Let $An^2 + Bn$ be aſſumed, according to the foregoing obſervations, as an univerſal expreſſion for the value of $1 + 2 + 3 + 4 \ldots\ldots n$, where A and B repreſent unknown but determinate quantities. Therefore, ſince the equation is ſuppoſed to hold univerſally, whatſoever is the number of terms, it is evident, that if the number of terms be increaſed by unity, or, which is the ſame thing, if $n + 1$ be wrote therein inſtead of n, the equation will ſtill ſubſiſt; and we ſhall have $A \times \overline{n+1}|^2 + B \times \overline{n+1} = 1 + 2 + 3 + 4 \ldots\ldots n + \overline{n-1}$. From which the firſt equation being ſubtracted, there remains $A \times \overline{n+1}|^2 - An^2 + B \times \overline{n-1} - Bn = n + 1$; this contracted will be $2An + A + B = n + 1$; whence we have $\overline{2A-1} \times n + A + B - 1 = 0$: Wherefore, by taking $2A - 1 = 0$, and $A + B - 1 = 0$, we have $A = \frac{1}{2}$, and $B = \frac{1}{2}$; and conſequently $1 + 2 + 3 + 4 \ldots\ldots n\ (= An^2 + Bn) = \frac{n^2}{2} + \frac{n}{2} = \frac{n \times \overline{n+1}}{2}$.

What is the ſum of the ten firſt terms of the ſeries $1 + 2 + 3$, &c.?

In this caſe $n = 10$, then $\frac{n \times \overline{n+1}}{2} = \frac{10 \times 11}{2} = 55$.

2. Required the ſum of the ſeries $1^2 + 2^2 + 3^2 \ldots\ldots n^2$, or 1, + 4 + 9 + 16......n?

Let $An^3 + Bn^2 + Cn$, according to the aforeſaid obſervations, be aſſumed $= 1^2 + 2^2 + 3^2 \ldots\ldots n^2$; then, as in the preceding caſe, we ſhall have $A \times \overline{n+1}|^3 + B \times \overline{n+1}|^2 + C \times \overline{n+1} = 1^2 + 2^2 + 3^2 \ldots\ldots n^2 \times \overline{n+1}|^2$; that is, by involving $n + 1$ to its ſeveral powers, $An^3 + 3An^2 + 3An + A + Bn^2 + 2Bn + B + Cn + C = 1^2 + 2^2 + 3^2 \ldots n^2 + \overline{n+1}|^2$; from which ſubtracting the former equation, we obtain $3An^2 + 3An + A + 2Bn + B + C\ (= \overline{n+1}|^2) = n^2 + 2n + 1$; and conſequently $\overline{3A-1} \times n^2 + \overline{3A+2B-2} \times n + A + B + C - 1 = 0$; whence $3A - 1 = 0$, $3A + 2B - 2 = 0$, and $A + B + C - 1 = 0$; therefore $A = \frac{1}{3}$, $B = \frac{2-3A}{3} = \frac{1}{2}$, $C = 1 - A - B = \frac{1}{6}$, and conſequently $1 + 4 + 9 + 16 \ldots\ldots n^2 = \frac{n^2}{3} + \frac{n^2}{2} + \frac{n}{6}$, or $\frac{n \cdot \overline{n+1} \cdot \overline{2n+1}}{6}$.

What is the ſum of the ten firſt terms of the ſeries $1^2 + 2^2 + 3^2$, &c.?

Hence $n = 10$, then $\frac{n \cdot \overline{n+1} \cdot \overline{2n+1}}{6} = \frac{10 \times 11 \times 21}{6} = 385$.

3. Required the ſum of the ſeries $1^3 + 2^3 + 3^3 + 4^3 \ldots\ldots n^3$ or $1 + 8 + 27 + 64 \ldots n^3$?

By putting $An^4 + Bn^3 + Cn^2 + Dn = 1 + 8 + 27 + 64 \ldots n^3$; and proceeding as above, we ſhall have $4An^3 + 6an + 4an + A + 3Bn^2 + 3Bn + B + 2Ca + C + D\ (= \overline{n+1}|^3) = n^3 + 3n^2 + 1$, and therefore, $\overline{4A-1} \times n^3 + \overline{6A+3B-3} \times n^2 + \overline{4A+3B+2C-3} \times n + A + B + C + D - 1 = 0$. Hence $A = \frac{1}{4}$, $B\left(= \frac{3-6A}{3}\right) = \frac{1}{2}$, $C\left(= \frac{3-4A-3B}{2}\right) = \frac{1}{4}$, $D\ (= 1 - A - B - C) = 0$; and therefore $1^3 + 2^3 + 3^3 + 4^3 \ldots\ldots n^3 = \frac{n^4}{4} + \frac{n^3}{2} + \frac{n^2}{4}$, or $= \frac{n^2 \times \overline{n+1}|^2}{4}$.

In the very ſame manner it will be found, that

$$1^4 + 2^4 + 3^4 \ldots\ldots n^4 = \frac{n^5}{5} + \frac{n^4}{2} + \frac{n^3}{3} - \frac{n}{30}$$

$$1^5 + 2^5 + 3^5 \ldots\ldots n^5 = \frac{n^6}{6} + \frac{n^5}{2} + \frac{5n^4}{12} - \frac{n^2}{12}$$

$$1^6 + 2^6 + 3^6 \ldots\ldots n^6 = \frac{n^7}{7} + \frac{n^6}{2} + \frac{n^5}{2} - \frac{n^3}{6} + \frac{n}{42}.$$

What is the ſum of the ten firſt terms of the ſeries $1^3 + 2^3 + 3^3$, &c.?

$n = 10$, then $\frac{n^2 \times \overline{n+1}|^2}{4} = \frac{100 \times 121}{4} = 25 \times 121 = 3025$.

4. Required the ſum of n terms of the ſeries of triangular numbers 0, 1, 3, 6, 10.....n.?

Let $An^3 + Bn^2 + Cn = 0, 1, 2, 3 \ldots\ldots n, = s$.—Now the $\overline{n+1}$th term of this ſeries, by Example 2. is $\frac{n^2}{2} + \frac{n}{2}$. Then $A \cdot \overline{n+1}|^3 + B \cdot \overline{n+1}|^2 \cdot C \cdot \overline{n+1} = s + \frac{n^2}{2} + \frac{n}{2}$. Now, the firſt equation being ſubtracted from this, we have $3An^2 + \overline{3A+2B} \times n + A + B + C = \frac{n^2}{2} + \frac{n}{2}$. Or, $3An^2 + 3An +$

$A + C = \frac{n^2}{2} + \overline{\tfrac{1}{2} - 2B} \times n - B.$

Whence, by equating the homologous terms, we have $3A = \frac{1}{2}$, and $A = \frac{1}{6} : \frac{1}{2} - 2B = 3A$; whence $2B = \frac{1}{2} - \frac{1}{2} = 0$, $A + C = - B$. Hence $C = -\frac{1}{6}$, Now, theſe values being ſubſtituted in the above equation, gives the ſum $= \frac{n^3}{6} - \frac{n}{6} =$ $\frac{n \cdot \overline{n-1} \cdot \overline{n+1}}{1 \cdot 2 \cdot 3}$; and if $n + 1$ be put for n, the ſum of n terms of this ſeries will be $\frac{n \cdot \overline{n+1} \cdot \overline{n+2}}{1 \cdot 2 \cdot 3}$.

By proceeding in the ſame manner, the ſum of n terms of pyramidal numbers, 1, 4, 10, 20, 35, &c.... n will be found $= \frac{n \cdot \overline{n+1} \cdot \overline{n+2} \cdot \overline{n+3}}{1 \cdot 2 \cdot 3 \cdot 4}$. And the ſum of any ſeries of figurate numbers is determined by a like formula, the law of continuation being obvious.

What is the ſum of the ten firſt terms of triangular numbers 1, 3, 6, 10, 15, &c.?

Here $n = 10$; then $\frac{n \cdot \overline{n+1} \cdot \overline{n+2}}{1 \cdot 2 \cdot 3} = \frac{10 \times 11 \times 12}{6} = 220$.

5. Let the ſum of the ſeries $\frac{1}{R} + \frac{2}{R^2} + \frac{3}{R^3}$ continued to n terms be required?

If we multiply this ſeries indefinitely continued by $\overline{R-1}|^2$, or $R^2 - 2R + 1$, the product is R; therefore the amount of the indefinite ſeries is $\frac{R}{\overline{R-1}|^2}$, and the ſum of n terms may be found by ſubtracting the terms after the nth from that amount. Now, the terms after the nth are $\frac{n+1}{R^{n+1}} + \frac{n+2}{R^{n+2}}$, &c. which may be divided into the two following ſeries:

Firſt, $\frac{n}{R^n} \times \overline{\frac{1}{R} + \frac{1}{R^2} + \frac{1}{R^3}}$, &c. $= \frac{n}{R^n} \times \frac{1}{R-1}$.

Second, $\frac{1}{R^n} \times \overline{\frac{1}{R} + \frac{2}{R^2} + \frac{3}{R^3}}$, &c. $= \frac{1}{R^n} \times \frac{R}{\overline{R-1}|^2}$.

Now, if we write a for $\frac{1}{R^n}$, and r for $R - 1$, and ſubtract the ſum of theſe two ſeries from the amount of the propoſed ſeries indefinitely continued, the remainder will be found $= \frac{1-a}{r} \times R - \frac{na}{r}$.

6. Let the ſum of the ſeries $\frac{n-1}{nR} + \frac{n-2}{nR^2} + \frac{n-3}{nR^2}$ &c. be required?

This ſeries is equal to the difference of the two following.

Firſt, $\frac{n}{nR} + \frac{n}{nR^2} + \frac{n}{nR^3}$, &c. $= \frac{1}{R} + \frac{1}{R^2} + \frac{1}{R^3}$, &c. $= \frac{1-a}{r}$.

Second, $\frac{1}{nR} + \frac{2}{nR^2} + \frac{3}{nR^3}$, &c. $= \frac{1}{n} \times \overline{\frac{1}{R} \times \frac{1}{R^2} + \frac{1}{R^3}}$ &c. $= \frac{1}{n} \times \frac{1-a}{r} \times R - \frac{a}{r}$.

The difference of theſe ſeries is $\frac{1-a}{r} - \frac{R}{n} \times \frac{1-a}{r} + \frac{a}{r}$, which reduced becomes $\frac{\overline{n+a-1} \times \overline{r+a-1}}{nr^2}$.

To proceed farther would lead us far beyond the limits aſſigned for this article; we muſt therefore refer thoſe who require more information on this ſubject to the following authors.—Bertrand's *Developpement*, &c. vol. 1; Dodſon's Mathematical Repoſitory, vol. 1; Emerſon's Algebra; Appendix to Graveſend's Algebra; Hutton's Paper on Cubic Equations and Infinite Series, in the Philoſophical Tranſactions for 1780; Maclaurin's Fluxions: Malcolm's Arithmetic; Maſere's Annuities; and *Scriptores Logarithmici*, &c.; De Moivre's Doctrine of Chances, and a Paper by the ſame author in the Philoſophical Tranſactions, n° 240: Simpſon's Algebra, Eſſays, Fluxions, and Miſcellanies; Sterling's *Summatio et Interpolatio Serierum; Syntagma Matheſios*, &c.

SERINGAPATAM, the capital of Myſore, the dominions of Tippoo Sultan, is ſituated in an iſland of the Cavery river, about 290 or 300 miles from Madras. The iſland, upon ſurvey, appeared to be about four miles in length by one and a half in breadth, acroſs the middle, where it is likewiſe higheſt, whence it gradually falls and narrows towards the extremities. The weſt end of the iſland, on which there is a fort of conſiderable ſtrength, ſlopes more, eſpecially towards the north; and the ground riſing on the oppoſite ſide of the river commands a diſtinct view of every part of the fort. The fort and outworks occupy about a mile of the weſt end of the iſland, and are diſtinguiſhed by magnificent buildings, and ancient Hindoo pagódas, contraſted with the more lofty and ſplendid monuments lately raiſed in honour of the Mahometan faith. The great garden, called the *Laul Baug*, covers about as much of the eaſt end of the iſland as the fort and outworks do of the weſt; and the whole intermediate ſpace, except a ſmall incloſure, on the north bank near the fort, was, before the laſt war, filled with houſes, and formed an extenſive ſuburb, of which the greateſt part was deſtroyed by Tippoo to make room for batteries to defend the iſland when attacked by the combined forces of Earl Cornwallis and the Mahratta chiefs in February 1792. This ſuburb, or town of modern ſtructure, is about half a mile ſquare, divided into regular croſs ſtreets, all wide, and ſhaded on each ſide by trees. It is ſurrounded by a ſtrong mud wall, contains many good houſes, and ſeems to have been preſerved by the Sultan for the accommodation of merchants, and for the convenience of troops ſtationed on that part of the iſland for its defence. A little to the eaſtward of the town is the entrance to the great garden, which was laid out in regular ſhady walks of large cypreſs trees, and abounding with fruit-trees, flowers, and vegetables of every deſcription. It poſſeſſed all the beauty and elegance of a country retirement, and was dignified by the mauſoleum of Hyder the late ſultan, and a ſuperb new palace built by his ſon. This noble garden was devoted to deſtruction; and the trees which had ſhaded their proud maſter, and contributed to his pleaſures, were formed into the means of protecting his enemies in ſubverting his empire. Before that event, ſo glorious to the arms of England, this inſulated metropolis

 (ſays

(says Major Dirom) must have been the richest, most convenient, and breautiful spot possessed in the present age by any native prince in India; but when the allies left it, the Sultan's fort and city only remained in repair amidst all the wrecks of his former grandeur, the island presenting nothing but the appearance of wretched barrenness. Tippoo is a man of talents, enterprise, and great wealth; but in the opinion of our author, the remaining years of his ill-fated life will be unequal to renew the beauties of his terrestrial paradise. N. Lat. 12° 31′ 45″. E. Long. 96° 46′ 45″.

SERINGHAM, an island of Indostan, formed about six miles north-west of Trinchinopoly by the river Cavery, which divides itself into two branches: that to the northward takes the name of *Coleroon*, but the southern branch preserves its old name the *Cavery*. Each of these rivers, after a course of about 90 miles, empty themselves into the sea; the Coleroon at Devicottah, and the Cavery near Tranquebar, at about 20 miles distance from one another. In this island facing Trinchinopoly, stood a famous pagoda surrounded by seven square walls of stone, 25 feet high and four feet thick. The space between the outward and second walls measured 310 feet, and so proportionably of the rest. Each enclosure had four large gates, with a high tower; which were placed, one in the middle of each side of the inclosure, and opposite to the four cardinal points. The outward wall was about four miles in circumference, and its gateway to the south was ornamented with pillars, some of which were single stones 33 feet in length and five in diameter; while those that formed the roof were still larger; and in the inmost inclosure were the chapels.—About half a mile to the east was another large pagoda called *Jumbikistna*, which had but one inclosure.

The pagoda of Seringham was held in great veneration, from a belief that it contained the identical image of the god Wistnou worshipped by Brama; and pilgrims came here from all parts of India with offerings of money to procure absolution. A large part of the revenue of the island was allotted for maintenance of the Bramins who inhabited the pagoda; and these, with their families, formerly amounted to no fewer than 40,000 persons, all maintained by the superstitious liberality of the adjacent country.

SERIOLA, in botany: A genus of plants belonging to the order of polygamia æqualis, and to the class of syngenesia; and in the natural system ranged under the 49th order, *Compositæ*. The receptacle is paleaceous; the calyx simple; and the pappus is somewhat plumose. There are four species; 1. The Levigata. 2. Æthnensis. 3. Cretensis. 4. Urens. The first is a native of the island of Candia, and flowers in July and August; the second is a native of Italy; and the fourth is a native of the south of Europe.

SERIPHIUM, in botany; a genus of plants belonging to the order of monogamia, and to the class of syngenesia. The calyx is imbricated; the corolla is monopetalous and regular, with one oblong seed under it. There is only one species, the *cinereum*, which is a native of the Cape of Good Hope.

SERIPHUS (anc. geog.), one of the Cyclades or islands in the Ægean sea, called *Saxum Seriphium* by Tacitus, as if all a rock; one of the usual places of banishment among the Romans. The people, *Seriphii*; who, together with the Siphnii, joined Greece against Xerxes, were almost the only islanders who refused to give him earth and water in token of submission, (Herodotus). *Seriphea Rana*, a proverbial saying concerning a person who can neither sing nor say; frogs in this island being said to be dumb, (Pliny).

SERMON, a discourse delivered in public, for the purpose of religious instruction and improvement.

Funeral Sermon. See *Funeral Orations*.

SERON of almonds, is the quantity of two hundred weight; of anise seed, it is from three to four hundred; of Castile soap, from two hundred and an half to three hundred and three quarters.

SEROSITY, in medicine, the watery part of the blood.

SERPENS, in astronomy, a constellation in the northern hemisphere, called more particularly *Serpens Ophiuchi*. The stars in the constellation Serpens, in Ptolemy's catalogue, are 18; in Tycho's, 13; in Hevelius's, 22; and in the Britannic catalogue, 64.

Serpens Biceps, or *Double-headed Snake*; a monster of the serpent kind there being no permanent species of this conformation. That represented on Plate CCCCXLIX. and copied from Edwards, came from the island of Barbadoes; and was said to have been taken out of an egg of the size of a small pullet's egg by a man who found it under-ground as he was digging. The heads were not in an hozontal position when the snake lay on its belly, but inclined to each other on their under-sides leaving an opening for the throat to come in between the two heads underneath, as is expressed at A. The upper side, for the whole length, was covered with small scales, falling one over another; the belly was covered with single scales running across it, in the form of half rings. It was all over of a yellowish colour, without any spots or variation. Mr Edwards also informs us, that a person brought to him a common English snake, which had two heads quite separate from each other, the necks parting about an inch from the head.

Serpens, *Serpent*, in the Linnæan system of zoology, an order of animals belonging to the class of *amphibia*, and comprehending six genera, viz. the *crotalus*, or rattle-snake; the *boa*, including ten species: the *coluber*, or viper; the *anguis*, or snake; the *amphisbæna*, or annulated snake, the body and tail of which are composed of annular segments; and the *cæcilia*, or tentaculated snake, the body and tail of which are wrinkled, without scales, and the upper part furnished with two feelers; and including two species. See an account of these genera under their respective names.

1 Distinguishing character of serpents.

The characters of serpents, according to Linnæus, are these: They are amphibious animals, breathing through the mouth by means of lungs only; having a tapering body, no distinct neck; the jaws not articulated, but dilatable, and destitute of feet, fins, and ears.

2 General observations.

The serpent has from the beginning been the enemy of man; and it has hitherto continued to terrify and annoy him, notwithstanding all the arts which have been practised to destroy it. Formidable in itself, it deters the invader from the pursuit; and from its figure, capable of finding shelter in a little space, it is not easily discovered by those who would venture to encounter it. Thus possessed at once of potent arms, and inaccessible or secure retreats, it baffles all the

Serpens. arts of man, though ever so earnestly bent upon its destruction. For this reason, there is scarce a country in the world that does not still give birth to this poisonous brood, that seems formed to quell human pride, and repress the boast of security. Mankind have driven the lion, the tyger, and the wolf, from their vicinity; but the snake and the viper still defy their power.

Their numbers, however, are thinned by human assiduity; and it is possible some of the kinds are wholly destroyed. In none of the countries of Europe are they sufficiently numerous to be truly terrible. The various malignity that has been ascribed to European serpents of old is now utterly unknown; there are not above three or four kinds that are dangerous, and their poison operates in all in the same manner. The drowsy death, the starting of the blood from every pore, the insatiable and burning thirst, the melting down the solid mass of the whole form into one heap of putrefaction, said to be occasioned by the bites of African serpents, are horrors with which we are entirely unacquainted.

But though we have thus reduced these dangers, having been incapable of wholly removing them, in other parts of the world they still rage with all their ancient malignity. In the warm countries that lie within the tropics, as well as in the cold regions of the north, where the inhabitants are few, the serpents propagate in equal proportion. But of all countries those regions have them in the greatest abundance where the fields are unpeopled and fertile, and where the climate supplies warmth and humidity. All along the swampy banks of the river Niger or Oroonoko, where the sun is hot, the forests thick, and the men but few, the serpents cling among the branches of the trees in infinite numbers, and carry on an unceasing war against all other animals in their vicinity. Travellers have assured us, that they have often seen large snakes twining round the trunk of a tall tree, encompassing it like a wreath, and thus rising and descending at pleasure.—We are not, therefore, to reject as wholly fabulous the accounts left us by the ancients of the terrible devastations committed by a single serpent. It is probable, in early times, when the arts were little known, and mankind were but thinly scattered over the earth, that serpents, continuing undisturbed possessors of the forest, grew to an amazing magnitude; and every other tribe of animals fell before them. It then might have happened, that the serpents reigned tyrants of the district for centuries together. To animals of this kind, grown by time and rapacity to 100 or 150 feet in length, the lion, the tiger, and even the elephant itself, were but feeble opponents. That horrible fœtor, which even the commonest and the most harmless snakes are still found to diffuse, might, in these larger ones, become too powerful for any living being to withstand; and while they preyed without distinction, they might thus also have poisoned the atmosphere around them. In this manner, having for ages lived in the hidden and unpeopled forest, and finding, as their appetites were more powerful, the quantity of their prey decreasing, it is possible they might venture boldly from their retreats into the more cultivated parts of the country, and carry consternation among mankind, as they had before desolation among the lower ranks of nature. We have many histories of antiquity, presenting as such a picture, and exhibiting a whole nation sinking under the ravages of a single serpent. At that time man had not learned the art of uniting the efforts of many to effect one great purpose. Opposing multitudes only added new victims to the general calamity, and increased mutual embarassment and terror. The animal was therefore to be singly opposed by him who had the greatest strength, the best armour, and the most undaunted courage. In such an encounter, hundreds must have fallen; till one, more lucky than the rest, by a fortunate blow, or by taking the monster in its torpid interval, and surcharged with spoil, might kill, and thus rid his country of the destroyer. Such was the original occupation of heroes; and those who first obtained that name, from their destroying the ravagers of the earth, gained it much more deservedly than their successors, who acquired their reputation only for their skill in destroying each other. But as we descend into more enlightened antiquity, we find these animals less formidable, as being attacked in a more successful manner. We are told, that while Regulus led his army along the banks of the river Bagrada in Africa, an enormous serpent disputed his passage over. We are assured by Pliny, that it was 120 feet long, and that it had destroyed many of the army. At last, however, the battering engines were brought out against it; and these assailing it at a distance, it was soon destroyed. Its spoils were carried to Rome, and the general was decreed an ovation for his success. There are, perhaps, few facts better ascertained in history than this: an ovation was a remarkable honour; and was given only for some signal exploit that did not deserve a triumph: no historian would offer to invent that part of the story at least, without being subject to the most shameful detection. The skin was kept for several years after in the Capitol; and Pliny says he saw it there. At present, indeed, such ravages from serpents are scarce seen in any part of the world; not but that, in Africa and America, some of them are powerful enough to brave the assaults of men to this day.

Nequent expleri corda tuendo
Terribiles oculos villosaque setis pectore.

If we take a survey of serpents in general, they have marks by which they are distinguished from all the rest of animated nature. They have the length and the suppleness of the eel, but want fins to swim with; they have the scaly covering and pointed tail of the lizard, but they want legs to walk with; they have the crawling motion of the worm, but, unlike that animal, they have lungs to breathe with: like all the reptile kind, they are resentful when offended; and nature has supplied them with terrible arms to revenge every injury.

3 Conformation of their mouth.

Though they are possessed of very different degrees of malignity, yet they are all formidable to man, and have a strong similitude of form to each other. With respect to their conformation, all serpents have a very wide mouth in proportion to the size of the head; and, what is very extraordinary, they can gape and swallow the head of another animal which is three times as big as their own. However, it is no way surprising that the skin of the snake should stretch to receive so large a morsel; the wonder seems how the jaws could take it

in.

in. To explain this, it muſt be obſerved, that the jaws of this animal do not open as ours, in the manner of a pair of hinges, where bones are applied to bones, and play upon one another: on the contrary, the ſerpent's jaws are held together at the roots by a ſtretching muſcular ſkin; by which means they open as widely as the animal chooſes to ſtretch them, and admit of a prey much thicker than the ſnake's own body. The throat, like ſtretching leather, dilates to admit the morſel; the ſtomach receives it in part, and the reſt remains in the gullet, till putrefaction and the juices of the ſerpent's body unite to diſſolve it.

4 Their teeth. Some ſerpents have fangs or canine teeth, and others are without them. The teeth in all are crooked and hollow; and, by a peculiar contrivance, are capable being erected or depreſſed at pleaſure.

5 Eyes. The eyes of all ſerpents are ſmall, if compared to the length of the body; and though differently coloured in different kinds, yet the appearance of all is malign and heavy; and, from their known qualities, they ſtrike the imagination with the idea of a creature meditating miſchief. In ſome, the upper eyelid is wanting, and the ſerpent winks only with that below; in others, the animal has a nictitating membrane or ſkin, reſembling that which is found in birds, which keeps the eye clean and preſerves the ſight. The ſubſtance of the eye in all is hard and horny; the cryſtalline humour occupying a great part of the globe.

The holes for hearing are very viſible in all: but there are no conduits for ſmelling; though it is probable that ſome of them enjoy that ſenſe in tolerable perfection.

6 Tongue. The tongue in all theſe animals is long and forky. It is compoſed of two long fleſhy ſubſtances, which terminate in ſharp points, and are very pliable. At the root it is connected very ſtrongly to the neck by two tendons, that give it a variety of play. Some of the viper kind have tongues a fifth part of the length of their bodies; they are continually darting them out; but they are entirely harmleſs, and only terrify thoſe who are ignorant of the real ſituation of their poiſon.

7 Gullet. If from the jaws we go on to the gullet, we ſhall find it very wide for the animal's ſize, and capable of being diſtended to a great degree; at the bottom of this lies the ſtomach, which is not ſo capacious, and receives only a part of the prey, while the reſt continues in the gullet for digeſtion. When the ſubſtance in the ſtomach is diſſolved into chyle, it paſſes into the inteſtines, and from thence goes to nouriſhment, or to be excluded by the vent.

8 Lungs and heart. Like moſt other animals, ſerpents are furniſhed with lungs, which we ſuppoſe are ſerviceable in breathing, though we cannot perceive the manner in which this operation is performed; for though ſerpents are often ſeen apparently to draw in their breath, yet we cannot find the ſmalleſt ſigns of their ever reſpiring it again. Their lungs, however, are long and large, and doubtleſs are neceſſary to promote their languid circulation. The heart is formed as in the tortoiſe, the frog, and the lizard kinds, ſo as to work without the aſſiſtance of the lungs. It is ſingle; the greateſt part of the blood flowing from the great vein to the great artery by the ſhorteſt courſe. By this contrivance of nature we eaſily gather two conſequences; that ſnakes are amphibious, being equally capable of living on land and in the water; and that alſo they are torpid in winter, like the bat, the lizard, and other animals formed in the ſame manner.

9 Mode of generation. The vent in theſe animals ſerves for the emiſſion of the urine and the fæces, and for the purpoſe of generation. The inſtrument of generation in the male is double, being forked like the tongue: the ovaries in the female are double alſo; and the aperture is very large, in order to receive the double inſtrument of the male. They copulate in their retreats; and it is ſaid by the ancients, that in this ſituation they appear like one ſerpent with two heads.

10 Number of joints in the back-bone. As the body of this animal is long, ſlender, and capable of bending in every direction, the number of joints in the back-bone are numerous beyond what one would imagine. In the generality of quadrupeds, they amount to not above 30 or 40; in the ſerpent kind they amount to 145 from the head to the vent, and 25 more from that to the tail. The number of theſe joints muſt give the back-bone a ſurpriſing degree of pliancy; but this is ſtill increaſed by the manner in which each of theſe joints are locked into the other. In man and quadrupeds, the flat ſurfaces of the bones are laid one againſt the other, and bound tight by ſinews; but in ſerpents, the bones play one within the other like ball and ſocket, ſo that they have full motion upon each other in every direction.

11 Number of ribs. Though the number of joints in the back-bone is great, yet that of the ribs is ſtill greater; for, from the head to the vent, there are two ribs to every joint, which makes their number 290 in all. Theſe ribs are furniſhed with muſcles, four in number; which being inſerted into the head, run along to the end of the tail, and give the animal great ſtrength and agility in all its motions.

12 Scales. The ſkin alſo contributes to its motions, being compoſed of a number of ſcales united to each other by a tranſparent membrane, which grows harder as it grows older, until the animal changes, which is generally done twice a-year. This cover then burſts near the head, and the ſerpent creeps from it by an undulatory motion, in a new ſkin, much more vivid than the former. If the old ſlough be then viewed, every ſcale will be diſtinctly ſeen like a piece of net-work, and will be found greateſt where the part of the body they covered was largeſt.

There is much geometrical neatneſs in the diſpoſal of the ſerpent's ſcales, for aſſiſting the animal's ſinuous motion. As the edge of the foremoſt ſcales lie over the ends of their following ſcales, ſo thoſe edges, when the ſcales are erected, which the animal has a power of doing in a ſmall degree, catch in the ground, like the nails in the wheel of a chariot, and ſo promote and facilitate the animal's progreſſive motion. The erecting theſe ſcales is by means of a multitude of diſtinct muſcles with which each is ſupplied, and one end of which is tacked each to the middle of the foregoing.

In ſome of the ſerpent kind there is the exacteſt ſymmetry in theſe ſcales; in others they are diſpoſed more irregulary. In ſome there are larger ſcales on the belly, and often anſwering to the number of ribs; in others, however, the animal is without them. Upon this ſlight difference, Linnæus has founded his diſtinctions of the various claſſes of the ſerpent tribe.

13 Their ſize. When we come to compare ſerpents with each other, the

the first great distinction appears in their size; no other tribe of animals differing so widely in this particular. This tribe of animals, like that of fishes, seems to have no bounds put to their growth: their bones are in a great measure cartilaginous, and they are consequently capable of great extension: the older, therefore, a serpent becomes, the larger it grows; and as they seem to live to a great age, they arrive at an enormous size.

Leguat assures us, that he saw one in Java that was 50 feet long. Carli mentions their growing to above 40 feet; and there is now the skin of one in the British Musæum that measures 32. Mr Wentworth, who had large concerns in the Berbices in America, assures us, that in that country they grow to an enormous length. He one day sent out a soldier, with an Indian, to kill wild fowl for the table; and they accordingly went some miles from the fort: in pursuing their game, the Indian, who generally marched before, beginning to tire, went to rest himself upon the fallen trunk of a tree, as he supposed it to be; but when he was just going to sit down, the enormous monster began to move; and the poor savage perceiving that he had approached a *boa*; the greatest of all the serpent kind. dropped down in an agony. The soldier, who perceived at some distance what had happened, levelled at the serpent's head, and by a lucky aim shot it dead: however, he continued his fire until he was assured that the animal was killed; and then going up to rescue his companion, who was fallen motionless by its side, he, to his astonishment, found him dead likewise, being killed by the fright. Upon his return to the fort, and telling what had happened, Mr Wentworth ordered the animal to be brought up, when it was measured, and found to be 36 feet long. He had the skin stuffed, and then sent to Europe as a present to the prince of Orange, in whose cabinet it was lately to be seen at the Hague; but the skin is shrunk, by drying, two or three feet. In the East Indies they grow also to an enormous size, particularly in the island of Java, where, we are assured, that one of them will destroy and devour a buffalo. See Boa.

14 Gluttony,

But it is happy for mankind that the rapacity of these frightful creatures is often their punishment; for when ever any of the serpent kind have gorged themselves in this manner, whenever their body is seen particularly distended with food, they then become torpid, and may be approached and destroyed with safety. Patient of hunger to a surprising degree, whenever they seize and swallow their prey, they seem, like surfeited gluttons, unwieldy, stupid, helpless, and sleepy: they at that time seek some retreat, where they may lurk for several days together, and digest their meal in safety: the smallest effort at that time is capable of destroying them; they can scarce make any resistance; and they are equally unqualified for flight or opposition: that is the happy opportunity of attacking them with success; at that time the naked Indian himself does not fear to assail them. But it is otherwise when this sleepy interval of digestion is over; they then issue, with famished appetites, from their retreats, and with accumulated terrors, while every animal of the forest flies before them.

15 And abstinence,

But though these animals are of all others the most voracious, and though the morsel which they swallow without chewing, is greater than what any other creature, either by land or water, can devour; yet no animals upon earth bear abstinence so long as they. A single meal, with many of the snake kind, seems to be the adventure of a season; it is an occurrence, of which they have been for weeks, nay sometimes for months, in patient expectation. When they have seized their prey, their industry for several weeks is entirely discontinued; the fortunate capture of an hour often satisfies them for the remaining period of their annual activity. As their blood is colder than that of most other terrestrial animals, and as it circulates but slowly through their bodes, so their powers of digestion are but feeble. Their prey continues, for a long time, partly in the stomach, partly in the gullet, and is often seen in part hanging out of the mouth. In this manner it digests by degrees; and in proportion as the part below is dissolved, the part above is taken in. It is not therefore till this tedious operation is entirely performed, that the serpent renews its appetite and its activity. But should any accident prevent it from issuing once more from its cell, it still can continue to bear famine for weeks, months, nay for years together. Vipers* are often kept in boxes for six or eight months, without any food whatever; and there are little serpents sometimes sent over to Europe from Grand Cairo, that live for several years in glasses, and never eat at all, nor even stain the glass with their excrements.

*See abstinence.

16 Food.

Other creatures have a choice in their provision: but the serpent indiscriminately preys upon all; the buffalo, the tiger, and the gazelle. One would think that the porcupine's quills might be sufficient to protect it; but whatever has life serves to appease the hunger of these devouring creatures: porcupines, with all their quills, have frequently been found in their stomachs when killed and opened; nay, they most frequently are seen to devour each other.

17 Places which they frequent.

A life of savage hostility in the forest offers the imagination one of the most tremendous pictures in nature. In those burning countries, where the sun dries up every brook for hundreds of miles round; when what had the appearance of a great river in the rainy season, becomes, in summer, one dreary bed of sand; in those countries a lake that is never dry, or a brook that is perennial—is considered by every animal as the greatest convenience of nature. When they have discovered this, no dangers can deter them from attempting to slake their thirst. Thus the neighbourhood of a rivulet, in the heart of the tropical continents, is generally the place where all the hostile tribes of nature draw up for the engagement. On the banks of this little envied spot, thousands of animals of various kinds are seen venturing to quench their thirst, or preparing to seize their prey. The elephants are perceived in a long line, marching from the darker parts of the forest; the buffaloes, are there, depending upon numbers for security; the gazelles relying solely upon their swiftness; the lion and tiger waiting a proper opportunity to seize; but chiefly the larger serpents are upon guard there, and defend the accesses of the lake. Not an hour passes without some dreadful combat; but the serpent, defended by its scales, and naturally capable of sustaining a multitude of wounds, is, of all others, the most formidable. It is the most wakeful also; for the whole tribe sleep with their eyes open, and are consequently for ever upon the watch; so that, till their rapacity is satisfied,

few

Serpens.

few other animals will venture to approach their station.

18 The sound which they utter.

In comparing serpents as to their voices, some are found silent, some have a peculiar cry; but hissing is the sound which they most commonly send forth, either as a call to their kind, or as a threat to their enemies. In the countries where they abound, they are generally silent in the middle of the day, when they are obliged to retire from the heat of the climate; but as the cool of the evening approaches, they are then heard issuing from their cells with continued hissings; and such is the variety of their notes, that some have assured us they very much resemble the music of an English grove. This some will hardly credit; at any rate, such notes, however melodious, can give but very little delight, when we call to mind the malignity of the minstrel. If considered, indeed, as they answer the animal's own occasions, they will be found well adapted to its nature, and fully answering the purposes of terrifying such as would venture to offend it.

19 How they move.

With respect to motion, some serpents, particularly those of the viper kind, move slowly; while others dart with amazing swiftness. The motion in all is similar; but the strength of body in some gives a very different appearance. The viper, that is but a slow feeble-bodied animal, makes way in a heavy undulating manner; advancing its head, then drawing up its tail behind, and bending the body into a bow; then from the spot where the head and tail were united, advancing the head forward as before. This, which is the motion of all serpents, is very different from that of the earth-worm or the naked snail. The serpent, as was said above, has a back-bone, with numerous joints; and this bone the animal has power of bending in every direction, but without being able to shorten or lengthen it at pleasure. The earth-worm, on the other hand, has no back-bone; but its body is composed of rings, which, like a barber's puff, it can lengthen or shorten as it finds necessary. The earth-worm, therefore, in order to move forward, lengthens the body; then by the fore part clings to the ground where it has reached, and then contracts and brings up its rear: then, when the body is thus shortened, the fore-part is lengthened again for another progression, and so on. The serpent, instead of shortening the body, bends it into an arch; and this is the principal difference between serpentine and vermicular progression.

We have instanced this motion in the viper, as most easily discerned; but there are many serpents that dart with such amazing swiftness, that they appear rather to leap than crawl. It is most probable, however, that no serpent can dart upon even ground farther than its own length at one effort. Our fears indeed may increase the force of their speed, which is sometimes found so fatal. We are told by some, that they will dart to a very great distance; but this we have never been able to ascertain. The manner of progression in the swiftest serpent we know, which is the jaculus, is by instantly coiling itself upon its tail, and darting from thence to its full extent: then carrying the tail, as quick as lightning, to the head; coiling and darting again; and by this means proceeding with extreme rapidity, without ever quitting the ground. Indeed, if we consider the length and the weakness of the back-bone in all these animals; if we regard the make of the vertebræ, in which we shall find the junctures all formed to give play, and none to give power; we cannot be of opinion that they have a faculty of springing from the ground, as they entirely want a *fulcrum*, if we may so express it, from whence to take their spring; the whole body being composed of unsupported muscles and joints that are yielding.

Serpens.

20 Though amphibious yet they die when immersed in water.

Though all serpents are amphibious, some are much fonder of the water than others; and though destitute of fins or gills, remain at the bottom, or swim along the surface, with great ease. From their internal structure, we see how well adapted they are for either element: and how capable their blood is of circulating at the bottom as freely as in the frog or the tortoise. They can, however, endure to live in fresh water only; for salt is an effectual bane to the whole tribe. The greatest serpents are most usually found in fresh water, either choosing it as their favourite element, or finding their prey in such places in the greatest abundance. But that all will live and swim in liquids, appears from an experiment of Redi; who put a serpent into a large glass vessel of wine, where it lived swimming about six hours; though, when it was by force immersed and put under that liquid, it lived only one hour and an half. He put another in common water, where it lived three days; but when it was kept under water it lived only about 12 hours. Their motion there, however, is perfectly the reverse of what it is upon land; for in order to support themselves upon an element lighter than their bodies, they are obliged to increase their surface in a very artificial manner. On earth their windings are perpendicular to the surface; in water they are parallel to it: in other words, if a person should wave his hand up and down, it will give an idea of the animal's progress on land; if to the right and left, it will give some idea of its progress on the water.

21 Fœtor.

Some serpents have a most horrible fœtor attending them, which is alone capable of intimidating the brave. This proceeds from two glands near the vent, like those in the weasel or polecat; and, like those animals, in proportion as they are excited by rage or by fear the scent grows stronger. It would seem, however, that such serpents as are most venomous are least offensive in this particular; since the rattle snake and the viper have no smell whatever; nay, we are told, that at Calicut and Cranganon, in the East Indies, there are some very noxious serpents, who are so far from being disagreeable, that their excrements are sought after, and kept as the most pleasing perfume. The Esculapian serpent is also of this number.

22 Some viviparous, others oviparous.

Some serpents bring forth their young alive, as the viper; some bring forth eggs, which are hatched by the heat of their situation, as the common black snake, and the majority of the serpent tribe. When a reader, ignorant of anatomy, is told, that some of those animals produce their young alive, and that some produce eggs only, he is apt to suppose a very great difference in the internal conformation, which makes such a variety in the manner of bringing forth. But this is not the case: these animals are internally alike, in whatever manner they produce their young; and the variety in their bringing forth is rather a slight than a real discrimination. The only difference is, that the viper hatches her eggs, and brings them to maturity, within her body; the snake is more premature in her productions,

Serpent.

tions, and sends her eggs into the light some time before the young ones are capable of leaving the shell. Thus, if either are opened, the eggs will be found in the womb, covered with their membranous shell, and adhering to each other like large beads on a string. In the eggs of both, the young ones will be found, though at different stages of maturity: those of the viper will crawl and bite in the moment the shell that incloses them is broke open: those of the snake are not yet arrived at their perfect form.

Father Labat took a serpent of the viper kind that was nine feet long, and ordered it to be opened in his presence. He then saw the manner in which the eggs of these animals lie in the womb. In this creature there were six eggs, each of the size of a goose egg, but longer, more pointed, and covered with a membranous skin, by which also they were united to each other. Each of these eggs contained from 13 to 15 young ones, about six inches long, and as thick as a goose-quill. Though the female from whence they were taken was spotted, the young seemed to have a variety of colours very different from the parent; and this led the traveller to suppose that the colour was no characteristic mark among serpents. These little mischievous animals were no sooner let loose from the shell, than they crept about, and put themselves into a threatening posture, coiling themselves up and biting the stick with which he was destroying them. In this manner he killed 74 young ones; those that were contained in one of the eggs escaped at the place where the female was killed, by the bursting of the egg and their getting among the bushes.

22 Fascinating power ascribed to serpents.

The fascinating power ascribed to serpents, especially to rattlesnakes, by which they are said to draw animals to them, is very curious. It has been described by so many different persons, who affirmed that they had seen instances of it, and has been believed by so many men of penetration and discernment, that it deserves at least to be mentioned. The rattlesnake fixes its eyes upon any animal, such as a bird or a squirrel. When the animal spies the snake, it skips from spray to spray, hovering and approaching nearer the enemy; descending, with distracted gestures and cries, from the top of the loftiest trees to the mouth of the snake, who opens his jaws, and in an instant swallows the unfortunate animal.

The following instances of fascination has so much the appearance of fiction, that it would require a very uncommon degree of evidence to render them credible. They are extracted from a paper in the Gentleman's Magazine for the year 1765, p 511. which was communicated by Mr Peter Collinson from a correspondent in Philadelphia.

"A person of good credit was travelling by the side of a creek or small river, where he saw a ground squirrel running to and fro between the creek and a great tree a few yards distant; the squirrel's hair looking very rough, which showed he was scared, and his returns being shorter and shorter, the man stood to observe the cause, and soon spied the head and neck of a rattlesnake pointing at the squirrel through a hole of a great tree, it being hollow; the squirrel at length gave over running, and laid himself quietly down with his head close to the snake's; the snake then opened his mouth wide, and took in the squirrel's head; upon which the man gave the snake a whip across the neck, and so the squirrel being released, he ran into the creek.

"When I was about 13 years old, I lived with William Atkinson, an honest men in Bucks county, who, returning from a ride in warm weather, told us, that while his horse was drinking at a run, he heard the cry of a blackbird, which he spied on the top of a sapling, fluttering and straining the way he seemed unwilling to fly, and holding so fast the sprigs he was perched upon that the sapling top bent. After he had viewed the bird a few minutes, it quitted the place, and made a circle or two higher in the air, and then resumed its former standing, fluttering and crying: Thereupon William rode the way the bird strained, and soon spied a large black snake in coil, steadily eyeing the bird. He gave the snake a lash with his whip, and this taking off the snake's eye from his prey, the charm was broken, and away fled the bird, changing its note to a song of joy.

"Mr. Nicholas Scull, a surveyor, told me, that when he was a young man, as he happened once to be leaning upon a fence, and looking over it, he saw a large rattlesnake in coil, looking steadfastly at him. He found himself surprised and listless immediately, and had no power for about a minute (as he thinks) but to look at the snake, and then he had the resolution to push himself from the fence, and turn away, feeling such horror and confusion as he would not undergo again for any consideration.

"Doctor Chew tells me, a man in Maryland was found fault with by his companion that he did not come along; the companion stepping towards him, observed that his eyes were fixed upon a rattlesnake which was gliding slowly towards him, with his head raised as if he was reaching up at him; the man was leaning towards the snake, and saying to himself, *he will bite me! he will bite me!* Upon which his companion caught him by the shoulder, and pulled him about, and cried out, *What the devil ails you? He will bite you sure enough!* This man found himself very sick after his enchantment."

The fascinating power of serpents was believed by Dr Mead and other eminent men, who certainly thought they had sufficient evidence for admitting it. Incredible therefore as it appears, it ought not to be rejected without examination; though being of a very extraordinary nature, it cannot be received without unquestionable evidence. Scepticism is no less absurd than credulity; and the true philosopher will carefully avoid both. Human knowledge is founded on observation and experience; not, however, on every man's personal observation and experience, but on the united observation and experience of all mankind. But this presupposes the credibility of human testimony in every case that does not involve an impossibility. All the laws of nature are not yet known, nor all the wonderful powers of which she is possessed. It is not more incredible *à priori*, that the eye of a serpent should attract an animal than that a magnet should attract a piece of iron, or a piece of iron attract electrical matter. The evidence of these facts rests entirely on personal observation or authentic testimony. The only thing requisite with respect to objects of testimony is, when the fact is so extraordinary as has not fallen within the observation of the generality of men, the strength of

Serpent. of the evidence must be in proportion to the extraordinary nature of the fact. To apply this to the present case: We have the testimony of many persons that some serpents have a power of fascination; but the generality of men have never observed this; it is therefore an extraordinary fact, and requires extraordinary evidence. But the evidence is not satisfactory; therefore we do not receive it as a fact: on the other hand, it is unphilosophical to reject it *à priori*.

23
How their poison operates.

No subject has excited more philosophical controversy than the poison of serpents, with regard to its nature and mode of operating. Antiquity has not been sparing in conjecture and fiction upon this subject, and its errors have been retained with the most reverential obstinacy by the vulgar: among these we are to reckon the fictitious sting fixed in the tail of the serpent, as the painters sometimes have groundlessly enough represented it; some have invented a similar fiction of a black forked tongue, which the serpent vibrates on both sides, and have ascribed its power of producing such noxious effect to this; while others, affecting an air of superior discernment, have, upon equally good reasons, ascribed it to the teeth in general: these are all errors of a magnitude that the most desultory attention to the subject would have been sufficient to have removed. There is a very small bone closely fixed to the upper jaw, in the inside of the lip of a poisonous serpent, which has a power of moving backward or forward; to this two or three fangs are annexed larger than the teeth, which the serpent, by its assistance, when enraged, darts forward, or withdraws and conceals at his pleasure, in a similar manner to the claws of a cat: these fangs, which the common people name the large teeth of the serpent, are excellently described by Tyson in the anatomy of the rattlesnake, which he has given in the Philosophical Transactions. "In these (the fangs) we observed a considerable cavity near the base; and near the point a very discernible fissure of some length like the slit of a pen: the part of the tooth from the fissure to the root was manifestly channelled, which we first discovered by lightly pressing the gums; we then saw the poison ascend through the cavity of the fang and flow out of the fissure; and as these fangs are so very acute, so firm and solid toward the point (the fissure being on the external and convex, not the internal side), nothing could be conceived more convenient either for inflicting a wound, or to insure the infusion of the poison." Each of the fangs is surrounded with a vesicle furnished with glands secreting a certain fluid; which, upon the vesicle being pressed, seems to flow out of the point of the fang. The serpent when incensed, raising his head, extends the small bone armed with the fangs mentioned above; and attacking his enemy with a force combined of the weight of his body and the action of the muscles, he wounds him with the expanded fangs, and the vesicle being compressed the poison immediately flows into the wound: this is clear from the experience of those who, having broken off their fangs with a pair of forceps, handled the serpent thus disarmed without any hurt. The North Americans, after carefully extracting these venomous fangs, suffer the rattlesnake to bite and gnaw them with his teeth till the blood flows freely, with total impunity.

Antiquity amused itself with a fable destitute of all appearance of truth, that anger was excited by black bile: they applied this fiction without hesitation to the present subject, and founded an hypothesis upon it, to account for the effects of the bite of an incensed serpent; pretending to have discovered an ideal canal which conducted the bile from its vesicle to the mouth of the serpent, whence it flowed into the part bitten, and produced the most fatal symptoms. But toward the end of the last century, this subject was greatly illustrated under the auspices of Ferdinand II. Great Duke of Tuscany: This prince, desirous of enquiring into that mysterious question, the nature of serpents, invited Steno, Rhedi, and some other philosophers of the first eminence, to his court; and a multitude of the most poisonous serpents being collected, Rhedi made several experiments upon them, which discovered to him a number of particulars before unknown; of which the following seem to have the best claim to our attention. When he either caused a living viper to bite a dog, or wounded him with the teeth of one newly dead (the poisonous vesicle remaining unbroken), the event was the same. If the bite was repeated, its effect became weaker, and at last was lost, the poison contained in the vesicle being totally exhausted. That the teeth of serpents, when extended to bite, were moistened over with a certain liquor; and when the vesicle at the base was pressed, a drop of poison flowed to the point of the fang. When the poison thus flowing from the vesicle was received in soft bread or a sponge, an animal bitten by the serpent received no more harm from the wound than from being pricked by a needle, till after a few days, when the venom was restored afresh: but when an animal was wounded with the point of a needle dipped in the poison, it was tormented with the same pains as if it had been bitten by the viper itself. Preserving some of this poison in a glass, and totally evaporating the moisture in the sun, when the residuum was diluted again with water, and the point of a needle dipped in the solution, Rhedi found to his great surprize that it had the same effect as when recent. But the boldness of Tozzi, one who charmed vipers, flung all these men who were deeply versed in natural philosophy into the utmost astonishment. They happening to fall into discourse (while the prince was present) upon the certain death which would attend any person's swallowing this poison of the viper by mistake, instead of spirit of wine or water; Tozzi, confiding in his art, drank a considerable portion of it without hesitation: they were all astonished at his apparent rashness, and predicted instant death to the man; however, he escaped as safely as if he had drunk only so much water. This event, which struck the prince and his illustrious associates in these philosophical enquiries by its novelty, was well known to the ancients. Lucan, in the 9th book of the Pharsalia, speaking of the serpents, says,

Noxia serpentum est admisso sanguine pestis.
Morsu virus habent et fatum dente minantur,
Pocula morte carent. Phar. l. 9. v. 614.

Mix'd with the blood that venom slays alone,
His bite is poison; death is in his fangs,
Yet is the draught innoxious.

Nor must we omit observing, that barbarous nations are perfectly acquainted with the property of the poison of serpents by which it retains its deadly power af-

ter

Serpent.

ter it has been long kept; they have been possessed of this fatal secret for ages past; it being their custom to tinge the points of their arrows with the juice of spurge, putrid flesh, or oil of tobacco, but more particularly with the poison of vipers. Some modern Indians continue the practice to this day; and we have the testimony of Pliny, in his Natural History, that the Scythians had long ago the same custom: "The Scythians (says that author) dip their arrows in the poison of vipers and human blood; a horrid practice, as the slightest wound inflicted by one of them defies all the art of medicine."

The poison of serpents produces fatal effects only by mixing with the blood. To confirm this principle, the Florentine philosophers collected a quantity of poison, and gave it to different animals without producing the least inconvenience; but when applied to an external wound, every one of those horrid symptoms which accompany the real bite followed, viz. inflammatory and malignant fevers, ending in death, unless nature, by a spontaneous hemorrhage, or some other evacuation, discharged this poison. With respect to the experiments of Rhedi, every one of his observations prove, that the liquid pressed out of the vesicle which moistens the fangs of the serpents is only noxious by being conveyed into the blood, by means of a puncture or wound; and the case of Tozzi, who drank a considerable quantity of this poison without suffering injury, proves that it hurts the blood only when externally mixed with it.

24 Symptoms attending the bite of different serpents.

The symptoms of the bite of the viper have already been described under Medicine, n° 408. with the cures recommended by Dr Mead for the bite of serpents in general. Under the article Poison, p. 269. we have mentioned the Abbe Fontana's method of cure, *viz.* ligatures, and the beneficial effects of the volatile alkali. We shall now therefore supply what has been omitted in these articles, by describing the symptoms which accompany the bite of other serpents.

The symptoms attending the bite of the *coluber prester*, a native of Sweden, are, pain in the wound, tumor, thirst, asthma, anxieties, convulsions, and death.

There is a serpent still more dreadful than any of the former, found in Sweden, called *coluber carcia*. The bite of this is followed by immediate change of colour, coldness, stupor, palpitation of the heart, acute pain all over the body, and death. Linnæus tried oil in this case, but it proved ineffectual.

The *crotalus horridus* of Linnæus, the rattlesnake, kills in a very sudden manner; his bite usually producing death within twelve hours.

