at $a$. This bar is called the plug-beam, and it must rise and fall with the piston, but with a slower motion. The use of this plug-beam is to give motion to the different pieces which turn the cocks.

The steam pipe $K$ is of one piece with the bottom of the cylinder, and rises within it an inch or two, to prevent any of the cold injection water from falling into the boiler. The lower extremity $Z$ of the steam-pipe penetrates the head of the boiler, projecting a little way. A flat plate of brass, in shape resembling a racket or battledore, called the regulator, applies itself exactly to the whole circumference of the steam-pipe, and completely excludes the steam from the cylinder. Being moveable round an upright axis, which is represented by the dotted lines at the side of the steam-pipe in the profile, it may be turned aside by the handle $i$, no. 1. The profile shows in the section of this plate a protrusion in the middle. This rolls on a strong flat spring, which is fixed below it at the mouth of the steam-pipe. This spring presses it strongly towards the steam-pipe, cauSing it to apply very close; and this knob slides along the spring, while the regulator turns to the right or left.

We have said that the injection water is furnished from a cistern placed above the cylinder. When this cistern cannot be supplied by pipes from some more abundant source, its water is raised by the machine itself. A small lifting pump $i k$ (fig. 7.), called the jack-bore or jacquettée, is worked by a rod $r$, suspended from a concentric arch near the outer end of the working beam. This forces a small portion of the pit water along the rising pipe $L M$ into the injection cistern.

In figure 8. no. 1 and 2. the letters $Q M$' represent the pipe which brings down the water from the injection cistern. This pipe has a cock at $K$ to open or shut the passage of this water. It spurts through the jet $j$, and dashing against the bottom of the piston, it is dispersed into drops, and scattered through the whole capacity of the cylinder, so as to produce a rapid condensation of the steam.

An upright post $A$ may be observed in the perspective view of the cylinder, &c. This supports one end $B$ of a horizontal iron axis $BC$. The end $C$ is supported by a similar post, of which the place only is marked by the dotted lines $A_{1}$, that the pieces connected with this axis may not be hid by it. A kind of flirrup $a b c d$ hangs from this axis, supported by the hooks $a$ and $d$. This flirrup is crooked near the bottom by a round bolt or bar, which passes through the eyes or rings that are at the ends of the horizontal fork $b f g$, whose long tail $k$ is double, receiving between its branches the handle $i$ of the regulator. It is plain from this construction, that when the flirrup is made to vibrate round the horizontal axis $BC$, on which it hangs freely by its hooks, the bolt $e$ must pull or push the long fork $b f g$ backwards and forwards horizontally, and by so doing will move the regulator round its axis, by means of the handle $i$. Both the tail of the fork and the handle of the regulator are pierced with several holes, and a pin is put through them which unites them by a joint. The motion of the handle may be increased or diminished by choosing for the joint a hole near to the axis or remote from it: and the exact position at which the regulator is to stop on both sides is determined by pins stuck in the horizontal bar on which the end of the handle appears to rest.

This alternate motion of the regulator to the right and left is produced as follows: There is fixed to the axis BC a piece of iron $o k$, called the Y, on account of its resemblance to that letter of the alphabet inverted. The flirrup $o$ carries a heavy lump $p$ of lead or iron; and a long leather strap $q r$ is fastened to $p$ by the middle, and the two ends are fastened to the beam above it, in such a manner that the lump may be alternately caught and held up to the right and left of the perpendicular. By adjusting the length of the two parts of the flirrup, the Y may be stopped in any desired position. The two claws $k$ and $l$ spread out from each other, and from the line of the flirrup, and they are of such length as to reach the horizontal bolt $e$, which crosses the flirrup below, but not to reach the bottom of the fork $b f g$. Now suppose the flirrup hanging perpendicularly, and the flirrup of the Y also held perpendicularly; carry it a littleeward from the cylinder, and then let it go. It will tumble farther out by its weight, without affecting the flirrup till the claw $l$ strikes on the horizontal bolt $e$, and then it pushes the flirrup and the lock towards the cylinder, and opens the regulator. It sets it in motion with a smart jerk, which is an effectual way of overcoming the cohesion and friction of the regulator with the mouth of the steam-pipe. This pull is adjusted to a proper length by the strap $g p$, which stops the Y, when it has gone far enough. If we now take hold of the flirrup of the Y, and move it up to the perpendicular, the width between its claws is such as to permit this motion, and something more, without affecting the flirrup. But when pushed still nearer to the cylinder, it tumbles towards it by its own weight, and then the claw $k$ strikes the bolt $e$, and drives the flirrup and fork in the opposite direction, till the lump $p$ is caught by the strap $r$, now stretched to its full length, while $q r$ hangs slack. Then by the motion of the Y the regulator is opened and shut. Let us now see how the motion of the Y is produced by the machine itself. To the horizontal axis $BC$ are attached two spanners or handles $w$ and $u$. The spanner $w$ passes through a long slit in the plug-beam, and is at liberty to move upwards or downwards by its motion round the axis $EC$. A pin $t$, which goes through the plug-beam catches hold of $w$ when the beam rides along with the piston; and the pin is so placed, that when the beam is within an inch or two of its highest rise, the pin has lifted $m$ and thrown the flirrup of the Y past the perpendicular. It therefore tumbles with great force, and gives a smart blow to the fork, and immediately shuts the regulator. By this motion the spanner $m$ is removed out of the neighborhood of the plug-beam. But the spanner $m$, moving along with it in the same direction, now comes into the way of the pins of the plug-beam. Therefore, when the piston descends again by the condensation of the steam in the cylinder, a pin marked $U$ in the side of the plug-beam catches hold of the tail of the spanner $m$, and by prising it down raises the lump on the flirrup.
flask of the Y till it passes the perpendicular, and it then falls down, outwards from the cylinder, and the claw of the fork in the direction b, and opens the steam valve. This opening and shutting of the steam valve is executed in the precise moment that is proper, by placing the pins x and y at a proper height in the plug-beam. For this reason, it is pierced through with a great number of holes, that the places of these pins may be varied at pleasure. This, and a proper curvature of the spanners w and n, make the adjustment as nice as we please.

The injection-ock R is managed in a similar manner. On its key may be observed a forked arm t, like a crab’s claw; at a little distance above it is the gudgeon or axis u of a piece y u z, called the hammer or the F, from its resemblance to that letter. It has a lump of metal y at one end, and a spear u projects from its middle, and pokes between the claws t and l of the arm of the injection-ock. The hammer y is held up by a notch in the underside of a wooden lever DE, moveable, and in line with the centre D, and supported at a proper height by a string E made fast to the joint above it.

Suppose the injection-ock shut, and the hammer in the position represented in the figure. A pin b of the plug-frame rises along with the piston, and catching hold of the detent DE, raises it, and difengages the hammer y from its notch. This immediately falls down, and strikes a board L, set in the way to stop it. The spear u, t, takes hold of the claw t, and forces it aside towards x, and opens the injection-ock. The piston immediately descends, and along with it the plug-frame. During its descent the pin b meets with the tail u z of the hammer, which is now raised considerably above the level, and brings it down along with it, raising the lump y, and gradually shutting the injection-ock, because the spear takes hold of the claw s of its arm. When the beam has come to its lowest situation, the hammer is again engaged in the notch of the detent DE, and supported by it till the piston again reaches the top of the cylinder.

In this manner the motions of the injection-ock are also adjusted to the precise moment that is proper for them. The different pins are so placed in the plug-frame, that the steam-ock may be completely shut before the injection-ock is opened. The inherent motion of the machine will give a small addition to the ascent of the piston without expending steam all the while; and by leaving the steam rather less elastic than before, the subsequent descent of the piston is promoted. There is a considerable propriety in the gradual shutting of the injection-ock. For after the first dash of the cold water against the bottom of the piston, the condensation is nearly complete, and very little more water is needed; but a continual accession of force is absolutely necessary for completing the condensation, as the capacity of the cylinder diminishes, and the water warms which is already injected.

In this manner the motion of the machine will be repeated as long as there is a supply of steam from the boiler, and of water from the injection-ock, and a discharge procured for what has been injected. We proceed to consider how these conditions also are provided by the machine itself.

The injection-ock is supplied with water by the jack-head-pump, as we have already observed. From this source all the parts of the machine receive their respective supplies. In the first place, a small branch 13, 13, is taken off from the injection-pipe immediately below the cistern, and conducted to the top of the cylinder, where it is furnished with a cock. The spout is so adjusted, that no more runs from it than what will keep a constant supply of a foot of water above the piston to keep it tight. Every time the piston comes to the top of the cylinder, it brings this water along with it, and the surplus of its evaporation and leakage runs off by a waste pipe 14, 14. This water necessarily becomes almost boiling hot, and it was thought proper to employ its overflow for supplying the waste of the boiler.

This was accordingly practised for some time; but Mr. Brighton improved this economical thought, by supplying the boiler from the eduction-pipe 2, 2, the water of which must be still hotter than that above the piston. This contrivance required attention to many circumstances, which the reader will understand by considering the perspective and profile. The eduction-pipe comes out of the bottom of the cylinder at 1 with a perpendicular part, which bends sidewise below, and is fast at the extremity 1. A deep cup 5 communicates with it, holding a metal valve nicely fitted to it by grinding, like the key of a cock. To secure its being always air-tight, a slender stream of water trickles into it from a branch 6 of the waste pipe from the top of the cylinder. The eduction-pipe branches off at 2, and goes down to the hot well, where it turns up, and is covered with a valve. In the perspective view may be observed an upright pipe 4, 4, which goes through the head of the boiler, and reaches to within a few inches of its bottom. This pipe is called the feeder, and rises about three or four feet above the boiler. It is open at both ends, and has a branch 3, 3, communicating with the bottom of the cup 5, immediately above the metal valve, and also a few inches below the level of the entry 2 of the eduction-pipe. This communicating branch has a cock by which its passage may be diminished at pleasure. Now suppose the steam in the boiler to be very strong; it will cause the boiling water to rise in the feeding pipe above 3, and coming along this branch, to rise also in the cup 5, and run over. But the height of this cup above the surface of the water in the boiler is such, that the steam is never strong enough to produce this effect. Therefore, on the contrary, any water that may be in the cup 5 will run off by the branch 3, 3, and go down into the boiler by the feeding pipe.

The things being understood, let us suppose an ingenuity contrivance.

An ingenuity contrivance.

No. 752
may be immediately taken even from a cold cistern, without fentiely diminishing the production of steam: for the quantity of heat necessary for raising the sensible heat of cold water to the boiling temperature is quite insignificant, when compared with the quantity of heat which must then be combined with it in order to convert the water into steam. No difference can be observed in the performance of such engines and of those in which the boilers are supplied from a brook. It has, however, the advantage of being purged of air; and when an engine must derive all its supplies from pit water, the water from the education-pipe is vastly preferable to that from the top of the cylinder.

We may here observe, that many writers (among them the Abbé Boulain), in their descriptions of the steam-engine, have drawn the branch of communication 3, 3, from the feeding pipe to a part of the crooked pipe 1, 1, lying below the valve in the cup 5. But this is quite erroneous; for, in this case, when the injection is made into the cylinder, and a vacuum produced, the water from the boiler would immediately rush up thro' the pipes 4, 3, and spout up into the cylinder; so would the external air coming in at the top of the feeder.

This contrivance has also enabled us to form some judgment of the internal state of the engine during the performance. Mr. Boulain points a minute attention to the situation of the water in the feeders and education-pipe of an engine, which seems to have been one of the best which has yet been erected. It was lifting a column of water whose weight was 4ths of the prejure of the air on its piston, and made 16 strokes, of 6 feet each, in a minute. This is acknowledged by all to be a very great performance of an engine of this form. He concluded that the elasticity of the steam in the cylinder was never more than one-tenth greater or less than the elasticity of the air. The water in the feeder never rose more than three feet and a half above the surface of the boiling water, even though it was now lighter by 4ths than cold water. The education-pipe was only 4¼ feet long (vertically), and yet it always discharged the injection water completely, and allowed some to pass into the feeder. This could not be if the steam was much more than 4ths weaker than air. By drawing this pipe in his hand during the rise of the piston, he could guide very well whereabouts the surface of the hot water in it raised during the motion, and he never found it supported so high as four feet. Therefore the steam in the cylinder had at least 4ths of the elasticity of the air.

Mr. Buat, in his examination of an engine which is erected at Montrelaix, in France, by an English engineer, and has always been considered as the pattern in that country, finds it necessary to suppose a much greater variation in the strength of the steam, and says that it must have been 5ths stronger and 4ths weaker than common air. But this engine has not been nearly so perfect. Its lift was not more than 4 of the prejure of the atmosphere, and it made but nine strokes in a minute. At W is a valve covering the mouth of a small pipe, and surrounded with a cup containing water to keep it air-tight. This allows the air to escape which had been extracted from the water of latt injection. It is driven out by the first strong puff of steam which is admitted into the cylinder, and makes a noise in its exit. This valve is therefore called the snuffing valve.

To finish our description, we observe, that besides the safety valve (called the PUPPET-CLACK), which is loaded with about 3 pounds on the square inch (though the engine will work very well with a load of 1 or 2 pounds), there is another DISCHARGER IN, TO, having a clack at its extremity supported by a cord. Its use is to discharge the steam without doors, when the machine gives over working. There is also a pipe B near the bottom of the boiler, by which it may be emptied when it needs repairs or cleaning.

There are two small pipes 11, 11, and 12, 12, with cocks called GAGE-PIPES. The first descends to within two inches of the surface of the water in the boiler, and the second goes about 2 inches below that surface. If both cocks emit steam, the water is too low, and requires a recruit. If neither give steam, it is too high, and there is not sufficient room above it for a collection of steam. Lastly, there is a filling pipe Q, by which the boiler may be filled when the machine is to be let to work.

The engine has continued in this form for many years. The only remarkable change introduced has been the manner of placing the boiler. It is no longer placed below the cylinder, but at one side, and the piston is introduced by a pipe from the top of the boiler into a flat box immediately below the cylinder. The use of the box is merely to lodge the regulator, and give room for its motions. This has been a very considerable improvement. It has greatly reduced the height of the building. This was formerly a tower. The wall which supported the beam could hardly be built with sufficient strength for withstanding the violent shocks which were repeated without ceasing; and the buildings seldom lasted more than a very few years. But the boiler is now set up in an adjoining shed, and the gudgeons of the main beam rest on the top of upright posts, which are framed into the joists which support the cylinder. Thus the whole moving parts of the machine are contained in one compact frame of carpentry, and have little or no connection with the flight walls of the building, which is merely a case to hold the machine, and protect it from the weather.

It is now time to inquire what is to be expected from this machine, and to ascertain the most advantageous proportion between the moving power and the load that is to be laid on the machine.

It may be considered as a great pulley, and is indeed sometimes so constructed, the arches at the ends of the working beam being completed to a circle. It must be unequally loaded that it may move. It is loaded, during the working stroke, by the prejure of the atmosphere on the piston side, and by the column of water to be raised and the pump-gear on the pump side. During the returning stroke it is loaded, on the piston side, by a small part of the atmospheric prejure, and on the pump side by the pump gear acting as a counter weight. The load during the working stroke must therefore consist of the column of water to be raised and this counter weight. The performance of the machine is to be measured only by the quantity of water raised in a given time to a given height. It varies, therefore, in the joint proportion of the weight of the column of water in the pumps, and the number of strokes made by the machine in an hour. Each stroke consists of two parts, which we have called the working and the returning stroke. It does not, therefore, depend simply on the velocity of the working stroke and the
quantity of water raised by it. If this were all that is to be attended to, we know that the weight of the column of water should be nearly 3/4ths of the preijure of the atmosphere, this being the proportion which gives the maximum in the common pulley. But the time of the returning stroke is a necessary part of the whole time elapsed, and therefore the velocity of the returning stroke equally merits attention. This is regulated by the counter weight. The number of strokes per minute does not give an immediate proof of the goodness of the engine. A small load of water and a great counter weight will ensure this, because these conditions will produce a brisk motion in both directions.

The proper adjustment of the preijure of the atmosphere on the piston, the column of water to be raised, and the counter weight, is a problem of very great difficulty; and mathematicians have not turned much of their attention to the subject, although it is certainly the most interesting question that practical mechanics affords them.

Mr. Boffut has solved it very short"y and simply, upon this supposition, that the working and returning stroke should be made in equal times. This, indeed, is generally aimed at in the erection of these machines, and they are not reckoned to be well arranged if it be otherwise. We doubt of the propriety of the maxim. Supposing, however, this condition for the present, we may compute the loadings of the two ends of the beam as follows. Let \( a \) be the length of the inner arm of the working beam, or that by which the great piston is supported. Let \( b \) be the outer arm carrying the pump rods, and let \( W \) be a weight equivalent to all the load which is laid on the machine. Let \( c \) be the area of the piston; let \( H \) be the height of a column of water having \( c \) for its base, and being equal in weight to the preijure exerted by the beam on the under side of the piston; and let \( b \) be the preijure of the atmosphere on the same area, or the height of a column of water of equal weight. It is evident that both strokes will be performed in equal times, if \( h^2 = x^2 = \frac{2W}{bW} \) be equal to \((b - H)^2 \cdot \frac{1}{a^2} \). The first of these quantities is the energy of the machine during the working stroke, and the second expresses the similar energy during the returning stroke. This equation gives us \( W = \frac{a^2 b^2 - H c^2 a}{2} - \frac{2W}{b} \).

If we suppose the arms of the lever equal and \( H = b \), we have \( W = \frac{a^2 b^2}{2} \); that is, the whole weight of the outer end of the beam should be half the preijure of the air on the great piston. This is nearly the usual practice; and the engineers express it by saying, that the engine is loaded with seven or eight pounds on the square inch. This has been found to be nearly the most advantageous load. This way of expressing the matter would do well enough, if the maxim were not founded on erroneous notions, which hinder us from seeing the flate of the machine, and the circumstances on which its improvement depends. The piston bears a preijure of 15 pounds, it is laid, on the square inch, if the vacuum below it be perfect; but as this is far from being the case, we must not load it above the power of its vacuum, which very little exceeds eight pounds. But this is very far from the truth. When the cylinder is tight, the vacuum is not more than \( \frac{1}{40} \)th deficient, when the cylinder is cooled by the injection to the degree that is every day practicable, and the piston really bears during its descent a preijure very near to 14 pounds on the inch. The load must be diminished, not on account of the imperfect vacuum, but to give the machine a reasonable motion. We must consider not only the moving force, but also the quantity of matter to be put in motion. This is so great in the steam-engine, that even if it were balanced, that is, if there were suspended on the piston arm a weight equal to the whole column of water and the counter weight, the full preijure of the atmosphere on the steam piston would not make it move twice as fast as it does.

This equation by Mr. Boffut is moreover essentially And faulty in another respect. The \( W \) in the first member of an other resist is not the same with the \( W \) in the second. In the first it is the column of water to be raised, together with the counter weight. In the second it is the counter weight only. Nor is the quantity \( H \) the same in both cases, as is most evident. The proper equation for expressing the equal duration of the two strokes may be had in the following manner. Let it be determined by experiment what portion of the atmospheric preijure is exerted on the great piston during its descent. This depends on the remaining elasticity of the steam. Suppose it \( \frac{1}{2} \)th; this we may express by \( ab \), \( a \) being \( = \frac{1}{2} \)s. Let it also be determined by experiment what portion of the atmospheric preijure on the piston remains unbalanced by the steam below it during its ascent. Suppose this \( \frac{1}{4} \)th, we may express this by \( bb \). Then let \( W \) be the weight of the column of water to be raised, and \( e \) the counter weight. Then, if the arms of the beam are equal, we have the energy during the working stroke \( = ab - W - c \), and during the returning stroke \( = c - bb \). Therefore \( e = bb = a = \frac{W - c}{2} \). Let \( c = \frac{(a + b)}{2} - W \), which, on the above supposition of the values of \( a \) and \( b \), gives us \( e = \frac{W}{2} \).

We shall make some use of this equation afterwards; but it affords us no information concerning the most advantageous proportion of \( b \) and \( W \), which is the material point.

We must consider this matter in another way. And that we may not involve ourselves in unnecessary difficulties, let us make the case as simple as possible, and suppose the arms of the working-beam to be of equal length.

We shall first consider the adjustment of things at the outer end of the beam.

Since the sole use of the steam is to give room for the action of the atmospheric preijure by its rapid condensation, it is admitted into the cylinder only to allow the piston to rise again; but without giving it any impulse. The pump-rods must therefore be returned to the bottom of the working barrels by means of a preponderancy at the outer end of the beam. It may be the weight of the pump-rods themselves, or may be considered as making part of this weight. A weight at the end of the beam will not operate on the rods which are suspended there by chains, and it must therefore be attached to the rods themselves, but above their respective pump-barrels, so that it may not lose part of its efficacy by immersion in the water. We may consider the whole under the notion of the pump-gear, and call it \( p \). Its office is to depress the pump-rods with sufficient
Steam-Engine.

1. From the inertia of the beams and all the parts of the apparatus which are in motion during the descent of the pump-rods.
2. From the loss of weight obtained by the immersion of the pump-rods in water.
3. From the friction of all the pillars and the weight of the plug-frame.
4. From the resistance to the piston's motion, arising from the velocity which must be generated in the water in passing through the descending pistons.

The sum of all these resistances is equal to the pressure of some weight (as yet unknown), which we may call \( m \).

When the pump-rods are brought up again, they bring along with them a column of water, whose weight we may call \( w \).

It is evident that the load which must be overcome by the pressure of the atmosphere on the steam piston consists of \( w \) and \( m \). Let this load be called \( L \), and the pressure of the air be called \( P \).

If \( P = L \), no water will be raised; if \( P = m \), the rods will not descend; therefore there is some intermediate value of \( P \) which will produce the greatest effect.

In order to discover this, let \( g \) be the fall of a heavy body in a second.

The descending mass is \( P \); but it does not descend with its full weight; because it is overcoming a set of resistances which are equivalent to a weight \( m \), and the moving force is \( P - m \). In order to discover the space through which the rods will descend in a second, when urged by the force \( P - m \) (supposed constant, notwithstanding the increase of velocity, and consequently of \( m \)), we must institute this proportion \( P - m = g \cdot \frac{L}{P} \).

The fourth term of this analogy is the space required.

Let \( t \) be the whole time of the descent in seconds.

Then \( t = \frac{L}{P} : \frac{L}{P} \cdot \frac{P}{P} \cdot \frac{P}{P} \cdot \frac{P}{P} \).

This last term is the whole descent or length of the stroke accomplished in the time \( t \).

The weight of the column of water, which has now got above the piston, is \( w = L - P \). This must be lifted in the next working stroke through the space \( \frac{L}{P} \cdot \frac{P}{P} \cdot \frac{P}{P} \).

Therefore the performance of the engine

must be \( \frac{L}{P} \cdot \frac{P}{P} \cdot \frac{P}{P} \cdot \frac{P}{P} \).

That this may be the greatest possible, we must consider \( P \) as the variable quantity, and make the fluxion of the fraction \( \frac{P}{P} \cdot \frac{L}{P} = a \).

This will be found to give us \( P = \sqrt{Lm} \); that is, the counter weight or preponderancy of the outer end of the beam is \( \sqrt{Lm} \).

This gives us a method of determining \( m \) experimentally. We can discover by actual measurement the quantity \( L \) in any engine, it being equal to the unbalanced weights on the beam and the weight of the water in the pumps. Then \( m = \frac{L}{L} \).

Also we have the weight of the column of water

\( = L - P = \sqrt{Lm} \).

When therefore we have determined the load which is to be on the outer end of the beam during the working stroke, it must be distributed into two parts, which have the proportion of \( \sqrt{Lm} \) to \( L - \sqrt{Lm} \). The first is the counter weight, and the second is the weight of the column of water.

If \( m \) is a fraction of \( L \), such as an aliquot part of it, that is, if

\[
\frac{m}{L} = \frac{1}{1}, \frac{1}{2}, \frac{1}{3}, ... \frac{1}{n}
\]

The circumstance which is commonly obtruded on us by local considerations is the quantity of water, and the depth from which it is to be raised; that is, \( w \), and it will be convenient to determine every thing in conformity to this.

We find that \( w = \sqrt{Lm} \). This gives us \( L = \sqrt{m^2 + m^2 + m^2 + m^2} \) and the counter weight

\( P = \sqrt{2m^2 + m^2 + m^2 + m^2} \).

Having thus ascertained that distribution of the load on the outer end of the beam, which produces the greatest effect, we come now to consider what proportion of moving force we must apply, so that it may be employed to the best advantage, or so that any expense of ed to the power may produce the greatest performance. It will be so much the greater as the work done is greater, and the power employed is less; and will therefore be properly measured by the quotient of the work done divided by the power employed.

The work immediately done is the lifting up the weight \( L \). In order to accomplish this, we must employ a pressure \( P \), which is greater than \( L \). Let it be \( L + \gamma \); also let \( \gamma \) be the length of the stroke.

If the mass \( L \) were urged along the space \( \gamma \) by the force \( L + \gamma \), it would acquire a certain velocity, which we may express by \( \sqrt{\gamma} \); but it is impelled only by the force \( \gamma \), the rest of \( P \) being employed in balancing \( L \). The velocities which different forces generate by impelling a body along the same space are as the square roots of the forces. Therefore \( \sqrt{L + \gamma} : \gamma = \gamma : \sqrt{\gamma} \).

The fourth term of this analogy expresses the velocity of the piston at the end of the stroke. The quantity of motion produced will be had by multiplying this velocity by the mass \( L \). This gives \( L \times \sqrt{\gamma} \) and this, divided by the power expended, or by \( L + \gamma \), gives us the measure of the performance; namely, \( \frac{L \times \sqrt{\gamma}}{L + \gamma} \).

That this may be a maximum, consider \( \gamma \) as the variable
riable quantity, and make the fluxion of this formula

\[ \frac{dy}{dx} = a. \]

This will give us \( y = \frac{L}{x} \).

Now \( P = L + y = L + \frac{L}{x} = \frac{1}{2} L \). Therefore the

whole load on the outer end of the beam, confisting of
the water and the counter weight, must be \( 3d \) of the
pressure of the atmosphere on the steam piston.

We have here supposed that the expenditure is the
atmospheric pressure; and so it is if we consider it me-
chanically. But the expenditure of which we are sen-
sible, and which we are anxious to employ to the best
advantage, is fuel. Supposing this to be employed with
the fame judgment in all cases, we are almost intitled,
by what we now know of the production of steam, to
say that the steam produced is proportional to the fuel
expended. But the beam requisite for merely filling
the cylinder is proportional to the area of the piston,
and therefore to the atmospheric pressure. The result
of our investigation therefore is still just; but the beam
wafted by condensation on the fides of the cylinder does
not follow this ratio, and this is more than what is nec-
esary for merely filling it. This regulates our calcula-
tions, and is in favour of large cylinders; but this ad-
vantage must be in a great measure compensated by a
similar variation in the production of the steam; for in
similar boilers of greater dimensions the fuel is less ad-
vantageously employed, because the surface to which
the fume is applied does not increaf in the ratio of the
capacity, but as the surface of the cylinder which waftes
the beam. The rule may therefore be confidered in as
pretty exact.

It is a fatisfactory thing to observe these results
agree very well with the most fucceful practice. By
many changes and trials engineers have established max-
ims of conftuction, which are probably not very far
from the beat. It is a pretty general maxim, that the
load of water should be \( \frac{1}{2} \) of the atmospheric pressure.
They call this loading the engine with \( 7 \frac{1}{2} \) pounds on
the inch, and they fay that fo small a load is necessary
on account of the imperfect vacuum. But we have
now feen that it is neceffary for giving a reasonable ve-
cocity of motion. Since, in this practice, \( \omega \) is made \( \frac{1}{2} 
\) or \( \frac{1}{4} \) of \( P \), and \( L \) should be \( \frac{3}{4} \) of \( P \), and \( L \) is

\[ \omega = \frac{w + \rho}{P}; \]

it follows, that the counter weight should be

\( \frac{3}{4} \) of \( P \); and we have foun this to be nearly the cafe
in feveral very good engines.

It must be remarked, that in the preceding inves-
tigation we introduced a quantity \( M \) to express the refi-
tances to the motion of the engine. This was done in
order to avoid a very troublesome investigation. The refi-
tances are of such a nature as to vary with the ve-
cocity, and moft of them as the fquare of the velocit.
This is the cafe with the refiitance arising from the mo-
tion of the water through the pistons of the pumps, and
that arising from the ftriftion in the long lift during the
working stroke. Had we taken the direcd method,
which is similar to the determination of the motion
through a medium which refiits in the duplicate ratio
of the velocity, we must have used a very intricate ex-
ponential calculus, which few of our readers would
have the patience to look at.

But the greateft part of the quantity \( M \) supposes a
motion already known, and its determination depends
on this motion. We muft now show how its different
component parts may be computed.

1. What arises from the inertia of the moving parts
is by far the moft conftiderable portion of it. To ob-
tain it, we muft find a quantity of matter which, when
placed at the end of the beam, will have the fame mo-
mentum of inertia with that of the whole moving parts in
their natural places. Therefore (in the returning stroke)
add together the weight of the great piston with its
rod and chains; the pit pump rods, chains, and any
weight that is attached to them; the arch-heads and
iron-work at the ends of the beam, and \( \frac{3}{4} \) of the
weight of the beam itself; also the plug-beam with its
arch-head and chains, multiplied by the fquare of its di-
stance from the axis, and divided by the fquare of half
the length of the beam; also the jack-head pump-rod,
chain, and arch-head, multiplied by the fquare of its di-
stance from the axis, and divided by the fquare of the
half-length of the beam. These articles added into one
sum may be called \( M \), and may be supposed to move
with the velocity of the end of the beam. Suppose this
beam to have made a fix-foot stroke in two fconds,
with an uniformly accelerated motion. In one fcond it
would have moved \( 1 \frac{1}{2} \) feet, and would have acquired
the velocity of three feet per fcond. But in one fec-
do fcond gravity would have produced a velocity of
\( 3 \) feet in the fame mass. Therefore the accelerating force
which has produced the velocity of three feet is nearly

\[ M \cdot 3 = \text{the weight of the beam.} \]

Thus we make up the value of \( M \) in the above inves-
tigation. If the observed velocity is greater or less than three feet per fcond, this value must be increafed or diminifhed in the fame pro-
portion.

The second caufe of refiitance, viz. the fimmer of
the pump-rod in water, is easily computed, being the
weight of the water which they dispave.

The third caufe, the friction of the pistons, &c. is al-
moft inappreciable, and muft be difcovered by experimen-
t.

The fourth caufe depends upon the ftructure of
the pumps. These pumps, when made of a proper strength,
can hardly have the perforation of the piston more than
a fourth part of the area of the working barrel; and
the velocit with which the water paffes through it is
increafed at leas \( \frac{1}{4} \) by the contradiction (see Pump).
The velocity of the water is therefore five times great-
er than that of the piston. A piton \( 12 \) inches diame-
ter, and moving one foot per fcond, meets with a refi-
tance equal to \( 20 \) pounds; and this increafes as the fquare of the diameter and as the fquare of the velocit.
If the whole depth of the pit be divided into feveral
lifts, this refiitance muft be multiplied by the number
of lifts, becaufe it obtains in each pump.

Thus we make up the value of \( M \); and we muft ac-
knowledge that the method is ftil! indired, because it
supposes the velocit to be known.

We may obtain it more easily in another way, but
still with this circumstance of being indired. We found
that \( p = \frac{1}{2} \) of \( \sqrt{L \cdot m} \), and confequently

\[ M = \frac{p^2}{L}. \]

Now in any engine \( L \) and \( p \) can always be had; and
unless \( p \) deviates greatly from the proportion which we
determined to be the beat, the value of \( M \) thus obtained
will not be very erroneous.
It was further presumed in this investigation, that the motion both up and down were uniformly accelerated; but this cannot be the case when the resistances increase with the velocity. This circumstance makes very little change in the working-stroke, and therefore the theorem which determines the best relation of $P$ to $L$ may be confided in. The resistances which vary with the velocity in this case are a mere trifle when compared with the moving power $y$. These resistances are, $t$, the straining of the water at the entry, and at the flanging valve of each pump. This is about 37 pounds from a pump 12 inches diameter, and the velocity one foot per second, increasing in the duplicate ratio of the diameter and velocity; and, $2d$, the friction of the water along the whole lift. This for a pump of the same size and with the same velocity, lifting 29 fathoms, is only about $2\frac{1}{2}$ pounds, and varies in the simple proportion of the diameter and the depth, and in the duplicate proportion of the velocity. The resistance arising from inertias is greater than in the returning stroke; because the $M$ in this case must contain the momentum of the water both of the pit-pumps and the jackhead-pump; but this part of the resistance does not affect the uniform acceleration. We may therefore confide in the propriety of the formula $y = L \cdot \frac{1}{2}$. And we may obtain the velocity of this stroke at the end of a second with great accuracy as follows. Let $2g$ be the velocity communicated by gravity in a second, and the velocity at the end of the first second of the steam-piston's descent will be somewhat less than $\frac{2}{M} \cdot 2g$; where $M$ expresses the inertia of all the parts which are in motion during the descent of the steam-piston, and therefore includes $L$. Compute the two resistances just mentioned for this velocity. Call this $r$. Then $\frac{y - r}{M} = 2g$ will give another velocity infinitely near the truth.

But the case is very different in the returning stroke, and the proper ratio of $P$ to $L$ is not ascertain'd with the same certainty: for the moving force $P$ is not so great in proportion to the resistance $m$; and therefore the acceleration of the motion is considerably affected by it, and the motion itself is considerably retarded, and in a very moderate time it becomes sensibly uniform: for it is precisely similar to the motion of a heavy body falling through the air, and may be determined in the manner laid down in the article Resistance of Fluids, viz. by an exponential calculus. We shall content ourselves here with saying, that the resistances in the present case are so great that the motion would be to all intents uniform before the pistons have descended $\frac{1}{2}$ of their strokes, even although there were no other circumstance to affect it.

But this motion is affected by a circumstance quite unconnected with any thing yet confidered, depending on conditions not mechanical, and so uncertain, that we are not yet able to ascertain them with any precision; yet they are of the utmost importance to the good performance and improvement of the engine, and therefore deserve a particular consideration.

The counter weight has not only to pull down the pump-rods, but also to drag up the great piston. This it cannot do unless the steam be admitted into the cylinder. If the steam be no stronger than common air, it cannot enter the cylinder except in consequence of the piston's being dragged up. If common air were admitted into the cylinder, some force would be required to drag up the piston, in the same manner as it is required to draw up the piston of a common syringe; for the air would rush through the small entry of the cylinder in the same manner as through the small nozzle of the syringe. Some part of the atmospheric pressure is employed in driving in the air with sufficient velocity to fill the syringe, and it is only with the remainder that the admitted air preys on the under surface of the syringe. Therefore some of the atmospheric pressure on its upper surface is not balanced. This is felt by the hand which draws it up. The same thing must happen in the steam-engine, and some part of the counter weight is expended in drawing up the steam-piston. We could tell how much is thus expended if we knew the density of the steam; for this would tell us the velocity with which its elasticity would cause it to fill the cylinder. If we suppose it 12 times rarer than air, which it certainly is, and the piston rises to the top of the cylinder in two seconds, we can demonstrate that it will enter with a velocity not less than 1400 feet per second, whereas 500 feet is enough to make it maintain a density $\frac{1}{3}$th of that of steam in equilibrium with the air. Hence it follows, that its elasticity will not be less than $\frac{3}{4}$ths of the elasticity of the air, and therefore not more than $\frac{1}{3}$th of counter weight will be expended in drawing up the steam-piston.

But all this is on the supposition that there is an unbounded supply of steam of undiminished elasticity. This is by no means the case. Immediately before opening the steam-cock, the steam was issuing through the safety-valve and all the crevices in the top of the boiler, and (in good engines) was about $\frac{5}{6}$th stronger or more elastic than air. This had been gathering during something more than the descent of the piston, viz. in about three seconds. The piston rises to the top in about two seconds; therefore about twice as much steam is let in, and the dome is filled to the top of the boiler now shared between the boiler and cylinder. The dome is commonly about six times more capacious than the cylinder. If therefore no steam is condensed in the cylinder, the density of the steam, when the piston has reached the top, must be about $\frac{3}{4}$ths of its former density, and still more elastic than air. But as much steam is condensed by the cold cylinder, its elasticity must be less than this. We cannot tell how much less, both because we do not know how much is thus condensed, and because by this diminution of its pressure on the surface of the boiling water, it must be more copiously produced in the boiler; but an attention to the observation of the engine will give us some information. The moment the steam-cock is opened we have a strong pull of steam through the safety-valve. At this time, therefore, it is still more elastic than air; but after this, the safety-valve remains that during the whole rise of the piston, and no steam any longer issues through the safety-valve or crevices; nay, the whole dome of the boiler may be observed to sink.

This fact gives abundant proof that the elasticity of the steam during the ascent of the piston is greatly diminished, and therefore much of the counter weight is expended in dragging up the steam-piston in opposition to the unbalanced part of the atmospheric pressure. The steam is then much weakened.
Steam-Engine.

Motion of the returning stroke is therefore so much delayed by this foreign and inappreciated circumstance, that it would have been quite useless to engage in the intricate exponential investigation, and we must fit down contented with a less perfect adjustment of the counter weight and weight of water. Any person who attends to the motion of steam-engine will perceive that the deficient of the pump-rods is so far from being accelerated, that it is nearly uniform, and frequently it is sensibly retarded towards the end. We learn by the way, that it is of the utmost importance not only to have a quick production of steam, but also a very capacious dome, or empty space above the water in the boiler. In engines where this space was but four or five times the capacity of the cylinder, we have always observed a very sensible check given to the deficient of the pump-rods after having made half their stroke. This obliges us to employ a greater counter weight, which diminishes the column of water, or retards the working stroke; it also obliges us to employ a stronger steam, at the risk of bursting the boiler, and increases the expense of fuel.

It would be a most desirable thing to get an exact knowledge of the elasticity of the steam in the cylinder; and this is by no means difficult. Take a long glass tube exactly calibrated, and close at the farther end. Put a small drop of some coloured fluid into it, so as to stand at the middle nearly. Let it be placed in a long box filled with water to keep it of a conflant temperature. Let the open end communicate with the cylinder, with a cock between. The moment the steam-cock is opened, open the cock of this instrument. The drop will be pulled towards the close end of the tube, while the steam in the cylinder is more elastic than the air, and it will be drawn the other way while it is less elastic, and, by a scale properly adapted to it, the elasticity of the steam corresponding to every position of the piston may be discovered. The same thing may be done more accurately by a barometer properly constructed, so as to prevent the oscillations of the mercury.

It is equally necessary to know the state of the cylinder during the deficient of the steam-piston. We have hitherto supposed P to be the full pressure of the atmosphere on the area of the piston, supposing the vacuum below it to be complete. But the inspection of our table of elasticity shows that this can never be the case, because the cylinder is always of a temperature far above 32°. We have made many attempts to discover its temperature. We have employed a thermometer in close contact with the side of the cylinder, which soon acquired a steady temperature; this was never less than 145°. We have kept a thermometer in the water which lies on the piston; this never fell below 135°. It is probable that the cylinder within may be cooled somewhat lower; but for this opinion we cannot give any very satisfactory reason. Suppose it cooled down to 120°; this will leave an elasticity which would support three inches of mercury. We cannot think therefore that the unbalanced pressure of the atmosphere exceeds that of 27 inches of mercury, which is about 13½ pounds on a square inch, or 10½ on a circular inch. And this is the value which we should employ in the equation \( P = L + y \). This question may be decided in the same way as the other, by a barometer connected with the inside of the cylinder.

And thus we shall learn the state of the moving forces in every moment of the performance, and the machine will then be as open to our examination as any water or horse mill; and till this be done, or something equivalent, we can only guess at what the machine is actually performing, and we cannot tell in what particular we can lend it a helping hand. We are informed that Messrs. Watt and Boulton have made this addition to some of their engines; and we are persuaded that, from the information which they have derived from it, they have been enabled to make the curious improvements from which they have acquired so much reputation and profit.

There is a circumstance of which we have as yet taken no notice, viz., the quantity of cold water injected. Here we confess ourselves unable to give any precise information. It is clear at first sight that no more than is absolutely necessary should be injected. It must generally be supplied by the engine, and this expends part of its power. An excess is much more hurtful by cooling the cylinder and piston too much, and therefore wasting steam during the next rise of the piston. But the determination of the proper quantity requires a knowledge, which we have not yet acquired, of the quantity of heat contained in the steam in a latent form. As much water must be injected as will absorb all this without rising near to the boiling temperature. But it is of much more importance to know how far we may cool the cylinder with advantage; that is, when will the loss of steam, during the next rise of the piston, compensate for the diminution of its elasticity during its present deficient? Our table of elasticities shows us, that by cooling the cylinder to 120°, we shall leave an elasticity equal to \( \frac{1}{3} \)th of the whole power of the engine; if we cool it to 140°, we leave an elasticity of \( \frac{1}{3} \)th; if we cool it to a blood-heat, we leave an elasticity of \( \frac{1}{4} \)th. It is extremely difficult to choose among these varieties. Experience, however, informs us, that the best engines are those which use the smallest quantities of injection water. We know an exceedingly good engine having a cylinder of 30 inches and a six-foot stroke, which works with something less than \( \frac{1}{2} \)th of a cubic foot of water at each injection; and we imagine that the quantity should be nearly in the proportion of the capacity of the cylinder. Desaguliers observed, that a very good engine, with a cylinder of 32 inches, worked with 300 inches of water at each injection, which does not much exceed \( \frac{1}{3} \)th of a cubic foot. Mr. Watt's observations, by means of the barometer, must have given him much valuable information in this particular, and we hope that he will not always withhold them from the public.

We have gone thus far in the examination, in order to ascertain the motion of the engine when loaded and balanced in any known manner, and in order to discover that proportion between the moving power and the load which will produce the greatest quantity of work. The result has been very unsatisfactory, because the computation of the returning stroke is acknowledged to be beyond our abilities. But it has given us the opportunity of directing the reader's attention to the leading circumstances in this inquiry. By knowing the internal state of the cylinder in machines of very different goodness, we learn the connection between the state of the steam and the performance of the machine; and it is very possible that the result of a full examination may be, that in situations where fuel is expensive, it may be proper to employ a weak steam which will expend less fuel, although less work is performed...
formed by it. We shall see this confirmed in the clear-

est manner in some particular employment of the new
engines invented by Watt and Boulton.

In the mean time, we see that the equation which
we gave from the celebrated Abbé Boffa is in every re-
spect erroneous even for the purpose which he had in
view. We also see that the equation which we substi-
tuted in its place, and which was intended for deter-
mizing that proportion between the counter weight and
the moving force, and the load which would render
the working stroke and returning stroke of equal dura-
tion, is also erroneous, because these two motions are ex-
tremely different in kind, the one being nearly uniform,
and the other nearly uniformly accelerated. This being
supposed true, it should follow that the counter weight
should be reduced to one half; and we have found
this to be very nearly true in some good engines which
we have examined.

We shall add but one observation more on this head.

The practical engineers have almost made it a maxim,
that the two motions are of equal duration. But
the only reason which we have heard for the maxim, is,
that it is awkward to see an engine go otherwise.
But we doubt exceedingly the truth of this maxim, and,
without being able to give any accurate determination,
we think that the engine will do more work if the work-
ing stroke be made shorter than the returning stroke.
Suppose the engine so constructed that they are made in
equal times; an addition to the counter weight will ac-
celerate the returning stroke and retard the working
stroke. But as the counter weight is but small in pro-
tion to the unbalanced portion of the atmospheric
preasure, which is the moving force of the machine.
it is evident that this addition to the counter weight must
bear a much greater proportion on the counter weight
than it does to the moving force, and must therefore ac-
celerate the returning stroke much more than it retards
the working stroke, and the time of both strokes taken
together must be diminished by this addition and the
performance of the machine improved; and this must
be the case as long as the machine is not extravagantly
loaded. The bell machine which we have seen, in re-
spect of performance, rivets a column of water whose
weight is very nearly a fourth of the pressure of the atmo-
sphere on the piston, making 11 strokes of six feet each per
minute, and the working stroke was almost twice as flow
as the other. This engine had worked pumps of 12
inches, which were changed for pumps of 14 inches, all
other things remaining the same. In its former state it
made from 12½ to 13½ strokes per minute, the working
stroke being considerably slower than the returning
stroke. The load was increased, by the change of the
pumps nearly in the proportion of 3 to 4. This had
retarded the working stroke; but the performance was
evidently increased in the proportion of 3 x 13 to 4 x 113
or of 39 to 44. About 300 pounds were added to the
counter weight, which increased the number of strokes
to more than 12 per minute. No sensible change could
be observed in the time of the working stroke. The
performance was therefore increased in the proportion of 39 to 48.
We have therefore no hesitation in saying, that
the nearly equality of the two strokes is a facsimile
of fancy. The engineer who observes the working
stroke to be slow, fears that his engine may be thought
feeble and unequal to its work; a similar notion has long
misled him in the construction of water-mills, especially
of over-shot mills; and, even now, he is submitting
with hesitation and fear to the daily corroboration of
experience.

It is needless to engage more deeply in scientific cal-
culations in a subject where so many of the data are so
imperfectly understood.

We venture to recommend as a maxim of con-struction
that the load (supposing always a large boiler and plentiful supply of
pure steam unmixed with air), that the load of work be
not less than 3 to 10 pounds for every square inch of the
piston, and the counter weight so proportioned that the
time of the returning stroke may not exceed 3/10 of that
square inch of the working stroke. A serious objection may
be made to this maxim, and it deferves mature consider-
ation. Such a load requires the utmost care of the
machine, that no admission be given to the common air;
and it precludes the possibility of its working in case
the growth of water, or deepening the pit, shall
make a greater load absolutely necessary. These consider-
ations must be left to the prudence of the engi-
neer. The maxim now recommended relates only to the belt
actual performance of the engine.

Before quitting this machine, it will not be amiss to
give some easy rules, founded by successful practice,
for computing its performance. These will enable any
artisan, who can go through simple calculations, to suit
the size of his engine to the task which it is to per-
f orm.

The circumstance on which the whole computation
must be founded is the quantity of water which must
be drawn in a minute and the depth of the mine; and the
performance which may be expected from a good
engine is at least 12 strokes per minute of six feet, working
against a column of water whose weight is equal to half of the atmospheric preasure on the fream-
piston, or rather to 7.64 pounds on every square inch of
its surface.

It is most convenient to eliminate the quantity of wa-
ter in cubic feet, or its weight in pounds, recollecting
that a cubic foot of water weighs 62 1/2 pounds. The
depth of the pit is usually reckoned in fathoms of six
feet, and the diameter of the cylinder and pump is usu-
ally reckoned in inches.

Let Q be the quantity of water to be drawn per
minute in cubic feet, and P the depth of the mine in
fathoms; Let E be the diameter of the cylinder, and p
that of the pump; and let us suppose the arms of the
beam to be of equal length.

11. To find the diameter of the pump, the area of
the piston in square feet is \( p^2 \times \frac{Q}{O.7854} \). The length
of the column drawn in one minute is 12 times 6 or 72
feet, and therefore its solid contents is \( p^2 \times \frac{72}{0.7854} \).

cubical feet, or \( p^2 \times 0.3927 \) cubical feet. This must be
equal to Q, therefore \( p^2 \) must be \( \frac{Q}{0.3927} \) or nearly
\( Q \times 2.5 \). Hence this practical rule: Multiply the
cubical feet of water which must be drawn in a minute by
2.5 and extract the square root of the product; this
will be the diameter of the pump in inches.

Thus suppose that 58 cubic feet must be drawn every
minute; 58 multiplied by 2.5 gives 145, of which the
square
2. To find the proper diameter of the cylinder.

The piston is to be loaded with 7,64 pounds on every square inch. This is equivalent to fix pounds on a circular inch very nearly. The weight of a cylinder of water an inch in diameter and a fathom in height is \( \frac{2}{3} \) pounds, or nearly two pounds. Hence it follows that \( c^2 \) must be made equal to \( 2fp^2 \), and that \( c^2 \) is equal to \( \frac{2fp^2 \text{in}}{p^2 \text{in}^2} \) or \( \frac{2f}{p} \).

Hence the following rule: Multiply the square of the diameter of the pump-piston (found as above) by the fathoms of lift, and divide the product by 3, the square root of the quotient is the diameter of the cylinder.

Suppose the pit to which the foregoing pump is to be applied is 24 fathoms deep; then \( \frac{24 \times 144}{3} \) gives 112, of which the square root is 34 inches very nearly.

This engine constructed with care will certainly do the work.

Whatever is the load of water proposed for the engine, let to be the pounds on every circular inch of the steam-piston, and make \( c^2 = \frac{p^2}{f} \), and the square root will be the diameter of the steam-piston in inches.

To free the practical engineer as much as possible from all trouble of calculation, we subjoin the following Table of Dimensions and Power of the Steam Engine, drawn up by Mr. Beighton in 1717, and fully verified by practice since that time. The measure is in English ale gallons of 282 cubic inches.

</table>

The first part of the table gives the size of the pump suitable to the growth of water. The second gives the size of the cylinder suitable to the load of water. If the depth is greater than any in this table, take its fourth part, and double the diameter of the cylinder. Thus if 150 hogsheads are to be drawn in an hour from the depth of 100 fathoms, the last column of part first gives for 149.40 a pump of 7 inches bore. In a line with this, under the depth of 50 yards, which is \( \frac{1}{4} \)th of 100 fathoms, we find 20.4, the double of which is 41 inches for the diameter of the cylinder.

It is almost impossible to give a general rule for strokes of different lengths, &c. but any one who professes the ability to erect an engine, should fully know as much arithmetic as will accommodate the rule now given to any length of stroke.

We venture to say, that no ordinary engineer can tell a priori the number per minute which an engine will give. We took 12 strokes of 3 feet each for a standard, which a careful engineer may easily accomplish, and which an employer has a right to expect, the engine being loaded with water to half the pressure of the atmosphere; if the load be less, there is some fault—a

an improper counter weight, or too little boiler, or leaks, &c. &c.

Such is the rate in which Newcomen's steam-engine had continued in use for 60 years neglected by the philosopher, although it is the most curious object which human ingenuity has yet offered to his contemplation, and abandoned to the efforts of the unlettered artisan.

Its use has entirely been confined to the raising of water.

Mr. Keane Fitzgerald indeed published in the Philosophical Transactions a method of converting its reciprocating motion into a continued rotatory motion by employing the great beam to work a crank or a train of wheel-work. As the real action of the machine is confined to its reciprocating action, it became necessary to connect with the crank or wheel a heavy large and heavy fly, which should accumulate in itself the whole pressure of the machine during its time of action, and therefore continue in motion, and urge forward the working machinery while the steam engine was going through its inactive returning stroke. This will be the case, provided that the resistance exerted by the working machine during the whole period of the working and returning stroke of the steam-engine, together with
with the friction of both, does not exceed the whole
prefire exerted by the steam-engine during its working
stroke; and provided that the momentum of the
fly, arising from its great weight and velocity, be very
great, so that the resistence of the work, during one
returning stroke of the steam-engine do not make any very
sensible diminution of the velocity of the fly. This is evi-
dently possible and easy. The fly may be made of any
magnitude; and being exactly balanced round its axis,
it will soon acquire any velocity consistent with the mo-
tion of the steam-engine. During the working stroke
of the engine it is uniformly accelerated, and by its ac-
quired momentum it produces in the beam the move-
ment of the returning stroke; but in doing this, its mo-
mentum is shared with the inert matter of the steam-
gine, and consequently its velocity diminished, but not
entirely taken away. The next working stroke there-
fore, by pressing on it afresh, increases its remaining
velocity by a quantity nearly equal to the whole that it
acquired during the first stroke. We say nearly, but
not quite equal, because the time of the second working
stroke must be shorter than that of the first, on account
of the velocity already in the machine. In this manner
the fly will be more and more accelerated every succe-
seding stroke, because the prefire of the engine during
the working stroke does more than restore to the fly the
momentum which it lost in producing the returning
movement of the steam-engine. Now suppose the
working part of the machine to be added. The acce-
seration of the fly during each working stroke of the
steam-engine will be less than it was before, because the
impelling prefire is now partly employed in driving the
working machine, and because the fly will lose more of
its momentum during the returning stroke of the steam-
engine, part of it being expended in driving the work-
ing machine. It is evident, therefore, that a time will
come when the successive augmentation of the fly's veloc-
ity will cease; for, on the one hand, the continual ac-
celeration diminishes the time of the next working
stroke, and therefore the time of action of the accelerat-
ing power. The acceleration must diminish in the fame propor-
tion; and on the other hand, the resistence of the
working machine generally, though not always, increa-
ses with its velocity. The acceleration ceases whenever the
addition made to the momentum of the fly during a
working stroke of the steam-engine is just equal to what it
loses by driving the machine, and by producing the
returning movement of the steam-engine.

This must be acknowledged to be a very important
addition to the engine, and though sufficiently obvious,
it is ingenious, and requires considerable skill and ad-
dress to make it effective (8). The movement of the work-
ing machine, or mill of whatever kind, must be in some degree hobbling or
unequal. But this may be made quite insensible, by mak-
ing the fly exceedingly large, and disposing the great-
part of its weight in the rim. By these means its mo-
mentum may be made so great, that the whole force
required for driving the mill and producing the return-
ing movement of the engine may bear a very small
proportion to it. The diminution of its velocity will
then be very trifling.

No counter weight is necessary here, because the re-
turning movement is produced by the inertia of the
fly. A counter weight may, however, be employed, and
should be employed, viz. as much as will produce the
returning movement of the steam-engine. It will
do this better than the same force accumulated in the
fly; for this force must be accumulated in the fly by
the intervention of rubbing parts, by which some of it
is lost; and it must be afterwards returned to the en-
gine with a similar loss. But, for the same reason, it
would be improper to make the counter weight also
able to drive the mill during the returning stroke.

By this contrivance Mr. Fitzgerald hoped to render
the steam-engine of most extensive use; and he, or others
associated with him, obtained a patent excluding all
others from employing the steam-engine for turning a
 crank. They also published proposals for erecting mills
of all kinds driven by steam-engines, and stated very
fairly their powers and their advantages. But their
proposals do not seem to have acquired the confidence of
the public; for we do not know of any mill ever having
been erected under this patent.

The great obstacle to this extensive use of the steam. The great engine is the prodigious expense of fuel. An engine
having a cylinder of four feet diameter, working night
and day, consumes about 3400 chaldron (London) of
good coals in a year.

This circumstance limits the use of steam-engines ex-
cedingly. To draw water from coal-pits, where they use of
can be worked with unfeasible small coal, they are of steam-en-
universal employment: also for valuable mines, for gins,
supplying a great and wealthy city with water, and a
few other purposes where a great expense can be borne,
they are very proper engines; but in a thousand cafes
where their unlimited powers might be vastly service-
able, the enormous expenses of fuel completely excludes
them. We cannot doubt but that the attention of engi-
ers was much directed to every thing that could pro-
mote a diminution of this expense. Every one had his
particular notion for the construction of his furnace,
and some were undoubtedly more successful than others.
But science was not yet sufficiently advanced: It was not
till Dr. Black had made his beautiful discovery of latent
heat, that we could know the intimate relation between
the heat expended in boiling off a quantity of water
and the quantity of steam that is produced.

(b) We do not recollect at present the date of this proposal of Mr. Fitzgerald; but in 1781 the Abbé Arnal,
canon of Alais in Languedoc, entertained a thought of the same kind, and proposed it for working lighters
in the inland navigations; a scheme which has been thought practicable by many ingenious men. His
brother, a major of engineers in the Austrian service, has carried the thing much farther, and applied it to manu-
factures; and the Æalic Chamber of mines at Vienna has patronized the project: (See Journal Encyclopédique,
1781). But these schemes are long posterior to Mr. Fitzgerald's patent, and are even later than the erection of
several machines driven by steam-engines which have been erected by Mefîra Watt and Boulton. We think it
our duty to state these particulars, because it is very usual for one man to assume the credit of another's inven-
tions.

5 D Much
Much about the time of this discovery, viz. 1763, Mr James Watt, established in Glasgow in the commercial line, was amusing himself with repairing a working model of the steam-engine which belonged to the philosophical apparatus of the university. Mr Watt was a person of a truly philosophical mind, eminently conversant in all branches of natural knowledge, and the pupil and intimate friend of Dr Black. In the course of the abovementioned amusement many curious facts in the production of steam occurred to him; and among others, that remarkable fact which is always appealed to by Dr Black as the proof of the immense quantity of heat which is contained in a very minute quantity of water in the form of elastic steam. When a quantity of water is heated several degrees above the boiling point in a close digester, if a hole be opened, the steam rushes out with prodigious violence, and the heat of the remaining water is reduced, in the course of three or four seconds, to the boiling temperature. The water of the steam which has issued amounts only to a very few drops; and yet these have carried off with them the whole excess of heat from the water in the digester.

Since then a certain quantity of steam contains so great a quantity of heat, it must expend a great quantity of fuel; and no construction of furnace can prevent this. Mr Watt therefore set his intention to work to discover methods of hubbarding this heat. The cylinder of his little model was heated almost in an instant, so that it could not be touched by the hand. It could not be otherwise, because it condensed the vapour by abstracting its heat. But all the heat thus communicated to the cylinder, and wasted by it on surrounding bodies, contributed nothing to the performance of the engine, and must be taken away at every injection, and again communicated and wasted. Mr Watt quickly understood the whole process which was going on within the cylinder, and which we have considered so minutely, and saw that a very considerable portion of the steam must be wasted in warming the cylinder. His first attempts were made to ascertain how much was thus wasted, and he found that it was not less than three or four times as much as would fill the cylinder and work the engine. He attempted to diminish this waste by using wooden cylinders. But though this produced a sensible diminution of the waste, other reasons forced him to give them up. He then cast his metal cylinders in a wooden case with light wood ashes between. By this, and using no more injection than was absolutely necessary for the condensation, he reduced the waste almost one half. But by using so small a quantity of cold water, the inside of the cylinder was hardly brought below the boiling temperature; and there consequently remained in it a steam of very considerable elasticity, which robbed the engine of a proportional part of the atmospheric pressure. He saw that this was unavoidable as long as the condensation was performed in the cylinder. The thought struck him to attempt the condensation in another place. His first experiment was made in the simplest manner. A globular vessel communicated by means of a long pipe of one inch diameter with the bottom, of his little cylinder of four inches diameter and 30 inches long. This pipe had a stop cock, and the globe was immersed in a vessel of cold water. When the piston was at the top, and the cylinder filled with strong steam, he turned the cock. It was scarcely turned, nay he did not think it completely turned, when the tides of his cylinder (only strong tin plate) were crushed together like an empty bladder. This surprised and delighted him. A new cylinder was immediately made of brass sufficiently thick, and nicely bored. When the experiment was repeated with this cylinder, the condensation was so rapid, that he could not say that any time was expended in it. But the most valuable discovery was, that the vacuum in the cylinder was, as he hoped, almost perfect. Mr Watt found, that when he used water in the boiler purged of air by long boiling, nothing was so feebly inferior to the pressuire of the atmosphere on the piston could hinder it from coming quite down to the bottom of the cylinder. This alone was gaining a great deal, for in most engines the remaining elasticity of the steam was not less than a fifth of the atmospheric pressure, and therefore took away a fifth of the power of the engine.

Having gained this capital point, Mr Watt found many difficulties to struggle with before he could get the machine to continue its motion. The water produced from the condensed steam, and the air which was extracted from it, or which penetrated through unavoidable leaks, tended to accumulate in the condensing vessel, and could not be removed in any way similar to that adopted in Newcomen's engine. He took another method: He applied pumps to extract both, which were worked by the great beam. The convenience is easy to any good mechanic; only we must observe, that the piston of the water-pump must be under the surface of the water in the condenser, that the water may enter the pump by its own weight, because there is no atmospheric pressure there to force it in. We must also observe, that a considerable force is necessarily expended here, because, as there is but one stroke for raising the air, and this rarefaction must be nearly complete, the air-pump must be of large dimensions, and its piston must act against the whole preasure of the atmosphere. Mr Watt, however, found that this force could be easily spared from his machine, already so much improved in respect of power.

Thus has the steam engine received a very considerable improvement. The cylinder may be allowed to remain very hot; nay, boiling hot, and yet the condensation be completely performed. The only elastic steam that now remains is the small quantity in the pipe of communication. Even this small quantity Mr Watt at last got rid of, by admitting a small jet of cold water up this pipe to meet the steam in its passage to the condenser. This both cooled this part of the apparatus in a situation where it was not necessary to warm it again, and it quickened the condensation. He found at last that the small pipe of communication was of itself sufficiently large for the condensation, and that no separate vessel, under the name of condenser, was necessary. This circumstance shows the prodigious rapidity of the condensation. We may add, that unless this had been the case, his improvement would have vastly diminished; for a large condenser would have required a much larger air-pump, which would have expended much of the power of the engine. By these means the vacuum below the piston is greatly improved; for it will appear clear to any person who understands the subject, that as long as any part of the condenser is kept...
kept of a low temperature, it will abstract and condense the vapour from the warmer parts, till the whole acquires the elasticity corresponding to the coldest part. By the same means much of the wafer is prevented, because the cylinder is never cooled much below the boiling temperature. Many engines have been erected by Mr. Watt in this form, and their performance gave universal satisfaction.

We have contented ourselves with giving a very short description without a figure of this improved engine, because we imagine it to be of very great common observation, and because it is only a preparation for still greater improvements, which, when understood, will at the same time leave no part of this more simple form unexplained.

During the progress of these improvements Mr. Watt made many experiments on the quantity and density of the steam of boiling water. Tho' fully convinced him, that although he had greatly diminished the wafer of steam, a great deal yet remained, and that the steam expanded during the rise of the piston was at least three times more than what would fill the cylinder. The cause of this was very apparent. In the subsequent descent of the piston, covered with water much below the boiling temperature, the whole cylinder was necessarily cooled and exposed to the air. Mr. Watt's fertile genius immediately suggested to him the expedient of employing the elasticity of the steam from the boiler, to impel the piston down the cylinder, in place of the preponderating by the counter pressure of the atmosphere; and thus he restored the engine to its first principles, making it an engine really moved by steam. As this is a new epoch in its history, we shall improve particular in the description; at the same time still restricting ourselves to the essential circumstances, and avoiding every peculiarity which is to be found in the prodigious varieties which Mr. Watt has introduced into the machines which he has erected, every individual of which has been adapted to local circumstances, or diversified by the progress of Mr. Watt's improvements.

Let A (fig. 9.) represent the boiler. This has received great improvements from his complete acquaintance with the production of steam. In some of his engines the fuel has been placed in the middle of the water, surrounded by an iron or copper vessel, while the exterior boiler was made of wood, which transmits, and therefore wastes the heat very slowly. In others, the flame not only plays round the whole outside, as in common boilers, but also runs along several fins which are conducted through the middle of the water. By such contrivances the fire is applied to the water in a most extensive surface, and for a long time, so as to impart to it the greatest part of its heat. So skilfully was it applied in the Albion Mills, that although it was perhaps the largest engine in the kingdom, its unconsumed smoke was inferior to that of a very small brewhouse. In this second engine of Mr. Watt, the top of the cylinder is skirted by a strong metal plate g h, in the middle of which is a collar or boss of leather k l, formed in the usual manner of a jack-head pump, through which the piston rod P D, nicely turned and polished, can move up and down, without allowing any air to pass by its sides. From the dome of the boiler proceeds a large pipe B C I O Q, which, after reaching the cylinder with its horizontal part B C, defecdes parallel to its side, sending off two branches, viz. I M to the top of the cylinder, and O N to its bottom. At I is a puppet valve opening from below upwards. At L, immediately below this branch, there is a similar valve, also opening from below upwards. The pipe descends to Q, near the bottom of a large cistern e d f, filled with cold water constantly renewed. The pipe is then continued horizontally along the bottom of this cistern (but not in contact), and terminates at R in a large pump S T. The piston S R is clack valves opening upwards, and its rod S T, passing through a collar of leathers at T, is supported by a chain to a small arch head on the outer arm of the beam. There is a valve R in the bottom of this pump, as usual, which opens when pressed in the direction Q R, and acts against a contrary pressure. This pump delivers its contents into another pump X Y, by means of the small pipe t X, which proceeds from its top. This second pump has a valve at X, and a clack in its piston Z as usual, and the piston rod Z s is supported from another arm head on the outer arm of the beam. The two valves I and L are opened and shut by means of spanners and handles, which are put in motion by a plug frame, in the same manner as in Newcomen's engine.

Lastly, there may be observed a crooked pipe a b s, which enters the upright pipe laterally a little above Q s. This has a small jet hole at o, and the other end a, which is considerably under the surface of the water of the condensing cistern, is covered with a puppet valve w, whose long flack w rises above the water, and may be raised or lowered by hand or by the plug beam. The valves R and X and the clacks in the pistons S and Z are opened or shut by the pressures to which they are immediately exposed.

This figure is not an exact copy of any of Mr. Watt's engines, but has its parts so disposed that all may come distinctly into view, and exactly perform their various functions. It is drawn in its quiescent position, the outer end of the beam preponderating by the counter weight, and the piston P at the top of the cylinder, and the pistons S and Z in their lowest situations.

In this situation let us suppose that a vacuum is produced in all the space below the piston, the valve I being shut. It is evident that the valve R will also be shut, as also the valve w. Now let the valve I be opened. The steam from the boiler, as elastic as common air, will rush into the space above the piston, and will exert on it a pressure as great as that of the atmosphere. It will therefore press it down, raise the outer end of the beam, and cause it to perform the same work as an ordinary engine.

When the piston P has reached the bottom of the cylinder, the plug frame shuts the valve I, and opens L. By thus the communication is open between the top and bottom of the cylinder, and nothing hinders the steam which is above the piston from going along the passage M L O N. The piston is now equally affected on both sides by the steam, even though a part of it is continually condensed by the cylinder, and in the pipe I O Q s. Nothing therefore hinders the piston from being dragged up by the counter weight, which acts with its whole force, undiminished by any remaining unbalanced elasticity of steam.
Whenever the piston P arrives at the top of the cylinder, the valve L is shut by the plug frame, and the valves I and v are opened. All the space below the piston at this time occupied by the steam which came from the upper part of the cylinder. This being a little wasted by condensation, is not a quite balance for the pressure of the atmosphere. Therefore, during the ascent of the piston, the valve R was shut, and it remains so. When, therefore, the valve v is opened, the cold water of the cylinder must flow up through the hole o, and condense the steam. To this must be added the coldness of the whole pipe O Q S. As fast as it is condensed, its place is supplied by steam from the lower part of the cylinder. We have already remarked, that this successive condensation is accomplished with astonishing rapidity. In the mean time, steam from the boiler press on the upper surface of the piston. It must therefore descend as before, and the engines must perform a second working stroke.

In the mean time the injection water lies in the bottom of the pipe O Q R, heated to a considerable degree by the condensation of the steam; also a quantity of air has been disengaged from it and from the water in the boiler. How is this to be discharged?—This is the office of the pumps S T and X Y. The capacity of S T is very great in proportion to the space in which the air and water are lodged. When, therefore, the piston S has got to the top of its course, there must be a vacuum in the barrel of this pump, and the water and air must open the valve R and come into it. When the piston S comes down again in the next returning stroke, this water and air gets through the valve of the piston; and in the next working stroke they are discharged by the piston into the pump X Y, and raised by its piston. The air escapes at Y, and as much of the water as is necessary is delivered into the boiler by a small pipe V g to supply its wants. It is a matter of indifference whether the pistons S and Z rise with the outer, or inner end of the beam, but it is rather better that they rise with the inner end. They are otherwise drawn here, in order to detach them from the rest and show them more distinctly.

Such is Mr Watt's second engine. Let us examine its principles, that we may see the causes of its avowed and great superiority over the common engines.

We have already seen one ground of superiority, the full operation of the counter weight. We are authorized by careful examination to say, that in the common engines at least one half of the counter weight is expended in counteracting an unbalanced pressure of the air on the piston during its ascent. In many engines, which are not the worst, this extends to 2/3 of the whole pressure. This is evident from the examination of the engine at Montreals by Boulton. This makes a very great counter weight necessary, which exhausting a proportional part of the moving force.

But the great advantage of Mr Watt's form is the almost total annihilation of the waste of steam by condensation in the cylinder. The cylinder is always boiling hot, and therefore perfectly dry. This must be evident to any person who understands the subject. By the time Mr Watt had completed his improvements, his experiments on the production of steam had given him a pretty accurate knowledge of its density; and he found himself authorized to say, that the quantity of steam employed did not exceed twice as much as would fill the cylinder, so that not above one half was unavoidably wasted. But before he could bring the engine to this degree of perfection, he had many difficulties to overcome: He included the cylinder in an outer wooden case at a small distance from it. This diminished the expense of heat by communication to surrounding bodies. Sometimes he allowed the steam from the boiler to occupy this interval. This undoubtedly prevented all dissipation from the inner cylinder but in its turn it dissipated much heat by the outer case, and a very sensible condensation was observed between them. This has occasioned him to omit this circumstance in some of his best engines. We believe it was omitted in the Albion Mills.

The greatest difficulty was to make the great piston tight. The old and effectual method, by water lying on it, was inadmissible. He was therefore obliged to have his cylinders most nicely bored, perfectly cylindrical, and finely polished; and he made hundreds of trials of different soft substances for packing his piston, which should be tight without enormous friction, and which would long remain so, in a situation perfectly dry, and not almoft to burning.

After all that Mr Watt has done in this respect, he thinks that the greatest part of the waste of steam which he still perceives in his engines arises from the unavoidable escape by the sides of the piston during its descent.

But the fact is, that an engine of this construction, of the same dimensions with a common engine, making the same number of strokes of the same extent, does not consume above one fourth part of the fuel that is consumed by the best engines of the common form. It is due to a very fortunate circumstance, that the performance of the engine is not immediately destroyed, nor indeed sensibly diminished, by a small want of tightness in the piston. In the common engine, if air get in, in this way, it immediately puts a stop to the work; but although even a considerable quantity of steam get past the piston during its descent, the rapidity of condensation is such, that hardly any diminution of pressure can be observed, and the waste of steam is the only inconvenience.

Mr Watt's penetration soon discovered another most valuable property of this engine. When an engine of the common form is erected, the engineer must make an accurate estimate of the work to be performed, and must proportion his engine accordingly. He must be careful that it be fully able to execute its task; but its power must not exceed its load in any extravagant degree. This would produce a variation which is too rapid and which, being alternately in opposite directions, would occasion jolts which no building or machinery could withstand. Many engines have been shattered by the pumps drawing air, or a pump-rod breaking; by which accidents the steam-piston descends with such rapidity that every thing gives way. But in most operations of mining, the task of the engine increases, and it must be so constructed at first as to be able to bear this addition. It is very difficult to manage an engine that is much superior to its task; and the safest way is,
Steam-Engine.

65
Is, that it can always be exactly fitted to the load which happens to be on it.

But this new engine can at all times be exactly fitted (at least during the working stroke) to the load of work that then happens to be on it. We have only to administer steam of a proper elasticity. At the first erection the engine may be equal to twice its task, if the steam admitted above the cylinder be equal to that of common boiling water; but when once the ebulition is fairly commenced, and the whole air expelled from all parts of the apparatus, it is evident, that by damping the fire, steam of half this elasticity may be continually supplied, and the water will continue boiling although its temperature does not exceed 185° of Fahrenheit's thermometer. This appears by inspecting our table of vaporous elasticity, and affords another argument for rendering that table more accurate by new experiments. We hope that Mr. Watt will not withhold from the public the knowledge which he has acquired on this subject.

66 One inconvenience.

It may very possibly result from an accurate investigation, that it would be advisable to work our steam-engines with weak steam, and that the diminution of work may be more than compensated by the diminution of fuel. It is more probable indeed, that it is Mr. Watt's opinion, that the contrary is the case, and that it is much more economical to employ great heats. At any rate, the decision of this question is of great importance for improving the engine; and we see, in the mean time, that the engine can at all times be fitted so as to perform its task with a moderate and manageable motion, and that as the task increases we can increase the power of the engine.

67 Remedied in some degree.

But the method now proposed has a great inconvenience. While the steam is weaker than the atmosphere, there is an external force tending to squeeze in the sides and bottom of the boiler. This could not be resisted when the difference is considerable, and common air would rush in through every crevice of the boiler and soon choke the engine; it must therefore be given up.

But the same effect will be produced by diminishing the passage from the steam into the cylinder. For this purpose, the puppet valve by which the steam enters the cylinder was made in the form of a long taper spigot, and it was lodged in a cone of the same shape; consequently the passage could be enlarged or contracted at pleasure by the distance to which the inner cone was drawn up.

In this way several engines were constructed, and the general purpose of using the power of the engine to its task was completely answered; but (as the mathematical reader will readily perceive) it was extremely difficult to make this adjustment precise and constant. In a great machine like this, going by jerks, it was hardly possible that every successive motion of the valve should be precisely the same. This occasioned very sensible irregularities in the motion of the engine, which increased and became hazardous when the joints worked loose by long use.

68 But the remedy attended with some difficulties.

69 Which Mr. Watt's genius, always fertile in resources, found out a complete remedy for all those inconveniences.

Making the valve of the ordinary form of a puppet clack, he adjusted the button of its stalk or tail so that it should always open full to the same height. He then regulated the pins of the plug-frame, in such a manner that the valve should shut the moment that the piston had descended a certain proportion (suppose one-fourth, one-third, one-half, &c.) of the cylinder. So far the cylinder was occupied by steam as elastic as common air. In pressing the piston farther down, it behaved the steam to expand, and its elasticity to diminish. It is plain that this could be done in any degree we please, and that the adjustment can be varied in a minute, according to the exigency of the case, by moving the plug-pins.

In the mean time, it must be observed, that the pressure on the piston is continually changing, and consequently the accelerating force. The motion therefore will no longer be uniformly accelerated: it will approach much faster to uniformity; nay, it may be retarded, because although the pressure on the piston at the beginning of the stroke may exceed the resistance of the load, yet when the piston is near the bottom the resistance may exceed the pressure. Whatever may be the law by which the pressure on the piston varies, an ingenious mechanic may contrive the connecting machinery in such a way that the chains or rods at the outer end of the beam shall continually exert the same pressure, or shall vary their pressure according to any law he finds most convenient. It is in this manner that the watchmaker, by the form of the fuze, produces an equal pressure on the wheel-work by means of a very unequal action of the main-spring. In like manner, by making the outer arch heads portions of a proper spiral instead of a circle, we can regulate the force of the beam at pleasure.

Thus we see how much more manageable an engine is in this form than Newcomen's was, and also more easily investigated in respect of its power in its various positions. The knowledge of this last circumstance was of mighty consequence, and without it no notion could be formed of what it could perform. This suggested to Mr. Watt the use of the barometer communicating with the cylinder; and by the knowledge acquired by these means has the machine been so much improved by its ingenious inventor.

We must not omit in this place one deduction made by Mr. Watt from his observations, which may be called a discovery of great importance in the theory of the engine.

Let ABCD (fig. 10) represent a section of the cylinder of a steam-engine, and EF the surface of its piston. Let us suppose that the steam was admitted while EF was in contact with AB, and that as soon as it had pressed it down to the situation EF the steam cock is shut. The beam will continue to press it down, and as the steam expands its pressure diminishes. We give EF the power of performing work, and we may express its pressure (exerted all the while the piston moves from the situation AB to the situation EF) by the line EF. If we suppose the elasticity of the steam proportional to its density, as is nearly the case with air, we may express the pressure on the piston in any other position, such as KL or DC, by the line KL, and that the diminution of pressure is caused by the diminution of the area of the rectilinear form of which KL is the asymptotes, and K the centre. The accumulated pressure during the motion of the piston from EF to DC will be expressed by the area EFDE, and the pressure during the whole motion by the area AFBEDA.
Now it is well known that the area $\text{EF} \times \text{DE}$ is equal to $\text{ABFE}$ multiplied by the hyperbolic logarithm of $\frac{\text{AD}}{\text{AE'}} = L$. $\frac{\text{AD}}{\text{AE'}}$, and the whole area $\text{ABF}$ 

$\varepsilon \text{DA} = \text{ABFE} \times (1 + L \frac{\text{AD}}{\text{AE'}})$. 

Thus let the diameter of the piston be 2.4 inches, and the pressure of the atmosphere on a square inch be 14 pounds; the pressure on the piston is 6333 pounds. Let the whole stroke be 6 feet, and let the steam be flopped when the piston has descended 18 inches, or 1.5 feet. The hyperbolic logarithm of 1.5 is $1,3862943$. 

Therefore the accumulated pressure $\text{ABFE} \times (1 + L \frac{\text{AD}}{\text{AE'}})$, $= 6333 \times 2.4 \times 1.5$, $= 15114$ pounds. 

As few professional engineers are possessed of a table of hyperbolic logarithms, while tables of common logarithms are, or should be, in the hands of every person who is much engaged in mechanical calculations, let the following method be practised. Take the common logarithm of $\frac{\text{AD}}{\text{AE}}$, and multiply it by $2,3026$; the product is the hyperbolic logarithm of $\frac{\text{AD}}{\text{AE}}$. 

The accumulated pressure while the piston moves from $\text{AB}$ to $\text{EF}$ is $6333 \times 1$, or simply 6333 pounds. Therefore the steam while it expands into the whole cylinder adds a pressure of 8781 pounds. 

Suppose that the steam had got free admission during the whole descent of the piston, the accumulated pressure would have been $6333 \times 4$, or 25332 pounds. 

Here Mr. Watt observed a remarkable result. The steam expended in this case would have been four times greater than when it was flopped at 4 ft, and yet the accumulated pressure is not twice as great, being nearly 4.5 times. One fourth of the steam performs nearly 4ths of the work, and an equal quantity performs more than twice as much work when thus admitted during 4th of the motion. 

This is a curious and an important information, and the advantage of this method of working a steam-engine increases in proportion as the steam is sooner flopped; but the increase is not great after the steam is rareified four times. The curve approaches near to the axis, and small additions are made to the area. The expense of such great cylinders is considerable, and may sometimes compensate this advantage.

Let the steam be flopped at

It is very pleasing to observe so many unlooked-for advantages resulting from an improvement made with the sole view of lessening the waste of steam by condensation. While this purpose is gained, we learn how to husband the steam which is not thus wasted. The engine becomes more manageable, and is more easily adapted to every variation in its task, and all its powers are more easily computed.
proper to suspend its rod by a chain from the great beam; for it must not only pull down that end of the beam, but also pull it upwards. It may indeed be suspended by double chains like the pistons of the engines for extinguishing fires; and Mr. Watt has accordingly done so in some of his engines. But in his drawing from which this figure is copied, he has communicated the force of the piston to the beam by means of a toothed rack QQ on which engages or works in the toothed sector QQ on the end of the beam. The reader will understand, without any further explanation, how the impulse given to the piston in either direction is thus transmitted to the beam without diminution. The fly XX, with its pinion Y, which also works in the toothed arch QQ, may be supposed to be removed for the present, and will be considered afterwards.

We shall take the present opportunity of describing Mr. Watt's method of communicating the force of the steam-engine to any machine of the rotary kind. VV represents the rim and arms of a very large and heavy metallic fly. On its axis is the concentric toothed wheel wheel U. There is attached to the end of the great beam a strong and stiff rod TT, to the lower end of which a toothed wheel W is firmly fixed by two bolts, so that it cannot turn round. This wheel is of the same size and in the same vertical plane with the wheel U; and an iron link or strap (which cannot be seen here, because it is on the other side of the two wheels) connects the centres of the two wheels so that the one cannot quit the other. The engine being in the position represented in the figure, suppose the fly to be turned once round by any external force in the direction of the darts. It is plain, that since the toothed wheels cannot quit each other, being kept together by the link, the inner half (that is, the half next the cylinder) of the wheel U will work on the inner half of the wheel W, so that at the end of the revolution of the fly the wheel W must have got to the top of the wheel U, and the outer end of the beam must be raised to its highest position. The next revolution of the fly will bring the wheel W and the beam connected with it to their first positions; and thus every two revolutions of the fly will make a complete period of the beam's reciprocating movements. Now, instead of supposing the fly to drive the beam, let the beam drive the fly. The motions must be perfectly the same, and the ascent or descent of the piston will produce one revolution of the fly.

A side view of this apparatus is given in fig. 12. marked by the same letters of reference. This shows the situation of parts which were fore-shortened in fig. 11. particularly the defending branch C of the steam pipe, and the situation and communications of the two pumps K and L. 8, 8 is the horizontal part of the steam pipe. 9 is a part of it whose base is represented by the dark circle of fig. 11. D is the box of the steam clack, and the little circle at its corner represents the end of the axis which turns it, as will be described afterwards. N is the place of the upper eduction valve. A part only of the upper eduction-pipe G is represented, the rest being cut off, because it would have covered the defending steam pipe CC. When continued down, it comes between the eye and the box E of the lower steam valve, and the box F of the lower eduction-valve.

Let us now trace the operation of this machine through all its steps. Recurring to fig. 11, let us suppose that the lower part of the cylinder BB is exhausted of all elastic fluids; that the upper steam valve D and the lower eduction valve F are open, and that the lower steam valve E and upper eduction valve N are shut. It is evident that the piston must be pressed toward the bottom of the cylinder, and must pull down the end of the working beam by means of the toothed rack OO and sector QQ, causing the other end of the beam to urge forward the machinery with which it is connected. When the piston arrives at the bottom of the cylinder, the valves D and E are shut by the plug frame, and E and N are opened. By this last passage the steam gets into the eduction-pipe, where it meets with the injection water, and is rapidly condensed. The steam from the boiler enters at the same time by E, and pressing on the lower side of the piston, forces it upwards, and by means of the toothed rack OO and toothed sector QQ forces up that end of the working beam, and causes the other end to urge forward the machinery with which it is connected; and in this manner the operation of the engine may be continued for ever.

The injection water is continually running into the eduction-pipe, because condensation is constantly going on, and therefore there is a continual atmospheric pressure to produce a jet. The air which is disengaged from the water, or enters by leaks, is evacuated only during the rise of the piston of the air-pump K. When this is very copious, it renders a very large air-pump necessary; and in some situations Mr. Watt has been obliged to employ two air-pumps, one worked by each arm of the beam. This in every case expends a very considerable portion of the power, for the air-pump is always working against the whole pressure of the atmosphere.

It is evident that this form of the engine, by maintaining an almost constant and uninterrupted impulse, is much fitter for driving any machinery of continued motion than any of the former engines, which were inactive during half of their motion. It does not, however, seem to have this superiority when employed to draw water: But it is equally fitted for this task. Let the engine be loaded with twice as much as would be proper for it if a single stroke engine, and let a fly be connected with it. Then it is plain that the power of the engine during the rise of the steam piston will be accumulated in the fly; and this, in conjunction with the power of the engine during the descent of the steam piston, will be equal to the whole load of water.

In speaking of the steam and eduction valves, we said that they were all puppet valves. Mr. Watt employed cocks, and also sliding valves, such as the regulator or steam-valves of the old engines. But he found them always lose their tightness after a short time. This is not surprising, when we consider that they are always perfectly dry, and almost burning hot. He was therefore obliged to change them all for puppet clacks, which, when truly ground and nicely fitted in their motions at first, are not found to go out of order by any length of time. Other engineers now universally use them in the old form of the steam-engine, without the same reasons, and merely by servile and ignorant imitation.

The way in which Mr. Watt opens and shuts these valves is as follows. Fig. 13. represents a clack with its...
its seat and box. Suppose it one of the elevation valves. HH is part of the pipe which introduces the steam, and GG is the upper part of the pipe which communicates with the condenser. At EE may be observed a piece more faintly shaded than the surrounding parts. This is the seat of the valve, and is a brass or bell-metal ring turned conical on the outside, so as to fit exactly into a conical part of the pipe G G. These two pieces are fitted by grinding, and the cone being of a long taper, the ring clings firmly in it, especially after having been there for some time and united by rust. The clack itself is a strong brass plate D, turned conical on the edge, so as to fit the conical or sloping inner edge of the seat. These are very nicely ground on each other with emery. This conical joining is much more obtuse than the outer side of the ring; so that although the joint is air-tight, the two pieces do not stick strongly together. The clack has a round tail D G, which is freely moveable up and down in the hole of a cross piece F F. On the upper side of the valve is a strong piece of metal D C firmly joined to it, one side of which is formed into a toothed rack. A is the section of an iron axle which turns in holes in the opposite sides of the valve-box, where it is nicely fitted by grinding, so as to be air-tight. Collars of thick leather, well soaked in melted tallow and rotten, are screwed on the outside of these holes to prevent all ingress of air. One end of this axis projects a good way without the box, and carries a spanner or handle, which is moved by the plug-frame. To this axis is fixed a strong piece of metal B, the edge of which is formed into an arch of a circle having the axis A in its centre, and is cut into teeth, which work in the teeth of the rack D C. K is a cover which is fixed by screws to the top of the box H J H, and may be taken off in order to get at the valve when it needs repairs.