The following account of the poison serpent of the East Indies is given by M. d'Obsonville. "Among the serpents of India, that which I believe to be most formidable is but about two feet long, and very small. Its skin is freckled with little traits of brown or pale red, and contrasted with a ground of dirty yellow: it is mostly found in dry and rocky places, and its bite mortal in less than one or two minutes. In the year 1759, and in the province of Cadapet, I saw several instances of it; and among others, one very singular, in the midst of a corps of troops commanded by M. de Bussy. An Indian Gentoo merchant perceived a Mahometan soldier of his acquaintance going to kill one of these reptiles, which he had found sleeping under his packet, the Gentoo flew to beg its life, protesting it would do no hurt if it was not first provoked; passing at the same time his hand under its belly to carry it out of the camp, when suddenly it twisted round, and bit his little finger; upon which this unfortunate martyr of a fanatic charity gave a shriek, took a few steps, and fell down insensible. They flew to his assistance, applied the serpent-stone, fire, and scarifications, but they were all ineffectual, his blood was already coagulated About an hour after, I saw the body as they were going to burn it, and I thought I perceived some indications of a complete dissolution of the blood.

"The *serpens brulans*, or burning serpent, is nearly of the same form with the last mentioned; its skin is not quite of so deep a brown, and is speckled with dark green spots; its poison is almost as dangerous, but it is less active, and its effects are very different: in some persons it is a devouring fire, which, as it circulates through the veins, presently occasions death; the blood dissolves into a lymphatic liquor, resembling thin broth, without apparently having passed through the intermediate state of coagulation, and runs from eyes, nose, and ears and even through the pores. In other subjects, the poison seems to have changed the very nature of the humours in dissolving them; the skin is chapped and become scaly, the hair falls off, the members are tumefied, the patient feels all over his body the most racking pains, numbness, and is not long in perishing. It is said, however, that people have been cured by remedies well and soon applied. Be that as it may, it seems to me that the poison of these different reptiles is in general more powerful the more they live in hot and dry places, where they feed upon insects that are full of saline, volatile, and acrimonious particles."

We are ignorant of what species the *hemorrhois* was, which is described by Lucan as causing by its bite a flux of blood from every part of the body. But the bite of an American serpent named *de la crux* kills in the same manner.

The *dipsasas* is at present likewise unknown. Lucan informs us, that the person wounded by it was attacked by an unquenchable thirst. This is finely painted by him; where A. Tuscus, standard-bearer of Cato, is described as bitten by that serpent:

Non decus imperii, non-mœsti jura Catonis
Ardentem tenuere virum, quin spargere signa
Auderet, totisque furens exquireret agris
Quas poscebat aquas sitiens in corde venenum.

Pharsal. l. 9.

His wild impatience, not his honour'd state,
Nor sorrowing Cato's high command, restrain;
Furious, dishonour'd in the dust, he flings
His sacred eagle, and o'er all the fields
Rapid he bursts to seek the cooling stream,
To quench the thirsty poison in his breast.

And a few verses after:

Scrutatur venas penitus squalentis arenæ
Nunc redit ad Syrtes, et fluctus accipit ore,
Æquoreusque placet, sed non sibi sufficit humor,
Nec sentit fatique genus, mortemque veneni,
Sed putat esse sitim; ferroque aperire tumentes
Sustinuit venas, atque os implere cruore.

Serpent.

Now tearing up the sands, some latent vein
Frustrate he seeks; now to the Syrtes shore
Return'd, he swallows down the briny flood
Mix'd with its rolling sands; nor knows his fate
And the sad poison's death, but calls it thirst;
Then with his sword opens his spouting veins,
And drinks the bursting blood.——

The *phytas*, or *ammodytes* of Linnæus, or according to others, the *coluber aspis*, seems to have been the serpent made use of by Cleopatra to destroy herself. This woman, to terminate a dissipated life with an easy death, ordered her physicians to prepare a poison for her which might best effect this purpose. Having tried a number of different experiments upon condemned criminals, they at last discovered this species of asp, which brings on death without any previous appearance of distemper or hiccough: the face seems in a slight perspiration, an easy insensibility and lethargy creeps upon the whole frame, and the person bitten seems almost totally ignorant of his approaching dissolution. Having acquainted the queen with their discovery, she applied the asp either to her bosom or her arms; or, according to some authors, dipping the point of a needle in the poison, and pricking herself with it, she expired in an easy sleep.

The bite of the *naja* is so fatal, that a man dies by it in the space of an hour, his flesh entirely falling off his bones in a semidissolved putrid state: this makes it probable that it is the same serpent which the ancients named the *seps*.

The experiments of Rhedi have not, in the opinion of some celebrated philosophers, so far cleared the theory of the operation of the poison of the viper, as to leave nothing further to be desired upon that subject. Fontana and Carminati have endeavoured to investigate its operations more clearly. Carminati, from 11• experiments, deduces the following conclusions: 1. That if poison be instilled into a nerve, the animal wounded dies almost instantly; and the whole nervous system, to which it is rapidly conveyed, is deprived of its quality called *sensibility*. 2. If a muscle be wounded, it is deprived of its irritability. This is confirmed by the experiments of Fontana. 3. The poison injected into a wounded muscle or tendon is considerably longer in killing an animal than that introduced into a nerve. 4. The symptoms which precede the death of the animal bitten are, a stupor, lethargy, tremors, convulsions, paralysis of the legs (part wounded), entire dissolution of the limbs. The blood is not always coagulated, nor its crasis dissolved. Marks of inflammation are sometimes discovered in certain parts of the animal after death, sometimes not: these are the effects of spasms and convulsions, not of the poison. 5. Not the least sign of the jaundice was discoverable in the eyes of any of the animals upon which Carminati made his experiments. 6. The stomach in every one of them was very much inflated; a symptom remarked only by Fallopius and Albertini. 7. A ligature applied instantly above the part bitten, if it be so placed as to admit one, was found by some experiments a good preventive against the diffusion of the poison: its compression should be considerable, but not excessive.

As few serpents, comparatively speaking, are poisonous, it may be interesting to our readers to know what are the characteristics which distinguish poisonous from harmless serpents. The external characteristics of the poisonous tribe are these:

15 How to distinguish poisonous serpents. Phil. Trans. vol. lxxix.

"1. A broad head, covered with small scales, though it be not a certain criterion of venomous serpents, is, with some few exceptions, a general character of them.

"2. A tail under one-fifth of the whole length is also a general character of venomous serpents; but, since many of those which are not venomous have tails as short, little dependence can be placed upon that circumstance alone. On the other hand, a tail exceeding that proportion, is a pretty certain mark that the species to which it belongs is not venomous.

"3. A thin and acute tail is by no means to be considered as peculiar to venomous serpents; though a thick and obtuse one is only to be found among those which are not venomous.

"4. Carinated scales are, in some measure, characteristic of venomous serpents, since in them they are more common than smooth ones, in the proportion of nearly four to one; whereas smooth scales are, in those serpents which are not venomous, more common, in the proportion of nearly three to one.

"Upon the whole therefore, it appears, that though a pretty certain conjecture may, in many instances, be made from the external characters, yet, in order to determine with certainty whether a serpent be venomous or not, it becomes necessary to have recourse to some certain diagnostic. This can only be sought for in the mouth: we must therefore next consider how the fangs, with which the mouths of venomous serpents are furnished, are to be distinguished from common teeth.

"To those who form their ideas of the fangs of a venomous serpent, from those of the rattlesnake, or even from those of the English viper, it will appear strange that there should be any difficulty in distinguishing those weapons from common teeth; and indeed the distinction would really be very easy, were all venomous serpents furnished with fangs as large as those of the fore mentioned species. But the fact is, that in many species the fangs are full as small as common teeth, and consequently cannot, by their size, be known from them; this is the case with the *coluber laticaudatus*, *lacteus*, and several others."

Linnæus thought that the fangs might be distinguished by their mobility and situation; but other naturalists have not found it a general fact that fangs are loose in their sockets, nor have they observed any difference in situation between the fangs of venomous serpents and the teeth of others. The following distinction is established by Dr Gray in a paper inserted in the Philosophical Transactions, Vol. lxxix. *All venomous serpents have only two rows of teeth in the upper jaw, and all others have four.*

In the preface to the *Museum Regis*, and in the introduction to the class amphibia in the *Systema Naturæ*, Linnæus says, that the proportion of venomous serpents to others is one in ten; yet, in the *Systema Naturæ*, of which the sum total in species in 131, he has marked 23 as venomous, which is somewhat more than one in six. How he came to be so much at variance with himself, it is not easy to say; but the last mentioned proportion seems to be not far from the truth, as Dr Gray, after examining 154 species of serpents, found only 26 that seemed to be venomous.

The

The *coluber stolatus* and *mycterizans*, though marked by Linnæus, we are assured by Dr Gray are not poisonous: he thinks the same may be said of the *leberis* and *dypsas*. On the other hand, he observes, that the *boa contortrix*, *coluber cerastes*, *laticaudatus*, and *coluber fulvus*, none of which are marked in the *Systema Naturæ*, are all poisonous.

In addition to the method of cure mentioned in the articles referred to above, we shall subjoin the prescrip-
* P. 32. tion of a new author, Dr Mosely*, who spent 12 years in the West Indies, and whose abilities and extensive practice very justly entitle his opinion to a place in this work, to the attention of the public, and to all medical gentlemen going to the West Indies.

26 Dr Moseley's method of cure.
"The bites and stings of all venomous animals are cured by the same local means; which are very simple, if they were always at hand. The injured part must be instantly destroyed or cut out. Destroying it is the most safe, and equally certain: and the best application for that purpose is the lapis infernalis or the butter of antimony.—These are preferable to an hot iron, which the ancients used, because an hot iron forms a crust, which acts as a defence to the under parts, instead of destroying them. The lapis infernalis is much better than any other caustic, as it melts and penetrates during its application. The bitten part must be destroyed to the bottom, and where there is any doubt that the bottom of the wound is not sufficiently exposed, butter of antimony should be introduced into it on the following day, as deep as possible; and incisions should be made to lay every part open to the action of these applications. Besides destroying, burning, or cutting out the part, incisions should be made round the wound, to prevent the communication of the virus. The wound is to be dressed for some time with poultices, to assuage the inflammation caused by the caustics; and afterwards with acrid dressings and hot digestives to drain the injured parts.

"Where the abovementioned caustics cannot be procured, corrosive sublimate, oil of vitriol, aquafortis, spirit of salt, common caustic, or a plaster made of quicklime and soap, may be applied to the wound. Gunpowder laid on the part, and fired, has been used with success. When a person is bitten remote from any assistance, he should make a tight ligature above the part, until proper application can be made. The Spanish writers say, that the *habilla de Carthagena*, or Carthagena bean, is a specific for poisonous bites, taken inwardly.

"Ulloa says, it is 'one of the most effectual antidotes known in that country (Carthagena) against the bites of vipers and serpents: for a little of it being eaten immediately after the bite, it presently stops the effects of the poison; and accordingly all who frequent the woods, either for felling trees or hunting, never fail to eat a little of this habilla fasting, and repair to their work without any apprehension.

'The natives tell you, that this habilla being hot in the highest degree, much of it cannot be eaten; that the common dose of it is less than the fourth part of a kernel; and that no hot liquor, as wine, brandy, &c. must be drunk immediately after taking it.'

"The Carthagena bean, or habilla, is found in great abundance in the West Indian islands, where it is generally known by the name of *Antidote* or *Cocoon*, or *Antidote Cocoon*. In small doses it is stomachic and diaphoretic; and in large doses emetic and purgative. In several disorders it is a powerful remedy; but its virtues are not sufficiently known, except among the Indians and negroes, who chiefly use an infusion or tincture of it made in rum. This is externally as well as internally used for many complaints (A).

"I have been informed by some intelligent Indians that any of the red peppers, such as bird pepper, or bell pepper, or what is called *Cayenne pepper*, powdered and taken in a glass of rum as much as the stomach can possibly bear, so as to cause, and keep up for some time, great heat and inflammation in the body and a vigorous circulation, will stop the progress of the poison of serpents, even after its effects are visible, and that the bitten part only afterwards mortifies and separates, and that the patient, with bark, wine, and cordials, soon recovers.

"This fiery practice is certainly agreeable to that of the ancients, and probably the only internal treatment that can have any good effect; as in these cases the powers of life, and the action of the heart, are suddenly enfeebled, and the pulse in strength and frequency observes almost a regular declension from the time of the bite until it entirely ceases in death."

Polygala senega, or rattlesnake-root, was formerly considered as a sovereign remedy for the bite of the rattlesnake; but this opinion is now exploded. 27 Why some serpents are poisonous.

If it be asked for what purpose were serpents created with such destructive weapons? we answer, that they were given for self-defence. Without these, serpents, of all other animals would be the most exposed and defenceless; without feet for escaping a pursuit, without teeth capable of inflicting a dangerous wound, or without strength for resistance; incapable, from their size, of finding security in very small retreats like the earthworm, and disgusting all from their deformity, nothing was left for them but a speedy extirpation. But furnished as they are with powerful poison, every rank of animals approach them with dread, and never seize them, but at an advantage. Nor is this all the benefit they derive from it. The malignity of a few serves for the protection of all. Though not above a tenth of their number are actually venomous, yet the similitude they all bear to each other excites a general terror of the whole tribe; and the uncertainty of their enemies about what serpents are poisonous, makes even the most harmless formidable. Thus Providence seems to have acted with double precaution: it has given some of them poison for the general defence of a tribe naturally feeble; but it has thinned the numbers of those which are venomous, lest they should become too powerful for the rest of animated nature.

From

(A) "This bean is the seed of the *Fevillea* foliis cordatis of Plumier, Ed. Burmanni, p. 203. tab. 209. *Fevillea* foliis cordatis, angulatis, of Linnæus, Spec. P. *Fevillea* foliis crassioribus, glabris, quandoque cordatis, quandoque trilobis, or *Antidote Cocoon*, of Brown, p. 374."

28 Enemies of ſerpents.

From theſe noxious qualities in the ſerpent kind, it is no wonder that not only man, but beaſts and birds, carry on an unceaſing war againſt them. The ichneumon of the Indians, and the peccary* of America, deſtroy them in great numbers. Theſe animals have the art of ſeizing them near the head; and it is ſaid that they can ſkin them with great dexterity. The vulture and the eagle alſo prey upon them in great abundance; and often, ſouſing down from the clouds, drop upon a long ſerpent, which they ſnatch up ſtruggling and writhing in the air. Dogs alſo are bred up to oppoſe them. Father Feuillée tells us, that being in the woods of Martinico, he was attacked by a large ſerpent, which he could not eaſily avoid, when his dog immediately came to his relief, and ſeized the aſſailant with great courage. The ſerpent entwined him, and preſſed him ſo violently, that the blood came out of his mouth, and yet the dog never ceaſed till he had torn it to pieces. The dog was not ſenſible of his wounds during the fight; but ſoon after his head ſwelled prodigiouſly, and he lay on the ground as dead. But his maſter having found a banana tree hard by, he applied its juice mixed with treacle to the wounds, which recovered the dog, and quickly healed his ſores.

* See Viverra and Sus.

29 Some perſons famous for charming them.

The Pſylli of old were famous for charming and deſtroying ſerpents ¶. Some moderns pretend to the ſame art. Caſaubon ſays that he knew a man who could at any time ſummon 100 ſerpents together, and draw them into the fire. Upon a certain occaſion, when one of them, bigger than the reſt, would not be brought in, he only repeated his charm, and it came forward, like the reſt, to ſubmit to the flames. Philoſtratus deſcribes particularly how the Indians charm ſerpents. "They take a ſcarlet robe, embroidered with golden letters, and ſpread it before a ſerpent's hole.— The golden letters have a faſcinating power; and by looking ſteadfaſtly, the ſerpent's eyes are overcome and laid aſleep." Theſe and many other feats have been often practiſed upon theſe animals by artful men, who had firſt prepared the ſerpents for their exerciſe, and then exhibited them as adventitiouſly aſſembled at their call. In India there is nothing ſo common as dancing ſerpents, which are carried about in a broad flat veſſel, ſomewhat reſembling a ſieve. Theſe erect and put themſelves in motion at the word of command. When their keeper ſings a ſlow tune, they ſeem by their heads to keep time; when he ſings a quicker meaſure, they appear to move more briſk and lively. All animals have a certain degree of docility; and we find that ſerpents themſelves can be brought to move and approach at the voice of their maſter. From this trick, ſucceſsfully practiſed before the ignorant, it is moſt probable has ariſen moſt of the boaſted pretenſions which ſome have made to charming of ſerpents; an art to which the native Americans pretend at this very day, but the exiſtence of which we are aſſured of by Mr Haſſelquiſt among the native Egyptians.

¶ See Psylli.

30 Regarded with veneration in ſome countries.

Though the generality of mankind regard this formidable race with horror, yet there have been ſome nations, and there are ſome at this day, that conſider them with veneration and regard. The adoration paid by the ancient Egyptians to a ſerpent is well known: many of the nations at preſent along the weſtern coaſt of Africa retain the ſame unaccountable veneration. Upon the gold and ſlave coaſts, a ſtranger, upon entering the cottages of the natives, is often ſurpriſed to ſee the roof ſwarming with ſerpents, that cling there without moleſting and unmoleſted by the natives. But this ſurpriſe will increaſe upon going farther ſouthward to the kingdom of Widah, when he finds that a ſerpent is the god of the country. This animal, which travellers deſcribe as a huge overgrown creature has its habitation, its temple, and its prieſts. Theſe impreſs the vulgar with an opinion of its virtues; and numbers are daily ſeen to offer not only their goods, their proviſions, and their prayers, at the ſhrine of their hideous deity, but alſo their wives and daughters. Theſe the prieſts readily accept of, and after ſome days of penance return them to their ſuppliants, much benefitted by the ſerpent's ſuppoſed embraces.

Serpent, a muſical inſtrument, ſerving as a baſe to the cornet, or *ſmall ſhawm*, to ſuſtain a chorus of ſingers in a large edifice. It has its name *ſerpent* from its figure, as conſiſting of ſeveral folds or wreaths, which ſerve to reduce its length, which would otherwiſe be ſix or ſeven feet.

It is uſually covered with leather, and conſiſts of three parts, a mouth-piece, a neck, and a tail. It has ſix holes, by means whereof it takes in the compaſs of two octaves.

Merſennus, who has particularly deſcribed this inſtrument, mentions ſome peculiar properties of it, *e. gr.* that the ſound of it is ſtrong enough to drown 20 robuſt voices, being animated merely by the breath of a boy, and yet the ſound of it may be attempered to the ſoftneſs of the ſweeteſt voice. Another peculiarity to this inſtrument is, that great as the diſtance between the third and fourth hole appears, yet whether the third hole be open or ſhut, the difference is but a tone.

Serpent, in mythology, was a very common ſymbol of the ſun, and he is repreſented biting his tail, and with his body formed into a circle, in order to indicate the ordinary courſe of this luminary, and under this form it was an emblem of time and eternity. The ſerpent was alſo the ſymbol of medicine, and of the gods which preſided over it, as of Apollo and Æſculapius: and this animal was the object of very ancient and general worſhip, under various appellations and characters. In moſt of the ancient rites we find ſome alluſion to the ſerpent, under the ſeveral titles of Ob, Ops, Python, &c. This idolatry is alluded to by Moſes, (Lev. xx. 27.) The woman at Endor who had a familiar ſpirit is called Oub, or Ob, and it is interpreted Pythoniſſa. The place where ſhe reſided, ſays the learned Mr Bryant, ſeems to have been named from the worſhip then inſtituted; for Endor is compounded of *En-ador*, and ſignifies *fons Pythonis*, "the fountain of light," the oracle of the god Ador, which oracle was probably founded by the Canaanites, and had never been totally ſuppreſſed. His pillar was alſo called *Abbadir* or *Abadir*, compounded of *ab* and *adir*, and meaning the ſerpent deity Addir, the ſame as Adorus.

In the orgies of Bacchus, the perſons who partook of the ceremony uſed to carry ſerpents in their hands, and with horrid ſcreams call upon Eva! Eva! Eva being, according to the writer juſt mentioned, the ſame as epha, or opha, which the Greeks rendered *ophis*, and by it denoted a ſerpent. Theſe ceremonies and this

this symbolic worship began among the Magi, who were the sons of Chus; and by them they were propagated in various parts. Wherever the Amonians founded any places of worship, and introduced their rites, there was generally some story of a serpent. There was a legend about a serpent at Colchis, at Thebes, and at Delphi; and likewise in other places. The Greeks called Apollo himself Python, which is the same as Opis, Oupis, and Oub.

In Egypt there was a serpent named Thermuthis, which was looked upon as very sacred; and the natives are said to have made use of it as a royal tiara, with which they ornamented the statues of Isis. The kings of Egypt wore high bonnets, terminating in a round ball, and surrounded with figures of asps; and the priests likewise had the representation of serpents upon their bonnets.

Abadon, or Abaddon, mentioned in the Revelations xx. 2. is supposed by Mr Bryant to have been the name of the Ophite god, with whose worship the world had been so long infected. This worship began among the people of Chaldea, who built the city of Ophis upon the Tigris, and were greatly addicted to divination, and to the worship of the serpent. From Chaldea the worship passed into Egypt, where the serpent deity was called Canoph, Can-eph, and C'neph. It had also the name of Ob or Oub, and was the same as the Basiliscus or royal serpent, the same as the Thermuthis, and made use of by way of ornament to the statues of their gods. The chief deity of Egypt is said to have been Vulcan, who was styled Opas. He was the same as Osiris, the Sun, and hence was often called Ob-el, or Pytho-sol; and there were pillars sacred to him, with curious hieroglyphical inscriptions bearing the same name; whence among the Greeks, who copied from the Egyptians, every thing gradually tapering to a point was styled obelos or obeliscus.

As the worship of the serpent began among the sons of Chus, Mr Bryant conjectures, that from thence they were denominated Ethiopians and Aithiopians, from Ath ope or Ath-opes the god whom they worshipped, and not from their complexion: the Ethiopes brought these rites into Greece, and called the island where they first established them *Ellopia, Solis Serpentis insula*, the same with *Eubœa*, or *Oubaia*, i. e. "the serpent island." The same learned writer discovers traces, of the serpent worship among the Hyperboreans, at Rhodes named Ophiusa, in Phrygia, and upon the Hellespont, in the island Cyprus, in Crete, among the Athenians, in the name of Cecrops, among the natives of Thebes in Bœotia, among the Lacedemonians, in Italy, in Syria, &c. and in the names of many places, as well as of the people where the Ophites settled. One of the most early heresies introduced into the Christian church was that of the Ophitæ. Bryant's Analysis of Ancient Mythology, vol. i. p. 43. &c. p. 473 &c.

Serpent Stones. See *Cornu Ammonis*.

Sea-Serpent. See *Sea-Serpent*.

SERPENTARIA, SNAKE-ROOT; a species of ARISTOLOCHIA.

SERPENTARIUS, in astronomy, a constellation of the northern hemisphere, called also Ophiuchus, and anciently Æsculapius. The stars in the constellation Serpentarius, in Ptolemy's catalogue, are 29; in Tycho's 15; in Hevelius's 40; in the Britannic catalogue they are 74.

SERPENTINE, in general, denotes any thing that resembles a serpent; hence the worm or pipe of a still, twisted in a spiral manner, is termed a *serpentine worm*.

SERPENTINE *Stone*, a genus of magnesian earths, of which there are different species: 1. The fibrous, composed of fibrous and coherent particles. This resembles the asbestos so much that it might be confounded with it, were not the fibres of the serpentine so closely coherent, that they cannot be distinguished when the stone is cut or polished. The fibres themselves are large, and seem to be twisted. There are two varieties, a dark green and a light one; the former from Germany, the latter from Sweden. 2. The zoeblitz serpentine, found near that place, of many different colours, as black, deep green, light green, red, bluish grey, and white; but the green colour is most predominant. 3. Porcelain earth mixed with iron. It is met with either diffusable in water or indurated. The former is found of a red colour from China and Montmartre. The water-clinkers, imported from some places in Germany, seem to be made of this kind of earth. There are two varieties of the indurated kind, viz. the martial soap-earth, of a red colour, from Jasberg and other places in Norway, or black from some parts of Sweden. 4. The telgston of the Swedes, the same with the lapis ollaris. It is found in various places of Norway, as light grey, dark grey, whitish yellow, and dark green. It is employed with great advantage for building fire-places, furnaces, &c. the extremities of the strata being turned towards the fire when it is slaty.

M. Magellan observes, that there is a great variety of colour as well as composition in this kind of stones; it being found either white, green, brown, yellow, light-blue, black, spotted, or streaked with veins of different colours. Its texture is either indistinct, obscurely laminar, or fibrous. The specific gravity is from 2400 to 2650; and it is harder than soap-rock or steatites; though not hard enough to strike fire with steel; being less smooth to the touch than steatites, but susceptible of a good polish, looking like marble; and is often met with in thin semitransparent plates. It melts in a strong heat without addition, and corrodes the crucibles, but hardens in a lower degree of heat. It is slowly and partially soluble in acids, but does not effervesce with them. According to Bayon's analysis, 100 parts of it contain about 41 of silex, or rather mica; 33 of magnesia; 10 of argillaceous earth; 12 of water and about 3 of iron. That brought from Corsica contains a greater proportion of argil. and a smaller one of silex. The serpentine commonly so called, according to Fabroni, is a true lapis ollaris; but has its name from being variegated with green, yellowish, and brown spots, like the skin of some serpents: great quantities of it are found in Italy and Switzerland, where it is frequently worked into dishes and other vessels.

SERPENTINE *verses*, are such as begin and end with the same word. As,

Ambo florentes ætatibus, Arcades ambo.

SERPENTINE, in the *Manege*. A horse is said to have a serpentine tongue, if it is always frisking and moving, and sometimes passing over the bit, instead of

keeping

keeping in the void space, called the liberty of the tongue.

SERPICULA, in botany; a genus of plants belonging to the class of monœcia, and to the order of tetrandia. The male calyx is qaudridentate, and the corolla consists of four petals: The female calyx is divided into four parts, and pericarpium is a tomentose nut. There are two species, the verticillata and repens.

SERPIGO, in surgery, a kind of herpes, popularly called a *tetter* or ringworm. See SURGERY.

SERPULA, in natural history; a genus belonging to the class of vermes, and to the order of testacea. The shell is single, tubular, and adhering to other bodies. The animal which inhabits it is the terebella.

SERRANUS, (Joannes), or John de Serres, a learned French Protestant, was born about the middle of the sixteenth century. He acquired the Greek and Latin languages at Lausanne, and grew very fond of the philosophy of Aristotle and Plato. On his return to France he studied divinity. He began to distinguish himself in 1572 by his writings, but was obliged to forsake his country after the dreadful massacre of St Bartholomew. He became minister of Nismes in 1582, but was never regarded as a very zealous Calvinist: he has even been suspected, though without reason, of having actually abjured the Protestant religion. He was one of the four clergymen whom Henry IV. consulted about the Romish religion, and who returned for answer, *that Catholics might be saved.* He wrote afterwards a treatise in order to reconcile the two communions, entitled *De fide Catholica, sive de principiis religionis Christianæ, communi omnium Christianorum consensu, semper et ubique ratis.* This work was disliked by the Catholics, and received with such indignation by the Calvinists of Geneva, that many writers have affirmed that they poisoned the author. It is certain at least that he died at Geneva in 1598, at the age of 50. His principal works are, 1. A Latin Translation of Plato, published by Henry Stephens, which owes much of its reputation to the elegance of the Greek copy which accompanies it. 2. A Treatise on the Immortality of the Soul. 3. *De statu religionis et republicæ in Francia.* 4. *Memoire de la 3me guerre civile et derniers troubles de France sous Charles IX &c.* 5. *Inventaire general de l'Histoire de France, illustre par la conference de l'Eglise et de l'Empire, &c.* 6. *Recueil de chose memorable ecvnue en France sous Henri II. François II. Charles IX. Henri III.* These three historical treatises have been justly accused of partiality and passion; faults which it is next to impossible for a contemporary writer to avoid, especially if he bore any part in the transactions which he describes. His style is exceedingly incorrect and inelegant; his mistakes too and mistatements of facts are very numerous.

SERRATED, in general, something indented or notched in the manner of a saw; a term much used in the description of the leaves of plants. See BOTANY.

SERRATULA, SAW-WORT, in botany: A genus of plants belonging to the class syngenesia, and to the order of polygamia æqualis. In the natural system it is ranged under the 49th order, *Compositæ*. The calyx is subcylindrical, imbricated; the scales of it pointed, but not spinous. There are 15 species: The tinctoria, alpina, arvensis, coronata, japonica, salicifolia, multiflora, noveboracensis, præalta, glauca, squarrosa, scariosa, spicata, amara, and centauroides. The three first species

are British. 1. The *tinctoria* is distinguished by a stem erect and slender, branched at the top, and three feet high. The leaves are smooth, pinnatified, and serrated: The flowers are purple, in umbels, and terminal. The down of the seed is glossy, with a brown or gold tinge. It grows in woods and wet pastures. It dyes cloth of an exceeding fine yellow colour, which stands well when fixed with alum. Goats eat this plant; horses are not fond of it; cattle, swine, and sheep, leave it untouched. 2. The *alpina*, or mountain saw-wort. The root and stem are woody; the latter being from one to two feet high. The leaves are numerous, triangular, long, pointed, substantial, dark green above, white beneath, and serrated, with round intervals between the teeth, on footstalks. The flowers are purple. The scales of the calyx are very short and downy. It grows on high mountains, and flowers commonly in July or August. 3. The *arvensis*, corn saw-wort, or way-thistle. The stem is generally erect, branched, and two or three feet high. The leaves are sinuated, serrated, and spinous; those above being almost entire. The flowers are of a pale purple; the down is very long. This plant grows in cultivated grounds and by waysides, and flowers in July or August. When burned it yields good ashes for making glass or fixed alkali.

SERRATUS, in anatomy, a name given to several muscles, from their resemblance to a saw. See ANATOMY, *Table of the Muscles.*

SERTORIUS (Quintus), an eminent Roman general; (see SPAIN), under the history of which his exploits are related.

SERTULARIA, in natural history, a genus belonging to the class of vermes, and to the order of zoophyta. The stem is radicated, fibrous, naked, and jointed; the florets are hydræ, and there is one at each joint. This genus comprehends 42 species of corallines.

SERVAL, mountain cat. See FELIS, xvi.

SERVANDONI (John Nicolas), was born at Florence in 1695. He rendered himself famous by his exquisite taste in architecture, and by his genius for decorations, fetes, and buildings. He was employed and rewarded by most of the princes in Europe. He was honoured in Portugal with the order of Christ: In France he was architect and painter to the king, and member of the different academies established for the advancement of these arts. He received the same titles from the kings of Britain, Spain, Poland, and from the duke of Wirtemberg. Notwithstanding these advantages, his want of economy was so great, that he left nothing behind him. He died at Paris in 1766. Paris is indebted to him for many of its ornaments. He made decorations for the theatres of London and Dresden. The French king's theatre, called *la salle des Machines*, was under his management for some time. He was permitted to exhibit shows consisting of simple decorations: Some of these were astonishingly sublime; his "Descent of Æneas into Hell" in particular, and his "Enchanted Forest," are well known. He built and embellished a theatre at Chambor for Mareschal Saxe; and furnished the plan and model of the theatre royal at Dresden. His genius for fetes was remarkable; he had the management of a great number in Paris, and even in London. He conducted one at Lisbon given on account of a victory gained by the duke of Cumberland. He was employed frequently by the king of Portugal, Servant.

Portugal, to whom he presented several elegant plans and models. The prince of Wales, too, father to the present king, engaged him in his service; but the death of that prince prevented the execution of the designs which had been projected. He presided at the magnificent *fete* given at Vienna on account of the marriage of the archduke Joseph and the Infanta of Parma. But it would be endless to attempt an enumeration of all his performances and exhibitions.

SERVANT, a term of relation, signifying a person who owes and pays obedience for a certain time to another in quality of a master.

As to the several sorts of servants: It was observed, under the article Liberty, that pure and proper slavery does not, nay cannot, subsist in Britain: such we mean whereby an absolute and unlimited power is given to the master over the life and fortune of the slave. And indeed it is repugnant to reason, and the principles of natural law, that such a state should subsist anywhere. See Slavery.

The law of England therefore abhors, and will not endure, the existence of slavery within this nation: so that when an attempt was made to introduce it, by statute 1 Edw. VI. c. 3. which ordained, that all idle vagabonds should be made slaves, and fed upon bread, water, or small drink, and refuse-meat; should wear a ring of iron round their necks, arms, or legs; and should be compelled, by beating, chaining, or otherwise, to perform the work assigned them, were it ever so vile; the spirit of the nation could not brook this condition, even in the most abandoned rogues; and therefore this statue was repealed in two years afterwards. And now it is laid down, that a slave or negro, the instant he lands in Britain becomes a freeman; that is, the law will protect him in the enjoyment of his person and his property. Yet, with regard to any right which the master may have lawfully acquired to the perpetual service of John or Thomas, this will remain exactly in the same state as before: for this is no more than the same state of subjection for life which every apprentice submits to for the space of seven years, or sometimes for a longer term. Hence, too, it follows, that the infamous and unchristian practice of withholding baptism from negro-servants, lest they should thereby gain their liberty, is totolly without foundation, as well as without excuse. The law of England acts upon general and extensive principles: it gives liberty, rightly understood, that is, protection, to a Jew, a Turk, or a Heathen, as well as to those who profess the true religion of Christ; and it will not dissolve a civil obligation between master and servant, on account of the alteration of faith in either of the parties; but the slave is entitled to the same protection in England before as after baptism; and, whatever service the Heathen negro owed of right to his master, by general, not by local law, the same (whatever it be) is he bound to render when brought to England and made a Christian.

1. The first sort of servants, therefore acknowledged by the laws of England, are *menial servants*; so called from being *intra mœnia*, or domestics. The contract between them and their masters arises upon the hiring. If the hiring be general, without any particular time limited, the law construes it to be a hiring for a year; upon a principle of natural equity, that the servant shall serve and the master maintain him, throughout all the revolutions of the respective seasons; as well when there is work to be done, as when there is not: but the contract may be made for any larger or smaller term. All single men between 12 years old and 60, and married ones under 30 years of age, and all single women between 12 and 40, not having any visible livelihood, are compellable by two justices to go out to service in husbandry or certain specific trades, for the promotion of honest industry; and no master can put away his servant, or servant leave his master, after being so retained, either before or at the end of his term, without a quarter's warning; unless upon reasonable cause, to be allowed by a justice of the peace: but they may part by consent, or make a special bargain.

2. Another species of servants are called *apprentices*, (from *apprendre*, to learn); and are usually bound for a term of years, by deed indented or indentures, to serve their masters, and be maintained and instructed by them. This is usually done to persons of trade, in order to learn their art and mystery; and sometimes very large sums are given with them as a premium for such their instruction: but it may be done to husbandmen, nay, to gentlemen and others. And children of poor persons may be apprenticed out by the overseers, with consent of two justices, till 24 years of age, to such persons as are thought fitting; who are also compellable to take them: and it is held, that gentlemen of fortune, and clergymen, are equally liable with others to such compulsion: for which purpose the statutes have made the indentures obligatory, even though such parish-apprentice be a minor. Apprentices to trades may be discharged on reasonable cause, either at the request of themselves or masters, at the quarter-sessions, or by one justice, with appeal to the sessions; who may, by the equity of the statute, if they think it reasonable, direct restitution of a rateable share of the money given with the apprentice: and parish-apprentices may be discharged in the same manner by two justices. But if an apprentice, with whom less than 10 pounds hath been given, runs away from his master, he is compellable to serve out his time of absence, or make satisfaction for the same, at any time within seven years after the expiration of his original contract. See Apprentice and Apprenticeship.

3. A third species of servants are *labourers*, who are only hired by the day or the week, and do not live *intra mœnia*, as part of the family; concerning whom the statutes before-cited have made many very good regulations; 1. Directing that all persons who have no visible effects may be compelled to work: 2. Defining how long they must continue at work in summer and in winter: 3. Punishing such as leave or desert their work: 4. Empowering the justices at sessions, or the sheriff of the county, to settle their wages: and, 5. Inflicting penalties on such as either give or exact more wages than are so settled.

4. There is yet a fourth species of servants, if they may be so called, being rather in a superior, a ministerial, capacity; such as *stewards*, *factors*, and *bailiffs*; whom, however, the law considers as servants *pro tempore*, with regard to such of their acts as affect their master's or employer's property.

As to the manner in which this relation affects the master, the servant himself, or third parties, see the article *Master and Servant*.

Servetists, Servetus.

For the condition of servants by the law of Scotland, see Law.

SERVETISTS, a name given to the modern Antitrinitarians, from their being supposed to be the fallowers of Michael Servetus; who, in the year 1553, was burnt at Geneva, together with his books.

SERVETUS (Michael), a learned Spanish physician, was born at Villaneuva, in Arragon, in 1509. He was sent to the university of Toulouse to study the civil law. The Reformation, which had awakened the most polished nations of Europe, directed the attention of thinking men to the errors of the Romish church and to the study of the Scriptures. Among the rest Servetus applied to this study. From the love of novelty, or the love of truth, he carried his inquiries far beyond the other reformers, and not only renounced the false opinions of the Roman Catholics, but went so far as to question the doctrine of the Trinity. Accordingly, after spending two or three years at Toulouse, he determined to go into Germany to propagate his new opinions, where he could do it with most safety. At Basil he had some conferences with Oecolampadius. He went next to Strasburgh to visit Bucer and Capito, two eminent reformers of that town. From Strasburgh he went to Hugenau, where he printed a book, intitled *De Trinitatis Erroribus*, in 1531. The ensuing year he published two other treatises on the same subject: in an advertisement to which, he informs the reader that it was not his intention to retract any of his former sentiments, but only to state them in a more distinct and accurate manner. To these two publications he had the courage to put his name, not suspecting that in an age when liberty of opinion was granted, the exercise of that liberty would be attended with danger. After publishing these books, he left Germany, probably finding his doctrines not so cordially received as he expected. He went first to Basil, and thence to Lyons, where he lived two or three years. He then removed to Paris, where he studied medicine under Sylvius, Fernelius, and other professors, and obtained the degree of master of arts and doctor of medicine. His love of controversy involved him in a serious dispute with the physicians of Paris; and he wrote an Apology, which was suppressed by an edict of the Parliament. The misunderstanding which this dispute produced with his colleagues, and the chagrin which so unfavourable a termination occasioned, made him leave Paris in disgust. He settled two or three years in Lyons, and engaged with the Frellons, eminent printers of that age, as a corrector to their press. At Lyons he met with Pierre Palmier, the archbishop of Vienne, with whom he had been acquainted at Paris. That Prelate, who was a great encourager of learned men, pressed him to accompany him to Vienne, offering him at the same time an apartment in his palace. Servetus accepted the offer, and might have lived a tranquil and happy life at Vienne, if he could have confined his attention to medicine and literature. But the love of controversy and an eagerness to establish his opinions, always possessed him. At this time Calvin was at the head of the reformed church at Geneva. With Servetus he had been acquainted at Paris, and had there opposed his opinions. For 16 years Calvin kept up a correspondence with him, endeavouring to reclaim him from his errors. Servetus had read the works of Calvin, but did not think they merited the high eulogies of the reformers, nor were they sufficient to convince him of his errors. He continued, however, to consult him; and for this purpose sent from Lyons to Geneva three questions which respected the divinity of Jesus Christ, regeneration, and the necessity of baptism. To these Calvin returned a civil answer. Servetus treated the answer with contempt, and Calvin replied with warmth. From reasoning he had recourse to abusive language; and this produced a polemical hatred, the most implacable disposition in the world. Calvin having obtained some of Servetus's papers, by means, it is said, not very honourable, sent them to Vienne along with the private letters which he had received in the course of their correspondence. The consequence was, that Servetus was arrested; but having escaped from prison, he resolved to retire to Naples, where he hoped to practise medicine with the same reputation which he had so long enjoyed at Vienne. He imprudently took his rout through Geneva, though he could not but know that Calvin was his mortal enemy. Calvin informed the magistrates of his arrival; Servetus was apprehended, and appointed to stand trial for heresy and blasphemy. It was a law at Geneva, that every acccuser should surrender himself a prisoner, that if the charge should be found false, the accuser should suffer the punishment in which he meant to involve the accused. Calvin not choosing to go to prison himself, sent one of his domestics to present the impeachment against Servetus. The articles brought against him were collected from his writings with great care; an employment which took up three days. One of these articles was, "that Servetus had denied that Judæa was a beautiful, rich, and fertile country; and affirmed, on the authority of travellers, that it was poor, barren, and disagreeable." He was also charged with "corrupting the Latin Bible, which he was employed to correct at Lyons, by introducing impertinent, trifling, whimsical, and impious notes of his own through every page." But the main article, which was certainly fatal to him, was, "that in the person of Mr Calvin, minister of the word of God in the church of Geneva, he had defamed the doctrine that is preached, uttering all imaginable injurious, blasphemous words against it."

Servetus.

Calvin visited Servetus in prison, and had frequent conferences with him; but finding that, in opposition to all the arguments he could employ, the prisoner remained inflexible in his opinions, he left him to his fate. Before sentence was passed, the magistrates of Geneva consulted the ministers of Bale, of Bern, and Zurich; and, as another account informs us, the magistrates of the Protestant Cantons of Switzerland. And to enable them to form a judgment of the criminality of Servetus, they transmitted the writings of Calvin, with his answers. The general opinion was, that Servetus ought to be condemned to death for blasphemy. He was accordingly sentenced to be burnt alive on the 27th of October 1553. As he continued alive in the midst of the flames more than two hours, it is said, finding his torment thus protracted, he exclaimed, "Unhappy wretch that I am! Will the flames be insufficient to terminate my misery! What then! Will the hundred pieces of gold, and the rich collar which they took from me, not purchase wood enough to consume me more quickly!" Though the sentence of death was passed against Servetus by the magistrates of Geneva, with the

Servetus ‖ Service.

approbation of a great number of the magistrates and ministers of Switzerland, yet it is the opinion of most historians that this dreadful sentence was imposed at the instigation of Calvin. This act of severity for holding a speculative opinion, however erroneous and absurd, has left a stain on the character of this illustrious reformer, which will attend the name of Calvin as long as history shall preserve it from oblivion. The address and art which he used in apprehending Servetus, his inhumanity to him during his trial, his dissimulation and malevolence after his condemnation, prove that he was as much influenced by personal hatred as by a desire to support the interest of religion, though probably, during the trial, Calvin believed he was performing a very pious action. This intolerant spirit of Calvin and the magistrates of Geneva gave the Roman Catholics a favourable opportunity to accuse the Protestants of inconsistency in their principles, which they did not fail to embrace. "How could the magistrates (says the author of the *Dictionare des Heresies*) who acknowledged no infallible interpretation of the Scriptures, condemn Servetus to death because he explained them differently from Calvin; since every man has the privilege to expound the Scripture, according to his own judgment, without having recourse to the church? It is a great injustice to condemn a man because he will not submit to the judgment of an enthusiast, who may be wrong as well as himself."

Servetus was a man of great acuteness and learning, and well versed in the arts and sciences. In his own profession his genius exerted itself with success. In his tract intitled *Christianismi Restitutio*, published in 1554, he remarks, that the whole mass of blood passes through the lungs by the pulmonary artery and vein, in opposition to the opinion which was then universally entertained, that the blood passes through the partition which divides the two ventricles. This was an important step towards the discovery of the circulation of the blood.

His works consist of Controversial Writings concerning the Trinity; an edition of Pagninus's Version of the Bible, with a preface and notes, published under the name of Michael Villanevanus; an Apology to the Physicians of Paris; and a book intitled *Ratio Syruporum*. Mosheim has written in Latin a History of the Heresy and Misfortunes of Servetus, which was published at Helmstadt, in 4to, in 1728. From the curious details which it gives it is extremely interesting.

SERVIA, a province of Turkey in Europe, bounded on the north by the rivers Danube and Save, which separate it from Hungary; on the east, by Bulgaria; on the west, by Bosnia; and on the south, by Albania and Macedonia. It is about 190 miles in length from east to west; 95 in breadth from north to south; and is divided into four sangiacates. Two of these were ceded to the Christians in 1718, who united them into one. This continued till 1739, when the Turks were victorious; and then they were abandoned to the Turks by the treaty of Belgrade. Belgrade is the capital town.

SERVICE, in law, is a duty which a tenant, on account of his fee, owes to his lord.

There are many divisions of service; as, 1. Into personal, where something is to be done by the tenant in person, as homage and fealty. 2. Real, such as wards, marriages, &c. 3. Accidental, including heriots, reliefs, and the like. 4. Entire, where, on the alienation of any part of the lands by a tenant, the services become multiplied. 5. Frank-service, which was performed by freemen, who were not obliged to perform any base service, but only to find a man and horse to attend the lord into the army or to court. 6. Knight's service, by which lands were anciently held of the king, on paying homage, service in war, &c.

Service.

As in every free and well regulated society there must be a diversity of ranks, there must be a great number of persons employed in service, both in agriculture and domestic affairs. In this country, service is a contract into which the servant voluntarily enters; and the master's authority extends no farther than to the performance of that species of labour for which the agreement was made.

"The treatment of servants (says that respectable moralist Mr Paley), as to diet discipline, and accommodation, the kind and quantity of work to be required of them, the intermission, liberty, and indulgence to be allowed them, must be determined in a great measure by custom; for where the contract involves so many particulars, the contracting parties express a few perhaps of the principal, and by mutual understanding refer the rest to the known custom of the country in like cases.

Paley's Moral and Political Philosophy, p. 139.

"A servant is not bound to obey the unlawful commands of his master; to minister, for instance, to his unlawful pleasures; or to assist him in unlawful practices in his profession; as in smuggling or adulterating the articles which he deals in. For the servant is bound by nothing but his own promise; and the obligation of a promise extends not to things unlawful.

"For the same reason, the master's authority does not justify the servant in doing wrong; for the servant's own promise, upon which that authority is founded, would be none.

"Clerks and apprentices ought to be employed entirely in the profession or trade which they are intended to learn. Instruction is their wages; and to deprive them of the opportunities of instruction, by taking up their time with occupations foreign to their business, is to defraud them of their wages.

"The master is responsible for what a servant does in the ordinary course of his employment; for it is done under a general authority committed to him, which is in justice equivalent to a specific direction. Thus, if I pay money to a banker's clerk, the banker is accountable: but not if I had paid it to his butler or his footman, whose business it is not to receive money. Upon the same principle, If I once send a servant to take up goods upon credit, whatever goods he afterwards takes up at the same shop, so long as he continues in my service, are justly chargeable to my account.

"The law of this country goes great lengths in intending a kind of concurrence in the master, so as to charge him with the consequences of his servant's conduct. If an innkeeper's servant rob his guests, the innkeeper must make restitution; if a farrier's servant lame your horse, the farrier must answer for the damage; and still farther, if your coachman or carter drive over a passenger in the road, the passenger may recover from you a satisfaction for the hurt he suffers. But these determinations stand, I think, rather upon the authority of the law, than any principle of natural justice."

There is a grievance which has long and justly been complained of, the giving of good characters to bad servants. This is perhaps owing to carelessness, to a desire of getting rid of a bad servant, or to mistaken compassion. But such carelessness is inexcusable. When a man gives his sanction to the character of a bad servant, he ought to reflect on the nature and consequences of what he is doing. He is giving his name to a falsehood; he is deceiving the honest man who confides in his veracity; and he is deliberately giving a knave an opportunity of cheating an honest man. To endeavour to get quit of a bad servant in this way, is surely not less criminal than concealing the faults and disadvantages of an estate which is advertised for sale, and ascribing to it advantages which it does not possess. In this case, we know the sale would be reduced, and the advertiser disgraced. Many masters give characters to servants out of compassion; but it is to this mistaken compassion that the disorderly behaviour of servants is perhaps principally owing: for if the punishment of dishonesty be only a change of place (which may be a reward instead of a punishment), it ceases to be a servant's interest to be true to his trust.

We have said above that a master's authority over his servant extends no farther than the terms of contract; by which we meant, that a master could give no unreasonable orders to his servant, or such as was inconsistent with the terms of contract. But the relation between a master and servant is certainly closer than the mere terms of a contract: it is a moral as well as a legal relation. A master of a family ought to superintend the morals of his servants, and to restrain them from vices. This he may do by his example, by his influence, and authority. Indeed every man possessed of authority is guilty of criminal negligence if he does not exert his authority for promoting virtue in his inferiors; and no authority is so well adapted for this purpose as that of masters of families, because none operates with an influence so immediate and constant. It is wonderful how much good a nobleman or gentlemen of fortune can do to his domestics by attending to their morals; and every master may be a blessing to individuals and to society, by exerting prudently that influence which his situation gives him over the conduct of his servant.

Choral Service, in church-history, denotes that part of religious worship which consists in chanting and singing. The advocates for the high antiquity of singing, as a part of church-music, urge the authority of St Paul in its favour (Ephes. chap. v. ver. 19. and Colos. chap. iii. ver. 16). On the authority of which passages it is asserted, that songs and hymns were, from the establishment of the church, sung in the assemblies of the faithful; and it appears from undoubted testimony, that singing, which was practised as a sacred rite among the Egyptians and Hebrews, at a very early period, and which likewise constituted a considerable part of the religious ceremonies of the Greeks and Romans, made a part of the religious worship of Christians, not only before churches were built, and their religion established by law, but from the first profession of Christianity. However, the era from whence others have dated the introduction of music into the service of the church, is that period during which Leontius governed the church of Antioch, *i. e.* between the year of Christ 347 and 356. See Antiphone.

From Antioch the practice soon spread through the other churches of the East; and in a few ages after its first introduction in the divine service, it not only received the sanction of public authority, but those were forbid to join in it who were ignorant of music. A canon to this purpose was made by the council of Laodicea, which was held about the year 372: and Zonanas informs us, that these canonical singers were reckoned a part of the clergy. Singing was introduced into the western churches by St Ambrose about the year 374, who was the institutor of the Ambrosian chant established at Milan about the year 386; and Eusebius (lib. ii. cap. 17.) tells us, that a regular choir, and method of singing the service, were first established, and hymns used, in the church at Antioch during the reign of Constantine, and that St Ambrose, who had long resided there, had his melodies thence. This was about 230 years afterwards amended by Pope Gregory the Great, who established the Gregorian chant; a plain, unisonous kind of melody, which he thought consistent with the gravity and dignity of the service to which it was to be applied. This prevails in the Roman church even at this day: it is known in Italy by the name of *canto fermo;* in France by that of *plain chant;* and in Germany and most other countries by that of the *cantus Gregorianus*. Although no satisfactory account has been given of the specific difference between the Ambrosian and Gregorian chants, yet all writers on this subject agree in saying, that St Ambrose only used the four authentic modes, and that the four plagal were afterwards added by St Gregory. Each of these had the same final, or key-note, as its relative authentic; from which there is no other difference, than that the melodies in the four authentic or principal modes are generally confined within the compass of the eight notes above the key-note, and those in the four plagal of relative modes, within the compass of the eight notes below the fifth of the key. See Mode.

Ecclesiastical writers seem unanimous in allowing that Pope Gregory, who began his pontificate in 590, collected the musical fragments of such ancient psalms and hymns as the first fathers of the church had approved and recommended to the first Christians; and that he selected, methodized, and arranged them in the order which was long continued at Rome, and soon adopted by the chief part of the western church. Gregory is also said to have banished from the church the *canto figurato*, as too light and dissolute; and it is added, that his own chant was called *canto fermo*, from its gravity and simplicity.

It has been long a received opinion, that the ecclesiastical tones were taken from the reformed modes of Ptolemy; but Dr Burney observes, that it is difficult to discover any connection between them, except in their names; for their number, upon examination, is not the same; those of Ptolemy being seven, the ecclesiastical eight; and indeed the Greek names given to the ecclesiastical modes do not agree with those of Ptolemy in the single instance of key, but with those of higher antiquity. From the time of Gregory to that of Guido, there was no other distinction of keys than that of authentic and plagal; nor were any semitones used but those from E to F, B to C, and occasionally A to B*b*.

With respect to the music of the primitive church, it may

Service.

may be obſerved, that though it conſiſted in the ſinging of pſalms and hymns, yet it was performed in many different ways; ſometimes the pſalms were ſung by one perſon alone, whilſt the reſt attended in ſilence; ſometimes they were ſung by the whole aſſembly; ſometimes alternately, the congregation being divided into ſeparate choirs; and ſometimes by one perſon, who repeated the firſt part of the verſe, the reſt joining in the cloſe of it. Of the four different methods of ſinging now recited, the ſecond and third were properly diſtinguiſhed by the names of *ſymphony* and *antiphony*; and the latter was ſometimes called *reſponſaria*, in which women were allowed to join. St Ignatius, who, according to Socrates (lib. vi. cap. 8.), converſed with the apoſtles, is generally ſuppoſed to have been the firſt who ſuggeſted to the primitive Chriſtians in the Eaſt the method of ſinging hymns and pſalms alternately, or in dialogue; and the cuſtom ſoon prevailed in every place where Chriſtianity was eſtabliſhed; though Theodoret in his hiſtory (lib. ii. cap. 24.) tells us, that this manner of ſinging was firſt practiſed at Antioch. It likewiſe appears, that almoſt from the time when muſic was firſt introduced into the ſervice of the church, it was of two kinds, and conſiſted in a gentle inflection of the voice, which they termed plain ſong, and a more elaborate and artificial kind of muſic, adapted to the hymns and ſolemn offices contained in its ritual; and this diſtinction has been maintained even to the preſent day.