From this description it is easy to see that by turning the handle which is on the axis A, the sector B will lift up the valve by means of its toothed rack D C, till the upper end of the rack touches the knob or button K. Turning the handle in the opposite direction brings the valve down again to its seat.

This valve is extremely tight. But in order to open it for the passage of the steam, we must exert a force equal to the pressure of the atmosphere. This in a large engine is a very great weight. A valve of six inches diameter sustains a pressure not less than 400 pounds. But this force is quite momentary, and hardly impedes the motion of the engine; for the infant the valve is detached from its seat, although it has not moved the 100th part of an inch, the pressure is over. Even this little inconvenience has been removed by a delicate thought of Mr Watt. He has put the spanner in such a position when it begins to raise the valve, that its mechanical energy is almost infinitely great. Let Q R (fig. 14) be part of the plug frame descending, and P one of its pins just going to lay hold of the spanner N O movable round the axis N. On the same axis is another arm N M connected by a joint with the leader ML which is connected also by a joint with the spanner L A that is on the axis A of the sector within the valve-box. Therefore when the pin P pushes down the spanner N O, the arm N M moves sidewise and pulls down the spanner L A, by means of the connecting rod. Things are so disposed, that when the cock is shut, L M and M N are in one straight line. The intelligent mechanic will perceive that, in this position, the force of the lever O N M is insuperable. It has this further advantage, that if any thing should tend to force open the valve, it would be infinitely far no force exerted at A, and transmitted by the rod L M, can possibly pull the joint M out of its position. Of such importance is it to practical mechanics, that its professors should be persons of penetration as well as knowledge. Yet this circumstance unheeded by hundreds who have servilely copied from Mr Watt, as may be seen in every engine that is puffed on the public as a discovery and an improvement. When these puppet valves have been introduced into the common engine, we have not seen one instance where this has been attended to; certainly because its utility has not been observed: and there is one situation where it is of more consequence than in Mr Watt's engine, viz. in the injection-cock. Here the valve is drawn back into a box, where the water is so awkwardly disposed that it can hardly get out of its way, and where the pressure even exceeds that of the atmosphere. Indeed this particular substitution of the button-valve for the cock is most injudicious.

We postponed any account of the office of the fly X X (fig. 11.) until it was not of use in a common engine regulated by the fly V V. The fly X X is only for regulating the reciprocating motion of the beam when the steam is not admitted during the whole descent of the piston. This it evidently must render more uniform, accumulating a momentum equal to the whole pressure of the full supply of steam, and then sharing it with the beam during the rest of the descent of the piston.

When a person properly skilled in mechanics and chemistry reviews these different forms of Mr Watt's steam-engine, he will easily perceive them susceptible of many intermediate forms, in which any one or more of the distinguishing improvements may be employed. The first great improvement was the condensation in a separate vessel. This increased the original powers of the engine, giving to the atmospheric pressure and to the counter weight their full energy; at the same time the waste of steam is greatly diminished. The next improvement by employing the pressure of the steam instead of that of the atmosphere, was only at a still further diminution of the waste; but was so full in advantages, rendering the machine more manageable, and particularly enabling us at all times, and without trouble, to fuit the power of the engine to its load of work, however variable and increasing; and brought into view a very interesting proposition in the mechanical theory of the engine, viz. that the whole performance of a given quantity of steam may be augmented by admitting it into the cylinder only during a part of the piston's motion. Mr Watt has varied the application of this proposition in a thousand ways; and there is nothing about the machine which gives more employment to the sagacity and judgment of the engineer. The third improvement of the double impulse may be considered as the finishing touch given to the engine, and renders it as uniform in its action as any water-wheel. In the engine in its most perfect form there does not seem to be above one-fourth of the steam wasted by warming the apparatus; so that it is not possible to make it one-fourth part more powerful than it is at present. The only thing that seems susceptible of considerable improvement
Steam-Engine.

The only improvement now wanting is to strengthen the great beam.

The enormous strains exerted on its arms require a proportional strength. This requires a vast mass of matter, not less indeed in an engine with a cylinder of 34 inches than three tons and a half, moving with the velocity of three feet in a second, which must be communicated in about half a second. This mass must be brought into motion from a plate of reef, must again be brought to reef, again into motion, and again to reef, to complete the period of a stroke.

This consumes much power; and Mr Watt has not been able to load an engine with more than 10 or 11 pounds on the inch and prefer a sufficient quantity of motion, so as to make 12 or 15 six-feet strokes in a second. Many attempts have been made to lessen this mass by using a light framed wheel, or a light frame of carpentry, in place of a solid beam. These have generally been contrived by persons ignorant of the true scientific principles of carpentry, and have failed accordingly. Mr Watt has made similar attempts; but found, that although at first they were abundantly strong, yet after a short time's employment the flaps and bolts with which the wooden parts were connected cut their way into the wood, and the framing grew loose in the joints, and, without giving any warning, went to pieces in an instant. A solid malleable beam, of sufficient strength, bends, and sufficiently complais (as the carpenters express it), before it breaks. In all great engines, therefore, such only are employed, and in smaller engines he sometimes uses cast-iron wheels or pulleys; nay, he frequently uses no beam or equivalent whatever, but employs the steam piston-rod to drive the machinery to which the engine is applied.

We premise that our thinking readers will not be displeased with this rational history of the progress of this engine in the hands of its ingenious and worthy inventor. We owe it to the communications of a friend, well acquainted with him, and able to judge of his merits. The public see him always associated with the no less celebrated mechanic and philosopher Mr Boulton of Soho near Birmingham (see Soho). They have shared the royal patent from the beginning; and the alliance is equally honourable to both.

The advantages derived from the patent-right flew both the superiority of the engine and the liberal minds of the proprietors. They erect the engines at the expense of the employers, or give working drafts of all the parts, with instructions, by which any resident engineer may execute the work. The employers select the best engine of the ordinary kind in the kingdom, compare the quantities of fuel expended by each, and pay to Meif's Watt and Boulton one-third of the annual savings for a certain term of years. By this the patentees are excited to do their utmost to make the engine perfect; and the employer pays in proportion to the advantage he derives from it.

It may not be here improper to state the actual performance of some of these engines, as they have been ascertained by experiment.

An engine having a cylinder of 31 inches in diameter, and making 17 double strokes per minute, performs the work of forty horses working night and day (for which three relays or 120 horses must be kept), and burns 11,000 pounds of Staffordshire coal per day. A cylinder of 19 inches, making 25 strokes of 4 feet each per minute, performs the work of 12 horses working contemporaneously, and burns 3,700 pounds of coal, per day.

Proposed to drain the Haerlem Meer by the steam-engine.
of its principle, and have more than once pointed out the real improvements, that they may be firmly fixed and always ready in the mind. By having recourse to them, the reader may pronounce with confidence on the merits of any new construction, and will not be deceived by the puff of an ignorant or dishonest engineer.

We must except from this general criticism a construction by Mr Jonathan Hornblower near Bristol, on account of its singularity, and the ingenuity and real skill which appears in some particulars of its construction. The following short description will sufficiently explain its principle, and enable our readers to appreciate its merit.

A and B (fig. 15.) represent two cylinders, of which A is the largest. A piston moves in each, having their rods C and D moving through collars at E and F. These cylinders may be supplied with steam from the boiler by means of the square pipe G, which has a flanch to connect it with the rest of the steam-pipe. This square part is represented as branching off to both cylinders. c and d are two cocks, which have handles and turnbroers as usual, worked by the plug-beam W.

On the fore-side (that is, the side next the eye) of the cylinders is represented another communicating pipe, whose section is also square or rectangular, having also two cocks a and b. The pipe Y, immediately under the cock b, establishes a communication between the upper and lower parts of the small cylinder B, by opening the cock b. There is a similar pipe on the other side of the cylinder A, immediately under the cock d. When the cocks c and a are open, and the cocks b and d are shut, the steam from the boiler has free admission into the upper part of the cylinder B, and the steam from the lower part of B has free admission into the upper part of A; but the upper part of each cylinder has no communication with its lower part.

From the bottom of the great cylinder proceeds the admission-pipe K, having a valve at its opening into the cylinder, which bends downwards, and is connected with the conical condenser L (c). The condenser is fixed on a hollow box M, on which stand the pumps N and O for extracing the air and water, which last runs along the trough T into a cistern U, from which it is raised by the pump V for recruiting the boiler, being already nearly boiling hot. Immediately under the condenser there is a figet valve at S, over which is a small jet pipe, reaching to the bend of the eduction-pipe. The whole of the condensing apparatus is contained in a cistern R of cold water. A small pipe P comes from the side of the condenser, and terminates on the bottom of the trough T, and there covered with a valve Q, which is kept tight by the water that is always running over it. Lastly, the pump-rods X cause the outer end of the beam to preponderate, so that the quickest position of the beam is that represented in the figure, the pistons being at the top of the cylinders.

Suppose all the cocks open, and steam coming in copiously from the boiler, and no condensation going on in L; the steam must drive out all the air, and at last follow it through the valve Q. Now shut the valves b and d, and open the valve S of the condenser. The condensation will immediately commence. There is now no preasure on the under side of the piston of A, and it immediately descends. The communication between the lower part of B and the upper part of A being open, the steam will go from B into the space left by the piston of A. It must therefore expand, and its elasticity must diminish, and will no longer balance the pressure of the steam above the piston of B. This piston therefore, if not with-held by the beam, would descend till it is in equilibrio, having steam of equal density above and below it. But it cannot descend so far; for the cylinder A is wider than B, and the arm of the beam at which its piston hangs is longer than the arm which supports the piston of B: therefore when the piston of B has descended as far as the beam will permit it, the steam between the two pistons occupies a larger space than it did when both pistons were at the tops of their cylinders. Its density, therefore, and its elasticity, diminish as its bulk increases. It is therefore not a balance; for the steam on the upper side of B, and the piston B, pull at the beam with all the difference of these pressures. The slightest view of the subject must show the reader, that as the pistons descend, the steam that is between them will grow continually rarer and less elastic, and that both pistons will pull the beam downwards.

Suppose now that each has reached the bottom of its cylinder. Shut the cock a and the aduction cock at the bottom of A, and open the cocks b and d. The communication being now established between the upper and lower part of each cylinder, nothing hinders the counter weight from raising the pistons to the top. Let them arrive there. The cylinder B is at this time filled with steam of the ordinary density, and the cylinder A with an equal absolute quantity of steam, but expanded into a larger space.

Shut the cocks b and d, and open the cock a, and the aduction cock at the bottom of A; the condensation will again operate, and the pistons descend. And thus, the operation may be repeated as long as steam is supplied; and one full of the cylinder B of ordinary steam is expended during each working stir. ke.

Let us now examine the power of this engine. It is evident, that when both pistons are at the top of their respective cylinders, the active pressure (that is, the difference of the pressure on its two sides) on the piston of B is nothing, while that on the piston of A is equal to the full pressure of the atmosphere on its area. This, multiplied by the length of the arm by which it is supported, gives its mechanical energy. As the pistons descend, the pressure on the piston of B increases, while that on the piston of A diminishes. When b-th are at the bottom, the pressure on the piston of B is at its maximum, and that on the piston of A at its minimum.

Mr Hornblower saw that this must be a beneficial employment of steam, and preferable to the practice of condensing it while its full elasticity remained; but he has not considered it with the attention necessary for ascertaining the advantage with precision.

Let a and b represent the areas of the pistons of A and...
and B, and let \( x \) and \( \beta \) be the lengths of the arms by which they are supported. It is evident, that when both pistons have arrived at the bottoms of their cylinders, the capacities of the cylinders are as \( x \) and \( \beta \).

Let this be the ratio of \( m \) to \( n \). Let \( g b k \) (fig. 16) and \( l m n \) be two cylinders of equal length, communicating with each other, and fitted with a piston-rod \( qr \), on which are fixed two pistons \( a a \) and \( b b \), whose areas are as \( m \) and \( n \). Let the distance between the pistons be precisely equal to the height of each cylinder, which height we shall call \( h \). Let \( x \) be the space \( g b \) or \( b a \), through which the pistons have descended. Let the upper cylinder communicate with the boiler, and the lower cylinder with the condenser or vacuum \( V \).

Any person in the least conversant in mechanics and pneumatics will clearly see that the strain or pressure on the piston-rod \( pq \) is precisely the same with the united energies of the two piston rods of Mr. Hornblower’s engine, by which they tend to turn the working beam round its axis.

The base of the upper cylinder being \( b \), and its height \( b \), its capacity or bulk is \( h b \) or \( b h \); and this expresses the natural bulk of the steam which formerly filled it, and is now expanded into the space \( b l a m l b \). The part \( b b b \) is plainly \( b - x \), and the part \( la am \) is \( m - x \). The whole space therefore is \( m + b - x \),

\[ = b + m - x \text{ or } b + m - 1 \times \]

Therefore the density of the steam between the pistons is

\[ \frac{b}{b + m - 1} \]

Let \( p \) be the downward pressure of the steam from the boiler on the upper piston \( b b \). This piston is also pressed up with a force \( \frac{p}{b + m - 1} \) by the steam between the pistons. It is therefore, on the whole,

\[ \text{pressed downward with a force } = p \left( \frac{1}{b + m - 1} \right) \times \]

The lower piston \( a a \), having a vacuum below it, is pressed downwards with a force \( \frac{mb}{b + m - 1} \times \). Therefore the whole pressure on the piston rod downwards is

\[ = \frac{p}{b + m - 1} \times \left( 1 + \frac{mb}{b + m - 1} \right) = \frac{p}{b + m - 1} + \frac{pmb}{b + m - 1} \times \]

This then is the momentary pressure on the piston rod corresponding to its descent \( x \) from its highest position. When the pistons are in their highest position, this pressure is equal to \( mb \). When they are in their lowest position, it is \( \frac{2mb}{b + m - 1} \). Herefore there is an accessional power. In the beginning the pressure is greater than on a single piston in the proportion of \( m \) to \( 1 \); and at the end of the stroke, where the pressure is weakest, it is still much greater than the pressure on a single piston. Thus, if \( m \) be 4, the pressure at the beginning of the stroke is \( 4p \), and at the end it is \( \frac{7}{4} p \), almost double, and in all intermediate positions it is greater. It is worth while to obtain the sum total of all the accumulated pressures, that we may compute it with the constant pressure on a single piston.

We may do this by considering the momentary pressure \( \frac{p}{h} + \frac{p}{b} \), as equal to the ordinate \( GF \),

\[ = \frac{p}{h} + \frac{p}{b} \]

H \( b \), or \( Mc \), of a curve \( F b c \) (fig. 10), which has for its axis the line \( GM \) equal to \( b \) the height of our cylinder. Call this ordinate \( y \). We have \( y = \frac{p}{h} + \frac{p}{b} \), and \( y - p = \frac{p}{h} \). Now it is plain that

\[ = \frac{p}{b} \]

is the ordinate of an equilateral hyperbola,

\[ = \frac{m - 1}{m} \times \]

of which \( p \) is the power or rectangle of the ordinate and absciss, and of which the absciss reckoned from the centre is \( \frac{b}{m - 1} \). Therefore make \( GE = p \), and draw \( DE A \) parallel to \( MG \), and make \( E A = \frac{GM}{m - 1} \)

equal to \( B \). The curve \( F b c \) is an equilateral hyperbola, having \( A \) for its centre and \( A D \) for its asymptote.

Draw the other asymptote \( AB \), and its ordinate \( FB \). Since the power of the hyperbola is \( \frac{pp}{b} = GEDM \) (for \( GE = p \), and \( GM = b \)); and since all the inscribed rectangles, such as \( AEFB \), are equal to \( p \), it follows that \( AEFB \) is equal to \( GEDM \), and that the area \( ABFD \) is equal to the area \( GFEM \), which expresses the accumulated pressure in Hornblower’s engine.

We can now compute the accumulated pressure very easily. It is evidently \( p \times (1 + \frac{L \times AD}{AE}) \).

The intelligent reader cannot but observe that this is the accumulated pressure with the accumulated pressure of a mulated quantity of steam admitted in the beginning, and flopped in Mr. Watt’s method, when the piston has descended through the middle part of the cylinder. In considering Mr. Hornblower’s engine, the thing was presented in so different a form that we did not perceive the analogy at first, and we were surprised at the result. We could not help even regretting it, because it had the appearance of a new principle and an improvement; and we doubt not but that it appeared so to the ingenious author; for we have had such proofs of his liberality of mind as permit us not to suppose that he faw it from the beginning, and availed himself of the difficulty of tracing the analogy. And as the thing may mislead others in the same way, we have done a service to the public by showing that this engine, so costly and so difficult in its construction, is no way superior in power to Mr. Watt’s simple method of dropping the steam. It is even inferior, because there must be a condensation in the communicating passages. We may add, that if the condensation is performed in the cylinder \( A \), which it must be unless with the permission of Watt and Boulton, the engine cannot be much superior to a common engine; for much of the steam from below \( B \) will be condensed between the pistons by the coldness of the cylinder \( A \); and this diminishes the
Steam-Engine.

"downward pressure on A more than it increases the downward pressure on B. We learn however that, by confining the condensation to a small part of the cylinder A, Mr. Hornblower has erected engines clear of Mr. Watt's patent, which are considerably superior to Newcomen's: for he has Mr. Symington.

"We said that there was much ingenuity and real skill observable in many particulars of this engine. The disposition and connection of the cylinders, and the whole condensing apparatus, are contrived with peculiar neatness. The cocks are very ingenious; they are composited of two flat circular plates ground very true to each other, and one of them turns round on a pin through their centres; each is pierced with three sectoral apertures, exactly corresponding with each other, and occupying a little less than one half of their surfaces. By turning the moveable plate so that the apertures coincide, a large passage is opened for the steam; and by turning it so that the solid of the one covers the aperture of the other, the cock is shut. Such regulators are now very common in the cast iron flues for warming rooms.

Mr. Hornblower's contrivance for making the collars for the piston rods air-tight is also uncommonly ingenious: This collar is in fact two, at a small distance from each other. A small pipe, branching off from the main steam-pipe, communicates with the space between the collars. This steam, being a little stronger than the pressure of the atmosphere, effectually hinders the air from penetrating by the upper collar; and though a little steam should get through the lower collar into the cylinder A, it can do no harm. We see many cases in which this pretty contrivance may be of signal service.

But it is in the framing of the great working beam that Mr. Hornblower's scientific knowledge is most conspicuous; and we have no hesitation in affirming that it is stronger than a beam of the common form, and containing twenty times its quantity of timber. There is hardly a part of it exposed to a transverse strain, if we except the strain of the pump V on the bucket by which it is worked. Every piece is either pushed or pulled in the direction of its length. We only fear that the bolts which connect the upper beam with the two iron bars under its ends will work loose in their holes, and tear out the wood which lies between them. We would propose to substitute an iron bar for the whole of this upper beam. This working beam highly deserves the attention of all carpenters and engineers. We have that opinion of Mr. Hornblower's knowledge and talents, that we are confident that he will see the fairness of our examination of his engine, and we trust to his candour for an excuse for our criticism.

The reciprocating motion of the steam-engine has always been considered as a great defect; for though it be now obviated by connecting it with a fly, yet, unless it is an engine of double stroke, this fly must be a source of much matter moving with great velocity. Any accident happening to it would produce dreadful effects: A part of the rim detaching itself would have the force of a bomb, and no building could withstand it. Many attempts have been made to produce a circular motion at once by the steam. It has been made to blow on the vanes of a wheel of various forms. But the reality of steam is such, that even if none is condensed by the cold of the vanes, the impulse is exceedingly feeble, and the expense of steam, so as to produce any serviceable impulse, is enormous. Mr. Watt, among his first speculations on the steam-engine, made some efforts of this kind. One in particular was uncommonly ingenious. It consisted of a drum turning air-tight within another, with cavities disposed that there was a constant and great pressure urging it in one direction. But no packing of the common kind could preserve it air-tight with sufficient mobility. He succeeded by immersing it in mercury, or in an amalgam which remained fluid in the heat of boiling water; but the continual trituration soon calcined the fluid and rendered it useless. He then tried Parent's or Dr. Barker's mill, including the arms in a metal drum, which was immersed in cold water. The steam rushed rapidly along the pipe which was the axis, and it was hoped that a great reaction would have been exerted at the ends of the arms; but it was almost nothing. The reason seems to be, that the greatest part of the steam was condensed in the cold arms. It was then tried in a drum kept boiling hot; but the impulse was now very small in comparison with the expense of steam. This must be the cafe.

Mr. Watt has described in his specification to the patent office some contrivances for producing a circular motion by the immediate action of the steam. Some of these produce alternate motions, and are perfectly analogous to his double stroke engine. Others produce a continued motion. But he has not given such a description of his valves for this purpose as can enable an engineer to construct one of them. From any guesses that we can form, we think the machine very imperfect; and we do not find that Mr. Watt has ever erected a continuous circular engine. He has doubtless found all his attempts inferior to the reciprocating engine with a fly. A very crude scheme of this kind may be seen in the transactions of the Royal Society of Dublin 1787. But although our attempts have hitherto failed, we hope that the cafe is not yet desperate. We see different principles which have not yet been employed.

We shall conclude our account of this noble engine by observing, that Mr. Watt's form suggests the construction of an excellent air-pump. A large vessel may be made to communicate with a boiler at one side, and with the pump-receiver on the other, and also with a condenser. Suppose this vessel of ten times the capacity of the receiver; fill it with steam from the boiler, and drive out the air from it; then open its communication with the receiver and the condenser. This will rarely the air of the receiver 10 times. Repeating the operation will rarely it 100 times; the third operation will rarely it 1000 times; the fourth 10,000 times, &c. All this may be done in half an hour.

Steam-Kitchen. Ever since Dr. Papin contrived his digester (about the year 1690), schemes have been proposed for dreeing victuals by the steam of boiling water. A philosophical club used to dine at Saltero's coffee-house, Chelsea, about 50 years ago, and had their victuals dreeed by hanging them in the boiler of the steam-engine which raies water for the supply of Piccadilly and its neighbourhood. They were competes, ly dreeed, and both expeditiously and with high flavour.

A patent.
Hornblower's
STEAM ENGINE

Fig. 14.

Fig. 15.

Fig. 16.
A patent was lately obtained for an apparatus for this purpose by a tin-man in London; we think of the name of Tate. They are made on a much more effectual plan by Gregory, an ingenious tradesman in Edinburgh, and are coming into very general use.

It is well known to the philosopher that the steam of boiling water contains a prodigious quantity of heat, which it retains in a latent state. This, however, is accounted for. Every cook knows the great cooling power of a cold vessel; and if he make the surface of the water in it, it will have heated the mafs of cold water as much as if we had thrown into it seven or eight hundred pounds of boiling hot water.

If, therefore, a boiler be properly fitted up in a furnace, and if the steam of the water boiling in it be conveyed by a pipe into a pan containing vessels to be dressed, every thing can be cooked that requires no higher degree of heat than that of boiling water: And this will be done without any risk of scorching, or any kind of overheating, which frequently spoils our dishes, and proceeds from the burning heat of air coming to those parts of the pot or pan which is not filled with liquor, and is covered only with a film, which quickly, and is covered only with a film, which quickly but a small portion of a kind of oil is poured over the liquor, and is covered only with a film, which quickly but a small portion of cold water, which the cook be scorching by the great heat of the open fire that is necessary for dressing at once a number of dishes, nor have his perfon and clothes soiled by the smoke and foot unavoidable in the cooking on an open fire. Indeed the whole process is so neat, so manageable, so open to inspection, and so cleanly, that it need neither fatigue nor offend the delicacy of the nicest lady.

We had great doubts, when we first heard of this as a general mode of cookery, as to its economy; we had none as to its efficacy. We thought that the steam, and consequently the fuel expended, must be vastly greater than by the immediate use of an open fire; but we have seen a large tavern dinner expeditiously dressed in this manner, seemingly with much less fuel than in the common method. The following simple narration of facts will show the superiority. In a paper manufacture near Edinburgh, the vats containing the pulp into which the frames are dipped are about six feet diameter, and contain above 200 gallons. This is brought to a proper heat by means of a small cockle or furnace in the middle of the liquor. This is heated by putting in about one hundred weight of coals about eight o'clock in the evening, and continuing this till four next morning, renewing the fuel as it burns away. This method was lately changed for a steam heater. A furnace, having a boiler of five or six feet diameter and three feet deep, is heated about one o'clock in the morning with two hundred weight of coals, and the water kept in brisk ebullition. Pipes go off from this boiler to fix vats, some of which are at go feet distance. The steam is conveyed to a flat box or vessel in the midst of the pulp where it condenes, imparting its heat to the fides of the box, and thus heats the surrounding pulp. These fix vats are as completely heated in three hours, expending about three hundred weight of coal, as they were formerly in eight hours, expending near 18 hundred weight of coals. Mr Gregory, the inventor of this steam-heater, has obtained (in company with Mr Scott plumber, Edinburgh) a patent for the invention; and we are persuaded that it will come into very general use for many similar purposes. The dyers, hatmakers, and many other manufacturers, have occasion for large vats kept in a continual heat; and there seems no way fo effectual.

Indeed when we reflect seriously on the subject, we see that this method has immense advantages considered merely as a mode of applying heat. The steam may be applied to the vessel containing the vituals in every part of its surface: it may either be made to enter the vessel, and apply itself immediately to the piece of meat: that is to be dressed; and without any risk of scorching or overdoing.—And it will give out about 2/3 of the heat which it contains, and will do this only if it be wanted; so that no heat whatever is wasted except what is required for heating the apparatus. Experience shows that this is a mere trifle in comparison of what was supposed necessary. But with an open fire we only apply the flame and hot air to the bottom and part of the sides of our boiling vessels: this application is hurried in the extreme; for to make a great heat, we must have a great fire, which requires a prodigious and most rapid current of air. This air touches our pans but for a moment, imparts to them but a small portion of its heat; and, we are persuaded, that three-fourths of the heat is carried up in the chimney, and escapes in pure waste, while another great portion beams out into the kitchen to the great annoyance of the scorching cook. We think, therefore, that a page or two of this work will not be thrown away in the description of a contrivance by which a saving may be made to the entertainer, and the providing the pleasures of his table prove a less fatiguing task to this valuable corps of practical chemists.

Let A represent a kitchen-boiler, either properly fitted up in a furnace, with its proper fire-place, althip, and flue, or set on a tripod on the open fire, or built up in the general fire-place. The steam-pipe BC rises from the cover of this boiler, and then is laid away with a gentle ascent in any convenient direction. C represents the section of this conducting steam-pipe. Branches are taken off from the side at proper distances. One of these is represented at CDE, furnished with a cock D, and having a taper nozzle E, fitted by grinding into a conical piece F, which communicates with an upright pipe GH, which is folded to the side of the flowing vessel PQRS, communicating with it by the short pipe I. The vessel is fitted with a cover OT, having a staple handle V. The piece of meat M is laid on a tin plate grate KL, pierced with holes like a cullender, and standing on three short feet n n n. The steam from the boiler comes in by the pipe I; and is condensed by the meat and by the sides of the vessel, communicating to them all its heat. What is not so condensed escapes between the vessel and its cover. The condensed water lies on the bottom of the vessel, mixed with a very small quantity of gravy and fatty matter from the vituals. Frequently, instead of a cover, another fixed-veil with a cullender bottom is set on this one, the bottom of the one fitting the mouth.
STE

EWR.

Fig. 6.

of the other: and it is observed, that when this is done, the dish in the under vessel is more expeditiously and better dressed, and the upper dish is more slowly, but as completely dried.

This description of a flowing vessel may serve to give a notion of the whole; only we must observe, that when broths, soups, and dishes with made sauces or containing liquids, are to be dressed, they must be put into a smaller vessel, which is set into the vessel PQRS, and is supported on three short feet, so that there may be a space all round it of about an inch or three quarters of an inch. It is observed, that dishes of this kind are not so expeditiously cooked as on an open fire, but as completely in the end, only requiring to be turned up now and then to mix the ingredients; because as the liquids in the inner vessel can never come into ebullition, unless the steam from the boiler be made of a dangerous heat, and every thing be close confined, there cannot be any of that tumbling motion that we observe in a boiling pot.

The performance of this apparatus is far beyond any expectation we had formed of it. In one of which we examined, four pans were flowing together by means of a boiler 10 inches in diameter, flanding on a brisk open fire. It boiled very briskly, and the steam puffed frequently through the chinks between the steam-pans and their covers. In one of them was a piece of meat considerably above 30 pounds weight. This required above four hours flowing, and was then very thoroughly and equally cooked; the outside being no more done than the heart, and it was near two pounds heavier than when put in, and greatly swelled. In the mean time, several dishes had been dressed in the other pans. As far as we could judge, this cooking did not consume one third part of the fuel which an open fire would have required for the same effect.

When we consider this apparatus with a little more knowledge of the mode of operation of fire than falls to the share of the cooks (we speak with deference), and consider the very injudicious manner in which the steam is applied, we think that it may be improved so as to surpass any thing that the cook can have a notion of.

When the steam enters the steam-pan, it is condensed on the meat and on the vessel; but we do not want it to be condensed on the vessel. And the surface of the vessel is much greater than that of the meat, and continues much colder; for the meat grows hot, and continues so, while the vessel, made of metal which is a very perfect conductor of heat, is continually robbed of its heat by the air of the kitchen, and carried off by it. If the meat touch the side of the pan in any part, no steam can be applied to that part of the meat, while it is continually imparting heat to the air by the intermediate of the vessel. Nay, the meat can hardly be dressed unless there be a current of steam through it; and we think this confirmed by what is observed above, that when another steam-pan is set over the first, and thus gives occasion to a current of steam through its cullender bottom to be condensed by its sides and contents, the lower dish is more expeditiously dried. We imagine, therefore, that not less than half of the steam is wafted on the sides of the different steam-pans. Our first attention is therefore called to this circumstance, and we with to apply the steam more economically and effectually.

We would therefore construct the steam-kitchen in the following manner:

We would make a wooden chest (which we shall call the Steam-chest) A B C D. This should be made of deal, in very narrow slips, not exceeding an inch, that it may not shrink. This should be lined with very thin copper, lead, or even strong tinfoil. This will prevent it from becoming a conductor of heat by soaking with steam. For further security it might be set in another chest, with a space of an inch or two all round, and this space filled with a composition of powdered charcoal and clay. This should be made by first making a mixture of fine potter's clay and water about as thick as poor cream; then as much powdered charcoal must be beat up with this as can be made to stick together. When this is rammed in and dry, it may be hot enough on one side to melt glass, and will not discolor white paper on the other.

This chest must have a cover L M N O, also of wood, having holes in it to receive the steam-pans P, Q, R. Between each pan is a wooden partition, covered on both sides with milled lead or tinfoil. This whole top must be covered with very spongy leather or felt, and made very flat. Each steam-pan must have a bearing or shoulder all round it, by which it is supported, refting on the felt, and lying so close and true that no steam can escape. Some of the pans should be fimple, like the pan F, for dressing broths and other liquid dishes. Others should be like E and G, having in the bottom a pretty wide hole H, K, which has a pipe in its upper side, rising about an inch or an inch and half into the steam-pan. The meat is laid on a cullender plate, as in the common way; only there must be no holes in the cullender immediately above the pipe. These steam-pans must be fitted with covers, or they may have others fitted to their mouths, for warming sauces or other dishes, or steaming greens, and many other subordinate purposes for which they may be fitted.

The main-pipe from the boiler must have branches, (each furnished with a cock), which admit the steam into these divisions. At its first entry some will be condensed on the bottom and sides; but we imagine that these will in two minutes be heated so as to condense no more, or almost nothing. The steam will also quickly condense on the steam-pan, and in h. If a minute make it boiling hot, so that it will condense no more; all the rest will now apply itself to the meat and to the cover. It may perhaps be advisable to allow the cover to condense steam, and even to waft it. This may be promoted by laying on it flannel soaked in water. Our view in this is to create a demand for steam, and thus produce a current through the steam-pan, which will be applied in its passage to the viands. But we are not certain of the necessity of this. Steam is not like common air of the same temperature, which would glide along the surfaces of bodies, and impart to them a small portion of its heat, and escape with the rest. To produce this effect there must be a current; for air hot enough to melt lead, will not boil water, if it be kept stagnant round the vessel. But steam imparts the whole of its latent heat to any body colder than boiling water, and goes no farther till this body be made boiling hot.
It is a most faithful carrier of heat, and will deliver its whole charge to any body that can take it. Therefore, although there were no partitions in the stew-chest, and the steam were admitted at the end next the boiler, if the pan at the farther end be colder than the rest, it will all go therewith, and will, in short, communicate to every thing impartially according to the demand. If any person has not the confidence in the steam which we express, he may still be certain that there must be a prodigious saving of heat by confining the whole in the stew-chest; and he may make the pans with entire bottoms, and admit the steam into them in the common way, by pipes which come through the sides of the chest and then go into the pan. There will be none lost by condenfation on the sides of the chest; and the pans will soon be heated up to the boiling temperature; and hardly any of their heat will be wasted, because the air in the chest will be flagrant. The chief reason for recommending our method is the much greater ease with which the stew-pans can be shifted and cleaned. There will be little difference in the performance.

Nay, even the common stew-kitchen may be prodigiously improved by merely wrapping each pan in three or four folds of coarse dry flannel, or making flannel bags of three or four folds fitted to their shapes, which can be put on or removed in a minute. It will also greatly conduce to the good performance to wrap the main steam-pipe in the same manner in flannel.

We find that this main-pipe is conducted from the boiler with a gentle ascent. The intention of this is, that the water produced by the unavoidable condenfation of the steam may run back into the boiler. But the rapid motion of the steam generally sweeps it up hill, and it runs into the branch-pipes and descends into the stew-pans. Perhaps it would be as well to give the main-pipe a declivity the other way, and allow all the water to collect in the hot well at the farther end, by means of a defending pipe, having aloaded valve at the end. This may be so contrived as to be close by the fire, where it would be so warm that it would not check the boiling if again poured into the boiler. But the utmost attention must be paid to cleanliness in the whole of this passage, because this water is boiled again, and its steam passes through the heart of every dish. The circumstance forbids us to return into the boiler what is condensed in the stew-pans. This would mix the tastes and flavors of every dish, and be very disagreeable. All this must remain in the bottom of each stew-pan; for which reason we put in the pipe rising up in the middle of the bottom. It might indeed be allowed to fall down into the stew-chest, and to be collected in a common receptacle, while the fat would float at top, and the clear gravy be obtained below, perhaps fit for many sauces.

The completed method for getting rid of this condensed steam would be to have a small pipe running along the under side of the main conductor, and communicating with it at different places, in a manner similar to the air-dicharger on the mains of water-pipes. In the paper manufacture mentioned above, each steam-box has a pipe in its bottom, with a float-cock, by which the water is discharged; and the main pipe being of great diameter, and laid with a proper acclivity, the water runs back into a boiler.

But these precautions are of little moment in a steam-kitchen even for a great table; and for the general use of private families, would hurt the apparatus, by making it complex and of nice management. For a small family, the whole apparatus may be set on a table four feet long and two broad, which may be placed on casters, so as to be wheeled out of the way when not in use. If the main conductor be made of wood, or properly cased in flannel, it will condense so little steam that the cooking table may stand in the remotest corner of the kitchen without sensibly impairing its performance; and if the boiler be properly set up in a small furnace, and the flue made so that the flame may be applied to a great part of its surface, we are persuaded that three fourths of the fuel used in common cookery will be saved. Its only inconvenience seems to be the indispensable necessity of the most anxious cleanliness in the whole apparatus. The most trivial neglect in this will destroy a whole dinner.

We had almost forgotten to observe, that the boiler must be furnished with a funnel for supplying it with water. This should pass through the top, and its pipe reach near to the bottom. It will be proper to have a cock on this funnel. There should also be another pipe in the top of the boiler, having a valve on the top. If this be loaded with a pound on every square inch, and the fire so regulated that steam may be observed to puff sometimes from this valve, we may be certain that it is passing through our dishes with sufficient rapidity; and if we shut the cock on the funnel, and lead the valve a little more, we shall cause the steam to blow at the covers of the stew-pans. If one of these be made very tight, and have a hole also furnished with a loaded valve, this pan becomes a digester, and will dissolve bones, and do many things which are impracticable in the ordinary cookery.

Si quid non habebis, aliter facies.

Candidus impar est; non est utraque serpens.

STEATITIS or Soap earth, a genus of the magnesian order of earths. Of this genus there are several species, for which see Mineralogy. According to the analysis of Bergman, 100 parts of the earth contain 80 parts of files, 17 of mild magnesia, 2 of argillaceous earth, and nearly 1 of iron in a semioxidised state. This substance may be formed into a paste with water, sufficiently ductile to be worked on the potter's wheel; and by exposure to a great heat it is hardened so as to strike fire with ease. It has also the property of Fuller's Earth in cleaning cloths from grime; but it does not diffuse in water so well as clays do; and when digested with vitriolic acid, it does not form alum, as clays do, but a salt similar to Epson salt. From its softness and ductility it may be easily formed into pots for the kitchen; and hence it has got the name of lipisollaris.

STEATOMA, a kind of encysted tumor, confiding, of a matter like fat or hard, salty, without pain, and without discolouring the skin.

STEEL, iron united with carbon. See Iron. Steel has properties distinct from those of iron, which render it of superior value. From its higher degree of hardness it admits a finer polish and assumes a brighter colour. When tempered, it poises a higher degree of elascity, and is also more sonorous. It is more weakly attracted by the load-stone, it receives more slowly the magnetic power, but it preserves it longer. When exposed to a moil air, it does not contract rust so easily as...
iron. It is also heavier, increasing in weight, according to Chaptal, one hundred and seventieth part. M. Rinman has given as the result of several accurate experiments on different kinds of steel the following specific gravity 7.195, while he makes dulcite iron 7,700, and crude iron 7,251.

All iron is convertible into steel by exposing it to a certain degree of heat for a certain time along with a quantity of charcoal. Chemists differ in opinion concerning the nature and effects of this process. Some say that steel is produced by absorbing a quantity of caloric or heat in a latent state, as the older chemists had said it was formed by absorbing phlogiston. Lavoisier seems to have ascribed the qualities of steel to a slight degree of oxidation, others to a combination with plumbago or black lead, and others to a union with carbon. In agreeing with those who say the formation of steel is owing to carbon, we do not differ essentially from those who attribute it to plumbago; for the art of chemistry has now found that these substances are very nearly allied. Plumbago is a true charcoal combined with a little iron. The brilliant charcoal of certain vegetable substances, more especially when formed by distillation in close vessels, possesses all the characters of plumbago. The coal of animal substances poiffeles characters still more peculiarly resembling it. Like it they are difficult to incinerate, they leave the same impression on the hands and upon paper; they likewise contain iron, and become converted into carbonic acid by combustion. When animal substances are distilled by a strong fire, a very fine powder sublimes, which attaches itself to the inner part of the neck of the retort, and this sublimation may be made into excellent black lead pencils.

There are two ways of making steel, namely, by fusion and by cementation. The first way is used to convert iron into steel immediately from the ore, or from crude or cast-iron. By the second way, bar-iron is exposed to a long continued heat surrounded by charcoal. Each of these ways has advantages peculiar to itself; but the same cauex in fact predominate in both, for both kinds of steel are produced by heat and charcoal. The only difference between the two methods is this; in making steel by fusion the charcoal is not so equally defended from the access of air as in the other way.

Swedenborgius has given the following description of the method used in Dalcarlia for making steel from cast-iron. The ore from which the crude iron to be converted into steel is obtained is of a good kind. It is black, friable, and composed of many small grains, and it produces very tough iron. The conversion into steel is made upon a forge-hearth, something smaller than common. The sides and bottom are made of cast-iron. The tuyere is placed, with very little inclination, on one of the side-plates. The breadth of the fire-place is fourteen inches; its length is greater. The lower part of the tuyere is six inches and a half above the bottom. In the interior part of the fire-place there is an oblong opening for the flowing of the superfluous scorie. The workmen first put charcoal on the bottom, then charcoal and powder of charcoal, and upon these the cast-iron run or cut into small pieces. They cover the iron with more charcoal, and excite the fire. When the pieces of iron are of a red white, and before they begin to melt, they stop the bellows, and carry the mafs under a large hammer, where they break it into pieces of three or four pounds each. The pieces are again brought to the hearth, and laid within reach of the workman who plunges some of them into the fire, and covers them with coal. The bellows are made to blow strongly till the iron is liquified. Then the fire is increased; and when the fumption has been long enough continued, the scorie are allowed to flow out; and at that time the iron hardens. The workman adds more of the pieces of crude iron, which he treats in the same manner; and so on a third and a fourth time, till he obtains a mass of steel of about a hundred pounds, which is generally done in about four hours. This mass is raised and carried to the hammer, where it is forged, and cut into four pieces, which are further heated into square bars four or five feet long. When the steel is thus forged, it is thrown into water so that it may be easily broken; for it is yet crude and coarse-grained. The steel is then carried to another hearth similar to the former, and there broken in pieces. These pieces are laid regularly in the fire-place, first two parallel, upon which seven or eight others are placed across; then a third row across the second, in such a manner that there is space left between those of the same row. The whole is then covered with charcoal, and the fire is excited. In about half or three quarters of an hour the pieces are made hot enough, and are then taken from the fire, one by one, to the hammer, to be forged into little bars from half a foot to two feet long, and while hot are thrown into water to be hardened. Of these pieces fifteen or twenty are put together so as to make a bundle, which is heated and welded, and afterwards forged into bars four inches thick, which are then broken into pieces of convenient length for use.

The method of converting iron into steel by cementation is a very simple process. It consists solely in expounding it for a certain time to a strong degree of heat, while closely covered with charcoal and defended from the external air. The furnaces employed for converting iron into steel (says a manufacturer of this metal) are of different sizes; some capable of converting only three or four tons weight, while others are capacious enough to contain from seven to eight or ten tons. The outsides of these furnaces rise up in form of a cone, or fugar-loaf, to the height of a very considerable number of feet. In the inside, opposite to each other, are placed two very long chests, made either of stone, or of bricks capable of bearing the strongest fire; which is placed between the two chests. The bars of iron, after the bottom is furnished with a necessary quantity of charcoal dust, are laid in firstum funder bratum, with intermediate beds of the charcoal dust, to such a height of the chests as only to admit of a good bed at top; which is then all covered over, to prevent the admission of the common air, which, could it procure an entrance, would greatly injure the operation. The iron being thus situated, the fire is lighted; which is some time before it can be raised to a sufficient degree of heat to produce any considerable effect. After which it is continued for so many days as the operator may judge proper; only now and then drawing out what they call a proof bar. This is done by openings fit for the purpose at the ends of the chest, which are easily and with expedition flapped up again, without occasioning any injury to the contents left behind. When the operator
tor apprehends; the conversion is sufficiently completed, the fire is suffered to go out, and the furnace, with its contents, is left gradually to cool. This may take up several days; after which the furnace is discharged, by taking out the bars of steel and the remainder of the charcoal dust.