Although we find a very early diſtinction made between the manner of ſinging the hymns and chanting the pſalms, it is, however, the opinion of the learned Martini, that the muſic of the firſt five or ſix ages of the church conſiſted chiefly in a plain and ſimple chant of uniſons and octaves, of which many fragments are ſtill remaining in the *canto fermo* of the Romiſh miſſals. For with reſpect to muſic in parts, as it does not appear, in theſe early ages, that either the Greeks or Romans were in poſſeſſion of harmony or counterpoint, which has been generally aſcribed to Guido, a monk of Arezzo in Tuſcany, about the year 1022, though others have traced the origin of it to the eighth century, it is in vain to ſeek it in the church. The choral muſic, which had its riſe in the church of Antioch, and from thence ſpread through Greece, Italy, France, Spain, and Germany, was brought into Britain by the ſingers who accompanied Auſtin the monk, when he came over, in the year 596, charged with a commiſſion to convert the inhabitants of that country to Chriſtianity. Bede tells us, that when Auſtin and the companions of his miſſion had their firſt audience of king Ethelbert, in the iſle of Thanet, they appoached him in proceſſion, ſinging litanies; and that afterwards, when they entered the city of Canterbury, they ſung a litany, and at the end of it Allelujah. But though this was the firſt time the Anglo Saxons had heard the Gregorian chant, yet Bede likewiſe tells us, that our Britiſh anceſtors had been inſtructed in the rites and ceremonies of the Gallican church by St Germanus, and heard him ſing Allelujah many years before the arrival of St Auſtin. In 680, John, præcentor of St Peter's in Rome, was ſent over by pope Agatho to inſtruct the monks of Weremouth in the art of ſinging; and he was prevailed upon to open ſchools for teaching muſic in other places in Northumberland. Benedict Biſcop, the preceptor of Bede, Adrian the monk, and many others, contibuted to diſſeminate the knowledge of the Roman chant. At length the ſucceſſors of St Gregory, and of Auſtin his miſſionary, having eſtabliſhed a ſchool for eccleſiaſtical muſic at Canterbury, the reſt of the iſland was furniſhed with maſters from that ſeminary. The choral ſervice was firſt introduced in the cathedral church of Canterbury; and till the arrival of Theodore, and his ſettlement in that ſee, the practice of it ſeems to have been confined to the churches of Kent; but after that, it ſpread over the whole kingdom; and we meet with records of very ample endowments for the ſupport of this part of public worſhip. This mode of religious worſhip prevailed in all the European churches till the time of the Reformation: the firſt deviation from it is that which followed the Reformation by Luther, who, being himſelf a lover of muſic, formed a liturgy, which was a muſical ſervice, contained in a work entitled *Pſalmodia*, h. e. *Cantica ſacra Veteris Eccleſiæ ſelecta*, printed at Norimberg in 1553, and at Wittemberg in 1561. But Calvin, in his eſtabliſhment of a church at Geneva, reduced the whole of divine ſervice to prayer, preaching, and ſinging; the latter of which he reſtrained. He excluded the offices of the antiphon, hymn, and motet, of the Romiſh ſervice, with that artificial and elaborate muſic to which they were ſung; and adopted only that plain metrical pſalmody, which is now in general uſe among the reformed churches, and in the parochial churches of Great Britain. For this purpoſe he made uſe of Marot's verſion of the Pſalms, and employed a muſician to ſet them to eaſy tunes only of one part. In 1553, he divided the Pſalms into pauſes or ſmall portions, and appointed them to be ſung in churches. Soon after they were bound up with the Geneva catechiſm; from which time the Catholics, who had been accuſtomed to ſing them, were forbid the uſe of them, under a ſevere penalty. Soon after the Reformation commenced in England, complaints were made by many of the dignified clergy and others of the intricacy and difficulty of the church-muſic of thoſe times: in conſequence of which it was once propoſed, that organs and curious ſinging ſhould be removed from the churches. Latimer in his dioceſe of Worceſter, went ſtill farther, and iſſued injunctions to the prior and convent of St Mary, forbidding in their ſervice all manner of ſinging. In the reign of Edward VI. a commiſſion was granted to eight biſhops, eight divines, eight civilians, and eight common lawyers, to compile a body of ſuch eccleſiaſtical laws as ſhould in future be obſerved throughout the realm. The reſult of this compilation was a work firſt publiſhed by Fox the martyrologiſt, in 1571, and afterwards in 1640, under the title of *Reformatio Legum Eccleſiaſticarum.* Theſe 32 commiſſioners, inſtead of reprobating church-muſic, merely condemned figurative and operoſe muſic, or that kind of ſinging which abounded with fugues, reſponſive paſſages, and a commixture of various and intricate proportions; which, whether extemporary or written, is by muſicians termed *deſcant.* However, notwithſtanding the objections againſt choral muſic, and the practice of ſome of the reformed churches, the compilers of the Engliſh liturgy in 1548, and the king himſelf, determined to retain muſical ſervice. Accordingly the ſtatute 2 & 3 Edw. VI. cap. 1. though it contains no formal obligation on the clergy, or others, to uſe or join in either vocal or inſtrumental muſic in the common prayer, does clearly recogniſe the practice of ſinging;

and

and in less than two years after the compiling of King Edward's liturgy, a formula was composed, which continues, with scarce any variation, to be the rule for choral service even at this day. The author of this work was John Marbecke, or Marbeike; and it was printed by Richard Grafton, in 1550, under the title of the Book of Common Prayer, noted. Queen Mary laboured to re-establish the Romish choral service; but the accession of Elizabeth was followed by the act of uniformity; in consequence of which, and of the queen's injunctions, the Book of Common Prayer, noted by Marbecke, was considered as the general formula of choral service. In 1560, another musical service, with some additions and improvements, was printed by John Day; and in 1565, another collection of offices, with musical notes. Many objections were urged by Cartwright and other Puritans against the form and manner of cathedral service, to which Hooker replied in his Ecclesiastical Polity. In 1664, the statues of Edward VI. and Elizabeth, for uniformity in the Common Prayer, were repealed; and the Directory for Public Worship, which allows only of the singing of psalms, established. But upon the restoration of Charles II. choral service was again revived, and has since uniformly continued. See on this subject Hawkins's History of Music, vol. i. p. 404. vol. ii. p. 264. vol. iii. p. 58—468, &c. vol. iv. p. 44—347.

Service-Tree. See Sorbus.

SERVITES, a religious order in the church of Rome, founded about the year 1233, by seven Florentine merchants, who, with the approbation of the bishop of Florence, renounced the world, and lived together in a religious community on mount Senar, two leagues from that city.

SERVITOR, in the university of Oxford, a student who attends on another for his maintenance and learning. See Sizar.

SERVITUDE, the condition of a servant, or rather slave.

Under the declension of the Roman empire, a new kind of servitude was introduced, different from that of the ancient Romans: it consisted in leaving the lands of subjugated nations to the first owners, upon condition of certain rents, and servile offices, to be paid in acknowledgment. Hence the names of *servi censiti, ascriptitii* and *addicti glebæ;* some whereof were taxable at the reasonable discretion of the lord; others at a certain rate agreed on; and others were mainmortable, who, having no legitimate children, could not make a will to above the value of five pence, the lord being heir of all the rest; and others were prohibited marrying, or going to live out of the lordship. Most of these services existed lately in France; but they were long ago abolished in England. Such, however, was the original of our tenures, &c. See Slave.

Servitude, in Scots law. See Law, Part III. Sect. ix.

SERVIUS (Maurus Honoratus) a celebrated grammarian and critic of antiquity, who flourished about the time of Arcadius and Honorius; now chiefly known by his Commentaries on Virgil. There is also extant a piece of Servius upon the feet of verses and the quantity of syllables, called *Centimetrum.*

SERUM; a thin, transparent, saltish liquor, which makes a considerable part of the mass of blood. See Anatomy, n° 126. and Blood.

SESAMOIDEA ossa, certain small bones somewhat resembling the seeds of sesamum, whence their name. They are placed at the under part of the bones of the last joints of the fingers and toes.

SESAMUM, oily grain, in botany: A genus of plants belonging to the class of didynamia, and to the order of angiospermia; and in the natural system ranging under the 20th order, *Luridæ.* The calyx is divided into five parts. The corolla is campanulated, the tube of which is nearly the length of the calyx; the throat is inflated, and very large; the border is divided into five parts, four of which are spreading and nearly equal; the fifth is the lowest and largest. There are four filaments, and the rudiments of a fifth. The stigma is lanceolated, and the capsule has four cells. There are only two species, the *orientale* and *indicum.* 1. The orientale has ovate, oblong, entire leaves. It is an annual, and grows naturally on the coast of Malabar and in the island of Ceylon; rising with an herbaceous four-cornered stalk, two feet high, sending out a few short side-branches; the leaves are oblong, oval, a little hairy, and stand opposite. The flowers terminate the stalks in loose spikes; they are small, of a dirty white colour, shaped somewhat like those of the fox-glove. After the flowers are past, the germen turns to an oval acute-pointed capsule with four cells, filled with oval compressed seeds, which ripen in autumn. 2. The indicum, with trifid lower leaves grows naturally in India: this is also an annual plant; the stalk rises taller than that of the former; the lower leaves are cut into three parts, which is the only difference between them.

The first sort is frequently cultivated in all the eastern countries, and also in Africa, as a pulse; and of late years the seeds have been introduced into Carolina by the African negroes, where they succeed extremely well. The inhabitants of that country make an oil from the seed, which will keep good many years, without having any rancid smell or taste, but in two years become quite mild; so that when the warm taste of the seed, which is in the oil when first drawn, is worn off, they use it as a salad-oil, and for all the purposes of sweet oil. The seeds of this plant are also used by the negroes for food; which seeds they parch over the fire, and then mix them with water, and stew other ingredients with them, which makes an hearty food. Sometimes a sort of pudding is made of these seeds, in the same manner as with millet or rice, and is by some persons esteemed, but is rarely used for these purposes in Europe. This is called *benny* or *bonny* in Carolina. In England these plants are preserved in botanic gardens as curiosities. Their seeds must be sown in the spring upon a hot bed; and when the plants are come up, they must be transplanted into a fresh hot-bed to bring them forward. After they have acquired a tolerable degree of strength, they should be planted into pots, and plunged into another hot-bed, managing them as hath been directed for amaranths; for if these plants are not thus brought forward in the former part of the summer, they will not produce good seeds in this country.

From nine pounds of this seed which came from Carolina,

rolina, there were upwards of two quarts of oil drawn, which is as great a quantity as hath been obtained from any vegetable whatever. This might occafion its being called the *oily grain.*

SESELI, MEADOW SAXIFRAGE, in botany: A genus of plants belonging to the clafs of pentandria, and to the order of digynia; and in the natural fyftem ranging under the 45th order, *Umbellatæ.* The umbels are globular; the involucrum confifts of one or two leaflets; the fruit is egg-fhaped and ftreaked. There are 11 fpecies, the *pimpinelloides, montanum, glaucum, annuum, ammoides, tortuofum, turbith, hyppomarathrum, pyrenæum, faxifragum,* and *elatum.* The montanum grows naturally in France and Italy; the glaucum is a native of France; the ammoides and tortuofum grow in the fouth of Europe; and the hyppomarathrum is a native of Auftria.

SESOSTRIS, king of Egypt. See EGYPT, p. 368.

SESQUI, a Latin particle, fignifying a whole and a half; which, joined with *altera, terza, quarta,* &c. is much ufed in the Italian mufic to exprefs a kind of ratios, particularly feveral fpecies of triples.

SESQUI-Alterate, in geometry and arithmetic, is a ratio between two lines, two numbers, or the like, where one of them contains the other once, with the addition of a half.

Thus 6 and 9 are in a fefqui-alterate ratio; fince 9 contains 6 once, and 3, which is half of 6, over; and 20 and 30 are in the fame; as 30 contains 20, and half 20 or 10.

SESQUI-Duplicate ratio, is when of two terms the greater contains the lefs twice, and half the lefs remains; as 15 and 6; 50 and 20.

SESQUI-Tertional proportion, is when any number or quantity contains another once and one third.

SESSILE, among botanifts. See BOTANY.

SESSION, in general, denotes each fitting or affembly of a council, &c.

SESSION of Parliament, is the feafon or fpace from its meeting to its prorogation. See PARLIAMENT.

Kirk-SESSION, the name of a petty ecclefiaftical court in Scotland. See *KIRK-Seffion.*

SESSIONS for weights and meafures. In London, four juftices from among the mayor, recorder, and aldermen (of whom the mayor or recorder is to be one), may hold a feffion to inquire into the offences of felling by falfe weights and meafures, contrary to the ftatutes; and to receive indictments, punifh offenders, &c. Char. king Charles I.

Court of SESSION. See LAW, Part III. Sect. ii.

Court of Quarter SESSIONS, an Englifh court that muft be held in every county once in every quarter of a year; which, by ftatute 2 Hen. V. c. 4. is appointed to be in the firft week after Michaelmas-day, the firft week after the epiphany, the firft week after the clofe of Eafter, and in the week after the tranflation of St Thomas the martyr, or the 7th of July. It is held before two or more juftices of the peace, one of which muft be of the quorum. The jurifdiction of this court, by 34 Edw. III. c. 1. extends to the trying and determining all felonies and trefpaffes whatfoever: though they feldom, if ever, try any greater offence than fmall felonies within the benefit of clergy; their commiffion providing, that if any cafe of difficulty arifes, they fhall not proceed to judgment, but in the prefence of one of the juftices of the courts of king's-bench or common-pleas, or one of the judges of affize: and therefore murders, and other capital felonies, are ufually remitted for a more folemn trial to the affizes. They cannot alfo try any new-created offence, without exprefs power given them by the ftatute which creates it. But there are many offences and particular matters which, by particular ftatutes, belong properly to this jurifdiction, and ought to be profecuted in this court; as, the fmaller mifdemeanors againft the public or commonwealth, not amounting to felony; and efpecially offences relating to the game, highways, alehoufes, baftard children, the fettlement and provifion for the poor, vagrants, fervants wages, and Popifh recufants. Some of thefe are proceeded upon by indictment: others in a fummary way, by motion, and order thereupon; which order may for the moft part, unlefs guarded againft by particular ftatutes, be removed into the court of king's-bench by writ of *certiorari facias,* and be there either quafhed or confirmed. The records or rolls of the feffions are committed to the cuftody of a fpecial officer, denominated *cuftos rotulorum,* who is always a juftice of the quorum; and among them of the quorum (faith Lambard) a man for the moft part efpecially picked out, either for wifdom, countenance, or credit. The nomination of the *cuftos rotulorum* (who is the principal officer in the county, as the lord-lieutenant is chief in military command) is by the king's fign-manual: and to him the nomination of the clerk of the peace belongs; which office he is exprefsly forbidden to fell for money.

In moft corporation-towns there are quarter-feffions kept before juftices of their own, within their refpective limits; which have exactly the fame authority as the general quarter-feffions of the county, except in a very few inftances; one of the moft confiderable of which is the matter of appeals from orders of removal of the poor, which, though they be from the orders of corporation-juftices, muft be to the feffions of the county, by ftatute 8 and 9 W. III. c. 30. In both corporations and counties at large, there is fometimes kept a fpecial or petty feffion, by a few juftices, for difpatching fmaller bufinefs in the neighbourhood between the times of the general feffions; as for licenfing alehoufes, paffing the account of parifh-officers, and the like.

SESTERCE, SESTERTIUS, a filver coin, in ufe among the ancient Romans, called alfo fimply *nummus,* and fometimes *nummus feftertius.* The feftertius was the fourth part of the denarius, and originally contained two affes and a half. It was at firft denoted by LLS; the two L's fignifying two libræ, and the S half. But the librarii, afterwards converting the two L's into an H, expreffed the feftertius by HS. The word *feftertius* was firft introduced by way of abbreviation for *femiftertius,* which fignifies two, and a half of a third, or, literally, only half a third; for in expreffing half a third, it was underftood that there were two before.

Some authors make two kinds of fefterces; the lefs called *feftertius,* in the mafculine gender; and the great one, called *feftertium,* in the neuter: the firft, that we have already defcribed; the latter containing a thoufand of the other. Others will have any fuch diftinction of great and little fefterces unknown to the Romans; *feftertius,* fay they, was an adjective, and fignified *as feftertius.*

tius, or two asses and a half; and when used in the plural, as in *quinquaginta sestertium*, or *sestertia*, it was only by way of abbreviation, and there was always understood *centena*, *millia*, &c.

This matter has been accurately stated by Mr Raper, in the following manner. The substantive to which sestertius referred, is either *as* or *pondus;* and *sestertius as* is two asses and a half; *sestertium pondus*, two pondera and a half, or two hundred and fifty denarii. When the denarius passed for ten asses, the sestertius of two asses and a half was a quarter of it; and the Romans continued to keep their accounts in these sesterces long after the denarius passed for sixteen asses; till, growing rich, they found it more convenient to reckon by quarters of the denarius, which they called *nummi*, and used the words *nummus* and *sestertius* indifferently, as synonymous terms, and sometimes both together, as *sestertius nummus;* in which case the word *sestertius*, having lost its original signification, was used as a substantive; for *sestertius nummus* was not two nummi and a half, but a single nummus of four asses. They called any sum under two thousand sesterces so many *sestertii* in the masculine gender; two thousand sesterces they called *duo* or *bina sestertia*, in the neuter, so many quarters making five hundred denarii, which was twice the sestertium; and they said *dena*, *vicena*, &c. *sestertia*, till the sum amounted to a thousand sestertia, which was a million of sesterces. But, to avoid ambiguity, they did not use the neuter *sestertium* in the singular number, when the whole sum amounted to no more than a thousand sesterces, or one sestertium. They called a million of sesterces *decies nummûm*, or *decies sestertiûm*, for *decies centena millia nummorum*, or *sestertiorum* (in the masculine gender), omitting *centena millia* for the sake of brevity. They likewise called the same sum *decies sestertium* (in the neuter gender) for *decies centies sestertium* omitting *centies* for the same reason; or simply *decies*, omitting *centena millia sestertiûm*, or *centies sestertium;* and with the numeral adverbs *decies*, *vicies*, *centies*, *millies*, and the like, either *centena millia* or *centies* was always understood. These were their most usual forms of expression; though for *bina*, *dena*, *vicena sestertia*, they frequently said *bina*, *dena*, *vicena millia nummûm*. If the consular denarius contained 60 troy grains of fine silver, it was worth somewhat more than eight-pence farthing and a half sterling; and the as, of 16 to the denarius, a little more than a halfpenny. To reduce the ancient sesterces of two asses and a half, when the denarius passed for 16, to pounds sterling, multiply the given number by 5454, and cut off six figures on the right hand for decimals. To reduce *nummi sestertii*, or quarters of the denarius, to pounds sterling; if the given sum be consular money, multiply it by 8727, and cut off six figures on the right hand for decimals; but for imperial money diminish the said product by one-eighth of itself. Phil. Transf. vol. lxi. part ii. art. 48.

To be qualified for a Roman knight, an estate of 400,000 *sesterces* was required; and for a senator, of 800,000.

Authors also mention a copper *sesterce*, worth about one-third of a penny English.

SESTERCE, or *sestertius*, was also used by the ancients for a thing containing two wholes and an half of another, as *as* was taken for any whole or integer.

SESTOS, a noted fortress of European Turkey, situated at the entrance of the Hellespont or Dardanelles, 24 miles south-west of Gallipoli. This place is famous for the loves of HERO and LEANDER, sung by the poet Musæus.

SESUVIUM, in botany; a genus of plants belonging to the class of icosandria, and to the order of trigynia. The calyx is coloured and divided into five parts; there are no petals; the capsule is egg-shaped, three-celled, opening horizontally about the middle, and containing many seeds. There is only one species, the *portulacastrum*, purslane-leaved sesuvian, which is a native of the West Indies.

SET, or SETS, a term used by the farmers and gardeners to express the young plants of the white thorn and other shrubs, with which they use to raise their quick or quick-set hedges. The white thorn is the best of all trees for this purpose; and, under proper regulations, its sets seldom fail of answering the farmer's utmost expectations.

Set-off, in law, is an act whereby the defendant acknowledges the justice of the plaintiff's demand on the one hand; but, on the other, sets up a demand of his own, to counterbalance that of the plaintiff, either in the whole, or in part: as, if the plaintiff sues for 10 l. due on a note of hand, the defendant may set off 9 l. due to himself for merchandise sold to the plaintiff; and, in case he pleads such set-off, must pay the remaining balance into court. This answers very nearly to the *compensatio* or stoppage of the civil law, and depends upon the statutes 2 Geo. II. cap. 22. and 8 Geo. II. cap. 24.

SETACEOUS WORM, in natural history, a name given by Dr Lister to that long and slender water-worm, which so much resembles a horse-hair, that it has been supposed by the vulgar to be an animated hair of that creature. These creatures, supposed to be living hairs, are a peculiar sort of insects, which are bred and nourished within the bodies of other insects, as the worms of the ichneumon flies are in the bodies of the caterpillars.

Aldrovand describes the creature, and tells us it was unknown to the ancients; but called *seta aquatica*, and *vermis setarius*, by the moderns, either from its figure resembling that of a hair, or from the supposition of its once having been the hair of some animal. We generally suppose it, in the imaginary state of the hair, to have belonged to a horse; but the Germans say it was once the hair of a calf, and call it by a name signifying *vitulus aquaticus*, or the "water calf."

Albertus, an author much reverenced by the common people, has declared that this animal is generated of a hair; and adds, that any hair thrown into standing water, will, in a very little time, obtain life and motion. Other authors have dissented from this opinion, and supposed them generated of the fibrous roots of water-plants; and others, of the parts of grasshoppers fallen into the water. This last opinion is rejected by Aldrovand as the most improbable of all. Standing and foul waters are most plentifully stored with them; but they are sometimes found in the clearest and purest springs, and sometimes out of the water, on the leaves of trees and plants, as on the fruit-trees in our gardens, and the elms in hedges. They are from three to five inches long, of the thickness of a large hair; and are brown,

brown upon the back, and white under the belly, and the tail is white on every part.

SETH, the third ſon of Adam, the father of Enos, was born 3874 B. C. and lived 912 years.

SETHIANS, in church-hiſtory, Chriſtian heretics; ſo called becauſe they paid divine worſhip to Seth, whom they looked upon to be Jeſus Chriſt the ſon of God, but who was made by a third divinity, and ſubſtituted in the room of the two families of Abel and Cain, which had been deſtroyed by the deluge. Theſe heretics appeared in Egypt in the ſecond century; and as they were addicted to all ſorts of debauchery, they did not want followers; and continued in Egypt above 200 years.

SETIMO, a town of Italy, in the province of Piedmont, ſituated on the river Po, eight miles north of Turin.

SETON, in ſurgery, a few horſe hairs, ſmall threads, or large packthread, drawn through the ſkin, chiefly the neck, by means of a large needle or probe, with a view to reſtore or preſerve health.

We find by experience, that ſetons are very uſeful in catarrhs, inflammations, and other diſorders, particularly thoſe of the eyes, as a gutta ſerena, cataract, and incipient ſuffuſion; to theſe we may add intenſe headachs, with ſtupidity, drowſineſs, epilepſies, and even the apoplexy itſelf.

SETTEE, in ſea-language, a veſſel very common in the Mediterranean with one deck and a very long and ſharp prow. They carry ſome two maſts, ſome three, without top-maſts. They have generally two maſts, equipped with triangular ſails, commonly called *lateen ſails*. The leaſt of them are of 60 tuns burden. They ſerve to tranſport cannon and proviſions for ſhips of war and the like. Theſe veſſels are peculiar to the Mediterranean ſea, and are uſually navigated by Italians, Greeks, or Mahometans.

SETTING, in aſtronomy, the withdrawing of a ſtar or planet, or its ſinking below the horizon. Aſtronomers and poets make three different kinds of ſetting of the ſtars, viz. the Cosmical, Acronycal, and Heliacal. See theſe articles.

Setting, in the ſea-language. To ſet the land or the ſun by the compaſs, is to obſerve how the land bears on any point of the compaſs, or on what point of the compaſs the ſun is. Alſo when two ſhips ſail in ſight of one another, to mark on what point the chaſed bears, is termed *ſetting the chaſe by the compaſs*.

Setting, among ſportſmen, a term uſed to expreſs the manner of taking partridges by means of a dog peculiarly trained to that purpoſe. See Shooting.

Act of SETTLEMENT, in Britiſh hiſtory, a name given to the ſtatute 12 and 13 W. III. cap. 2. whereby the crown was limited to his preſent majeſty's illuſtrious houſe; and ſome new proviſions were added, at the ſame fortunate era, for better ſecuring their religion, laws, and liberties; which the ſtatute declares to be the birthright of the people of England, according to the ancient doctrine of the common law.

SEVENTH, in muſic, an interval called by the Greeks *heptachordon*. See Interval.

SEVERANCE in law, the ſingling or ſevering two or more that join or are joined in the ſame writ or action. As if two join in a writ, *de libertate probanda*, and the one be afterwards nonſuited; here ſeverance is permitted, ſo as notwithſtanding the nonſuit of the one, the other may ſeverally proceed.

There is alſo ſeverance of the tenants in aſſize; when one, two, or more diſſeiſees appear upon the writ, and not the other. And ſeverance in debt, where two executors are named plaintiffs, and the one refuſes to proſecute. We alſo meet with ſeverance of ſummons, ſeverance in attaints, &c. An eſtate in joint tenancy may be ſevered and deſtroyed by deſtroying any of its unities. 1. That of time, which reſpects only the original commencement of the joint eſtate, cannot indeed (being now part) be affected by any ſubſequent tranſaction. But, 2. The joint-tenants eſtate may be deſtroyed without any alienation, by merely diſuniting their poſſeſſion. 3. The jointure may be deſtroyed, by deſtroying the unity of title. And, 4. By deſtroying the unity of intereſt.

SEVERIA, a province of the Ruſſian empire, with the title of a duchy, bounded on the north by Smolenſko and Muſcovy, on the eaſt by Vorotinſbi and the country of the Coſſacks, on the ſouth by the ſame, and on the weſt by Zernegovia. It is a country overrun with woods, and on the ſouth part is a foreſt of great length. Novogrodec, or Novogorod, is the capital town.

St SEVERINA, a town of Italy, in the kingdom of Naples, and in Lower Calabria, with an archbiſhop's ſee. It is very well fortified, and ſeated on a craggy rock, on the river Neeto; in E. Long. 17. 14. N. Lat. 39. 15.

SEVERINO, a town of Italy, in the territory of the church, and in the Marche of Anconia, with a biſhop's ſee. It has fine vineyards, and is ſeated between two hills on the river Petenza, in E. Long. 13. 6. N. Lat. 43. 16.

SEVERN, a river which riſes near Plimlimmon-Hill in Montgomeryſhire, and before it enters Shropſhire receives about 30 ſtreams, and paſſes down to Laudring, where it receives the Morda, that flows from Oſweſtry. When it arrives at Monford, it receives the river Mon, paſſing on to Shrewſbury, which it almoſt ſurrounds, then to Bridgeworth; afterwards it runs through the ſkirts of Staffordſhire, enters Worceſterſhire, and paſſes by Worceſter; then it runs to Tewkeſbury, where it joins the Avon, and from thence to Glouceſter, keeping a north-weſterly courſe, till it falls into the Briſtol Channel. It begins to be navigable for boats at Welchpool, in Montgomeryſhire, and takes in ſeveral other rivers in its courſe, beſides thoſe already mentioned, and *is the ſecond in England*. By the late inland navigation, it has communication with the rivers Merſey, Dee, Ribble, Ouſe, Trent, Derwent, Humber, Thames, Avon, &c. which navigation, including its windings, extends above 500 miles in the counties of Lincoln, Nottingham, York, Lancaſter, Weſtmoreland, Cheſter, Stafford, Warwick, Leiceſter, Oxford, Worceſter, &c. A canal from Stroud-Water, a branch of the Severn, to join the Thames, has lately been undertaken, by which great undertaking of conveying a tunnel 16 feet high and 16 feet wide, under Sapperton-Hill and Hayley-Wood (very high ground), for two miles and a quarter in length, through a very hard rock, lined and arched with brick, is entirely completed, and boats paſſed through it the 21ſt of May 1789. By this opening, a communication is made between the river Severn at

Lucombe's English Gazetteer.

Severus.

Framiload and the Thames near Leechlade, and will be continued over the Thames near Inglesham, into deep water in the Thames below St John-Bridge, and so to Oxford, &c. and London, for conveyance of coals, goods, &c. It is now navigable from the Severn to Themsford, by way of Stroud, Cirencester, Cricklade, &c. being filled with water for that purpose near 40 miles.

SEVERUS (Cornelius), an ancient Latin poet of the Augustan age; whose *Ætna*, together with a fragment *De morte Ciceronis*, were published, with notes and a prose interpretation, by Le Clerc, 12mo, Amsterdam, 1703. They were before inserted among the *Catalecta Virgilii* published by Scaliger; whose notes, with others, Le Clerc has received among his own.

Severus (Septimus), a Roman emperor, who has been so much admired for his military talents, that some have called him the most warlike of the Roman emperors. As a monarch he was cruel, and it has been observed that he never did an act of humanity or forgave a fault. In his diet he was temperate, and he always showed himself an open enemy to pomp and splendor. He loved the appellation of a man of letters, and he even composed an history of his own reign, which some have praised for its correctness and veracity. However cruel Severus may appear in his punishments and in his revenge, many have endeavoured to exculpate him, and observed that there was need of severity in an empire where the morals were so corrupted, and where no less than 3000 persons were accused of adultery during the space of 17 years. Of him, as of Augustus, some were fond to say, that it would have been better for the world if he had never been born, or had never died. See Rome, n° 372.

Severus's Wall, in British topography, the fourth and last barrier erected by the Romans against the incursions of the North Britons. See the articles Adrian, and *Antoninus's Wall*.

We learn from several hints in the Roman historians, that the country between the walls of Hadrian and Antoninus continued to be a scene of perpetual war and subject of contention between the Romans and Britons, from the beginning of the reign of Commodus to the arrival of the emperor Septimius Severus in Britain, A. D. 206. This last emperor having subdued the Mæatæ, and repulsed the Caledonians, determined to erect a stronger and more impenetrable barrier than any of the former, against their future incursions.

Though neither Dio nor Herodian make any mention of a wall built by Severus in Britain for the protection of the Roman province, yet we have abundant evidence from other writers of equal authority, that he really built such a wall. "He fortified Britain (says Spartian) with a wall drawn cross the island from sea to sea; which is the greatest glory of his reign. After the wall was finished, he retired to the next station (York), not only a conqueror, but the founder of an eternal peace." To the same purpose, Aurelius Victor and Orosius, to say nothing of Eutropius and Cassiodorus: "Having repelled the enemy in Britain, he fortified the country, which was suited to that purpose, with a wall drawn cross the island from sea to sea."—"Severus drew a great ditch, and built a strong wall, fortified with several turrets, from sea to sea, to protect that part of the island which he had recovered from the yet unconquered nations." As the residence of the emperor Severus in Britain was not quite four years, it is probable that the two last of them were employed in building this wall; according to which account, it was begun A. D. 209, and finished A. D. 210.

This wall of Severus was built nearly on the same tract with Hadrian's rampart, at the distance only of a few paces north. The length of this wall, from Cousins' house near the mouth of the river Tyne on the east, to Boulness on the Solway frith on the west, hath been found, from two actual mensurations, to be little more than 68 English miles, and a little less than 74 Roman miles. To the north of the wall was a broad and deep ditch, the original dimensions of which cannot now be ascertained, only it seems to have been larger than that of Hadrian. The wall itself, which stood on the south brink of the ditch, was built of free-stone, and where the foundation was not good, it is built on piles of oak; the interstices between the two faces of this wall are filled with broad thin stones, placed not perpendicularly, but obliquely on their edges; the running mortar or cement was then poured upon them, which, by its great strength and tenacity, bound the whole together, and made it firm as a rock. But though these materials are sufficiently known, it is not easy to guess where they were procured, for many parts of the wall are at a great distance from any quarry of free stone; and, though stone of another kind was within reach, yet it does not appear to have been anywhere used. The height of this wall was 12 feet besides the parapet, and its breadth 8 feet, according to Bede, who lived only at a small distance from the east end of it, and in whose time it was almost quite entire in many places. Such was the wall erected by the command and under the direction of the emperor Severus in the north of England; and, considering the length, breadth, height, and solidity, it was certainly a work of great magnificence and prodigious labour. But the wall itself was but a part, and not the most extraordinary part, of this work. The great number and different kinds of fortresses which were built along the line of it for its defence, and the military ways with which it was attended, are still more worthy of our admiration, and come now to be described.

The fortresses which were erected along the line of Severus's wall for its defence, were of three different kinds, and three different degrees of strength; and were called by three different Latin words, which may be translated *stations*, *castles*, and *turrets*. Of each of these in their order.

The *stationes*, stations, were so called from their stability and the stated residence of garrisons. They were also called *castra*, which hath been converted into *chestres*, a name which many of them still bear. These were by far the largest, strongest, and most magnificent of the fortresses which were built upon the wall, and were designed for the head-quarters of the cohorts of troops which were placed there in garrison, and from whence detachments were sent into the adjoining castles and turrets. These stations, as appears from the vestiges of them which are still visible, were not all exactly of the same figure nor of the same dimensions; some of them being exactly squares, and others oblong, and some of them a little larger than others. These variations were no doubt occasioned by the difference of situation

tuation and other circumſtances. The ſtations were fortified with deep ditches and ſtrong walls, the wall itſelf coinciding with and forming the north wall of each ſtation. Within the ſtations were lodgings for the officers and ſoldiers in garriſon; the ſmalleſt of them being ſufficient to contain a cohort, or 600 men. Without the walls of each ſtation was a town, inhabited by labourers, artificers, and others, both Romans and Britons, who choſe to dwell under the protection of theſe fortreſſes. The number of the ſtations upon the wall was exactly 18; and if they had been placed at equal diſtances, the interval between every two of them would have been four miles and a few paces: but the intervention of rivers, marſhes, and mountains; the conveniency of ſituations for ſtrength, proſpect, and water; and many other circumſtances to us unknown, determined them to place theſe ſtations at unequal diſtances. The ſituation which was always choſen by the Romans, both here and everywhere elſe in Britain where they could obtain it, was the gentle declivity of a hill, near a river, and facing the meridian ſun. Such was the ſituation of the far greateſt part of the ſtations on this wall. In general, we may obſerve, that the ſtations ſtood thickeſt near the two ends and in the middle, probably becauſe the danger of invaſion was greateſt in theſe places. But the reader will form a clearer idea of the number of theſe ſtations, their Latin and Engliſh names, their ſituation and diſtance from one another, by inſpecting the following table, than we can give him with equal brevity in any other way. The firſt column contains the number of the ſtation, reckoning from eaſt to weſt; the ſecond contains its Latin, and the third its Engliſh name; and the three laſt its diſtance from the next ſtation to the weſt of it, in miles, furlongs, and chains.

N°	Latin Name.	Engliſh Name.	M.	F.	C.
1	Segedunum	Couſin's-houſe	3	5	1½
2	Pons Ælii	Newcaſtle	2	0	9
3	Condercum	Benwell hill	6	6	5
4	Vindobala	Rutcheſter	7	0	3½
5	Hunnum	Halton-cheſters	5	1	7
6	Cilurnum	Walwick-cheſters	3	1	8
7	Procolitia	Carrawburgh	4	5	3½
8	Borcovicus	Houſeſteeds	1	3	8
9	Vindolana	Little Cheſters	3	6	4
10	Æſica	Great Cheſters	2	1	6½
11	Magna	Carrvoran	2	6	0
12	Amboglanna	Burdoſwald	6	2	8
13	Petriana	Cambeck	2	6	6
14	Aballaba	Watchcroſs	5	1	9
15	Congavata	Stanwix	3	3	4
16	Axelodunum	Brugh	4	0	9
17	Gabroſentum	Brumbrugh	3	4	1
18	Tunnocelum	Boulneſs	0	0	0
		Length of the wall	68	3	3

The *caſtella*, or caſtles, were the ſecond kind of fortifications which were built along the line of this wall for its defence. Theſe caſtles were neither ſo large nor ſtrong as the ſtations, but much more numerous, being no fewer than 81. The ſhape and dimenſions of the caſtles, as appears from the foundations of many of them which are ſtill viſible, were exact ſquares of 66 feet every way. They were fortified on every ſide with thick and lofty walls, but without any ditch, except on the north ſide; on which the wall itſelf, raiſed much above its uſual height, with the ditch attending it, formed the fortification. The caſtles were ſituated in the intervals between the ſtations, at the diſtance of about ſeven furlongs from each other; though particular circumſtances ſometimes occaſioned a little variation. In theſe caſtles, guards were conſtantly kept by a competent number of men detached from the neareſt ſtations.

The *turres*, or turrets, were the third and laſt kind of fortifications on the wall. Theſe were ſtill much ſmaller than the caſtles, and formed only a ſquare of about 12 feet, ſtanding out of the wall on its ſouth ſide. Being ſo ſmall, they are more entirely ruined than the ſtations and caſtles, which makes it difficult to diſcover their exact number. They ſtood in the intervals between the caſtles; and from the faint veſtiges of a few of them, it is conjectured that there were four of them between every two caſtles, at the diſtance of about 300 yards from one another. According to this conjecture, the number of the turrets amounted to 324. They were deſigned for watch-towers and places for ſentinels, who, being within hearing of one another, could convey an alarm or piece of intelligence to all parts of the wall in a very little time.

Such were the ſtations, caſtles, and turrets, on the wall of Severus; and a very conſiderable body of troops was conſtantly quartered in them for its defence. The uſual complement allowed for this ſervice was as follows:

1. Twelve cohorts of foot, conſiſting of 600 men each, - -	7,200
2. One cohort of mariners in the ſtation at Boulneſs, - -	600
3. One detachment of Moors, probably equal to a cohort, - -	600
4. Four alæ or wings of horſe, conſiſting, at the loweſt computation, of 400 each, -	1,600
	10,000

For the conveniency of marching theſe troops from one part of the wall to another, with the greater eaſe and expedition, on any ſervice, it was attended with two military ways, paved with ſquare ſtones, in the moſt ſolid and beautiful manner. One of theſe ways was ſmaller, and the other larger. The ſmaller military way run cloſe along the ſouth ſide of the wall, from turret to turret, and caſtle to caſtle, for the uſe of the ſoldiers in relieving their guards and ſentinels, and ſuch ſervices. The larger way did not keep ſo near the wall, nor touch at the turrets or caſtles, but purſued the moſt direct courſe from one ſtation to another; and was deſigned for the conveniency of marching larger bodies of troops.

It is to be regretted, that we cannot gratify the reader's curioſity, by informing him by what particular bodies of Roman troops the ſeveral parts of this great work were executed; as we were enabled to do with regard to the wall of Antoninus Pius from inſcriptions. For though it is probable that there were

Severus.

ftones with infcriptions of the fame kind, mentioning the feveral bodies of troops, and the quantity of work performed by each of them, originally inferted in the face of this wall, yet none of them are now to be found. There have indeed been difcovered, in or near the ruins of this wall, a great number of fmall fquare ftones, with very fhort, and generally imperfect, infcriptions upon them; mentioning particular legions, cohorts, and centuries; but without directly afferting that they had built any part of the wall, or naming any number of paces. Of thefe infcriptions, the reader may fee no fewer that twenty-nine among the Northumberland and Cumberland infcriptions in Mr Horfley's Britannia Romana. As the ftones on which thefe infcriptions are cut are of the fame fhape and fize with the other facing-ftones of this wall, it is almoft certain that they have been originally placed in the face of it. It is equally certain, from the uniformity of thefe infcriptions, that they were all intended to imitate fome one thing, and nothing fo probable as that the adjacent wall was built by the troops mentioned in them. This was, perhaps, fo well underftood, that it was not thought neceffary to be expreffed; and the diftance of thefe infcriptions from one another fhowed the quantity of work performed. If this was really the cafe, we know in general, that this great work was executed by the fecond and fixth legions, thefe being the only legions mentioned in thefe infcriptions. Now, if this prodigious wall, with all its appendages of ditches, ftations, caftles, turrets, and military ways, was executed in the fpace of two years by two legions only, which, when moft complete, made no more than 12,000 men, how greatly muft we admire the fkill, the induftry, and excellent difcipline of the Roman foldiers, who were not only the valiant guardians of the empire in times of war, but its moft active and ufeful members in times of peace?

This wall of Severus, and its fortreffes, proved an impenetrable barrier to the Roman territories for near 200 years. But about the beginning of the 5th century, the Roman empire being affaulted on all fides, and the bulk of their forces withdrawn from Britain, the Mæatæ and Caledonians, now called *Scots* and *Picts*, became more daring; and fome of them breaking through the wall, and others failing round the ends of it, they carried their ravages into the very heart of Provincial Britain. Thefe invaders were indeed feveral times repulfed after this by the Roman legions fent to the relief of the Britons. The laft of thefe legions, under the command of Gallio of Ravenna, having, with the affiftance of the Britons, thoroughly repaired the breaches of Severus's wall and its fortreffes, and exhorted the Britons to make a brave defence, took their final farewell of Britain. It foon appeared, that the ftrongeft walls and ramparts are no fecurity to an undifciplined and daftardly rabble, as the unhappy Britons then were. The Scots and Picts met with little refiftance in breaking through the wall, while the towns and caftles were tamely abandoned to their deftructive rage. In many places they levelled it with the ground, that it might prove no obftruction to their future inroads.—From this time no attempts were ever made to repair this noble work. Its beauty and grandeur procured it no refpect in the dark and taftelefs ages which fucceeded. It became the common quarry for more than a thoufand years, out of which all the towns and villages around were built; and is now fo entirely ruined, that the penetrating eyes of the moft poring and patient antiquarian, can hardly trace its vanifhing foundations.

Sevigné.

SEVIGNÉ (Marie de Rabutin, Marquiffe de), a French lady, was born in 1626. When only a year old fhe loft her father, who was killed in the defcent of the Englifh on the ifle of Rhé, where he commanded a company of volunteers. In 1644 fhe married the Marquis of Sevigné, who was flain in a duel by the Chevalier d'Albret, in 1651. She had by him a fon and a daughter, to the education of whom fhe afterwards religioufly devoted herfelf. Her daughter was married in 1669 to the Count of Grignan, who conducted her to Provence. Madame de Sevigné confoled herfelf by writing frequent letters to her daughter. She fell at laft the victim to her maternal tendernefs. In one of her vifits to Grignan, fhe fatigued herfelf fo much during the ficknefs of her daughter, that fhe was feized with a fever, which carried her off on the 14th of January 1696. We have two portraits of Madame de Sevigné; the one by the Compte de Buffi, the other by Madame de la Fayette. The firft exhibits her defects; the fecond her excellencies. Buffi defcribes her as a lively gay coquette, a lover of flattery, fond of titles, honour, and diftinction: M. de la Fayette as a woman of wit and good fenfe, as poffeffed of a noble foul, formed for difpenfing benefits, incapable of debafing herfelf by avarice, and bleffed with a generous, obliging, and faithful heart. Both thefe portraits are in fome meafure juft. That fhe was vainglorious, appears evident from her own letters, which, on the other hand, exhibit undoubted proofs of her virtue and goodnefs of heart.

This illuftrious lady was acquainted with all the wits of her age. It is faid that fhe decided the famous difpute between Perrault and Boileau concerning the preference of the ancients to the moderns, thus, "The ancients are the fineft, and we are the prettieft." She left behind her a moft valuable collection of letters, the beft edition of which is that of 1775, in 8 vols 12mo. "Thefe letters (fays Voltaire) are filled with anecdotes, written with freedom, and in a natural and animated ftyle; are an excellent criticifm upon ftudied letters of wit, and ftill more upon thofe fictitious letters which aim at the epiftolary ftyle, by a recital of falfe fentiments and feigned adventures to an imaginary correfpondent." It were to be wifhed that a proper felection had been made of thefe letters. It is difficult to read eight volumes of letters, which, though inimitably written, prefent frequent repetitions, and are often filled with trifles. What makes them in general perhaps fo interefting is, that they are in part hiftorical. They may be looked upon as a relation of the manners, the ton, the genius, the fafhions, the etiquette, which reigned in the court of Louis XIV. They contain many curious anecdotes nowhere elfe to be found: But thefe excellencies would be ftill more ftriking, were they fometimes ftripped of that multitude of domeftic affairs and minute incidents which ought naturally to have died with the mother and the daughter. A volume entitled *Sevigniana* was publifhed at Paris in 1756, which is nothing more than a collection of the fine fentiments, literary and hiftorical anecdotes, and moral apothegms, fcattered throughout thefe letters.

Siecle de Louis XIV tom. ii.

SEVILLE,

Seville.

SEVILLE, a large and populous city of Spain, ſtands on the banks of the Guadalquiver, in the midſt of a rich, and to the eye a boundleſs, plain; in W. Long. 5° 5' N. Lat. 37° 20'. This city is ſuppoſed to have been founded by the Phœnicians, who gave it the name of *Hiſpalis*. When it fell under the power of the Romans, it was called *Julia*; and at laſt, after a variety of corruptions, was called *Sebilla* or *Sevilla*; both of which names are retained by the Spaniards. The Romans embelliſhed it with many magnificent edifices; of which ſcarce any veſtige now remains. The Gothic kings for ſome time made it their reſidence: but in proceſs of time they removed their court to Toledo; and Seville was taken by ſtorm ſoon after the victory obtained at Xeres over the Gothic king Rodrigo.—In 1027, Seville became an independent monarchy; but was conquered 70 years afterwards by Yuſef Almoravides, an African prince. At laſt it was taken by Ferdinand III. after a year's ſiege; and 300,000 Moors were then obliged to leave the place. Notwithſtanding this prodigious emigration, Seville continued to be a great and populous city, and ſoon after it was enlarged and adorned with many magnificent buildings, the chief of which is the cathedral. Seville arrived at its utmoſt pitch of grandeur a little after the diſcovery of America, the reaſon of which was, that all the valuable productions of the Weſt Indies were carried thither. Its court was then the moſt ſplendid in Europe; but in the courſe of a few years all this grandeur diſappeared, owing to the impediments in navigating the Guadalquiver. The ſuperior excellence of the port of Cadiz induced government to order the galeons to be ſtationed there in time to come.

Seville is of a circular form, and is ſurrounded by a wall about five miles and a half in circumference, containing 176 towers. The ditch in many places is filled up. The ſtreets of Seville are crooked and dirty, and moſt of them ſo narrow that two carriages can ſcarcely paſs one another abreaſt.

Seville is ſaid to contain 80,268 ſouls, and is divided into 30 pariſhes. It has 84 convents, with 24 hoſpitals.

Townſend's Travels, vol. ii.

Of the public edifices of this city the cathedral is the moſt magnificent. Its dimenſions are 420 feet in length, 263 in breadth within the walls, and 126 feet in height. It has nine doors, 80 altars, at which 500 maſſes are daily celebrated, and 80 windows of painted glaſs, each of which coſt 1000 ducats. At one angle ſtands a tower of Mooriſh workmanſhip 350 feet high. On the top of it is the giralda, or large brazen image, which, with its palm branch, weighs near one ton and a half, yet turns as a weather-cock with the ſligheſt variation of the wind. The whole work is brick and mortar. The paſſage to the top is an inclined plane, which winds about in the inſide in the manner of a ſpiral ſtaircaſe, ſo eaſy of aſcent that a horſe might trot from the bottom to the top; at the ſame time it is ſo wide that two horſemen may ride abreaſt. What appears very unaccountable, the ſolid maſonry in the upper half is juſt as thick again as that in the lower, though on the outſide the tower is all the way of the ſame dimenſions. In the opinion of Mr Swinburne, this cathedral is inferior to Yorkminſter. Its treaſures are ineſtimable; one altar with all its ornaments is ſolid ſilver; of the ſame metal are the images of St Iſidore and St Leander, which are as large as the life; and a tabernacle for the hoſt more than four yards high, adorned with eight and forty columns. Before the choir of the cathedral is the tomb of the celebrated Chriſtopher Columbus, the diſcoverer of America. His monument conſiſts of one ſtone only, on which theſe words are inſcribed, *A Caſtella y Arragon otro mundo dio Colon*; that is, "To Caſtile and Arragon Columbus gave another world:" an inſcription ſimple and expreſſive, the juſtneſs of which will be acknowledged by thoſe who have read the adventures of this illuſtrious but unfortunate man. The cathedral was begun by Don Sancho the Brave, about the cloſe of the 13th century, and finiſhed by John II. about an hundred years after. To the cathedral belongs a library of 20,000 volumes, collected by Hernando the ſon of Columbus; but, to the diſgrace of the Spaniards, it has ſcarcely received any addition ſince the death of the founder. The organ in this cathedral is a very ingenious piece of mechaniſm †. "I was much pleaſed (ſays Mr Townſend in his intereſting travels) with the conſtruction of a new organ, containing 5300 pipes, with 110 ſtops, which latter, as the builder told me, is 50 more than are in the famous one of Harlem; yet, ſo ample are the bellows, that when ſtretched they ſupply the full organ 15 minutes. The mode of filling them with air is ſingular; for inſtead of working with his hands, a man walks backwards and forwards along an inclined plane of about 15 feet in length, which is balanced in the middle on its axis; under each end is a pair of bellows, of about ſix feet by three and an half. Theſe communicate with five other pair united by a bar; and the latter are ſo contrived, that when they are in danger of being overſtrained, a valve is lifted up, and gives them relief. Paſſing 10 times along the inclined plane fills all theſe veſſels."

Bourgoanne's Travels, vol. ii

† Vol. ii. p. 318.

The Canus de Carmone, or great aqueduct of Seville, is reckoned by the hiſtorians of this city one of the moſt wonderful works of antiquity. Mr Swinburne, however, remarks, that it is ugly, crooked, the arches unequal, and the architecture neglected. The conduit is ſo leaky, that a rivulet is formed by the waſte water. Nevertheleſs, it ſtill conveys to the city an ample ſupply of water ſufficient to turn ſeveral mills, and to give almoſt every houſe in town the benefit of it.

Swineburne's Travels, p. 283.

Many of the convents are remarkable for the beauty of their architecture; but in Seville the eye covets only pictures, of which there is a wonderful profuſion. Among theſe are the works of the famous painter Murillo, with many others univerſally admired.

The convent of the Franciſcans contains 15 cloiſters, with apartments for 200 monks, though, when Mr Townſend viſited them, they amounted only to 140. The annual expenditure of theſe, who are all fed on charity, is about L. 4000 Sterling. "In the principal cloiſter (ſays the ſame intelligent traveller), which is entirely incloſed by a multitude of little chapels, are repreſented, in 14 pictures, each called a *ſtation*, all the ſufferings of the Redeemer. Theſe are ſo arranged as to mark given diſtances by walking round the cloiſter from the firſt to the ſecond, and ſo in order to the reſt. Over them is mentioned the number of ſteps taken by our Lord between the ſeveral incidents of his paſſion in his way to Cavalry; and theſe preciſely are the paces mea-

Townſend's Travels, vol. ii. p. 326.

meaſured for the penitents in their progreſs from one ſtation to another. Over one is the following inſcription: 'This ſtation conſiſts of 1087 ſteps. Here the bleſſed Redeemer fell a ſecond time under the weight of his croſs, and here is to be gained the indulgence of ſeven years and forty quarantines. Mental prayer, the Paternoſter, and the Ave Maria.' This may ſerve as an example for the reſt."

The principal manufacture of Seville is ſnuff. Mr Townſend, who paid particular attention to it, informs us, that the building in which it is carried on is elegant and ſimple in its form, and is about 600 feet by 480, and not leſs than 60 feet in height, with four regular fronts, incloſing 28 quadrangles. It coſt 37,000,000 of reals, or about L. 370,000 Sterling. At preſent (1787), no more than 1700 workmen are employed, and 100 horſes or mules; but formerly 3000 men were engaged, and near 400 horſes. This falling off is attributed by Mr Swinburne to a practice which the directors followed, of adulterating the tobacco with the red earth of Almazaron. When Mr Townſend viſited this manufacture, they had changed their ſyſtem. From the year 1780, he informs us, the annual ſale of tobacco from Brazil has been 1,500,000 pounds, purchaſed from the Portugueſe at three reals a pound; and of ſnuff from the produce of their own colonies 1,600,000 pounds, beſide *cigars* (A) to a very conſiderable amount. They have lying by them more than 5,000,000 of pounds of ſnuff unſold; but as it will not ſuffer by age, they are not uneaſy at this accumulation. Beſides the peculiar kind of ſnuff with which Spain was accuſtomed to ſupply the market, they have lately introduced the manufacture of rappee. In this branch alone are employed 220 perſons, old and young, with 16 mules.

"All the workmen (continues Mr Townſend) depoſit the cloaks at the door; and when they go out are ſo ſtrictly examined, that they have little chance of being able to conceal tobacco; yet they ſometimes venture to hide it about their perſons. An officer and a guard is always attending to take delinquents into cuſtody; and that they may prevent reſiſtance, no workman is permitted to enter with a knife. Were it not for this precaution, the conſequence of a detection might be fatal. The whole buſineſs is conducted by a director, with a ſalary of 40,000 reals a-year, and 54 ſuperior officers, aſſiſted by as many ſubordinate to them. For grinding their ſnuff, they have 40 mills, each conſiſting of a ſtone roller, moved by a large horſe or mule, with the traces faſtened to a beam of eight feet in length, in the angle of 45 degrees, conſequently loſing preciſely half his force."

Before Mr Townſend left Seville, according to his uſual practice, which was truly laudable, he enquired into the prices of labour and proviſions. As a piece of curious and uſeful information, and as an example to other travellers, we preſent them to our readers. They are as follow:

Day labourers - $4\frac{1}{2}$ reals, about	L. 0	0	$10\frac{1}{4}$
Carpenters from 7 to 11 ——			
Joiners, if good workmen - 24 —— or -	0	4	9
Weavers, if good workmen, 15 reals, about - -	L. 0	3	0
Bread, for 3 lb. of 16 oz. or 16 quartos, or	0	0	$4\frac{1}{2}$
—— ſometimes 28 quartos, or	0	0	$7\frac{7}{8}$
Beef, 30 quartos for 32 oz. per lb. about	0	0	$4\frac{1}{2}$
Mutton, 38 do. do. - -	0	0	$5\frac{11}{32}$
Kid, 24 do. - -	0	0	$3\frac{3}{8}$
Pork from 36 to 42 quartos, do. or	0	0	$5\frac{1}{16}$
to	0	0	$5\frac{30}{31}$

The price of wheat has at different periods been very remarkable. In 1652, it ſold at the rate of 15 s. $3\frac{1}{2}$d. the buſhel; and in 1657, it fell ſo low as 1 s. $4\frac{1}{2}$d. per buſhel, reckoning the tanega at $109\frac{1}{2}$ lb. and the buſhel at 70.

SEVUM Minerale, mineral tallow; a ſubſtance ſomewhat reſembling tallow, found on the ſea-coaſts of Finland in the year 1736. It burns with a blue flame, and ſmell of greaſe, leaving a black viſcid matter which cannot eaſily be conſumed. It is extremely light; being only of the ſpecific gravity of 0.770; whereas tallow is not leſs than 0.969. It is partly ſoluble in highly rectified ſpirit of wine; but entirely ſo in expreſſed oils when boiling. It is met with in ſome of the rocky parts of Perſia, but there it appears to be mixed with petrolæum. Dr Herman of Straſburg mentions a ſpring in the neighbourhood of that city which contains a ſubſtance of this ſort diffuſed through it, ſeparating, and capable of being collected on ebullition.—A fat mineral matter reſembling butter or tallow has lately been extracted from peat in Lancaſhire. See Peat.

SEWAURY, a Hindoo word uſed in Bengal, and ſignifying the train of attendants that accompany a nabob or great man.

SEWER, *in the Houſehold*, an officer who arranges on the table the diſhes of a king or nobleman.

Sewer is alſo a paſſage or gutter made to carry water into the ſea or a river, whereby to preſerve the land, &c. from inundations and other annoyances.

Court of Commiſſions of Sewars in England, a temporary tribunal, erected by virtue of a commiſſion under the great ſeal; which formerly uſed to be granted *pro re nata* at the pleaſure of the crown, but now at the diſcretion and nomination of the lord chancellor, lord treaſurer, and chief juſtices, purſuant to the ſtatute 23 Hen. VIII. c. 5. Their juriſdiction is to overlook the repairs of ſea-banks and ſea-walls, and the cleanſing of rivers, public ſtreams, ditches, and other conduits, whereby any waters are carried off; and is confined to ſuch county or particular diſtrict as the commiſſion ſhall expreſsly name. The commiſſioners are a court of record, and may fine and impriſon for contempts; and in the execution of their duty may proceed by jury, or upon their own view, and may take order for the removal of any annoyances, or the ſafeguard and conſervation of the ſewers within their commiſſion, either according to the laws and cuſtoms of Romney-marſh, or otherwiſe at their own diſcretion. They may alſo aſſeſs ſuch rates or ſcots upon the owners of lands within their diſtrict as they ſhall judge neceſſary: and if any perſon refuſes to pay them, the commiſſioners may levy the

(A) Theſe are little rolls of tobacco which the Spaniards ſmoke without a pipe.

Sewer. the fame by diftrefs of his goods and chattels; or they may, by ftatute 23 Hen. VIII. c. 5. fell his freehold-lands (and by the 7 Ann. c. 10. his copyhold alfo), in order to pay fuch fcots or affeffments. But their conduct is under the controul of the court of King's-bench, which will prevent or punifh any illegal or tyrannical proceedings. And yet in the reign of King James I. (8th Nov. 1616.), the privy-council took upon them to order, that no action or complaint fhould be profecuted againft the commiffioners unlefs before that board; and committed feveral to prifon who had brought fuch actions at common law, till they fhould releafe the fame: and one of the reafons for difcharging Sir Edward Coke from his office of lord chief-juftice, was for countenancing thofe legal proceedings. The pretence for thefe arbitrary meafures was no other than the tyrant's plea of the *neceffity* of unlimited powers in works of evident utility to the public, "the fupreme reafon above all reafons, which is the falvation of the king's lands and people." But now it is clearly held, that this (as well as all other inferior jurifdictions) is fubject to the difcretionary coertion of his majefty's court of King's-bench.

Fergufon's Roman Hiftory. *Common Sewers*, in Rome, were executed at a great expence. It was propofed that they fhould be of fufficient dimenfions to admit a waggon loaded with hay. When thefe common fewers came to be obftructed, or out of repair, under the republic, the cenfors contracted to pay a thoufand talents, or about 193,000 l. for clearing and repairing them. They were again in difrepair at the acceffion of Auguftus Cæfar, and the reinftating them is mentioned among the great works of Agrippa. He is faid to have turned the courfe of feven rivers into thefe fubterraneous paffages, to have made them navigable, and to have actually paffed in barges under the ftreets and buildings of Rome. Thefe works are ftill fuppofed to remain; but as they exceed the power and refources of the prefent city to keep them in repair, they are quite concealed, except at one or two places. They were in the midft of the Roman greatnefs, and ftill are, reckoned among the wonders of the world; and yet they are faid to have been works of the elder Tarquin, a prince whofe territory did not extend, in any direction, above 16 miles; and, on this fuppofition, they muft have been made to accommodate a city that was calculated chiefly for the reception of cattle, herdfmen, and banditti. Rude nations fometimes execute works of great magnificence, as fortreffes and temples, for the purpofes of war and fuperftition; but feldom palaces, and ftill more feldom works of mere convenience and cleanlinefs, in which for the moft part they are long defective. It is not unreafonable, therefore, to queftion the authority of tradition in refpect to this fingular monument of antiquity, which fo greatly exceeds what the beft accommodated city of modern Europe could undertake for its own conveniency. And as thofe works are ftill entire, and may continue fo for thoufands of years, it may be fufpected that they were even prior to the fettlement of Romulus, and may have been the remains of a more ancient city, on the ruins of which the followers of Romulus fettled, as the Arabs now hut or encamp on the ruins of Palmyra and Balbeck. Livy owns, that the common fewers were not accommodated to the plan of Rome, as it was laid out in his time; they were carried in directions acrofs the ftreets, and paffed under buildings of the greateft antiquity. This derangement indeed he imputes to the hafty rebuilding of the city after its deftruction by the Gauls; but hafte, it is probable, would have determined the people to build on their old foundations, or at leaft not to change them fo much as to crofs the direction of former ftreets.

Sex. SEX, the property by which any animal is male or female.

Lavater has drawn the following characteriftic diftinctions between the male and female of the human fpecies.

"The primary matter of which women are conftituted appears to be more flexible, irritable, and elaftic, than that of man. They are formed to maternal mildnefs and affection; all their organs are tender, yielding, eafily wounded, fenfible, and receptible. Among a thoufand females there is fcarcely one without the generic feminine figns; the flexible, the circular, and the irritable.

"They are the counterpart of man, taken out of man, to be fubject to man; to comfort him like angels, and to lighten his cares. 'She fhall be faved in child-bearing, if they continue in faith, and charity, and holinefs, with fobriety" (1 Tim. ii. 15.) This tendernefs, this fenfibility, this light texture of her fibres and organs, this volatility of feeling, render them fo eafy to conduct and to tempt; fo ready of fubmiffion to the enterprife and power of the man; but more powerful through the aid of her charms than man, with all his ftrength. The man was not firft tempted, but the woman, afterward the man by the woman. And, not only eafy to be tempted, fhe is capable of being formed to the pureft, nobleft, moft feraphic virtue; to every thing which can deferve praife or affection. Highly fenfible of purity, beauty, and fymmetry, fhe does not always take time to reflect on internal life, internal death, internal corruption. 'The woman faw that the tree was good for food, and that it was pleafant to the eyes, and a tree to be defired to make one wife, and fhe took of the fruit thereof.' (Gen. iii. 6.)

"The female thinks not profoundly; profound thought is the power of the man. Women feel more. Senfibility is the power of woman. They often rule more effectually, more fovereignly, than man. They rule with tender looks, tears, and fighs; but not with paffion and threats; for if, or when, they fo rule, they are no longer women but abortions. They are capable of the fweeteft fenfibility, the moft profound emotion, the utmoft humility, and the excefs of enthufiafm. In their countenance are the figns of fanctity and inviolability, which every feeling man honours, and the effects of which are often miraculous. Therefore, by the irritability of their nerves, their incapacity for deep inquiry and firm decifion, they may eafily from their extreme fenfibility become the moft irreclaimable, the moft rapturous enthufiafts. Their love, ftrong and rooted as it is, is very changeable; their hatred almoft incurable, and only to be effaced by continued and artful flattery. Men are moft profound; women are more fublime.

"Men moftly embrace the whole; women remark individually, and take more delight in felecting the minutiæ which form the whole. Man hears the burfting

thunder,

Sex.

thunder, views the destructive bolt with serene aspect, and stands erect amidst the fearful majesty of the streaming clouds. Woman trembles at the lightning, and the voice of distant thunder; and shrinks into herself or sinks into the arms of man. Man receives a ray of light single, woman delights to view it through a prism in all its dazzling colours. She contemplates the rainbow as the promise of peace; he extends his inquiring eye over the whole horizon. Woman laughs, man smiles; woman weeps, man remains silent. Woman is in anguish when man weeps, and in despair when man is in anguish; yet has she often more faith than man. Man without religion, is a diseased creature, who would persuade himself he is well, and needs not a physician; but woman without religion, is raging and monstrous. A woman with a beard is not so disgusting as a woman who acts the freethinker; her sex is formed to piety and religion; to them Christ first appeared; but he was obliged to prevent them from too ardently, and too hastily, embracing him: 'Touch me not.' They are prompt to receive and seize novelty, and become its enthusiasts. The whole world is forgotten in the emotion caused by the presence and proximity of him they love. They sink into the most incurable melancholy, as they also rise to the most enraptured heights.

"Male sensation is more imagination, female more heart. When communicative, they are more communicative than man; when secret, more secret. In general they are more patient, long-suffering, credulous, benevolent, and modest. Woman is not a foundation on which to build. She is the gold, silver, precious stones, wood, hay, stubble (1 Cor. iii. 12.); the materials for building on the male foundation. She is the leaven, or more expressively the oil to the vinegar of man: the second part of the book of man.

"Man singly is but half man; at least but half human; a king without a kingdom. Woman, who feels properly what she is, whether still or in motion, rests upon the man; nor is man what he may and ought to be, but in conjunction with woman: therefore, 'it is not good that man should be alone, but that he should leave father and mother, and cleave to his wife, and they two shall be one flesh."

They differ also in their exterior form and appearance.

"Man is the most firm; woman the most flexible. Man is the straightest; woman the most bending. Man stands stedfast; woman gently retreats. Man surveys and observes; woman glances and feels. Man is serious; woman is gay. Man is the tallest and broadest; woman the smallest and weakest. Man is rough and hard; woman smooth and soft. Man is brown; woman is fair. Man is wrinkly; woman is not. The hair of man is more strong and short; of woman more long and pliant. The eyebrows of man are compressed; of woman less frowning. Man has most convex lines; woman most concave. Man has most straight lines; woman most curved. The countenance of man taken in profile is more seldom perpendicular than that of the woman. Man is most angular; woman most round."

Fitzosborne's Letters.

In determining the comparative merit of the two sexes, it is no derogation from female excellency that it differs in kind from that which distinguishes the male part of our species: and if, in general, it should be found (what upon an impartial inquiry will most certainly be found) that women fill up their appointed circle of action with greater regularity than men, the claim of preference cannot justly be decided in our favour. In the prudential and economical parts of life, it is undeniable that they rise far above us: and if true fortitude of mind is best discovered by a cheerful resignation to the measures of Providence, we shall not find reason, perhaps, to claim that most singular of the human virtues as our peculiar privilege. There are numbers of the other sex who, from the natural delicacy of their constitution, pass through one continued scene of suffering from their cradles to their graves, with a firmness of resolution that would deserve so many statues to be erected to their memories, if heroism were not esteemed more by the splendor than the merit of actions.

But whatever real difference there may be between the moral or intellectual powers of the male and female mind, Nature does not seem to have marked the distinction so strongly as our vanity is willing to imagine; and after all, perhaps, education will be found to constitute the principal superiority. It must be acknowledged, at least, that in this article we have every advantage over the softer sex that art and industry can possibly secure to us. The most animating examples of Greece and Rome are set before us, as early as we are capable of any observation; and the noblest compositions of the ancients are given into our hands almost as soon as we have strength to hold them; while the employments of the other sex, at the same period of life, are generally the reverse of every thing that can open and enlarge their minds, or fill them with just and rational notions. The truth of it is, female education is so much worse than none, as it is better to leave the mind to its natural and uninstructed suggestions, than to lead it into false pursuits, and contract its views, by turning them upon the lowest and most trifling objects. We seem, indeed, by the manner in which we suffer the youth of that sex to be trained, to consider women agreeably to the opinion of certain Mahometan doctors, and treat them as if we believed they had no souls: why else are they

> Bred only, and completed to the taste
> Of lustful appetence, to sing, to dance,
> To dress, and troul the tongue, and roll the eye.
>
> MILTON.

This strange neglect of cultivating the female mind can hardly be allowed as good policy, when it is considered how much the interest of society is concerned in the rectitude of their understandings. That season of every man's life which is most susceptible of the strongest impressions, is necessarily under female direction; as there are few instances, perhaps, in which that sex is not one of the secret springs which regulates the most important movements of private or public transactions. What Cato observes of his countrymen is in one respect true of every nation under the sun: "the Romans (said he) govern the world, but it is the women that govern the Romans."

If it be true then (as true beyond all peradventure it is) that female influence is thus extensive, nothing certainly can be of more importance than to give it a proper tendency, by the assistance of a well-directed education. Far are we from recommending any attempts to to render women learned; yet surely it is necessary they should be raised above ignorance. Such a general tincture of the most useful sciences as may serve to free the mind from vulgar prejudices, and give it a relish for the rational exercise of its powers, might very justly enter into a plan of female erudition. That sex might be taught to turn the course of their reflections into a proper and advantageous channel, without any danger of rendering them too elevated for the feminine duties of life. In a word, they ought to be considered as designed by Providence for use as well as show, and trained up, not only as women, but as rational creatures.

Sex of Bees. See Bee.

Sex of Plants. See Botany, p. 448.

SEXAGENARY, something relating to the number sixty: thus sexagenary or sexagesimal arithmetic is a method of computation proceeding by sixties; such is that used in the division of a degree into sixty minutes, of the minute into sixty seconds, of the second into sixty thirds, &c. Also sexagenary tables are tables of proportional parts, showing the product of two sexagenaries that are to be multiplied, or the quotient of the two that are to be divided.

SEXAGESIMA, the second Sunday before Lent, or the next to Shrove-Sunday, so called as being about the 60th day before Easter.

SEXAGESIMALS, or *Sexagesimal Fractions*, fractions whose denominators proceed in a sexagecuple ratio; that is, a prime, or the first minute, $=\frac{1}{60}$: a second $=\frac{1}{3600}$; a third $=\frac{1}{216000}$. Anciently, there were no other than sexagesimals used in astronomy; and they are still retained in many cases, though decimal arithmetic begins to grow in use now in astronomical calculations. In these fractions, which some call *astronomical fractions*, the denominator being always 60, or a multiple thereof, is usually omitted, and the numerator only written down: thus $4^{\circ}, 59', 32'', 50''', 16''''$ is to be read, 4 degrees, 59 minutes, 32 seconds, 50 thirds, 16 fourths, &c.

SEXTANS, Sextant, a sixth part of certain things. The Romans having divided their *as* into 12 ounces or uncia, the sixth part of that, or two ounces, was the sextans.—*Sextans* was also a measure which contained two ounces of liquor, or two cyathi.

Sextans, in astronomy, a constellation of the southern hemisphere, made by Hevelius out of unformed stars. In Hevelius's catalogue it contains 11, but in the Britannic catalogue 41 stars.

SEXTANT, in mathematics, denotes the sixth part of a circle, or an arch comprehending 60 degrees.

The word *sextant*, is more particularly used for an astronomical instrument made like a quadrant, excepting that its limb only comprehends 60 degrees. The use and application of the sextant is the same with that of the quadrant. See Quadrant; and Navigation, p. 737, &c.

SEXTILE, *sextilis*, the position or aspect of two planets when at 60 degrees distance, or at the distance of two signs from one another. It is marked thus (*) See Aspect.

SEXTIUS (Quintus), a Pythagorean philosopher, flourished in the time of Augustus. He seemed formed to rise in the republic; but he shrunk from civil honours, and declined accepting the rank of senator when it was offered him by Julius Cæsar, that he might have time to apply to philosophy. It appears that he wished to establish a school at Rome, and that his tenets, though chiefly drawn from the doctrines of Pythagoras, in some particulars resembled those of the Stoics.

He soon found himself involved in many difficulties. His laws were tinctured with great severity; and in an early period of his establishment, he found his mind so harassed, and the harshness of the doctrines which he wished to establish so repulsive to his feelings, that he had nearly worked himself up to such a height of desperation as to resolve on putting a period to his existence.

Of the school of Sextius were Fabianus, Sotion, Flavianus, Crassitius, and Celsus. Of his works only a few fragments remain; and whether any of them formed a part of the work which Seneca admired so much, cannot now be determined. Some of his maxims are valuable. He recommended an examination of the actions of the day to his scholars when they retired to rest; he taught, that the road to Heaven (*ad astra*) was by frugality, temperance, and fortitude. He used to recommend holding a looking-glass before persons disordered with passion. He enjoined his scholars to abstain from animal food.

SEXTON, a church-officer, thus called by corruption of the Latin *sacrista*, or Saxon *segerstone*, which denotes the same. His office is to take care of the vessels, vestments, &c. belonging to the church; and to attend the minister, church-warden, &c. at church. He is usually chosen by the parson only. Sextons, as well as parish-clerks, are regarded by the common law as persons who have freehold in their offices; and, therefore, though they may be punished, yet they cannot be deprived, by ecclesiastical censures.

The office of Sexton in the pope's chapel is appropriated to the order of the hermits of St Augustine. He is generally a bishop, though sometimes the pope only gives a bishopric, *in partibus*, to him on whom he confers the post. He takes the title of *Prefect of the Pope's Sacristy*, and has the keeping the vessels of gold and silver, the relics, &c. When the pope says mass, the sexton always tastes the bread and wine first. If it be in private he says mass, his holiness, of two wafers, gives him one to eat; and, if in public, the cardinal, who assists the pope in quality of deacon, of three wafers, gives him two to eat. When the pope is desperately sick, he administers to him the sacrament of extreme unction, &c. and enters the conclave in quality of first conclavist.

The office of a sexton in Sweden is somewhat singular. During M. Outhier's stay at Stockholm in 1736 he visited the church of St Clara, and during divine service he observed a sexton going about with a long rod, waking those persons who had fallen asleep.

SEXTUPLE, in music, denotes a mixed sort of triple, which is beaten in double time.

SEXTUS Empiricus, a famous Pyrrhonian philosopher, lived in the second century, under the reign of Antoninus the Debonair. He was a physician of the sect of the Empirics, and is said to have been one of the preceptors of Antoninus the philosopher. There are still extant his Pyrrhonian Institutions, and a large work against the mathematicians, &c. The best edition of Sextus Empiricus is that of Fabricius in Greek and Latin, printed at Leipsic in 1718, folio.

SEXUALISTÆ, among botanical writers, those who have established the classes of plants upon the differences of the sexes and parts of fructification in plants, according to the modern method; as Linnæus, &c.

SEZAWUL, a Hindoo word, used in Bengal to express an officer employed at a monthly salary to collect the revenues.

SFORZA (James), was the founder of the illustrious house of Sforza, which acted so conspicuous a part in Italy during the 15th and 16th centuries, which gave six dukes to Milan, and contracted alliances with almost every sovereign in Europe. James Sforza was born on the 28th of May 1369, at Catignola, a small town in Italy, lying between Imola and Faenza. His father was a day-labourer, or, according to Commines, a shoemaker. A company of soldiers happening one day to pass through Catignola, he was seized with the desire of accompanying them to the wars. "I will go (said he to himself), and dart my hatchet against that tree, and if it stick fast in the wood, I will immediately become a soldier." The hatchet accordingly stuck fast, and our adventurer enlisted; and because, says the Abbé de Choisi, he had thrown the axe with all his force, he assumed the name of Sforza; for his true name was Giacomuzzo, or James Attendulo. He rose rapidly in the army, and soon became commander of 7000 men. He defended the cause of Jane II. queen of Naples for many years, and was made constable of her kingdom. He was created Count of Catignola by pope John XXII. by way of paying a debt of 14000 ducats which the church of Rome owed him. His exploits became every day more illustrious: he obliged Alphonso king of Arragon to raise the siege of Naples; and reduced several places that had revolted in Abruzzo and Le Labour; but while in pursuit of his enemies he was unfortunately drowned in the river Aterno on the 3d January 1424, at the age of 54 years. His heroic qualities and the continual wars in which he was engaged, did not hinder him from forming an attachment to the fair sex. In his youth he fell in love with a woman called *Lucia Trezana*, whom he married after she had born him several children. He married afterwards Antoinette Salembini, who brought him several excellent estates; she bore him Bosio Sforza, compte of Santa-Flor, a warrior and governor of Orvietta for Pope Martin V. His third wife was Catharine Alopa, sister of Rodolpho, grand chamberlain to the sovereign of Naples. His last wife, for he was four times married, was Mary Marzana, daughter to the duke of Sessa. She bore him Charles Sforza, who was general of the order of Augustines, and archbishop of Milan.

Sforza (Francis), the son of James Sforza by Lucia Trezana, was born in 1401, and trained up by his father to the profession of arms. At the age of 23 he defeated the troops of Braccio, who disputed with him the passage of the Aterno. In this action his father was drowned, and Francis, though illegitimate, succeeded him. He fought successfully against the Spaniards, and contributed a great deal both towards raising the siege of Naples, and to the victory which was gained over the troops of Braccio near Aquilla in 1425, where that general was killed. After the death of queen Jane, in 1435, he espoused the interests of the duke of Anjou, to whom she had left her crown, and by his courage and abilities ably supported that unfortunate prince. He made himself master of several places in Ancona, from which he was driven by pope Eugenius IV. who defeated and excommunicated him; but he soon re-established his affairs by a victory. His reputation was now so great, that the pope, the Venetians, and the Florentines, chose him for their general against the duke of Milan. Sforza had already conducted Venetian armies against that prince, though he had espoused his daughter. The duke dying in 1447, the inhabitants of Milan invited Sforza, his son-in-law, to lead them against that duke. But, after some exertions in their favour, he turned his arms against themselves, laid siege to Milan, and obliged them to receive him as duke, notwithstanding the rights of Charles duke of Orleans, the son of Valentine of Milan. In 1464, Louis XI. who hated Orleans, gave up to Sforza the rights which the crown of France had over Genoa, and even put into his hands Savona, a town belonging to that republic. The duke of Milan soon after made himself master of Genoa. He died in 1466, with the reputation of a man who was willing to sell his blood to the best purchaser, and who was not too scrupulous an observer of his word. His second wife was Blanche Marie, natural daughter of Philip Marie duke of Milan. She bore him Galeas Marie, and Ludovic Marie, dukes of Milan, Philip Marie count of Pavia, Sforza Marie duke of Bari, Ascagne Marie bishop of Pavia and Cremona, and a cardinal. He was taken prisoner by the troops of Louis XII. and confined for some time in the tower of Bourges. He was a cunning man, and deceived Cardinal d'Amboise when that prelate aspired at the papacy. His daughters were Hyppolita, married to Alphonso of Arragon, afterwards king of Naples; and Elizabeth, married to William marquis of Monferrat. He had besides several natural children.

SHACK, in ancient customs, a liberty of winter-pasturage. In the counties of Norfolk and Suffolk, the lord of the manor has shack, *i. e.* a liberty of feeding his sheep at pleasure in his tenants lands during the six winter months. In Norfolk, shack also extends to the common for hogs, in all men's grounds, from the end of harvest till seed-time. Whence to go *a-shack*, is to feed at large

SHACKLES, aboard a ship, are those oblong iron rings, bigger at one end than at the other, with which the ports are shut fast, by thrusting the wooden bar of the port through them. There is also a sort of shackles to lift the hatches up with, of a like figure, but smaller. They are fastened at the corners of the hatches.

SHAD, in ichthyology, a species of Clupea.

SHADDOCK, a species of Citrus.

SHADOW, in optics, a privation or diminution of light by the interposition of an opaque body: or it is a plane where the light is either altogether obstructed, or greatly weakened, by the interposition of some opaque body between it and the luminary.

Shadow, in painting, an imitation of a real shadow, effected by gradually heightening and darkening the colours of such figures as by their dispositions cannot receive any direct rays from the luminary that is supposed to enlighten the piece.

Shadow, in perspective, the appearance of an opaque body, and a luminous one, whose rays diverge (*e. gr.* a candle, lamp, &c.), being given; to find the just appearance

pearance of the shadow, according to the laws of perspective. The method is this: From the luminous body, which is here considered as a point, let fall a perpendicular to the perspective plain or table; *i. e.* find the appearance of a point upon which a perpendicular, drawn from the middle of the luminary, falls on the perspective plane; and from the several angles, or raised points of the body, let fall perpendiculars to the plane. These points, whereon the perpendiculars fall, connect by right lines, with the point upon which the perpendicular let fall from the luminary falls; and continue the lines to the side opposite to the luminary. Lastly, through the raised points draw lines through the centre of the luminary, intersecting the former; the points of intersection are the terms or bounds of the shadow.

SHADWELL (Thomas), descended of an ancient family in Staffordshire, was born in 1640, and educated at Caius college, Cambridge. He then was placed in the Middle Temple to study the laws; where having spent some time, he travelled abroad. Upon his return home, he became acquainted with the most celebrated persons of wit in that age. He applied himself chiefly to dramatic writing, in which he had great success; and upon the revolution was made poet laureat and historiographer to king William and queen Mary, in the room of Mr Dryden. These employments he enjoyed till his death, which happened in 1692. Besides his dramatic writings, he composed several other pieces of poetry; the chief of which are his congratulatory poem on the prince of Orange's coming to England; another on queen Mary; his translation of Juvenal's 10th satire, &c. Mr Dryden treats him with great contempt, in his satire called *Mac-Fleckno.* The best judges of that age, however, gave their testimony in favour of his comedies, which have in them fine strokes of humour; the characters are often original, strongly marked, and well sustained. An edition of his works, with some account of his life and writings prefixed, was published in 1720, in 4 vols 8vo.

SHAFT, *of a* COLUMN, in building, is the body thereof between the base and capital; so called from its straightness. See ARCHITECTURE.

SHAFT, in mining, is the pit or hollow entrance into the mine. In the tin-mines, after this is sunk about a fathom, they leave a little, long, square place, which is called a *shamble.*

Shafts are sunk some ten, some twenty fathoms deep into the earth, more or less. Of these shafts, there is the landing or working shaft, where they bring up the work or ore to the surface; but if it be worked by a horse engine or whim, it is called a *whim-shaft;* and where the water is drawn out of the mine, it is indifferently named an *engine-shaft*, or the *rod-shaft.* See MINE.

SHAFT, in ornithology. See TROCHILUS.

SHAFTESBURY, a town of Dorsetshire in England, in W. Long. 2. 20. N. Lat. 51. 0. It stands on a high hill, and is built in the form of a bow. It enjoys a serene wholesome air, and has a fine prospect. It is a good thoroughfare, is governed by a mayor, and sends two members to parliament. This town is supposed to have been built in the 8th century, and to have been enlarged by king Alfred, and had 12 churches, besides a Benedictine monastery, in the time of the Saxons, but has now only three. St Edward the martyr was buried here. It had three mints before the conquest, and, in the reign of Henry VIII. was the see of a suffragan bishop. It was incorporated by queen Elizabeth and Charles II. and is governed by a mayor, recorder, twelve aldermen, bailiffs, and a common-council. It contains about 320 houses, many of which are of free-stone. Water is so scarce, that it used to be supplied from Motcomb; but it was obtained more commodiously in 1718, by means of engines, which raised the water above 300 feet perpendicular, and conveyed it to a large cistern in the middle of the town, from the distance of two miles. Yet even this is laid aside, and they have dug several pits, in which they preserve the rain-water; and the poor get their living to this day by fetching it in pails or on horses. It gives the title of earl to the noble family of Cooper.

SHAFTESBURY (earl of). See COOPER.

SHAG, in ornithology. See PELICANUS.

SHAGREEN, or CHAGREEN, in commerce, a kind of grained leather prepared of the skin of a species of SQUALUS, much used in covering cases, books, &c.

Manner of preparing SHAGREEN. The skin, being flayed off, is stretched out, covered over with mustard-seed, and the seed bruised on it; and thus it is exposed to the weather for some days, and then tanned.

The best is that brought from Constantinople, of a brownish colour; the white is the worst. It is extremely hard; yet, when steeped in water, it becomes very soft and pliable; whence it is of great use among case-makers. It takes any colour that is given it, red, green, yellow, or black. It is frequently counterfeited by morocco, formed like shagreen; but this last is distinguished by its peeling off, which the first does not.

SHAIK properly signifies an old man. In the east it is used to denote a lord or chief, a man of eminence and property. See SCHIECHS.

SHAKE, in singing. See TRILL.

SHAKESPEARE or SHAKSPEARE (William) the prince of dramatic writers, was born at Stratford upon Avon in Warwickshire, on the 23d of April 1564. From the register of that town, it appears that a plague broke out there on the 30th of June following, which raged with great violence; but fortunately it did not reach the house in which this infant prodigy lay. His father, John Shakespeare, enjoyed a small patrimonial estate, and was a considerable dealer in wool; his mother was the daughter and heir of Robert Arden of Wellingcote. Our illustrious poet being designed for the business of his father, received no better education than the instructions which the free-school of Stratford could afford. After applying some time to the study of Latin, he was called home to assist his father, who seems by some accident to have been reduced in his circumstances. Before arriving at the age of 19, he married the daughter of Mr Hathaway, a substantial yeoman in the neighbourhood of Stratford. This lady was eight years older than her husband. Having the misfortune to fall into bad company, he was seduced into some profligate actions, which drew on him a criminal prosecution, and at length forced him to take refuge in the capital. In concert with his associates, he broke into a park belonging to Sir Thomas Lucy of Charlecote, and carried off some of his deer. Every admirer of Shakespeare will regret that such a blemish should have stained his character:

but perhaps, if any thing can extenuate his guilt, we might ascribe it to the opinions of the age, which perhaps, as was formerly the case in Scotland, might not distinguish the killing of deer by any mark of disgrace, or any charge of criminality. One thing at least is certain, that Shakespeare himself thought that the prosecution which Sir Thomas raised against him was carried on with too great severity; an opinion which he could not have entertained had this action been at that time viewed in the same criminal light as it is at present. Shakespeare testified his resentment against Sir Thomas, by writing a satirical ballad, which exasperated him so much, that the process was carried on with redoubled violence; and the young poet, in order to avoid the punishment of the law, was obliged to make his escape. This ballad would be considered as a curious relict, on account of its being the first production of Shakespeare; it would also be interesting to peruse a poem which could irritate the baronet to so high a degree. Tradition has preserved the first stanza:

A parliamente member, a justice of peace,
At home a poor scare-crow, at London an asse.
If lowsie is Lucy, as some volke miscalle it,
Then Lucy is lowsie whatever befall it:
He thinks himself greate,
Yet an asse in his state,
We allowe by his ears, but with asses to mate.
If Lucy is lowsie, as some volke miscalle it,
Sing lowsie Lucy whatever befall it.

If the rest of the ballad was of a piece with this stanza, it might assist us to form some opinion of the irritability of the baronet, but will enable us to form no idea of the opening genius of Shakespeare.

Thus expelled from his native village, he repaired to London, where he was glad to accept a subordinate office in the theatre. It has been said that he was first engaged, while the play was acting, in holding the horses of those who rode to the theatre; but this story rests on a slender foundation. As his name is found printed among those of the other players before some old plays, it is probable that he was some time employed as an actor; but we are not informed what characters he played; we are only told, that the part which he acted best was that of the Ghost in Hamlet; and that he appeared in the character of Adam in *As you like it*. If the names of the actors prefixed to Ben Johnson's play of *Every Man in his Humour* were arranged in the same order as the persons represented, which is very probable, Shakespeare played the part of Old Knowell. We have reason therefore to suppose, as far as we can argue from these few facts, that he generally represented old men. See Malone's Chronology, in his edition of Shakespeare.

But though he was not qualified to shine as an actor, he was now in the situation which could most effectually rouse those latent sparks of genius which afterwards burst forth with so resplendent a flame. Being well acquainted with the mechanical business of the theatre and the taste of the times; possessed of a knowledge of the characters of men resembling intuition, an imagination that ranged at large through nature, selecting the grand, the sublime, and the beautiful; a judicious caution, that disposed him to prefer those plots which had already been found to please; an uncommon fluency and force of expression; he was qualified at once to eclipse all who had gone before him.

Notwithstanding the unrivalled genius of Shakespeare, most of his plots were the invention of others; which, however, he certainly much improved, if he did not entirely new-model. We are assured, that prior to the theatrical compositions of Shakespeare, dramatic pieces were written on the following subjects, viz. King John, King Richard II. and III. King Henry IV. and V. King Henry VIII. King Lear, Antony and Cleopatra, Measure for Measure, the Merchant of Venice, the Taming of a Shrew, and the Comedy of Errors.

Among his patrons, the earl of Southampton is particularly honoured by him, in the dedication of two poems, Venis and Adonis, and Lucrece; in the latter especially, he expressed himself in such terms as gives countenance to what is related of that patron's distinguished generosity to him. In the beginning of king James I.'s reign (if not sooner) he was one of the principal managers of the playhouse, and continued in it several years afterward; till, having acquired such a fortune as satisfied his moderate wishes and views in life, he quitted the stage, and all other business, and passed the remainder of his time in an honourable ease, at his native town of Stratford, where he lived in a handsome house of his own purchasing, to which he gave the name of *New Place;* and he had the good fortune to save it from the flames in the dreadful fire that consumed the greatest part of the town in 1614.

In the beginning of the year 1616, he made his will, wherein he testified his respect to his quondam partners in the theatre: he appointed his youngest daughter, jointly with her husband, his executors, and bequeathed to them the best part of his estate, which they came into the possession of not long after. He died on the 23d of April following, being the 53d year of his age; and was interred among his ancestors on the north side of the chancel, in the great church of Stratford, where there is a handsome monument erected for him, inscribed with the following elegiac distich in Latin.

Judicio Pylium, genio Socratem, arte Maronem,
Terra tegit, Populus mæret, Olympus habet.

In the year 1740, another very noble one was raised to his memory, at the public expence, in Westminster-abbey; an ample contribution for this purpose being made upon exhibiting his tragedy of Julius Cæsar, at the theatre-royal in Drury-Lane, April 28th 1738.

Nor must we omit mentioning another testimony of the veneration paid to his manes by the public in general, which is, that a mulberry-tree planted upon his estate by the hands of this reverend bard, was cut down not many years ago; and the wood being converted to several domestic uses, was all eagerly bought at a high price, and each single piece treasured up by its purchaser as a precious memorial of the planter.

The character of Shakespeare as a dramatic writer has been often drawn, but perhaps never with more accuracy than by the pen of Dr Johnson: "Shakespeare (says he) is above all writers, at least above all modern writers, the poet of nature; the poet that holds up to his readers a faithful mirror of manners and of life.

Shakespeare.

His characters are not modified by the customs of particular places, unpractised by the rest of the world; by the peculiarities of studies or professions, which can operate but upon small numbers; or by the accidents of transient fashions or temporary opinions: they are the genuine progeny of common humanity, such as the world will always supply, and observation will always find. His persons act and speak by the influence of those general passions and principles by which all minds are agitated, and the whole system of life is continued in motion. In the writings of other poets, a character is too often an individual; in those of Shakespeare, it is commonly a species.

"It is from this wide extension of design that so much instruction is derived. It is this which fills the plays of Shakespeare with practical axioms and domestic wisdom. It was said of Euripides, that every verse was a precept; and it may be said of Shakespeare, that from his works may be collected a system of civil and economical prudence. Yet his real power is not shown in the splendour of particular passages, but by the progress of his fable, and the tenor of his dialogue; and he that tries to recommend him by select quotations, will succeed like the pedant in Hierocles, who, when he offered his house to sale, carried a brick in his pocket as a specimen.

"Upon every other stage the universal agent is love, by whose power all good and evil is distributed, and every action quickened or retarded. But love is only one of many passions; and as it has no great influence upon the sum of life, it has little operation in the dramas of a poet who caught his ideas from the living world, and exhibited only what he saw before him. He knew that any other passion, as it was regular or exorbitant, was a cause of happiness or calamity.

"Characters thus ample and general were not easily discriminated and preserved; yet perhaps no poet ever kept his personages more distinct from each other.

"Other dramatists can only gain attention by hyperbolical or aggravated characters, by fabulous and unexempled excellence or depravity, as the writers of barbarous romances invigorated the reader by a giant and a drawf; and he that should form his expectations of human affairs from the play, or from the tale, would be equally deceived. Shakespeare has no heroes, his scenes are occupied only by men, who act and speak as the reader thinks that he should himself have spoken or acted on the same occasion: Even where the agency is supernatural, the dialogue is level with life. Other writers disguise the most natural passions and most frequent incidents; so that he who contemplates them in the book will not know them in the world: Shakespeare approximates the remote, and familiarizes the wonderful; the event which he represents will not happen, but if it were possible, its effects would probably be such as he has assigned; and it may be said, that he has not only shown human nature as it acts in real exigencies, but as it would be found in trials to which it cannot be exposed.

"This therefore is the praise of Shakespeare, that his drama is the mirror of life; that he who has mazed his imagination, in following the phantoms which other writers raise up before him, may here be cured of his delirious ecstasies, by reading human sentiments in human language; by scenes from which a hermit may estimate the transactions of the world, and a confessor predict the progress of the passions."

The learning of Shakespeare has frequently been a subject of inquiry. That he possessed much classical knowledge does not appear, yet he was certainly acquainted with the Latin poets, particularly with Terence, as Colman has justly remarked, which appears from his using the word *thrasonical*. Nor was he unacquainted with French and Italian. We are indeed told, that the passages in which these languages occur might be impertinent additions of the players; but is it probable, that any of the players so far surpassed Shakespeare?

That much knowledge is scattered over his works is very justly observed by Pope; but it is often such knowledge as books did not supply. "There is, however, proof enough (says Dr Johnson) that he was a very diligent reader; nor was our language then so indigent of books, but that he might very liberally indulge his curiosity without excursion into foreign literature. Many of the Roman authors were translated, and some of the Greek; the Reformation had filled the kingdom with theological learning; most of the topics of human disquisition had found English writers; and poetry had been cultivated, not only with diligence, but success. This was a stock of knowledge sufficient for a mind so capable of appropriating and improving it."

The works of Shakespeare consist of 35 dramatic pieces. The following is the chronological order which Mr Malone has endeavoured to establish, after a minute investigation, in which he has in general been successful:

1.	First Part of King Henry VI.	1589
2.	Second Part of King Henry VI.	1591
3.	Third Part of King Henry VI.	1591
4.	A Midsummer Night's Dream	1592
5.	Comedy of Errors	1593
6.	Taming of the Shrew	1594
7.	Love's Labour Lost	1594
8.	Two Gentlemen of Verona	1595
9.	Romeo and Juliet	1595
10.	Hamlet	1596
11.	King John	1596
12.	King Richard II.	1597
13.	King Richard III.	1597
14.	First Part of King Henry IV.	1597
15.	Second Part of King Henry IV.	1598
16.	The Merchant of Venice	1598
17.	All's Well that Ends Well	1598
18.	King Henry V.	1599
19.	Much Ado about Nothing	1600
20.	As you like it	1600
21.	Merry Wives of Windsor	1601
22.	King Henry VIII.	1601
23.	Troilus and Cressida	1602
24.	Measure for Measure	1603
25.	The Winter's Tale	1604
26.	King Lear	1605
27.	Cymbelline	1605
28.	Macbeth	1606
29.	Julius Cæsar	1607
30.	Anthony and Cleopatra	1608
31.	Timon of Athens	1609
32.	Coriolanus	1610

33. Othello - - - - 1611
34. The Tempest - - - - 1612
35. Twelfth Night - - - - 1614

The three first of these, Mr Malone thinks, there is very strong reason to believe are not the original productions of Shakespeare; but that he probably altered them, and added some new scenes.

In the first folio edition in 1623, these plays were entitled "Mr William Shakespeare's Comedies, Histories, and Tragedies." They have been published by various editors. The first folio edition by Isaac Jaggard and Edward Blount; the second, folio, 1632, by Thomas Cotes for Robert Allot; the third 1664, for P. C; the fourth, 1685, for H. Herringman, E. Brewster, and R. Bentley. Rowe published an 8vo edition in 1709, in 7 vols, and a 12mo edition in 1714, in 9 vols, for which he received L. 36 10s. Pope published a 4to edition in 1725, in 6 vols, and a 12mo in 1728, in 10 vols; for which he was paid L. 217, 12s. Theobald gave a new edition in 8vo in 1733, in 7 vols, another in 12mo in 1740, in 8 vols; and received for his labour L. 652. 10s. Sir Thomas Hanmer published an edition 1744, in 6 vols 4to. Dr Warburton's 8vo edition came out in 1747, in 8 vols; for which he was paid L. 560. The editions published since that time, are Dr Johnson's in 1765, in 8 vols 8vo. Stevens's in 1766, in 4 vols 8vo. Capell's in 1768, in 10 vols, crown 8vo; for this the author was paid L. 300. A second edition of Hanmer's in 1771, 6 vols. Johnson's and Stevens's in 1773, in 10 vols 8vo; a second edition in 1778; a third by Reed in 1785; and Malone's crown 8vo edition in 1789, in 10 vols.

The most authentic of the old editions is that of 1623. "At last (says Dr Johnson) an edition was undertaken by Rowe; not because a poet was to be published by a poet, for Rowe seems to have thought very little on correction or explanation, but that our author's works might appear like those of his fraternity, with the appendages of a life and recommendatory preface. Rowe has been clamorously blamed for not performing what he did not undertake, and it is time that justice be done him, by confessing, that though he seems to have had no thought of corruption beyond the printer's errors, yet he has made many emendations, if they were not made before, which his successors have received without acknowledgment, and which, if they had produced them, would have filled pages with censures of the stupidity by which the faults were committed, with displays of the absurdities which they involved, with ostentatious expositions of the new reading, and self-congratulations on the happiness of discovering it."

The nation had been for many years content enough with Mr Rowe's performance, when Mr Pope made them acquainted with the true state of Shakespeare's text, showed that it was extremely corrupt, and gave reason to hope that there were means of reforming it. Mr Pope's edition, however, he observes, fell below his own expectations; and he was so much offended, when he was found to have left any thing for others to do, that he passed the latter part of his life in a state of hostility with verbal criticism.

The only task, in the opinion of Mr Malone, for which Pope was eminently and indisputably qualified, was to mark the faults and beauties of his author.—When he undertook the office of a commentator, every anomaly of language, and every expression that was currently in use, were considered as errors or corruptions, and the text was altered or amended, as it was called, at pleasure. Pope is openly charged with being one of the great corrupters of Shakespeare's text.

Pope was succeeded by Theobald, who collated the ancient copies, and rectified many errors. He was, however, a man of narrow comprehension and of little learning, and what is worse, in his reports of copies and editions, he is not to be trusted without examination. From the liberties taken by Pope, the edition of Theobald was justly preferred, because he professed to adhere to the ancient copies more strictly, and illustrated a few passages by extracts from the writers of our poet's age. Still, however, he was a considerable innovator; and while a few arbitrary changes made by Pope were detected, innumerable sophistications were silently adopted.

Sir Thomas Hanmer, who comes next, was a man of critical abilities, and of extensive learning. His corrections are commonly just, but sometimes capricious. He is censurable, too, for receiving without examination almost all the innovations of Pope.

The original and predominant error of Warburton's commentary, is acquiescence in his first thoughts; that precipitation which is produced by a consciousness of quick discernment; and that confidence which presumes to do, by surveying the surface, what labour only can perform, by penetrating to the bottom. His notes exhibit sometimes perverse interpretations, and sometimes improbable conjectures; he at one time gives the author more profundity of meaning than the sentence admits, and at another discovers absurdities where the sense is plain to every other reader. But his emendations are likewise often happy and just; and his interpretation of obscure passages learned and sagacious.

It has indeed been said by his defenders, that his great object was to display his own learning; and certainly, in spite of the clamour raised against him for substituting his own chimerical conceits instead of the genuine text of Shakespeare, his work increased his reputation. But as it is of little value as a commentary on Shakespeare, since Warburton is now gone, his work will probably soon sink into oblivion.

In 1765 Dr Johnson's edition, which had long been impatiently expected, was given to the public. His vigorous and comprehensive understanding threw more light on his author than all his predecessor's had done. The character which he gave of each play is generally just. His refutation of the false glosses of Theobald and Warburton, and his numerous explications of involved and difficult passages, entitle him to the gratitude of every admirer of Shakespeare.

The last editor is Mr Malone, who was eight years employed in preparing his edition. By collating the most authentic copies, he has been careful to purify the text. He has been so industrious, in order to discover the meaning of the author, that he has ransacked many volumes, and trusts that, besides his additional illustrations, not a single valuable explication of any obscure passage in these plays has ever appeared, which he has not inserted in his edition. He rejects Titus Andronicus, as well as the three plays formerly mentioned, as not

not being the authentic productions of Shakespeare. To the whole he has added an appendix, and a copious glossary.—Of this work a less expensive edition has been published in 7 vols 12mo, in which the general introductory observations prefixed to the different plays are preserved, and the numerous notes abridged.

This judicious commentator has certainly done more for the elucidation and correction of Shakespeare than all who came before him, and has followed with indefatigable patience the only road which a commentator of Shakespeare ought to observe.

Within 50 years after our poet's death, Dryden says that he was become "a little obsolete;" and in the beginning of the present century Lord Shaftesbury complains of his rude and unpolished style, and his antiquated phrase and wit. These complaints were owing to the great revolution which the English language has undergone, and to the want of an enlightended commentator. These complaints are now removed, for an enlightened commentator has been found in Mr Malone.

We have only farther to add, that in the year 1790 a copious index to the remarkable passages and words in the plays of Shakespeare was published by the Reverend Mr Ayscough; a gentleman to whom the literary world is much indebted for several very valuable keys of knowledge. In fine, the admirers of Shakespeare are now, by the labours of several eminent men, furnished with every help that can enable them to understand the sense and to taste the beauties of this illustrious poet.

SHAKLES. See SHACKLES.

SHALE, in natural history, a species of SCHISTUS. It is a black flaty substance, or a clay hardened into a stony consistence, and so much impregnated with bitumen that it becomes somewhat like a coal. The acid emitted from shale, during its calcination, uniting itself to the argillaceous earth of the shale, forms alum. About 120 tons of calcined shale will make one ton of alum. The shale, after being calcined, is steeped in water, by which means the alum, which is formed during the calcination of the shale, is dissolved: this dissolved alum undergoes various operations before it is formed into the alum of the shops. Watson's Chemical Essays, vol. ii. p. 315. See ALUM.

This kind of slate forms large strata in Derbyshire; and that which lies near the surface of the earth is of a softer and more shivery texture than that which lies deeper. It is also found in large strata, generally above the coal, in most coal counties of Great Britain. Dr Short informs us, that the shale wastes the lead ore near it, by its strong acid; and that it corrodes and destroys all minerals near it except iron or coal, of whose vitriol it partakes.

SHALLOP, SHALLOOP, or SLOOP, is a small light vessel, with only a small main-mast, and fore-mast, and lug-sails, to hale up, and let down, on occasion.—Shallops are commonly good sailers, and are therefore often used as tenders upon men of war.

SHALLOT, or ESCHALOT. See ALLIUM.

SHAMANS are wizards or conjurers, in high repute among several idolatrous nations inhabiting different parts of Russia. By their enchantments they pretend to cure diseases, to divert misfortunes, and to foretel futurity. They are great observers of dreams, by the interpretation of which they judge of their good or bad fortune. They pretend likewise to chiromancy, and to foretel a man's good or ill success by the lines of his hand. By these and such like means they have a very great ascendency over the understandings, and a great influence on the conduct, of those people.

SHAMBLES, among miners, a sort of niches or landing places, left at such distances in the adits of the mines, that the shovel-men may conveniently throw up the ore from shamble to shamble, till it comes to the top of the mine.

SHAMOIS, CHAMOIS, or SHAMMY, a kind of leather, either dressed in oil or tanned, much esteemed for its softness, pliancy, &c. It is prepared from the skin of the chamois, or shamois, a kind of rupicapra, or wild goat, called also isard, inhabiting the mountains of Dauphiny, Savoy, Piedmont, and the Pyrenees. Besides the softness and warmth of the leather, it has the faculty of bearing soap without damage; which renders it very useful on many accounts.

In France, &c. some wear the skin raw, without any preparation. Shammy leather is used for the purifying of mercury; which is done by passing it through the pores of this skin, which are very close. The true chamois leather is counterfeited with common goat, kid, and even with sheep skins, the practice of which makes a particular profession, called by the French *chamoiseur*. The last, though the least esteemed, is yet so popular, and such vast quantities of it are prepared, especially about Orleans, Marseilles, and Thoulouse, that it may not be amiss to give the method of preparation.

Manner of shamoising, or preparing sheep, goat, or kid skins in oil, in imitation of shammy.—The skins, being washed, drained, and smeared over with quicklime on the fleshy side, are folded in two lengthwise, the wool outwards, and laid on heaps, and so left to ferment eight days, or, if they had been left to dry after flaying, then fifteen days.

Then they are washed out, drained, and half dried; laid on a wooden leg, or horse, the wool stripped off with a round staff for that purpose, and laid in a weak pit, the lime whereof had been used before, and has lost the greatest part of its force.

After 24 hours they are taken out, and left to drain 24 more; they are then put in another stronger pit. This done, they are taken out, drained, and put in again, by turns; which begins to dispose them to take oil; and this practice they continue for six weeks in summer, or three months in winter: at the end whereof they are washed out, laid on the wooden leg, and the surface of the skin on the wool side peeled off, to render them the softer; then made into parcels, steeped a night in the river, in winter more, stretched six or seven over one another on the wooden leg, and the knife passed strongly on the flesh side, to take off any thing superfluous, and render the skin smooth. Then they are steeped, as before, in the river, and the same operation is repeated on the wool side; they are then thrown into a tub of water, with bran in it, which is brewed among the skins till the greatest part sticks to them, and then separated into distinct tubs, till they swell, and rise of themselves above the water. By this means the remains of the lime are cleared out; they are then wrung out, hung up to dry on ropes, and sent to the mill, with the quantity of oil necessary to scour them: the best oil is that of stock-fish. Here they are first thrown in bundles into the river for 12 hours, then laid in the mill-trough, and fulled without oil till they be well softened; then oiled with the hand, one by one, and thus formed into parcels of four skins each; which are milled and dried on cords a second time; then a third; and then oiled again, and dried. This process is repeated as often as necessity requires; when done, if there be any moisture remaining, they are dried in a stove, and made up into parcels wrapped up in wool; after some time they are opened to the air, but wrapped up again as before, till such time as the oil seems to have lost all its force, which it ordinarily does in 24 hours. The skins are then returned from the mill to the chamoiser to be scoured: which is done by putting them in a lixivium of wood-ashes, working and beating them in it with poles, and leaving them to steep till the lee hath had its effect; then they are wrung out, steeped in another lixivium, wrung again; and this is repeated till all the grease and oil be purged out. When this is done, they are half dried, and passed over a sharp-edged iron instrument, placed perpendicular in a block, which opens, softens, and makes them gentle. Lastly, they are thoroughly dried, and passed over the same instrument again; which finishes the preparation, and leaves them in form of shammy.