There is a manufactory established in the parish of Cradmond, about five miles from Edinburgh, in which this method is practised with great success. Great quantities of steel are made there, which we have reason to believe is of as excellent a quality as any that can be procured from other countries.

When the charcoal is taken out, it is found as black as before it was introduced into the furnace, unless by accident the external air has got admittance. The bars prefer their exterior form only; the surface frequently exhibits a great number of tumors or blisters, whence they are called blistered steel.

The hardnefs of steel is much increased by tempering. This consists in heating it to a red heat, and then plunging it suddenly into cold water. If it be allowed to cool slowly, it still preserves its ductility; or if it be heated again after being tempered, it lofs its hardnefs, and again becomes ductile. In heating steel for tempering it, the most remarkable circumstance is, the different colours it assumes, according to the degree of heat it has received. As it is gradually heated, it becomes white, then yellow, orange, purple, violet, and at last of a deep blue colour.

According to Reaumur, the steel which is most heated in tempering is generally the hardest. Hence it is believed, that the more violent the heat to which steel is exposed, and the more suddenly it is plunged into cold water, the harder the steel will be. Rinman, again, has deduced a conclusion directly opposite, that the steel which is naturally hardest demands the least degree of heat to temper it. Different methods have been proposed to determine what degree of heat is most proper; but the easiest method is to take a bar of steel, five lines long, that while one end is exposed to a violent heat, the other may be kept cold. By examining the intermediate portions, it may be found what degree of heat has produced the greatest hardnefs.

By tempering, steel is said to increase both in bulk and in weight. Reaumur says, that a small bar five inches long, five lines broad, and half an inch thick, was increased at least a line in length after being tempered to a reddish white colour; that is, supposing the dilatation proportional in all dimensions increasing at the rate of 48 to 49. Iron also expands when heated; but when the heat passes off, it returns to its former dimensions.

That the weight of steel is also augmented by tempering, has been found by experiment. Rinman having weighed exactly in a hydrostatic balance two kinds of fine steel made by cementation, and not tempered, found their density to be that of water as 2.991 to 1; after being tempered, the density of the one was 7.553, and that of the other 7.708. M. de Morveau took three bars just of a size to enter a certain caliber 28 lines long, and each edfe two lines broad; one of the bars was soft iron, and the two others were taken from the same piece of fine steel. In order to communicate an equal degree of heat to each, in an external vessel in the midft of a wind furnace, the bar of soft iron and one of the bars of steel were thrown into cold water; the other bar of steel was cooled slowly over some pieces of charcoal at a distance from the furnace. The bar of iron and the one of steel that was allowed to cool slowly passed easily into the caliber again; but the bar of tempered steel was lengthened almost one-ninth of a line.

There is no doubt but tempering changes the grain; that is, the appearance of the texture of a piece of steel when broken. This is the mark which is usually observed in judging of the quality of steel, on account of the tempering which suits it best. The tempered bar is broken in several places after having received different degrees of heat in different places. What proves completely the effect of heat upon the grain, at least in some kinds of steel, is, that a bar of steel exposed to all the intermediate degrees of heat, from the smallest sensible heat to a red heat, is found to increase in fineness of grain from the slightly heated to the strongly heated end. The celebrated Rinman has made many experiments on the qualities of steel exposed to different degrees of heat in tempering, but particularly to three kinds, viz. steel heated to an obscure red, to a bright red, and to red white. Hard brittle steel, made by cementation, and heated to an obscure red and tempered, exhibited a fine grain, somewhat shining, and was of a yellow white colour. When tempered at a bright red heat, the grain was coarser and more shining; when tempered at a red white heat, the grain was also coarser and shining.

With a view to determine how far steel might be improved in its grain by tempering it in different ways, M. de Morveau took a bar of blistered steel, and broke it into four parts nearly of the same weight. They were all heated to a red heat in the same furnace, and withdrawn from the fire at the same instant. One of the pieces was left at the side of the furnace to cool in the air, the second was plunged into cold water, the third into oil, and the fourth into mercury. The piece of steel that was cooled in the air refiifted the hammer a long time before it was broken; it was necessary to notch it by the file, and even then it was broken with difficulty. It showed in its fracture a grain sensibly more fine and more shining than it was before. The second piece, which had been plunged into water, broke easily; its grain was rather finer than the firft, and almost of the same white colour. The third piece, which was tempered in oil, appeared very hard when tried by the file; it was scarcely possible to break it. Its grain was as fine, but not quite so bright, as that which was tempered in water. The fourth piece, which was dipped into mercury, was evidently superior to all the rest in fineness and colour of the grain. It broke into many fragments with the firft stroke of the hammer, the fractures being generally transverse.

M. de Morveau was not altogether satisfied with his experiments, and therefore thought it necessary to repeat them with finer steel. He took a bar of steel two lines square, such as is used in Germany for tools by engravers and watchmakers; he divided it into four pieces, and treated them in the same way as he had done the blistered steel. The firft piece, which was cooled in the air, it was very difficult to break; the fracture appeared in the midft of the grain very fine, but white and shining. The second, which was tempered in water, was broken into three fragments at the first
The balance of the people.—

By an edge on the long arm, from A and E, the edge of the nail D, are in the weights of unequal arms, and, in its parallel to the line of the weight, it balances the long arm unloaded. When no goods are in the scale, and the counter weight w ith its hook are removed, the steelyard acquires a horizontal position, in consequence of its centre of gravity being below the axis of fulpenion. The rules for its accurate construction are the same as for a common balance.

The instrument indicates different weights in the following manner: The distance CD of the two naiis, is considered as an unit, and the long arm is divided into a number of parts equal to it; and these are subdivided as low as is thought proper: or in general, the long arm is made a scale of equal parts, commencing at the edge of the nail C; and the short arm contains some determined number of these equal parts. Suppose, then, that a weight A of 10 pounds is put into the scale B. The counterpoise P must be of such a weight, that when hanging at the division 10, it shall balance this weight A. Now let any unknown weight W be put into the scale. Slide the hook of the counterpoise along the long arm till it balances this weight. Suppose it then hanging at the division 38. We conclude that there is 38 pounds in the scale. This we do on the authority of the fundamental property of the lever, that forces acting on it, and balancing each other, are in the inverse proportion of the distances from the fulcrum to their lines of direction. Whatever weight the counterpoise is, it is to A as CD to 10, and it is to the weight W as CD to 38; therefore A is to the weight W as 10 to 38, and W is 38 pounds; and thus the weight in the scale will always be indicated by the division at which it is balanced by the counterpoise.

Our well informed readers know that this fundamental property of the lever was discovered by the renowned Archimedes, or at least first demonstrated by him; and that his demonstration, besides the defect of being applicable only to commensurable lengths of the arms, has been thought by metaphysicians of the first note to proceed on a postulate which seems equally to need a demonstration. It has accordingly employed the utmost refinement of the first mathematicians of Europe to furnish a demonstration free from objection. Mr D'Alembert has given two, remarkable for their ingenuity and facility; Forcineux has done the same; and Professor Hamilton of Trinity college, Dublin, has given one which is thought the least exceptionable. But critics have even objected to this, as depending on a postulate which should have been demonstrated.

Since we published the volume containing the article Mechanics, there has appeared (Phil. Trans. 1794) a demonstration by Mr Vince, which we think unexceptionable, and of such simplicity that it is astonishing that it has not occurred to any person who thinks on the subject. Our readers will not be displeased with an account of it.

Let AE (fig. 2.) be a mathematical lever, or inflexible straight line, resting on the point A, and supported at E by a force acting upwards. Let two equal weights k and d be hung on at B and D, equidistant from A and E. Pressures are now exerted at A and E; and because every circumstance of weight and distance is the same, the pressure at E, arising from the action of the weight k on the point B, must be the same with the pressure at A, arising from the action of the weight d on the point D; and the pressure at E, occasioned by the weight d, must be the same with the pressure at A, occasioned by the weight k. This must be the case wherever the weights are hung, provided that the distance AB and DE are equal. Moreover,
...the sum of the pressures at A and E is unquestionably equal to the sum of the weights, because the weights are supported solely at A and E. Let the two weights be hung on at C the middle point; the pressure at E is still the same. Therefore, in general, the pressure excited at the point E, by two equal weights hanging at any points B and D, is the same as if they were hung on at the middle point between them: but the pressure excited at E is a direct measure of the effort or energy of the weights d and d to urge the lever round the point A. It is, at least, a measure of the opposite force which must be applied at E to sustain or balance this pressure. A very fallacious metaphysician may still say, that the demonstration is limited to a point E, whose distance from A is twice AC, or = AB + AD. But it extends to any other point, on the authority of a postulate which cannot be refuted, viz. that in whatever proportion the pressure at E is augmented or diminished, the pressure at this other point must augment or diminish in the same proportion. This being proved, the general theorem may be demonstrated in all proportions of distance, in the manner of Archimedes, at once the most simple, perspicuous, and elegant of all.

We cannot help observing, that all this difficulty (and it is a real one to the philosopher who aims at rendering mechanics a demonstrative science) has arisen from an improper search after simplicity. Had Archimedes taken a lever as it really exists, and considered it as material, consisting of atoms united by cohesion; and had he traced the intermediate pressures by whose means the two external weights are put in opposition to each other, or rather to the support given to the fulcrum; all difficulty would have vanished. (See what is said on this subject in the article Strength of Timber, &c.)

The quantity of goods which may be weighed by this instrument depends on the weight of the counterpoise, and on the distance CD from the fulcrum at which the goods are suspended. A double counterpoise hanging at the same division will balance or indicate a double quantity of goods hanging at D; and any counterpoise will balance and indicate a double quantity of goods, if the distance CD is reduced to one-half. Many fleelyards have two or more points of suspension D, to which the scale may occasionally be attached. Fig. 6, of Plate CXL. Vol. II. represents one of these. It is evident, that in this case the value or indication of the divisions of the long arm will be different, according to the point from which the scale is suspended. The same division which would indicate 20 pounds when CD is three inches, will indicate 30 pounds when it is two inches. As it would expose to chance of mistakes, and be otherwise troublesome to make this reduction, it is usual to make as many divided scales on the long arm as there are points of suspension D on the short arm; and each scale has its own numbers, all trouble and all chance of mistake is avoided.

But the range of this instrument is not altogether at the pleasure of the maker. Besides the liability of a slender beam to carry a great load, the divisions of the scales answearing to pounds or half-pounds become very minute when the distance CD is very short; and the balance becomes less delicate, that is, less sensibly affected by small differences of weight. This is because in such cases the thickness which it is necessary to give the edges of the nails does then bear a sensible proportion to the distance CD between them; so that when the balance inclines to one side, that arm is sensibly shortened, and therefore the energy of the preponderating weight is lessened.

We have hitherto supposed the fleelyard to be in equilibrio when not loaded. But this is not necessary, nor is it usual in those which are commonly made. The long arm commonly preponderates considerably. This makes no difference, except in the beginning of the scale. The preponderance of the long arm is equivalent to some goods already in the scale, suppose four pounds. Therefore when there are really 10 pounds in the scale, the counterpoise will balance it when hanging at the division 6. This division is therefore reckoned 10, and the rest of the divisions are numbered accordingly.

A scientific examination of the fleelyard will convince us that it is inferior to the balance of equal arms in point of sensibility; but it is extremely compendious and convenient; and when accurately made and attentively used, it is abundantly exact for most commercial purposes. We have seen one at Leipzig which has been in use since the year 1718, which is very sensible to a difference of one pound, when loaded with nearly three tons on the short arm; and we saw a waggon loaded with more than two tons weighed by it in about six-minutes.

The fleelyard in common use in the different countries of Europe is of a construction still simpler than what we have described. It consists of a batten of hard wood, having a heavy lump A (fig. 3.) at one end, and a twisel-hook B at the other. The goods to be weighed are suspended on the hook, and the whole is carried in a loop of whip-cord C, in which it is slid backward and forward, till the goods are balanced by the weight of the other end. The weight of the goods is estimated by the place of the loop on a scale of divisions in harmonic proportion. They are marked (we presume) by trial with known weights.

The chief use that is now made of the fleelyard in Great Britain is for the weighing of loaded waggons and carts. For this it is extremely convenient, and more than sufficiently exact for the purpose in view. We shall describe one or two of the most remarkable; and we shall begin with that at Leipzig already mentioned.

This fleelyard is represented in fig. 4. as run out, and just about to be hooked for lifting up the load. The fleelyard itself is OPQ, and is about 12 feet long. The short arm PQ has two points of suspension 6 and 7, and the stirrup which carries the chains for holding the load is made with a double hook, instead of a double eye, that it may be easily removed from the one pin to the other. For this purpose the two hooks are connected above by an haip or flaple, which goes over the arm of the fleelyard like an arch. This is represented in the little figure above the fleelyard. The suspension is lifted when the fleelyard is run in under cover, by hooking to this flaple the running block of a small tackle which hangs in the door through which the fleelyard is run out and in. This operation is easy,
The outer pin is 14 inches, and the inner one is seven inches, distant from the great nail which rests in the shears. The other arm is about 120 feet long, formed with an obtuse edge above. On the inclined plane on each side of the ridge is drawn the scale of weights adapted to the inner pin e. The scales corresponding to the outer pin b are drawn on the upright sides. The counterpoise slides along this arm, hanging from a fiddle-piece made of brass, that it may not contract suit. The motion is made easy by means of rollers. This is necessary, because the counterpoise is greatly above a hundred weight. This fiddle-piece has like two laps on each side, on which are engraved vernier scales, which divide their respective scales on the arm to quarters of a pound. Above the fiddle is an arch, from the summit of which hangs a little plummet, which shows the equilibrium of the steelyard to the weigher, because the shears are four feet out of the house, and he cannot see their coincidence with the needle of the steelyard. Lastly, near the end of the long arm are two pins d and e, for suspending occasionally two eke weights for continuing the scale. These are kept hanging on adjoining hooks, ready to be lifted on by a little tackle, which is also hooked immediately above the pins d and e.

The scales of weights are laid down on the arm as follows. Let the eke-weights appropriated to the pins d and e be called D and E, and call the counterpoise C. Although the fiddle with its chains and fagge weigh some hundreds, yet the length and size of the arm QP gives it a preponderance of 300 pounds. Here, then, the scale of weights must commence. The counterpoise weighs about 125 pounds. Therefore,

1. When the load hangs by the pin b, 14 inches from the centre, the distance from one hundred to another on the scale is about 11 inches, and the first scale (on the side of the arm) reaches from 300 to 1200. In order to repeat or continue this, the eke-weight E is hung on the pin e, and the counterpoise C is brought back to the mark 300; and the two together balance 1100 pounds hanging at b. Therefore a second load is begun on the side of the arm, and continued as far out as the first, and therefore its extremity marks 2000; that is, the counterpoise C at 2000, and the eke-weight E at balance 2000 hanging at b.

2. To continue the scale beyond 2000, the load must be hung on the inner pin e. The eke-weight E is taken off, and the eke-weight D is hung on its pin d. The general counterpoise being now brought close to the shears, it, together with the weight D at d, balance 2000 pounds hanging at e. A scale is therefore begun on one of the inclined planes a-top, and continued out to 4000, which falls very near to the pin d, each hundred pounds occupying about five inches on the arm. To complete the scale, hang on the eke-weight E on its pin e, and bring back the counterpoise to the shears, and the three together balance 3000 hanging at e. Therefore when the counterpoise is now filled out to 4000, it must complete the balance with 5000 hanging at e.

It required a little consideration to find out what proportion of the three weights C, D, and E, would make the repetitions of the scale extend as far as possible. Having very little of it expressed twice, or upon two scales, as is the case here. We see that the space corresponding to a single pound is a very sensible quantity on both scales, being one-ninth of an inch on the first two scales, and one-twentieth on the last two.

This very ponderous machine, with its many weights, cannot be easily managed without some assistance from mechanics. It is extremely proper to have the susceptible of motion out and in, that it may be protected from the weather, which would soon destroy it by rust. The contrivance here is very effectual, and abundantly simple.

When the steelyard is not in use, it is supported at one end by the iron-rod F, into which the upper end of the shears is hooked. The upper end of this rod has a strong hook E, and a little below at a it is pierced with a hole, in which is a very strong bolt or pin of tempered steel, having a roller on each end close to the rod on each side. These rollers rest on two joists, one of which is represented by MN, which traverse the building, with just room enough between them to allow the rod F to hang freely down. The other end O of the steelyard rests in the bight of a large flat hook at the end of a chain W, which hangs down between the joists, and is supported on them by a frame with rollers H. This is connected with the rollers at G, which carry the shears by means of two iron-rolls, of which the one only can be seen. There are two sets of rollers in such a manner that they must always move together, and keep their distance invariable. This motion is produced by means of an endless rope HI ZLKVH passing over the pulleys I and K, which turn between the joists, and hanging down in a bight between them. It is evident that by pulling on the part LZ we pull the frame of rollers in the direction GH, and thus bring the whole into the house in the position marked by the dotted figure. It is also plain, that by pulling on the part I K we force the roller frame and the whole apparatus out again.

It remains to show how the load is raised from the ground and weighed. When the steelyard is run out for use, the upper hook E just enters into the ring D, which hangs from the end of the great caken lever BCA about 22 feet long, turning on gudgeons at C about 5 feet from this end. From the other end A defends a long iron rod SR, which has one side formed into a toothed rack that is acted on by a frame of wheel work turned by an endless screw and winch Q. Therefore when the hook E is well engaged in the ring D, a man turns the winch, and thus brings down the end A of the great lever, and raises the load two or three inches from the ground. Everything is now at liberty, and the weigher now manages his weights on the arm of the steelyard till he has made an equilibrium.

We need not describe the operation of letting down the load, disengaging the steelyard from the great lever, and bringing it again under cover. The whole of this service is performed by two men, and may be done in succession by one, and is over in five or six minutes.

The most compendious and economical machine of this kind that we have seen is one, first used (we have heard) for weighing the riders of race-horses, and afterwards...
Fig. 5. is a plan of the machine. KLMN is the plan of a rectangular box, which has a platform lid or cover, of size sufficient for placing the wheels of a cart or waggon. The box is about a foot deep, and is sunk into the ground till the platform-cover is even with the surface. In the middle of the box is an iron lever supported on the fulcrum pin \( i, k \), formed like the nail of balance, which rests with its edge on arches of hardened steel firmly fastened to the bottom of the box. This lever goes through one side of the box, and is furnished at its extremity with a hard steel pin \( l, m \), also formed to an edge below. In the very middle of the box it is crooked by a third nail of hardened steel \( g, h \), also formed to an edge, but on the upper side. These three edges are in one horizontal plane, as in a well made balance.

In the four corners \( A, A', E, E' \), of the box are firmly fixed four blocks of tempered steel, having their upper surfaces formed into spherical cavities, well polished and hard tempered. ABCDE represents the upper edge of an iron bar of considerable strength, which rests on the cavities of the steel blocks in \( A \) and \( E \), and of \( B \) and \( D \), as being made of two hard steel flats projecting from its under edge, and formed into obtuse angled points or cones. The points are in a straight line parallel to the side \( KN \) of the box. The middle part \( C \) of this crooked bar is faced with hard-tempered steel below, and is there formed into an edge parallel to \( AE \) and \( KN \), by which it rests on the upper edge of the steel flat \( g, h \) which is in the lever. In a line parallel to \( AE \), and on the upper side of the crooked bar \( ACE \), are fixed two flats or points of hardened steel \( B \) and \( D \) projecting upwards above half an inch. The platform-cover has four short feet like a foot, terminated by hard steel flats, which are shaped into spherical cavities and well polished. With these it rests on the four steel points \( B, B', D, D' \). The bar \( ACE \) is knifed in such a manner vertically, that the points \( A, B, D, E \) and the edge \( C \) are all in a horizontal plane. These particulars will be better understood by looking at the elevation in fig. 6. What has been said of the bar \( ACE \) must be understood as also said of the bar \( A'C' \).

Draw through the centre of the box the line \( a b \) perpendicular to the line \( AE, BD \). It is evident that the bar \( ACE \) is equivalent to a lever \( a b \), having the fulcrum or axis \( AE \) resting with its extremity \( C \) in the pin \( b, g \) and loaded at \( b \). It is also evident that \( C \) is to \( a \) as \( b \) to \( a b \), or to \( b \) as \( a \) to \( ab \), the same proportion subsists between the total load on the platform and the pressure which it exerts on the pin \( g, h \) and that the same proportion subsists between the whole load on the platform and the pressure which it exerts on the pin \( g, h \). It will also appear, on an attentive consideration, that this proportion is nowhere deranged in whatever manner the load is placed on the platform. If very unequally, the two ends of the pin \( g, h \) may be unequally pressed, and the lever bent and strained a little, but the total pressure is still the same as before. If here be now placed a balance or balance-yard at the side \( LK \), in such a manner that one end of it may be directly above the pin \( l, m \) in the end of the lever \( EOF \), they may be connected by a wire or slender rod, and a weight on the other arm of the balance or scale-yard may be put in equilibriv with any load that can be laid on the platform. A small counterpoise being first hung on to balance the apparatus when unloaded, steel-yard, any additional weight will measure the load really laid on the platform. If \( a b \) be to \( ac \) as 1 to 8, and \( IO \) to \( EF \) also as 1 to 8, and if a common balance be used above, 64 pounds on the platform will be balanced by one pound in the scale, and every pound will be balanced by \( \frac{1}{8} \)th of an ounce. This would be a very convenient partition for most purposes, as it would enable us to use a common balance and common weights to complete the machine; or it may be made with a balance of unequal arms, or with a steel-yard.

Some have thought to improve this instrument by using edges like those of the nails of a balance, instead of points. But unless made with uncommon accuracy, they will render the balance very dull. The small deviation of the two edges \( A \) and \( E \), or of \( B \) and \( D \), from perfect parallelism to \( KN \), is equivalent to a broad surface equal to the whole deviation. We imagine that, with no extraordinary care, the machine may be made to weigh within one-sixtieth of the truth, which is exact enough for any purpose in commerce.

It is necessary that the points be attached to the bars. Some have put the points at \( A \) and \( E \) in the blocks of steel fastened to the bottom, because the cavity they lodged water or dirt, which soon destroyed the instrument with rust. But this occasions a change of proportion in the first lever by any shifting of the crooked bars; and this will frequently happen when the wheels of a loaded cart are pushed on the platform. The cavity in the steel flat should have a little rim round it, and it should be kept full of oil. In a nice machine a quarter of an inch of quicksilver would effectually prevent all these inconveniences.

The simplest and most economical form of this machine is to have no balance or second steel-yard; but to make the first steel-yard \( EOF \) a lever of the first kind, viz., having the fulcrum between \( O \) and \( F \), and allow it to project far beyond the box. The longer outward arm of this lever is then divided into a scale of weights, commencing at the side of the box. A counterpoise must be chosen, such as will, when at the beginning of the scale, balance the smallest load that will probably be examined. It will be convenient to carry on this scale by means of eke-weights hung on at the extremity of the lever, and to use but one movable weight. By this method the divisions of the scale will have always one value. The best arrangement is as follows: Place the mark \( O \) at the beginning of the scale, and let it extend only to 100, if for pounds; or to 112, if for cwt.; or to 10, if for stones; and let the eke-weights be numbered 1, 2, 3, &c. Let the lowest weight be marked on the beam. This is always to be added to the weight shown by the operation. Let the eke-weights stand at the end of the beam, and let the general counterpoise always hang at \( O \). When the cart is put on the platform, the end of the beam tilts up. Hang on the heaviest eke-weight that is sufficient to press it down. Now complete the balance by sliding out the counterpoise. Suppose the constant load to be 312 lb., and that the counterpoise-stands at 86, and that the eke-weight is 9; we have the load 986, which is 1258 lbs.

STEELE (Sir Richard), was born about the year 1676 in Dublin; in which kingdom one branch of the family was possessed of a considerable estate in the county.
The county of Wexford. His father, a counsellor at law in Dublin, was private secretary to James duke of Ormond; but he was of English extraction: and his son, while very young, being carried to London, he put him to school at the Charter-house, whence he was removed to Merton College in Oxford. Our author left the university, which he did without taking any degree, in the full resolution to enter into the army. This step was highly displeasing to his friends; but the ardour of his passion for a military life rendered him deaf to any other proposal. Not being able to procure a better station, he entered as a private gentleman in the horse-guards, notwithstanding he thereby loft the succession to his Irish estate. However, as he had a flow of good-natured, a generous openness and frankness of spirit, and a sparkling vivacity of wit, these qualities rendered him the delight of the soldiers, and procured him an enkind's commission in the guards. In the mean time, as he had made choice of a profession which fet him free from all the ordinary restraints in youth, he spared not to indulge his inclinations in the wildest excesses. Yet his gaieties and revels did not put without some cool hours of reflection; it was in thee that he drew up his little treatise intitled The Christian Hero, with a design, if we may believe himself, to be a check upon his passions. For this purpofe it had lain some time by him, when he printed it in 1701, with a dedication to Lord Clotis, who had not only appointed him his private secretary, but procured for him a company in Lord Lucas's regiment of Footfellers.

The fame year he brought out his comedy called The Fanére ou Gisif à la mode. This play procured him the regard of King William, who resolved to give him some official marks of his favour; and though, upon that prince's death, his hopes were disappointed, yet, in the beginning of Queen Anne's reign, he was appointed to the profitable place of gazetter. He owed this poft to the friendship of lord Halifax and the earl of Sunderland, to whom he had been recommended by his school-fellow Mr Addison. That gentleman also lent him an helping hand in promoting the comedy called The Tender Husband, which was acted in 1704 with great success. But his next play, The Lying Lover, had a very different fate. Upon this rebuff from the good fortune, he began to publish the Tatler; which admirable paper was undertaken in concert with Dr Swift. His reputation was perfectly established by this work; and, during the course of it, he was made a commissioner of the stamp duties in 1709. Upon the change of the ministry the same year, he joined the duke of Marlborough, who had several years entertained a friendship for him; and upon his Grace's dismissal from all employments in 1711, Mr Steele addreffed a letter of thanks to him for the favours which he had done to his country. However, as our author still continued to hold his place in the stamp office under the new administration, he forbore entering with his pen upon political subjects; but, adhering more closely to Mr Addison, he dropped the Tatler, and afterwards, by the assistance chiefly of that ready friend, he carried on the same plan much improved, under the title of The Spectator. The success of this paper was equal to that of the former; which encouraged him, before the clofe of it, to proceed upon the fame design in the character of the Guardian. This was opened in the beginning of the year 1713, and was laid down in October the fame year. But in the course of it his thoughts took a stronger turn to politics: he engaged with great warmth against the ministry; and being determined to pro- cede his views that way by procuring a feat in the house of commons, he immediately removed all ob- stacles thereto. For that purpofe he took care to pre- vent a forcible difmissal from his post in the stamp office, by a timely resignation of it to the Earl of Orrery, and at the fame time gave up a penfion, which had been till this time paid him by the queen as a fervant to the late prince George of Denmark. This done, he wrote the famous Guardian upon the demolition of Dunkirk, which was published Aug. 7, 1713: and the parliament being difolved next day, the Guardian was soon followed by several other warm political tracts against the administration. Upon the meeting of the new parliament, Mr Steele having been returned a member for the borough of Stockbridge in Dorsetshire, took his seat accordingly in the house of commons; but was expelled thence in a few days after, for writing the clofe of the paper called the Englishman, and one of the political pieces intituled the Grifts. Presently after his expu- sition, he publifhed proposals for writing the history of the duke of Marlborough: at the fame time he also wrote the Spanfer; and, in oppofition to the Examiner, he fet up a paper called the Reader, and continued pub- lishing several other things in the fame spirit till the death of the queen. Immediately after which, as a re- ward for these favours, he was taken into favour by her successor to the throne, king George I. He was appointed fervant of the royal fables at Hampton- Court, governor of the royal company of comedians, put into the commiジョン of the peace for the county of Middlesex, and in 1715 received the honour of knighthood. In the firft parliament of that king, he was chosen member for Boroughbridge in Yorkshire; and, after the fuppression of the rebellion in the north, was appointed one of the commiジョンers of the forfeited eftates in Scotland. In 1718, he buried his second wife, who had brought him a handsome fortune and a good eftate in Wales; but neither that, nor the ample additions lately made to his income, were fufficient to answer his demands. The thoughtlefs vivacity of his spirit often reduced him to little thifts of wit for its support; and the project of the Fifh-pool this year owed its birth chiefly to the projector's neceffities. This vessel was intended to carry fifts alive, and without waiting, to any part of the kingdom: but notwithstanding all his towering hopes, the scheme proved very ruinous to him; for after he had been at an immense expence in contriving and building his veffeIl, besides the charge of the patent, which he had procured, it turned out upon trial to be a mere project. His plan was to bring salmon alive from the coast of Ireland; but these fifts, though supplied by this convenience with a continual stream of water while at sea, yet unceafly at their confinement, shattered themselves to pieces against the sides of the pool; fo that when they were brought to market they were worth very little.

The following year he opposed the remarkable peer- age bill in the house of commons; and, during the course
course of this opposition to the court, his licence for acting plays was revoked, and his patent rendered ineffectual; at the instance of the lord chamberlain. He did his utmost to prevent its great loss; and finding every direct avenue of approach to his royal master effectually barred against him by his powerful adversary, he had recourse to the method of applying to the public, in hopes that his complaints would reach the ear of his sovereign, though in an indirect course, by that channel. In this spirit he formed the plan of a periodical paper, to be published twice a week, under the title of the Theatre; the first number of which came out on the 2d of January 1719-20. In the mean time, the misfortune of being out of favour at court, like other misfortunes, drew after it a train of more. During the course of this paper, in which he had assumed the reign'd name of Sir John Edgar, he was outrageously attacked by Mr Dennis, the noted critic, in a very abusive pamphlet, intitled The Character and Conduct of Sir John Edgar. To this intitul our author made a proper reply in the Theatre.

While he was struggling with all his might to save himself from ruin, he found time to turn his pen against the mischievous South-Sea scheme, which had nearly brought the nation to ruin in 1720; and the next year he was restored to his office and authority in the playhouse in Drury Lane. Of this it was not long before he made an additional advantage, by bringing his celebrated comedy called the Conjuror Lovers upon that stage, where it was acted with prodigious success; so that the receipt there must have been very considerable, besides the profits accruing by the sale of the copy, and a purée of 500l. given to him by the king, to whom he dedicated it. Yet notwithstanding these ample supplies, about the year following, being reduced to the utmost extremity, he sold his mare in the playhouse, and soon after commenced a law-suit with the managers, which in 1726 was determined to his disadvantage. Having now again, for the last time, brought his fortune, by the most hecules' prudence, into a desperate condition, he was rendered altogether incapable of retrieving the loss, by being feized with a paralytic disorder, which greatly impaired his understanding. In these unhappy circumstances, he retired to his seat at Langnumor near Caermarthens in Wales, where he paid the last debt to nature on the 21st of September 1729, and was privately interred, according to his own desire, in the church of Caermarthen. Among his papers were found the manuscripts of two plays, one called The Gentleman, founded upon the cunach of Terence, and the other intituled The School of Allon, both nearly finished.

Sir Richard was a man of undismelled and extensive benevolence, a friend to the friendless, and, as far as his circumstances would permit, the father of every orphan. His works are chaste and manly. He was a stranger to the most dilate appearance of envy or malevolence; never jealous of any man's growing reputation; and so far from arrogating any praise to himself from his conjunction with Mr Addison, that he was the first who defined him to distinguish his papers. His greatest error was want of economy; however, he was certainly the most agreeable, and (if we may) be allowed the expression) the most innocent that ever trod the rounds of dilipation.

**STEPELE**, an appendage erected generally on the western end of churches, to hold the bells. Steeples are denominated from their form, either spires or towers: the first are such as ascend continually diminishing either conically or pyramidal; the latter are mere parallelopipeds, and are covered a top platform like.

**STEERAGE**, on board a ship, that part of the ship next below the quarter deck, before the bulkhead of the great cabin where the steersman stands, in most ships of war. See Steering.

**STEERING**, in navigation, the art of directing the ship's way by the movements of the helm; or of applying its efforts to regulate her course when the advances.

The perfection of steering consists in a vigilant attention to the motion of the ship's head, so as to check every deviation from the line of her course in the first instant of its motion; and in applying as little of the power of the helm as possible. By this the ship will run more uniformly in a straight path, as declining left to the right and left; whereas, if a greater effort of the helm is employed, it will produce a greater declination from the course, and not only increase the difficulty of steering, but also make a more rapid and irregular track through the water. See Helm—The helmman should diligently watch the movements of the head by the land, clouds, moon, or stars; because, although the course is in general regulated by the compass, yet the vibrations of the needle are not so quickly perceived as the fulness of the ship's head to the right or left, which, if not immediately restrained, will acquire additional velocity in every instant of their motion, and demand a more powerful impulse of the helm to reduce them; the application of which will operate to turn her head as far as her contrary side of her course.

—The phrases used in steering a ship vary according to the relation of the wind to her course. Thus, if the wind is fair or large, the phrases used by the pilot or officer who superintends the steering are: port, starboard, and steady. The first is intended to direct the ship's course further to the right; the second is to guide her further to the left; and the last is designed to keep her exactly in the line; whereas in his advances, according to the course to windward, the excess of the first and second movement is called hard a port, and hard a starboard; the former of which gives her the greatest possible inclination to the right, and the latter an equal tendency to the left.—If, on the contrary, the wind is foul or scant, the phrases are leeward, thus, and nearer: the first of which is the order to keep her close to the wind; the second, to retain her in her present situation; and the third, to keep her close full.

In a ship of war, the exercise of steering the ship is usually divided amongst a number of the most expert sailors, who attend the helm in their turns; and are accordingly called timoniers, from the French term timonier, which signifies "helmman." The steering is constantly superintended by the quarter-masters, who also attend the helm by rotation. In merchant-ships every seaman takes his turn in this service, being directed therein by the mate of the watch, or some other officer.

As the safety of a ship, and all contained therein, depends in a great measure on the steering or effects of the helm, the apparatus by which it is managed should often be diligently examined by the proper officers. In
STEGANUM, a negligece in this important duty appears almost unpardonable, when the fatal effects which may result from it are duly considered.

STEGANUM. See Slate.

STEGANOGRAPHY, the art of secret writing, or of writing in ciphers, known only to the persons corresponding. See Cipher.

STELLARIA, Stichwort, in botany: A genus of plants belonging to the class of decandria, and order of trigyna; and in the natural system arranged under the 22d order, Caryophyllaceae. The calyx is pentaphyllous and spreading. There are five petals, each divided into two segments. The capsule is oval, unilocular, and polypermous. There are nine species, the nema- rum, dichotoma, radians, holoflosa, graminea, cerafloides, and arenaria. Three of these are British plants: 1. Nemorum, broad-leaved stichwort. The flanks are about a foot or eighteen inches high, and branched in a panicle at the top. The leaves are heart-shaped, and of a paler green on the under than on the upper side; the lower ones being supported by foot-flasks which are hairy and channelled; the upper ones are felise. The calyx is erect, somewhat hairy and white on the margins. The petals are bifid almost to the base. There is a small nectarium between the longer flamina and the calyx.—2. Holoflosa, greater stichwort. The flanks are about two feet long; the petals are nearly twice the length of the calyx, and divided half-way to the base. It is common in woods and hedges.—3. Graminea, less stichwort. The item is near a foot high. The leaves are linear and entire, and the flowers grew in loose panicles. It is frequent in dry pastures. There is a variety of this species called bog stichwort, with smooth, oval, felise leaves, and few leaves, which grows often in wet marshy places. The flanks are quadrangular; the petals scarcely longer than the calyx, and bifid to the base.

STELLATE, among botanists, expresses leaves which grow not less than half an inch at a joint, and are arranged like the rays of a star.

STELLARIA, German Grundsel, in botany: A genus of plants belonging to the class of echandria, and order of monogyna; and in the natural system arranged under the 40th order, Peronate. The calyx is quinquepartite; the corolla bilatrated; there are four flamina; each of the filaments is bifid, and have two anthers. The capsule is bilocular. There is only one species, the mariina.

ST Emmata, in the history of insects, are three smooth hemispheric dots, placed generally on the top of the head, in molt of the hymenoptera and other classes. The name was first introduced by Linneus.

STEMODIA, in botany: A genus of plants belonging to the class of didynamia, and order of angio sperma; and in the natural system ranging under the 40th order, Peronate. The calyx is quinquepartite; the corolla bilatrated; there are four flamina; each of the filaments is bifid, and have two anthers. The capsule is bilocular. There is only one species, the mariina.

STEMPHYLA, a word used by the ancients to express the hulks of grapes, or the remains of the pressings of wine. The same word is also used by some to express the remaining mass of the olives, after the oil is pressed out.

STEMPHYLITES, a name given by the ancients to a fort of wine pressed hard from the hulks.

STEMPLES, in mining, cross bars of wood in the shafts which are sunk to mines. In many places the way is to sink a perpendicular hole, or shaft, the sides of which they strengthen from top to bottom with wood-work, to prevent the earth from falling in; the transverse pieces of wood used to this purpose they call stemples, and by means of these the miners in some places descend, without using any rope, catching hold of these with their hands and feet.

STEMSON, in a ship, an arching piece of timber fixed within the apron, to reinforce the scarp thereof, in the same manner as the apron supports the scarp of the item. In large ships it is usually formed of two pieces.
STENOGRAPHY (A).

CHAP. I.

The art of stenography, or short writing, was known and practiced by most of the ancient civilized nations. The Egyptians, who were distinguished for learning at an early period, at first expressed their words by a delineation of figures called hieroglyphics. A more concise mode of writing seems to have been afterwards introduced, in which only a part of the symbol or picture was drawn. This answered the purpose of short-hand in some degree. After them the Hebrews, the Greeks, and the Romans*, adopted different methods of abbreviating their words and sentences, suited to their respective languages. The initials, the finals, or radicals, often served for whole words; and various combinations of these sometimes formed a sentence. Arbitrary marks were likewise employed to determine the meaning, and to affiit legibility; and it seems probable that every writer, and every author of antiquity, had some peculiar method of abbreviation, calculated to facilitate the expression of his own sentiments, and intelligible only to himself.

It is also probable, that some might by these means take down the heads of a discourse or oration; but few, very few, it is prefixed, could have followed a speaker through all the meanders of rhetoric, and noted with precision every syllable, as it dropped from his mouth, in a manner legible even to themselves.

To arrive at such consummate perfection in the art was reserved for more modern times, and is still an acquisition by no means general.

In every language of Europe, till about the close of the 16th century, the Roman plan of abbreviating (viz. substituting the initials or radicals, with the help of arbitraries, for words) appears to have been employed. Till then no regular alphabet had been invented expressly for stenography, when an English gentleman of the name of Willis invented and published one (A). His plan was soon altered and improved, or at least pretended to be so. One alteration succeeded another; and at intervals, for a series of years past, some men of ingenuity and application have composed and published systems of stenography, and doubtless have themselves reaped all the advantages that attend it. But among the various methods that have been proposed, and the different plans that have been adopted by individuals, none has yet appeared fortunate enough to gain general approbation; or proved sufficiently simple, clear, and concise, to be universally studied and practiced.

Some systems are replete with unmeaning symbols, perplexing arbitraries, and ill-judged contractions: which render them so difficult to be attained by a common capacity, or ordinary application, that it is not to be wondered at if they have sunk into neglect, and are now no longer known (c). Other systems, by being too prolix, by containing a multiplicity of characters, and those characters not simply or easily remembered, become inefficient to the purpose of expedition, and are only superior in obscurity to a common hand. Some, again, not only reject all arbitraries and contractions, but even prepositions and terminations; which last, if not too lavishly employed and badly devised, highly contribute to promote both expedition and legibility; and though they reduce their characters to fewer than can possibly express the various modifications of sound, yet they make nearly one half of them complex. In the disposition of the vowels, there is the greatest perplexity in most systems. A dot is sometimes substituted for all the vowels indiscriminately, and the judgment is left to determine which letter out of any alphabet is intended to express; or a minute space is allotted them; so that unless they be arranged with mathematical precision they cannot be distinguished from one another; but such a minute attention is inconsistent with the nature of short-hand, which should teach us to write down in a short time, as well as in small bounds, what we wish to preserve of what we hear. Nor is the plan of lifting the pen and putting the next consonant in the vowel's place, less liable to objections; or that of representing all the vowels by different characters, being obviously ill calculated for facility and dispatch, and consequently inadmissible into any useful system.

It is to be confessed, that the person who first propo

---

(A) The value of stenography is not unknown to the learned; and the care and success with which it has been lately cultivated in these kingdoms will, in all probability, soon render it an object of general attention. No one, however, appears to us to have simplified and improved the art so much as Dr. Mavor, author of Universal Stenography, who has liberally permitted us to present our readers with a complete view of his scheme. To those who wish to become proficient in Short-Writing, we earnestly recommend his entire publication (printed for Cadell and Davis, Strand, London), which in many schools of the first reputation now forms a desired class-book.

(b) Mr. Locke says, a regular method of short-writing seems to be known and practiced only in Britain. This is not now the case; and indeed there is no reason to doubt whether characters may not be invented to express the various sounds, or letters, employed in any language, either ancient or modern.

(c) A list of writers on stenography. Mr. Addy, Aldridge, Angell, Ather, Blandmore, Blofett, Boley, Bridges, Byrom, Colls, Crofis, Dix, Everard, Ewen, Facey, Farthing, Gibbs, Grime, Gurney, Heath, Holdworth, Hopkins, Jeake, Labourer, Lane, Lyle, Macauley, Mafon, Mavor, Metcalfe, Nicholas, Palmer, Rich, Ridpath; Shelton, Steele, Tanner, Taylor, Thickness, Tiffin, Webster, Welton, Williamson, Willis, B. D., and Willis, &c.
reformed the omission of vowels in the middle of words, which it is obvious, and invented letters, which could be connected as in a running hand without lifting the pen in the middle of the word, made a real improvement on the works of his predecessors. But, in fine, most systems, either in their plan or execution, labour under some capital defect, attended with circumstances highly discouraging to the learner, and which is a great measure defeat the end of their invention, by being too complicated to be learned with ease and remembered with accuracy, or to be practised with the expedition which is requisite; and so difficult to be deciphered, that a man can scarcely read what he has just written.