Kid and goat skins are shamoised in the same manner as those of sheep, excepting that the hair is taken off without the use of any lime; and that when brought from the mill they undergo a particular preparation called *ramalling*, the most delicate and difficult of all the others. It consists in this, that, as soon as brought from the mill, they are steeped in a fit lixivium, taken out, stretched on a round wooden leg, and the hair is scraped off with the knife; this makes them smooth, and in working to cast a kind of fine knap. The difficulty is in scraping them evenly.

SHANK, or *Shank-Painter*, in a ship, is a short chain fastened under the foremast-shrouds, by a bolt, to the ship's sides, having at the other end a rope fastened to it. On this shank-painter the whole weight of the aft part of the anchor rests, when it lies by the ship's side. The rope, by which it is hauled up, is made fast about a timber-head.

Shank, in the manege, that part of a horse's foreleg which lies between the knee and the footlock.

SHANKER, or Chancre, in medicine, a malignant ulcer, usually occasioned by some venereal disorder. See Medicine, n° 350.

SHANNON, the largest river in Ireland, and one of the finest in the British dominions, not only on account of its rolling 200 miles, but also of its great depth in most places, and the gentleness of its current, by which it might be made exceedingly serviceable to the improvement of the country, the communication of its inhabitants, and consequently the promoting of inland trade, through the greatest part of its long course. But the peculiar prerogative of the Shannon is its situation, running from north to south, and separating the province of Connaught from Leinster and Munster, and of consequence dividing the greatest part of Ireland into what lies on the east and that on the west of the river; watering in its passage the valuable county of Leitrim, the plentiful shire of Roscommon, the fruitful county of Galway, and the pleasant county of Clare; the small but fine shire of Longford, the King's county, and fertile county of Meath in Leinster, the populous county of Tipperary, the spacious shire of Limerick, and the rough but pleasant county of Kerry in Munster; visiting 10 counties in its passage, and having on its banks the following remarkable places, viz. Leitrim, Jamestown, Lanesborough, Athlone, Clonfert, Killaloe, and Limerick; at 20 leagues below the latter it spreads gradually several miles in extent, so that some have considered its expansion as a lake. It at last joins its waters to the sea, being navigable all that way for the largest vessels.

SHANSCRIT the language of the Bramins of Hindostan. See Philology, sect. v.

SHARE, *of a Plough*, that part which cuts the ground; the extremity forwards being covered with a sharp-pointed iron, called the *point of the share*, and the end of the wood behind the *tail of the share*.

SHARK, in ichthyology. See Squalus.

SHARON, a name common to three cantons of Palestine. The first lay between mount Tabor and the sea of Tiberias; the second between the city of Cæsarea of Palestine, and Joppa; and the third lay beyond Jordan. To give an idea of perfect beauty, Isaiah said, the glory of Lebanon aud the beauty of Carmel must be joined to the abundance of Sharon. (Isaiah xxxiii. 9. xxxi. 2.) The plains of Sharon are of vast extent; and, when surveyed by the Abbé Mariti a few years ago, they were sown with cucumbers; and he informs us, that such a number is annually produced, as not only to supply the whole neighbourhood, but also all the coasts of Cyprus and the city of Damietta. In the middle of the plain, between Arsus and Lydda, rises a small mountain, upon the ridge of which there is a small village called Sharon, from the name of the ancient city whose king was conquered by Joshua.

SHARP (James), Archbishop of St Andrew's, was born of a good family in Banffshire in 1618. He devoted himself very early to the church, and was educated for that purpose in the University of Aberdeen. When the solemn league and covenant was framed in 1638, the learned men in that seminary, and young Sharp in particular, declared themselves decidedly against it. To avoid the insults and indignities to which he was subjected in consequence of this conduct, he retired to England, where he contracted an acquaintance with some of the most celebrated divines in that country.

At the commencement of the civil wars he returned to Scotland. During his journey thither, he accidentally met with Lord Oxenford, who was so charmed with his conversation, that he invited him to his house. While he resided with that nobleman, he became known to the earl of Rothes, who procured him a professorship at St Andrew's. By the interest of the earl of Crawford he was soon after appointed minister of Crail; where he conducted himself, it is said, in an exemplary manner.

Sharp had always inclined to the cause of royalty, and had for some time kept up a correspondence with his exiled prince. Ater the death of the protector he began to declare himself more openly, and seems to have enjoyed a great share of the confidence of Monk, who was at that time planning the restoration of Charles II. When that general marched to London, the presbyterians sent Sharp to attend him in order to support their interests. At the request of general Monk and the chief presbyterians in Scotland, Mr Sharp was soon after

ter sent over to the king at Breda to procure from him, if possible, the establishment of presbyterianism. On his return, he assured his friends that "he had found the king very affectionate to Scotland, and resolved not to wrong the settled government of the church: but he apprehended they were mistaken who went about to establish the presbyterian government."

Charles was soon after restored without any terms. All the laws passed in Scotland since the year 1633 were repealed; the king and his ministers resolved at all hazards to restore prelacy. Mr Sharp, who had been commissioned by the Scotch presbyterians to manage their interests with the king, was prevailed upon to abandon the party; and, as a reward for his compliance, he was made archbishop of St Andrew's. This conduct rendered him very odious in Scotland; he was accused of treachery and perfidy, and reproached by his old friends as a traitor and a renegado. The absurd and wanton cruelties which were afterwards committed, and which were imputed in a great measure to the archbishop, rendered him still more detested. Nor is it probable that these accusations were without foundation: the very circumstance of his having been formerly of the presbyterian party would induce him, after forsaking them, to treat them with severity. Besides, it is certain, that when after the rout at Pentland-hills he received an order from the king to stop the executions, he kept it for some time before he produced it to council.

There was one Mitchell a preacher, and a desperate fanatic, who had formed the design of taking vengeance for these cruelties by assassinating the archbishop. He fired a pistol at him as he was sitting in his coach; but the bishop of Orkney, lifting up his hand at the moment, intercepted the ball. Though this happened in the midst of Edinburgh, the primate was so much detested, that nobody stopped the assassin; who, having walked leisurely home, and thrown off his disguise, returned, and mixed unsuspected with the crowd. Some years after, the archbishop observing a man eyeing him with keenness, suspected that he was the assassin, and ordered him to be brought before him. It was Mitchell. Two loaded pistols were found in his pocket. The primate offered him a pardon if he would confess the crime: the man complied; but Sharp, regardless of his promise, conducted him to the council. The council also gave him a solemn promise of pardon if he would confess his guilt, and discover his accomplices. They were much disappointed to hear that only one man was privy to his purpose, who was since dead. Mitchell was then brought before a court of justice, and ordered to make a third confession, which he refused. He was imprisoned for several years, and then tried. His own confession was urged against him. It was in vain for him to plead the illegality of that evidence, and to appeal to the promise of pardon previously given. The council took an oath that they had given no such promise; and Mitchell was condemned. Lauderdale, who at that time governed Scotland, would have pardoned him, but the primate insisted on his execution; observing, that if assassins were permitted to go unpunished, his life must be continually in danger. Mitchell was accordingly executed.

Sharp had a servant, one Carmichael, who by his cruelty had rendered himself particularly odious to the zealots. Nine men formed the resolution of waylaying him in Magus-muir, about three miles from St Andrew's. While they were waiting for this man, the primate himself appeared with very few attendants. This they looked upon as a declaration of heaven in their favour; and calling out, "the Lord has delivered him into our hands," they ran up to the carriage. They fired at him without effect; a circumstance which was afterwards imputed to magic. They then dispatched him with swords, regardless of the tears and intreaties of his daughter, who accompanied him (A).

Thus fell archbishop Sharp, whose memory is even at present detested by the common people of Scotland. His abilities were certainly good, and in the early part of his life he appears with honour and dignity. But his conduct afterwards was too cruel and insincere to merit approbation. His treatment of Mitchell was mean and vindictive. How far he contributed to the measures adopted against the presbyterians is not certain. They were equally cruel and impolitic; nor did their effects cease with the measures themselves. The unheard-of cruelties exercised by the ministers of Charles II. against the adherents of the covenant, raised such a flame of enthusiasm and bigotry as is not yet entirely extinguished.

Sharp (Dr John), archbishop of York, was descended from the Sharps of Little Norton, a family of Bradford Dale in Yorkshire; and was son of an eminent tradesman of Bradford, where he was born in 1644. He was educated at Cambridge, and in 1667 entered into orders. That same year he became domestic chaplain to Sir Heneage Finch, then attorney-general. In 1672 he was collated to the archdeaconry of Berkshire. In 1675 he was installed a prebendary in the cathedral church of Norwich; and the year following was instituted into the rectory of St Bartholomew near the Royal Exchange, London. In 1681 he was, by the interest of his patron Sir Heneage Finch, then lord high chancellor of England, made dean of Norwich; but in 1686 was suspensed for taking occasion, in some of his sermons, to vindicate the doctrine of the church of England in opposition to Popery. In 1688 he was sworn chaplain to king James II. being then probably restored after his suspension; for it is certain that he was chaplain to king Charles II. and attended as a court chaplain

(A) Such is the account given by all our historians of the murder of archbishop Sharp; and that he fell by the hands of fanatics, whom he persecuted, is certain. A tradition, however, has been preserved in different families descended from him, which may be mentioned, and is in itself certainly not incredible. The primate, it seems, who, when minister of Crail, was peculiarly severe in punishing the sin of fornication, had, in the plenitude of his archiepiscopal authority, taken notice of a criminal amour carried on between a nobleman high in office and a lady of some fashion who lived within his diocese. This interference was in that licentious age deemed very impertinent; and the archbishop's descendants believe that the proud peer instigated the deluded rabble to murder their ancestor.

plain at the coronation of king James II. In 1689 he was declared dean of Canterbury; but never could be persuaded to fill up any of the vacancies made by the deprived bishops. Upon the death of Dr Lamplugh, he was promoted to the see of York. In 1702 he preached the sermon at the coronation of queen Anne; and the same year was sworn of the privy-council, and made lord almoner to her majesty. He died at Bath in 1713; and was interred in the cathedral of York, where a monument is erected to his memory.—His sermons which were collected after his death and published in 7 vols 8vo, are justly admired.

SHARP, in music. See INTERVAL.

SHASTER, or BEDANG, the name of a sacred book, in high estimation among the idolaters of Hindostan, containing all the dogmas of the religion of the bramins, and all the ceremonies of their worship; and serving as a commentary on the VEDAM.

The term *Shaster* denotes "science" or "system;" and is applied to other works of astronomy and philosophy, which have no relation to the religion of the Indians. None but the bramins and rajahs of India are allowed to read the Vedam; the priests of the Banians, called *shuderers*, may read the Shaster; and the people, in general, are allowed to read only the Peran or Pouran, which is a commentary on the Shaster.

The Shaster is divided into three parts: the first containing the moral law of the Indians; the second, the rites and ceremonies of their religion; and the third, the distribution of the people into tribes or classes, with the duties pertaining to each class.

The principal precepts of morality contained in the first part of the Shaster are the following: that no animal be killed, because the Indians attribute souls to brute-animals as well as to mankind; that they neither hear nor speak evil, nor drink wine, nor eat flesh, nor touch any thing that is unclean; that they observe the feasts, prayers, and washings, which their law prescribes; that they tell no lies, nor be guilty of deceit in trade; that they neither oppress nor offer violence to one another; that they celebrate the solemn feasts and fasts, and appropriate certain hours of ordinary sleep to cultivate a disposition for prayer; and that they do not steal or defraud one another.

The ceremonies contained in the second part of the Shaster are such as these: that they wash often in the rivers, hereby obtaining the pardon of their sins; that they mark their forehead with red, in token of their relation to the Deity; that they present offerings and prayers under certain trees, set apart for this purpose; that they pray in the temples, make oblations to their pagodas, or idols, sing hymns, and make processions, &c. that they make pilgrimages to distant rivers, and especially to the Ganges, there to wash themselves and make offerings; that they make vows to particular saints, according to their respective departments; that they render homage to the Deity at the first sight of the sun; that they pay their respect to the sun and moon, which are the two eyes of the Deity; and that they treat with particular veneration those animals that are deemed more pure than others; as the cow, buffaloe, &c.; because the souls of men have transmigrated into these animals.

The third part of the Shaster records the distribution of the people into four classes: the first being that of the bramins or priests, appointed to instruct the people; the second, that of the kutteris or nobles, who are the magistrates; the third, that of the shudderis or merchants; and the fourth, that of the mechanics. Each person is required to remain in the class in which he was born, and to pursue the occupation assigned to him by the Shaster. According to the bramins, the Shaster was imparted by God himself to Brahma, and by him to the Bramins; who communicated the contents of it to the people.

Modern writers have given us very different accounts of the antiquity and importance of the Shaster. Mr Holwell, who had made considerable progress in the translation of this book, apprehends, that the mythology as well as the cosmogony of the Egyptians, Greeks, and Romans, were borrowed from the doctrines of the bramins, contained in it, even to the copying of their exteriors of worship, and the distribution of their idols, though grossly mutilated and adulterated. With respect to the Vedam and Shaster, or scriptures of the Gentoos, this writer informs us, that *Vedam*, in the Malabar language, signifies the same as *Shaster* in the Shanscrit; and that the first book is followed by the Gentoos of the Malabar and Coromandel coasts, and also of the island of Ceylon. The Shaster is followed by the Gentoos of the provinces of Bengal, and by all the Gentoos of the rest of India, commonly called *India Proper*, along the course of the rivers Ganges and Jumna to the Indus. Both these books (he says) contain the institutes of their respective religion and worship, as well as the history of their ancient rajahs and princes, often couched under allegory and fable. Their antiquity is contended for by the partisans of each; but he thinks, that the similitude of their names, idols, and great part of their worship, leaves little room to doubt, nay plainly evinces, that both these scriptures were originally one. He adds, if we compare the great purity and chaste manners of the Shaster with the great absurdities and impurities of the Vedam, we need not hesitate to pronounce the latter a corruption of the former.

With regard to the high original of these scriptures, the account of the bramins is as follows. Brahma (that is, "Mighty Spirit"), about 4866 years ago, assumed the form of man and the government of Indostan. He translated the divine law (designed for the restoration of mankind, who had offended in a pre-existent state, and who are now in their last scene of probation, to the dignity from which they were degraded) out of the language of angels into the well known Shanscrit language, and called his translation the *Chartah Bhade Shastah of Birmah*, or *the Six Scriptures of Divine Words of the Mighty Spirit*. He appointed the bramins, deriving their name from him, to preach the word of God; and the doctrines of the Shaster were accordingly preached in their original purity 1000 years. About this time there was published a paraphrase on the Chartah Bhade; and about 500 years afterwards a second exposition, called the *Aughtorrah Bhade Shasta*, or *Eighteen Books of Divine Words*, written in a character compounded of the common Indostan and the Shanscrit. This innovation produced a schism among the Gentoos; on which occasion, it is said, those of Coromandel and Malabar formed a scripture of their own, which they pretended to be founded on the Chartah

Shaster. Bhade of Bramah, and called it *the Vedam of Birmah*, or *Divine Words of the Mighty Spirit*. The original Chartah Bhade was thrown aside, and at length wholly unknown, except to a few families; who can still read and expound it in the Shanscrit character. With the establishment of the Aughtorrah Bhade, and Vedam, which, according to the Gentoo account, is 3366 years ago, their polytheism commenced; and the principles of religion became so obscure, and their ceremonies so numerous, that every head of a family was obliged to keep a bramin as a guide both in faith and practice. Mr Holwell is of opinion, that the Chartah Bhade, or Original Scriptures, are not copied from any other system of theology, promulgated to or obtruded upon mankind. The Gentoos do not attribute them to Zoroaster; and Mr Holwell supposes, that both Zoroaster and Pythagoras visited Indostan, not to instruct, but to be instructed.

From the account of Mr Dow, we learn, that the books which contain the religion and philosophy of the Hindoos are distinguished by the name of *Bedas;* that they are four in number, and, like the sacred writings of other nations, said to be penned by the Divinity. Beda, he says, in the Shanscrit language, literally signifies *science;* and these books treat not only of religion and moral duties, but of every branch of philosophic knowledge. The bramins maintain, that the Bedas are the divine laws, which Brimha, at the creation of the world, delivered for the instruction of mankind; but they affirm, that their meaning was perverted in the first age by the ignorance and wickedness of some princes, whom they represent as evil spirits, who then haunted the earth.

The first credible account we have of the Bedas is, that about the commencement of the Cal Jug, of which era the year 1768 was the 4886th year, they were written, or rather collected, by a great philosopher and reputed prophet, called *Beäss Muni*, or *Beäss the Inspired*.

The Hindoos, says Mr Dow, are divided into two great religious sects: the followers of the doctrine of Bedang, which is the original Shaster, or commentary upon the Bedas; and those who adhere to the principles of the Neadirsen. The original Shaster is called *Bedang*, and is a commentary upon the Bedas. This book, he says, is erroneously called in Europe the *Vedam*. It is ascribed to Beäss Muni, and is said to have been revised some years after by one Serrider Swami, since which it has been reckoned sacred, and not subject to any farther alterations.

Almost all the Hindoos of the Decan, and those of the Malabar and Coromandel coasts, are of this sect. The followers of the Bedang Shaster do not allow that any physical evil exists; they maintain that God created all things perfectly good; but that man, being a free agent, may be guilty of moral evil, which may be injurious to himself, but can be of no detriment to the general system of nature. God, they say, being perfectly benevolent, never punished the wicked otherwise than by the pain and affliction which are the natural consequences of evil actions; and hell, therefore, is no other than a consciousness of evil.

The Neadirsen Shaster is said to have been written by a philosopher called *Goutam*, near four thousand years ago. The bramins, from Mr Dow's account of their sacred books, appear to believe invariably in the unity, eternity, omniscience, and omnipotence of God; and the polytheism of which they have been accused is no more than a symbolical worship of the divine attributes, which they divide into three classes. Under the name of *Brimha*, they worship the wisdom and creative power of God; under the appellation of *Bishen*, his providential and preserving quality; and under that of *Shibah*, that attribute which tends to destroy.

As few of our readers may have an opportunity of perusing the Shaster, we shall, by way of specimen subjoin a passage from it, which, though it contains some metaphysical mysteries concerning the creation, yet discovers views of God so enlightened that they would not disgrace more refined nations. The passage which we shall quote is the first chapter of the Shaster, which is a dialogue between Brimha the Wisdom of the Divinity, and Narud or Reason, who is represented as the son of Brimha. Narud desires to be instructed by his father; and for that purpose puts the following questions to him:

"*Narud.* O father! thou first of God, thou art said to have created the world, and thy son Narud, astonished at what he beholds, is desirous to be instructed how all these things were made.

"*Brimha.* Be not deceived, my son! do not imagine that I was the creator of the world, independent of the Divine Mover, who is the great original essence and creator of all things. Look, therefore, only upon me as the instrument of the great *will*, and a part of his being, whom he called forth to execute his eternal designs.

"*Narud.* What shall we think of God?

"*Brimha.* Being immaterial, he is above all conception; being invisible, he can have no form; but, from what we behold in his works, we may conclude that he is eternal, omnipotent, knowing all things and present everywhere.

"*Narud.* How did God create the world?

"*Brimha.* Affection dwelt with God from all eternity. It was of three different kinds; the creative, the preserving, and the destructive. This first is represented by Brimha, the second by Bishen, and the third by Shibah. You, O Narud! are taught to worship all the three in various shapes and likenesses, as the Creator, the Preserver, and the Destroyer. The affection of God then produced power, and power, at a proper conjunction of time and fate, embraced goodness, and produced matter. The three qualities then acting upon matter, produced the universe in the following manner: From the opposite actions of the creative and destructive quality in matter, self-motion first arose. Self-motion was of three kinds; the first inclining to plasticity, the second to discord, and the third to rest. The discordant actions then produced the Akash (a kind of celestial element), which invisible element possessed the quality of conveying sound; it produced air, a palpable element; fire, a visible element; water, a fluid element; and earth, a solid element.

"The Akash dispersed itself abroad. Air formed the atmosphere; fire, collecting itself, blazed forth in the host of heaven; water rose to the surface of the earth, being forced from beneath by the gravity of the latter element. Thus broke forth the world from the veil of darkness, in which it was formerly comprehended by God. Order rose over the universe. The seven heavens were formed, and the seven worlds were fixed in their places; there to remain till the great dissolution, when all things shall be absorbed into God.

"God seeing the earth in full bloom, and that vegetation was strong from its seeds, called forth for the first time intellect, which he endued with various organs and shapes, to form a diversity of animals upon the earth. He endued the animals with five senses; feeling, seeing, smelling, tasting, and hearing; but to man he gave reflection, to raise him above the beasts of the field.

"The creatures were created male and female, that they might propagate their species upon the earth. Every herb bore the seed of its kind, that the world might be clothed with verdure, and all animals provided with food.

"*Narud.* What dost thou mean, O father! by Intellect?

"*Brimha.* It is a portion of the *great soul* of the universe breathed into all creatures, to animate them for a certain time.

"*Narud.* What becomes of it after death?

"*Brimha.* It animates other bodies, or returns, like a drop, into that unbounded ocean from which it first arose.

"*Narud.* Shall not then the souls of good men receive rewards? nor the souls of the bad meet with punishment?

"*Brimha.* The souls of men are distinguished from those of other animals; for the first are endued with reason, and with a consciousness of right and wrong. If therefore man shall adhere to the first, as far as his powers shall extend, his soul, when disengaged from the body by death, shall be absorbed into the divine essence, and shall never more reanimate flesh: But the souls of those who do evil are not, at death, disengaged from all the elements. They are immediately clothed with a body of fire, air, and akash, in which they are for a time punished in hell. After the season of their grief is over, they reanimate other bodies; but till they shall arrive at a state of purity they can never be absorbed into God.

"*Narud.* What is the nature of that absorbed state which the souls of good men enjoy after death?

"*Brimha.* It is a participation of the divine nature, where all passions are utterly unknown, and where consciousness is lost in bliss.

"*Narud.* Thou sayest, O father, that unless the soul is perfectly pure it cannot be absorbed into God: now, as the actions of the generality of men are partly good and partly bad, whither are their spirits sent immediately after death?

"*Brimha.* They must atone for their crimes in hell, where they must remain for a space proportioned to the degree of their iniquities; then they rise to heaven to be rewarded for a time for their virtues; and from thence they will return to the world to reanimate other bodies.

"*Narud.* What is time?

"*Brimha.* Time existed from all eternity with God: but it can only be estimated since motion was produced, and only be conceived by the mind, from its own constant progress.

"*Narud.* How long shall this world remain?

"*Brimha.* Until the four lungs shall have revolved. Then Rudder (the same with *Shibah*, the destroying quality of God), with the ten spirits of dissolution, shall roll a comet under the moon, that shall involve all things in fire, and reduce the world into ashes. God shall then exist alone, for matter will be totally annihilated."

Those who desire more information on this subject may consult *Dow's History of Indostan*, and *Holwell's Interesting Historical Events*.

SHAW (Dr Thomas), known to the learned world by his travels to Barbary and the Levant, was born at Kendal in Westmoreland (England) about the year 1692. He was appointed chaplain to the English consul at Algiers, in which station he continued for several years; and from thence took proper opportunities of travelling into different parts. He returned in 1733; was elected fellow of the Royal Society; and published the account of his travels at Oxford, folio, 1738. In 1740 he was nominated principal of St Edmund-hall, which he raised from a ruinous state by his munificence; and was regius professor of Greek at Oxford until his death, which happened in 1751. Dr Clayton, Bp. of Clogher, having attacked these Travels in his Description of the East, Dr Shaw published a supplement by way of vindication, which is incorporated into the second edition of his Travels, prepared by himself, and published in 4to, 1757.

SHAWLS, are woollen handkerchiefs, an ell wide, and near two long. The wool is so fine and silky, that the whole handkerchief may be contained in the two hands closed. It is the produce of a Thibet sheep; but some say that no wool is employed but that of lambs torn from the belly of their mother before the time of birth. The most beautiful shawls come from Cashmire: their price is from 150 livres (about six guineas) to 1200 livres (or L. 50 Sterling.)

In the Transactions of the Society for Encouraging Arts, Manufactures, &c. for the year 1792, we are informed that a shawl counterpane, four yards square, manufactured by Mr P. J. Knights of Norwich, was presented to the society; and that, upon examination, it appeared to be of greater breadth than any goods of equal fineness and texture that had ever before been presented to the society, or to their knowledge woven in England. The shawls of Mr Knights's manufacture, it is said, can scarcely be distinguished from Indian shawls, though they can be afforded at one-twentieth part of the price. When the shawl is 16 quarters square, Mr Knights says it may be retailed at L. 20; if it consisted of 12 quarters, and embroidered as the former, it will cost L. 15; if plain, with a fringe only, a shawl of 16 quarters square may be sold at L. 8. 8 s.; if 12 quarters and fringed, at L. 6. 6 s.

Mr Knights maintains, that his counterpane of four yards square is equal in beauty, and superior in strength, to the Indian counterpanes which are sold at 200 guineas. The principal consumption of this cloth is in train-dresses for ladies; as likewise for long scarfs, in imitation of the real Indian scarfs, which are sold from L. 60 to L. 80; whereas scarfs of this fabric are sold for as many shillings, and the ladies' square shawls in proportion.

SHEADING, a riding, tithing, or division, in the Isle of Man; the whole island being divided into six sheadings; in every one of which is a coroner or chief constable,

conſtable, appointed by the delivery of a rod at the annual convention.

SHEARBILL, the *Rhynchops Nigra* of Linnæus, the *Black Skimmer* of Pennant and Latham, and *Cut-water* of Cateſby. Its bill is much compreſſed; the edges are ſharp; the lower mandible is four inches and a half long; the upper only three; the baſe red; the reſt is black: the forehead, chin, front of the neck, the breaſt, and belly, are white: the head and whole upper part of the body are black: the wings are of the ſame colour: the lower part of the inner webs of the primaries is white: the tail is ſhort, and a little forked; the middle feathers are duſky; the others are white on their ſides: the legs are weak and red: the length is one foot eight inches: the extent is three feet ſeven inches. It inhabits America from New York to Guiana. It ſkims nimbly along the water, with its under mandible juſt beneath the ſurface, feeding on the inſects and ſmall fiſh as it proceeds. It frequents alſo oyſter-banks; its bill being partly like that of the oyſter-catcher, adapted for preying on thoſe ſhell-fiſh.

SHEATHING, in the ſea-language, is the caſing that part of a ſhip which is to be under water with firboard of an inch thick; firſt laying hair and tar mixed together under the boards, and then nailing them on, in order to prevent worms from eating the ſhip's bottom.—Ships of war are now generally ſheathed with copper: but copper ſheathing is liable to be corroded by the action of ſalt water, and ſomething is ſtill wanting to effect this purpoſe. It is very probable that tar might anſwer very well.

In the Corniſh mines, copper or braſs pumps are often placed in the deepeſt parts, and are conſequently expoſed to the vitriolic or other mineral waters with which ſome of theſe mines abound, and which are known to have a much ſtronger effect on copper than ſea-water. Theſe pumps are generally about ſix feet long, and are ſcrewed together, and made tight by the interpoſition of a ring of lead, and the joinings are afterwards tarred. One of theſe pumps was ſo much corroded as to render it unfit for uſe; but the ſpots of tar, which by accident had dropped on it, preſerved the parts they covered from the action of the water. Theſe projected in ſome places more than a quarter of an inch; and the joints were ſo far defended by the thin coat of tar, that it was as perfect as when it came from the hands of the manufacturer. If tar thus effectually defends copper from theſe acrimonious waters, can there remain a doubt of its preſerving it from the much milder waters of the ſea?

SHEATS, in a ſhip, are ropes bent to the clews of the ſails; ſerving in the lower ſails to haul aft the clews of the ſail; but in topſails they ſerve to haul home the clew of the ſail cloſe to the yard-arm.

SHEEP, in zoology. See Ovis and Wool.

Amongſt the various animals with which Divine Providence has ſtored the world for the uſe of man, none is to be found more innocent, more uſeful, or more valuable, than the ſheep. The ſheep ſupplies us with food and clothing, and finds ample employment for our poor at all times and ſeaſons of the year, whereby a variety of manufactures of woollen cloth is carried on without interruption to domeſtic comfort and loſs to friendly ſociety or injury to health, as is the caſe with many other occupations. Every lock of wool that grows on its back becomes the means of ſupport to ſtaplers, dyers, pickers, ſcourers, ſcribblers, carders, combers, ſpinners, ſpoolers, warpers, queelers, weavers, fullers, tuckers, burlers, ſhearmen, preſſers, clothiers, and packers, who, one after another, tumble and toſs, and twiſt, and bake, and boil, this raw material, till they have each extracted a livelihood out of it; and then comes the merchant, who, in his turn, ſhips it (in its higheſt ſtate of improvement) to all quarters of the globe, from whence he brings back every kind of riches to his country, in return for this valuable commodity which the ſheep affords.

Sheep. 1 Sheep ſerve a wonderful variety of purpoſes.

Beſides this, the uſeful animal, after being deprived of his coat, produces another againſt the next year; and when we are hungry, and kill him for food, he gives up his ſkin to employ the fell-mongers and parchment-makers, who ſupply us with a durable material for ſecuring our eſtates, rights, and poſſeſſions; and if our enemies take the field againſt us, ſupplies us with a powerful inſtrument for rouſing our courage to repel their attacks. When the parchment-maker has taken as much of the ſkin as he can uſe, the glue-maker comes after and picks up every morſel that is left, and therewith ſupplies a material for the carpenter and cabinet-maker, which they cannot do without, and which is eſſentially neceſſary before we can have elegant furniture in our houſes; tables, chairs, looking glaſſes, and a hundred other articles of convenience: and when the winter nights come on, while we are deprived of the cheering light of the ſun, the ſheep ſupplies us with an artificial mode of light, whereby we preſerve every pleaſure of domeſtic ſociety, and with whoſe aſſiſtance we can continue our work, or write or read, and improve our minds, or enjoy the ſocial mirth of our tables. Another part of the ſlaughtered animal ſupplies us with an ingredient neceſſary for making good common ſoap, a uſeful ſtore for producing cleanlineſs in every family, rich or poor. Neither need the horns be thrown away; for they are converted by the button-makers and turners into a cheap kind of buttons, tips for bows, and many uſeful ornaments. From the very trotters an oil is extracted uſeful for many purpoſes, and they afford good food when baked in an oven.

Even the bones are uſeful alſo; for by a late invention of Dr Higgins, they are found, when reduced to aſhes, to be an uſeful and eſſential ingredient in the compoſition of the fineſt artificial ſtone in ornamental work for chimney-pieces, cornices of rooms, houſes, &c. which renders the compoſition more durable by effectually preventing its cracking (A).

If it is objected to the meek inoffenſive creature, that he

(A) Any curious perſon would be much entertained to ſee the manufactury of bone-aſh, now carried on by Mr Miniſh of White-chapel, New Road, wherein the bones of ſheep and cows undergo many ingenious proceſſes. 1. There is a mill to break them; 2. A cauldron to extract their oil, marrow, and fat; 3. A reverberatory to heat them red-hot; 4. An oven for thoſe bones to moulder to aſhes; 5. A ſtill to collect the fumes of the burnt bones

Sheep.

he is expensive while living, in eating up our grass, &c. it may be answered that it is quite the contrary; for he can feed where every other animal has been before him and grazed all they could find; and that if he takes a little grass on our downs or in our fields, he amply repays us for every blade of grass in the richness of the manure which he leaves behind him. He protects the hands from the cold wintry blast, by providing them with the softest leather gloves. Every gentleman's library is also indebted to him for the neat binding of his books, for the sheath of his sword, and for cases for his instruments; in short, not to be tedious in mentioning the various uses of leather, there is hardly any furniture or utensil of life but the sheep contributes to render either more useful, convenient, or ornamental.

As the sheep is so valuable an animal, every piece of information concerning the proper method of managing it must be of importance. It will not therefore be useless nor unentertaining to give some account of the manner of managing sheep in Spain, a country famous for producing the best wool in the world.

2 Account of the Spanish sheep.

In Spain there are two kinds of sheep: the coarse-woolled sheep, which always remain in their native country, and are housed every night in winter; and the fine-woolled sheep, which are always in the open air, and travel every summer from the cool mountains of the northern parts of Spain, to feed in winter on the southern warm plains of Andalusia, Mancha, and Estramadura. Of these latter, it appears from accurate computations, that there are about five millions (B); and that the wool and flesh of a flock of 10,000 sheep produce yearly about 24 reals a head, or about the value of 12 English sixpences, one of which belongs to the owner, three to the king, and the other eight are allowed for the expences of pasture, tythes, shepherds, dogs, salt, shearing, &c. Ten thousand sheep form a flock, which is divided into ten tribes, under the management of one person, who has absolute dominion over fifty shepherds and fifty dogs.

3 Of Segovia,

Bourgoanne's Travels, vol. i. p. 53.

M. Bourgoanne, a French gentleman, who resided many years in Spain, and directed his inquiries chiefly to the civil government, trade, and manufactures, of that country, gives the following account of the wandering sheep of Segovia. "It is (says he) in the neighbouring mountains that a part of the wandering sheep feed during the fine season. They leave them in the month of October, pass over those which separate the two Castiles, cross New Castile, and disperse themselves in the plains of Estramadura and Andalusia. For some years past those of the two Castiles, which are within reach of the Sierra-Morena, go thither to pass the winter; which, in that part of Spain, is more mild: the length of their day's journey is in proportion to the pasture they meet with. They travel in flocks from 1000 to 1200 in number, under the conduct of two shepherds; one of whom is called the *Mayoral*, the other the *Zagal*. When arrived at the place of their destination, they are distributed in the pastures previously assigned them. They return in the month of April; and whether it be habit or natural instinct that draws them towards the climate, which at this season becomes most proper for them, the inquietude which they manifest might, in case of need, serve as an almanac to their conductors."

Mr Arthur Young, in that patriotic work which he conducted with great industry and judgment, the Annals of Agriculture, gives us a very accurate and interesting account of the Pyrenean or Catalonian sheep.

4 Of Catalonia.

Annals of Agriculture, vol. viii. p. 195.

"On the northern ridge, bearing to the west, are the pastures of the Spanish flocks. This ridge is not, however, the whole; there are two other mountains, quite in a different situation, and the sheep travel from one to another as the pasturage is short or plentiful. I examined the soil of these mountain pastures, and found it in general stony; what in the west of England would be called a *stone brash*, with some mixture of loam, and in a few places a little peaty. The plants are many of them untouched by the sheep; many ferns, narcissus, violets, &c. but burnet *(poterium sanguisorba)* and the narrow-leaved plaintain *(plantago lanceolata)* were eaten, as may be supposed, close. I looked for trefoils, but found scarcely any: it was very apparent that soil and peculiarity of herbage had little to do in rendering these heights proper for sheep. In the northern parts of Europe, the tops of mountains half the height of these (for we were above snow in July) are bogs, all are so which I have seen in our islands, or at least the proportion of dry land is very trifling to that which is extremely wet: Here they are in general very dry. Now a great range of dry land, let the plants be what they may, will in every country suit sheep. The flock is brought every night to one spot, which is situated at the end of the valley on the river I have mentioned, and near the port or passage of Picada: it is a level spot sheltered from all winds. The soil is 8 or 9 inches deep of old dung, not at all inclosed: from the fredoom from wood all around, it seems to be chosen partly for safety against wolves and bears. Near it is a very large stone, or rather a rock, fallen from the mountain. This the shepherds have taken for a shelter, and have built a hut against it; their beds are sheep skins, and their door so small that they crawl in. I saw no place for fire; but they have it, since they dress here the flesh of their sheep, and

bones into a brown fluid, from whence hartshorn is made; 6. Furnaces for making parts thereof into Glauber's salts; 7. A sand heat containing twelve jars, for collecting a crystallizing vapour into sal-ammoniac.

(B) In the 16th century the travelling sheep were estimated at seven millions: under Philip III. the number was diminished to two millions and a half. Ustariz, who wrote at the beginning of this century, made it amount to four millions. The general opinion is, that at present it does not exceed five millions. If to this number the eight millions of stationary sheep be added, it will make nearly thirteen millions of animals, all managed contrary to the true interests of Spain, for the advantage of a few individuals. For the proprietors of stationary flocks also have privileges which greatly resemble those of the members of the Mesta. According to Arriquebar, Spain contains eight millions of fine-woolled sheep, ten millions of coarse-woolled, and five hundred thousand bulls, oxen and cows.

and in the night ſometimes keep off the bears, by whirling fire-brands: four of them belonging to the flock mentioned above lie here. I viewed their flock very carefully, and by means of our guide and interpreter, made ſome inquiries of the ſhepherds, which they anſwered readily, and very civilly. A Spaniard at Venaſque, a city in the Pyrenees, gives 600 livres French (the livre is 10½d. Engliſh) a-year for the paſturage of this flock of 2000 ſheep. In the winter he ſends them into the lower parts of Catalonia, a journey of 12 or 13 days, and when the ſnow is melted in the ſpring, they are conducted back again. They are the whole year kept in motion, and moving from ſpot to ſpot, which is owing to the great range they everywhere have of paſture. They are always in the open air, never houſed or under cover, and never taſte of any food but what they can find on the hills.

"Four ſhepherds, and from four to ſix large Spaniſh dogs, have the care of this flock: the latter are in France called of the *Pyrenees breed;* they are black and white, of the ſize of a large wolf, a large head and neck, armed with collars ſtuck with iron ſpikes. No wolf can ſtand againſt them; but bears are more potent adverſaries: if a bear can reach a tree, he is ſafe; he riſes on his hind legs, with his back to the tree, and ſets the dogs at defiance. In the night the ſhepherds rely entirely on their dogs; but on hearing them bark are ready with fire-arms, as the dogs rarely bark if a bear is not at hand. I was ſurpriſed to find that they are fed only with bread and milk. The head ſhepherd is paid 120 livres a-year wages and bread; the others 80 livres and bread. But they are allowed to keep goats, of which they have many which they milk every day. Their food is milk and bread, except the fleſh of ſuch ſheep or lambs as accidents give them. The head ſhepherd keeps on the mountain top, or an elevated ſpot, from whence he can the better ſee around while the flock traverſes the declivities. In doing this the ſheep are expoſed to great danger in places that are ſtony; for by walking among the rocks, and eſpecially the goats, they move the ſtones, which, rolling down the hills, acquire an accelerated force enough to knock a man down, and ſheep are often killed by them; yet we ſaw how alert they were to avoid ſuch ſtones, and cautiouſly on their guard againſt them. I examined the ſheep attentively. They are in general polled, but ſome have horns; which in the rams turn backwards behind the ears and project half a circle forward; the ewes horns turn alſo behind the ears, but do not project: the legs white or reddiſh; ſpeckled faces, ſome white, ſome reddiſh; they would weigh fat, I reckon, on an average, from 15 lb. to 18 lb. a quarter. Some tails ſhort, ſome left long. A few black ſheep among them: ſome with a very little tuft of wool on their foreheads. On the whole they reſemble thoſe on the South Downs; their legs are as ſhort as thoſe of that breed; a point which merits obſervation, as they travel ſo much and ſo well. Their ſhape is very good; round ribs and flat ſtraight backs; and would with us be reckoned handſome ſheep; all in good order and fleſh. In order to be ſtill better acquainted with them, I deſired one of the ſhepherds to catch a ram for me to feel, and examine the wool, which I found very thick and good of the carding ſort, as may be ſuppoſed. I took a ſpecimen of it, and alſo of a hoggit, or lamb of laſt year. In regard to the mellow ſoftneſs under the ſkin, which, in Mr Bakewell's opinion, is a ſtrong indication of a good breed, with a diſpoſition to fatten, he had it in a much ſuperior degree to many of our Engliſh breeds, to the full as much ſo as the South Downs, which are for that point the beſt ſhort-woolled ſheep which I know in England. The fleece was on his back, and weighed, as I gueſſed, about 8 lb. Engliſh; but the average, they ſay, of the flock is from four to five, as I calculated by reducing the Catalonian pound of 12 oz. to ours of 16, and is all ſold to the French at 30 s. the lb. French. This ram had the wool of the back part of the neck tied cloſe, and the upper tuft tied a ſecond knot by way of ornament; nor do they ever ſhear this part of the fleece for that reaſon: we ſaw ſeveral in the flock with this ſpecies of decoration. They ſaid that this ram would ſell in Catalonia for 20 livres. A circumſtance which cannot be too much commended, and deſerves univerſal imitation, is the extreme docility they accuſtom them to. When I deſired the ſhepherd to catch one of his rams, I ſuppoſed he would do it with his crook, or probably not be able to do it at all; but he walked into the flock, and ſingling out a ram and a goat, bid them follow him, which they did immediately; and he talked to them while they were obeying him, holding out his hand as if to give them ſomething. By this method he brought me the ram, which I caught, and held without difficulty."

5 What ſheep produce the beſt wool.

The beſt ſort of ſheep for fine wool are thoſe bred in Herefordſhire, Devonſhire, and Worceſterſhire; but they are ſmall, and black-faced, and bear but a ſmall quantity. Warwick, Leiceſterſhire, Buckinghamſhire, and Northamptonſhire, breed a large-boned ſheep, of the beſt ſhape and deepeſt Engliſh wool. The marſhes of Lincolnſhire breed a very large kind of ſheep, but their wool is not good, unleſs the breed be mended by bringing in ſheep of other countries among them, which is a ſcheme of late very profitably followed there. In that county it is no uncommon thing to give fifty guineas for a ram, and a guinea for the admiſſion of an ewe to one of theſe valuable males, or twenty guineas for the uſe of it for a certain number of ewes during one ſeaſon. Suffolk alſo breeds a very valuable kind of ſheep. The northern counties in general breed ſheep with long but hairy wool: however, the wool which is taken from the neck and ſhoulders of the Yorkſhire ſheep is uſed for mixing with Spaniſh wool in ſome of their fineſt cloths.

Wales bears a ſmall hardy kind of ſheep, which has the beſt taſted fleſh, but the worſt wool of all. Nevertheleſs it is of more extenſive uſe than the fineſt Segovian fleeces; for the benefit of the flannel manufacture is univerſally known. The ſheep of Ireland vary like thoſe of Great Britain: thoſe of the ſouth and eaſt being large and their fleſh rank: thoſe of the north and the mountainous parts ſmall and their fleſh ſweet. The fleeces in the ſame manner differ in degrees of value. Scotland breeds a ſmall kind, and their fleeces are coarſe.

But the new Leiceſterſhire breed is the moſt faſhionable, and of courſe the moſt profitable breed in the iſland. Joſeph Altom of Cliſton, who raiſed himſelf from a plough-boy, was the firſt who diſtinguiſhed himſelf

Sheep. ſelf in the midland counties of England for a ſuperior breed of ſheep. How he improved his breed is not known; but it was cuſtomary for eminent farmers in his time to go to Clifton in ſummer to chooſe and purchaſe ram-lambs, for which they paid two or three guineas. This man was ſucceeded by Mr Bakewell; and it may reaſonably be ſuppoſed that the breed, by means of Altom's ſtock, had paſſed the firſt ſtage of improvement before Mr Bakewell's time. Still, however, it muſt be acknowledged, that the Leiceſterſhire breed of ſheep owes its preſent high ſtate of improvement to the ability and care of Mr Bakewell.

6 Account of Mr Bakewell's breed. Marſhall's Midland Counties, vol. i. p. 382.

"The manner in which Mr Bakewell raiſed his ſheep to the degree of celebrity in which they deſervedly ſtand, is, notwithſtanding the recentneſs of the improvement, and its being done in the day of thouſands now living, a thing in diſpute; even among men high in the profeſſion, and living in the very diſtrict in which the improvement has been carried on!

7 How it is ſuppoſed he improved it.

"Some are of opinion that he effected it by a croſs with the Wiltſhire breed; an improbable idea, as their form altogether contradicts it: others, that the Ryeland breed were uſed for this purpoſe; and with ſome ſhow of probability. If any croſs whatever was uſed, the Ryeland breed, whether we view the form, the ſize, the wool, the fleſh, or the fatting quality, is the moſt probable inſtrument of improvement.

"Theſe ideas, however, are regiſtered merely as matters of opinion. It is more than probable that Mr Bakewell alone is in poſſeſſion of the ſeveral minutiæ of improvement; and the public can only hope that at a proper time the facts may be communicated for the direction of future improvers.

"Whenever this ſhall take place, it will moſt probably come out that no croſs with any alien breed whatever has been uſed; but that the improvement has been effected by ſelecting individuals from kindred breeds; from the ſeveral breeds or varieties of long-woolled ſheep, with which Mr Bakewell was ſurrounded on almoſt every ſide, and by breeding, *inandin* (c), with this ſelection: ſolicitouſly ſeizing the ſuperior accidental varieties produced; aſſociating theſe varieties; and ſtill continuing to ſelect, with judgment, the ſuperior individuals.

8 Deſcription of his ewes and weathers.

"It now remains to give a deſcription of the ſuperior claſs of individuals of this breed eſpecially ewes and weathers, in full condition, but not immoderately fat. The rams will require to be diſtinguiſhed afterwards.

"The head is long, ſmall, and hornleſs, with ears ſomewhat long, and ſtanding backward, and with the noſe ſhooting forward. The neck thin, and clean toward the head; but taking a conical form; ſtanding low, and enlarging every way at the baſe; the fore-end altogether ſhort. The boſom broad, with the ſhoulders, ribs, and chine extraordinary full. The loin broad, and the back level. The hauches comparatively full toward the hips, but light downward; being altogether ſmall in proportion to the fore-parts. The legs, at preſent, of a moderate length; with the bone extermely fine. The bone throughout remarkably light. The carcaſe, when fully fat, takes a remarkable form; much wider than it is deep, and almoſt as broad as it is long. Full on the ſhoulder, wideſt on the ribs, narrowing with a regular curve towards the tail; approaching the form of the turtle nearer perhaps than any other animal. The pelt is thin, and the tail ſmall. The wool is ſhorter than long wools in general, but much longer than the middle wools; the ordinary length of ſtaple five to ſeven inches, varying much in fineneſs and weight."

9 Fatten remarkably well.

This breed ſurpaſſes every other in beauty of form; they are full and weighty in the fore-quarters; and are remarkable for ſmallneſs of bone. Mr Marſhal, who has been of ſo much benefit to agriculture and his country by his publications, informs us, in his Rural Economy of the Midland Counties, that he has ſeen a rib of a ſheep of this breed contraſted with one of a Norfolk ſheep: the diſparity was ſtriking; the latter nearly twice the ſize; while the meat which covered the former was three times the thickneſs: conſequently the proportion of meat to bone was in the one incomparably greater than in the other. Therefore, in this point of view, the improved breed has a decided preference: for ſurely while mankind continue to eat fleſh and throw away bone, the former muſt be, to the conſumer at leaſt, the more valuable.

The criterions of good and bad fleſh while the animal is alive differ in different ſpecies, and are not properly ſettled in the ſame ſpecies. One ſuperior breeder is of opinion, that if the fleſh is not looſe, it is of courſe good; holding, that the fleſh of ſheep is never found in a ſtate of hardneſs, like that of ill-fleſhed cattle: while others make a fourfold diſtinction of the fleſh of ſheep; as looſeneſs, mellowneſs, firmneſs, hardneſs: conſidering the firſt and the laſt equally exceptionable, and the ſecond and third equally deſirable; a happy mixture of the two being deemed the point of perfection.

The fleſh of ſheep, when ſlaughtered, is well known to be of various qualities. Some is compoſed of large coarſe grains, interſperſed with wide empty pores like a ſponge: others, of large grains, with wide pores filled with fat; others, of fine cloſe grains, with ſmaller pores filled with fat: and a fourth, of cloſe grains, without any intermixture of fatneſs.

The fleſh of ſheep, when dreſſed, is equally well known to poſſeſs a variety of qualities: ſome mutton is coarſe, dry, and inſipid; a dry ſponge, affording little or no gravy of any colour. Another ſort is ſomewhat firmer, imparting a light-coloured gravy only. A third plump, ſhort, and palatable; affording a mixture of white and red gravy. A fourth likewiſe plump and well-flavoured, but diſcharging red gravy, and this in various quantities.

It is likewiſe obſervable, that ſome mutton, when dreſſed, appears covered with a thick, tough, parchment-like integument; others with a membrane comparatively fine and flexible. But theſe, and ſome of the other qualities of mutton, may not be wholly owing to breed, but in part to the age and the ſtate of fatneſs at the time of ſlaughter. Examined in this light, whether

(c) *Inandin* is a term uſed in the midland counties of England to expreſs breeding from the ſame family.

Sheep. ther we consider the degree of fatness, or their natural propensity to a state of fatness, even at an early age, the improved breed of Leicestershire sheep appear with many superior advantages.

The degree of fatness to which the individuals of this breed are capable of being raised, will perhaps appear incredible to those who have not had an opportunity of being convinced by their own observation. "I have seen wedders (says Mr Marshall) of only two shear (two to three years old) so loaded with fat as to be scarcely able to make a run; and whose fat lay so much without the bone, it seemed ready to be shaken from the ribs on the smallest agitation.

Midland Counties, vol. 1. p. 398.

"It is common for the sheep of this breed to have such a projection of fat upon the ribs, immediately behind the shoulder, that it may be easily gathered up in the hand, as the flank of a fat bullock. Hence it has gained, in technical language, the name of the *fore-flank*; a point which a modern breeder never fails to touch in judging of the quality of this breed of sheep.

"What is, perhaps, still more extraordinary, it is not rare for the rams, at least of this breed, to be 'cracked on the back;' that is, to be cloven along the top of the chine, in the manner fat sheep generally are upon the rump. This mark is considered as an evidence of the best blood.

"Extraordinary, however, as are these appearances while the animals are living, the facts are still more striking after they are slaughtered. At Litchfield, in February 1785, I saw a fore quarter of mutton, fatted by Mr Prineep of Croxall, and which measured upon the ribs four inches of fat. It must be acknowledged, however, that the Leicestershire breed do not produce so much wool as most other long-wooled sheep."

As the practice of letting rams by the season is now become profitable, it may be useful to mention the method of rearing them.

10 How the rams are reared.

"The principal ram-breeders save annually twenty, thirty, or perhaps forty ram lambs; castration being seldom applied, in the first instance, to the produce of a valuable ram: for in the choice of these lambs they are led more by blood, or parentage, than by form; on which, at an early age, little dependence can be placed. Their treatment from the time they are weaned, in July or August, until the time of shearing, the first week in June, consist in giving them every indulgence of keep, in order to push them forward for the show; it being the common practice to let such as are fit to be let the first season, while they are yet yearlings—provincially 'sharhogs.'

"Their first pasture, after weaning, is pretty generally, I believe, clover that has been mown early, and has got a second time into head; the heads of clover being considered as a most forcing food of sheep. After this goes off, turnips, cabbages, colewort, with hay, and (report says) with corn. But the use of this the breeders severally deny, though collectively they may be liable to the charge.

"Be this as it may, something considerable depends on the *art of making up*, not lambs only, but rams of all ages. Fat, like charity, covers a multitude of faults; and besides, is the best evidence of their fatting quality which their owners can produce (*i.e.* their natural propensity to a state of fatness), while in the fatness of the sharhogs is seen their degree of inclination to fat at an early age.

"Fatting quality being the one thing needful in grazing stock, and being found, in some considerable degree at least, to be hereditary, the fattest rams are of course the best; though other attachments, well or ill placed, as to form or fashionable points, will perhaps have equal or greater weight in the minds of some men, even in this enlightened age. Such shearlings as will not make up sufficiently as to form and fatness, are either kept on to another year to give them a fair chance, or are castrated, or butchered while sharhogs."

11 What sums Mr Bakewell received for letting them.

From the first letting, about 40 years ago, to the year 1780, the prices kept gradually rising from fifteen shillings to a guinea, and from one to ten. In 1780 Mr Bakewell let several at ten guineas each; and, what is rather inexplicable, Mr Parkinson of Quarndon let one the same year for twenty-five guineas; a price which then astonished the whole country.

From that time to 1786 Mr Bakewell's stock rose rapidly from ten to a hundred guineas; and that year he let two thirds of one ram (reserving one third of the usual number of ewes to himself) to two principal breeders, for a hundred guineas each, the entire services of the ram being rated at three hundred guineas! Mr Bakewell making that year, by letting twenty rams only, more than a thousand pounds!