To obviate these defects, to provide against prolixity and conciseness, which might occasion obscurity, to exhibit a system founded on the simplest principles, which might be easily learned and read, and yet be capable of the utmost expedition—were the motives that gave rise to the present attempt.

This method will be found different from any yet published, and superior to all in the disposition of the vowels and the facility of arranging them; the confusion in placing which seems to detract from the merit of the best performances on the subject; and it may be affirmed, without ostentation, that characters simpler in their form, and more perfect in their union, have not been applied to the art of stenography.

As well as it could be determined, the simplest characters are appropriated to the letters most usually employed; indeed, as far as possible, those which are complex have been rejected; but as it was an object always kept in view that the writing should be on a line, a few were admitted into the alphabet for that reason.

The characters for the double and triple consonants are the easiest that could be invented, consistent with perspicuity (v); for care has been taken to provide against all obscurity which might arise by adopting letters too similar in their formation; and with respect to the prepositions and terminations, those which occur most frequently are expressed by the simplest characters, which will be found perfectly easy in their application.

The arithmetics are few in number (v), and the arithmetical abbreviations, as they are entirely from the letters of the alphabet, and chosen from some thousands of words in common use, will well repay the learner for an hour's trouble in committing them to memory.

The last chapter lays down a scheme of abbreviation, compiled in a few rules, perfectly easy to be understood and practised by proficient in this art, which we hope will answer the expectation of the author, and will be found free from the perplexity complained of in many systems where abbreviation is admitted. The principal rules are new, are so easy, so extensive in their use, and so consistent with expedition and legibility, if applied with judgment, that they alone must suffice. The learner is however advised by no means to adopt any of them, till experience has convinced him that they may be used without error or injury to legibility. All abbreviating rules are suited to those only who have made some progress in the phonographic art; for although they certainly promote expedition in a wonderful manner, and afford the greatest ease to a proficient, yet a learner, as expedition is not his first, though his ultimate view, should admit of nothing that in the least renders the reading difficult.

CHAP. II.

The English alphabet consists of twenty-six letters; the gene-

of which are vowels, a, e, i, o, u, and y; and the other twenty consonants, b, c, d, f, g, h, j, l, m, n, p, q, r, s, t, v, w, x, y, and z.

This alphabet, as is observed by the best grammarians that have written on the language, is both defective and redundant in expressing the various modifications of sound.

Custom or prejudice has assigned some letters a place, when others would with much more propriety express the same sound; and to this may be added, that several letters, sometimes in one word, seem to be admitted for no other reason than to perplex a young beginner or a foreigner, as an obstruction to true pronunciation, and to add to the apparent length of the word, when they are entirely superfluous and useless. That this is the genius of the orthography of our language must be perceived by the most superficial observer; but no modern tongue is absolutely free from the same exceptions. In particular, the French has a great number of dormant letters, which, it is obvious, render the pronunciation more difficult and perplexing to learners (c).

But as it is neither our business nor our intention to propose a mode of spelling different from that in common use, when applied to printing or long-hand writing (since several innovators in orthography have fallen into contempt, and their plans have been only preserved as beacons to warn others of the folly of endeavouring to subvert established principles (b)), we shall only observe, that in phonography, where the most expedients and the following simple rules are studiously to be regarded and practised.

**Rule I. All quiescent consonants in words are to be**
The page contains a text discussing the rules and principles of stenography, a system for shorthand writing. The text outlines various rules for abbreviating vowels, consonants, and the use of diacritical marks. It also describes the formation and application of characters used in stenography, with an emphasis on legibility and precision in writing.

The text covers:
- Rules for the vowels
- The stenographic alphabet
- The general principles of stenography

The section on rules for the vowels explains how to abbreviate vowels and consonants, providing examples and guidelines for easy recognition. The stenographic alphabet is introduced with 18 distinct characters, including rules for the formation and application of these characters. Finally, the text addresses the general principles of stenography, emphasizing the importance of legibility and precision in writing.

By following the rules and principles outlined in this page, one can efficiently and accurately record spoken words using the shorthand method of stenography.
The characters expressing nine of the consonants are all perfectly distinct from one another; eight only remain which are needful, viz. f, g or h, j, p, q, v, w, and x. To find characters for which we must have recourse to mixed curves and lines. The characters which we have adopted are the simplest in nature after those already applied, admit of the easiest jointing, and tend to preserve lineality and beauty in the writing.

It must be observed that we have no character for c when it has a hard sound, as in coffee; or soft, as in city; for it naturally takes the sound of k or t, which in all ciphers is sufficiently to supply its place.

R likewise is represented by the same character as l; only with this difference, r is written with an ascender stroke (1), and l with a descender; which is always to be known from the manner of its union with the following character; but in a few monosyllables where r is the only consonant in the word, and consequently stands alone, it is to be made as is shown in the alphabet for distinction's sake.

Z, as it is a letter seldom employed in the English language, and only a coarser and harder expression of s, must be supplied by s whenever it occurs; as for Zakaria write Zakarias, &c.

CHAP. IV.

The prepositions and terminations in this scheme are so simple, that the greatest benefit may be reaped from them, and very little trouble required to attain them; as the incipient letter or the incipient consonant of all the prepositions and of several of the terminations is used to express the whole. But although in Plate CCCCLXXXII. sufficient specimens are given of the manner of their application, that the learner of ingenuity or more flow perception may have every assistance, we have subjoined the following directions.

Rule I. The preposition is always to be written without joining, yet so near as plainly to show what word it belongs to; and the belt way is to observe the same order as if the whole was to be connected.

Rule II. A preposition, though the same letters that constitute it may be met with in the middle or end of a word, is never to be used, because it would expose to obscurity.

Rule III. Observe that the preposition omni is expressed by the vowel e in its proper position; and for anti, anti, ante, by the vowel a, which the radical part of the word will easily distinguish from being only simple vowels.

The first rule for the prepositions is (allowing such exceptions as may be seen in the Plate) to be observed for the terminations; and also the second mutatis mutandis; except that whenever fis, fis, fis, nius, and ces occur, they are to be expressed as directed in the fourth rule for the consonants, whether in the beginning, middle, or end of words (x).

Rule IV. The terminative character for tion, fion, cion, cian, cian, is to be expressed by a small circle joined to the nearest letter, and turned to the right; and the plurals tions, fions, cions, cians, cians, cians, tiences, by a dot on the same side.

Rule V. The terminative character for ing, is to be expressed likewise by a small circle, drawn to the left hand; and its plural inge by a dot (l).

Rule VI. The plural sign z is to be added to the terminative characters when necessary.

Rule VII. The separated terminations are never to be used but in poly syllables or words of more syllables than one.

These rules duly observed will point out a method as concise and elegant as can be desired, for expressing the most frequent and longest prepositions and terminations in the English language. If it should be thought necessary to increase their number by the addition of others, it will be an easy matter for any one of the least discernment to do so, by proceeding on the principles before laid down.

CHAP. V.

Though a more concise method of writing, or more rules for numerous abbreviations, may not be indubitably necessary, if the foregoing directions be professed for a certain considerable time, yet contradictions will be found extremely.

---

(1) The character for b, when lineality requires it, may be made from the bottom and inverted (see Plate CCCCLXXXII). And often b may be omitted entirely; or a vowel may be substituted in its stead, without any injury to legibility, it being rather a breathing than letter.

(x) But in a few words where three horizontal characters meet, it will be better to express the fis, &c. by the semicircular character in Plate CCCCLXXXII. opposite tiou.

(l) In horizontal characters, by the left hand is meant the top, and by the right the space below the letter (see ing joined, Plate CCCCLXXXII). In all other characters the right and left positions will naturally be known.
tremely useful and convenient to those who have attained a proper knowledge of the subject, and lead to a greater degree of expedition, at the same time that they diminish the labour of writing. It has been observed in the introduction, that abbreviations are only to be employed by proficients in this art; because expedience is not the first, though the ultimate, object in view; and that an easy legibility is of the utmost consequence to the learner; which, however, cannot be preferred, if he adopts too soon those very rules which in time will afford him the greatest ease when applied with judgment.

The following short and practical rules will be found, we hope, fully adequate to every purpose for which they were intended, and are far superior in the facility of their application to any which we have seen.

 Rule I. The usual abbreviations in long-hand are always to be followed; as M. for Master, M. D. for Doctor of Physic, and Abp. for Archbishop, &c.

 Rule II. Substantives, adjectives, verbs, and particles, when the sense will direct to the meaning, are to be expressed by their initial consonant with the following marks exhibited in Plate CCCCXXXII. viz. a substantival must have the dot exactly over its initial consonant; an adjective must have a dot under it; a verb is to be expressed by a comma over its initial consonant; and a participle by a comma under (m). These being the four principal parts of speech will be sufficient; and an adept will never be at a loss to know when he can with safety apply this rule to them.

 Rule III. To render the writing more legible, the last letter of the word may be joined to the first, and the proper mark applied.

 Rule IV. The constituent or radical part of words, especially if they are long, will often serve for the whole, or sometimes the first syllable; as, we ought to moderate our ex. by our circums; a man's man, commonly shape his for.

 Rule V. All long words without exception may have their prepositions or terminations expressed by the incipient consonant of such preposition or termination.

 Rule VI. When there is a great dependence between the parts of a sentence, the initial letter will often suffice; as L. is the capital of Great B.; the eldest S. of the king of Great B. is styled prince of W. Every one, it is prefumed, will allow this to be perfectly legible in long-hand, then why may it not in stenography?

 Rule VII. The terminations ng and lef may be omitted; as faithfullyf is only to be written faithful; forward, forwards; heed, heed's; scholarad, scholar, &c.

 Rule VIII. The second and third persons of verbs ending in eth and oft may be expressed by s; as, he loves, thou teachest; instead of he loves, thou teachest; or even without; as, he loves, &c.

 Rule IX. Words may often be entirely omitted, and yet no ambiguity ensue; as, In beginning God created heaven and earth, for in the beginning God created the heaven and the earth.

 Rule X. When there is an immediate repetition of a sentence or word, a line is to be drawn under the sentence or word to be repeated; as, Amen, Amen, is to be written Amen; but if any words intervene before a word or sentence is to be repeated, the line must be drawn as before, and a or mark of omission placed where the repetition should begin; as, Is it just the innocent should be condemned a reviled?

The Contents of the Stenographic Plate.

Fabricius's Reply to Pyrrhus.

As to my poverty, you have indeed, Sir, been rightly informed. My whole estate consists in a house of but mean appearance, and a little spot of ground, from which by my own labour I draw my support. But if by any means you have been persuaded to think, that this poverty makes me less considerate in my country, or in any degree unhappy, you are extremely deceived. I have no reason to complain of fortune, the supplies me with all that nature requires; and if I am without superfluities, I am also free from the desire of them. With these I confess I should be more able to succour the neccessitous, the only advantage for which the wealthy are to be envied; but as small as my possessions are, I can still contribute something to the support of the state and the affilliance of my friends. With regard to honours, my country places me, poor as I am, upon a level with the richest: for Rome knows no qualifications for great employments but virtue and ability. She appoints me to officiate in the most august ceremonies of religion; she entrusts me with the command of her armies; she confides to my care the most important negotiations. My poverty does not lessen the weight and influence of my counsels in the senate; the Roman people honour me for that very poverty which you consider as a disgrace; they know the many opportunities I have had in war to enrich myself without incurring cenfure; they are convinced of my disinterested zeal for their prosperity; and if I have any thing to complain of in the return they make, it is only the excess of their applause. What value then can I set upon your gold and silver! What king can add any thing to my fortune! Always attentive to discharge the duties incumbent on me, I have a mind free from self-reproach, and I have an honest fame. Diedly's Preceptor.

Letter to a Friend against Waste of Time.

Conversate often with yourself, and neither lavish your time, nor suffer others to rob you of it. Many of our hours are stolen from us, and others pass insensibly away; but of both these losses the most shameful is that which happens through our own neglect. If we take the trouble to observe, we shall find that one considerable part of our life is spent in doing evil, and the other in doing.

(a) The dot or comma being placed thus will never occasion them to be mistaken for vowels, because they should always be on one side or other; whereas the mark for parts of speech must constantly be placed exactly over or under.
St Paul's Speech before Agrippa and Felix.

I think myself happy, king Agrippa, that I shall answer for myself this day before you, touching all things whereof I am accused of the Jews; especially because I know thee to be expert in all customs and questions which are among the Jews, wherefore I beseech thee to hear me patiently. My manner of life from my youth, which was at first among mine own nation at Jerusalem, know all the Jews, which knew me from the beginning (if they would testify), that, after the firstest feet of it, I lived a Pharisee. And now I stand and am judged for the hope of the promises made by God unto our fathers: unto which promise our twelve apostles and prophets did declare that the fruit should never fail, of which of that world some have believed is come. For the truth is in me, and I judge to speak freely. And the king Agrippa, believe thou the prophets? I know that thou believest.

Once more I write to you as I promised, and this time I fear will be the last; the curtain will soon be drawn between my friend and me, and nothing left but to wish you a long good night; may you enjoy a flate of repose in this life not unlike that sleep of the soul which some have believed to succeed it, where we lie utterly forgetful of that world from which we are gone, and ripeing for that to which we are to go. If you retain any memory of the past, let it only image to you what has pleased you best; sometimes present a dream of an absent friend, or bring you back an agreeable conversation. But, upon the whole, I hope you will think less of the time past than the future; as the former has been less kind to you than the latter infamibly will be. Do not envy the world your studies: They will tend to the benefit of men, against whom you can have no complaint; I mean, of all posterity; and, perhaps, at your time of life, nothing else is worth your care. What is every year of a wise man's life but a cenure or critic on the past? Tho' whose whole date is the shortest, live long enough to laugh at one half of it: The boy despises the infant, the man the boy, the philosopher both, and the Christian all. You may now begin to think your manhood was too much a puerility; and you will never suffer your age to be but a second infancy. The toys and babbles of your childhood are hardly now more below you than the toys of our riper and our declining years; the drums and rattles of ambition, and the dirt and bubbles of avarice. At this time, when you are cut off from a little society, and made a citizen of the world at large, you should bend your talents not to serve a party, or a few, but all mankind. Your genius should mount above that mist, in which its participation and neighbourhood with earth hath long involved it: To shine abroad, and to heaven, ought to be the business and the glory of your present situation. Remember it was at such a time that the greatest lights of antiquity dazzled and blazed the moth; in their retreat, in their exile, or in their death. But why do I talk of dazzling or blazing? It was then that they did good, that they gave light, and that they became guides to mankind. Tho' aims alone are worthy of spirits truly great, and such I therefore hope will be yours. Reintendment indeed may remain, perhaps cannot be quite extinguished, in the noblest minds; but revenge will never harbour there: Higher principles

### The Lords Prayer

**The Lords Prayer**

The text for the Lords Prayer is not fully visible in the image, but it likely follows the traditional Lord's Prayer format in English.
FABRICIUS' REPLY TO PYRRHUS.

ST. PAUL'S SPEECH.

LETTER &C.

POPE TO ATTERBURY.
than those of the first, and better principles than those of the latter, will infallibly influence men whose thoughts and whose hearts are enlarged, and cause them to prefer the whole to any part of mankind, especially to fo small a part as one's native self. Believe me, my Lord, I look upon you as a spirit entered into another life, as one just upon the edge of immortality, where the passions and affections must be much more exalted, and where you ought to despise all little views and all mean retropsects. Nothing is worth your looking back; and therefore look forward, and make (as you can) the world look after you; but take care it be not with pity, but with esteem and admiration. I am, with the greatest sincerity and passion for your fame as well as happiness, your, &c.

The above most charming and most affectionate letter was written about a month before Atterbury bishop of Rochester was sent into banishment, and is universally admired.

STENTOROPHONIC TUBE, a speaking trumpet; thus called from Stentor, a person mentioned by Homer. See TRUMPET.

STEP, in a ship, a block of wood fixed on the decks or bottom of a ship, and having a hole in its upper side, fitted to receive the heel of a mast or capstern. The steps of the main and foremasts of every ship rest upon the keelson, to which they are firmly secured by knees, bolts, or screws. The step of the mizen-mast usually rests upon the lower deck.

STEPHANION in botany: A genus of the morgenia order, belonging to the pentandra class of plants; and in the natural method ranking under the 47th order, Stellatae. The calyx is monophylous, turbinate, and quinquenervate; the corolla is monopetalous, funnel-shaped, having its tubes curved and ventricose; the pericarpiurn is a bilocular berry containing two seeds, flattened on one side and round on the other. This genus is nearly allied to that of Psychotria. There is only one species, viz. Gutanera, a native of the warmer parts of America.

STEPHANOPHORUS, in antiquity, the chief priest of Pallas, who presided over the reft. It was usual for every god to have a chief priest; that of Pallas was the Stephanophorus just mentioned, and that of Hercules was called Dadoucous. Stephonophorus was also a priest that afflicted the women in the celebration of the festival Theophoria.

STEPHANUS (Byzantius), an able grammanian, who lived in the 5th or 6th century. He wrote a Dictionary, in which he made a great number of observations, borrowed from mythology and history, which showed the origin of cities and colonies, of which we have nothing remaining but a mean abridgment by Hermolaus the grammanian; but from that work the learned have received great light; and Sigonius, Calabron, Scaliger, Salmasius, &c. have employed themselves in illustrating it.

Stephen, or St Stephen's Day, a festival of the Christian church, obsev'd on the 26th of December, in memory of the first martyr St Stephen.

STEPHEN, a family of printers deservedly celebrated. They flourished at the revival of learning, and contributed a great deal towards dispelling the cloud of ignorance which had so long overshadowed Europe. Some of the classes before the 16th century were in a great measure lost, and all of them were exceedingly corrupted. By their abilities and indefatigable industry these defects were supplied, and the learned were furnished with beautiful and correct editions of the Greek and Roman authors. Thus the world was not only supplied with an inexhaustible fund of amusement and instruction in their ancient writings; but it is to the authors which they inspired, and to the model of elegance which they displayed, that the present advanced state of literature is in a great measure owing.

Henry Stephens, the first of these illustrious men, was born in France, soon after the discovery of printing, perhaps about the year 1465. He settled as a printer at Paris, and was probably patronized by Louis XII. A great proportion of the books which he published were Latin: They are printed in the Roman letter, and are not inelegant, though some of them abound rather too much in contradictions. He died about the year 1520, and left behind him three sons, Francis, Robert, and Charles. His widow married Simon de Colinus (Colinus in Latin), who thus got possession of Henry's printing-house, and continued the profession till his death.

Of Francis, the eldest son, little more is known than that he carried on business along with his father-in-law Colinus, and that he died at Paris in 1550.

Robert Stephens, the second son, was born in 1503. In his youth he made great proficiency in the Roman, Greek, and Hebrew languages, and at the age of 19 had acquired so much knowledge, that his father-in-law entrusted him with the management of his press. An edition of the New Testament was published under his inspection, which gave great offence to the Paris divines, who accused him of heresy, and threatened to prevent the sale of the book. Soon after he began business himself, and married Perrette the daughter of Jodocus Dadius, a printer and an author. She was a woman of learning, and understood Latin, which indeed was the necessary consequence of her situation. Her husband always entertained a number of learned men as correctors of the press: Being foreigners, and of different nations, they made use of no other language but Latin; which Perrette being accustomed to hear, was able in a short time not only to understand, but even to speak with tolerable ease.

In 1531 he published his Latin " Theaurus," a work of great importance, which he laboured at for two years. The mark which he put upon all his books was a tree branched, with a man looking upon it, and these words sola altum sapere, to which he sometimes added aed time. In 1539, Francis I. made him his printer, and ordered a new set of elegant types to be founded for him. His frequent editions of the New Testament gave great offence to the doctors of the Sorbonne, who accused
Henry, the French king, in some measure protected him, the persecution of these divines rendered him so unhappy, not to mention the expense and loss of time which an almost constant attendance at court unavoidably occasioned. In 1552 he abandoned his country and went to Geneva. Here he embraced the Protestant religion, and thus justified in some measure the suspicions of his theological enemies. It has been affirmed by several writers that he carried along with him the royal type, and the moulds also in which they were cast; but it is certain that he never afterwards made use of these tools. Besides, is it possible that the author of so daring a theft could have been not only protected in Geneva, but even courted and honoured by the most eminent men of the age? Is it credible that such a crime could have been concealed for 60 years; or that Henry, the son and heir of the perpetrator, would have enjoyed the favour of the French king, if Robert Stephens had acted such a shameful part? If he was burnt in effigy at Paris, it was for theft, but for having changed his religion.

After his arrival at Geneva, he published an account of the dispute between him and the Paris divines, which does as much honour to his abilities as his Thesaurus does to his learning. He died in 1559, after a life of the most extraordinary industry. The books of which he was the editor were not fewer than 360. Many of them were ancient classics in different languages. Several were accompanied with annotations which he collected, and all of them were corrected by collating manuscripts. He was so anxious to attain perfect accuracy, that he used to expose his proofs in public, and reward those who discovered a mistake. His books consequently were very correct. It is said that his New Testament, called O Mirificam (because the preface begins with these words), has not a single fault.

It was Robert Stephens who first divided the New Testament into verses during a journey between Paris and Lyons. The advantages of this improvement are fully counterbalanced by its defects. It has detached the unity of the books, and induced many commentators to consider every verse as a distinct and independent aphorism. To this in some measure is to be ascribed the many absurd interpretations and creeds that have been forced out of that book.

By his will his estate was left exclusively to such of his children as should settle at Geneva. He left behind him three sons, Henry, Robert, and Francis. Charles Stephens, the third son of Henry, was like the rest of his family, familiarly acquainted with the learned languages. This recommended him to Lazarus de Baif, who made him tutor to his own, and in 1540 carried him along with him to Germany. He studied medicine, and practised it with success in France. He did not, however, forsake the profession of his family, but exercised it in Paris, where he became the editor of many books remarkable for neatness and elegance. He wrote above thirty treatises on different subjects, particularly on botany, anatomy, and history. He died in 1562.

Robert Stephens, the son of Robert the first of that name, did not accompany his father to Geneva, but continued to profess the Catholic religion, and to reside at Paris. His letter was remarkably beautiful. He was made king's printer, and died about 1589. His brother Francis was also a printer. He embraced the Protestant religion, and resided at Geneva.

Henry Stephens, the remaining son of Robert, was born at Paris in 1548. He became the most learned of all his family. From his very birth almost he gave proofs of uncommon abilities, and displayed an ardent passion for knowledge. The Medea of Euripides, which he saw acted while at school, first kindled his love for poetry, and inspired him with the desire of acquiring the language in which this tragedy is written. He intreated his father not to condemn him to study Latin, which he already understood from conversation, but to initiate him at once into the knowledge of Greek. His father willingly granted his request; and Henry applied with such vigour, that in a short time he could repeat the Medea by heart. He afterwards studied Greek under Peter Danelius, who was tutor to the Dauphin, and finally heard the lectures of Tufanus and Turnebus. He became eager at an early age to understand astrology, and accordingly attended a professor of that mysterious art; but he was not long in discovering its absurdity. At 19 he began his travels, which he undertook in order to examine foreign libraries, and to become acquainted with learned men. He spent two years in Italy, and returned into France completely master of Italian, and bringing along with him copies of several scarce authors, particularly a part of Anacreon, which before was thought lost.

He found his father publishing an edition of the New Testament, to which he prefixed some Greek verses.—Soon after, he visited England and the Netherlands, where he met with John Clement, an Englishman, to whom he was indebted for the remaining odes of Anacreon. During this journey he learned the Spanish language, which was very much spoken at that time in the Low Countries.

Whether Henry accompanied his father to Geneva or not is uncertain; at least he must have returned immediately to France, for we find him soon after established at Paris, and publishing a work of Anacreon. In 1554 he went to Rome, and thence to Naples. This journey was undertaken at the request, and in the service, of the French government. He was discovered, and would have been arrested as a spy, had he not by his address and skill in the language of the country been able to pass himself for a native of Italy. On his return to France he assumed the title of printer to Ulric Fugger, a very rich and learned German nobleman, who allowed him a considerable pension.

In 1560 he married a relation, as is generally supposed, of Henry Scrimgour, a Scotch nobleman, with whom he was intimately acquainted. She was a woman, as he himself informs us, endowed with the noblest spirit and the most amiable dispositions. Her death, which happened in 1566, brought on a disease that had twice attacked him before. It was a disease at all those pursuits which had formerly charmed him, an aversion to reading and the fight of books. It was probably occasioned by too constant and feverous an application to literary pursuits. In 1572 he published his Thesaurus Linguae Graecae, one of the greatest works, perhaps, that ever was executed by one man, if we consider...
der the wretched materials which more ancient dictionaries could furnish, if we consider the size and perfection of the work, and the immense labour and learning which must have been employed in the compilation. This work had been carried on at a greater expense than he could well bear. He expected to be reimbursed by the sale of the book, but he was unfortunately disappointed.

John Scapula, one of his own servants, extracted from it whatever he thought would be most serviceable to students, and published it beforehand in 4to. By this act of treachery Henry reduced to poverty, and refided frequently in France, who treated him so kindly, and made him a favourite at court. But these promises were never fulfilled, owing to the civil wars which soon unsettled him. During the remainder of his life his situation was as wretched as it could well be. A large number of the ancient classics, but his Stercorarians, or Stercoranists, formed from Hercules "dung," a name which the council of the Romish church anciently gave to such as held that the soul was liable to digestion, and all its concomitants, like other food.

STERCULIA, in botany: A genus of plants belonging to the class of magenta, and order of monodelphus; and in the natural system under the 36th order, dicotytes. The male calyx is quinquepartite; there is no corolla; there are 15 filaments. The female calyx is quinquepartite; there is no corolla; the germen is placed on a pillar, and the capsule is quinquepartite, and many-seeded. There are three species, the Stelina, fidefi, and platanifolium, all foreign plants.

STEREOGRAPHIC PROJECTION, is the projection of the circles of the sphere on the plane of some one great circle, the eye being placed in the pole of that circle. See Projection of the Sphere.

STEREOLOGY, the art of solid figures, and solid measure, that part of geometry which teaches how to measure solid bodies, i.e. to find the solidity or solid contents of bodies; as globes, cylinders, cones, spheres, &c.

STEROTOMY, formed from sponges and tuba section, the art or act of cutting solids, or making sections thereof; as walls and other membranes in the profiles of architecture.

STERILITY, barrenness, in opposition to fertility. It has been asserted by many authors, that all monstrosities produced by a mixture of different species of animals, such as mules, are barren; but this does not hold universally, even with the mule, which is the offspring most generally added. See Mule.

Sterility in women sometimes happens from a miscarriage, or violent labour injuring some of the genital parts; but one of the most frequent causes is the supposition of the menstural flux.—There are other causes arising from various diseases incident to those parts, by which the uterus may be unfit to receive or retain the male seed;—from the tube fallopian being too short, or having lost its erectile power; in either of which cases no conception can take place;—from universal debility and relaxation; or a local debility of the genital system, by which means, the parts having lost their power of contraction, the semen is thrown off immediately post coitum— from imperfection of the vagina, the uterus, or the inside, or from diseased ova, &c. Hence medical treatment can only avail in cases arising from topical or universal debility; in correcting irregularities of the menstrual flux, or in removing tumors, cicatrizes, or constrictions of the pudenda, by the art of surgery.

STERIS, in botany: A genus of plants belonging to the class of pentaeris, and order of digynia. The calyx is quinquepartite; the corolla wheel-shaped; the berry is unilocular, and many-seeded. There is only one species, the janava, a foreign plant.

STERLING, an epithet by which genuine English money is distinguished. It is unnecessary to mention the various conjectures of antiquaries about the origin and meaning of this appellation. The most probable opinion seems to be this, that some artificers from Germany, who were called Efterlings, from the situation of their country, had been employed in fabricating this coin, vol. 5, p. 54.
Thefe birds are also found in America; come into New England in May, and go away in autumn, and are called there the mackerel gull. At Hudson's Bay they are known by the name of black-head. They are observed to lay their eggs in small hollows on the shore, sometimes lined with a few leaves. They are often found in great numbers on the islets in the middle of the rivers, and are thought good eating. The natives of Hudson's Bay call them Renoum ou beauf. They are bold, not fearing mankind, and in the time of incubation will attack anyone, frequently darting down so as to touch a person's hat, without his giving the least offence.

2. The minuta, or smaller sea-swallow, (called by Linnaeus larus minuta), weighs only two ounces five grains; the length 8 inches and a half; the breadth 19 and a half. The bill is yellow, tipt with black; the forehead and cheeks white; from the eyes to the bill is a black line; the top of the head and hind part black; the breast and under side of the body clothed with feathers so closely fet together, and of such an exquisite rich gloss and so fine a white, that no fattin can be compared to it: the back and wings of a pale grey; the tail short, fels forked than that of the former, and white: the legs yellow; the irides dull.—These two species are very delicate, and seem unable to bear the inclemency of the weather on our shores during winter, for we observe that they quit their breeding places at the approach of it, and do not return till spring. The manners, haunts, and food of this species are the same with those of the former; but they are far left numerous.

3. The sifipes, or black tern, is of a middle size between the first and second species. The usual length is 10 inches; the breadth 24; the weight two ounces and a half. The head, neck, breast, and belly, as far as the vent, are black; beyond is white; the male has a white spot under its chin; the back and wings are of a deep ash colour: the tail is short and forked; the exterior feather on each side is white; the others ash-coloured: the legs and feet of a dulky red. Mr Ray calls this a cloven-footed gull, as the webs are depressed in the middle, and form a crecent. These birds frequent fresh waters, breed on their banks, and lay three small eggs of a deep olive colour, much spotted with black. They are found during spring and summer in vast numbers in the Fens of Lincolnshire, make an incessant noise, and feed on flies as well as water insects and small fish. Birds of this species are seen very remote from land. Kalm faw flocks of hundreds in the Atlantic Ocean, midway between England and America, and a later voyager faw one 240 leagues from the Lizard, in the same ocean.

STERNE (Laurence), an English writer of a very peculiar cast, was born at Cloadwell, in the south of Ireland, on 24th November 1713. His father Roger Sterne was the grandson of Sterne archbishop of York, who has been supposes, we know not upon what grounds,
Sternomantis, in antiquity, a designation given to the Delphian priestess, more usually called Pythia.—Sternomantis is also used for any one that had a prophesying demon within him.

Sternostomaedéus, a muscle. See Table of the Muscles, under Anatomy.

Sternothyricideus, a muscle. See Table of the Muscles, under Anatomy.

Sternum. See Anatomy, no. 37.

Sternutative, or sternutatory, a medicine proper to produce sneezing. See Sneezing.

Stetin, or Stettin, a seaport town of Germany, in the circle of Upper Saxony, and capital of Hither Pomerania, with the title of a duchy, and a castle. It had long a famous school, which the wars of Germany never disturbed. The ancient dukes of Pomerania resided here; and it was taken by the elector of Brandenburg in 1676; but given to Sweden by the treaty of Nimsgen. In 1713 it submitted to the allies; and then the said elector was put in possession of this important place, which is a bulwark to the March of Brandenburg, and the fortifications have been greatly improved. It is now a flourishing place, and carries on a considerable trade. It is seated on the river Oder, 72 miles north of Frankfort, and 90 north by east of Berlin. E. Long. 14. 38. N. Lat. 53. 35. The duchy is 125 miles in length, and borders upon Mecklenburg, and partly upon Brandenburg. The breadth is from 17 to 25 miles, and it is divided by the river Oder into two parts.

Stew, a small kind of fish-pond, the peculiar use of which is to maintain fish, and keep them in readiness for the daily use of the family, \\

Stews (from the French eau, i.e. eauerna, balnum), those places which were permitted in England to women of professed incontinency, and that for here would prostitute their bodies to all comers; so called, because dilute persons are wont to prepare themselves for venereal acts by bathing; and hot baths were by Homer reckoned among the eminence lot of pleasures. Their flames were supplicated by King Hen. VIII. about the year 1546.

Steward (feneallus, compounded of the Saxon fletla, i.e. "room" or "stead and ward," "a ward" or "keeper"), an officer appointed in another's stead or place, and always taken for a principal officer within his jurisdiction. Of these there are various kinds. The greatest officer under the crown is the lord high-steward of England, an office that was anciently the inheritance of the earls of Leicester, till forfeited by Simon de Montfort to King Henry III. But the power of this officer is so very great, that it has not been judged safe to trust it any longer in the hands of a subject, excepting only pro hac vice, occasionally: as to officiate at a coronation, at the arrayment of a nobleman for high treason, or the like. During his office, the steward bears a white staff in his hand; and the trial, &c. ended, he breaks the staff, and with it his commission expires. There is likewise a lord-steward of the king's household, who is the chief officer of the king's court, has the care of the king's house, and authority over all the officers and servants of the household, except such as belong to the chapel, chamber, and stable.

Steward, an officer in a ship of war, appointed by the purser to distribute the different species of provis...
Court of the Lord High Steward of Great Britain, is a court instituted for the trial of peers indicted for treason, felony, or misprision. The office of this great magistrate is hereditary, and was formerly inherited, or at least held for life; but now it is usually, and hath been for many centuries past, granted pro hac vice only; and it hath been the constant practice (and therefore seems now to have become necessary) to grant it to a lord of parliament, else he is incapable to try such delinquent peer. When such an indictment is therefore found by a grand jury of freeholders in the King's bench, or at the assizes before the justices of eyre and termini, it is to be removed by a writ of certiorari into the court of the lord high-steward, which has the only power to determine it. A peer may plead a pardon before the court of the King's bench, and the judges have power to allow it, in order to prevent the trouble of appointing an high-steward merely for the purpose of receiving such plea: but he may not plead in that inferior court any other plea, as guilty or not guilty of the indictment, but only in this court; because, in consequence of such plea, it is possible that judgment of death might be awarded against him. The king, therefore, in case a peer be indicted of treason, felony, or misprision, creates a court high-steward pro hac vice by commission under the great seal; which receives the indictment so found, and gives his grace power to receive and try it se cum legem et consultis Angliae. Then when the indictment is regularly removed by writ of certiorari, commanding the inferior court to certify it up to him, the lord high-steward directs a precept to a serjeant at arms, to summon the lords to attend and try the indicted peer. This precept was formerly issued to summon only 18 or 20 selected from the body of the peers; then the number came to 1, indefinite; and the custom was for the lord high-steward to summon as many as he thought proper (but of late years not less than 23); and that these lords only should sit upon the trial, which threw a monstrous weight of power into the hands of the crowd, and this, its great officer, of selecting only such peers as the then predominant party should most approve of. And accordingly, when the earl of Clarendon fell into disgrace with Charles II., there was a design formed to prorogue the parliament, in order to try him by a selected number of peers; it being doubted whether the whole house could be induced to fall in with the views of the court. But now, by statute 7 W. III. c. 3. upon all trials of peers for treason or misprision, all the peers who have a right to sit and vote in parliament shall be summoned at least 20 days before such trial, to appear and vote therein; and every lord appearing shall vote in the trial of such peer, first taking the oaths of allegiance and supremacy, and subscribing the declaration against popery.

During the feission of parliament, the trial of an indicted peer is not properly in the court of the lord high-steward, but before the court last mentioned of our lord the king in parliament. It is true, a lord high-steward is always appointed in that case to regulate and add weight to the proceedings: but he is rather in the nature of a speaker pro tempore, or chairman of the court, than the judge of it; for the collective body of the peers are therein the judges both of law and fact, and the high-steward has a vote with the rest in right of his peerage. But in the court of the lord high-steward, which is held in the recess of parliament, he is the sole judge of matters of law, as the lords triors are in matters of fact; and as they may not interfere with him in regulating the proceedings of the court, so he has no right to intermix with them in giving any vote upon the trial. Therefore, upon the conviction and attainder of a peer for murder in full parliament, it hath been held by the judges, that in case the day appointed in the judgment for execution should lapse before execution done, a new time of execution may be appointed by either the high court of parliament during its sitting, though no high-steward be existing or, in the recess of parliament, by the court of King's bench, the record being removed into that court.

It has been a point of some controversy, whether the bishops have now a right to sit in the court of the lordhigh-steward to try indecencies of treason and misprision. Some incline to imagine them included under the general words of the statute of King William "all peers who have a right to sit and vote in parliament;" but the expression had been much clearer, if it had been "all lords." and not "all peers," for though bishops, on account of the baronies annexed to their bishoprics, are clearly lords of parliament, yet their blood not being ennobled, they are not universally allowed to be peers with the temporal nobility: and perhaps this word might be inferred purposely with a view to exclude them. However, there is no influence of their sitting on trials for capital offences, even upon impeachments or indictments in full parliament, much less in the court we are now treating of; for indeed they usually withdraw voluntarily, but enter a protest, declaring their right to stay. It is observable, that in the 11th chapter of the constitutions of Clarendon, made in parliament 11 Hen. II. they are expressly executed, rather than excluded, from sitting and voting in trials, when they come to concern life or limb: episcopi, sciat ecclesiae barones, debent inter se judicium cum baronibus, qusuo quod ipse ad diminutionem membrorum habetur. And Becket's quarrel with the king, upon which his not on account of the exception (which was agreeable to the canon law), but of the general rule, that compelled the bishops to attend at all. And the determination of the house of lords in the earl of Danby's case, which hath ever since been adhered to, is conformable to these constitutions; "that the lords spiritual have a right to sit and vote in court in capital cases, till the court proceeds to the vote of guilty or not guilty." It must be noted, that this resolution extends only to trials in full parliament; for to the court of the lord high-steward (in which no vote can be given, but merely that of guilty or not guilty), no bishop, as such, ever was or could be summoned: and though the statute of King William regulates the proceedings in that court, as well as in the court of parliament, yet it never intended to new-model or alter its constitution, and consequently does not give the lords spiritual any right, in cases of blood, which they had not before. And what makes their exclusion more reasonable is, that they have no right to be tried themselves in the court of the lord high-steward, and therefore surely ought not to be judges there. For the privilege of being thus tried
Stewart (Dr. Matthew), was in 1717 born at Rothlafy in the Isle of Bute, of which parish his father was the minister. Being intended for the church, he went through the usual course of a grammar-school education, and was in 1734 received as a student into the University of Glasgow. There he had the happiness of having for his preceptors in moral science and in mathematics the celebrated professors Hutchison and Simson; by the latter of whom he was instructed in what may not improperly be called the *arcsana* of the ancient geometry.

Mr. Stewart's views making it necessary for him to remove to Edinburgh, he was introduced by Dr. Simson to Mr. Maclaurin, that his mathematical studies might suffer no interruption; and he attended the lectures of that great master with such advantage as might be expected from eminent abilities, directed by the judgment of him who made the philosophy and geometry of Newton intelligible to ordinary capacities. Mr. Stewart, however, had acquired, from his intimacy with Dr. Simson, such a predilection for the ancient geometry, as the modern analysis, however powerfully recommended, could not leaft; and he kept up a regular correspondence with his old master, giving him an account of his progress and his discoveries in geometry, and receiving in return many curious communications respecting the *Locs Planis* and the porisms of Euclid. See Portiam and Simson.

While the second invention of porisms, to which more genius was perhaps required than to the first discovery of them, employed Dr. Simson, Mr. Stewart pursued the same subject in a different and new direction. In doing so, he was led to the discovery of those curious and interesting propositions which were published under the title of *General Theorems* in 1746. They were given without the demonstrations; but did not fail to place their discoverer at once among the geometers of the first rank. They are for the most part porisms, though Mr. Stewart, careful not to anticipate the discoveries of his friend, gave them no other name than that of theorems.

Our author had before this period entered into the church; and obtained, through the patronage of the Duke of Argyle and the Earl of Bute, the living of Rofeneth, a retired country parish in the west of Scotland: but in 1747 he was elected to the mathematical chair in the University of Edinburgh, which had become vacant the year before by the death of Mr. Maclaurin. The duties of this office gave a turn somewhat different to his pursuits, and led him to think of the most simple and elegant means of explaining those difficult propositions which were hitherto only accessible to men deeply versed in the modern analysis. In doing this, he was pursuing the object which all others he most ardently wished to attain, *viz.* the application of geometry to such problems as the algebraic calculus alone had been thought able to resolve. His solution of Kepler's problem was the first specimen of this kind which he gave to the world; and it was impossible to have produced one more to the credit of the method he followed, or of the abilities with which he applied it. On this problem the utmost resources of the integral calculus had been employed. But though many excellent solutions had been given, there was none of them at once directed in its method and simple in its principles. Mr. Stewart was so happy as to attain both these objects; and his solution appeared in the second volume of the *Eloyals of the Philosophical Society of Edinburgh* for the year 1756. In the first volume of the same collection there are some other propositions of Mr. Stewart's, which are an extension of a curious theorem in the fourth book of Pappus. They have a relation to the subject of porisms, and one of them forms the 91st of Dr. Simson's *Reflections*. They are besides very beautiful propositions, and are demonstrated with all the elegance and simplicity of the ancient analysis.

The prosecution of the plan which he had formed of introducing into the higher parts of mixed mathematics the brief and simple form of ancient demonstration, produced the *Treats Physical and Mathematical*, which were published in 1761, and the *Eloyals of the Societ'S Difiinace*, which was published in 1765. In this last work it is acknowledged that he employed geometry on a talk which geometry cannot perform; but while it is granted that his determination of the sun's distance is by no means free from error, it may safely be asserted that it contains a great deal which will always interest geometers, and will always be admired by them. Few errors in science are redeemed by the display of so much ingenuity, and what is more singular, of so much found reasoning. The investigation is everywhere elegant, and will probably be long regarded as a specimen of the most arduous inquiry which has been attempted by more geometry.

The *Sun's Distance* was the last work which Dr. Stewart published; and though he lived to see several animadversions on it made public, he declined entering into any controversy. His disposition was far from polemical; and he knew the value of that quiet which a literary man should rarely suffer his antagonists to interrupt. He used to say, that the decision of the point in question was now before the public; that if his investigation was right it would never be overturned, and if it was wrong it ought not to be defended. A few months before he published the *Eloyal* just mentioned, he gave to the world another work, intitled *Proposiones Geometricae More Vetrum D. Montiitiae*. This title, it is said, was given to it by Dr. Simson, who rejoiced in the publication of a work so well calculated to promote the study of the ancient geometry. It consists of a series of geometrical theorems for the most part new; investigated first by an analysis, and afterwards synthetically demonstrated by the inversion of the same analysis.