Since that time the prices have been still rising. Four hundred guineas have been repeatedly given. Mr Bakewell, this year (1789) makes, says Mr Marshall, twelve hundred guineas by three rams (brothers, we believe); two thousand of seven; and of his whole letting, full three thousand guineas!

Besides this extraordinary sum made by Mr Bakewell, there are six or seven other breeders who make from five hundred to a thousand guineas each. The whole amount of monies produced that year in the Midland Counties, by letting rams of the modern breed for one season only, is estimated, by those who are adequate to the subject, at the almost incredible sum of ten thousand pounds.

12 The treatment of the rams and choice of the ewes.

Rams previous to the season are reduced from the cumbrous fat state in which they are shown. The usual time of sending them out is the middle of September. They are conveyed in carriages of two wheels with springs, or hung in slings, 20 or 30 miles a day, sometimes to the distance of 200 or 300 miles. They are not turned loose among the ewes, but kept apart in a small inclosure, where a couple of ewes only are admitted at once. When the season is over every care is taken to make the rams look as fat and handsome as possible.

In the choice of ewes the breeder is led by the same criterions as in the choice of rams. Breed is the first object of consideration. Excellency, in any species or variety of live-stock, cannot be attained with any degree of certainty, let the male be ever so excellent, unless the females employed likewise inherit a large proportion of the genuine blood, be the species or variety what it may. Hence no prudent man ventures to give the higher prices for the Dishley rams, unless his ewes are deeply tinctured with the Dishley blood. Next to breed is flesh, fat, form, and wool.

After the lambs are weaned, the ewes are kept in common feeding places, without any alteration of pasture,

ture, previous to their taking the ram. In winter they are kept on graſs, hay, turnips, and cabbages. As the heads of the modern breed are much finer than moſt others, the ewes lamb with leſs difficulty.

The female lambs, on being weaned, are put to good keep, but have not ſuch high indulgence ſhown them as the males, the prevailing practice being to keep them from the ram the firſt autumn.

At weaning time, or previouſly to the admiſſion of the ram, the ewes are culled, to make room for the thaves or ſhearlings, whoſe ſuperior blood and faſhion intitle them to a place in the breeding flock. In the work of culling, the ram-breeder and the mere grazier go by ſomewhat different guides. The grazier's guide is principally age, ſeldom giving his ewes the ram after they are four ſhear. The ram-breeder, on the contrary, goes chiefly by merit; an ewe that has brought him a good ram or two is continued in the flock ſo long as ſhe will breed. There are inſtances of ewes having been prolific to the tenth or twelfth year; but in general the ewes of this breed go off at ſix or ſeven ſhear.

In the practice of ſome of the principal ram-breeders, the culling ewes are never ſuffered to go out of their hands until after they are ſlaughtered, the breeders not only fatting them, but having them butchered, on their premiſes. There are others, however, who ſell them; and ſometimes at extraordinary prices. Three, four, and even ſo high as ten, guineas each have been given for theſe outcaſts.

There are in the flocks of ſeveral breeders ewes that would fetch at auction twenty guineas each. Mr Bakewell is in poſſeſſion of ewes which, if they were now put up to be ſold to the beſt bidder, would, it is eſtimated, fetch no leſs than fifty each, and perhaps, through the preſent ſpirit of contention, much higher prices.

13 Inſtructions for purchaſing ſheep.

The following inſtructions for purchaſing ſheep, we hope, will be acceptable to our country readers.—The farmer ſhould always buy his ſheep from a worſe land than his own, and they ſhould be big-boned, and have a long greaſy wool, curling cloſe and well. Theſe ſheep always breed the fineſt wool, and are alſo the moſt approved of by the butcher for ſale in the market. For the choice of ſheep to breed, the ram muſt be young, and his ſkin of the ſame colour with his wool, for the lambs will be of the ſame colour with his ſkin. He ſhould have a large long body; a broad forehead, round, and well riſing; large eyes; and ſtraight and ſhort noſtrils. The polled ſheep, that is, thoſe which have no horns, are found to be the beſt breeders. The ewe ſhould have a broad back; a large bending neck; ſmall, but ſhort, clean, and nimble legs; and a thick, deep wool covering her all over.

To know whether they be ſound or not, the farmer ſhould examine the wool that none of it be wanting, and ſee that the gums be red, the teeth white and even, and the briſket-ſkin red, the wool firm, the breath ſweet, and the feet not hot. Two years old is the beſt time for beginning to breed; and their firſt lambs ſhould not be kept too long, to weaken them by ſuckling, but be ſold as ſoon as conveniently may be. They will breed advantageouſly till they are ſeven years old. The farmers have a method of knowing the age of a ſheep, as a horſe's is known, by the mouth. When a ſheep is one ſhear, as they expreſs it, it has two broad teeth before; when it is two ſhear, it will have four; when three, ſix; and when four, eight. After this their mouths begin to break.

The difference of land makes a very great difference in the ſheep. The fat paſtures breed ſtraight tall ſheep, and the barren hills and downs breed ſquare ſhort ones; woods and mountains breed tall and ſlender ſheep; but the beſt of all are thoſe bred upon new-ploughed land and dry grounds. On the contrary, all wet and moiſt lands are bad for ſheep, eſpecially ſuch as are ſubject to be overflowed, and to have ſand and dirt left on them. The ſalt marſhes are, however, an exception to this general rule, for their ſaltneſs makes amends for their moiſture; ſalt, by reaſon of its drying quality, being of great advantage to ſheep.

14 When rams ought to be admitted to the ewes.

As to the time of putting the rams to the ewes, the farmer muſt conſider at what time of the ſpring his graſs will be fit to maintain them and their lambs, and whether he has turnips to do it till the graſs comes; for very often both the ewes and lambs are deſtroyed by the want of food; or if this does not happen, if the lambs are only ſtinted in their growth by it, it is an accident that they never recover. The ewe goes 20 weeks with lamb, and according to this it is eaſy to calculate the proper time. The beſt time for them to yean is in April, unleſs the owner has very forward graſs or turnips, or the ſheep are field ſheep. Where you have not incloſures to keep them in, then it may be proper they ſhould yean in January, that the lambs may be ſtrong by May-day, and be able to follow the dam over the fallows and water-furrows; but then the lambs that come ſo early muſt have a great deal of care taken of them, and ſo indeed ſhould all other lambs at their firſt falling, elſe while they are weak the crows and magpies will pick their eyes out.

When the ſheep are turned into fields of wheat or rye to feed, it muſt not be too rank at firſt, for if it be, it generally throws them into ſcourings. Ewes that are big ſhould be kept but bare, for it is very dangerous to them to be fat at the time of their bringing forth their young. They may be well fed, indeed, like cows, a fortnight beforehand, to put them in heart. Mortimer's Huſbandry, p. 243.

The feeding ſheep with turnips is one great advantage to the farmers. When they are made to eat turnips they ſoon fatten, but there is ſome difficulty in bringing this about. The old ones always refuſe them at firſt, and will ſometimes faſt three or four days, till almoſt famiſhed; but the young lambs fall to at once. The common way, in ſome places, of turning a flock of ſheep at large into a field of turnips, is very diſadvantageous, for they will thus deſtroy as many in a fortnight as would keep them a whole winter. There are three other ways of feeding them on this food, all of which have their ſeveral advantages.

15 The firſt way of feeding ſheep with turnips.

The firſt way is to divide the land by hurdles, and allow the ſheep to come upon ſuch a portion only at a time as they can eat in one day, and ſo advance the hurdles farther into the ground daily till all be eaten. This is infinitely better than the former random method; but they never eat them clean even this way, but leave the bottoms and outſides ſcooped in the ground: the people pull up theſe indeed with iron crooks, and lay them before the ſheep again, but they are commonly ly ſo fouled with the creature's dung and urine, and with the dirt from their feet, that they do not care for them; they eat but little of them, and what they do eat does not nouriſh them like the freſh roots.

16 The ſecond.

The ſecond way is by incloſing the ſheep in hurdles, as in the former; but in this they pull up all the turnips which they ſuppoſe the ſheep can eat in one day, and daily remove the hurdles over the ground whence they have pulled up the turnips: by this means there is no waſte, and leſs expence, for a perſon may in two hours pull up all thoſe turnips; the remaining ſhells of which would have employed three or four labourers a-day to get up with their crooks out of the ground trodden hard by the feet of the ſheep; and the worſt is, that as in the method of pulling up firſt, the turnips are eaten up clean; in this way, by the hook, they are waſted, the ſheep do not eat any great part of them, and when the ground comes to be tilled afterwards for a crop of corn, the fragments of the turnips are ſeen in ſuch quantities on the ſurface, that half the crop at leaſt ſeems to have been waſted.

17 The third, which is the beſt.

The third manner is to pull up the turnips, and remove them in a cart or waggon to ſome other place, ſpreading them on a freſh place every day; by this method the ſheep will eat them up clean, both root and leaves. The great advantage of this method is, when there is a piece of land not far off which wants dung more than that where the turnips grew, which perhaps is alſo too wet for the ſheep in winter, and then the turnips will, by the too great moiſture and dirt of the ſoil, ſometimes ſpoil the ſheep, and give them the rot. Yet ſuch ground will often bring forth more and larger turnips than dry land, and when they are carried off, and eaten by the ſheep on ploughed land, in dry weather, and on green ſward in wet weather, the ſheep will ſucceed much better; and the moiſt ſoil where the turnips grew not being trodden by the ſheep, will be much fitter for a crop of corn than if they had been fed with turnips on it. The expence of hurdles, and the trouble of moving them, are ſaved in this caſe, which will counterbalance at leaſt the expence of pulling the turnips and carrying them to the places where they are to be eaten. They muſt always be carried off for oxen.

18 Diſeaſes of ſheep.

The diſeaſes to which ſheep are ſubject are theſe, rot, red-water, foot-rot and hoving, ſcab, dunt, rickets, fly-ſtruck, flux, and burſting. Of each of theſe we ſhall give the beſt deſcription in our power, with the moſt approved remedies.

19 The rot.

The *rot*, which is a very pernicious diſeaſe, has of late engaged the attention of ſcientific farmers. But neither its nature nor its cauſe has yet been fully aſcertained. Some valuable and judicious obſervations have, however, been made upon it, which ought to be circulated, as they may perhaps, in many caſes, furniſh an antidote for this malignant diſtemper, or be the means of leading others to ſome more efficacious remedy. Some have ſuppoſed the rot owing to the quick growth of graſs or herbs that grow in wet places. Without premiſing, that all-bounteous Providence has given to every animal its peculiar taſte, by which it diſtinguiſhes the food proper for its preſervation and ſupport, if not vitiated by fortuitous circumſtances, it ſeems very difficult to diſcover on philoſophical principles why the quick growth of graſs ſhould render it noxious, or why any herb ſhould at one ſeaſon produce fatal effects, by the admiſſion of pure water only into its component parts, which at other times is perfectly innocent, although brought to its utmoſt ſtrength and maturity by the genial influence of the ſun. Beſides, the conſtant practice of moſt farmers in the kingdom, who with the greateſt ſecurity feed their meadows in the ſpring, when the graſs ſhoots quick and is full of juices, militates directly againſt this opinion.

Mr Arthur Young, to whom agriculture is much indebted, aſcribes this diſeaſe to moiſture. In confirmation of this opinion, which has been generally adopted, we are informed in the Bath ſociety papers*, by a correſpondent, that there was a paddock adjoining to his park which had for ſeveral years cauſed the rot in moſt of the ſheep which were put into it. In 1769 he drained it, and from that time his ſheep were free from this malady. But there are facts which render it doubtful that moiſture is the ſole cauſe. We are told, the dry limed land in Derbyſhire will produce the rot as well as water meadows and ſtagnant marſhes; and that in ſome wet grounds ſheep ſuſtain no injury for many weeks. 20

* Vol. I. art. xlvi.

Its cauſe.

Without attempting to enumerate other hypotheſes which the ingenious have formed on this ſubject, we ſhall purſue a different method in order to diſcover the cauſe. On diſſecting ſheep that die of this diſorder, a great number of inſects called *flukes* (See FASCIOLA) are found in the liver. That theſe flukes are the cauſe of the rot, therefore, is evident; but to explain how they come into the liver is not ſo eaſy. It is probable that they are ſwallowed by the ſheep along with their food while in the egg ſtate. The eggs depoſited in the tender germ are conveyed with the food into the ſtomach and inteſtines of the animals, whence they are received into the lacteal veſſels, carried off in the chyle, and paſs into the blood; nor do they meet with any obſtruction until they arrive at the capillary veſſels of the liver. Here, as the blood filtrates through the extreme branches, anſwering to thoſe of the *vena portæ* in the human body, the ſecerning veſſels are too minute to admit the impregnated ova, which, adhering to the membrane, produce thoſe animalculæ that feed upon the liver and deſtroy the ſheep. They much reſemble the flat fiſh called plaice, are ſometimes as large as a ſilver two-pence, and are found both in the liver and in the pipe (anſwering to that of the *vena cava*) which conveys the blood from the liver to the heart.

The common and moſt obvious objection to that opinion is, that this inſect is never found but in the liver, or in ſome parts of the viſcera, of ſheep that are diſeaſed more or leſs; and that they muſt therefore be bred there. But this objection will loſe its force, when we conſider that many inſects undergo ſeveral changes, and exiſt under forms extremely different from each other. Some of them may therefore appear and be well known under one ſhape, and not known to be the ſame under a ſecond or third. The fluke may be the laſt ſtate of ſome aquatic animal which we at preſent very well know under one or other of its previous forms.

If this be admitted, it is eaſy to conceive that ſheep may, on wet grounds eſpecially, take multitudes of theſe ova or eggs in with their food; and that the ſtomach and viſcera of the ſheep being a proper nidus for them, they of courſe hatch, and appearing in their fluke

or

Sheep. or last state, feed on the liver of the animal, and occasion this disorder.

It is a singular fact, "that no ewe ever has the rot while she has a lamb by her side." The reason of this may be, that the impregnated ovum passes into the milk, and never arrives at the liver. The rot is fatal to sheep, hares, and rabbits, and sometimes to calves; but never infests animals of a larger size.

21 And most approved cure. Miller says that parsley is a good remedy for the rot in sheep. Perhaps a strong decoction of this plant, or the oil extracted from its seeds, might be of service. Salt is also a useful remedy. It seems to be an acknowledged fact that salt marshes never produce the rot. Salt indeed is pernicious to most insects. Common salt and water expel worms from the human body; and sea-weed, if laid in a garden, will drive away insects; but if the salt is separated by steeping it in the purest spring-water for a few days, it abounds with animalculæ of various species.

Lisle, in his book of husbandry, informs us of a farmer who cured his whole flock of the rot by giving each sheep a handful of Spanish salt for five or six mornings successively. The hint was probably taken from the Spaniards who frequently give their sheep salt to keep them healthy. On some farms perhaps the utmost caution cannot always prevent this disorder. In wet and warm seasons the prudent farmer will remove his sheep from the lands liable to rot. Those who have it not in their power to do this may give each sheep a spoonful of common salt, with the same quantity of flour, in a quarter of a pint of water, once or twice a-week. When the rot is recently taken, the same remedy given four or five mornings successively will in all probability effect a cure. The addition of the flour and water (in the opinion of Mr Price of Salisbury, to whose excellent paper in the Bath Society's Transactions we own ourselves much indebted) will not only abate the pungency of the salt, but dispose it to mix with the chyle in a more gentle and efficacious manner.

A farmer of a considerable lordship in Bohemia visiting the hot-wells of Carlsbad, related how he preserved his flocks of sheep from the mortal distemper which raged in the wet year 1769, of which so many perished. His preservative was very simple and very cheap: "He fed them every night, when turned under a shed, cover, or stables, with hashed fodder straw; and, by eating it greedily, they all escaped."

22 Red-water. "*Red-water* is a disorder most prevalent on wet grounds. I have heard (says Mr Arthur Young) that it has sometimes been cured by tapping, as for a dropsy. This operation is done on one side of the belly towards the flank, just below the wool.

23 Foot-rot. "*The foot-rot* and *hoving*, which is very common on low fenny grounds, is cured by keeping the part clean, and lying at rest in a dry pasture."

24 Scab. The *scab* is a cutaneous disease owing to an impurity of the blood, and is most prevalent in wet lands or in rainy seasons. It is cured by tobacco-water, brimstone, and alum, boiled together, and then rubbed over the sheep. If only partial, tar and grease may be sufficient. But the simplest and most efficacious remedy for this disease was communicated to the Society for the Encouragement of Arts, &c. by Sir Joseph Banks. 25 Remedy recommended by Sir Joseph Banks.

"Take one pound of quicksilver, half a pound of Venice turpentine, half a pint of oil of turpentine, and four pounds of hogs lard (c). Let them be rubbed in a mortar till the quicksilver is thoroughly incorporated with the other ingredients; for the proper mode of doing which, it may be proper to take the advice, or even the assistance, of some apothecary or other person used to make such mixtures.

"The method of using the ointment is this: Beginning at the head of the sheep, and proceeding from between the ears along the back to the end of the tail, the wool is to be divided in a furrow till the skin can be touched; and as the furrow is made, the finger slightly dipped in the ointment is to be drawn along the bottom of it, where it will leave a blue stain on the skin and adjoining wool: from this furrow similar ones must be drawn down the shoulders and thighs to the legs, as far as they are wooly; and if the animal is much infected two or more should be drawn along each side parallel to that on the back, and one down each side between the fore and hind legs.

"Immediately after being dressed, it is usual to turn the sheep among other stock, without any fear of the infection being communicated; and there is scarcely an instance of a sheep suffering any injury from the application. In a few days the blotches dry up, the itching ceases, and the animal is completely cured: it is generally, however, thought proper not to delay the operation beyond Michaelmas.

"The *hippobosca ovina*, called in Lincolnshire *sheep fagg*, an animal well known to all shepherds, which lives among the wool and is hurtful to the thriving of sheep both by the pain its bite occasions and the blood it sucks, is destroyed by this application, and the wool is not at all injured. Our wool-buyers purchase the fleeces on which the stain of the ointment is visible, rather in preference to others, from an opinion that the use of it having preserved the animal from being vexed either with the scab or faggs, the wool is less liable to the defects of joints or knots; a fault observed to proceed from every sudden stop in the thriving of the animal, either from want of food or from disease.

"This mode of curing was brought into that part of Lincolnshire where my property is situated about 12 years ago, by Mr Stephenson of Mareham, and is now so generally received, that the scab, which used to be the terror of the farmers, and which frequently deterred the more careful of them from taking the advantage of pasturing their sheep in the fertile and extensive commons with which that district abounds, is no longer regarded with any apprehension: by far the most of them have their flock anointed in autumn, when they return from the common, whether they show any symptoms of scab or not; and having done so, conclude them

(c) By some unaccountable mistake the last ingredient, the four pounds of hogs lard, is omitted in the receipt published in the Transactions of the Society; a circumstance that might be productive of bad effects.—The leaf which contained the receipt has since been cancelled, and a new one printed.

Sheep. them safe for some time from either giving or receiving infection. There are people who employ themselves in the business, and contract to anoint our large sheep at five shillings a score, insuring for that price the success of the operation; that is, agreeing, in case many of the sheep break out afresh, to repeat the operation gratis even some months afterwards."

26 The dunt, The *dunt* is a distemper caused by a bladder of water gathering in the head. No cure for this has yet been discovered.

27 Rickets, The *rickets* is a hereditary disease for which no antidote is known. The first symptom is a kind of light-headedness, which makes the affected sheep appear wilder than usual when the shepherd or any person approaches him. He bounces up suddenly from his lare, and runs to a distance, as though he were pursued by dogs. In the second stage the principal symptom is the sheep's rubbing himself against trees, &c. with such fury as to pull off his wool and tear away his flesh. "The distressed animal has now a violent itching in his skin, the effect of an highly inflamed blood; but it does not appear that there is ever any cutaneous eruption or salutary critical discharge. In short, from all circumstances, the fever appears now to be at its height."—The last stage of this disease "seems only to be the progress of dissolution, after an unfavourable crisis. The poor animal, as condemned by Nature, appears stupid, walks irregularly (whence probably the name *rickets*), generally lies, and eats little: these symptoms increase in degree till death, which follows a general consumption, as appears upon dissection of the carcase; the juices and even solids having suffered a general dissolution.

In order to discover the seat and nature of this disease, sheep that die of it ought to be dissected. This is said to have been done by one gentleman, Mr Beal; and he found in the brain or membranes adjoining a maggot about a quarter of an inch long, and of a brownish colour. A few experiments might easily determine this fact.

28 Fly-struck, The *fly-struck* is cured by clipping the wool off as far as infected, and rubbing the parts dry with lime or wood ashes; curriers oil will heal the wounds, and prevent their being struck any more; or they may be cured with care, without clipping, with oil of turpentine, which will kill all the vermin where it goes; but the former is the surest way.

29 Flux, The *flux* is another disease to which sheep are subject. The best remedy is said to be, to house the sheep immediately when this distemper appears, to keep them very warm, and feed them on dry hay, giving them frequent glysters of warm milk and water. The cause of that distemper is either their feeding on wet lands, or on grass that is become mossy by the lands having been fed many years without being ploughed. When the farmer perceives his sheep-walks to become mossy, or to produce bad grass, he should either plough or manure with hot lime, making kilns either very near or in the sheep walks, because the hotter the lime is put on, the sweeter the grass comes up, and that early in the year.

30 And bursting. *Bursting*, or as it is called in some places the *blast*, attacks sheep when driven into fresh grass or young clover. They overeat themselves, foam at the mouth, swell exceedingly, breathe very quick and short, then jump up, and instantly fall down dead. In this case, the only chance of saving their life is by stabbing them in the maw with an instrument made for the purpose. The instrument is a hollow tube, with a pointed weapon passing through it. A hole is made with the pointed weapon; which is immediately withdrawn, and the hole is kept open by inserting the tube till the wind is discharged.

Sheep are infested with worms in their nose called *œstrus oves*, and produced from the egg of a large two-winged fly. The frontal sinuses above the nose in sheep and other animals are the places where these worms live and attain their full growth. These sinuses are always full of a soft white matter, which furnishes these worms with a proper nourishment, and are sufficiently large for their habitation; and when they have here acquired their destined growth, in which they are fit to undergo their changes for the fly-state, they leave their old habitation, and, falling to the earth, bury themselves there; and then these are hatched into flies, the female, when she has been impregnated by the male, knows that the nose of a sheep or other animal is the only place for her to deposit her eggs, in order to their coming to maturity. Mr Vallisnieri, to whom the world owes so many discoveries is the insect class, is the first who has given any true account of the origin of these worms. But though their true history had been till that time unknown, the creatures themselves were very early discovered, and many ages since were esteemed great medicines in epilepsies. 31 Account of the nose-worms which infest sheep.

The fly produced from this worm has all the time of its life a very lazy disposition, and does not like to make any use either of its legs or wings. Its head and corselet together are about as long as its body, which is composed of five rings, streaked on the back; a pale yellow and brown are there disposed in irregular spots; the belly is of the same colours, but they are there more regularly disposed, for the brown here makes three lines, one in the middle, and one on each side, and all the intermediate spaces are yellow. The wings are nearly of the same length with the body, and are a little inclined in their position, so as to lie upon the body: they do not, however, cover it; but a naked space is left between them. The ailerons or petty wings which are found under each of the wings are of a whitish colour, and perfectly cover the balancers, so that they are not to be seen without lifting up these.

The fly will live two months after it is first produced, but will take no nourishment of any kind; and possibly it may be of the same nature with the butterflies, which never take any food during the whole time of their living in that state. Reaumur, Hist. Inf. vol. iv. p. 552, &c.

To find a proper composition for marking sheep is a matter of great importance, as great quantities of wool are every year rendered useless by the pitch and tar with which they are usually marked. The requisite qualities for such a composition are, that it be cheap, that the colour be strong and lasting, so as to bear the changes of weather, and not to injure the wool. Dr Lewis recommends for this purpose melted tallow, with so much charcoal in fine powder stirred into it as is sufficient to make it of a full black colour, and of a thick consistence. This mixture, being applied warm with a marking iron, on pieces of flannel, quickly fixed or hardened, bore moderate rubbing, resisted the sun and rain, and 32 Composition for marking sheep.

and yet could be washed out freely with soap, or ley, or stale urine. In order to render it still more durable, and prevent its being rubbed off, with the tallow may be melted an eighth, sixth, or fourth, of its weight of tar, which will readily wash out along with it from the wool. Lewis's Com. Phil. Techn. p. 361.

Sheep-Stealing. See Theft.

SHEERING, in the sea-language. When a ship is not steered steadily, they say she sheers, or goes sheering; or when at anchor, she goes in and out by means of the current of the tide, they also say she sheers.

SHEERNESS, a fort in Kent, seated on the point where the river Medway falls into the Thames. It was built by king Charles II. after the insult of the Dutch, who burnt the men of war at Chatham. The buildings belonging to it, in which the officers lodge, make a pretty little neat town; and there is also a yard and a dock, a chapel and a chaplain. Mr Lyons, who sailed with the Honourable Captain Phipps in his voyage towards the pole, fixed the longitude of Sheerness to 0. 48′. E. its latitude 51° 25′. N.

SHEERS, a name given to an engine used to hoist or displace the lower masts of a ship. The sheers employed for this purpose in the royal navy are composed of several long masts, whose heels rest upon the side of the hull, and having their heads declining outward from the perpendicular, so as to hang over the vessel whose masts are to be fixed or displaced. The tackles, which extend from the head of the mast to the sheer-heads, are intended to pull in the latter toward the mast-head, particularly when they are charged with the weight of a mast after it is raised out of any ship, which is performed by strong tackles depending from the sheer-heads. The effort of these tackles is produced by two capsterns, fixed on the deck for this purpose.

In merchant ships this machine is composed of two masts or props, erected in the same vessel wherein the mast is to be planted, or from whence it is to be removed. The lower ends of these props rest on the opposite sides of the deck, and their upper parts are fastened across, so as that a tackle which hangs from the intersection may be almost perpendicularly above the station of the mast to which the mechanical powers are applied. These sheers are secured by stays, which extend forward and aft to the opposite extremities of the vessel.

SHEET-Lead. See Plumbery.

Sheet, in sea-language, a rope fastened to one or both the lower corners of a sail, to extend and retain it in a particular station. When a ship sails with a lateral wind, the lower corner of the main and fore sail are fastened by a tack and a sheet; the former being to windward, and the latter to leeward; the tack, however, is entirely diffused with a stern wind, whereas the sail is never spread without the assistance of one or both of the sheets. The stay-sails and studding-sails have only one tack and one sheet each: the stay-sail tacks are always fastened forward, and the sheet drawn aft; but the studding-sail tack draws the under clue of the sail to the extremity of the boom, whereas the sheet is employed to extend the inmost.

SHEFFIELD, a town in the west riding of Yorkshire, about 162 miles from London, is a large, thriving, populous town on the borders of Derbyshire; has a fine stone bridge over the Don, and another over the Sheaf, and a church built in the reign of Henry I It had a castle built in the reign of Henry III. in which, or else in the manor-house of the Park, Mary Queen of Scots was prisoner 16 or 17 years; but after the death of Charles I. it was, with several others, by order of parliament demolished. In 1673 an hospital was erected here, and endowed with 200l. a-year. There is a charity-school for 30 boys, and another for 30 girls. This town has been noted several hundred years for cutlers and smiths manufactures, which were encouraged and advanced by the neighbouring mines of iron, particularly for files and knives, or whittles; for the last of which especially it has been a staple for above 300 years; and it is reputed to excel Birmingham in these wares, as much as it is surpassed by it in locks, hinges, nails, and polished steel. The first mills in England for turning grindstones were also set up here. The houses look black from the continual smoke of the forges. Here are 600 master cutlers, incorporated by the style of the *Cutlers of Hallamshire* (of which this is reckoned the chief town), who employ not less than 40,000 persons in the iron manufactures; and each of the masters gives a particular stamp to his wares. There is a large market on Tuesday for many commodities, but especially for corn, which is brought up here for the whole West Riding, Derbyshire, and Nottinghamshire. It has fairs on Tuesday after Trinity-Sunday, and November 28. In the new market-place, erected by the Duke of Norfolk, the shambles are built upon a most excellent plan, and strongly inclosed. There are several other new good buildings, such as a large and elegant octagon chapel belonging to the hospital or alms-houses; likewise a good assembly-room and theatre. We must not omit the large steam-engine, lately finished, for the purpose of polishing and grinding the various sorts of hardware. The parish being very large, as well as populous, Mary I. incorporated 12 of the chief inhabitants, and their successors for ever, by the style of the *Twelve Capital Burgesses of Sheffield*, empowering them to elect and ordain three priests to assist the vicar, who were to be paid out of certain lands and rents which she gave out of the crown; and since this settlement two more chapels have been built in two hamlets of this parish, which are served by two of the assistants, while the third, in his turn, helps the vicar in his parish-church. James I. founded a free grammar-school here, and appointed 13 school burgesses to manage the revenue, and appoint the master and usher. A new chapel was built lately by the contributions of the people of the town and of the neighbouring nobility and gentry. Water is conveyed by pipes into Sheffield, whose inhabitants pay but a moderate rent for it. In the neighbourhood there are some mines of alum. The remains of the Roman fortification between this town and Rotheram, which is six miles lower down the river, are still visible; and here is also the famous trench of five miles long, by some called *Devil's* or *Dane's Bank*, and by others *Kemp Bank* and *Temple's Bank*. W. Long. 1. 29. N. Lat. 53. 20.

Sheffield (John), duke of Buckinghamshire, an eminent writer of the last and present century, of great personal bravery, and an able minister of state, was born about 1650. He lost his father at nine years of age; and his mother marrying lord Offulston, the care of his education was left entirely to a governor, who did not greatly improve him in his studies. Finding that he was deficient in many parts of of literature, he resolved to devote a certain number of hours every day to his studies; and thereby improved himself to the degree of learning he afterwards attained. Though possessed of a good estate, he did not abandon himself to pleasure and indolence, but entered a volunteer in the second Dutch war; and accordingly was in that famous naval engagement where the duke of York commanded as admiral; on which occasion his lordship behaved so gallantly, that he was appointed commander of the Royal Catharine. He afterward made a campaign in the French service under M. de Turenne. As Tangier was in danger of being taken by the Moors, he offered to head the forces which were sent to defend it; and accordingly was appointed to command them. He was then earl of Mulgrave, and one of the lords of the bed-chamber to king Charles II. The Moors retired on the approach of his majesty's forces; and the result of the expedition was the blowing up of Tangier. He continued in several great posts during the short reign of king James II. till that unfortunate prince was dethroned. Lord Mulgrave, though he paid his respects to king William before he was advanced to the throne, yet did not accept of any post in the government till some years after. In the sixth year of William and Mary he was created marquis of Normandy in the county of Lincoln. He was one of the most active and zealous opposers of the bill which took away Sir John Fenwick's life; and exerted the utmost vigour in carrying through the Treason Bill, and the bill for Triennial Parliaments. He enjoyed some considerable posts under king William, and enjoyed much of his favour and confidence. In 1702 he was sworn lord privy-seal; and in the same year was appointed one of the commissioners to treat of an union between England and Scotland. In 1703 he was created duke of Normandy, and soon after duke of Buckinghamshire. In 1711 he was made steward of her majesty's household, and president of the council. During queen Anne's reign he was but once out of employment; and then he voluntarily resigned, being attached to what were called the *Tory principles*. Her majesty offered to make him lord chancellor; but he declined the office. He was instrumental in the change of the ministry in 1710. A circumstance that reflects the highest honour on him is, the vigour with which he acted in favour of the unhappy Catalans, who afterward were so inhumanly sacrificed. He was survived by only one legitimate son (who died at Rome in 1735); but left several natural children. His worst enemies allow that he lived on very good terms with his last wife, natural daughter to king James II. the late duchess of Buckingham, a lady who always behaved with a dignity suitable to the daughter of a king. He died in 1721. He was admired by the poets of his age; by Dryden, Prior, and Garth. His Essay on Poetry was applauded by Addison, and his Rehearsal is still read with pleasure. His writings were splendidly printed in 1723, in two volumes 4to; and have since been reprinted in 1729, in two vols 8vo. The first contains his poems on various subjects: the second, his prose works; which consist of historical memoirs, speeches in parliament, characters, dialogues, critical observations, essays, and letters. It may be proper to observe, that the edition of 1729 is castrated; some particulars relating to the revolution in that of 1723 having given offence.

SHEFFIELDIA, in botany; a genus of plants belonging to the class of pentandria, and to the order of monogynia. The corolla is bell-shaped; the filaments are 10, of which every second is barren. The capsule consists of one cell, which has four valves. There is only one species, the *repens*.

SHEIK, in the oriental customs, the person who has the care of the mosques in Egypt; his duty is the same as that of the imams at Constantinople. There are more or fewer of these to every mosque, according to its size or revenue. One of these is head over the rest, and answers to a parish-priest with us; and has under him, in large mosques, the readers, and people who cry out to go to prayers; but in small mosques the sheik is obliged to do all this himself. In such it is their business to open the mosque, to cry to prayers, and to begin their short devotions at the head of the congregation, who stand rank and file in great order, and make all their motions together. Every Friday the sheik makes an harangue to his congregation.

SHEIK-*Bellet*, the name of an officer in the Oriental nations. In Egypt the sheik-bellet is the head of a city, and is appointed by the pacha. The business of this officer is to take care that no innovations be made which may be prejudicial to the Porte, and that they send no orders which may hurt the liberties of the people. But all his authority depends on his credit and interest, not his office: for the government of Egypt is of such a kind, that often the people of the least power by their posts have the greatest influence; and a caia of the janizaries or Arabs, and sometimes one of their meanest officers, an oda-basha, finds means, by his parts and abilities, to govern all things.

SHEILDS. See SHIELDS.

SHEKEL, the name of a weight and coin current among the ancient Jews. Dr Arbuthnot makes the weight of the shekel equal to 9 pennyweights $2\frac{4}{7}$ grains Troy weight; and the value equal to 2 s. $3\frac{3}{8}$d. Sterling. The golden shekel was worth L. 1 : 16 : 6.

SHELDRAKE, in ornithology. See ANAS.

SHELF, among miners, the same with what they otherwise call *fast ground* or *fast country*; being that part of the internal structure of the earth which they find lying even and in an orderly manner, and evidently retaining its primitive form and situation.

SHELL in natural history, a hard, and, as it were, stony covering, with which certain animals are defended, and thence called *shell-fish*.

1 Formation of shells.

The singular regularity, beauty and delicacy in the structure of the shells of animals, and the variety and brilliancy in the colouring of many of them, at the same time that they strike the attention of the most incurious observers, have at all times excited philosophers to inquire into and detect, if possible, the causes and manner of their formation. But the attempts of naturalists, ancient and modern, to discover this process, have constantly proved unsuccessful. M. de Reaumur hitherto appears alone to have given a plausible account, at least, of the formation of the shell of the garden-snail in particular, founded on a course of very ingenious experiments, related in the Paris Memoirs*. He there endeavours to show, that this substance is produced merely by the perspirable matter of the animal condensing and afterwards hardening on its surface, and accordingly taking the figure of its body, which has performed the office of a mould to it; in short, that the shell of a snail, and, as he supposed, of all other animals possessed

*See Mem. de l'Acad. année 1709. p. 475. Edit. de Hollande, in 12mo.

Shell.

fessed of shells, was only the product of a viscous transudation from the body of the animal, containing earthy particles united by mere juxtaposition. This hypothesis, however, is liable to very great and insurmountable difficulties, if we apply it to the formation of some of the most common shells: for how, according to this system, it may be asked, can the oyster, for instance, considered simply as a mould, form to itself a covering so much exceeding its own body in dimensions?

2 Are composed of an earthy and an animal substance.

M. Herissant, in the Memoirs of the Academy of Sciences for 1766, has discovered the structure of shells to be organical. In the numerous experiments that he made on an immense number, and a very great variety, of animal shells, he constantly found that they were composed of two distinct substances; one of which is a cretaceous or earthy matter: and the other appeared, from many experiments made upon it by burning, distillation, and otherwise, to be evidently of an animal nature. These two substances he dexterously separated from each other by a very easy chemical analysis; by the gentle operation of which they were exhibited distinctly to view, without any material alteration from the action of the solvent, or instrument employed for that purpose. On an entire shell or a fragment of one, contained in a glass vessel, he poured a sufficient quantity of the nitrous acid, considerably diluted either with water or spirit of wine. After the liquor has dissolved all the earthy part of the shell (which may be collected after precipitation by a fixed or volatile alkali), there remains floating in it a soft substance, consisting of innumerable membranes of a retiform appearance, and disposed, in different shells, in a variety of positions, which constitutes the animal part of it. This, as it has not been affected by the solvent, retains the exact figure of the shell; and, on being viewed through a microscope, exhibits satisfactory proofs of a vascular and organical structure. He shows that this membranous substance is an appendix to the body of the animal, or a continuation of the tendinous fibres that compose the ligaments by which it is fixed to its shell; and that this last owes its hardness to the earthy particles conveyed through the vessels of the animal, which fix themselves into, and incrust, as it were, the meshes formed by the reticular filaments of which this membranous substance is composed. In the shell called *porcelaine*, in particular, the delicacy of these membranes was so great, that he was obliged to put it into spirit of wine, to which he had the patience to add a single drop of spirit of nitre day by day, for the space of two months; lest the air generated, or let loose by the action of the acid on the earthy substance, should tear the compages of its fine membranous structure into shatters; as it certainly would have done in a more hasty and less gentle dissolution. The delicate reticulated film, left after this operation, had all the tenuity of a spider's web; and accordingly he does not attempt to delineate its organization. In other shells he employed even five or six months in demonstrating the complicated membranous structure of this animal-substance by this kind of chemical anatomy. In general, however, the process does not require much time.

Their membranous structure produces great variety of colours.

Of the many singular configurations and appearances of the membranous part of different shells, which are described in this memoir, and are delineated in several well executed plates, we shall mention only, as a specimen, the curious membranous structure observed in the laminæ of mother-of-pearl, and other shells of the same kind, after having been exposed to the operation of the author's solvent. Beside the great variety of fixed or permanent colours with which he found the animal-filaments of these shells to be adorned, it is known, that the shell itself presents to the view a succession of rich and changeable colours, the production of which he easily explains from the configurations of their membranes. Nature, he observes, always magnificent in her designs, but singularly frugal in the execution of them, produces these brilliant decorations at a very small expence. The membranous substance abovementioned is plaited and rumpled, as it were, in such a manner, that its exterior laminæ, incrusted with their earthy and semi-transparent matter, form an infinite number of little prisms, placed in all kinds of directions, which refract the rays of light, and produce all the changes of colour observable in these shells.

With respect to the figures and colours of shells, it is observed, that river shells have not so agreeable or diversified a colour as the land and sea shells; but the variety in the figure, colours, and other characters of sea shells, is almost infinite. The number of distinct species we find in the cabinets of the curious is very great; and doubtless the deep bottoms of the sea, and the shores yet unexplored contain multitudes still unknown to us. Even the same species differ in some degree in almost every individual; so that it is rare to find any two shells which are alike in all respects.

4 Whence the most beautiful shells are obtained.

This wonderful variety, however, is not all the produce of one sea or one country; the different parts of the world afford us their different beauties. Bonani observes, that the most beautiful shells we are acquainted with come from the East Indies and from the Red Sea. This is in some degree countenanced by what is found to this day; and from the general observations of the curious, it seems, that the sun, by the great heat that it gives to the countries near the line, exalts the colours of the shells produced there, and gives them a lustre and brilliancy that those of colder climates always want: and it may be, that the waters of those vast seas, which are not subject to be weakened by fresh rivers, give a nourishment to the fish, that may add to the brilliancy of their shells.

5 Shells found in Asia.

The shores of Asia furnish us with the pearl-oysters and scallops in great perfection. About Amboyna are found the most beautiful specimens of the cabbage-shell, the arosoir, the ducal mantle, and the coral oysters, or echinated oysters. Here also are found a great variety of extremely beautiful muscles, tellinæ, and volutæ; some fine buccinums, and the shell called the *Ethiopian crown*, in its greatest perfection. The dolia, the murices, and the cassandræ, are also found on these coasts in great beauty. Many elegant snails and screw-shells are also brought from thence; and finally, the serapion and spider-shells. The Maldive and Phillippine islands, Bengal, and the coast of Malabar, abound with the most elegant of all the species of snails, and furnish many other kinds of shells in great abundance and perfection. China abounds in the finest species of porcelain shells, and has also a great variety of beautiful snails. Japan furnishes us with all the thicker and larger bivalves; and the isle of Cyprus is famous above all other parts of the world for the beauty and variety of the patella or limpet found there.

America

Shells.

6 In America.

America affords many very elegant shells, but neither in so great abundance nor beauty as the shores of Asia. Panama is famous for the cylinders or rhombi, and we have beside, from the same place, some good porcelains, and a very fine species of *dolium*, or *concha globosa*, called from this place the *Panama purple shell*. One of the most beautiful of the cylinders is also known among our naturalists under the name of the *Panama shell*. About Brasil, and in the gulph of Mexico, there are found murices and dolia of extreme beauty; and also a great variety of porcelains, purpuræ, pectens, neritæ, bucardiæ or heart shells, and elegant limpets. The isle of Cayenne affords one of the most beautiful of the buccinum kind, and the Midas ear is found principally about this place. Jamaica and the island of Barbadoes have their shores covered with porcelains, chamæ, and buccina; and at St Domingo there are found almost all the same species of shells that we have from the East Indies; only they are less beautiful, and the colours more pale and dead. The pearl-oyster is found also on this coast, but smaller than in the Persian gulf. At Martinico there are found in general the same shells as at St Domingo, but yet less beautiful. About Canada are found the violet chamæ, and the lakes of that country abound with muscles of a very elegant pale blue and pale red colours. Some species of these are remarkably light and thin; others are very thick and heavy. The Great Bank of Newfoundland is very barren in shells: the principal kind found there are muscles of several species, some of which are of considerable beauty. About Carthagena there are many mother-of pearl shells, but they are not of so brilliant colours as those of the Persian gulf. The island of Magellan, at the southern point of America, furnishes us with a very remarkable species of muscle called by its name; and several very elegant species of limpets are found there, particularly the pyramidal.

7 In Africa.

In Africa, on the coast of Guinea, there is a prodigious quantity of that small species of porcelain which is used there as money; and there is another species of porcelain on the same coast which is all over white: the women make bracelets of these, and the people of the Levant adorn their hair with them. The coast of Zanguebar is very rich in shells: we find there a vast variety of the large porcelains, many of them of great beauty; and the *nux maris* or sea-nut is very frequent there. Beside these, and many other shells, there are found on this coast all the species of nautili, many of which are very beautiful. The Canary isles abound with a vast variety of the murices, and some other good shells; and we have from Madeira great variety of the echini or sea-eggs different from those of the European seas. Several species of muscles are also common there, and the auris marina is nowhere more abundant. The Red sea is beyond all other parts of the world abundant in shells, scarce any kind is wanting there; but what we principally have from thence are the purpuræ, porcelains, and echini marini.

8 In some islands of the Mediterranean and the coasts surrounding it.

The Mediterranean and northern ocean contain a great variety of shells, and many of very remarkable elegance and beauty; they are upon the whole, however, greatly inferior to those of the East Indies. The Mediterranean abounds much more in shells than the Ocean. The gulf of Tarentum affords great variety of pupuræ, of porcelains, nautili, and elegant oysters; the coasts of Naples and Sardinia afford also the same, and with them a vast number of the solens of all the known species. The island of Sicily is famous for a very elegant kind of oyster which is white all over; pinnæ marinæ and porcelains are also found in great plenty there, with tellinæ and chamæ of many species, and a great variety of other beautiful shells. Corsica is famous, beyond all other places, for vast quantities of the pinnæ marinæ; and many other very beautiful shells are found there. (Leister, Hist. Conchyl.) About Syracuse are found the gondola shell, the alated murex, and a great variety of elegant snails, with some of the dolia and neritæ. The Adriatic sea, or gulf of Venice, is less furnished with shells than almost any of the seas thereabout. Muscles and oysters of several species are however found there, and some of the cordiform or heart-shells; there are also some tellinæ. About Ancona there are found vast numbers of the pholades buried in stone; and the aures marinæ are particularly frequent about Puzzoli. *(Bonani, Recreat. Ment. et Ocul.)*

9 On the coast of France,

The ports of Marseilles, Toulon, and Antibes, are full of pinnæ marinæ, muscles, tellinæ, and chamæ. The coasts of Bretagne afford great numbers of the conchæ anatiferæ and pousepieds; they are found on old rotten boards, on sea substances, and among clusters of sponges. The other ports of France, as Rochelle, Dunkirk, Brest, St Maloes, and others, furnish oysters excellent for the table, but of the common kind, and of no beauty in their shells; great numbers of muscles are also found there; and the common tillinæ, the onion-peel oysters, the solens, and conchæ anatiferæ, are also frequent there. At Granville, in Lower Normandy, there are found very beautiful pectens, and some of the cordiform or heart-shells.

10 Of Britain,

The English coasts are not the least fruitful in shells, though they do not produce such elegantly painted ones as the Indies. About Plymouth are found oysters, muscles, and solens, in great abundance; and there, and on most of the other shores, are numbers of the aures marinæ and dentalia, with pectens, which are excellent food; and many elegant species of the chamæ and tellinæ are fished up in the sea about Scarborough and other places. Ireland affords great numbers of muscles, and some very elegant scallop-shells in great abundance, and the pholades are frequent on most of the British shores. They have also great variety of the buccina and cochleæ, some volutæ; and, on the Guernsey coast, a peculiarly beautiful snail, called thence the *Guernsey-snail*.

11 Of Spain and Portugal, &c.

The coasts of Spain and Portugal afford much the same species of shells with the East Indies, but they are of much fainter colours, and greatly inferior in beauty. There are, according to Tavernier and others, some rivers in Bavaria in which there are found pearls of a fine water. About Cadiz there are found very large pinnæ marinæ, and some fine buccina. The isles of Majorca and Minorca afford a great variety of extremely elegant shells. The pinnæ marinæ are also very numerous there, and their silk is wrought into gloves, stockings, and other things. The Baltic affords a great many beautiful species, but particularly an orange-coloured pecten, or scallop-shell, which is not found in any other part of the world.

12 Fresh water shells.

The fresh water shells are found much more frequently, and in much greater plenty than the sea-kinds; there is scarce a pond, a ditch, or a river of fresh water in any part of the world in which there are

are not found vast numbers of these shells with the fish living in them. All these shells are small, and they are of very little beauty, being usually of a plain greyish or brownish colour. Our ditches afford us chamæ, buccina, neritæ, and some patellæ; but the Nile, and some other rivers, furnished the ancients with a species of tellina which was large and eatable, and so much superior to the common sea tellina in flavour, that it is commonly known by the name of *tellina regia*, "the royal tellina." We have a small species of buccinum common in our fresh waters, which is very elegant, and always has its operculum in the manner of the larger buccina; a small kind of muscle is also very common, which is so extremely thin and tender, that it can hardly be handled without breaking to pieces. The large fresh water muscle, commonly called in England the *horse-muscle*, is too well known to need a description; and the size sufficiently distinguishes it from all other fresh water shells.

In collecting shells, it is most advisable, whenever it can be done, to get those which have in them the living animals; because we shall thus obtain the natural history of the animals, and the shells themselves in their natural beauty, and the full glow of their colours. Shells should be also procured from the deeper parts of their resorts, and immediately after storms on the sea beaches and shores; because, by being much exposed to the sun, their colours fade, and they are liable to other accidents that injure them. In order to kill the fish that inhabits them, Mr Da Costa advises to give them a quick dip in boiling water, and when they are cooled, to lay them in cold water till they are cleaned; and in this operation they should not be touched with aquafortis, or any other acid, nor exposed to the heat of the fire and sun.

13 Art of polishing shells.

The art of polishing shells arrived but lately at its present state of perfection; and as the love of sea-shells is become so common among us, it may not be disagreeable to the reader to find some instructions in executing so pleasing a method of adding to their natural beauty, the rules for which are at present so little known, though the effect of them be so much esteemed.

Among the immense variety of shells which we are acquainted with, some are taken up out of the sea, or found on its shores in all their perfection and beauty; their colours being all spread by nature upon the surface, and their natural polish superior to any thing that art could give. Where nature is in herself thus perfect, it were madness to attempt to add any thing to her charms: but in others, where the beauties are latent and covered with a coarser outer skin, art is to be called in; and the outer veil being taken off, all the internal beauties appear.

Among the shells which are found naturally polished are the porcelains, or cowries; the cassanders; the dolia, or conchæ globosæ, or tuns; some buccina, the volutes, and the cylinders, or olives, or, as they are generally though improperly called, the *rhombi;* excepting only two or three, as the tiara, the plumb, and the butter-tub rhombus, where there is an unpromising film on the surface, hiding a very great share of beauty within. Though the generality of the shells of these genera are taken out of the sea in all their beauty, and in their utmost natural polish, there are several other genera, in which all or most of the species are taken up naturally rough and foul, and covered with an epidermis, or coarse outer skin, which is in many rough and downy or hairy. The tellinæ, the muscles, the cochleæ, and many others, are of this kind. The more nice collectors, as naturalists, insist upon having all their shells in their native and genuine appearance, as they are found when living at sea; but the ladies, who make collections, hate the disagreeable outsides, and will have all such polished. It would be very advisable, however, for both kinds of collectors to have the same shells in different specimens both rough and polished: the naturalist would by this means, besides knowing the outside of the shell, be better acquainted with its internal characters than he otherwise could be, and the lady would have a pleasure in comparing the beauties of the shell, in its wrought state, to its coarse appearance as nature gives it. How many elegancies in this part of the creation must be wholly lost to us, if it were not for the assistance of an art of this kind! Many shells in their native state are like rough diamonds; and we can form no just idea of their beauties till they have been polished and wrought into form.

Though the art of polishing shells is a very valuable one, yet it is very dangerous to the shells; for without the utmost care, the means used to polish and beautify a shell often wholly destroy it. When a shell is to be polished, the first thing to be examined is whether it have naturally a smooth surface, or be covered with tubercles or prominences.

A shell which has a smooth surface, and a natural dull polish, need only be rubbed with the hand, or with a piece of chamoy leather, with some tripoli, or fine rotten stone, and will become of a perfectly bright and fine polish. Emery is not to be used on this occasion, because it wears away too much of the shell. This operation requires the hand of an experienced person, that knows how superficial the work must be, and where he is to stop; for in many of these shells the lines are only on the surface, and the wearing away ever so little of the shell defaces them. A shell that is rough, foul, and crusty, or covered with a tartareous coat, must be left a whole day steeping in hot water: when it has imbibed a large quantity of this, it is to be rubbed with rough emery on a stick, or with the blade of a knife, in order to get off the coat. After this, it may be dipped in diluted aquafortis, spirit of salt, or any other acid; and after remaining a few moments in it, be again plunged into common water. This will add greatly to the speed of the work. After this it is to be well rubbed with linen cloths, impregnated with common soap; and when by these several means it is made perfectly clean, the polishing is to be finished with fine emery and a hair-brush. If after this the shell when dry appears not to have so good a polish as was desired, it must be rubbed over with a solution of gum arabic; and this will add greatly to its gloss, without doing it the smallest injury. The gum-water must not be too thick, and then it gives no sensible coat, only heightening the colours. The white of an egg answers this purpose also very well; but it is subject to turn yellow. If the shell has an epidermis, which will by no means admit the polishing of it, it is to be dipped several times in diluted aquafortis, that this may be eaten off; and then the shell is to be polished in the usual way with putty, fine emery, or tripoli, on the hair of a fine brush. When it is only a pellicle that hides the colours, the shells must be steeped in hot water, and after that the

Shells. ſkin worked off by degrees with an old file. This is the caſe with ſeveral of the cylinders, which have not the natural poliſh of the reſt.

When a ſhell is covered with thick and fatty epidermis, as is the caſe with ſeveral of the muſcles and tellinæ; in this caſe aquafortis will do no ſervice, as it will not touch the ſkin: then a rough bruſh and coarſe emery are to be uſed; and if this does not ſucceed, ſeal-ſkin, or, as the workmen call it, *fiſh-ſkin* and *pumice ſtone*, are to be employed.

When a ſhell has a thick cruſt, which will not give way to any of theſe means, the only way left is to plunge it ſeveral times into ſtrong aquafortis, till the ſtubborn cruſt is wholly eroded. The limpits, auris marina, the helmet-ſhells, and ſeveral other ſpecies of this kind, muſt have this ſort of management; but as the deſign is to ſhow the hidden beauties under the cruſt, and not to deſtroy the natural beauty and poliſh of the inſide of the ſhell, the aquafortis muſt be uſed in this manner: A long piece of wax muſt be provided, and one end of it made perfectly to cover the whole mouth of the ſhell; the other end will then ſerve as a handle, and the mouth being ſtopped by the wax, the liquor cannot get in to the inſide to ſpoil it; then there muſt be placed on a table a veſſel full of aquafortis, and another full of common water.