Dr. Stewart's conflagrant use of the geometrical analysis had put him in possession of many valuable propositions which did not enter into the plan of any of the works that have been enumerated. Of these not a few have...
have found a place in the writings of Dr Simfon, where they will for ever remain to mark the friendship of these two mathematicians, and to evince the esteem which Dr Simfon entertained for the abilities of his pupil.

Soon after the publication of the Sun's Distance, Dr Stewart's health began to decline, and the duties of his office became burdensome to him. In the year 1772 he retired to the country, where he afterwards spent the greater part of his life, and never resumed his labours in the university. But though mathematics had now ceased to be his business, they continued to be his amusement till a few very years before his death, which happened on the 23d of January 1785, at the age of 68.

The habits of study, in a man of original genius, are objects of curiosity, and deserve to be remembered. Concerning those of Dr Stewart, his writings have made it unnecessary to remark, that from his youth he had been accustomed to the most intense and continued application. In consequence of this application, added to the natural vigour of his mind, he retained the memory of his discoveries in a manner that will hardly be believed. He rarely wrote down any of his inventions till it became necessary to do so for the purpose of publication. When he discovered any proposition, he would put down the enunciation with great accuracy, and on the same piece of paper would construct very neatly the figure to which it referred. To these he trusted for recalling to his mind at any future period the demonstration or the analysis, however complicated it might be. Experience had taught him, that he might place this confidence in himself without any danger of disappointment; and for this singular power he was probably more indebted to the activity of his invention than the mere tenacity of his memory. Tho' he was extremely studious, he read few books, and verified the observation of M. D'Alembert, that of all the men of letters, mathematicians read least of the writings of one another. His own investigations occupied him sufficiently; and indeed the world would have had reason to regret the misapplication of his talents, had he employed in the mere acquisition of knowledge that time which he could dedicate to works of invention.

STEWART, in Scots law. See LAW, No. clviii. 5.

STEWARTIA, in botany : A genus of plants belonging to the class of monodelphus, and order of polyandria; and in the natural system ranging under the 37th order, Columnifera. The calyx is simple; the style is simple, with a quinquefoliate stigma; the apple is without juice, quinquilobed, mononemorous, bursilating open with a spring five ways. There is only one species, the mastoecidendron, which is a foreign plant.

STIBIDURUM, among the Romans, a low kind of table-couch or bed of a circular form, which succeeded to the triclinia, and was of different sizes, according to the number of guests they were designed for. They were called hexaedra, octaedra, or enneas, according as they held fix, eight, or nine guests, and of any other number.

STIBIUM, a name for Antimony.

STICHOS, a name given by the old writers to a petiforal confection, the principal ingredient of which was the herb marrubium or horshound.

STICKLEBACK, in ichthyology. See CASTREOSTEUS.
STILLAGO, chosen of a fine gold yellow, very fine, tender, and friable, and free from dirt.

STILLAGO, in botany; a genus of plants belonging to the class of Gynandria, and order of Triandria. There is one female. The calyx is monophyllous, and almost three-lobed. There is no corolla, and the berry is globular. There is only one species, the bunius.

STILBE, in botany; a genus of plants belonging to the class of Polygium, and order of Dicota. The exterior calyx of the hermaphrodite flower is triphyllous; the interior is quinquedentate and cartilaginous. The corolla is funnel-shaped and quinquefid. There are four stamens; and there is one seed in the interior calyx calyptra. The female flower is similar, has no interior calyx nor fruit. There are three species, the pinata, ericoides, and cornua, all foreign plants.

STILBE. See STILBE.

STILFA, the name of an apparatus used in chemistry and in the distillation of ardent spirits. See Chemistry-Index at Distillation and Still.

STILL-BOTTOMS, in the distillery, a name given by the traders to what remains in the still after working the wash into low wines. These bottoms are procured in the greatest quantity from the malt-wash, and are of so much value to the distiller in the fattening of hogs, &c. that he often finds them one of the most valuable articles of the business.

STILLINGFLEET (Edward), bishop of Worcester, was the son of Samuel Stillingfleet gentleman, and was born at Cranborn in Dorsetshire in 1635. He was educated at St John's College, Cambridge; and having received holy orders, was, in 1657, presented in the dedication of his Calendar of Flora. During the Watford, Mr (afterwards Dr) Solander, Mr Hudson, and Mr Price of Foxley, and some others; to whom may be added the ingenious Mr Pennant. Nor can we omit the flattering mention which the late Mr Gray makes of him in one of his letters, dated from London in 1761: “I have lately made an acquaintance with this philanthropist, who lives in a garret here in the winter, that he may support some near relations who depend upon him. He is always employed, consequently (according to my old maxim) always happy, always cheerful, and seems to me a very worthy honest man.

His present scheme is to send some persons, properly qualified, to reside a year or two in Attica, to make themselves acquainted with the climate, productions, etc.
Mr. Stillingfleet published a volume of miscellaneous tracts, which is in much esteem, and does great honour to his head and heart. They are chiefly translations of some essays in the "Amendations Academica," published by Linnaeus, interspersed with some observations and additions of his own. In this volume he shows also a taste for classical learning, and entertains us with some elegant poetical effusions of his own. But his Essay on Conversation, published in the first volume of Dodd's Collection of Poems, entitles him to a distinguished rank among the English poets. This poem is addressed to Mr. Wyndham, with all that warmth of friendship which distinguishes Mr. Stillingfleet. As it is chiefly didactic, it does not admit of so many ornaments as some compositions of other kinds. However, in contains much good sense, shows a considerable knowledge of mankind, and has several passages that in point of harmony and easy verification would not disgrace the writings of the most admired poets. More than once Mr. Stillingfleet shows himself still sore for Dr. Bentley's cruel treatment of him; and towards the beautiful and moral close of it (where it is supposed he gives us a sketch of himself) seems to hint at a mortification of a more delicate nature, which he is said to have suffered from the other sex.

To these disappointments it was perhaps owing that Mr. Stillingfleet neither married nor went into orders. His London residence was at a saddler's in Piccadilly; where he died in 1771, aged above 70, leaving several valuable papers behind him. He was buried in St. James's church, without the slightest monument of his having existed.

STILLINGIA, in botany; a genus of plants belonging to the class of monactia, and to the order of monodelphia. The male calyx is hemispherical and multiflorous. The corolla is tubulous, and erose or gnawed. The female calyx is uniflorous and inferior. The corolla is superior. The style is trichid, and the capsule three-grained. There is only one species, the fylvatia.

STILYARD. See Stere-Fard.

STILPO, a celebrated philosoper of Megara, flourished under the reign of Ptolemy Euergetes. In his youth he had been addicted to licentious pleasures, from which he religiously refrained from the moment that he ranked himself among philosophers. When Ptolemy invited him to the taking of Megara, offered him a large sum of money, and requested that he would accompany him into Egypt, he accepted but a small part of the offer and retired to the island of Aegina, whence, on Ptolemy's departure, he returned to Megara. That city being again taken by Demetrius the son of Antigonos, and the philosopher required to give an account of any effects which he had loit during the interview of the plunder, he replied, that he had lost nothing; for no one could take from him his learning and elegance. So great was the fame of Stilpo, that the most eminent philosophers of Athens took pleasure in attending upon his discourses. His peculiar doctrines were, that species or universals have no real existences, and that one thing cannot be predicated of another. With respect to the former of these opinions, he seems to have taught the same doctrine with the felt afterwards known by the appellation of Nominalists. To prove that one thing cannot be predicated of another, he said, that goodness and man, for instance, are different things, which cannot be confounded by asserting the one to be the other; he argued farther, that goodness is an universal, and universals have no real existence; consequently, since nothing cannot be predicated of any thing, goodness cannot be predicated of man. Thus, whilst this subtle logician was, through his whole argument, predicating one thing of another, he denied that any one thing could be the accident or predicate of another. If Stilpo was serious in this reasoning; if he meant any thing more than to exprose the sophistry of the school, he must be confessed to have been an eminent master of the art of wrangling; and it was not wholly without reason that Glycera, a celebrated courtezan, when she was reproved by him as a corrupter of youth, replied, that the charge might be justly returned upon himself, who spent his time in filling their heads with sophistical quibbles and ufeless subtilities. In ethics he seems to have been a Stoic, and in religion he had a public and a private doctrine, the former for the multitude, and the latter for his friends. He admitted the existence of a supreme divinity, but had no reverence for the Greek superstitions.

STILBOTUM, in architecture, denotes the body of the pedestal of any column.

STILTON, a town of England, in the county of Huntingdonshire, 75 miles from London, south-west of Yaxley, on the Roman highway from Calig to Huntingdon, called Ermine-street some parts of which, in this neighbourhood, appear still paved with stone. This place is famous for cheeses which is called English Parmesan, and is brought to table full of mites or maggots. For making Stilton cheese, we have the following receipt in the first volume of the "Repository of Arts and Manufactures:"

"Take the night's cream, and put it to the morning's new milk, with the rennet; when the curd is come, it is not to be broken, as is done with other cheeses, but take it out with a full-dish altogether, and place it in a sieve to drain gradually; and as it drains, keep gradually predrying it till it becomes firm and dry; then place it in a wooden hoop; afterwards to be kept dry on boards, turned frequently, with cloth binders round it, which are to be tightened as occasion requires, and changed every day until the cheese become firm enough to support itself; after the cloth is taken off, the cheese is rubbed every day all over, for two or three months, with a brush; and if the weather be damp or moist twice a day; and even before the cloth is taken off, the top and bottom are well rubbed every day.

STIMULANTS, in medicine, substances which increase the action of certain parts of the body. In particular, they quicken the motion of blood, increase the action of the muscular fibres, and affect the nervous system.

STIMULI, in botany; a species of armature or offensive weapon, with which some plants, as nasturtium, calsida, acalypha, and tragia, are furnished. Their ufe, says Linnaeus, is by their venomous punctures to keep
keep off naked animals that would approach to hurt them.

STING, an apparatus in the bodies of certain insects, in form of a little spear, serving them as a weapon of offence.

STING-Ray, in ichthyology. See RAIA.

STINK-Pot, an earthen jar or shell, charged with powder, grenades, and other materials of an offensive and suffocating smell. It is frequently used by privates, in the western ocean, in the attack of an enemy whom they design to board; for which purpose it is furnished with a light fuse at the opening or touch-hole. See BOOKING.

STING, a species of the Tringa.

STIPA, Feather Grass, in botany: A genus of plants belonging to the class of triandria, and order of digynia: and in the natural system ranging under the 4th order, Gramineae. The calyx is bivalved. The exterior valve of the corolla is terminated by an awn; the base is jointed.

There are nine species, the pennata, juncea, capillata, aristella, tenerissima, avenacea, membranacea, arguens, and spicata. Of these one only is British, the pennata, or common feather grass. The beards are feathered. The plant rises to the height of 10 inches, grows on mountains, and flowers in July or August.

STIPEND, among the Romans, signifies the fame with tribute; and hence stipendiarii were the same with tributarii.

STIPEND, in Scots law. See LAW, 6 clix. 12.

STIPULA, in botany, one of the fulcra or props of they endeavoured to obliterate every memorial of that people. They not only gave new names to provinces and towns, but, with all the rage of barbarians, demolished many magnificent and useful edifices which had been reared up by them, and this fortress among the Scots and Northumbrians; each of whose dominions did, for some time, terminate near it.

When the Scots, under Kenneth II. overthrew the Pictish empire near the middle of the ninth century, they endeavoured to obliterate every memorial of that people. They not only gave new names to provinces and towns, but, with all the rage of barbarians, demolished many magnificent and useful edifices which had been reared up by them, and this fortress among the Picts. It was, however, soon rebuilt, though upon an occasion not very honourable to the Scots.

Upon the death of Kenneth II. in 855, his brother Donald V. mounted the throne of Scotland. In the beginning of his reign the kingdom was invaded by Ósfreid and Ella, two Northumbrian princesses, who, uniting their forces with the Cumbrian Britons, and a number of Picts, who upon their expulsion from their native country had taken refuge in England, advanced to Jedburgh, where Donald encountered them; and, after a fierce and bloody battle, obtained a complete victory: but, having taken up his station in Berwick, in open security, the Northumbrians, informed of the careless posture in which the Scottish army lay, surprised them by a hasty march, dispersed them, and made a prisoner of the king. Pursuing the advantage they had gained, they marched northward, and subdued all before them to the Frith of Forth and the town of Stirling. But the forlorn situation of the Scots, without a king and without an army, oblige them to sue for peace, they obtained it, upon condition that they should pay a sum of money for the ransom of the king, and yield up all their dominions upon the south side of the Forth to the conquerors.

The Northumbrians taking possession of the territories ceded to them by this treaty, rebuilt the castle of Stirling, and planted it with a strong garrison, in order to preserve their new conquests, upon the frontiers of which it was situated. Our authorities also inform...
us, that they erected a stone-bridge over the Forth, upon the summit of which a croos was raised, with the following inscription in monkith rhyme:

Anglos a Scottis separat cruix jfa remotis;
Armis his plant Britis, Scotts plant hic, cruce tuti.

Which is thus translated by Bellenden.

I am a free marche, as passengers may ken,
To Scottis, to Britonis, and to Ingliemen.

None of the ancient English historians mention this conquest. The whole story, as well as the inscription, wears much of a monkith garb; yet its authenticity is not a little confirmed by the arms of the town of Stirling, upon which is a bridge, with a croos, and the last line of the above Latin ditich is the motto round it.

We must not, however, imagine, that in those times that fortresses bore any resemblance to the present structure, which is adapted to the use of fire-arms. Its size and form probably resembled those castles which, under the feudal constitution, the English and Scottish barons used to erect upon their estates for dwelling-houses; and which, in those barbarous ages, they found necessary to fortify for their defence, not only against foreign invaders, but often against the attacks of their own neighbours. It is directly such a Gothic figure as this which represents the Caflrum Strivelicae upon the arms of Stirling.

This fortress, after it had continued in the possession of the Northumbrian Saxons about 20 years, was, together with the whole country upon the south side of the Forth, restored to the Scots, upon condition of their affilling the Saxons against their turbulent invaders the Danes. Upon the arms of Stirling are two branches of a tree, to represent the Norm Strivelicae; but the situation and boundaries of that fortress, which was probably a wing of the Caledonian, cannot be ascertained. Upon the south of Stirling, vestiges of a forest are still discernible for several miles. Banks of natural timber still remain in the castle-park, at Murray's wood, and near Nether Bannockburn; and stumps of trees, with much brushtwood, are to be seen in all the adjacent fields.

When Kenneth III. received intelligence of the Danes having invaded his dominions, he appointed the castle of Stirling to be the place of rendezvous for his army; and he marched from thence to the battle of Loncart, where he obtained a large sum of money and treasures, in the south of Scotland, which in those times was occupied by the family of the earl of Douglas, whom he stabbed with his own hand. The royal apartments were at that time in the north-west corner of the castle, and are now the residence of the Duke of Hamilton. The room where the murder was committed still goes by the name of Douglas's room. See SCOTLAND, No. 304, 305.

James III. contracting a fondness for the castle on account of its pleasant situation, made it the chief place of his residence, and added several embellishments to it. He built within it a magnificent hall, which in those days was deemed a noble structure, and is still entire. It now goes by the name of the parliament-house, having been designed for the accommodation of that supreme court. It was covered with an oaken roof of exquisite workmanship, which, though very little decayed, was a few years ago removed to make way for one of more modern structure. James also erected a college of secular priests in the castle, which he called the chapel-royal, and which proved one of his own ruins. As the expenses necessary for maintaining the numerous officers of such an institution were considerable, he annexed to it the revenues of the rich priory of Coldingham in the Merse, which at that time happened to become vacant. This priory had for a long time been held by persons connected with the family of Hume; and that family, considering it as belonging to them, strongly opposed the annexation. The dispute seems to have lasted several years; for one parliament had passed a vote, annexing the priory to the chapel-royal, and a subsequent one enacted a statute prohibiting every attempt that was contrary or prejudicial to that annexation.

James V. was crowned in the castle of Stirling; and the palace, which is the chief ornament of it, was the work of that prince. This is a stately and commodious structure, all of hewn stone, with much stately work upon it. It is built in form of a square, with a small court in the middle, in which the king's lions are said to have been kept; and hence it still goes by the name of the lions' den. The palace contains many large and elegant apartments; the ground-floor is now converted into barracks for the soldiers of the garrison; the upper affords a house for the governor, with lodgings for some of the subaltern officers.

Opposite to the palace, upon the north, stands an elegant chapel, which was built by James VI. for the baptism of his son prince Henry in 1594. In this chapel is preserved the bulk of a large boat, which that whimsical monarch caused to be built and placed upon carriages, in order to convey into the castle the provisions for that solemnity.

A strong battery, with a tier of guns pointing to the bridge over the Forth, was erected during the regency of Mary of Lorraine, mother to queen Mary. It is called the French battery, probably because contructed by engineers of that nation. The last addition was made...
to the fortifications in the reign of queen Anne. Formerly they reached no farther than the old gate, upon which the flag-staff now stands; but in that reign they were considerably enlarged upon the side towards the town; and barracks, which are bomb-proof, with several other conveniences for a siege, were erected.

Upon the south side of the castle lies a park inclosed with a stone-wall, called the king's park, and near to the foot of the rock on which the castle stands, lay the royal gardens; velliges of the walks and parterres, with a few Stumps of fruit-trees, are still visible; but by long neglect, and the natural wastes of the soil, the place is now little better than a marsh. In the gardens is a mount of earth in form of a table, with benches of earth around it, where, according to tradition, the court sometimes held festes-champetre. In the caille-hill is an hollow, comprehending about an acre of ground, and having all the appearance of an artificial work, which was used for jousts, tournaments, and other feats of chivalry.

Northward of the castle lies the Covat, or perhaps more properly the Gogling hill (A); in the middle of which is a small mount called Hurly Hokey, upon which duke Murdoch and his two sons were executed for treasonable practices in the reign of James I.

The prospect from the castle is most delightful, as well as extensive, being greatly beautified, especially upon the east, by the windings of the Forth; which, though the distance by land from Stirling to Alloa is, in a straight line, not quite six miles, it is said to be 24 by water. As this river generally runs upon plain ground, it rolls its flow, and silent a manner, that what Silus Italicus faith of the Ticinus is applicable to it, if, instead of luscenti in that poet, we should for once read lutoso; for the clay-banks, together with the tide, which flows above Stirling, render the Forth perpetually muddy:

Vin credas labi, ripis tam mitis opacis
Sonniferam ductis lutoso gurgite lympham.

The lordship and castle of Stirling were a part of the usual dowry of the queens of Scotland, at least after the family of Stuart came to the throne, in which they were invested at their marriage.

Robert lord Erkine was appointed governor of the castle by king David II. and the office continued in that family till 1715.

This fortress hath been the scene of many transactions. Being by its situation considered as a key to the northern parts of the kingdom, the possession of it hath been always esteemed of great importance to those who fought to be masters of Scotland. It was undoubtedly a place of strength when the art of war by ordnance was in its infancy; but though it resisted the utmost efforts of the rebels in 1746, it could not now hold out three days if besieged, by an army of a few thousand men conducted by an engineer of knowledge and integrity.

STIRLINGSHIRE, a county of Scotland, of which Stirling is the capital. It extends 20 miles in length and 12 in breadth; being bounded on the west by part of Lennox and Clydesdale; on the east, by Clackmannanshire, the river Forth, and part of Lothian; on the south-east, by Lothian; and on the north, by Montech. The face of the country is open and agreeable, diversified by hill and dale, well watered with streams and rivers; the principal of which is the Forth, rising in the neighbouring of a high mountain called Ben-Lomond, and, running eastward, forms the frith of Edinburgh. The souther part is hilly, affording plenty of game, and pasturage for sheep, horses, and black cattle. The eastern part is fertile, producing plentiful harvests of corn, and great abundance of coal. Lead-ore is found in different parts of the shire; and the rivers abound with pike, trout, and salmon.

STIRRUP, in the manage a reft or support for the horseman's foot, for enabling him to mount and for keeping him firm in his seat.

Stirrups were unknown to the ancients. The want of them in getting upon horseback was supplied by agility or art. Some horses were taught to fly to take their riders up; but the riders often leapt up by the help of their spears, or were affisted by their slaves, or made use of ladders for the purpose. Gracchus filled the highways with stones, which were intended to answer the same end. The fame was also required of the surveyors of the roads in Greece as part of their duty.

Menage observes, that St Jerome is the first author who mentions them. But the passage alluded to is not to be found in his epistles; and if it were there, it would prove nothing, because St Jerome lived at a time when stirrups were supposed to have been invented, and after the use of saddles. Montfaucon denies the authenticity of this passage; and, in order to account for the ignorance of the ancients with regard to an instrument so useful and so easy of invention, he observes, that while cloths and houfings only were laid upon the horses backs, on which the riders were to fit, stirrups could not have been used, because they could not have been fastened with the fame security as upon a saddle. But it is more probable, that in this infinite, as in many others, the progress of human genius and invention is uncertain and flow, depending frequently upon accidental causes.

STIRRUP of a Ship, a piece of timber put upon a ship's keel, when some of her keel happens to be broken off, and they cannot come conveniently to put or fit in a new piece; then they patch in a piece of timber, and bind it on with an iron, which goes under the ship's keel, and comes up on each side of the ship, where it is nailed strongly with spikes; and this they call a stirrup.

STOBÆUS (John), a laborious Greek writer, who lived at the end of the fourth century, composed many works, of which there are only his Collections remaining, and even these are not as he composed them; many things being inserted by later authors. This work contains many important sentiments collected from the ancient writers, poets, and philosophers.

STOCK, in gardening, &c. the stem or trunk of a tree. What stock is most proper for each kind of fruit, ought as well to be considered and known, as what soil is

---

(a) So called from the wailings and lamentations (in Scotch gowlings) that were made for Duke Murdoch.
Stockholm, the capital of Sweden, is situated in the province of Upland, in E. Long. 19° 30' and N. Lat. 59° 20'. Its foundation is by the bold Swedish writers generally attributed to Birger Jarl, regent of the kingdom about the middle of the 13th century during the minority of his son Waldemar, who had been raised to the throne by the fleet of the kingdom; but it was not before the last century that the royal residence was transferred from Upsal to this city.

This capital, which is very long and irregular, occupies, beside two peninsulas, seven small rocky islets, scattered in the Maler, in the streams which issue from that lake, and in a bay of the gulf of Bothnia. A variety of contrasted and enchanting views are formed by numberless rocks of granite rising boldly from the surface of the water, partly bare and craggy, partly dotted with housetops, or feathered with wood. The harbour is an inlet of the Baltic; the water is clear as crystal, and of such depth that ships of the largest bireme can approach the quay, which is of considerable breadth, and lined with spacious buildings and ware-houses. At the extremity of the harbour several streets rise one above another in the form of an amphitheatre; and the palace, a magnificent building, crowns the summit. Towards the sea, about two or three miles from the town, the harbour expands into a magnificent basin, which is remarkable for the height of its sides, and winding among high rocks, disappears from the sight; and the prospect is terminated by distant hills, overspread with forest. It is far beyond the power of words, or of the pencil, to delineate these singular views. The central islet, from which the city derives its name, and the Ritterholm, are the handsomest parts of the town. Excepting in the suburbs, where the housetops are of wood painted red, the generality of the buildings are of stone, or brick flued white. The royal palace, which stands in the centre of Stockholm, and upon the highest spot of ground, was begun by Charles XI.; it is a large quadrangular stone edifice, and the style of architecture is both elegant and magnificent.

It is the habitation not only of the royal family, but also of the greater part of the officers belonging to the household. It likewise comprehends the national or supreme court of justice, the colleges of war, chancery, treasury, and commerce; a chapel, armoury, library, and office for the public records; but the greater number of inferior officers and servants belonging to the court are, with the foot-guards, quartered on the burgheers. The castle, and all the stately edifices in the kingdom, are covered with copper. The palace of the nobility, in which this order sits during the feasion of the diet, is an elegant building adorned on the outside with marble statues and columns, and on the inside with painting and sculpture. This and three other palaces stand on the banks of the lake, and are built on the same model, so as to compose an uniform piece of architecture. The bank, built at the expense of the city, is a noble edifice, and joins with many sumptuous houses belonging to the nobility in exhibiting a splendid appearance. The houses of the burgheers are generally built of brick in the city, but in the suburbs they are commonly made up of timber, and therefore very subject to conflagrations. These houses are often framed in Finland, according to the plan and dimensions prescribed; whence they are transported in pieces to Stockholm by water, and there set up by the carpenters. These wooden habitations, if kept in proper repair, will last 30 or 40 years, and are deemed warmer, neater, and more healthy than those of brick or stone. To prevent the danger of conflagrations, the city is divided into wards. In each of these there is a master and four bailiffs, who forthwith repair to the place where the fire breaks out; and all porters and labourers are obliged to range themselves under the master of the ward to which they belong. A fire-watch patrols the streets by night, to give warning or assistance as it may be wanted; and a centinel is maintained in the staple of every church to toll the bell on the first appearance of any such accident. The police of Stockholm is entirely subjected to the regulations of the grand governor, assisted by a deputy and bailiff of the castle. This city is the staple of Sweden, to which all the commodities of the kingdom are brought for exportation, and where almost all the imports from abroad are deposited. The port or haven formed by the lake Maler is large enough to contain 1000 sail of shipping; and furnished with a key or wharf about an English mile in length, to which the vessels may lie with their broadsides. The greatest inconvenience attending this situation are, the distance from the sea, which is not within ten miles of the town; the want of tide; and the winding of the river which is remarkable. It opens into the Baltic; and the entrance, for want of more commodious harbours, has been made by a number of small batteries, which are kept in proper repair, to harmonize with the king's gardens, and for the great number of artisans who have chosen their habitations in this quarter. In the southern suburbs the Muffcovite commodities are sold; and here is a magnificent exchange where the merchants daily assemble.

STOCKING, that part of the clothing of the leg and foot which immediately covers and screens them from the rigour of the cold. Anciently, the only stockings in use were made of cloth, or of milled stuffs sewed together; but since the invention of knitting and weaving stockings of silk, wool, cotton, thread, &c. the use of cloth stockings is quite discontinued. Dr Howel, in his History of the World (vol. ii. p. 222.) relates, that queen Elizabeth, in 1501, was presented with a pair of black knit silk stockings by her silk woman, and thenceforth she never wore cloth ones any more. The same author adds, that king Henry VIII. ordinarily wore cloth hose, except there came from Spain, by great chance, a pair of silk stockings. His son, king Edward VI. was presented with a pair of long Spanish silk stockings by Sir Thomas Grefham.
and the present was then much taken notice of. Hence it should seem, that the invention of knit silk stockings originally came from Spain. Others relate, that one William Rider, an apprentice on London bridge, seeing at the house of an Italian merchant a pair of knit worsted stockings from Mantua, took the hint, and made a pair exactly like them, which he presented to William earl of Pembroke, and that they were the first of that kind worn in England, anno 1564.

The modern stockings, whether woven or knit, are formed of an infinite number of little knots, called fitches, loops, or threads, intermingled in one another.

Knit stockings are wrought with needles made of polished iron, or brass wire, which interweave the threads and form the meshes the stocking consists of. At what time the art of knitting was invented it is perhaps impossible to determine, though it has been usually attributed to the Scots, as it is said that the first works of this kind came from Scotland. It is added, that it was on this account that the company of knitting-knitters, established at Paris 1527, took for their patron St Fiacre, who is said to have been the son of a king of Scotland. But it is most probable that the method of knitting stockings by wires or needles was first brought from Spain.

Woven stockings are generally very fine; they are manufactured on a frame or machine made of polished iron, the structure of which is needles to describe, as it may be seen in almost every considerable town in this country. The invention of this machine is, by Mr. Anderson, attributed to William Lee, M. A. of St John's College, Cambridge, at a period so early as 1589. Others have given the credit of this invention to a student of Oxford at a much later period, who, it is said by Aaron Hill, was driven to it by dire necessity. This young man, falling in love with an inn-keeper's daughter, married her though she had not a penny, and he by his marriage lost a fellowship. They soon fell into extreme poverty; and their marriage producing the consequences naturally to be expected from it, the amorous pair became miserable, not so much on account of their sufferings, as from the melancholy dread of what would become of their yet unborn infant. Their only means of support were the knitting of stockings, at which the woman was very expert: "But sitting contently together from morning to night, and the scholar often fixing his eyes, with steadfast observation, on the motion of his wife's fingers in the dexterous management of her needles, he took it into his imagination, that it was not impossible to contrive a little loom which might do the work with much more expedition. This thought he communicated to his wife, and joining his head to her hands, the endeavour succeeded to their wish. Thus the ingenious stocking-loom, which is so common now, was first invented; by which he did not only make himself and his family happy, but has left his nation indebted to him for a benefit which enables us to export silk stockings in great quantities, and to a vast advantage, to those very countries from whence before we used to bring them at considerable loss in the balance of our trade."

STOCKS, or Public Funds in England. By the word flock was originally meant a particular sum of money contributed to the establishing of a fund to enable a company to carry on a certain trade, by means of which the person became a partner in that trade, and received a share of the profit made thereby, in proportion to the money employed. But this term has been extended farther, though improperly, to signify any sum of money which has been lent to the government, on condition of receiving a certain interest till the money is repaid, and which makes a part of the national debt. As the security both of the government and of the public companies is esteemed preferable to that of any private person, as the stocks are negotiable and may be sold at any time, and as the interest is always punctually paid when due; so they are thereby enabled to borrow money on a lower interest than what could be obtained from lending it to private persons, where there must be always some danger of losing both principal and interest.

But as every capital stock or fund of a company is railed for a particular purpose, and limited by parliament to a certain sum, it necessarily follows, that when that fund is completed, no stock can be bought of the company; though shares already purchased may be transferred from one person to another. This being the case, there is frequently a great disproportion between the original value of the shares and what is given for them when transferred: for if there are more buyers than sellers, a person who is indifferent about selling will not part with his share without a considerable profit to himself; and on the contrary, if many are disposed to sell, and few inclined to buy, the value of such shares will naturally fall in proportion to the impatience of those who want to turn their stock into specie.

A flock may likewise be affected by the court of chancery; for if that court should order the money, which is under their direction, to be laid out in any particular flock, that flock, by having more purchasers, will be raised to a higher price than any other of the like value. By what has been said, the reader will perceive how much the credit and interest of the nation depends on the support of the public funds. While the amusements and interest for money in each particular country is there regularly paid, and the principal invested by both prince and people (a security not to be had in some nations), foreigners will lend them their property, and all Europe be interested in their welfare; the paper of the companies will be converted into money and merchandise, and Great Britain can never want cash to carry her schemes into execution. See the article Fund.

STOCKS, a frame erected on the shore of a river or harbour, whereon to build flapping. It generally consists of a number of wooden blocks, ranged parallel to each other, at convenient distances, and with a gradual declivity towards the water.

STOCKS, a wooden machine to put the legs of offenders in, for securing disorderly persons, and by way of punishment in divers cafes.

STOCKTON upon Tees, a handsome town in the county of Durham, about 16 miles south of the city of Durham. It is now a port of considerable trade; though, at the Restoration, it was a despicable village, the belt house in which could hardly be done any thing better than clay-walls and a thatched roof. About
About 40 years ago it sent out in one year 75 vessels for the port of London; and the trade is much increased since.

STOEBE, BASTARD ETHIOPIAN, in botany: A genus of plants belonging to the class of gynaeceia, and order of polyanthus margarites; and in the natural range under 49th order compound. The calyx is unisexual; the corollas are tubular and hermaphrodite; the receptacle is naked, and the pappus is feathery. There are nine species, the ethiopica, ericoides, prostrata, gnaphaloides, gomphrene, rubra, reflexa, rhinoceros, and disticha; all plants of foreign growth.

STOICS, the name given to a sect of Greek philosophers, from συζευκοτίον, "the porch in Athens," which founder of the sect chose for his school. For the peculiar tenets of this sect, see Metaphysics, Chap. IV. Part 3. Moral Philosophy, no. 8, and Zeno.

STOLBERG, a small town of Germany, in the circle of Upper Saxony, and territory of Thuringia, of which it is the capital place. It is fited between two mountains, 58 miles north-west of Leipzig. E. Long. 11.8. N. Lat. 51.42.

STOLE, a blazonary ornament worn by the Roman parish-priests above their surplices, as a mark of superiority in their respective churches; and by other priests over the alb, at celebrating of mass, in which case it goes across the stomach, and by deacons, over the left-shoulder, scarf-wise: when the priest reads the gospel for any one, he lays the bottom of his stole on his head. The stole is a broad swath, or slip of stuff, hanging from the neck to the feet, with three crosses thereon.

STOOLS, in England, the eldest gentleman of his Majesty's bed-chamber, whose office it is to present and put on his majesty's first garment, or shirt, every morning, and to order the things in the chamber.

STOMACH, in anatomy. See Anatomia, no. 91. STOMACHIC, medicines that strengthen the stomach and promote digestion, &c.

Stomachic corroboreatives are such as strengthen the tone of the stomach and intestines; among which are carminatives, as the roots of galangula, red gentian, ancho-ur, pimipenella, calamus aromaticus, and arum. Of barks and rinds, those of canella alba, sassafras, citrons, Seville and China oranges, &c. Of spices, pepper, ginger, cloves, cinnamon, cardamum, and mace.

STONE (Edmund), a distinguished self-taught mathematician, was born in Scotland, but neither the place nor time of his birth are well known; nor have we any memoirs of his life, except a letter from the Chevalier de Ramfay, author of the Travels of Cyrus, in a letter to father Caillé, a Jesuit at Paris, and published in the Memoires de Trevoux, p. 109, as follows: "True genius overcomes all the disadvantages of birth, fortune, and education; of which Mr Stone is a rare example. Born a son of a gardener of the duke of Argyle, he arrived at eight years of age before he learnt to read.—By chance a fevant having taught young Stone the letters of the alphabet, there needed nothing more to discover and expand his genius. He applied himself to study, and he arrived at the knowledge of the most sublime geometry and analysis, without a master, without a conductor, without any other guide but pure genius."

At 18 years of age he had made these considerate advances without being known, and without knowing himself the prodigies of his acquisitions. The duke of Argyle, who joined to his military talents a great knowledge of every science that adorns the mind of a man of his rank, walking one day in his garden, saw lying on the grans a Latin copy of Sir Isaac Newton's celebrated Principia. He called some one to him to take and carry it back to his library. Our young gardener told him that the book belonged to him. "To you?" replied the Duke. "Do you understand geometry, Latin, Newton?" I know a little of them, replied the young man with an air of simplicity arising from a profound ignorance of his own knowledge and talents. The duke was surprised; and having a taste for the sciences, he entered into conversation with the young mathematician; he asked him several questions, and was astonished at the force, the accuracy, and the candour of his answers. "But how, said the Duke, came you by the knowledge of all these things?" Stone replied, "A servant taught me, ten years since, to read: does one need to know any thing more than the 24 letters in order to learn every thing else that one wishes?"

The duke's curiosity redoubled—he sat down upon a bank, and requested a detail of all his proceedings in becoming so learned.

"I first learned to read, said Stone: the masons were then at work upon your house: I went near them one day, and saw that the architect used a rule, compasses, and that he made calculations. I inquired what might be the meaning and use of these things; and I was informed that there was a science called Arithmetic: I purchased a book of arithmetic, and I learned it.—I was told there was another science called Geometry: I bought the books, and I learnt geometry. By reading I found that there were good books in these two sciences in Latin: I bought a dictionary, and I learned Latin. I understood also that there were good books of the same kind in French: I bought a dictionary, and I learned French. And this, my lord, is what I have done: it seems to me that we may acquire every thing when we know the 24 letters of the alphabet."

"This account charmed the duke. He drew this wonderful genius out of his obscurity; and he provided him with an employment which left him plenty of time to apply himself to the sciences. He discovered in him also the fame genius for music, for painting, for architecture, for all the sciences which depend on calculations and proportions."

"I have seen Mr Stone. He is a man of great simplicity. He is at present sensible of his own knowledge; but he is not puffed up with it. He is policed with a pure and disinterested love for the mathematics, though he is not folicitous to pass for a mathematician; vanity having no part in the great labour he sustains to excel in that science. He despises fortune also; and he has solicited me twenty times to requite the duke to give him his employment, which may not be worth the half of that he now has, in order to be more retired, and less taken off from his favourite studies. He discovers sometimes, by methods of his own,
own, truths which others have discovered before him. He is charmed to find on these occasions that he is not a first inventor, and that others have made a greater progress than he thought. Far from being a plagiarist, he attributes ingenious solutions, which he gives to certain problems, to the hands he has found in others, although the connection is but very dilatory."

Mr Stone was an author and translator of several useful works; viz. 1. A New Mathematical Dictionary, in 3 vol. 8vo, first printed in 1726. 2. Fluxions, in 1 vol. 8vo, 1730. The Direct Method is a translation from the French, of Hospital's Analyse des Infiniments Petits; and the Inverse Method was supplied by Stone himself. 3. The elements of Euclid, in 2 vols. 8vo, first published in 1730. A neat and useful edition of these Elements, with an account of the life and writings of Euclid, and a defence of his elements against modern objection. Besides other smaller works. Stone was a fellow of the Royal Society, and had inserted in the Philosophical Transactions (vol. 41, p. 218) an "Account of two species of lines of the 3d order, not mentioned by Sir Isaac Newton or Mr. Stirling."

Stone (Jerome), the son of a reputed seaman, was born in the parish of Scone, in the county of Fife, North Britain. His father died abroad when he was but three years of age, and his mother, with her young family, was left in very narrow circumstances. Jerome, like the rest of the children, having got the ordinary school education, reading English, writing, and arithmetic, betook himself to the business of a travelling chapman. But the dealing in buckles, garters, and such small articles, not suiting his superior genius, he soon converted his little stock into books, and for some years went through the country, and attended the fairs as an itinerant bookseller. There is great reason to believe that he engaged in this new species of traffic, more with a view to the improvement of his mind than for any pecuniary emolument. Formed by nature for literature, he possessed a peculiar talent for acquiring languages with amazing facility. Whether from a desire to understand the Scriptures in their original languages, or from being informed that these languages are the parent of many others, he began his philological pursuits with the study of the Hebrew and Greek tongues; and, by a wonderful effort of genius and application, made himself so far master of these, without any kind of afflatus, as to be able to interpret the Hebrew Bible and Greek Testament into English adepturam libri. At this time he did not know one word of Latin. Sensitive that he could make no great progress in learning, without the knowledge of at least the grammar of that language, he made application to the parish schoolmaster for his afflatus. Some time afterwards, he was encouraged to prosecute his studies at the University of St. Andrew's. An unexampled proficiency in every branch of literature recommended him to the选ector of the professors and an uncommon fund of wit and pleasantry rendered him, at the same time, the favourite of all his fellow students, some of whom spoke of him to this day with an enthusiastic degree of admiration and respect. About this period some very humorous poetical pieces of his composition were published in the Scots Magazine. Before he had finished his third session, or term, at St. Andrew's, on an application to the College by the master of the school of Dunkeld for an usher, Mr. Stone was recommended as the best qualified for that office; and about two or three years after, the master being removed to Perth, Mr. Stone, by the favour of his Grace the Duke of Atholl, who had conceived a high opinion of his abilities, was appointed his successor.

When he first went to Dunkeld, he entertained but an unfavourable opinion of the Cicilian language, which he considered as nothing better than a barbarous inarticulate gibberish; but being bent on investigating the origin and descent of the ancient Scots, he suffered not his prejudices to make him neglect the study of their primitive tongue. Having, with his usual alacrity and suavity, mastered the grammatical difficulties which he encountered, he felt himself to discover something of the true genius and character of the language. He collected a number of ancient poems, the production of Irish or Scottish bards, which, he said, were daring, innocent, passionate, and bold. Some of these poems were translated into English verse, which several persons now alive have seen in manuscript, before Mr. Macpherson published any of his translations from Oftian.

He died while he was writing and preparing for the press a treatise, intitled, "An Inquiry into the Original of the Nation and Language of the ancient Scots, with Conjectures about the Primitive State of the Celtic and other European Nations," an idea which could not have been conceived by an ordinary genius. In this treatise he proves that the Scots drew their original, as well as their language, from the ancient Gauls. Had Mr. Stone lived to finish this work, which discovers great ingenuity, immense reading, and indefatigable industry, it would have thrown light upon the dark and early periods of the Scottish history, as he opens a new and plain path for leading us through the unexplored byways of antiquity. But a fever put an end to his life, his labours, and his usefulness, in the year 1757, being then only in the 30th year of his age. He left, in manuscript, a much esteemed and well-known allegory, intitled "The Immortality of Authors," which has been published and often reprinted since his death, and will be a lasting monument of a lively fancy, found judgement, and correct taste. It was no small ornament of this extraordinary character, that he paid a pious regard to his aged mother, who survived him two years, and received an annual pension from the Dukes of Atholl as a testimony of respect to the memory of her son.

STONEHIVE, or STONEHAVEN, a small town in the county of Kincardine, in Scotland, 15 miles south from Aberdeen. It was built in the time of Charles II. and stands at the foot of some high cliffs, in a small bay, with a rocky bottom, opening a little in one part, so that small vessels may find admittance, but only at high water. A pier laps over this harbour from the north side to secure them after their entrance. The town contains about 800 inhabitants. The manufactures are sail-cloths and Oilnaburghs, knit worsted and thread stockings.

STONES, in natural history, bodies which are insipid, not dudile, nor inflammable, nor soluble in water. But as this is the definition given of earths by chemists and naturalists, we must refer the reader to the articles EARTII, and MINERALOGY, Part II. clafs L for a
As philosophers have perplexed themselves much about the origin and formation of the earth (a subject certainly far beyond the ken of the human intellect, at least if we believe that it was made by the almighty power of God), so they have also proposed theories to explain the origin of stones. When philosophers limit their inquiries within the boundaries of science, where they are led by the sober and fast conduct of observation and experiment, their conclusions may be solid and may be useful; but when, throwing experiment and observation aside, they rear a theory upon an airy nothing, or upon a single detached fact, their theories will vanish before the touch of true philosophy as a romantic palace before the rod of the enchantress. Sometimes from whim, or caprice, or vanity, they attempt to confound every thing: They wish to prove that the soul is mere matter, that plants are animals, and that fossils are plants, and thus would vanquish two substances, spirit and dead matter, entirely from the world; as if the Author of Nature were actuated by forbid views of perjury in the works of creation, though we evidently see that a generous profusion is one of the characteristic marks of these works. We leave the task of confounding the different classes of being to those philosophers whose minds are too contracted to comprehend a great variety of being at one view, or who prefer novelty to every thing else. We content ourselves with the old opinion, that the soul is a spiritual substance; that plants are plants, and that stones are stones.