The ſhell is to be plunged into the aquafortis; and after remaining a few minutes in it, is to be taken out, and plunged into the common water. The progreſs the aquafortis makes in eroding the ſurface is thus to be carefully obſerved every time it is taken out: the point of the ſhell, and any other tender parts, are to be covered with wax, to prevent the aquafortis from eating them away; and if there be any wormholes, they alſo muſt be ſtopped up with wax, otherwiſe the aquafortis would ſoon eat through in thoſe places. When the repeated dippings into the aquafortis ſhow that the coat is ſufficiently eaten away, then the ſhell is to be wrought carefully with fine emery and a bruſh; and when it is poliſhed as high as can be by this means, it muſt be wiped clean, and rubbed over with gum-water or the white of an egg. In this ſort of work the operator muſt always have the caution to wear gloves; otherwiſe the leaſt touch of the aquafortis will burn the fingers, and turn them yellow; and often, if it be not regarded, will eat off the ſkin and the nails.

Theſe are the methods to be uſed with ſhells which require but a moderate quantity of the ſurface to be taken off; but there are others which require to have a larger quantity taken off, and to be uncovered deeper; this is called entirely ſcaling a ſhell. This is done by means of a horizontal wheel of lead or tin, impregnated with rough emery; and the ſhell is wrought down in the ſame manner in which ſtones are wrought by the lapidary. Nothing is more difficult, however, than the performing this work with nicety: very often ſhells are cut down too far by it, and wholly ſpoiled; and to avoid this, a coarſe vein muſt be often left ſtanding in ſome place, and taken down afterwards with the file, when the cutting it down at the wheel would have ſpoiled the adjacent parts.

After the ſhell is thus cut down to a proper degree it is to be poliſhed with fine emery, tripoli, or rotten ſtone, with a wooden wheel turned by the ſame machine as the leaden one, or by the common method of working with the hand with the ſame ingredients. When a ſhell is full of tubercles, or protuberances, which muſt be preſerved, it is then impoſſible to uſe the wheel: and if the common way of dipping into aquafortis be attempted, the tubercles being harder than the reſt of the ſhell, will be eat through before the reſt is ſufficiently ſcaled, and the ſhell will be ſpoiled. In this caſe, induſtry and patience are the only means of effecting a poliſh. A camel's-hair pencil muſt be dipped in aquafortis; and with this the intermediate parts of the ſhell muſt be wetted, leaving the protuberances dry: this is to be often repeated; and after a few moments the ſhell is always to be plunged into water to ſtop the eroſion of the acid, which would otherwiſe eat too deep, and deſtroy the beauty of the ſhell. When this has ſufficiently taken off the foulneſs of the ſhell, it is to be poliſhed with emery of the fineſt kind, or with tripoli, by means of a ſmall ſtick, or the common poliſhing-ſtone uſed by the goldſmiths may be uſed.

14 Some ſhells are ſo much diſguiſed by poliſhing as not to be known, ſuch as

This is a very tedious and troubleſome thing, eſpecially when the echinated oyſters and murices, and ſome other ſuch ſhells, are to be wrought: and what is worſt of all is, that when all this labour has been employed, the buſineſs is not well done; for there ſtill remain ſeveral places which could not be reached by any inſtrument, ſo that the ſhell muſt neceſſarily be rubbed over with gum-water or the white of an egg afterwards, in order to bring out the colours and give a gloſs; in ſome caſes it is even neceſſary to give a coat of varniſh.

Theſe are the means uſed by artiſts to brighten the colours and add to the beauty of ſhells; and the changes produced by poliſhing in this manner are ſo great, that the ſhell can ſcarcely be known afterwards to be the ſame it was; and hence we hear of new ſhells in the cabinets of collectors, which have no real exiſtence as ſeparate ſpecies, but are ſhells well known, diſguiſed by poliſhing. To caution the reader againſt errors of this kind, it may be proper to add the moſt remarkable ſpecies thus uſually altered.

15 The onyx-ſhell.

The onyx-ſhell or volute, called by us the *purple* or *violet-tip*, which in its natural ſtate is of a ſimple pale brown, when it is wrought ſlightly, or poliſhed with juſt the ſuperficies taken off, is of a fine bright yellow; and when it is eaten away deeper, it appears of a fine milk-white, with the lower part bluiſh: it is in this ſtate that it is called the *onyx-ſhell*; and it is preſerved in many cabinets in its rough ſtate, and in its yellow appearance, as different ſpecies of ſhells.

16 Violet ſhells.

The *violet ſhell*, ſo common among the curious, is a ſpecies of porcelain, or common cowry, which does not appear in that elegance till it has been poliſhed; and the common auris marina ſhows itſelf in two or three different forms, as it is more or leſs deeply wrought. In its rough ſtate it is duſky and coarſe, of a pale brown on the outſide, and pearly within; when it is eaten down a little way below the ſurface, it ſhows variegations of black and green; and when ſtill farther eroded, it appears of a fine pearly hue within and without.

17 Nautilus.

The *nautilus*, when it is poliſhed down, appears all over of a fine pearly colour; but when it is eaten away but to a ſmall depth, it appears of a fine yellowiſh colour with duſky hairs. The burgau, when entirely cleared of its coat, is of the moſt beautiful pearl-co-

Shells. lour; but when but slightly eroded, it appears of a variegated mixture of green and red; whence it has been called the *parroquet shell.* The common helmet-shell, when wrought, is of the colour of the finest agate; and the muscles, in general, though very plain shells in their common appearance, become very beautiful when polished, and show large veins of the most elegant colours. The Persian shell, in its natural state, is all over white, and covered with tubercles; but when it has been ground down on a wheel, and polished, it appears of a grey colour, with spots and veins of a very bright and highly polished white. The limpets, in general, become very different when polished, most of them showing very elegant colours; among these the tortoise-shell limpet is the principal; it does not appear at all of that colour or transparence till it has been wrought.

18 Junquil-chama. That elegant species of shell called the *junquil-chama,* which has deceived so many judges of these things into an opinion of its being a new species, is only a white chama with a reticulated surface; but when this is polished, it loses at once its reticular work and its colour, and becomes perfectly smooth, and of a fine bright yellow. The violet-coloured chama of New England, when worked down and polished, is of a fine milk-white, with a great number of blue veins, disposed like the variegations in agates.

19 The asses-ear shell. The *asses-ear shell,* when polished after the working it down with the file, becomes extremely glossy, and obtains a fine rose-colour all about the mouth. These are some of the most frequent among an endless variety of changes wrought on shells by polishing; and we find there are many of the very greatest beauties of this part of the creation which must have been lost but for this method of searching deep in the substance of the shell for them.

20 Dutch method of polishing shells. The Dutch are very fond of shells, and are very nice in their manner of working them: they are under no restraint, however, in their works; but use the most violent methods, so as often to destroy all the beauty of the shell. They file them down on all sides, and often take them to the wheel, when it must destroy the very characters of the species. Nor do they stop at this: but, determined to have beauty at any rate, they are for improving upon nature, and frequently add some lines and colours with a pencil, afterwards covering them with a fine coat of varnish, so that they seem the natural lineations of the shell: the Dutch cabinets are by these means made very beautiful, but they are by no means to be regarded as instructors in natural history. There are some artificers of this nation who have a way of covering shells all over with a different tinge from that which nature gives them; and the curious are often enticed by these tricks to purchase them for new species.

There is another kind of work bestowed on certain species of shells, particularly the nautilus; namely, the engraving on it lines and circles, and figures of stars, and other things. This is too obvious a work of art to suffer any one to suppose it natural. Buonani has figured several of these wrought shells at the end of his work; but this was applying his labour to very little purpose; the shells are spoiled as objects of natural history by it, and the engraving is seldom worth any thing.—They are principally done in the East Indies.

Shells are subject to several imperfections; some of which are natural and others accidental. The natural defects are the effect of age, or sickness in the fish. The greatest mischief happens to shells by the fish dying in them. The curious in these things pretend to be always able to distinguish a shell taken up with the fish alive from one found on the shores: they call the first a *living*, the second a *dead* shell; and say that the colours are always much fainter in the dead shells. When the shells have lain long dead on the shores, they are subject to many injuries, of which the being eaten by sea-worms is not the least: age renders the finest shells livid or dead in their colours. 21 Imperfections of shells natural and accidental.

Besides the imperfections arising from age and sickness in the fish, shells are subject to other deformites, such as morbid cavities, or protuberances, in parts where there should be none. When the shell is valuable, these faults may be hid, and much added to the beauty of the specimen, without at all injuring it as an object of natural history, which should always be the great end of collecting these things. The cavities may be filled up with mastic, dissolved in spirit of wine, or with isinglass: these substances must be either coloured to the tinge of the shell, or else a pencil dipped in water-colours must finish them up to the resemblance of the rest; and then the whole shell being rubbed over with gum-water, or with the white of an egg, scarce any eye can perceive the artifice: the same substances may also be used to repair the battered edge of a shell provided the pieces chipped off be not too large. And when the excrescences of a shell are faulty, they are to be taken down with a fine file If the lip of a shell be so battered that it will not admit of repairing by any cement, the whole must be filed down or ground on the wheel till it become even.

Fossil Shells. Those found buried at great depths in the earth.

Of these some are found remaining almost entirely in their native state, but others are variously altered by being impregnated with particles of stone and of other fossils; in the place of others there is found mere stone or spar, or some other native mineral body, expressing all their lineaments in the most exact manner, as having been formed wholly from them, the shell having been first deposited in some solid matrix, and thence dissolved by very slow degrees, and this matter left in its place, on the cavities of stone and other solid substances, out of which shells had been dissolved and washed away, being afterwards filled up less slowly with these different substances, whether spar or whatever else: these substances, so filling the cavities, can necessarily be of no other form than that of the shell, to the absence of which the cavity was owing, though all the nicer lineaments may not be so exactly expressed. Besides these, we have also in many places masses of stone formed within various shells; and these having been received into the cavities of the shells while they were perfectly fluid, and having therefore nicely filled all their cavities, must retain the perfect figures of the internal part of the shell, when the shell itself should be worn away or perished from their outside. The various species we find of these are, in many genera, as numerous as the known recent ones; and as we have in our own island not only the shells of our own shores, but those of many other very distant ones, so we have also

also many species, and those in great numbers, which are in their recent state, the inhabitants of other yet unknown or unsearched seas and shores. The cockles, muscles, oysters, and the other common bivalves of our own seas, are very abundant: but we have also an amazing number of the nautilus kind, particularly of the nautilus græcorum, which though a shell not found living in our own or any neighbouring seas, yet is found buried in all our clay-pits about London and elsewhere; and the most frequent of all fossil shells in some of our counties are the conchæ anomiæ, which yet we know not of in any part of the world in their recent state. Of this sort also are the cornua ammonis and the gryphitæ, with several of the echinitæ and others.

The exact similitude of the known shells, recent and fossil, in their several kinds, will by no means suffer us to believe that these, though not yet known to us in their living state, are, as some have idly thought, a sort of *lusus naturæ*. It is certain, that of the many known shores, very few, not even those of Great Britain, have been yet carefully searched for the shell-fish that inhabit them; and as we see in the nautilus græcorum an instance of shells being brought from very distant parts of the world to be buried here, we cannot wonder that yet unknown shores, or the unknown bottoms of deep seas, should have furnished us with many unknown shell-fish, which may have been brought with the rest; whether that were at the time of the general deluge, or the effect of any other catastrophe of a like kind, or by whatever other means, to be left in the yet unhardened matter of our stony and clayey strata.

Shells, in gunnery, are hollow iron balls to throw out of mortars or howitzers, with a fuse-hole of about an inch diameter, to load them with powder, and to receive the fuse. The bottom, or part opposite to the fuse, is made thicker than the rest, that the fuse may fall uppermost. But in small elevations this does not always happen, nor indeed is it necessary; for, let the shell fall as it will, the fuse sets fire to the powder within, which bursts the shell, and causes great devastation. The shells had much better be of an equal thickness; for then they burst into more pieces.

Message Shells, are nothing more than howitz-shells, in the inside of which a letter or other papers are put; the fuse hole is stopped up with wood or cork, and the shells are fired out of a royal or howitz, either into a garrison or camp. It is supposed, that the person to whom the letter is sent knows the time, and accordingly appoints a guard to look out for its arrival.

Shell-Fish. These animals are in general oviparous, very few instances having been found of such as are viviparous. Among the oviparous kinds, anatomists have found that some species are of different sexes, in the different individuals of the same species; but others are hermaphrodites, every one being in itself both male and female. In both cases their increase is very numerous, and scarce inferior to that of plants, or of the most fruitful of the insect class. The eggs are very small, and are hung together in a sort of clusters by means of a glutinous humour, which is always placed about them, and is of the nature of the jelly of frog's spawn. By means of this, they are not only kept together in the parcel, but the whole cluster is fastened to the rocks, shells, or other solid substances; and thus they are preserved from being driven on shore by the waves, and left where they cannot succeed. See Testacea.

Shell-Gold. See Gold.

SHELTIE, a small but strong kind of horse, so called from Shetland, or Zetland, where they are produced.

SHELVES, in sea-language, a general name given to any dangerous shallows, sand banks, or rocks, lying immediately under the surface of the water, so as to intercept any ship in her passage, and endanger her destruction.

SHENAN. See *Dying of Leather*, vol. ix. p. 750, foot-note.

SHENSTONE (William), an admired English poet, the eldest son of a plain country gentleman, who farmed his own estate in Shropshire, was born in November 1714. He learned to read of an old dame, whom his poem of the "School mistress" has delivered to posterity; and soon received such delight from books, that he was always calling for new entertainment, and expected that, when any of the family went to market, a new book should be brought him, which, when it came, was in fondness carried to bed, and laid by him. It is said, that when his request had been neglected, his mother wrapped up a piece of wood of the same form, and pacified him for the night. As he grew older, he went for a while to the grammar-school in Hales-Owen, and was placed afterwards with Mr Crumpton, an eminent school-master at Solihul, where he distinguished himself by the quickness of his progress. When he was young (June 1724), he was deprived of his father; and soon after (August 1726) of his grandfather; and was, with his brother, who died afterwards unmarried, left to the care of his grandmother, who managed the estate. From school he was sent, in 1732, to Pembroke college in Oxford, a society which for half a century has been eminent for English poetry and elegant literature. Here it appears that he found delight and advantage; for he continued his name there ten years, though he took no degree. After the first four years he put on the civilian's gown, but without showing any intention to engage in the profession. About the time when he went to Oxford, the death of his grandmother devolved his affairs to the care of the reverend Mr Dolman, of Brome, in Staffordshire, whose attention he always mentioned with gratitude. —At Oxford he applied to English poetry; and, in 1737, published a small Miscellany, without his name. He then for a time wandered about, to acquaint himself with life, and was sometimes at London, sometimes at Bath, or any place of public resort; but he did not forget his poetry. He published, in 1740, his "Judgment of Hercules," addressed to Mr Lyttleton, whose interest he supported with great warmth at an election; this was two years afterwards followed by the "School-mistress." Mr Dolman, to whose care he was indebted for his ease and leisure, died in 1745, and the care of his fortune now fell upon himself. He tried to escape it a while, and lived at his house with his tenants, who were distantly related; but, finding that imperfect possession inconvenient, he took the whole estate into his own hands, an event which rather improved its beauty than increased its produce. Now began his delight in rural pleasures, and his passion of rural elegance; but in time his expences occasioned

occasioned clamours that overpowered the lamb's bleat and the linnet's song, and his groves were haunted by beings very different from fawns and fairies. He spent his estate in adorning it, and his death was probably hastened by his anxieties. He was a lamp that spent its oil in blazing. It is said, that if he had lived a little longer, he would have been assisted by a pension; such bounty could not have been more properly bestowed, but that it was ever asked is not certain; it is too certain that it never was enjoyed. —He died at the Leasowes, of a putrid fever, about five on Friday morning, Feb. 11. 1763; and was buried by the side of his brother, in the churchyard of Hales-Owen.

In his private opinions, our author adhered to no particular sect, and hated all religious disputes. Tenderness, in every sense of the word, was his peculiar characteristic; and his friends, domestics, and poor neighbours, daily experienced the effects of his benevolence. This virtue he carried to an excess that seemed to border upon weakness; yet if any of his friends treated him ungenerously, he was not easily reconciled. On such occasions, however, he used to say, "I never will be a revengeful enemy; but I cannot, it is not in my nature, to be half a friend." He was no economist; for the generosity of his temper prevented his paying a proper regard to the use of money: he exceeded therefore the bounds of his paternal fortune. But, if we consider the perfect paradise into which he had converted his estate, the hospitality with which he lived, his charities to the indigent, and all out of an estate that did not exceed 300 l. a-year, one should rather wonder that he left any thing behind him, than blame his want of economy: he yet left more than sufficient to pay all his debts, and by his will appropriated his whole estate to that purpose. Though he had a high opinion of many of the fair sex, he forbore to marry. A passion he entertained in his youth was with difficulty surmounted. The lady was the subject of that admirable pastoral, in four parts, which has been so universally and so justly admired, and which, one would have thought, must have softened the proudest and most obdurate heart. His works have been published by Mr Dodsley, in 3 vols 8vo. The first volume contains his poetical works, which are particularly distinguished by an amiable elegance and beautiful simplicity; the second volume contains his prose works; the third his letters, &c. *Biographical Dictionary.*

SHEPPEY, an island at the mouth of the river Medway, about 20 miles in circumference. It is separated from the main land by a narrow channel, and has a fertile soil, which feeds great flocks of sheep. The borough-town of Queenborough is seated thereon; besides which it has several villages.

SHERARDIA, in botany: A genus of the monogynia order, belonging to the tetandria class of plants; and in the natural method ranking under the 47th order, *Stellatæ*. The calyx is small, quadridentate; the corolla monopetalous, long, and funnel shaped. The two seeds are naked, and crowned with the calyx. There are three species, viz. 1. Arvensis; 2. Muralis; 3. Fruticosa.

SHERBET, or SHERBIT, a compound drink, first brought into England from Turkey and Persia, consisting of water, lemon-juice, and sugar, in which are dissolved perfumed cakes made of excellent Damascus fruit, containing an infusion of some drops of rose water. Another kind of it is made of violets, honey, juice of raisins, &c.

SHERIDAN (Thomas), D. D. the intimate friend of Dean Swift, is said by Shield in Cibber's "Lives of the Poets," to have been born about 1684, in the county of Cavan, where, according to the same authority, his parents lived in no very elevated state. They are described as being unable to afford their son the advantages of a liberal education: but he, being observed to give early indications of genius, attracted the notice of a friend to his family, who sent him to the college of Dublin, and contributed towards his support while he remained there. He afterwards entered into orders, and set up a school in Dublin, which long maintained a very high degree of reputation, as well for the attention bestowed on the morals of the scholars as for their proficiency in literature. So great was the estimation in which this seminary was held, that it is asserted to have produced in some years the sum of L. 1000. It does not appear that he had any considerable preferment; but his intimacy with Swift, in 1725, procured for him a living in the south of Ireland worth about L. 150 a-year, which he went to take possession of, and, by an act of inadvertence, destroyed all his future expectations of rising in the church; for being at Corke on the 1st of August, the anniversary of King George's birth-day, he preached a sermon, which had for its text, "Sufficient for the day is the evil thereof." On this being known, he was struck out of the list of chaplains to the lord lieutenant, and forbidden the castle.

This living Dr Sheridan afterwards changed for that of Dunboyne, which, by the knavery of the farmers, and power of the gentlemen in the neighbourhood, fell so low as L. 80 *per annum*. He gave it up for the free school of Cavan, where he might have lived well in so cheap a country on L. 80 a-year salary, besides his scholars; but the air being, as he said, too moist and unwholesome, and being disgusted with some persons who lived there, he sold the school for about L. 400; and having soon spent the money, he fell into bad health, and died Sept. 10. 1738, in his 55th year.

Lord Croke has given the following character of him: "Dr Sheridan was a school-master, and in many instances perfectly well adapted for that station. He was deeply versed in the Greek and Roman languages, and in their customs and antiquities. He had that kind of good nature which absence of mind, indolence of body, and carelessness of fortune, produce; and although not over strict in his own conduct, yet he took care of the morality of his scholars, whom he sent to the university remarkably well founded in all kinds of classical learning, and not ill instructed in the social duties of life. He was slovenly, indigent, and cheerful. He knew books much better than men; and he knew the value of money least of all. In this situation, and with this disposition, Swift fastened upon him as upon a prey with which he intended to regale himself whenever his appetite should prompt him." His Lordship then mentions the event of the unlucky sermon, and adds: "This ill-starred, good-natured, improvident man, returned to Dublin, unhinged from all favour at court, and even banished from the castle. But still he remained a punster, a quibbler, a fiddler, and a wit. Not a day

Sheridan, Sheriff. day passed without a rebus, an anagram, or a madrigal. His pen and his fiddlestick were in continual motion; and yet to little or no purpose, if we may give credit to the following verses, which shall serve as the conclusion of his poetical character:

"With music and poetry equally bless'd,
"A bard thus Apollo most humbly address'd;
"Great author of poetry, music, and light,
"Instructed by thee, I both fiddle and write;
"Yet unheeded I scrape, or I scribble all day,
"My tunes are neglected, my verse flung away.
"Thy substitute here, Vice-Apollo disdains
"To vouch for my numbers, or list to my strains.
"Thy manual sign he refuses to put
"To the airs I produce from the pen or the gut:
"Be thou then propitious, great Phœbus, and grant
"Relief, or reward, to my merit or want.
"Tho' the Dean and Delany transcendantly shine,
"O! brighten one solo or sonnet of mine:
"Make one work immortal, 'tis all I request.
"Apollo look'd pleas'd, and resolving to jest,
"Replied—Honest friend, I've consider'd your case,
"Nor dislike your unmeaning and innocent face.
"Your petition I grant, the boon is not great,
"Your works shall continue, and here's the receipt,
"On rondeaus hereafter your fiddle-strings spend,
"Write verses in circles, they never shall end."

"One of the volumes of Swift's miscellanies consists almost entirely of letters between him and the Dean. He published a prose translation of Perseus; to which he added the best notes of former editors, together with many judicious ones of his own. This work was printed at London, 1739, in 12mo. *Biographical Dictionary.*

SHERIDAN (Mrs Frances), wife to Thomas Sheridan, M. A. was born in Ireland about the year 1724, but descended from a good English family which had removed thither. Her maiden name was Chamberlaine, and she was grand-daughter of Sir Oliver Chamberlaine. The first literary performance by which she distinguished herself was a little pamphlet at the time of a violent party-dispute relative to the theatre, in which Mr Sheridan had newly embarked his fortune. So well-timed a work exciting the attention of Mr Sheridan, he by an accident discovered his fair patroness, to whom he was soon afterwards married. She was a person of the most amiable character in every relation of life, with the most engaging manners. After lingering some years in a very weak state of health she died at Blois in the south of France, in the year 1767. Her "Sydney Biddulph" may be ranked with the first productions of that class in ours or in any other language. She also wrote a little romance in one volume called *Nourjahad*, in which there is a great deal of imagination productive of an admirable moral. And she was the authoress of two comedies, "The Discovery" and "The Dupe."

Blackstone's Commentaries, vol. i. p. 339.

SHERIFF, an officer, in each county in England, nominated by the king, invested with a judicial and ministerial power, and who takes place of every nobleman in the county during the time of his office.

The sheriff is an officer of very great antiquity in this kingdom, his name being derived from two Saxon words, signifying the *reeve*, *bailiff*, or *officer* of the shire. He is called in Latin *vice-comes*, as being the deputy of the earl or *comes*, to whom the custody of the shire is said to have been committed at the first division of this kingdom into counties. But the earls, in process of time, by reason of their high employments and attendance on the king's person, not being able to transact the business of the county, were delivered of that burden; reserving to themselves the honour, but the labour was laid on the Sheriff. So that now the sheriff does all the king's business in the county; and though he be still called *vice-comes*, yet he is entirely independent of, and not subject to, the earl; the king, by his letters patent, committing *custodiam comitatus* to the sheriff, and to him alone.

Sheriffs were formerly chosen by the inhabitants of the several counties. In confirmation of which it was ordained, by statute 28 Edw. I. c. 8. that the people should have an election of sheriffs in every shire where the shrievalty is not of inheritance. For anciently in some counties the sheriffs were hereditary; as we apprehend they were in Scotland till the statute 20 Geo. II. c. 43; and still continue in the county of Westmoreland to this day; the city of London having also the inheritance of the shrievalty of Middlesex vested in their body by charter. The reason of these popular elections is assigned in the same statute, c. 13. "that the commons might choose such as would not be a burden to them." And herein appears plainly a strong trace of the democratical part of our constitution; in which form of government it is an indispensable requisite, that the people should choose their own magistrates. This election was in all probability not absolutely vested in the commons, but required the royal approbation. For in the Gothic constitution, the judges of their county-courts (which office is executed by the sheriff) were elected by the people, but confirmed by the king: and the form of their election was thus managed; the people, or *incolæ territorii*, chose twelve electors, and they nominated three persons, *ex quibus rex unum confirmabit*. But, with us in England, these popular elections, growing tumultuous, were put an end to by the statute 9 Edw. II. st. 2. which enacted, that the sheriffs should from thenceforth be assigned by the chancellor, treasurer, and the judges; as being persons in whom the same trust might with confidence be reposed. By statutes 14 Edw. III. c. 7. 23 Hen. VI. c. 8. and 21 Hen. VIII. c. 20. the chancellor, treasurer, president of the king's council, chief justices, and chief baron, are to make this election; and that on the morrow of All Souls, in the exchequer. And the king's letters patent, appointing the new sheriffs, used commonly to bear date the sixth day of November. The statute of Cambridge, 12 Ric. II. c. 2. ordains, that the chancellor, treasurer, keeper of the privy-seal, steward of the king's house, the king's chamberlain, clerk of the rolls, the justices of the one bench and the other, barons of the exchequer, and all other that shall be called to ordain, name, or make justices of the peace, sheriffs, and other officers of the king, shall be sworn to act indifferently, and to name no man that sueth to be put in office, but such only as they shall judge to be the best and most sufficient. And the custom now is (and has been at least ever since the time of Fortescue, who was chief-justice and chancellor to Henry the sixth), that all the judges, together with the other great officers, meet in the exchequer chamber on the morrow of All Souls yearly, (which day is now altered to the morrow

of

Sheriff. of St Martin by the last act for abbreviating Michaelmas term), and then and there propose three persons to the king, who afterwards appoints one of them to be sheriff. This custom of the twelve judges proposing three persons seems borrowed from the Gothic constitution before-mentioned: with this difference, that among the Goths the 12 nominors were first elected by the people themselves. And this usage of ours, at its first introduction, there is reason to believe, was founded upon some statute, though not now to be found among our printed laws; first, because it is materially different from the direction of all the statutes before-mentioned; which it is hard to conceive that the judges would have countenanced by their concurrence, or that Fortescue would have inserted in his book, unless by the authority of some statute; and also, because a statute is expressly referred to in the record, which Sir Edward Coke tells us he transcribed from the council-book of 3d March, 34 Hen. VI. and which is in substance as follows. The king had of his own authority appointed a man sheriff of Lincolnshire, which office he refused to take upon him; whereupon the opinions of the judges were taken, what should be done in this behalf. And the two chief justices, Sir John Fortescue and Sir John Prisot, delivered the unanimous opinion of them all; "that the king did an error when he made a person sheriff that was not chosen and presented to him according to the statute; that the person refusing was liable to no fine for disobedience, as if he had been one of the three persons chosen according to the tenor of the statute; that they would advise the king to have recourse to the three persons that were chosen according to the statute, or that some other thrifty man be intreated to occupy the office for this year; and, that the next year, to eschew such inconveniences, the order of the statute in this behalf made be observed." But, notwithstanding this unanimous resolution of all the judges of England, thus entered in the council-book, and the statute 34 and 35 Hen. VIII. c. 26. § 61. which expressly recognizes this to be the law of the land, some of our writers have affirmed, that the king, by his prerogative, may name whom he pleases to be sheriff, whether chosen by the judges or not. This is grounded on a very particular case in the fifth year of queen Elizabeth, when, by reason of the plague, there was no Michaelmas term kept at Westminster; so that the judges could not meet there *in crastino animarum* to nominate the sheriffs: whereupon the queen named them herself, without such previous assembly, appointing for the most part one of two remaining in the last year's list. And this case, thus circumstanced, is the only authority in our books for the making these extraordinary sheriffs. It is true, the reporter adds, that it was held that the queen by her prerogative might make a sheriff without the election of the judges, *non obstante aliquo statuto in contrarium*; but the doctrine of *non obstante*, which sets the prerogative above the laws, was effectually demolished by the bill of rights at the revolution, and abdicated Westminster-hall when king James abdicated the kingdom. However, it must be acknowledged, that the practice of occasionally naming what are called *pocket-sheriffs*, by the sole authority of the crown, hath uniformly continued to the reign of his present majesty; in which, it is believed, few (if any) instances have occurred.

Sheriffs, by virtue of several old statutes, are to continue in their office no longer than one year; and yet it hath been said that a sheriff may be appointed *durante bene placito*, or during the king's pleasure; and so is the form of the royal writ. Therefore, till a new sheriff be named, his office cannot be determined, unless by his own death, or the demise of the king; in which last case it was usual for the successor to send a new writ to the old sheriff; but now, by statute 1 Anne st. 1. c. 8. all officers appointed by the preceding king may hold their offices for six months after the king's demise, unless sooner displaced by the successor. We may farther observe, that by statute 1 Ric. II. c. 11. no man that has served the office of sheriff for one year can be compelled to serve the same again within three years after.

We shall find it is of the utmost importance to have the sheriff appointed according to law, when we consider his power and duty. These are either as a judge, as the keeper of the king's peace, as a ministerial officer of the superior courts of justice, or as the king's bailiff.

In his judicial capacity he is to hear and determine all causes of 40 shillings value and under, in his county-court: and he has also a judicial power in divers other civil cases. He is likewise to decide the elections of knights of the shire, (subject to the controul of the House of Commons), of coroners, and of verderors; to judge of the qualification of voters, and to return such as he shall determine to be duly elected.

As the keepers of the king's peace, both by common law and special commission, he is the first man in the county, and superior in rank to any nobleman therein, during his office. He may apprehend, and commit to prison, all persons who break the peace, or attempt to break it; and may bind any one in a recognizance to keep the king's peace. He may, and is bound, *ex officio*, to pursue and take all traitors, murderers, felons, and other misdoers, and commit them to gaol for safe custody. He is also to defend his county against any of the king's enemies when they come into the land; and for this purpose, as well as for keeping the peace and pursuing felons, he may command all the people of his county to attend him; which is called the *posse comitatus*, or power of the county; which summons, every person above 15 years old, and under the degree of a peer, is bound to attend upon warning, under pain of fine and imprisonment. But though the sheriff is thus the principal conservator of the peace in his county, yet, by the express directions of the great charter, he, together with the constable, coroner, and certain other officers of the king, are forbidden to hold any pleas of the crown, or, in other words, to try any criminal offence. For it would be highly unbecoming, that the executioners of justice should be also the judges; should impose, as well as levy, fines and amercements; should one day condemn a man to death, and personally execute him the next. Neither may he act as an ordinary justice of the peace during the time of his office; for this would be equally inconsistent, he being in many respects the servant of the justices.

In his ministerial capacity, the sheriff is bound to execute all process issuing from the king's courts of justice. In the commencement of civil causes, he is to serve the writ, to arrest, and to take bail; when the cause comes to trial he must summon and return the jury; when it is determined, he must see the judgment of of the court carried into execution. In criminal matters, he also arrests and imprisons, he returns the jury, he has the custody of the delinquent, and he executes the sentence of the court, though it extend to death itself.

As the king's bailiff, it is his business to preserve the rights of the king within his bailiwick; for so his county is frequently called in the writs: a word introduced by the princes of the Norman line; in imitation of the French, whose territory is divided into bailiwicks, as that of England into counties. He must seize to the king's use all lands devolved to the crown by attainder or escheat; must levy all fines and forfeitures, must seize and keep all waifs, wrecks, estrays, and the like, unless they be granted to some subject; and must also collect the king's rents within his bailiwick, if commanded by process from the exchequer.

To execute these various offices, the sheriff has under him many inferior officers; an under-sheriff, bailiffs, and gaolers, who must neither buy, sell, nor farm their offices, on forfeiture of 500 l.

The under-sheriff usually performs all the duties of the office; a very few only excepted, where the personal presence of the high-sheriff is necessary. But no under-sheriff shall abide in his office above one year; and if he does, by statute 23 Hen. VI. c. 8. he forfeits 200l. a very large penalty in those early days. And no under-sheriff or sheriff's officer shall practise as an attorney during the time he continues in such office: for this would be a great inlet to partiality and oppression. But these salutary regulations are shamefully evaded, by practising in the names of other attorneys, and putting in sham deputies by way of nominal under-sheriffs: by reason of which, says Dalton, the under-sheriffs and bailiffs do grow so cunning in their several places, that they are able to deceive, and it may well be feared that many of them do deceive, both the king, the high-sheriff, and the county.

Sheriff, in Scotland. See Law, Part iii. sect. 3.

SHERLOCK (William), a learned English divine in the 17th century, was born in 1641, and educated at Eaton school, where he distinguished himself by the vigour of his genius and his application to study. Thence he was removed to Cambridge, where he took his degrees. In 1669 he became rector of the parish of St George, Botolph-lane, in London; and in 1681 was collated to the prebend of Pancras, in the cathedral of St Paul's. He was likewise chosen master of the Temple, and had the rectory of Therfield in Hertfordshire. After the Revolution he was suspended from his preferment, for refusing the oaths to king William and queen Mary; but at last he took them, and publicly justified what he had done. In 1691 he was installed dean of St Paul's. His Vindication of the Doctrine of the Trinity engaged him in a warm controversy with Dr South and others. Bishop Burnet tells us, he was "a clear, a polite, and a strong writer; but apt to assume too much to himself, and to treat his adversaries with contempt." He died in 1707. His works are very numerous; among these are, 1. A discourse concerning the knowledge of Jesus Christ, against Dr Owen. 2. Several pieces against the Papists, the Socinians, and Dissenters. 3. A practical Treatise on Death, which is much admired. 4. A practical Discourse on Providence. 5. A practical Discourse on the future Judgment; and many other works.

Sherlock (Dr Thomas), bishop of London, was the son of the preceding Dr William Sherlock, and was born in 1678. He was educated in Catherine-hall, Cambridge, where he took his degrees, and of which he became master: he was made master of the Temple very young, on the resignation of his father; and it is remarkable that this mastership was held by father and son successively for more than 70 years. He was at the head of the opposition against Dr Hoadley bishop of Bangor; during which contest he published a great number of pieces. He attacked the famous Collins's "Grounds and Reasons of the Christian Religion," in a course of six sermons, preached at the Temple-church, which he entitled, "The use and Intent of Prophecy in the several Ages of the World." In 1728, Dr Sherlock was promoted to the bishopric of Bangor; and was translated to Salisbury in 1734. In 1747 he refused the archbishopric of Canterbury, on account of his ill state of health; but recovering in a good degree, accepted the see of London the following year. On occasion of the earthquakes in 1750, he published an excellent Pastoral Letter to the clergy and inhabitants of London and Westminster: of which it is said there were printed in 4to, 5000; in 8vo, 20,000; and in 12mo, about 30,000; besides pirated editions, of which not less than 50,000 were supposed to have been sold. Under the weak state of body in which he lay for several years, he revised and published 4 vols of sermons in 8vo, which are particularly admired for their ingenuity and elegance. He died in 1762, and by report worth 150,000l. "His learning," says Dr Nicholas, "was very extensive: God had given him a great and an understanding mind, a quick comprehension, and a solid judgment. These advantages of nature he improved by much industry and application. His skill in the civil and canon law was very considerable; to which he had added such a knowledge of the common law of England as few clergymen attain to. This it was that gave him that influence in all causes where the church was concerned; as knowing precisely what it had to claim from its constitutions and canons, and what from the common law of the land." Dr Nicholas then mentions his constant and exemplary piety, his warm and fervent zeal in preaching the duties and maintaining the doctrines of Christianity, and his large and diffusive munificence and charity; particularly by his having given large sums of money to the corporation of clergymen's sons, to several of the hospitals, and to the society for propagating the Gospel in foreign parts; also his bequeathing to Catharine-hall in Cambridge, the place of his education, his valuable library of books, and his donations for the founding a librarian's place and a scholarship, to the amount of several thousand pounds.

SHERRIFFE of Mecca, the title of the descendants of Mahomet by Hassan Ibn Ali. These are divided into several branches, of which the family of Ali Bunemi, consisting at least of three hundred individuals, enjoy the sole right to the throne of Mecca. The Ali Bunemi are, again, subdivided into two subordinate branches, Darii Sajid, and Darii Barkad; of whom sometimes the one, sometimes the other, have given sovereigns to Mecca and Medina, when these were separate states.

Not only is the Turkish Sultan indifferent about the order of succession in this family, but he seems even to foment the diſſenſions which ariſe among them, and favours the ſtrongeſt, merely that he may weaken them all. As the order of ſucceſſion is not determinately fixed, and the ſherriffes may all aſpire alike to the ſovereign power, this uncertainty of right, aided by the intrigues of the Turkiſh officers, occaſions frequent revolutions. The grand ſherriffe is ſeldom able to maintain himſelf on the throne; and it ſtill ſeldomer happens that his reign is not diſturbed by the revolt of his neareſt relations. There have been inſtances of a nephew ſucceeding his uncle, an uncle ſucceeding his nephew; and ſometimes of a perſon, from a remote branch, coming in the room of the reigning prince of the ancient houſe.

When Niebuhr was in Arabia, in 1763, the reigning Sherriffe Meſad had ſitten fourteen years on the throne, and, during all that period, had been continually at war with the neighbouring Arabs, and with his own neareſt relations ſometimes. A few years before, the Pacha of Syria had depoſed him, and raiſed his younger brother to the ſovereign dignity in his ſtead. But after the departure of the caravan, Jafar, the new ſherriffe, not being able to maintain himſelf on the throne, was obliged to reſign the ſovereignty again to Meſad. Achmet, the ſecond brother of the ſherriffe, who was much beloved by the Arabs, threatened to attack Mecca while Niebuhr was at Jidda. Our traveller was ſoon after informed of the termination of the quarrel, and of Achmet's return to Mecca, where he continued to live peaceably in a private character.

Theſe examples ſhow that the Muſſulmans obſerve not the law which forbids them to bear arms againſt their holy places. An Egyptian Bey even preſumed, a few years ſince, to plant ſome ſmall cannons within the compaſs of the Kaba, upon a ſmall tower, from which he fired over that ſacred manſion, upon the palace of Sherriffe Meſad, with whom he was at variance.

The dominions of the ſherriffe comprehend the cities of Mecca, Medina, Jambo, Taif, Sadie, Ghunfude, Hali, and thirteen others leſs conſiderable, all ſituated in Hedjas. Near Taif is the lofty mountain of Gazvan, which, according to Arabian authors, is covered with ſnow in the midſt of ſummer. As theſe dominions are neither opulent nor extenſive, the revenue of their ſovereign cannot be conſiderable.

He finds a rich reſource, however, in the impoſts levied on pilgrims, and in the gratuities offered him by Muſſulman monarchs. Every pilgrim pays a tax of from ten to an hundred crowns, in proportion to his ability. The Great Mogul remits annually ſixty thouſand roupees to the ſherriffe, by an aſſignment upon the government of Surat. Indeed, ſince the Engliſh made themſelves maſters of this city, and the territory belonging to it, the Nabob of Surat has no longer been able to pay the ſum. The ſherriffe once demanded it of the Engliſh, as the poſſeſſors of Surat; and, till they ſhould ſatisfy him, forbade their captains to leave the port of Jidda. But the Engliſh diſregarding this prohibition, the ſherriffe complained to the Ottoman Porte, and they communicated his complaints to the Engliſh anbaſſador. He at the ſame time opened a negociation with the nominal Nabob, who reſides in Surat. But theſe ſteps proved all fruitleſs: and the ſovereign of Mecca ſeems not likely to be ever more benefited by the contribution from India.

The power of the ſherriffe extends not to ſpiritual matters; theſe are entirely managed by the heads of the clergy, of different ſects, who are reſident at Mecca. Rigid Muſſulmans, ſuch as the Turks, are not very favourable in their ſentiments of the ſherriffes, but ſuſpect their orthodoxy, and look upon them as ſecretly attached to the tolerant ſect of the Zeidi.

SHETLAND, the name of certain iſlands belonging to Scotland, and lying to the northward of Orkney. There are many convincing proofs that theſe iſlands were very early inhabited by the Picts, or rather by thoſe nations who were the original poſſeſſors of the Orkneys; and at the time of the total deſtruction of theſe nations, if any credit be due to tradition, their woods were entirely ruined (A). It is highly probable that the people in Shetland, as well as in the Orkneys, flouriſhed under their own princes dependent upon the crown of Norway; yet this ſeems to have been rather through what they acquired by fiſhing and commerce, than by the cultivation of their lands. It may alſo be reaſonably preſumed, that they grew thinner of inhabitants after they were annexed to the crown of Scotland; and it is likely that they revived again, chiefly by the very great and extenſive improvements which the Dutch made in the herring-fiſhery upon their coaſts, and the trade that the crews of their buſſes, then very numerous, carried on with the inhabitants, neceſſarily reſulting from their want of proviſions and other conveniencies, which in thoſe days could not be very conſiderable.

There are many reaſons which may be aſſigned why theſe iſlands, though part of the Britiſh dominions, have not hitherto been better known. They were commonly placed two degrees too far to the north in all the old maps, in order to make them agree with Ptolemy's deſcription of Thule, which he aſſerted to be in the latitude of 63 degrees; which we find urged by Camden as a reaſon why Thule muſt be one of the Shetland iſles, to which Speed alſo agrees, though from their being thus wrong placed he could not find room for them in his maps. Another, and that no light cauſe, was the many falſe, fabulous, and impertinent relations publiſhed concerning them (B), as if they were countries inhoſpitable and uninhabitable; and laſtly, the indolence, or rather indifference, of the natives, who, contenting themſelves

(A) The tradition is, that this was done by the Scots when they deſtroyed the Picts; but is more probably referred to the Norwegians rooting out the original poſſeſſors of Shetland.

(B) They repreſented the climate as intenſely cold; the ſoil as compoſed of crags and quagmire, ſo barren as to be incapable of bearing corn; to ſupply which, the people, after drying fiſh-bones, powdered them, then kneaded and baked them for bread. The large fiſh-bones were ſaid to be all the fuel they had. Yet, in ſo dreary a country, and in ſuch miſerable circumſtances, they were acknowledged to be very long-lived, cheerful, and contented.

Shetland.

themselves with those necessaries and conveniences procured by their intercourse with other nations, and conceiving themselves neglected by the mother country, have seldom troubled her with their applications.

There are few countries that have gone by more names than these islands; they were called in Islandic, *Hialtlandia*, from *hialt*, the " the hilt of a sword ;" this might be possibly corrupted into *Hetland*, *Hitland*, or *Hethland*, though some tell us this signifies a " high land." they have been likewise, and are still in some maps, called *Zetland* and *Zealand*, in reference, as has been supposed, to their situation. By the Danes, and by the natives, they are styled *Yealtaland;* and notwithstanding the oddness of the orthography, this differs very little, if at all, from their manner of pronouncing Zetland, out of which pronunciation grew the modern names of *Shetland* and *Shotland*.

The islands of *Shetland* as we commonly call them, are well situated for trade. The nearest continent to them is Norway; the port of Bergen lying 44 leagues east, whereas they lie 46 leagues north north-east from Buchanness; east north-east from Sanda, one of the Orkneys, about 16 or 18 leagues ; six or seven leagues north-east from Fair Isle ; 58 leagues east from the Ferroe isles; and at nearly the same distance north-east from Lewis. The southern promontory of the main land, called *Sumburgh Head*, lies in 59 degrees and 59 minutes of north latitude; and the northern extremity of Unst, the most remote of them all, in the latitude of 61 degrees 15 minutes. The meridian of London passes through this last island, which lies about 2 degrees 30 minutes west from Paris, and about 5 degrees 15 minutes east from the meridian of Cape Lizard. According to Gifford's " Historical Description of Zetland," the inhabited islands are 33, of which the principal is styled *Main Land*, and extends in length from north to south about 60 miles, and is in some places 20 broad, though in others not more than two.

It is impossible to speak with precision; but, according to the best computation which we have been able to form, the Shetland isles contain near three times as much land as the Orkneys: they are considered also as equal in size to the island of Madeira; and not inferior to the provinces of Utrecht, Zealand, and all the rest of the Dutch islands taken together; but of climate and soil they have not much to boast. The longest day in the island of Unst is 19 hours 15 minutes, and of consequence the shortest day 4 hours and 45 minutes. The spring is very late, the summer very short; the autumn also is of no long duration, dark, foggy, and rainy; the winter sets in about November, and lasts till April, and sometimes till May. They have frequently in that season storms of thunder, much rain, but little frost or snow. High winds are indeed very frequent and very troublesome, yet they seldom produce any terrible effects. The aurora borealis is as common here as in any of the northern countries. In the winter season the sea swells and rages in such a manner, that for five or six months their ports are inaccessible, and of course the people during that space have no correspondence with the rest of the world.

The soil in the interior part of the main land, for the most part, is mountainous, moorish, and boggy, yet not to such a degree as to render the country utterly impassable; for many of the roads here, and in some of the northern isles, are as good as any other natural roads, and the people travel them frequently on all occasions. Near the coast there are sometimes for miles together flat pleasant spots, very fertile both in pasture and corn. The mountains produce large crops of very nutritive grass in the summer; and they cut considerable quantities of hay, with which they feed their cattle in the winter. They might with a little attention bring more of their country into cultivation: but the people are so much addicted to their fishery, and feel so little necessity of having recourse to this method for subsistence, that they are content, how strange soever that may seem to us, to let four parts in five of their land remain in a state of nature.

They want not considerable quantities of marle in different islands, though they use but little; hitherto there has been no chalk found ; limestone and freestone there are in the southern parts of the main land in great quantities, and also in the neighbouring islands particularly Fetlar ; and considerable quantities of slate, very good in its kind. No mines have been hitherto wrought, though there are in many places visible appearances of several kinds of metal. Some solid pieces of silver, it is said have been turned up by the plough. In some of the smaller isles there are strong appearances of iron ; but, through the want of proper experiments being made, there is in this respect at least, hitherto nothing certain. Their meadows are inclosed with dikes, and produce very good-grass. The little corn they grow is chiefly barley, with some oats ; though even in the northern extremity of Unst the little land which they have is remarkable for its fertility. The hills abound with medicinal herbs; and their kitchen-gardens thrive as well, and produce as good greens and roots, as any in Britain. Of late years, and since this has been attended to, some gentlemen have had even greater success than they expected in the cultivating of tulips, roses, and many other flowers. They have no trees, and hardly any shrubs except juniper, yet they have a tradition that their country was formerly overgrown with woods ; and it seems to be a confirmation of this, that the roots of timber-trees have been, and are still, dug up a great depth ; and that in some, and these too inaccessible, places, the mountain ash is still found growing wild. That this defect, *viz.* the want of wood at present does not arise entirely from the soil or climate, appears from several late experiments ; some gentlemen having raised ash, maple, horse chesnuts, &c. in their gardens. Though the inhabitants are without either wood or coals, they are very well supplied with fuel, having great plenty of heath and peat. The black cattle in this country are in general of a larger sort than in Orkney, which is owing to their having more extensive pastures ; a clear proof that still farther improvements might be made in respect to size. Their horses are small, but strong, stout, and well-shaped, live very hardy, and to a great age. They have likewise a breed of small swine, the flesh of which, when fat, is esteemed very delicious. They have no goats, hares, or foxes; and in general no wild or venomous creatures of any kind except rats in some few islands. They have no moor-fowl, which is the more remarkable, as there are everywhere immense quantities of heath ; but there are many sorts of wild and water fowl, particularly the dunter-goose, clack-goose, solan-goose, swans, ducks, Shetland.

ducks, teal, whaps, foists, lyres, kittiwaiks, maws, plovers, cormorants, &c. There is likewise the amber-goose, which is said to hatch her egg under her wing. Eagles and hawks, as also ravens, crows, mews, &c. abound here.

All these islands are well watered; for there are everywhere excellent springs, some of them mineral and medicinal. They have inded no rivers; but many pleasant rills or rivulets, which they call *burns*, of different sizes; in some of the largest they have admirable trouts, some of which are of 15 and even of 20 pounds weight. They have likewise many fresh-water lakes, well stored with trout and eels, and in most of them there are also large and fine flounders; in some very excellent cod. These fresh-water lakes, if the country was better peopled, and the common people more at their ease, are certainly capable of great improvements. The sea-coasts of the main land of Shetland, in a straight line, are 55 leagues; and therefore there cannot be a country conceived more proper for establishing an extensive fishery. What the inhabitants have been hitherto able to do, their natural advantages considered, does not deserve that name, notwithstanding they export large quantities of cod, tusk, ling, and skate, insomuch that the bounty allowed by acts of parliament amounts from L. 1400 to L. 2000 annually. They have, besides, haddocks, whitings, turbot, and a variety of other fish. In many of the inlets there are prodigious quantities of excellent oysters, lobsters, muscles, cockles, and other shell-fish. As to amphibious creatures, they have multitudes of otters and seals; add to these, that amber, ambergris, and other spoils of the ocean, are frequently found upon the coasts.

The inhabitants are a stout, well-made, comely people; the lower sort of a swarthy complexion. The gentry are allowed, by all who have conversed with them, to be most of them polite, shrewd, sensible, lively, active, and intelligent persons; and these, to the number of 100 families, have very handsome, strong, well-built houses, neatly furnished; their tables well served, polished in their manners, and exceedingly hospitable and civil to strangers. Those of an inferior rank are a hardy, robust, and laborious people, who, generally speaking, get their bread by fishing in all weathers in their yawls, which are little bigger than Gravesend wherries; live hardily, and in the summer season mostly on fish; their drink, which, in reference to the British dominions, is peculiar to the country, is called *bland*, and is a sort of butter-milk, long kept, and very sour. Many live to great ages, though not so long as in former times. In respect, however, to the bulk of the inhabitants, from the poorness of living, from the nature of it, and from the drinking great quantities of corn-spirits of the very worst sort, multitudes are afflicted with an inveterate scurvy; from which those in better circumstances are entirely free, and enjoy as good health as in any other country in Europe. As they have no great turn to agriculture, and are persuaded that their country is not fit for it, they do not (though probably they might) raise corn enough to support them for more than two-thirds of the year. But they are much more successful in their pasture-grounds, which are kept well inclosed, in good order, and, together with their commons, supply them plentifully with beef and mutton. They pay their rents generally in butter at Lammas, and in money at Martinmas. As to manufactures, they make a strong coarse cloth for their own use, as also linen. They make likewise of their own wool very fine stockings. They export, besides the different kinds of fish already mentioned, some herrings, a considerable quantity of butter and train-oil, otter and seal skins, and no inconsiderable quantity of the fine stockings just mentioned. Their chief trade is to Leith, London, Hamburgh, Spain, and to the Straits. They import timbers, deals, and some of their best oats, from Norway; corn and flour from the Orkneys, and from North Britain; spirits, and some other things from Hamburgh; cloths and better sort of linen from Leith; grocery, household furniture, and other necessaries from London. The superior-duties to the earl of Morton are generally let in farm; and are paid by the people in butter, oil, and money. The remains of the old Norwegian constitution are still visible in the division of their lands; and they have some udalmen or freeholders amongst them. But the Scots laws, customs, manners, dress, and language, prevail; and they have a sheriff, and other magistrates for the administration of justice, as well as a customhouse, with a proper number of officers. In reference to their ecclesiastical concerns, they have a presbytery, 12 ministers, and an itinerant for Foula, Fair Island, and the Skerries. Each of these ministers has a stipend of between 40 and 50 pounds, besides a house and glebe free from taxes. The number of souls in these islands may be about 20,000.

Shew-bread, Shield.

SHEW-BREAD, the loaves of bread which the priest of the week put every Sabbath-day upon the golden-table in the sanctuary, before the Lord, in the temple of the Jews. They were twelve in number, and were offered to God in the name of the twelve tribes of Israel. They were shaped like a brick, were ten palms long and five broad, weighed about eight pounds each. They were unleavened, and made of fine flour by the Levites. The priests set them on the table in two rows, six in a row, and put frankincense upon them to preserve them from moulding. They were changed every Sabbath, and the old ones belonged to the priest upon duty. Of this bread none but the priests might eat, except in cases of necessity. It was called the *bread of faces*, because the table of the shew-bread, being almost over against the ark of the covenant, the loaves might be said to be set before the face of God. The original table was carried away to Babylon, but a new one was made for the second temple. It was of wood overlaid with gold. This, with the candlestick and some other spoils, was carried by Titus to Rome.