We have been led into these remarks by finding that some philosophers say that stones are vegetables; that they grow and increase in size like a plant. This theory, we believe, was first offered to the world by M. Tournefort, in the year 1702, after returning from his travels in the east. It was founded on a curious fact. In surveying the labyrinth of Crete, he observed that the names which visitors had engraved upon the rock were not formed of hollow but of prominent letters like bafio relievos. He supposes that these letters were at first hollowed out by knives; that the hollows have since been filled up by the growth of the stone; and hence he concludes that stones vegetate. We have been fully assured of the fact that the letters were at first hollowed, before we attempt to account for their prominence. But even allowing the supposition to be true that they were at first hollow, we reply it is only a single fact, and that it is altogether unphilosophical to deduce a general system from a single fact.

In the second place, this protuberance of the character is very improperly called vegetation, for it is not produced by a process in any respect like the vegetation of a plant. Vegetation supposes vessels containing fluids and growth by expansion; but who ever heard of vessels in a stone, of fluids moving in them, or of the different parts expanding and swelling like the branch or trunk of a tree? Even the fact which Tournefort mentions proves nothing. He does not pretend to say, that the rock itself is increasing, but only that a few small hollows are filled with new stone matter, which rises a little above the surrounding surface of the rock. This matter evidently has been once liquid, and at length has congealed in the channel into which it had run.—But is not this easily explained by a common process, the formation of stalactites? When water charged with calcareous matter is exposed to the action of air, the water evaporates, and leaves the calcareous earth behind, which hardens and becomes like a stone.

Having thus examined the principal fact upon which M. Tournefort founds his theory, it is unnecessary to follow him minutely through the rest of his subject. He compares the accretion of matter in the labyrinth to the conglomeration of a bone when broken, by a callus formed of the extruded nutritious juice. This observation is thought to be confirmed, by finding that the projecting matter of the letters is whithil and the rock itself greyish. But it is easy to find comparisons. The difficulty, as Pope says, is to apply them. The resemblance between the filling up of the hollow of a stone, and the conglomeration of a broken bone by a calculus, we confess ourselves not philosophers enough to see. Were we writing poetry in bad taste, perhaps it might appear. The circumstance, that the prominent matter of the letters is whithil, while the rock is greyish, we flatter ourselves strengthens our supposition that it consists of a deposition of calcareous matter. Upon the whole, we conclude, we hope logically, that no such theory as this, that stones are vegetables, can be drawn from the supposed fact respecting the labyrinth. We have to regret, that the account which we have seen of the subject is so imperfect, that we have not sufficient materials for a proper investigation. Tournefort has not even told us of what kind of stone or earth the accretion consists; yet this single information would probably have decided the question (A).

(a) To give a more distinct notion of Tournefort's theory, we shall subjoin his conclusions: From these observations (he says) it follows, that there are stones which grow in the quarries, and of consequence that are fed; that the same juice which nourishes them serves to rejoin their parts when broken; just as in the bones of animals, and the branches of trees, when kept up by bandages; and, in a word, that they vegetate. There is, then (he says), no room to doubt but that they are organized; or that they draw their nutritious juice from the earth. This juice must be first filtrated and prepared in their surface, which may be here esteemed as a kind of bark; and hence it must be conveyed to all the other parts. It is highly probable the juice which filled the cavities of the letters was brought thither from the bottom of the roots; nor is there any more difficulty in conceiving this than in comprehending how the sap should pass from the roots of our largest oaks to the very extremities of their highest branches. Some stones, then (he concludes), must be allowed to vegetate and grow like plants; but this is not all; (he adds), that probably they are generated in the same manner; at least, that there are abundance of stones whose generation is inconceivable, without supposing that they come from a kind of feeds, wherein the organical parts of the stones are wrapped up as those of the largest plants are in their feeds.
Artificial Stone. See Stucco.
Elagic Stone. See Elagic Marble.
Philosopher’s Stone. See Philosopher’s Stone.
Precious Stones. See Gem.

Rocking Stone, or Logan, a stone of a prodigious firmness exactly poised, that it would rock or shake with the slightest force. Of these stones the ancients give us some account. Pliny says, that at Harpafla, a town of Asia, there was a rock of such a wonderful nature, that if touched with the finger it would shake, but could not be moved from its place with the whole force of the body. Ploemey Herpeton mentions a gigymonian stone near the ocean, which was agitated when struck by the flail of an alpheid, but could not be removed by any exertion of force. The word gigymus seems to be Celtic; for gigynges signifies musical.

Many rocking stones are to be found in different parts of Britain; some natural, others artificial, or placed in their position by human art. In the parish of St Leon, Cornwall, there is a promontory called Caftle Trecrn. On the western side of the middle group, near the top, lies a very large stone, so evenly poised that any hand may move it from one side to another; yet it is so fixed in its balf, that no lever nor any mechanical force can remove it from its present situation. It is called the Logan stone, and is at such a height from the ground that no person can believe that it was raised to its present position by art. But there are other rocking stones, which are so shaped and so situated, that there can be no doubt but they were erected by human strength. Of this kind Boralfe thinks the great Quoy or Karn-lebay, in the parish of Tywidneke, to be. It is 39 feet in circumference, and four feet thick at a medium, and stands on a single pedestal. There is also a remarkable stone of the same kind in the island of St Agnes in Scilly. The under rock A is 10 feet 6 inches high, 47 feet round the middle, and touches the ground with no more than half its base. The upper rock C rests on one point only, and is so nicely balanced, that two or three men with a pole can move it. It is eight feet six inches high, and 47 in circumference. On the top there is a bason D hollowed out, three feet eleven inches in diameter at a medium, but wider at the trim, and three feet deep. From the globular shape of this upper stone, it is highly probable that it was rounded by human art, and perhaps even placed on its pedestal by human strength.

In Sidney parish, near He’ston, in Cornwall, stood the famous Logan, or rocking stone, commonly called Men Anker, q. d. Men on Bar, or the 100 f. men, in 117 feet eleven by six and four high, and so nicely poised on another stone that a little child could move it, and all travellers who came this way desired to see it. But Shrubfall, Cromwell’s governor of Pendennis, with much ado caused it to be undermined, to the great grief of the country. There are some marks of the tool on it, and, by its quadrangular shape, it was probably dedicated to Mercury. That the rocking stones are monuments erected by the Druids cannot be doubted; but tradition has not informed us for what purpose they were intended. Mr Golland thinks that the Druids made the people believe that they alone could move them; and that by a miracle: and that by this pretended miracle they condemned or acquitted the accused, and brought criminals to confess what could not otherwise be extorted from them. How far this conjecture is right we shall leave to those who are deeply versed in the knowledge of antiquities to determine.

Sonorous Stone, a kind of stone remarkable for emitting an agreeable sound when struck, and much used in China for making musical instruments which they call King.

The various kinds of sonorous stones known in China differ considerably from one another in beauty, and in the strength and duration of their tone; and what is very surprising, is, that this difference cannot be discovered either by the different degrees of their hardness, weight, or fineness of grain, or by any other qualities which might be supposed to determine it. Some stones are found remarkably hard, which are very sonorous; and others exceedingly soft, which have an excellent tone; some extremely emit a very sweet sound; and there are others as light as pumice which have an agreeable found.

The chemists and naturalists of Europe and America have never yet attempted to discover, whether some of our stones may not have the same properties as the sonorous stones of the extremities of Asia. It however appears, that the Romans were formerly acquainted with a sonorous stone of the class of *biong-she*. Pliny (says the Abbé du Bos, in his Reflections on Poetry and Painting, when speaking of curious stones) observes that the stone called *chalephonas,* or *braven found,* is black; and that, according to the etymology of its name, it lends forth a sound much resembling that of brass when it is struck. The passage of Pliny is as follows: *Chalephonas nigra eff; ed elia aris tinnitum reddit.*

Some sonorous stones were at length sent into France, and the late Duke de Chaulnes examined them with particular attention. The following are some of his observations: “The Academy of Sciences, Mr Romé de Lisle, and several other learned mineralogists, when asked if they were acquainted with the black stone of which the Chinese king was made, for answer cited the passage of Pliny mentioned by Boethius de Bott. Linnaeus, and in the Dictionary of Bomare, and added what Mr Anderson says in his Natural History of Iceland respecting a bluish kind of stone which is very sonorous. As the black stone of the Chinese becomes a bluish colour when filed, it is probably of the same species. None of the rest who were consulted had ever seen it. The Chinese stone has a great resemblance at first sight to black marble, and like it is calcareous; but marble generally is not sonorous. It also externally resembles touchstone, which is a kind of bafaltes, and the bafaltes found near volcanoes; but these two stones are vitrifications.”

The duke next endeavoured to procure some information from the stone-cutters. They all replied, that blue-coated marble was very sonorous, and that they had seen large blocks of it which emitted a very strong sound; but the duke, having ordered a king to be constructed of this kind of stone, it was found that it did not possess that property. By trying the black marble of Flanders, a piece was at length found which emitted an agreeable sound; it was cut into a king, which is almost as sonorous as those of China. All these observa-

"
Anderfon's only the coarse yellow, red, black, and mottled wares, commerce, the king are formed are nothing of marble, the constituent parts of which are the same as those of the marble of Europe, but that some difference in their organization renders them more or less sonorous. Strue Stone (lapic falsus) or stetd stone, so called from its excessively stetd smell, calcareous earth impregnated with petroleum. It is found, 1. Solid, with the particles scarcely visible, of a black colour, as the marble found in Flanders, and in the province of Jutland in Sweden. 2. With visible grains of a blackish brown colour, found likewise in some places of Sweden. 3. With coarse scales, found also in Sweden. Great part of the limestone found in England belong to this class, and emit a very stetd smell when struck violently, but it soon goes off in the fire.

Stone-Ware, a species of pottery so called from its hardnefs. See Delft-Ware, Porcelain, and Pottery. Clay is a principal ingredient in pottery of all kinds which has the property of hardening in the fire, and of receiving and preferring any form into which it is moulded. One kind of clay refits the most violent action of the fire after being hardened to a certain degree, but is incapable of receiving a sufficient degree of hardnefs and solidity. A second kind assumes a hardnefs resembling that of stint, and such a compactness that vessels made of it have a glossy appearance in their fracture resembling porcelain. These two species owe their peculiar properties of resisting heat without melting, to sand, chalk, gypsum or ferruginous earth, which they contain. A third species of clay begins to harden with a moderate fire, and melts entirely with a strong fire. It is of the second species that stone-ware is made.

The most famous manufactory of stone-ware, as well as other kinds of pottery, is at Burlem in Staffordshire. This can be traced with certainty at least two centuries back; but of its first introduction no tradition remains. In 1686, as we learn from Dr Plot's Natural History of Staffordshire published in that year, the coarse yellow, red, black, and mottled wares, were made in this country, and the only materials employed for them appear to have been the different coloured clays which are found in the neighbourhood, and which form some of the meafures or iritata of the coal-mines. These coarse clays made the body of the ware, and the glaze was produced by powdered leadore, sprinkled on the pieces before firing, with the addition of a little manganese for some particular colours. The quantity of goods manufactured was at that time so inconsiderable, that the chief sale of them, the Doctor says, was "to poor crate-men, who carried them on their backs all over the country."

About the year 1690, two ingenious artifans from Germany, of the name of Eller, settled near Burlem, and carried on a small work for a little time. They brought into this country the method of glazing stone-ware, by casting stalt into the kiln while it is hot, and some other improvements of less importance: but finding they could not keep their secrets to themselves, they left the place rather in disgust. From this time various kinds of stone-ware, glazed by the fumes of stalt in the manner abovementioned, were added to the wares before made. The white kind, which afterwards became, and for many succeeding years continued, the staple branch of pottery, is said to have owed its origin to the following accident. A potter, Mr Albury, travelling to London, perceiving somathing amifs with one of his horses' eyes, an hofer at Dunstable told he could soon cure him, and for that purpofe put a common black flint stalt into the fire. The potter obferving it, when taken out, to be of a fine white, immediately conceived the idea of improving his ware by the addition of this material to the stetd clay he could procure: accordingly he fent home a quantity of the flint stones of that country, where they are plentiful among the chalk, and by mixing them with tobacco-pipe clay, produced a white stone-ware much superior to any that had been seen before.

Some of the other potters soon discovered the fource of this superiority, and did not fail to follow his example. For a long time they pounded the flint stones in private rooms by manual labour in mortars; but many of the poor workmen fuffered severely from the dust of the flint getting into their lungs, and producing dreadful coughs, consumption, and other pulmonary disorders. These difafers, and the increased demand for the flint powder, induced them to try to grind it by mills of various conftuctions; and this method being found both effectual and safe, has continued in practice ever since. With these improvements, in the beginning of the prent century, various articles were produced for tea and coffee equipages. Soon after attempts were made to furnish the dinner table also; and before the middle of the century, utensils for the table were manufactured in quantity as well for exportation as home consumption.

But the salt glaze, the only one then in use for this purpofe, is in its own nature fo imperfect, and the potter, from an injudicious competition among themselves for cheapnefs, rather than excellence, had been fo inattentive to elegance of form and neatnefs of workmanship, that this ware was rejected from the tables of persons of rank; and about the year 1760, a white ware, much more beautiful and better glazed than ours, began to be imported in considerable quantities from France.

This inundation of a foreign manufacture, fo much superior to any of our own, must have had very bad effects upon the potteries of this kingdom, if a new one, still more to the public taste, had not appeared soon after. In the year 1763, Mr Josiah Wedgwood, who had already introduced several improvements into this art, invented a species of earthen ware for the table quite new in its appearance, covered with a rich and brilliant glaze, bearing sudden alterations of heat and cold, manufactured with ease and expedition, and consequently cheap, and having every requisite for the purpofe intended. To this new manufacture the queen was pleased to give her name and patronage, commanding it to be called Queen's ware, and honouring the inventor by appointing him her majesty's potter.

The common clay of the country is used for the ordinary forms; the finer kinds are made of clay from Devonshire and Dorsetshire, chiefly from Biddeford, but the flints from the Thames are all brought rough by sea, either to Liverpool or Hull, and so by Burton. There is no conjecture formed of the original rea
stoneworne.

"The flints first are ground in mills, and the clay pre-
pared by breaking, washing, and fitting, and then they are
mixed in the requisite proportions. The flints
are bought first by the people about the country, and
by them burnt and ground, and sold to the manufac-
turers by the peck.

"The mixture is then laid in large quantities on kilns
to evaporate the moisture; but this is a nice work, as it
must not be too dry; next it is beat with large wooden
hammers, and then is in order for throwing, and is
moulded into the forms in which it is to remain; this
is the most difficult work in the whole manufacture. A
boy turns a perpendicular wheel, which by means of thongs
turns a small horizontal one, just before the thrower, with
such velocity, that it twirls round the lump of clay he
lays on it into any form he directs it with his fingers.

"There are 300 houses which are calculated to em-
ploy, upon an average, twenty hands each, or 6000
in the whole; but of all the variety of people that
work, in what may be called the preparation for the
employment of the immediate manufacturers, the total
total number cannot be much short of 12,000, and it is
increasing every day. Large quantities are exported to
Germany, Ireland, Holland, Russia, Spain, the East
Indies, and much to America; some of the finest sorts
to France."

Stone in the Bladder. See Medicine, no. 400. Surgery-
Index: and Alkalai, no. 17, 18, 19.

Stone, in merchandise, denotes a certain weight
for weighing commodities. A stone of beef at Lon-
don is the quantity of eight pounds: in Herefordshire
12 pounds: in the North 16 pounds. A stone of glass
is five pounds; of wax eight pounds. A stone of wool
(according to the stature of 11 Hen. VII.) is to weigh
14 pounds; yet in some places it is more, in others
less; as in Gloucestershire 15 pounds: in Herefordshire
12 pounds. Among horse-couriers a stone is the weight
of 14 pounds.

The reason of the name is evident. Weights at first
were generally made of stone. See Deut. xxxv. 13, where
the word סַלַּֽעַּֽו translated weight, properly signifies a flone.

Stone-Clater, in ornithology. See MOTACILLA.

STONEHENGE, a celebrated monument of antiqui-
yty, stands in the middle of a flat area near the fump-
mic of a hill five miles distant from Salisbury. It is
inclosed by a circular double bank and ditch near 35 feet
broad, after cutting which we ascend 30 yards before
we reach the work. The whole fabric consisted of two
circles and two ovals. The outer circle is about 108
feet diameter, consisting when entire of 60 stones, 50
uprights and 50 impost, of which remain only 24 up-
rights, 17 standing and 7 down, 31 feet saddler, and 8
imposts. Eleven uprights have their 2 impost on them
by the grand entrance. These stones are from 13 to 20
feet high. The inner circle is somewhat more than 8
feet from the inside of the outer one, and consisted of
40 fltons (the highest 6 feet), of which only 19
remain, and only 11 standing; the walk between these
two circles is 300 feet in circumference. The Adytum
or Cell is a oval formed of 10 flons (from 16 to 22
feet high), in pairs, with impost, which Dr Stukeley
calls triiblons, and above 50 feet high, rising in height
as they go round, and each pair separate, and not con-
ected as the outer pair; the highest 8 feet. Within
there are 19 more smaler single fltons, of which only 6
are standing. At the upper end of the Adytum is the
altar, a large slab of bluestone about 24 inches thick,
16 feet long, and a breadth; pressed down by the weight
of the vault flons that have fallen upon it. The whole
number of flons, uprights, impost, and altar, is exactly
150. The flons are far from being artificial, but
were most probably brought from those called the Grey
Weathers on Marlborough Downs, 15 or 16 miles off;
and if tried with a tool they appear of the same hard-
ness, grain, and colour, generally reddish. The heads
of oxen, deer, and other beasts, have been found on
digging in and about Stonehenge; and human bones in
the circumjacent barrows. There are three entrances
from the plain to this structure, the most condelable
of which is from the north-east, and at each of them
were raised on the outside of the trench two huge
flons with two smaller within parallel to them.

"It has been a dispute among the learned, by
what nation, and for what purpose, these enormous
flons were collacted and arranged. The first account
of this structure we meet with is in Geoffrey of Mon-
mouth, who, in the reign of King Stephen, wrote the
history of the Britons in Latin. He tells us,
that it was erected by the councll of Merlin the Brit-
ish enchanter, at the command of Aurelius Ambro-
sius the lait Britih king, in memory of 460 Brit-
ons who were murdered by Hengift the Saxon.
The next account is that of Polydore Virgil, who says
that the Britons erected this as a sepulchral monument
of Aurelius Ambrosius. Others suppose it to have been
a sepulchral monument of Boadicea the famous British
Queen. Inigo Jones is of opinion, that it was a Roman
temple: from a stone 16 feet long, and four broad,
placed in an exact position to the easterly, altar-fashion
Mr Charlton attributed it to the Danes, who were two
years masters of Wiltshire; a tin tablet, on which were
some unknown characters, supposed to be Punic, was
digged up near it in the reign of Henry IV. but is
lost; probably that might have given some information
respecting its founders. Its common name, Stone-
henge, is Saxan, and signifies a "stone gallows," to which
those stones, having transferred impost, bear some
resemblance. It is also called in Welsh choir gour,
or "the giant's dance."

Mr Grofe thinks that Dr Stukeley has completely
proved this structure to have been a British temple in
which the Druids officiated. He supposes it to have
been the metropolitan temple of Great Britain, and
translates the words choir gour "the great choir or
temple." The learned Mr Bryant is of opinion that it Grofe's
was erected by a colony of Cuthites probably before the
time of the Druids; because it was usual with them
to place one vault stone upon another for a religious
memorial; and they as they often placed so equably, that even
a breath of wind would not make them vibrate. Of
such stones one remains at this day in the pile of Stone-
henge. The ancients distinguished flons erected with a
religious view, by the name of awbrx; by which was sig-
nified any thing solid and divine. The Greeks called
them 
agathé

Stonehenge, according to
According to Mr. Bryant, is composed of these amber stones: hence the next town is denominated Ambrosia; not from a Roman Ambrosius, for no such person ever existed, but from the ambrosia petrae, in whose vicinity it floomed. Some of these were rocking stones; and there was a wonderful monument of this sort near Penzance in Cornwall, which still retains the name of main amber, or the sacred stones. Such a one is mentioned by Apollonius Rhodius, supposed to have been raised in the time of the Argonauts, in the island Teos, as the monument of the two-winged sons of Boeotia, flain by Hercules; and there are others in China and other countries.

Stoek, a term used in many parts of Britain for a flock of corn containing 12 sheaves.

Stoil, in medicine, an evacuation or discharge of the feaces by the anus.

Stoat, in mining, is used when the miners leave off digging deeper, and work in the ends forward. The end before them is called the foot.

Stooping, in falconry, is when a hawk, being upon her wings at the height of her pitch, bends down violently to take the fowl.

Stoppers, in a ship, certain short pieces of rope, which are usuallly knotted at one or both ends, according to the purpose for which they are designed. They are either used to suspend any heavy body, or to retain a cable, shroud, &c. in a fixed position. Thus, the anchors, when first holed up from the ground, are hung to the cat-head by a flopper attached to the latter, which passing through the anchor-ring, is afterwards fastened to the timber-head; and the same rope serves to fasten it on the bow at sea; or to suspend it by the ring which is to be fink from the ship to the bottom. The stoppers of the cable have a large knot and a laniard at one end, and are fastened to a ring-bolt in the deck by the other. They are attached to the cable by the laniard, which is fastened securely round both by several turns passed behind the knot, or about the neck of the flopper; by which means the cable is restrained from running out of the ship when the rades at anchor.

The stoppers of the shroud have a knot and a laniard at each end. They are only used when the shrouds are cut afunder in battle, or disabled by tempestuous weather; at which time they are lashed, in the same manner as those of the cables, to the separated parts of the shroud, which are thereby reunited, so as to be fit for immediate service. This, however, is only a temporary expedient.

Stops. See Punctuation; and Scripture, p. 156.

Storax. See Styrax.

Stork, in ornithology. See Ardea.

Stove, for heating apartments, greenhouses, hot-houses, fruit-walls, &c.

When treating of the mechanical properties of air, we explained in sufficient detail the manner in which the expansion produced in a mass of air by heat produces that motion up our chimneys which is called the draught of the chimney; and, in the article Smoke, we considered the circumstances which tend to check, to promote, or to direct this current, so as to free us from the smoke and vitiated air which necessarily accompanies the consumption of the fuel. In Pneumatics we also attended to the manner in which our fires immediately operate in warming our apartments. At present, when about to describe a method of warming intrinsically different, we must pay some more attention to the diluting circumstance. Without pretending to explain the physical connection of heat and light, it may suffice to observe, that heat, as well as light, is communicated to distant bodies in an instant by radiation. A person passing halfly by the door of a glass-house, and beholding the glow of heat in the very moment he sees the dazzling light of the furnace mouth, and it is interrupted by merely screening his face with his hand. In this way is an apartment partly warmed by an open fire; and we avoid the oppressive heat by sitting where the fire is not seen, or by interposing a screen. We are apt to connect this so strongly in the imagination with the light emitted by the fire, that we attribute the heat to the immediate action of the light. This opinion is shown to be gratuitous by a curious experiment made before the Royal Society by Dr Hooke, and afterwards, with more care and accurate examination, by Mr. Scheele. They found, that by bringing a plate of the most transparent glass briskly between the fire and one's face, the heat is immediately intercepted without any sensible diminution of the light. Scheele, by a very pretty investigation, discovered that the glass made the separation, and did it both in refraction and reflection; for he found, that when the light of the fame fire was collected into a focus by means of a polished metal concave speculum, a thermometer placed there was infinitely affected. But if we employ a glass speculum foiled in the usual manner with quicksilver, of the same diameter and focal distance, and of equally brilliant reflection, there is hardly any sensible heat produced in the focus, and the thermometer must remain there for a very long while before it is sensibly affected. When we repeated this curious experiment, we found, that after the glass has remained a long while in this position, whether transmitting or reflecting the light, it loses in a great measure its power of intercepting the heat. By varying this observation in many of its circumstances, we think ourselves entitled to conclude, that the glass absorbs the heat which it intercepts, and is very quickly heated by the absorption. While it rises in its own temperature, it intercepts the heat powerfully; but when it is, as it were, saturated, attracting no more than what it immediately imparts to the air in corporeal contact with it, the heat passes freely through along with the light. If the glass be held so near the fire that the surrounding air is very much heated, no sensible interruption of heat is perceived after the glass is thus faturated. We found the cheek more quickly sensible than the thermometer of this instantaneous radiation of the heat which accompanies the light, or is separated from it in this experiment. It is a very instructive experiment in the physiology of heat.

We cannot say how far this radiation of heat may extend, nor whether the accompaniment of light is absolutely necessary. The mathematician proceeds on the supposition that it extends as far as the radiation of light, and that, being also rectilinear, the density of the heat is proportional to that of the light. But these notions are somewhat gratuitous; and there are appearances,
appearances which render them doubtful. When with a lens of an inch in diameter we form a focus on a piece of black unpolished marble of an inch diameter, the mathematician must allow that no more rays fall on the marble than if the lens were away; therefore the marble should be equally warmed in either case. But it is by no means so, as we have repeatedly found by exposing it during equal times, and then dropping it into water. The water which is heated by the marble on which the focus has been formed will be found to have acquired from it much more heat than from the ether. The tops of lofty mountains which are never shaded by clouds, but enjoy perpetual sunshine and serenity, instead of being warmer than the valleys below, are covered with never-melting snow; and we have some grounds to suspect that the genial influence of the sun requires the co-operation of the atmosphere, and to doubt whether there is any warmth at the moon, on which no atmosphere like ours can be observed. Perhaps the heat which cheers us, and fertilizes our earth, is chemically separated from our atmosphere by its elective attraction for the light of the sun. Our successors in the study of meteorology need not fear that the phenomena of meteorology need not fear that the phenomenon is precisely similar to the radiation of light. We are obliged therefore to acknowledge that the heat is radiated in this experiment in the same way that light is in the common optical experiments.

Although this is the most usual way that we in this country employ fuel for warming our apartments, it is by no means the only way in which the heat diffused from this fuel may be imparted to distant bodies. It is not even the most effectual method; it is diffused also by immediate communication to bodies in contact. The air in immediate contact with the burning fuel is heated, and imparts some of its heat to the air lying beyond it, and this is partly shared with the air which is still farther off; and this diffusion, by communication in contact, goes on till the remote air contiguous to the walls, the floor, the ceiling, the furniture, the company, all get a share of it in proportion to their attractions and their capacities. And as the air is thus continually supplied, and continually gives out heat, the walls, &c., become gradually warmer, and the room becomes comfortable and pleasant. But we apprehend that no great proportion of the heat actually acquired by the room is produced in this way. This diffusion by contact is but slow, especially in air which is very dry; so slow indeed, that the air in the immediate neighbourhood of the fuel is hurried up the chimney before it has time to impart any of the heat received in contact. We know that the time employed in diffusing itself in this way through stagnant air to any moderate distance is very considerable. We imagine therefore that the heat communicated to our rooms by an open fire is chiefly by radiation, but in a way something different from what we mentioned before. We imagine, that as the piece of glass in Dr Hooke's experiment absorbs the heat, so the whole mass of air which fills the room intercepts the radiated heat in every part of the room where the fire is seen, and is as if it were saturated with it throughout, and ready to impart it to every body immersed in it. We cannot otherwise account for the equality of the heat in the different parts of the room. More radiation on the solid bodies would warm them in the inverse duplicate ratio of their distances from the fire; and diffusion by contact, if compatible with the rapid current up the chimney, would heat the room still more unequally. Recollect how slowly, and with what rapid diminution of intensity, the colour of blue vitriol is communicated to water even to a very small distance. But because all parts of the air of the room absorb radiated heat, what is saturated at a higher temperature, being nearer to the fire, rises to the ceiling, spreads outwards along the ceiling, and has its place supplied by the air, which is thus pulled towards the fire from the places which are not directly illuminated.

Far different is the method of warming the room by a stove. Here the radiation, if any, is very feeble or scanty; and if a passage were allowed the chimney for the warmed air, it would be quickly carried off. This is well known to the English who reside in the cold climates of St Petersburg, Archangel, &c. They love the exhilarating flutter of an open fire, and often have one in their parlours; but this, so far from warming the room during the extreme cold weather, obliges them to heat their stoves more frequently, and even abounds the heat from a whole suite of apartments. But all passages this way are shut up when we warm a room by stoves. The air immediately contiguous to the stove is heated by contact, and this heat is gradually, though not very much, diffused through the whole room. The diffusion would however be very slow if increased, were it not for the great expansibility of air by heat. But the air surrounding the stove quickly expands and rises to the ceiling, while the neighbouring air slides in to supply the place, and is even pushed in by the air which goes outwards aloft. Thus the whole air is soon mixed, and the room acquires almost an equal temperature throughout.

The warming by stoves must therefore be managed upon very different principles from those adopted in the employment of open fires. The general principle is, 1st, To employ the fuel in the most effectual manner for heating the external part of the stove, which is immediately efficient in warming the contiguous air; and, 2d, To keep in the room the air already warmed, at least as much as is sufficient with wholesomeness and cleanliness.

The first purpose is accomplished by conducting the flue of the furnace round its external parts, or, in front, by making every part of the flue external. Of all forms, that of a long pipe, returned backwards and forwards, up and down (provided only that the place of
the canal. Even this might be avoided by making each of these side-chambers a detached hollow pillar. But this would greatly increase the trouble of contruction and joining together, and is by no means necessary. The arch H has a graceful appearance, and affords a very warm situation for any thing that requires it, such as a drink in a sick person's bed-chamber, &c. Perions of a certain class use this place for keeping a dish warm; nay, the lower part of the arch is frequently occupied by an inclosed chamber, where the heat rises high enough even for dressing viurals, as will be easily imagined when we reflect that the sole of it is the roof of the fire-place.

The stove now described is supplied with fuel and air by the front door opening into the room. That there may be room for fuel, this middle part projects a few inches before the two side-chambers. These last, with the whole upper part of the stove, are not more than ten inches deep. The passages, therefore, from the fire-place are towards the back of it; so that if we have a mind to see the fire (which is always cheerful), the door may be thrown open, and there is no danger of the smoke coming out after the current has once warmed the upper part of the stove. When the stove is of such dimensions that the bafe is about two feet and a half or three feet high, the fire-place may be furnished with a small grate in the Britifh style. If the door is so hung that it can not only be thrown back, but lifted off its hinges, we have a stove grate of the comple- telt kind, fully adequate, in our mild climate, to warm a handfome apartment, even with an open fire; and when we hang on the door, and shut up the fire-place, a stove of the dimensions already given is almost too much for a large drawing-room.

We have frequently remarked, that one side of these stoves grows much warmer than the other, and that it was difficult to prevent or remedy this; and we imagine that this is an unavoidable defect in all stoves with a double flue. It is fearly poifible to make the fire fole quall in the fire-place, that one side fhall not be a little warmer than the other, and a brisker current will then be produced in it. This must increase the consumption of the fuel on that side, which will increase the current, will heat this side full more, and thus go on continually till the fuel on this side is expended; after which the other side will obtain and increase the superiority. The fume is made double, that the fire-place may occupy the middle of the front; and it will be difficult to gain this point of symmetry with one flue. The inconvenience may, however, be correfted by damping valves placed in fome part of the upright funnels E, E.

In the colder winters on the continent, it is thought necessary to increafe the effect by making the fire-place open to the back of the flove. Its mouth or door communicates with or is joined to an opening of the fame dimensions formed in the wall, and the door is on the other side in an antichamber or lobby. In Wolpha- lia, and other places of Germany, the apartments are disposed round a fpacious lobby, into which all their fire-places open, and are there supplied with fuel. By this contruction it is plain that the air of the room, already warmed by the flove, is not carried off, and the room is more heated. But this method is very unfavourable to cheerfulness and health. The fame air confined, and repeatedly
repeatedly breathed and compounded with all the volatile emanations of the room, quickly loses that refreshing quality that is so desirable, and even so necessary for health. It is never renewed except by very partial admixtures when the room doors are thrown open, and becomes disagreeable to any person coming in from the open air; and in the houses of the less opulent becomes really offensive and nauseous.

Something of this is unavoidable in all rooms heated by stoves. Even in our apartments in this country, persons of delicate nerves are hurt by what they call the close air of a room; and it is long before the smell of dinner is quite removed from a dining-room, notwithstanding the copious current up the chimney. This must be incomparably more sensible in a room heated by a stove; and this inconvenience in peculiarly sensible with respect to the stove which we are considering at present, where we employ a small surface heated to a great degree.

Such stoves are seldom made of anything else than cast-iron. This (in those parts at least which are in immediate contact with the fuel) is in a state of continual calcination, and even throwing off scales. This indeed is not seen, because it is the bottom or sole of the fire-place which is so heated: but the effect on the air of the room is the same. The calcination of the iron is occasioned by the combination of pure vital air with the iron. This is abstained from by the general mass of atmospheric air in the room, on which it usually consists about itself. By this abstraction the residue becomes less fit for supporting animal life or flame, and may even become highly deleterious. In every degree the remainder becomes less refreshing, and grows dull and oppressive. This is always accompanied by a peculiar smell, which, though not disgusting, is unpleasant. It resembles the smell of burnt feathers, or more exactly the smell we feel if we rub violently for some time the palms of our hands together when perfectly dry.

For similar reasons these iron stoves occasion a sickly smell, by burning every particle of dust which falls on the hot parts; and if they be wiped with a woollen cloth, or any cloth not perfectly free from every kind of grease or oily matter, a smell is produced for a day or days afterwards; so that without the most scrupulous attention we suffer by our very cleanliness.

For such reasons we think that the stoves of brick work covered with stucco or with glazed tiles are vastly preferable. These are much used in the genteeler houses in Flanders and Holland, where they are made in the most elegant forms, and decorated with beautiful sculpture or ornament; but it is plain that they cannot be so effectual, nor equally warm with the more expensive of fuel. Earthen ware, especially when covered with porous stucco, is far inferior to metal in its power of conducting heat. If built of bricks, they must be vastly more bulky when the fire-place and stoves are of the same dimensions. The most perfect way of constructing them would certainly be to make them of pottery, in parts exactly fitted to each other, and joined by a proper cement. This mode of constructing would admit of every elegance of form or richness of ornament, and would not be so bulky as those which are built of bricks. The great difficulty is to prevent their cracking by the heat. Different parts of the stove being of very different heats, they expand unequally, and there is no cement which can withstand this, especially when we recollect that the same heat which expands the baked earth causes the clay or cement, with which the parts of the stove are put together or covered, to contract. Accordingly those earthen ware stoves seldom stand a winter or two without cracking in some place or other, even when strengthened by iron hoops and cramps judiciously disposed within them. Even loopholing them externally, which would be very unfeiture, will not prevent this; for nothing can resist the expansion and contraction by heat and cold. When a crack happens in a stove, it is not only unsefitlly, but highly dangerous; because it may be so situated, that it will discharge into the room the air vitiated by the fire.

For these and other reasons, we can scarcely hope to make stoves of brick work or pottery which shall bear the necessary heat without cracking; and their use must therefore be confined to cafes where very moderate heat is sufficient. We need not describe their construction. It is evident that it should be more simple than that of iron stoves; and we imagine that in the very few cafes in which they are likely to be employed in this country, a single fire-place and an arch over it, divided, if we please, by a partition or two of thin tiles to lengthen the flue, will be quite enough. If the stove is made in whole or in part of pottery ware, a base for the fire-place, with an urn, column, obelisk, or pyramid, above it, for increasing the surface, will also be sufficient. The failure commonly happens at the joinings, where the different pieces of a different heat, and perhaps of a different baking, are apt to expand unequally, and by working on each other one of them must give way. Therefore, instead of making the joints close and using any cement, the upper piece should stand in a groove formed in the undermold, having a little powdered chalk or clay sprinkled over it, which will effectually prevent the passage of any air; and room being thus given for the unequal expansion, the joint remains entire. This may be considered as a general direction for all furnace-work, where it is in vain to attempt to hinder the mutual working of the parts.

We have seen stoves in small apartments at St Petersburg, which were made internally of pottery ware, in a great variety of forms, and then covered with a thick coat of stucco, finished externally with the utmost elegance of ornament, and we were informed that they were very rarely subject to crack. They did not give much heat, on account of the very low conducting power of the porous stucco; but we imagine that they would be abundantly warm for a moderate room in this country. When fitted up in these situations, and with these precautions, the brick or pottery stoves are incomparably more sweet and pleasant than the iron ones.

But in the intense colds of Russia and Sweden, or even for very large rooms in this country, stoves of these small dimensions are not sufficiently powerful, and we must follow the practice of those countries, where they are made of great size, and very moderately heated. It is needless to describe their external form, which may be varied at pleasure. Their internal structure is the same in all, and is distinctly described in Pneumatics, n° 364. We shall only enlarge a little on the
peculiarities connected with the general principle of their construction.

The stove is intended as a sort of magazine, in which a great quantity of heat may be quickly accumulated, to be afterwards slowly communicated to the air of the room. The stove is therefore built extremely massive; and it is found that they are more powerful when coated with clay as wet as can be made to hang together. We imagine the reason of this to be, that very wet clay, and more particularly flueco, must be exceedingly porous when dry, and therefore a very slow conductor of heat. Instead of flocking on the glazed tiles with no more clay or flueco than is sufficient to attach them, each tile has at its back a sort of box baked in one piece about two or three inches deep. It is represented in fig. 2. This is filled with mortar, and then stuck on the brick-work of the stove, which has a great number of iron pins or hooks driven into the joints, which may stick into this clay and keep it firmly attached when dry. This coating, with the massive brick-work, forms a great mass of matter to be heated by the fuel. The heated chamber, which is the fire-place, is somewhat wider, and considerably thicker than the stories above, which are merely flues. When the fire-place is finished and about to be arched over, a flat iron bar of small thickness is laid along the top of the side-wall on both sides, a set of finishing bricks being moulded on purpose with a notch to receive the iron bar. Cross bars are laid over these, one at each end and one or two between, having a bit turned down at the ends, which takes hold of the longitudinal bars, and keeps them from being thrust outwards either by the pressure of the arch or by the felling in consequence of the heat. In fig. 3, A is the cross section of one of the long bars, and BC is part of one of the cross bars, and CD is the chenise which confines the bar A. This precaution is chiefly necessary, because the contraction of the stove upwards oblige the walls of the other stories to bear a little on the arch of the fire-place. The building above is kept together in like manner by other courses of iron bars at every second return of the flue. The top of the stove is finished by a pretty thick covering of brick-work. The half passage for the air at H (see Pneumatics, fig. 22,) has a ring lining its upper extremity, and projecting an inch or two above it. The flat round it is covered with sand. When we would stop this passage, a cover shaped like a bason or cover for dishes at table, is wraped over it. The rim of this, resting on the sand, effectually prevents all air from coming through and getting up the vent. Access is had to this damper by a door which can be shut tight enough to prevent the heated air of the room from getting itself up the vent. When the room is too warm, it may be very rapidly cooled by opening this door. The warm air rushes up with great rapidity, and is replaced by cool air from without.

The management of the stove is as follows. About eight o'clock in the morning the pietrich, or servant who has the charge of the stove, takes off the cover, thrusts the damper-door, and opens the fire-place door. He then puts in a handful of wood thavings or straw, and kindles it. This warms the stove and vent, and begins a current of air through it. He then lays a few chips on the sole of the fire-place, immediately within the door; and behind this he arranges the billets of birchwood, with their ends inwards. Then he lays on more wood in the front, till he thinks there is enough. He sets fire to the chips, thrusts the door, and opens the small wicket at its bottom. The air blows the flame of the chips upon the billets behind them, and thus kindles them. They conduce slowly, while the billets in front remain untouched by the fire. The servant, having made his first round of the rooms, returns to this stove, and opens the door above to admit air into the vent. This is to supply its draught, and thus to check the draught in the body of the stove, which is generally too strong at this time, and would consume the fuel too fast. By this time the billets in the front are burning, first at the bottom, and the rest in succession as they sink down on the embers, and come opposite to the wicket. The room does not yet feel any effect from the fire, the heat of which has not yet reached its external surface; but in about half an hour this grows warm. The upper door is shut again, that no heat may now be wasted. The pietrich, by and by, spreads the embers and takes over the whole bottom of the fire-place with a rake, by which the bottom is greatly heated, and heats the air contiguous to it externally (for it stands on little pillars) very powerfully. He takes care to bring up to the top of the ashes every bit of wood or coal that is not yet consumed, that all may be completely expended. He does this as briskly as possible, that the room may not lose much warmed air by keeping open the fire-place door. At his last visit, when he observes no more glowing embers, he shuts the fire-place door and wicket, and puts the damper on the passage above, and shuts its door. All this is over in about an hour and a half after kindling the fire. All current of air is now at an end within the stove, and it is now a great mass of brick-work, heated to a great degree within, but only about blood warm externally. The heat gradually spreads outwards, and the external surface of the stove acquires its greatest heat about three o'clock in the afternoon; after which it gradually cools till next morning.

This heat seldom is so great that one cannot bear to touch the stove with his cheek, and to keep it there. In consequence of this it can burn none of the dust which unavoidably falls on the stove, and we are never troubled with the sickening smells that are unavoidable when we employ the small cast iron stoves much heated. The great expense of heat in a room arises from the glass windows. The pane is too thin that the external air keeps it continually cold, and thus the windows are continually robbing the air of the room of its heat. This expense of heat is reduced to less than one third by double casements. The inner casement is about as much colder than the room as the outer casement is warmer than the air of the fields; and we have the singular advantage of having no ice formed on the glasses. But to ensure this last advantage, the seams of the inner casement must be pasted with paper, and those of the outer casement must be left unpasted. If we do the contrary, we shall certainly have ice on the outer casement; the reason of which is easily seen.

We have been thus particular in our description of the management, because the reasons of some particulars are not very obvious, and the practice would not readily occur to many people; so that a person who, on the
faith of our recommendation, should prefer one of these flues to the German stove, whose management is simple and obvious, might be greatly disappointed. But by following this method, we are confident that the Russian flue will be found much superior both in warmth and agreeable air. The spreading out of the embers, and waiting until all is reduced to ashes before the doors are shut, is also absolutely necessary, and a neglect of it would expose us to imminent danger of suffocation by fixed air; and this is the only inconvenience of the Russian flue, from which the other flue is free. The fixed air has no smell; and the first indication of its presence is a slight giddiness and latitude, which induces us to sit down and to sleep. This would be fatal; and as the air should immediately open the upper passage and the fire-place door, so as to produce a strong current to carry the vitiated air of the room up the chimney. Throwing up the fashes, if at least opening all the doors, is proper on such an occasion.

If we burn pit-coal, either raw or charred, this precaution is still more necessary; because the cinder is not so easily or so soon completely consumed. This fuel will require a little difference in the management from wood fuel, which is only easily seen by any person of reflection. The safe way would be to rake out all half-burnt coal before shutting up the doors.

If we use raw pit-coal, great care is necessary to prevent the accumulation of foot in the upper part of the flue. It is an inaccessible place for the chimney sweep; and if we attempt to burn it out, we run a great risk of splitting that part of the flue which is the most slightly constructed. It is advisable therefore to burn it away every day, by giving a brisk draught with an open door for five minutes. With wood or coal there is no danger.

It will not be improper in this place to give some instructions for the construction of flues for warming several floors in a great manufactury, such as a cotton-mill, or a public library or museum.

In such situations we think cleanliness, wholesomeness, and sweetness of air, not less necessary than in the drawing room of a man of opulence. We therefore recommend the brick-flue in preference to the iron one; and though it would not be the best or most economical practice to heat it but once a day, and we should rather prefer the German practice of constant feeding, we think it highly proper to limit the heat to a very moderate degree, and employ a large surface.

If the disposition of the rooms allows us the conveniency of a thick party-wall, we would place the flue in the middle of this wall, in an arch which pierces through the wall. Immediately above this arch we would carry up a very wide chimney through the whole height. This chimney must have a passage opening into each floor on both sides, which may be very accurately shut up by a door. The flue being set up under the arch, it must have a pipe communicating with its flue, and rising up through this chimney. Could an earthen pipe be properly supported, and secured from splitting by hoops, we should prefer it for the reasons already given. But as this is perhaps expecting too much, we must adopt the use of a cast iron pipe. This is the real chimney or flue, the flue, and must be of as great diameter as possible, that it may not, by an extensive surface, all the way up.

The propriety of flutting the valves of the upright long, for
above, which robs the air of its heat as it glides down upon their heads. This is more particularly felt by those sitting in the fronts of the galleries. We imagine that this arises chiefly from the extensive surface of the upper row of windows, and of the cold stone-walls above, which rob the air of its heat as it glides up along the sides of the church. It becomes heavier by collapsing, and in this state descends in the middle of the church.

The stove S is placed against the middle of the west wall at the distance of a few inches, and is completely inclosed in a case of late and plaster. The vent, which is to carry off the smoke and burnt air, is conveyed up or down along the wall, and through the roof or side-wall, but without any communication with the case. In like manner the fire-place door is open to the passage, without communicating with the case; and care is taken that the holes which admit the air into the case are so disposed that they shall run no risk of drawing in any air from the fire-place door.

From the top of this case proceed two trunks Q, R, each of which is two feet broad and six inches deep, coated within and without with the most spungy plaster that can be composed. For this purpose we should recommend a composition of powdered charcoal and as much clay and quicklime as will give it a very light cohesion. We know that a piece of this may be held in the hand, without inconvenience, within an inch of where it is of a glowing red heat. These trunks open into another trunk XVTYZ, which ranges along the partition immediately under the galleries, and may be formed externally into a cornice, a little massive indeed, but not unseightly in a building of this style. This trunk is coated in the same manner. It has several openings a, a, &c., which have flinders that can be drawn aside by means of handles accessible from the outer passage. At the extremities X and Z of this trunk are two perpendicular trunks which come up through the galleries, and are continued to a considerable height. At their junction with their horizontal trunks are two doors large enough to admit a lamp. Each perpendicular trunk has also a valve by which it can be completely stopped.

The stove is managed as follows: Early in the morning the superintendent fluts all the flinders, and sets a lamp (burning) in each of the trunks X and Z, and fluts the doors. He then puts on and kindles the fire in the stove, and manages it either in the Russian or German method. Perhaps the latter is preferable, as being liable to few accidents from miltake or neglect.

The lamps set in the lower ends of the upright trunks presently warm them, and produce a current of air upwards. This must be supplied by the horizontal trunk, which must take it from the case round the stove. Thus a current is begun in the direcution we wish. By and by the air in the case acquires heat from the stove, and the current becomes extremely brisk. When the manager perceives this, he removes the lamps, shuts the valves, and opens the holes a, a, &c., beginning with the most remote, and proceeding slowly towards the stove from each extremity of the horizontal branches. The heated air now issues through these holes, glides along the ceiling below the galleries, and escapes, by rising up along the fronts of the galleries, and will be sensibly felt by those sitting there, coming on their faces with a gentle warmth. It will then rise (in great part) straight up, while some of it will glide backwards, to the comfort of those who sit behind.

The propriety of flutting the valves of the upright trunks is evident. If they were left open, no air would come but by the holes a, a, &c.; but, on the contrary, the air would go in at these holes to supply the current, and the stove be rendered blazing. The air delivered by these holes will keep close to the ceiling, and will not, as we imagine, inconvenience those who sit below the galleries. But if it should be found to render these parts too warm, holes may be pierced through the ceiling, by which it will rise among the people above, and must be very comfortable. It will require the careful attention of some intelligent person to bring all this into a proper train at first, by finding the proper apertures of the different holes, so as to render the heat equable through the whole space. But this being once ascertained the difficulty is over.

The air trunks must be very capacious, but may be contracted towards the extremities as their lateral discharges diminish; and the row of holes which admit the air to the case round the stove must be fully able to supply them.

It must be observed, that in this construction the ascencional force is but small. It is only the height of a short column of warm air from the ground to the galleries. At first indeed it is great, having the unlimited height of the perpendicular trunks at X and Z; but during the use of the stove it is reduced to nine or ten feet. It is necessary, therefore, that the stove be highly heated, perhaps considerably beyond the Russian practice, but yet inferior to the heat of the German iron stoves. But till we strongly recommend the brick or pottery stoves, on account of the wholesome sweetness of the air which they furnish, and we are certain that a stove of moderate dimensions, eight feet long, for instance, by eight feet high, will be sufficient for warming a church holding 1,200 or 1,500 people. If the stove could be placed lower, which in many situations is very practicable, its effect would be proportionally greater, because all depends on the rapidity of the current. When we are limited in height, we must extend the stove so much the more in length, and make the air trunks more capacious. These and many other circumstances of local modification must be attended to by the creator of the stove; and without the judicious attention of an intelligent artist, we may expect nothing but disappointment. It is hardly possible to give instrucutions suited to every situation; but a careful attention to the general principle which determines the ascencional force will free the artist from any great risk of failure.
We may say the same thing of stores for conservatories, hot houses, hot walls, &c. and can hardly add any thing of consequence to what we have already laid on these heads in the article Pneumatics.

We must not, however, dismiss the subject without taking notice of the very specious projects which have been frequently offered for drying malt by stores. Many of these are to be seen in the publications of the Academies of Stockholm, Upsal, Copenhagen, and some have been erected in Great Britain; but they have not been found to answer.

We apprehend that they cannot answer. To dry malt, and make it fit for the ales and beers for which this island is so famous, it is by no means enough that we give it a proper and an equable supply of heat.—This alone would bake it and make it flinty, causing the moisture to penetrate the mealy particles of the grain; and, by completely dissolving the soluble parts, would render each kernel an uniform mass, which would dry into a flinty grain, breaking like a piece of glass.—A grain of malt is not an inert pulp. It is a seed, in an active state, growing, and of an organized structure. We wish to stop it in this state, and kill it, not by heating it, but by abating its moisture. We thus leave it in its granulated or organized form, pungy., heating it, but by

Some collectors, in our common glossaries, &c. This has not escaped the attention of Saint John, who calls him an indefatigable antiquarian, a faithful historian, and an honest man.

STOWMARKET, a town of Suffolk, in England, situated in E. Long. 1. 6. N. Lat. 52. 16. It is a large
handsome place, situated between the branches of the
rivers Gypping and Orwell, and is remarkable for having
the belt cherries in England.

STOWAGE, the general disposition of the several
materials contained in a ship's hold, with regard to their
figure, magnitude, or solidity.

In the rowage of different articles, as ballast, casks,
cafes, bales, and boxes, there are several general rules
to be observed, according to the circumstances or qual-
ities of those materials. The casks which contain any
liquid are, according to the sea phrase, to be hung-up
and bilge-free, i.e. closely wedged up in an horizontal
position, and reposing on their quarters; so that the bilges
where they are thickest being entirely free all round,
cannot rub against each other by the motion of the ves-
sel. Dry goods, or stuff as may be damaged by the
water, are to be carefully inclosed in casks, bales, cafes,
or wrappers; and wedged off from the bottom and sides
of the ship, as well as from the bow, masts, and pum-
pwell. Due attention must likewise be had to their dis-
position with regard to each other, and to the trim and
centre of gravity of the ship; so that the heaviest may
always be nearest the keel, and the lightest gradually
above them.

STRABISMUS, squinting. See Medicine.-

STRABO, a celebrated Greek geographer, philo-
sopher, and historian, was born at Amasia, and was
defended from a family settled at Gnossus in Crete. He
was the disciple of Xenarchus, a Peripatetic philo-
sopher, and at length attached himself to the Stoics.
He contracted a brief friendship with Cornelius Gallus,
governor of Egypt, and travelled into several countries to
observe the situation of places, and the customs of na-
tions. He flourished under Augustus, and died under
Tiberius about the year 25, in a very advanced age.
He composed several works, all of which are lost ex-
cept his Geography in 17 books; which are justly
called very precious remains of antiquity.

The two first books are employed in showing, that the study
of geography is not only worthy of, but even necessary to
a philosopher; the third describe Spain; the fourth,
Gaul and the British isles; the fifth and sixth, Italy
and the adjacent isles; the seventh, which is imperfect
at the end, Germany, the countries of the Gete and
Ilyrii, Taurica, Cevennes, and Epirus; the eighth,
sinth, and tenth, Greece with the neighbouring isles;
the four following, Asia within Mount Taurus; the
fifteenth and sixteenth, Asia without Taurus, India,
Peris, Syria, Arabia; and the seventeenth, Egypt,
Ethiopia, Carthage, and other places of Africa.

Strabo's work was published with a Latin version by Xy-
lander, and Notes by Isaac Casaubon (or rather by
Henry Sermozer, from whom Casaubon chiefly stole
them), at Paris, 1620 in folio. But the best edition
is that of Amstérdam in 1707, in two volumes folio,
by the learned Theodore Janonius ab Almeloveen,
with the entire notes of Xylander, Casaubon, Meursius,
Cruver, Holleins, Salmantus, Bochart, Ez. Sphanheim,
Cellarius, and others. To this edition is subjoined the
Christiathike, or epitome of Strabo; which according to
Mr Dodwell, who has written a very elaborate and
learned dissertation about it, was made by some unknown
person between the years of Christ 676 and 996. It
has been found of some use, not only in helping to cor-
rect the original, but in supplying in some measure the
defect in the seventh book. Mr Dodwell's disser-
tation is prefixed to this edition.

STRADA (Famianus), a very ingenious and learned
 Jesuit, was born at Rome the latter end of the 16th
century, and taught rhetoric there, in a public man-
ner, for fifteen years. He wrote several pieces upon
the art of oratory, and published some orations with
a view of illustrating by example what he had incul-
cated by precept. But his Prolusions Academicæ and
his Historia de Bello Belgico are the two works which raised
his reputation, and have preferred his memory.
His history of the war of Flanders was published at
Rome; the first decade in 1639, the second in 1647,
the whole extending from the death of Charles V,
which happened in 1558, to the year 1599. It is
written in good Latin, as all allow; but its merit in
other respects has been variously determined. His
Prolusions Academicæ show great ingenuity, and a
mastery skill in classical literature; that prolixity espe-
cially in which he introduces Lucan, Lucrètius, Clau-
dian, Ovid, Statius, and Virgil, each of them verifying
according to his own strain. They have been of
often printed. We know not the year of Strada's birth
or of his death.

STRAHAN (William,) an eminent printer,
was born at Edinburgh in the year 1715. His father,
who had a small appointment in the customs, gave his
son the education which every one of decent rank then
received in a country where the avenues to learning
were easy, and open to men of the most moderate cir-
cumstances. After having passed through the tuition
of a grammar-school, he was put apprentice to a print-
er; and when a very young man, removed to a
wider sphere in that line of business, and went to follow
his trade in London. Sober, diligent, and attentive,
while his emoluments were for some time very scanty,
he contrived to live rather within than beyond his in-
come; and though he married early, and without such
a provision as prudence might have looked for in the
establishment of a family, he continued to thrive, and to
better his circumstances. This he would often mention
as an encouragement to early matrimony; and used to
say, that he never had a child born that Providence did
not send him increase of income to provide for the in-
crease of his household. With sufficient vigour of mind,
he had that happy flow of animal spirits that is not
calmed discouraged by unpromising appearances.

His abilities in his profession, accompanied with
perfect integrity and unceasing diligence, enabled
him, after the first difficulties were overcome, to ad-
vance with rapid success. And he was one of the most
flourishing men of the trade, when, in the year 1779,
he purchased a share of the patent for king's printer
of Mr Eyre, with whom he maintained the most cordial
intimacy during the rest of his life. Beside the emolu-
ments arising from this appointment, as well as from a
very extensive private business, he now drew largely
from a field which required some degree of speculative
fagacity to cultivate on account of the great literary pro-
erty which he acquired by purchasing the copy-rights
of the most celebrated authors of the time. In this his
liberality kept equal pace with his prudence, and in some
cases went perhaps rather beyond it. Never had such re-
wards been given to the labourers of literary men as now-
were received from him and his associates in those pur-
chases of copy-rights from authors.
Having now attained the first great object of business, wealth, Mr Strahan looked with a very allowable ambition on the stations of political rank and eminence. Politics had long occupied his active mind, which he had for many years pursued as his favourite amusement, by corresponding on that subject with some of the first characters of the age. Mr Strahan's queries to Dr Franklin in the year 1769, respecting the discontents of the Americans, published in the London Chronicle of 28th July 1778, show the conception he entertained of the important consequences of that dispute, and his anxiety as a good subject to investigate, at that early period, the proper means by which their grievances might be removed, and a permanent harmony restored between the two countries. In the year 1775 he was elected a member of Parliament for the borough of Malmburg in Wiltshire, with a very illustrious colleague, the Hon. C. J. Fox; and in the succeeding parliament, for Wootton Basset, in the same county. In this station, applying himself with that industry which was natural to him, he was a useful member, and attended the house with a scrupulous punctuality. His talents for business acquired the consideration to which they were intimated, and were not unnoticed by the minister.

In his political connections he was constant to the friends to whom he had first been attached. He was a ready supporter of that party who were turned out of administration in Spring 1784, and lost his seat in the house of commons by the dissolution of parliament with which that change was followed: a situation which he did not show any desire to resume on the return of the new parliament; arising from a feeling of some decline in his health, which had latter suffered from the long fittings and late hours with which the political warfare in the preceding had been attended. Without any fixed dislike, his strength visibly declined; and though his spirits survived his strength, yet the vigour and activity of his mind were also considerably impaired. Both continued gradually to decline till his death, which happened on the 26th of July 1785 in the 71st year of his age.

Endued with much natural sagacity, and an attentive observation of life, he owed his rise to that station of opulence and respect which he attained, rather to his own talents and exertion, than to any accidental occurrence of favourable or fortunate circumstances. His mind was not uninformed by letters; and from a habit of attention to style, he acquired a considerable portion of critical acuteness in the discernment of its beauties and defects. In one branch of writing he particularly excelled—the epistolary; in which he not only showed the precision and neatness of business, but polished a neatness as well as a fluency of expression which few letter-writers have been known to surpass. Letter-writing was one of his favourite amusements; and among his correspondents were men of such eminence and talents as well repaid his endeavours to entertain them. Among these, as before mentioned, was the justly celebrated Dr Franklin, originally a printer like Mr Strahan, whose friendship and correspondence, notwithstanding the difference of their sentiments in political matters, he continued to enjoy till his death. One of the latest letters which he received from his illustrious and venerable friend, contained a humorous allegory of the first of politics in Britain, drawn from the profession of printing; of which, though the Doctor had quitted the exercise, he had not forgotten the terms.

The judicious disposition which Mr Strahan made of his property, affords an evident proof of his good sense and propriety. After providing munificently for his widow and children his principal study seems to have been to mitigate the affliction of those (and many there were) who would more immediately have felt his loss, by bequeathing them liberal annuities for their lives; and (recollecting that all of a profession are not equally provident) he left 1000l. to the Company of Stationers, the interest to be divided among inform old printers.

As the virtuous connections of the life and the heart are always pleasing to trace—of Mr Strahan it may briefly be said, that his capacity, diligence, and probity, raised him to the head of his profession. The good humour and obliging disposition which he owed to nature, he cultivated with care, and confirmed by habit. His sympathetic heart beat time to the joy and sorrow of his friends. His advice was always ready to direct youth, and his purse open to relieve indigence. Living in times not the purer in the English annals, he escaped unfurled through the arts of trade and the corruption of politics. In him a strong natural sagacity, improved by an extensive knowledge of the world, served only to render respectable his unaffected simplicity of manners, and to make his Christian philanthropy more discerning and useful. The uninterrupted health and happiness which accompanied him for half a century in the capital, proves honestly to be the best policy, temperance the greatest luxury, and the essential duties of life its most agreeable amusement. In his elevated fortune, none of his former acquaintance ever accused him of neglect. He attained prosperity without envy, enjoyed wealth without pride, and dispensed bounty without ostentation.

STRAINS, in the military art, are strong plates of iron, fixed in number, fixed with large nails called strails, on the circumference of a cannon-wheel, over the shoulders of the fellows; both to strengthen the wheel, and to take the fellows from wearing on hard ways or streets.

STRAIN, a pain occasioned by the violent extension of some membranous or tendinous part.

STRAINS, Stret, in mechanics, are terms indiscriminately used to express the force which is excited in any part of a machine or structure of any kind tending to break it in that part. Thus every part of a rope is equally strained by the weight which it supports. Every part of a pillar is equally strained by the load which it supports. A mill axle is equally twitted and strained in every part which lies between the part of the wheel actuated by the moving power and the part which is fulfilled by the work to be performed. Every part of a lever or joist is differently strained by a force acting on a different part.

It is evident that we cannot make the structure fit for its purpose, unless the strength in every part be at least equal to the stress laid on, or the strain excited in that part. It is no less plain, that if we are ignorant of the principles which determine this strain, both in intensity and direction, in relation to the magnitude and the situation of its remote cause, the only security we have for success is to give to every part of the tautology...
blige such facility that we can leave no doubt of its sufficiency. But daily experience shows us that this vague security is in many cases uncertain, if we are thus ignorant. In all cases it is slovenly, unlike an artist, attended with useless expense, and in machines is attended with a loss of power which is wasted in changing the motions of a needle's load of matter.

It must therefore greatly tend to the improvement of all professions occupied in the erection or employment of such structures to have a distinct notion of the strains to which their parts are exposed. Frequently, say generally, these strains are not immediate, but arise from the action of forces on distant parts, by which the assemblage is strained, and there is a tendency to rupture in every part. This strain is induced on every part, and is there modified by fixed mechanical laws. These it is our business to learn; but our chief object in this investigation is to determine the strength of materials with which it is necessary to oppose in every part to this strain; and how to oppose this strength in such a manner that it shall be exerted to the best advantage. The notions of strain and strength therefore hardly admit of separation; for it is even by means of the strength of the intermediate parts that the strain is propagated to, or excited in, the part under consideration. It is proper therefore to consider the whole together under the article Strength of Materials in mechanics.

STRAINING, is the clarification of a liquor, by passing it through a sieve or filter. The word is derived from the French, efreindre; which is formed from es, "out of," and fringere, "to press."

STRAIT, a narrow channel or arm of the sea, shut up between lands on either side, and affording a passage out of one great sea into another.

There are three kinds of straits. 1. Such as join one ocean to another. Of this kind are the straits of Magellan and Le Maire. 2. Those which join the ocean to a gulf: the straits of Gibraltar and Babelmandel are of this kind, the Mediterranean and Red Sea being only large gulfs. 3. Those which join one gulf to another; as the straits of Caffa, which join the Pelus Mæotis to the Euxine or Black Sea. The passage of straits is commonly dangerous, on account of the rapidity and opposite motion of currents. The most celebrated strait in the world is that of Gibraltar, which is about from 24 to 36 miles long, and from 15 to 24 broad, joining the Mediterranean sea with the Atlantic ocean. The straits of Magellan, discovered in 1520 by F. Magellan, were used some time as a passage out of the North into the South Sea; but since the year 1616, that the strait of Le Maire has been discovered, the former has been diffused; both because of its length, which is full three hundred miles, and because the navigation thereof is very dangerous, from the waves of the North and South Seas meeting in it and clashing. The strait at the entrance of the Baltic is called the Sound. That between England and France, Le pas de Calais, or the Channel. There are also the straits of Weights, of Jefo, of Anian, of Davis, and Hudson, &c.

STRAKES, or STREAKS, in a ship, the uniform ranges of planks on the bottom and sides of a ship, or the continuation of planks joined to the ends of each other, and reaching from the stem to the stern-post and fathion-pieces; the lowest of these, which is called the garboard-streak, is let into the keel below, and into the stem and stern-post. They say also a ship bears a streak, that is, hangs or inclines to one side the quantity of a whole plank's breadth.

Streaks, or streaks, in mining, are frames of boards fixed on or in the ground, where they wash and dress the small ore in a little stream of water, hence called streaked ore.

STRAALSUND, a strong and rich sea-port town of Germany, in Hither Pomerania, and was formerly an important trading-place. In 1678 it was forced to surrender to the elector of Brandenburg, after 1800 houses had been burnt to ashes in one night's time. After this the Swedes defended the last extremity; and Charles XII. in 1714, came hither after his return out of Turkey. But the crown of Sweden not being able to hold out against five great powers, it was forced to submit in 1715. In 1720 it was rendered back to Sweden, but in a very poor condition. It is almost surrounded by the sea and the lake Francia, and has a harbour separated from the isle of Rügen by a narrow strait. It is 15 miles north-west of Grippswald, and 40 north-east of Gutsow. E. Long. 13. 28. N. Lat. 54. 17.

STRAMONIUM, in botany; a species of Datura.

STRAW, any shore or bank of a sea or great river. Hence the street in the west suburbs of London, which lies next to the shore or bank of the Thames, was called the Strand. An immunity from custom, and all impositions upon goods or vessels by land or water, was usually expressed by strand or stream.

STRAINED (from the Saxon sirand), is when a ship is by tempest, or by the flowers, run on ground, and so perishes. Where a vessel is stranded, judges of the peace, &c. shall command constables to the seacoast to call assistance for the preservation of the ship; and officers of men of war are to aiding and assisting thereto.

STRANGE (Sir Robert), "who carried the art of engraving to so great perfection in this country, was a man of such general merit, that a life of him, not merely illuminating his character as an artist, but also portraying his private virtues and domestic habits, would be both useful and entertaining. Such a life, we have reason to believe, will be presented to the public. Modest as he was ingenious, he used indeed to say that the works of an artist should serve for a life and monument to him. His works no doubt will perpetuate his name whilst any taste for the fine arts remains. In the mean time, we cannot but here give a short sketch of his history, the accuracy of which may be depended on.

"Sir Robert Strange was born in the isle of Pomona in Orkney, July the 14th 1721; and died at London July the 5th 1792. He was lineally descended from David Strange or Strang, a younger son of the family of the Stranges or Strangts (a) of Balcaiky, in the coumty of

(a) The name of Strange or Strang is indiscriminately used in the old charters and deeds of the Balcaiky family, now in the possession of Sir Robert Anstruther of Balcaiky, baronet.
Strange.

Strange, Mr. of Tife, who settled in Orkney at the time of the Reformation. But as there were no males remaining of the elder branch of the Stranges of Balnafy, Sir Robert became the sole representative of it, and was found by a legal investigation to have a right to the armorial bearings and every other mark of honour belonging to that ancient family.

He received his classical education at Kirkwall in Orkney under the care of a learned, worthy, and much respected gentleman, Mr. Murdoch Mackenzie, still alive (1795), who has rendered infinite service to his country by the accurate surveys and charts he has given of the islands of Orkney and of the British and Irish coasts.

"Originally intended for the law, Mr. Strange soon became tired of that profession, and, received that his genius decisively led him to the arts of drawing and engraving. For this purpose he was introduced to the late Mr. Richard Cooper at Edinburgh, the only person there who had then any taste in that line of the fine arts. He was bound with him as an apprentice for five years; during which time he made such progress in his new profession, that his friends entertained the highest expectation of his success; nor were they disappointed.

"In the year 1747 he married Isabella, only daughter of William Lumfden, son of Bishop Lumfden; and soon after his marriage he went to France, where with the most ardent application he prosecuted his studies, chiefly at Paris, under the direction of the celebrated Le Bas, who engraved many excellent prints from the Dutch painters. It was from Le Bas he had the first hint of the use of the instrument commonly called the dry needle; but which he afterwards greatly improved by his own genius, and which has added such superior beauties to his engravings.

"In the year 1751 Mr. Strange removed with his family from Edinburgh and settled at London, where he engraved several fine historical prints, which justly acquired to him great reputation. At this period historical engraving had made little progress in Britain, and he may be properly considered as its father.

"The admiration he always had for the works of the great Italian painters made him long desire to visit Italy, the seat of the fine arts; and the further he advanced in life, he became the more persuaded that a journey to that country was essential to an artist who had the laudable ambition to excel in his profession. He therefore undertook this journey in the year 1790. In Italy he made many admirable drawings, several of which he afterwards engraved. These drawings are now in the possession of Lord Dundas.

"Everywhere in Italy singular marks of attention were bestowed on Mr Strange; not only by great personages, but by the principal academies of the fine arts in that country. He was made a member of the academies of Rome, Florence, and Bologna, and professor in the royal academy at Parma.

"To show the estimation in which his talents were held at Rome, we cannot but record the following anecdote. The ceiling of the room of the Vatican library, in which the collection of engravings is kept, is elegantly painted by Signor Ribottelli. It represents the progresses of engraving; and the portraits of the most eminent artists in that line are there introduced, among which is that of our artist. Under his arm he holds a portfolio, on which his name is inscribed. He is the only British artist on whom this honour has been conferred.

"In France, where he resided many years at different periods, his talents likewise received every mark of attention that could be bestowed on a foreigner. He was made a member of the royal academy of painting at Paris.

"His majesty George III. ever attentive to the progress of the fine arts in Britain, and fond of the advantages of which engraving particularly has been to this country, even in a commercial light; and desirous to give a mark of his royal approbation of the merit of Mr. Strange, whom he considered as the head of his profession and the great improver of it—was graciously pleased to confer the honour of knighthood on him the 5th of January 1787.

"Such was Sir Robert Strange as an artist; nor was he less distinguished by his truly amiable moral qualities, which endeared him to all who had the happiness to know him.

"With regard to his works, he left fifty capital plates, still in good condition, which are carefully preserved in his family. They are engraved from pictures by the most celebrated painters of the Roman, Florentine, Lombard, Venetian, and other schools. They are historical, both sacred and profane, poetical, allegorical.

"From his earliest establishment in life, Sir Robert carefully preserved about eighty copies of the finest and most choice impressions of each plate he engraved; which, from length of time, have acquired a beauty, mellowness, and brilliancy, easier seen than described. He did this with a view of presenting them to the public at a period when age should disable him from adding to their number. Thence he collected into as many volumes, and arranged them in the order in which they were engraved. To each volume he prefixed two portraits of himself, on the same plate, the one an etching, the other a finished proof, from a drawing by John Baptiste Greuze. This is the last place he engraved; and which is a proof that neither his eyes nor hand were impaired by age. It likewise shows the use he made both of aquafortis and the gravure. Each volume, besides a dedication to the king, contains an introduction on the progress of engraving, and critical remarks on the pictures from which his engravings are taken. These volumes were ready to be given to the public, when Sir Robert's death and consequent circumstances delayed this magnificent publication; a publication which does so much honour to the artist, and to the country which gave him birth (a).

STRANGER.

(a) Solicitous to make all our biographical articles the vehicles of truth, we applied for information respecting Sir Robert Strange, to the person whom we considered as the most capable of furnishing us, and who we imagined would be gratified by our application. With some difficulty we obtained, as a favour to ourselves, the sketch...
STRANGER, in law, denotes a person who is not privy or party to an act. Thus a stranger to a judgement is he to whom a judgment does not belong; in which sense the word hands directly opposed to party or privy.

STRANGLES, in Farriery. See that article, § 22.

STRANGURY, a suppression of urine. See Medicine, n° 119.

STRAP, among surgeons, a sort of band used to stretch out limbs in the setting of broken or disjointed bones.

STRAP, in a ship, the rope which is spliced about any block, and made with an eye to fasten it any where on occasion.

STRAPS, in the manage. The straps of a saddle are small leather strips, nailed to the bows of the saddle, with which we make the girths fast to the saddle.

STRAPPADO, or STRAPPADO, a kind of military punishment, wherein the criminal's hands being tied behind him, he is hoisted up with a rope to the top of a long piece of wood, and let fall again almost to the ground; so that, by the weight of his body in the shock, his arms are dissected. Sometimes he is to undergo three strappados or more.

STRASBURG, an ancient, large, handsome, populous, and strong city of France in Alsace. It contains about 200 streets, part of which are very narrow, and most of the houses are built after the ancient taste. However, there are a great number of handsome buildings, such as the hotel of the marquis of Hamilton, the house of the cardinal of Renc, the bishop's palace, the Jesuits college, the royal hospital, the hotel of Heffe-Darmstadt, the arsenal, the town-houses, and the cathedral. It has a wooden bridge over the Rhine, which is thought to be one of the finest in Europe; as is likewise the cathedral church, whose tower is the handomest in Germany, and the clock is greatly admired by all travellers. Some look upon it as one of the wonders of the world, and the fleeter is allowed to be the highest in Europe. The clock not only shows the hours of the day, but the motion of the sun, moon, and stars. Among other things there is an angel, which turns an hour-glass every hour; and the twelve apostles proclaim noon, by each of them striking a blow with a hammer on a bell. There is likewise a cock, which is a piece of clock-work, that crows every hour. There are 750 steps up to the tower or fleeter, it being 500 feet high. It was a free and imperial city; but the king of France became master of it in 1681, and greatly augmented the fortifications, though before it had as many cannon as there are days in the year. The inhabitants were formerly Protestants, and carried on great trade; but most of them have been obliged to embrace the Catholic religion, though there is still a sort of toleration. Such was Strasbourg before the French revolution; what it is now we have not leisure to inquire. It is seated on the river Ill, 55 miles north of Basel, 112 south-west of Mentz, and 255 east of Paris. E. Long: 7° 51' N. Lat. 4° 35'

STRATA, in natural history, the several beds or layers of different matters whereof the earth is composed. See Quarrv.

The strata whereof the earth is composed are so very different in different countries, that it is impossible to say anything concerning them that may be generally applicable: and indeed the depths to which we can penetrate are so small, that only a very few can be known to
to us at any rate; those that lie near the centre, or even
a great way from it, being for ever hid. One reason
why we cannot penetrate to any great depth is, that as
we go down the air becomes foul, loaded with permi-
cious vapours, inflammable air, fixed air, &c. which de-
strupt the miners, and there is no possibility of going on.
In many places, however, these vapours become permi-
cious much sooner than in others; especially where
sulphureous minerals abound, as in mines of metal,
coal, &c.

But however great differences there may be among
the other strata, the upper one is in some respects the
same all over the globe, at least in this respect, that
it is fit for the support of vegetables, which the others
are not, without long exposure to the air. Properly
speaking, indeed, the upper stratum of the earth all
round, is composed of the pure vegetable mould, though
in many places it is mixed with large quantities of
other strata, as clay, sand, gravel, &c.; and hence pro-
cceed the differences of soil so well known to those who
practice agriculture.

It has been supposed, by some naturalists, that the
different strata of which the earth is composed were
originally formed at the creation, and have continued
in a manner immutable ever since: but this cannot pos-
sibly have been the case, since we find that many of the
strata are strangely intermixed with each other; the
bones of animals both marine and terrestrial are fre-
quently found at great depths in the earth; beds of
oyster-shells are found of immense extent in several
countries; and concerning these and other shell fish it is re-
markable, that they are generally found much farther
from the bones or teeth either of marine or terrestrial animals. Neither are the shells or other remains of fish found in those countries adjoining
to the seas where they grow naturally, but in the most
distant regions. Mr Whitchurch, in his Inquiry into the
Original State and Formation of the Earth, has given
the following account of many different kinds of ani-
mal's, whose shells and other remains are found
in England; though at present the living animals are
not to be found except in the East and West Indies.

A CATALOGUE of extensi OUS Fossils, shewing where
they were dug up; also their native Climates. Mostly
selected from the curious Cabinet of Mr Russell, in
King-street, Red-Lion Square.

Their names, and Places where found.

There begins the sand, formed in some places from small shells and rubbed pieces of coral; but in others the shores are covered with blackish sand, consisting of the former sort mixed with black, sometimes glittering, particles of mica, and here and there some particles of the refractory iron ores called in England Srim, the ferrum nigrum of Linnaeus, and KALL the molybdenum psamna lapi of the same author. The plains from the shores to the foot of the hills are covered with a very fine thick stratum of black mould, mixed with the abovementioned sand, which the natives manage with shells. The first and lower range of hills are formed of a red ochreous earth, sometimes so intensely red, that the natives use it to paint their canoes and cloth. The higher hills consist of a hard compact, and stiff clayey substance, hardening into stone when out of the reach of the sun and air. At the top of the valleys, along the banks of the rivers, are large masses of coarse granite stones of various mixtures; in one place are pillars of a grey, flinty basalt; and, in several others, fragments of black basalt.

Mr. Forster has given an account of some of the strata of the South-Sea islands, the substance of which may be seen in the following table:

**South Georgia.**

1. No foil, except in a few crevices of the rocks.
2. Ponderous flate, with some irony particles, in horizontal strata, perpendicularly intersected with veins of quartz.

**Southern Isle of New Zealand.**

1. Fine light black mould, in some places nine inches deep, but generally not so much.
2. An argillaceous substance, nearly related to the class of TALCONS, turned into earth by the action of the air.
3. The same substance farther indurated, in oblique strata, generally dipping to the south.

**EASTER ISLAND.**

1. Reddish-brown drily mould, looking as if it had been burnt.
2. Burnt rocks, resembling flags or drofs and other volcanic matters.

**Marquesas.**

1. Clay mixed with mould.
2. An earthy argillaceous substance mixed with tarras and puzzolana.

**Otaheite.**

The shores are coral rock, extending from the reef encircling these isles to the very high-water mark.

---

The chief strata here are clay mixed with aluminous earth, interspersed with lumps of pure chalk. The strata of the clay are about six inches, deviating very little from the horizontal line.

**New Caledonia and the adjacent Isles.**

The strata consist of shell-land, and particles of quartz; the soil in the plains a black mould mixed with this sand. The sides of the hills composed of a yellow ochreous clay, richly speckled with small particles of cat-silver, or a whitish kind of dust, the mica argentia of Linnaeus. The higher parts of the hills consist of a stone called by the German miners geftelstein, composed of quartz and great lumps of the above cat-silver. The latter is sometimes of an intensely red or orange colour, by means of an iron ochre.

"From the above account," says Mr. Forster, "it appears, I think, evidently, that all the high tropical isles of the South Sea have been subject to the action of volcanoes. Pyritic and sulphureous substances, together with a few iron-flakes, and some veiglies of copper, are no doubt found in several of them; but the mountains of New Caledonia are the most likely to contain the richest metallic veins; and the fame opinion, I suppect, may be formed of the mountains in New Zealand."

In the city of Modena in Italy, and for some miles round that place, there is the most singular arrangement of strata perhaps in the whole world. From the surface of the ground to the depth of 14 feet, they meet with nothing but the ruins of an ancient city. Being come to that depth, they find paved streets, artificers' shops, floors of houses, and several pieces of inlaid work. After these ruins they find a very solid earth, which one would think had never been removed; but a little lower they find it black and marshy, and full of briers. Signior Ramazzini in one place found a heap of wheat entire at the depth of 24 feet; in another, he found filbert-
Stratagus.

Stratagus with their nuts. At the depth of about 28 feet, they find a bed of chalk, about 11 feet deep, which cuts very easily; after this a bed of marly earth of about two feet, mixed with ruffs, leaves, and branches. After this bed comes another of chalk, nearly of the same thickness; and which ends at the depth of 42 feet. This is followed by another bed of marly earth like the former; after which comes a new chalk-bed, but thinner, which also has a marly bed underneath it. This ends at the depth of 63 feet; after which they find sand mingled with small gravel, and several marine shells. This stratum is usually about five feet deep, and underneath it is a vast reservoir of water. It is on account of this water that the soil is frequently dug, and the stratagems were often used in this part of the world. After coming to the sandy bottom abovementioned, the workmen pierce the ground with a terabra or auger, when the water immediately springs up with great force, and fills the well to the brim. The flow is perpetual, and neither increases by rain, nor decreases by drought. Sometimes the auger meets with great trees, which give the workmen much trouble; they also sometimes see at the bottom of these wells great bones, coals, flints, and pieces of iron.

It has been ascertained by some, that the specific gravity of the strata constantly increases with the depth from the surface. But Dr. Leigh, in his Natural History of Lancashire, speaking of the coal-pits, denies the strata to lie according to the laws of gravitation; observing, that if the strata there be not a bed of marle, then free-flone, next iron-flone, then coal, or channel mire, then some other strata, then coal again, &c. This determined Mr. Derham to make a nearer inquiry into the matter; accordingly, in 1712, he caused divers places to be bored, laying the several strata by themselves; and afterwards determined very carefully their specific gravity. The result was, that in his yard the strata were gradually specifically heavier and heavier the lower and lower they went; but in another place in his fields, he could not perceive any difference in the specific gravities.

Acquainting the Royal Society therewith, their operator Mr. Haukbee was ordered to try the strata of a coal pit, which he did to the depth of 30 strata: the thickness and specific gravity of each whereof he gives us in a table in the Philosophical Transactions; and from the whole makes this inference, that it evidently appears the gravities of the several strata are in no manner of order, but purely casual, as if mixed by chance.

Stratagem, in the art of war, any device for deceiving and surprising an enemy. The ancients dealt very much in stratagems; the moderns wage war more openly, and on the square. Frontius has made a collection of the ancient stratagems of war.

Strategus, στρατηγός, in antiquity, an officer among the Athenians, whereof there were two chosen yearly, to command the troops of the state.

Plutarch says, there was one chosen from out of each tribe; but Pollux seems to say they were chosen differently out of the people. The people themselves made the choice; and that on the last day of the year, in a place called Paros. The two strategi did not command together, but took their turns day by day; as we find from Herodotus and Cornelius Nepos. Sometimes indeed, as when a person was found of merit, they were found of merit, superior, and exceedingly famed in war, the command was given to him alone: but it was ever a rule, not to put any person in the office but whose estate was in Attica, and who had children, that there might be some inheritances and securities for his conduct and fidelity. Containing the Great, besides many other privileges granted to the city of Athens, honoured its chief magistrate with the title of Meles Strategus, Magnus Deus.

Strath, in the Scottish language, signifies a long narrow valley, with a river running along the bottom.

Strathhearn, a beautiful and extensive valley in Perthshire, bounded on the north by the lofty ridge of mountains called the Grampians, and on the south by the Ochils, which are rounded on the tops and covered with verdure. It is called Strathearn from the river Earn, which runs through the middle of it from west to east for about 30 miles. On each side of the banks of this beautiful stream are many villages and country-seats distinguished for romantic situations. Were we to single out any of the villages, we would mention Crieff, which stands on a fine floping ground on the north side of the Earn, and has been much admired by travellers for its situation, and the variety, contrivance, singularity, and beauty of the prospects which it affords.

Strathnaver, a subdivision or district of the county of Sutherland in Scotland; bounded on the north by the ocean, on the east by Caithness, on the south by Sutherland properly so called, and on the west partly by Ross and partly by the ocean.

Stratiformes, Water-soldiers, in botany: A genus of plants belonging to the class of polyandra, and to the order of Hexagonia; and in the natural system ranking under the first order, palmae. The flower is diphylous: the perianth is trifid. There are three petal, and the berry is six celled and inferior. There are three species, the aloides, the acoroides, and aliso-moides. The aloides alone is of British extraction, which is also called the water alce, or fresh-water soldier. The root confits of long fibres tufted at the ends. The leaves are thick, triangular, pointed, and prickly at the edges. The flowers are white and floating on the water, and blossom in June. This plant may be seen in flow rivers and fen.

Strato, a philosopher of Lampacus, disciple and successor in the school of Xenocrates, about 248 years before the Christian era. He applied himself with uncommon industry to the study of nature; and after the most mature investigations, he supported that nature was inanimate, and that there was no god but nature. (See Plastic Nature.) He was appointed preceptor to Ptolemy Philadephus, who not only revered his abilities, and learning, but also rewarded his labours with unbounded liberality. He wrote different treatises, all now lost.

Strawberry, in botany. See Fragaria. Strawberry Tree. See Arbutus.

END OF THE SEVENTEENTH VOLUME.
ERRATA.

Vol. III. p. 238. col. 1. 20. For "in the 50th," read "in the 75th."

Vol. X. p. 7. col. 1. 22. from bottom. For "isosceles rectangle," read "isosceles triangle."
   p. 471. col. 1. 27. from bottom. For "prevents," read "perverts."

Vol. XIII. p. 304. col. 2. 1. 17. For "after the 364th. in the year 440," read "in the year 312, or, as Caelernus says, in the year 393."

Vol. XIV. p. 67. col. 1. 27. from bottom. For "St Claget," read "Dr Claget."

Vol. XVI. p. 196. col. 2. 1. 23. Instead of the sentence beginning with "In the mean time," read "On the 9th June Admiral Montague fell in with the French fleet returning to port, amounting to 19 sail of the line."
   p. 682. col. 1. 37. For "Milan," read "Milanaw."
   p. 696. col. 2. 1. For "cruising," read "crushing."

Vol. XVII. p. 180. col. 2. 1. 16 from bottom. For "covers them," read "they cover."
   p. 514. col. 2. 1. 12. For "where," read "when."
   p. 533. col. 2. 1. 50. After the word "likewise," add "possibly."
   p. 556. col. 2. 1. 18. from bottom. Erase the sentence beginning with the word "Candidates."