SHIELD, an ancient weapon of defence, in form of a light buckler, borne on the arm to fend off lances, darts, &c. The form of the shield is represented by the escutcheon in coats of arms. The shield was that part of the ancient armour on which the persons of distinction in the field of battle always had their arms painted; and most of the words used at this time to express the space that holds the arms of families are derived from the Latin name for a shield, *scutum*. The French *escu* and *escusson*, and the English word *escutcheon*, or, as we commonly speak it, *scutcheon*, are evidently from this origin; and the Italian *scudo* signifies both the shield of arms and that used in war. The Latin name *clypeus*, for the same thing, seems also to be derived from the

the Greek word γλυφειν, *to engrave;* and it had this name from the several figures engraved on it, as marks of distinction of the person who wore it.

The shield in war, among the Greeks and Romans, was not only useful in the defence of the body, but it was also a token, or badge of honour, to the wearer; and he who returned from battle without it was always treated with infamy afterwards. People have at all times thought this honourable piece of the armour the properest place to engrave, or figure on the signs of dignity of the possessor of it; and hence, when arms came to be painted for families in aftertimes, the heralds always chose to represent them upon the figure of a shield, but with several exterior additions and ornaments; as the helmet, supporters, and the rest.

The form of the shield has not only been found different in various nations, but even the people of the same nation, at different times, have varied its form extremely; and among several people there have been shields of several forms and sizes in use, at the same period of time, and suited to different occasions. The most ancient and universal form of shields, in the earlier ages, seems to have been the triangular. This we see instances of in all the monuments and gems of antiquity: our own most early monuments show it to have been the most antique shape also with us, and the heralds have found it the most convenient for their purposes, when they had any odd number of figures to represent; as if three, then two in the broad bottom part, and one in the narrow upper end, it held them very well; or if five, they stood as conveniently, as three below, and two above. The other form of a shield, now universally used, is square, rounded, and pointed at the bottom: this is taken from the figure of the Samnitic shield used by the Romans, and since copied very generally by the English, French, and Germans.

The Spaniards and Portuguese have the like general form of shields, but they are round at the bottom without the point; and the Germans, beside the Samnite-shield, have two others pretty much in use: these are, 1. The bulging shield, distinguished by its swelling or bulging out at the flanks; and, 2. The indented shield, or shield chancree, which has a number of notches and indentings all round its sides. The use of the ancient shield of this form was, that the notches served to rest the lance upon, that it might be firm while it gave the thrust; but this form being less proper for the receiving armorial figures, the two former have been much more used in the heraldry of that nation.

Beside this different form of the shields in heraldry, we find them also often distinguished by their different positions, some of them standing erect, and others slanting various ways, and in different degrees; this the heralds express by the word *pendant*, "hanging," they seeming to be hung up not by the centre, but by the right or left corner. The French call these *ecu pendant*, and the common antique triangular ones *ecu ancien*. The Italians call this *scuto pendente;* and the reason given for exhibiting the shield in these figures in heraldry is, that in the ancient tilts and tournaments, they who were to just at these military exercises, were obliged to hang up their shields with their armories, or coats of arms on them, out at the windows and balconies of the houses near the place; or upon trees, pavilions, or the barriers of the ground, if the exercise was to be performed in the field.

Those who were to fight on foot, according to Columbier, had their shields hung up by the right corner, and those who were to fight on horseback had theirs hung up by the left. This position of the shields in heraldry is called *couche* by some writers, though by the generality *pendant*.

It was very frequent in all parts of Europe, in arms given between the 11th and 14th centures; but it is to be observed, that the hanging by the left corner, as it was the token of the owner's being to fight on horseback, so it was esteemed the most honourable and noble situation; and all the pendant shields of the sons of the royal family of Scotland and England of the nobility at that time, are thus hanging from the left corner. The hanging from this corner was a token of the owner's being of noble birth, and having fought in the tournaments before; but no sovereign ever had a shield pendant any way, but always erect, as they never formally entered the lists of the tournament.

The Italians generally have their shields of arms of an oval form; this seems to be done in imitation of those of the popes and other dignified clergy: but their herald Petro Sancto seems to regret the use of this figure of the shield, as an innovation brought in by the painters and engravers as most convenient for holding the figures, but derogatory to the honour of the possessor, as not representing either antiquity or honours won in war, but rather the honours of some citizen or person of learning. Some have carried it so far as to say, that those who either have no ancient title to nobility, or have sullied it by any unworthy action, cannot any longer wear their arms in shields properly figured, but were obliged to have them painted in an oval or round shield.

In Flanders, where this author lived, the round and oval shields are in the disrepute he speaks of; but in Italy, beside the popes and dignified prelates, many of the first families of the laity have them.

The secular princes, in many other countries, also retain this form of the shield, as the most ancient and truly expressive of the Roman clypeus.

Shield, in heraldry, the escutcheon or field on which the bearings of coats of arms are placed. See Heraldry.

SHIELDRAKE, in ornithology. See Anas.

SHIELDS, North and South, two sea-port towns, the one north of the Tyne in Northumberland, the other on the south of the Tyne in the county of Durham. South Shields contains above 200 salt-pans, and on both banks of the river are many convenient houses for the entertainment of seamen and colliers, most of the Newcastle coal fleet having their station here usually till their coals are brought down in the barges and lighters from Newcastle. A very large Roman altar, of one entire stone, was found some years ago near this place, and put into the hands of the learned Dr Lister, who, in his account of it sent to the Royal Society, says it was erected to Marcus Aurelius Antoninus Caracalla, when he took upon him the command of the empire and the whole army (after his father's death at York), for his safe return from his successful expedition against the Scots and Picts. W. Long. 1. 12. N. Lat. 55. 44.

Shifters. || Shilling.

SHIFTERS, on board a man of war, certain men who are employed by the cooks to ſhift and change the water in which the fleſh or fiſh is put, and laid for ſome time, in order to fit it for the kettle.

SHIFTING A TACKLE, in ſea language, the act of removing the blocks of a tackle to a greater diſtance from each other, on the object to which they are applied in order to give a greater ſcope or extent to their purchaſe. This operation is otherwiſe called *fletting*. Shifting the helm denotes the alteration of its poſition, by puſhing it towards the oppoſite ſide of the ſhip. Shifting the voyal, ſignifies changing its poſition on the capſtern, from the right to the left, and *vice verſa*.

SHILLING, an Engliſh ſilver coin equal to twelve pence or the twentieth part of a pound.

Freherus derives the Saxon *ſcilling*, whence our ſhilling, from a corruption of *ſiliqua*; proving the derivation by ſeveral texts of law, and, among others, by the 26th law, *De annuis legatis*. Skinner deduces it from the Saxon *ſcilid* "ſhield," by reaſon of the eſcutcheon of arms thereon.

Biſhop Hooper derives it from the Arabic *ſchecle*, ſignifying *a weight*; but others, with greater probability, deduce it from the Latin *ſicilicus*, which ſignified in that language *a quarter of an ounce*, or the 48th part of a Roman pound. In confirmation of this etymology it is alleged, that the ſhilling kept its original ſignification, and bore the ſame proportion to the Saxon pound as ſicilicus did to the Roman and the Greek, being exactly the 48th part of the Saxon pound; a diſcovery which we owe to Mr Lambarde*.

*Explicatio Rerum et Verborum in Leg. Sax. voc. Libra.

However, the Saxon laws reckon the pound in the round number at 50 ſhillings, but they really coined out of it only 48; the value of the ſhilling was fivepence; but it was reduced to fourpence above a century before the conqueſt; for ſeveral of the Saxon laws, made in Athelſtan's reign, oblige us to take this eſtimate. Thus it continued to the Norman times, as one of the Conqueror's laws ſufficiently aſcertains; and it ſeems to have been the common coin by which the Engliſh payments were adjuſted. After the conqueſt, the French *ſolidus* of twelvepence, which was in uſe among the Normans, was called by the Engliſh name of ſhilling; and the Saxon ſhilling of fourpence took a Norman name, and was called the *groat*, or great coin, becauſe it was the largeſt Engliſh coin then known in England.

It has been the opinion of the biſhops Fleetwood and Gibſon, and of the antiquaries in general, that, though the method of reckoning by pounds, marks, and ſhillings, as well as by pence and farthings, had been in conſtant uſe even from the Saxon times, long before the Norman conqueſt, there never was ſuch a coin in England as either a pound or a mark, nor any ſhilling, till the year 1504 or 1505, when a few ſilver ſhillings or twelve-pences were coined, which have long ſince been ſolely confined to the cabinets of collectors.

Mr Clark combats this opinion, alleging that ſome coins mentioned by Mr Folkes, under Edward I. were probably Saxon ſhillings new minted, and that archbiſhop Aelfric expreſsly ſays†, that the Saxons had three names for their money, viz. mancuſes, ſhillings, and pennies. He alſo urges the different value of the Saxon ſhilling at different times, and its uniform proportion to the pound, as an argument that their ſhilling was a coin; and the teſtimony of the Saxon goſpels, in which the word we have tranſlated *pieces of ſilver* is rendered *ſhillings*, which, he ſays, they would hardly have done, if there had been no ſuch coin as a ſhilling then in uſe. Accordingly the Saxons expreſſed their ſhilling in Latin by *ſiclus* and *argenteus*. He farther adds, that the Saxon ſhilling was never expreſſed by *ſolidus* till after the Norman ſettlements in England; and howſoever it altered during the long period that elapſed from the conqueſt to the time of Henry VII. it was the moſt conſtant denomination of money in all payments, though it was then only a ſpecies of account, or the twentieth part of the pound Sterling: and when it was again revived as a coin, it leſſened gradually as the pound Sterling leſſened, from the 28th of Edward III. to the 43d of Elizabeth.

† Gram. Saxon, p. 52.

Shilling, Shiloh.

In the year 1560 there was a peculiar ſort of ſhilling ſtruck in Ireland, of the value of ninepence Engliſh, which paſſed in Ireland for twelvepence. The motto on the reverſe was, *poſui Deum adjutorem meum*. Eighty-two of theſe ſhillings, according to Malynes, went to the pound; they therefore weighed 20 grains, one-fourth each, which is ſomewhat heavier in proportion than the Engliſh ſhilling of that time, 62 whereof went to the pound, each weighing 92 grains ſeven-eighths; and the Iriſh ſhilling being valued at the Tower at ninepence Engliſh, that is, one-fourth part leſs than the Engliſh ſhilling, it ſhould therefore proportionably weigh one-fourth part leſs, and its full weight be ſomewhat more than 62 grains; but ſome of them found at this time, though much worn, weighed 69 grains. In the year 1598, five different pieces of money of this kind were ſtruck in England for the ſervice of the kingdom of Ireland. Theſe were ſhillings to be current in Ireland at twelvepence each; half ſhillings to be current at ſixpence, and quarter ſhillings at threepence. Pennies and halfpennies were alſo ſtruck of the ſame kind, and ſent over for the payment of the army in Ireland. The money thus coined was of a very baſe mixture of copper and ſilver; and two years after there were more pieces of the ſame kinds ſtruck for the ſame ſervice, which were ſtill worſe; the former being three ounces of ſilver to nine ounces of copper; and theſe latter only two ounces eighteen pennyweights to nine ounces two pennyweights of the alloy.

The Dutch, Flemiſh, and Germans, have likewiſe their ſhilling, called *ſchelin*, *ſchilling*, *ſcalin*, &c. but theſe not being of the ſame weight or fineneſs with the Engliſh ſhilling, are not current at the ſame value. The Engliſh ſhilling is worth about 23 French ſols; thoſe of Holland and Germany about 11 ſols and an half; thoſe of Flanders about nine. The Dutch ſhillings are alſo called *ſols de gros*, becauſe equal to twelve gros. The Danes have copper ſhillings worth about one-fourth of a farthing Sterling.

SHILOH is a term famous among interpreters and commentators upon Scripture. It is found (Gen. xlix. 10.) to denote the Meſſiah. The patriarch Jacob foretels his coming in theſe words; "The ſceptre ſhall not depart from Judah, nor a lawgiver from between his feet, until Shiloh come; and unto him ſhall the gathering of the people be." The Hebrew text reads, עד כי יבא שלה *until Shiloh come*. All Chriſtian commentators agree, that this word ought to be underſtood of the Meſſiah, or Jeſus Chriſt; but all are not agreed

about

about its literal and grammatical signification. St Jerome, who translates it by *Qui mittendus est*, manifestly reads *Shiloach* "sent," instead of *Shiloh*. The Septuagint have it Εως αν ελθη τα αποκειμενα αυτω; or, Εως αν ελθη ὡ αποκειται, (as if they had read שלן instead of שלה), *i. e.* "Until the coming of him to whom it is reserved;" or, "Till we see arrive that which is reserved for him."

It must be owned, that the signification of the Hebrew word *Shiloh* is not well known. Some translate, "the sceptre shall not depart from Judah, till he comes to whom it belongs;" שלה or שלי instead of לי אלן. Others, "till the coming of the peace-maker;" or, "the pacific;" or, "of prosperity," שלה *prosperatus est*. *Shalah* signifies, "to be in peace, to be in prosperity;" others, "till the birth of him who shall be born of a woman that shall conceive without the knowledge of a man," שול or עליא *secundina fluxus*†; otherwise, "the sceptre shall not depart from Judah, till its end, its ruin; till the downfal of the kingdom of the Jews," שאל or שלה *it has ceased, it has finished* ¶. Some Rabbins have taken the name *Siloh* or *Shiloh*, as if it signified the city of this name in Palestine: "The sceptre shall not be taken away from Judah till it comes to Shiloh; till it shall be taken from him to be given to Saul at Shiloh." But in what part of Scripture is it said, that Saul was acknowledged as king or consecrated at Shiloh? If we would understand it of Jereboam the son of Nebat, the matter is still as uncertain. The Scripture mentions no assembly at Shiloh that admitted him as king. A more modern author derives *Shiloh* from שלה, *fatigar*, which sometimes signifies *to be weary, to suffer*; "till his labours, his sufferings, his passion, shall happen."

† Arab. Lud de Dieu.

¶ Le Clerc in Genes.

But not to amuse ourselves about seeking out the grammatical signification of Shiloh, it is sufficient for us to show, that the ancient Jews are in this matter agreed with the Christians: they acknowledge, that this word stands for the *Messiah the King*. It is thus that the paraphrasts Onkelos and Jonathan, that the ancient Hebrew commentaries upon Genesis, and that the Talmudists themselves, explain it. If Jesus Christ and his apostles did not make use of this passage to prove the coming of the Messiah, it was because then the completion of this prophecy was not sufficiently manifest. The sceptre still continued among the Jews; they had still kings of their own nation in the persons of the Herods; but soon after the sceptre was entirely taken away from them, and has never been restored to them since.

The conceited Jews seek in vain to put forced meanings upon this prophecy of Jacob; saying, for example, that the sceptre intimates the dominion of strangers, to which they have been in subjection, or the hope of seeing one day the sceptre or supreme power settled again among themselves. It is easy to perceive, that all this is contrived to deliver themselves out of perplexity. In vain likewise they take refuge in certain princes of the captivity, whom they pretend to have subsisted beyond the Euphrates, exercising an authority over their nation little differing from absolute, and being of the race of David. This pretended succession of princes is perfectly chimerical; and though at certain times they could show a succession, it continued but a short time, and their authority was too obscure, and too much limited, to be the object of a prophecy so remarkable as this was.

SHINGLES, in building, pieces of wood sawn to a certain scantling, or, as is more usual, cleft and made like wedges. There are different sizes; the largest three feet by about six inches, and in thickness tapering from less than three fourths to about the ninth of an inch. There are some two feet, and others eighteen inches in length; these have breadth and thickness corresponding to their length. They are made of different kinds of wood, but cedar affords the lightest and most durable.

Shingles are made in, and great numbers annually exported from, many parts of the United States. The want of them is in many countries supplied by thatch, tiles, and slates: the first of these is inferior in every respect; the two others are more secure from fire, but on account of their great weight embarrass the architect, and are not so fit for the construction of large roofs.

SHIP, a general name for all large vessels, particularly those equipped with three masts and a bowsprit; the masts being composed of a lowermast, topmast, and top-gallant-mast: each of these being provided with yards, sails, &c. Ships, in general, are either employed for war or merchandize.

Ships of War are vessels properly equipped with artillery, ammunition, and all the necessary martial weapons and instruments for attack or defence. They are distinguished from each other by their several ranks or classes, called *rates*, as follows: Ships of the first rate mount from 100 guns to 110 guns and upwards; second rate, from 90 to 98 guns; third rate, from 64 to 74 guns; fourth rate, from 50 to 60 guns; fifth rate, from 32 to 44 guns; and sixth rates, from 20 to 28 guns. See the article Rate. Vessels carrying less than 20 guns are denominated *sloops*, *cutters*, *fire-ships*, and *bombs*. It has lately been proposed to reduce the number of these rates, which would be a saving, and also productive of several material advantages.

In Plate CCCCL. is the representation of a first rate, with rigging, &c. the several parts of which are as follow:

Parts of the hull.—A, The cathead; B, The fore-chain-wales, or chains; C, The main-chains; D, The mizen-chains; E, The entering port; F, The hawse-holes; G, The poop-lanterns; H, The chess-tree; I, The head; K, The stern.

1, The bowsprit. 2, Yard and sail. 3, Gammoning. 4, Manrope. 5, Bobstay. 6, Spritsail-sheets. 7, Pendants. 8, Braces and pendants. 9, Halliards. 10, Lifts. 11, Clue-lines. 12, Spritsail horses. 13, Buntlines. 14, Standing lifts. 15, Bowsprit-shroud. 16, Jib-boom. 17, Jibstay and sail. 18, Halliards. 19, Sheets. 20, Horses. 21, Jib-guy. 22, Spritsail-topsail yard. 23, Horses. 24, Sheets. 25, Lifts. 26, Braces and pendants. 27, Cap of bowsprit. 28, Jack staff. 29, Truck. 30, Jack flag.—31, *Foremast*. 32, Runner and tackle. 33, Shrouds. 34, Laniards. 35, Stay and laniard. 36, Preventer-stay and laniard. 37, Woolding of the mast. 38, Fore-yard and sail. 39, Horses. 40, Top. 41, Crowfoot. 42, Jeers. 43, Yard-tackles. 44, Lifts. 45, Braces and pendants. 46, Sheets. 47, Foretacks. 48, Bowlines and bridles. 49, Fore bunt lines. 50, Fore leech-lines. 51, Preventer-brace. 52, Futtock-shrouds.—53, *Foretop-mast*. 54, Shrouds and laniards. 55. Foretop-sail yard and sail. 56, Stay and sail. 57, Runner. 58, Back-stays 59, Halliards. 60, Lifts. 61, Braces and pendants. 62, Horses. 63, Clew-lines. 64, Bowlines and bridles. 65, Reef-tackles. 66, Sheets. 67, Buntlines.

Ship.

Bunt-lines. 68, Cross-trees. 69, Cap. 70, Foretop-gallant-mast. 71, Shrouds. 72, Yard and sail. 73, Backstays. 74, Stay. 75, Lifts. 76, Clew-lines. 77, Braces and pendants. 78, Bowlines and bridles. 79, Flag-staff. 80, Truck. 81, Flag-stay-staff. 82, Flag of the lord-high admiral.—83, *Mainmast*. 84, Shrouds. 85, Laniards. 86, Runner and tackle. 87, Futtock-shrouds. 88, Top-lantern. 89, Crank of ditto. 90, Stay. 91, Preventer stay. 92, Stay-tackles. 93, Woolding of the mast. 94, Jeers. 95, Yard-tackles. 96, Lifts. 97, Braces and pendants. 98, Horses. 99, Sheets. 100, Tacks. 101, Bowlines and bridles. 102, Crow-foot. 103, Cap. 104, Top. 105, Bunt-lines. 106. Leech-lines. 107, Yard and sail.—108, *Main-topmast*. 109, Shrouds and laniards. 110, Yard and sail. 111, Futtock shrouds. 112, Backstays. 113, Stay. 114, Staysail and halliards. 115, Tye. 116, Halliards. 117, Lifts. 118, Clew-lines. 119, Braces and pendants. 120, Horses. 121, Sheets. 122, Bowlines and bridles. 123, Buntlines. 124, Reef-tackles. 125, Cross-trees. 126, Cap.—127, *Main-top-gallant-mast*. 128, Shrouds and laniards. 129, Yard and sail. 130, Backstays. 131, Stay. 132, Stay-sail and halliards. 133, Lifts. 134, Braces and pendants. 135, Bowlines and bridles. 136, Clew-lines. 137, Flagstaff. 138, Truck. 139, Flagstaff-stay. 140, Flag-standard.—141, *Mizen-mast*. 142, Shrouds and laniards. 143, Cap. 144, Yard and sail. 145, Block for signal halliards. 146, Sheet. 147, Pendant lines. 148, Peck-brails. 149, Staysail. 150, Stay. 151, Derrick and span. 152, Top. 153, Cross-jack-yard. 154, Cross-jack lifts. 155, Cross-jack braces. 156, Cross-jack slings.—157, *Mizen-top-mast*. 158, Shrouds and laniards. 159, Yard and sail. 160, Backstays. 161, Stay. 162, Halliards. 163, Lifts. 164, Braces and pendants. 165, Bowlines and bridles. 166, Sheets. 167, Clew-lines. 168, Staysail. 169, Cross-trees. 170, Cap. 171, Flag-staff. 172, Flagstaff-stay, 173, Truck. 174, Flag, union. 175, Ensign-staff. 176, Truck. 177. Ensign. 178, Stern ladder. 179, Bower cable.

Fig. 2. Plate CCCCLI. is a vertical longitudinal section of a first rate ship of war, with references to the principal parts; which are as follow:

A, Is the head, containing,—1, The stem; 2, The knee of the head or cutwater; 3, The lower and upper cheek; 4, The trail-board; 5, The figure; 6, The gratings; 7, The brackets; 8, The false stem; 9, The breast hooks; 10, The hause holes; 11, The bulkhead forward; 12, The cat-head; 13, The cat-hook; 14, Necessary seats; 15, The manger within board; 16, The bowsprit.

B, Upon the forecastle—17, The gratings; 18, The partners of the mast; 19, The gunwale; 20, The belfry; 21, The funnel for smoke; 22, The gangway going off the forcastle; 23, The forecastle guns.

C, In the forecastle—24, The door of the bulkhead forward; 25, Officers cabins; 26, Staircase; 27, Fore-top-sail sheet bits; 28, The beams: 29, The carlings.

D, The middle gun-deck forward—30, The fore-jeer bits; 31, The oven and furnace of copper; 32, The captain's cook room; 33, The ladder or way to the forecastle.

E, The lower gun-deck forward—34, The knees fore and aft; 35, The spirketings, or the first streak next to each deck, the next under the beams being called *clamps*; 36, The beams of the middle gun-deck fore and aft; 37, The carlings of the middle gun-deck fore and aft; 38, The fore-bits; 39, The after or main bits; 40, The hatchway to the gunner's and boatswain's store-rooms; 41, The jeer-capstan.

F, The orlop—42, 43, 44, The gunner's, boatswain's, and carpenter's store-rooms; 45, The beams of the lower gun-deck; 46, 47, The pillars and the riders, fore and aft; 48, The bulkhead of the store-rooms.

G, The hold—49, 50, 51, The foot-hook rider, the floor rider, and the standard, fore and aft; 52, The pillars; 53, The step of the foremast; 54, The kelson, or false keel, and dead rising; 55, The dead-wood.

H, At midships in the hold—56, The floor-timbers; 57, The keel; 58, The well; 59, The chain-pump; 60, The step of the mainmast; 61, 62, Beams and carlings of the orlop, fore and aft.

I, The orlop amidships—63, The cable tire; 64, The main hatchway.

K, The lower gun-deck amidships—65, The ladder leading up to the middle gun-deck; 66, The lower tire of ports.

L, The middle gun-deck amidship—67, The middle tire of ports; 68, The entering port; 69, The main jeer bits; 70, Twisted pillars or stanchions; 71, The capstan; 72, Gratings; 73, The ladder leading to the upper deck.

M, The upper gun-deck amidships—74, The maintop-sail-sheet bits; 75, the upper partners of the mainmast; 76, The gallows on which spare topmasts, &c. are laid; 77, The foresheet blocks: 78, The rennets; 79, The gunwale; 80, The upper gratings; 81, The drift brackets; 82, The piss dale; 83, The capstan pall.

N, Abaft the mainmast—84, The gangway off the quarterdeck; 85, The bulkhead of the coach; 86, The staircase down to the middle gun-deck; 87, The beams of the upper deck; 88, The gratings about the main-mast; 89, The coach or council-chamber; 90, The staircase up to the quarterdeck.

O, The quarterdeck—91, The beams; 92, The carlings; 93, The partners of the mizenmast; 94, The gangway up to the poop; 95, The bulkhead of the cuddy.

P, The poop—96, The trumpeter's cabin; 97, The tafforel.

Q, The captain's cabin.

R, the cuddy, usually divided for the master and secretary's officers.

S, The state-room, out of which is made the bed-chamber and other conveniencies for the commander in chief; 98, The entrance into the gallery; 99, The bulkhead of the great cabin; 100, The stern lights and after galleries.

T, The ward-room, allotted for the lieutenants and marine officers; 101, The lower gallery; 102, The steerage and bulkhead of the wardroom; 103, The whip-staff, commanding the tiller; 104, The after staircase leading down to the lower gun-deck.

V, Several officers cabins abaft the mainmast, where the soldiers generally keep guard.

W, The gun-room—105, The tiller commanding the rudder; 106, The rudder; 107, The stern-post; 108, The tiller-transom; 109, The several transoms, viz. 1, 2, 3, 4, 5.; 110, The gun-room ports, or stern-chase; 111,

SHIP.

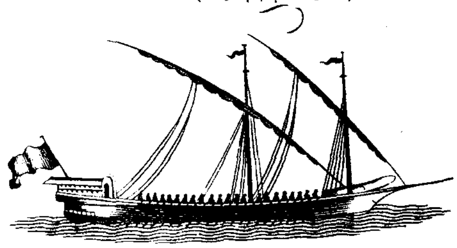

Fig. 11

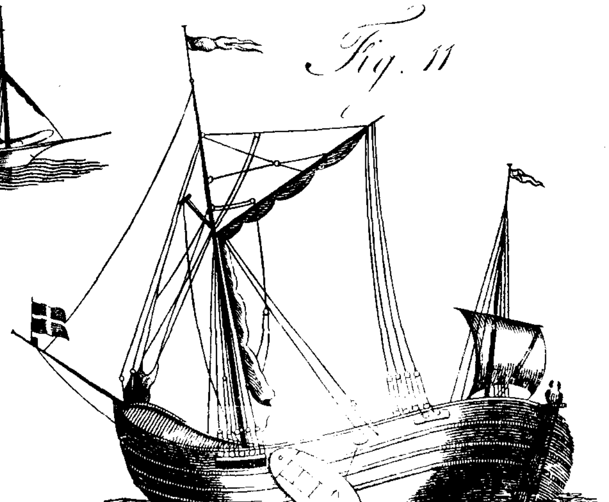

Fig. 13

Allardice Sc.

Ship. 111, The bread-room ſcuttle, out of the gun room; 112, The main capſtan; 113, The pall of the capſtan; 114, The partner; 115, The bulkhead of the bread-room.

X, The bread-room.

Y, The ſteward's room, where all proviſions are weighed and ſerved out.

Z, The cockpit, where are ſubdiviſions for the purſer, the ſurgeon, and his mates.

AA, The platform or orlop, where proviſion is made for the wounded in the time of ſervice; 116, The hold abaft the main-maſt; 117, The ſtep of the mizen-maſt; 118, The kelſon, or falſe keel; 119, The dead wood, or riſing.

Ships of war are fitted out either at the expence of the ſtate or by individuals. Thoſe fitted out by the Britiſh government are called *King's ſhips*, and are divided into *ſhips of the line*, *frigates*, *ſloops*, &c. For an account of each of theſe, ſee the reſpective articles. Ships of war fitted out by individuals are called *privateers*. See the article PRIVATEER.

Armed-SHIP. See *ARMED-Ship*.

Bomb-SHIP. See *BOMB-Veſſels*.

Double-SHIP. See *SHIP-Building*.

Fire-SHIP. See *FIRE-Ship*.

Hoſpital-SHIP, a veſſel fitted up to attend on a fleet of men of war, and receive their ſick or wounded; for which purpoſe her decks ſhould be high, and her ports ſufficiently large. Her cables ought alſo to run upon the upper deck, to the end that the beds or cradles may be more commodiouſly placed between decks, and admit a free paſſage of the air to diſperſe that which is offenſive or corrupted.

Merchant-SHIP, a veſſel employed in commerce to carry commodities of various ſorts from one port to another.

The largeſt merchant ſhips are thoſe employed by the different companies of merchants who trade to the Eaſt-Indies. They are in general larger than Engliſh 40 gun ſhips; and are commonly mounted with 20 guns on their upper-deck, which are nine pounders; and ſix on their quarter-deck, which are ſix pounders.

Regiſter-SHIP. See *REGISTER-Ship*.

Store-SHIP, a veſſel employed to carry artillery or naval ſtores for the uſe of a fleet, fortreſs, or garriſon.

Tranſport-SHIP, is generally uſed to conduct troops from one place to another.

Beſides the different kinds of ſhips abovementioned, which are denominated from the purpoſe for which they are employed, veſſels have alſo, in general, been named according to the different manner of rigging them. It would be an endleſs, and at the ſame time an unneceſſary taſk, to enumerate all the different kinds of veſſels with reſpect to their rigging; and therefore a few only are here taken notice of. Fig. 3. Plate CCCCLI. is a *ſhip* which would be converted into a *bark* by ſtripping the mizen maſt of its yards and the ſails belonging to them. If each maſt, its correſponding topmaſt and topgallant-maſt, inſtead of being compoſed of ſeparate pieces of wood, were all of one continued piece, then this veſſel with very little alteration would be a *polacre*. Fig. 4. repreſents a *ſnow*; fig. 5. a *bilander*; fig. 6. a *brig*; fig. 7. a *ketch*; fig. 8. a *ſchooner*; fig. 9. a *ſloop*; fig. 10. a *zebec*; fig. 11. a *galliot*; fig. 12. a *dogger*; fig. 13. a *galley* under ſail; fig. 14. ditto rowing. Plate CCCCLII.

Ships are alſo ſometimes named according to the different modes of their conſtruction. Thus we ſay, a *cat*-built ſhip, &c.

To SHIP, is either uſed actively, as to embark any perſon or put any thing aboard ſhip: or paſſively, to receive any thing into a ſhip; as, "we ſhipped a heavy ſea at three o'clock in the morning."

To SHIP, alſo implies to fix any thing in its place; as, to ſhip the oars, that is, to put them in their rowlocks; to ſhip the ſwivel guns, is to fix them in their ſockets; to ſhip the handſpokes, &c.

Machine for drawing Bolts out of SHIPS, an inſtrument invented by Mr. William Hill for this purpoſe. His account of which is as follows*.

"Firſt, The uſe of this machine is to draw the kelſon and dead wood bolts out, and to draw the knee of the head bolts.—Secondly, The heads of the kelſon bolts heretofore were all obliged to be driven thro' the kelſon, floor timbers, and keel, to get them out: by this means the kelſon is often entirely deſtroyed, and the large hole the head makes materially wounds the floors; and frequently, when the bolt is much corroded, it ſcarfs, and the bolt comes out of the ſide of the keel.—Thirdly, The dead wood bolts that are driven with two or three drifts, are ſeldom or never got out, by which means the dead-wood is condemned, when ſome of it is really ſerviceable.—Fourthly, In drawing the knee of the head-bolts, ſometimes the knee ſtarts off, and cannot be got to again, but ſurs up, and with this machine may be drawn in; for it has been proved to have more power in ſtarting a bolt than the maul."

* Tranſactions of the Society for the Encouragement of Arts, &c. vol. x.

In fig. 1. "A, A, repreſent two ſtrong male ſcrews, working in female ſcrews near the extremities of the cheeks, againſt plates of iron E, E. C C is the bolt to be drawn; which, being held between the chaps of the machine at DD, is, by turning the ſcrews by the lever B, forced upwards out of the wood or plank of the ſhip. F, F, are two dogs, with hooks at their lower extremities; which, being driven into the plank, ſerve to ſupport the machine till the chaps have got faſt hold of the bolt. At the upper part of theſe dogs are rings paſſing thro' holes in a collar, moveable near the heads of the ſcrew. Fig. 2. is a view of the upper ſide of the cheeks when joined together; *a, a*, the holes in which the ſcrews work; *b*, the chaps by which the bolts are drawn. Fig. 3. The under ſide of the cheek: *a, a*, the holes in which the ſcrews work; *b*, the chaps by which the bolts are drawn, and where the teeth that gripe the bolt are more diſtinctly ſhewn. Fig. 4. One of the cheeks ſeparated from the other, the letters referring as in fig. 2. and 3. Plate CCCCLIII.

This machine was tried in his majeſty's yard at Deptford, and was found of the greateſt utility.—"Firſt, it drew a bolt that was driven down ſo tight as only to go one inch in ſixteen blows with a double-headed maul, and was well clenched below: the bolt drew the ring a conſiderable way into the wood, and wire drew itſelf through, and left the ring behind. Secondly, it drew a bolt out of the Venus's dead-wood that could not be got out by the maul. That part of it which went through the keel was bent cloſe up to the lower part of the dead-wood, and the machine drew the bolt ſtraight, and drew it out with eaſe. It alſo drew a kelſon bolt out of the Stanley Weſt Indiaman, in Meſſrs Wells's yard, Deptford; which being a bolt of two drifts, could not be driven out.

Management

Ship.

Management of Ships at single anchor, is the method of taking care of a ship while riding at single anchor in a tide-way, by preventing her from fouling her anchor, &c. The following rules for this purpose, with which we have been favoured by Mr. Henry Taylor* of North Shields, will be found of the utmost consequence.

* Taylor's Instructions to Young Mariners Riding at Anchor in moderate weather.

Riding in a tide-way, with a fresh-of-wind, the ship should have what is called *a short* or *windward service*, say 45 or 50 fathoms of cable, and always sheered to windward (A), not always with the helm hard down, but more or less so according to the strength or weakness of the tide. It is a known fact, that many ships sheer their anchors home, drive on board of other ships, and on the sands near which they rode, before it has been discovered that the anchor had been moved from the place where it was let go.

1 When the ship will back.

When the wind is cross, or nearly cross, off shore, or in the opposite direction, ships will always back. This is done by the mizen-topsail, assisted, if needful, by the mizen-staysail; such as have no mizen-topsail commonly use the main-topsail, or if it blows fresh, a top-gallant-sail, or any such sail at the gaff.

In backing, a ship should always wind with a taught cable, that it may be certain the anchor is drawn round. In case there is not a sufficiency of wind for that purpose, the ship should be hove apeak.

2 How the yards ought to be braced.

Riding with the wind afore the beam, the yards should be braced forward; if abaft the beam, they are to be braced all aback.

3 Riding windward tide in danger of breaking her sheer.

If the wind is so far aft that the ship will not back (which should not be attempted if, when the tide eases, the ship forges ahead, and brings the buoy on the lee quarter), she must be set ahead: if the wind is far aft, and blows fresh, the utmost care and attention is necessary, as ships riding in this situation often break their sheer, and come to windward of their anchors again. It should be observed, that when the ship lies in this ticklish situation, the after-yards must be braced forward, and the fore-yards the contrary way: she will lay safe, as the buoy can be kept on the lee quarter, or suppose the helm is aport, as long as the buoy is on the larboard quarter. With the helm thus, and the wind right aft, or nearly so, the starboard main and fore braces should be hauled in. This supposes the main braces to lead forward.

4 Tending to leeward when the ship must be set ahead.

When the ship begins to tend to leeward, and the buoy comes on the weather-quarter, the first thing to be done is to brace about the fore-yard; and when the wind comes near the beam, set the fore-staysail, and keep it standing until it shakes; then brace all the yards sharp forward, especially if it is likely to blow strong.

5 How to manage when the ship breaks her sheer.

If laying in the aforesaid position, and she breaks her sheer, brace about the main-yard immediately; if she recovers and brings the buoy on the lee or larboard quarter, let the main-yard be again braced about; but if she come to a sheer the other way, by bringing the buoy on the other quarter, change the helm and brace the fore-yard to.

6 When a long service is out, and the ship is likely to go to windward.

Riding leeward tide with more cable than the windward service, and expecting the ship will go to windward of her anchor, begin as soon as the tide eases to shorten in the cable. This is often hard work; but it is necessary to be done, otherwise the anchor may be fouled by the great length of cable the ship has to draw round; but even if that could be done, the cable would be damaged against the bows or cut-water. It is to be observed, that when a ship rides windward tide the cable should be cackled from the short service towards the anchor, as far as will prevent the bare part touching the ship.

When the ship tends to windward and must be set ahead, hoist the fore-staysail as soon as it will stand, and when the buoy comes on the leequarter, haul down the fore-staysail, brace to the fore-yard, and put the helm a-lee; for till then the helm must be kept a-weather and the yards full.

7 How to manage in a storm.

When the ship rides leeward tide, and the wind increases, care should be taken to give her more cable in time, otherwise the anchor may start, and probably it will be troublesome to get her brought up again; and this care is the more necessary when the ship rides in the hause of another ship. Previous to giving a long service it is usual to take a weather-bit, that is, a turn of the cable over the windlass end, so that in veering away the ship will be under command. The service ought to be greased, which will prevent its chafing in the hause.

If the gale continues to increase, the topmasts should be struck in time; but the fore-yard should seldom, if ever, be lowered down, that in case of parting the fore-sail may be ready to be set. At such times there should be more on deck than the common anchor-watch, that no accident may happen from inattention or falling asleep.

In a tide-way a second anchor should never be let go but when absolutely necessary; for a ship will sometimes ride easier and safer, especially if the sea runs high, with a very long scope of cable and one anchor, than with less

(A) It has been thought by some theorists, that ships should be sheered to leeward of their anchors; but experience and the common practice of the best informed seamen are against that opinion: for it is found, that when a ship rides leeward tide and sheered to windward, with the wind two or three points upon the bow, and blowing hard in the interval between the squalls, the sheer will draw her towards the wind's eye; so that when the next squall comes, before she be pressed astream of her anchor, it is probable there will be a lull again, and the spring which the cable got by the sheer will greatly ease it during the squall.

Every seaman knows that no ship without a rudder, or the helm left loose, will wear; they always in such situations fly to: this proves that the wind pressing upon the quarter and the helm alee, a ship will be less liable to break her sheer than when the helm is a-weather. Besides, if the helm is a-lee when she breaks her sheer, it will be a-weather when the wind comes on the other quarter, as it ought to be until she either swing to leeward, or bring the buoy on the other quarter. Now if the ship breaks her sheer with the helm a-weather, it throws her head to the wind so suddenly as scarce to give time to brace the yards about, and very probably she will fall over her anchor before the fore-staysail can be got up.

Ship. less length and two cables; however, it is advisable, as a preventive, when ships have not room to drive, and the night is dark, to let fall a second anchor under foot, with a range of cable along the deck. If this is not thought necessary to be done, the deep-sea lead should be thrown overboard, and the line frequently handled by the watch, that they may be assured she rides fast.

8 Caution respecting the anchor watch. If at any time the anchor-watch, presuming on their own knowledge, should wind the ship, or suffer her to break her sheer without calling the mate, he should immediately, on the very first opportunity, oblige the crew to heave the anchor in sight; which will prevent the commission of the like fault again; for besides the share of trouble the watch will have, the rest of the crew will blame them for neglecting their duty.

9 The particular duty of the chief mate. Prudent mates seldom lie a week in a road-stead without heaving their anchor in sight; even though they have not the least suspicion of its being foul. There are other reasons why the anchor should be looked at; sometimes the cable receives damage by sweeping wrecks or anchors that have been lost, or from rocks or stones; and it is often necessary to trip the anchor, in order to take a clearer birth, which should be done as often as any ship brings up too near.

Method for the safe removal of such SHIPS *as have been driven on shore.* For this purpose empty casks are usually employed to float off the vessel, especially if she is small, and at the same time near the port to which it is proposed to conduct her. In other cases, the following method adopted by Mr Barnard* will answer.

"On January 1, 1779 (says Mr Barnard), in a most dreadful storm, the York East Indiaman, of eight hundred tons, homeward bound, with a pepper cargo, parted her cables in Margate roads, and was driven on shore, within one hundred feet of the head and thirty feet of the side of Margate pier, then drawing twenty-two feet six inches water, the flow of a good spring tide being only fourteen feet at that place.

"On the third of the same month I went down, as a ship-builder, to assist, as much as lay in my power, my worthy friend Sir Richard Hotham, to whom the ship belonged. I found her perfectly upright, and her shere (or side appearance) the same as when first built, but sunk to the twelve feet water-mark fore and aft in a bed of chalk mixed with a stiff blue clay, exactly the shape of her body below that draft of water; and from the rudder being torn from her as she struck coming on shore, and the violent agitation of the sea after her being there, her stern was so greatly injured as to admit free access thereto, which filled her for four days equal to the flow of the tide. Having fully informed myself of her situation and the flow of spring-tides, and being clearly of opinion she might be again got off, I recommended, as the first necessary step, the immediate discharge of the cargo; and, in the progress of that business, I found the tide always flowed to the same height on the ship; and when the cargo was half discharged, and I knew the remaining part should not make her draw more than eighteen feet water, and while I was observing the water at twenty-two feet six inches by the ship's mark, she instantly lifted to seventeen feet eight inches; the water and air being before excluded by her pressure on the clay, and the atmosphere acting upon her upper part equal to six hundred tons, which is the weight of water displaced at the difference of these two drafts of water.

"The moment the ship lifted I discovered she had received more damage than was at first apprehended, her leaks being such as filled her from four to eighteen feet water in an hour and an half. As nothing effectual was to be expected from pumping, several scuttles or holes in the ship's side were made, and valves fixed thereto, to draw off the water at the lowest ebb of the tide, to facilitate the discharge of the remaining part of the cargo; and, after many attempts, I succeeded in an external application of sheep-skin sewed on a sail and thrust under the bottom, to stop the body of water from rushing so furiously into the ship. This business effected, moderate pumping enabled us to keep the ship to about six feet water at low water, and by a vigorous effort we could bring the ship so light as (when the cargo should be all discharged) to be easily removed into deeper water. But as the external application might be disturbed by so doing, or totally removed by the agitation of the ship, it was absolutely necessary to provide some permanent security for the lives of those who were to navigate her to the river Thames. I then recommended as the cheapest, quickest, and most effectual plan, to lay a deck in the hold, as low as the water could be pumped to, framed so solidly and securely, and caulked so tight, as to swim the ship independent of her own leaky bottom.

"Beams of fir-timber twelve inches square were placed in the hold under every lower deck beam in the ship, as low as the water would permit; these were in two pieces, for the conveniency of getting them down, and also for the better fixing them of an exact length, and well bolted together when in their places. Over these were laid long Dantzic deals of two inches and an half thick, well nailed and caulked. Against the ship's side, all fore and aft, was well nailed a piece of fir twelve inches broad and six inches thick on the lower and three inches on the upper edge, to prevent the deck from rising at the side. Over the deck, at every beam, was laid a cross piece of fir timber six inches deep and twelve inches broad, reaching from the pillar of the hold to the ship's side, on which the shores were to be placed to resist the pressure of the water beneath. On each of these, and against the lower-deck beam, at equal distances from the side and middle of the ship, was placed an upright shore, six inches by twelve, the lower end let two inches into the cross piece. From the foot of this shore to the ship's side, under the end of every lower deck beam, was placed a diagonal shore six inches by twelve, to ease the ship's deck of part of the strain by throwing it on the side. An upright shore of three inches by twelve was placed from the end of every cross piece to the lower deck beams at the side, and one of three inches by twelve on the midship end of every cross piece to the lower deck beam, and nailed to the pillars in the hold. The firm tight bulkheads or partitions were made as near the extremes of the ship as possible. The ceiling or inside plank of the ship was very securely caulked up to the lower deck, and the whole formed a complete ship with a flat bottom within side, to swim the outside leaky one; and the bottom being depressed six feet below the external water, resisted the ship's weight above it equal to five hundred and eighty-one tons, and safely conveyed her to the dry-dock at Deptford."

* Philosophical Transactions, vol. lxx. part I.

SHIP-BUILDING.

1 Definition. SHIP-BUILDING, or NAVAL ARCHITECTURE, is the art of constructing a ship so as to answer a particular purpose either of war or merchandise.

2 History. To whom the world is indebted for the invention of ships is, like all other things of equal antiquity, uncertain.

A very small portion of art or contrivance was seen in the first ships: they were neither strong nor durable; but consisted only of a few planks laid together, without beauty or ornament, and just so compacted as to keep out the water. In some places they were only the hulks or stocks of trees hollowed, and then consisted only of one piece of timber. Nor was wood alone applied to this use; but any other buoyant materials, as the Egyptian reed papyrus; or leather, of which the primitive ships were frequently composed; the bottom and sides being extended on a frame of thin battens or scantlings, of flexible wood, or begirt with wickers, such as we have frequently beheld amongst the American savages. In this manner they were often navigated upon the rivers of Ethiopia, Egypt, and Sabæan Arabia, even in later times. But in the first of them, we find no mention of any thing but leather or hides sewed together. In a vessel of this kind, Dardanus secured his retreat to the country afterwards called *Troas*, when he was compelled by a terrible deluge to forsake his former habitation of Samothrace. According to Virgil, Charon's infernal boat was of the same composition.

But as the other arts extended their influence, naval architecture likewise began to emerge from the gloom of ignorance and barbarism; and as the ships of those ages were increased in bulk, and better proportioned for commerce, the appearance of those floating citadels of unusual form, full of living men, flying with seemingly expanded wings over the surface of the untravelled ocean, struck the ignorant people with terror and astonishment: and hence, as we are told by Aristophanes, arose the fable of Perseus flying to the Gorgons, who was actually carried thither in a ship! Hence, in all probability, the famous story of Triptolemus riding on a winged dragon is deduced, only because he sailed from Athens, in the time of a great dearth, to a more plentiful country, to supply the necessities of his people. The fiction of the flying horse Pegasus may be joined with these, who, as several mythologists report, was nothing but a ship with sails, and thence said to be the offspring of Neptune the sovereign of the sea; nor does there appear any other foundation for the stories of griffins, or of ships transformed into birds and fishes, which we so often meet with in the ancient poets. So acceptable to the first ages of the world were inventions of this nature, that whoever made any improvements in navigation or naval architecture, building new ships better fitted for strength or swiftness than those used before, or rendered the old more commodious by additional contrivances, or discovered countries unknown to former travellers, were thought worthy of the greatest honours, and often associated into the number of their deified heroes. Hence we have in astronomy the signs of Aries and Taurus, which were no other than two ships: the former transported Phryxus from Greece to Colchos, and the latter Europa from Phœnicia to Crete. Argo, Pegasus, and Perseus, were likewise new ships of a different sort from the former, which being greatly admired by the barbarous and uninstructed people of those times, were translated amongst the stars, in commemoration of their inventors, and metamorphosed into constellations by the poets of their own and of succeeding ages. History.

The chief parts, of which ships anciently consisted, were three, viz. the belly, the prow, and the stern: these were again composed of other smaller parts, which shall be briefly described in their order. In the description, we chiefly follow Scheffer, who hath so copiously treated this subject, and with such industry and learning collected whatever is necessary to illustrate it, that very little room is left for enlargement by those who incline to pursue this investigation.

1. In the belly, or middle part of the ship, there was τροπις, *carina*, or the "keel," which was composed of wood: it was placed at the bottom of the ship, being designed to cut and glide through the waves, and therefore was not broad, but narrow and sharp; whence it may be perceived that not all ships, but only the μακραι, which ships of war are called, whose bellies were straight and of a small circumference, were provided with keels, the rest having usually flat bottoms. Around the outside of the keel were fixed pieces of wood, to prevent it from being damaged when the ship was first launched into the water, or afterwards struck on any rocks; these were called χελευσματα, in Latin *cunei*.

Next to the keel was φαλκις, the "pump-well, or well-room," within which was contained the αντλιον, or "pump;" through which water was conveyed out of the ship.

After this, there was δευτερα τροπις, or the "second keel," somewhat resembling what is now called the *kelson*; it was placed beneath the pump, and called λεσβιον, χαλκηνες, κλειτοποδιον: by some it is falsely supposed to be the same with φαλκις.

Above the pump was an hollow place, called by Herodotus κοιλη της νηος, by Pollux κυτος and γαστρα, because large and capacious, after the form of a belly; by the Latins, *testudo*. This was formed by crooked ribs, with which it was surrounded, which were pieces of wood rising from the keel upwards, and called by Hesychius νομεις, and by others, εγκοιλια, the belly of the ship being contained within them: in Latin, *costæ;* and in English, *timbers*. Upon these were placed certain planks, which Aristophanes calls εντερονεια, or εντερονιδα.

The πλευραι, *latera*, or "sides" of the ship, encompassed all the former parts on both hands; these were composed of large rafters extending from prow to stern, and called ζωστηρες, and ζωμιαματα, because by them the whole fabric was begirt or surrounded.

In both these sides the rowers had their places, called τοιχοι and εδωλια, in Latin *fori* and *transtra*, placed above one another; the lowest was called θαλαμος, and those that laboured therein θαλαμιοι the middle, ζυγα, and the men ζυγιοι; the uppermost θρανοι, whence the

rowers

rowers were termed θρανιται. In theſe apartments were ſpaces through which the rowers put their oars; theſe were ſometimes one continued vacuity from one end to the other, called τραφηξ, but more uſually diſtinct holes, each of which was deſigned for a ſingle oar; theſe were ſtyled τρηματα, τρυπηματα, as alſo οφθαλμοι, becauſe not unlike the eyes of living creatures. All of them were by a more general name termed εγκωπα, from containing the oars; but εγκωπιν ſeems to have been another thing, ſignifying the ſpaces between the banks of oars on each ſide, where the paſſengers appear to have been placed. On the top of all there was a paſſage or place to walk, called παροδος, and παραθρανις, as joining to the θρανοι, or uppermoſt bank of oars.

2. Πρωρα, the "prow or fore-deck," whence it is ſometimes called μετωπον, and commonly diſtinguiſhed by other metaphorical titles taken from human faces. In ſome ſhips there is mention of two prows, as alſo two ſterns; ſuch was Danaus's ſhip adorned by Minerva when he fled from Egypt. It was uſual to beautify the prow with gold and various ſorts of paint and colours; in the primitive times red was moſt in uſe; whence Homer's ſhips were commonly dignified with the titles of μιλτοπαρηοι, and φοινικοπαρηοι, or "red faced;" the blue likewiſe, or ſky-colour, was frequently made uſe of, as bearing a near reſemblance to the colour of the ſea; whence we find ſhips called by Homer κυανοπρωροι, by Ariſtophanes κυανεμβολοι. Several other colours were alſo made uſe of; nor were they barely varniſhed over with them, but very often annealed by wax melted in the fire, ſo as neither the ſun, winds, nor water, were able to deface them. The art of doing this was called from the wax κηρογραφια, from the fire εγκαυςικη, which is deſcribed by Vitruvius, and mentioned in Ovid.

——— *Picta coloribus uſtis*
Cæruleam matrem concava puppis habet.

The painted ſhip with melted wax anneal'd
Had Tethys for its deity ———

In theſe colours the various forms of gods, animals, plants, &c. were uſually drawn, which were likewiſe often added as ornaments to other parts of the ſhips, as plainly appears from the ancient monuments preſented to the world by Bayſius.

The ſides of the prow were termed πτερα, or "wings," and παρια, according to Scheffer, or rather παρειαι; for ſince the prow is commonly compared to a human face, it will naturally follow that the ſides ſhould be called *cheeks*. Theſe are now called *bows* by our mariners.

3. Πρυμνη, "the hind-deck or poop," ſometimes called ουρα, the "tail," becauſe the hindmoſt part of the ſhip; it was of a figure more inclining to round than the prow, the extremity of which was ſharp, that it might cut the waters; it was alſo built higher than the prow, and was the place where the pilot ſat to ſteer; the outer-bending part of it was called επισειον, anſwering to our term *quarter*.

They had various ornaments of ſculpture on the prow; as helmets, animals, triumphal wreaths, &c.—The ſtern was more particularly adorned with wings, ſhields, &c. Sometimes a little maſt was erected whereon to hang ribbands of divers colours, which ſerved inſtead of a flag to diſtinguiſh the ſhip; and a weather-cock, to ſignify the part from whence the wind blew.

On the extremity of the prow was placed a round piece of wood called the πτυχις, from its bending; and ſometimes οφθαλμος, the "eye" of the ſhip, becauſe fixed in the fore-deck; on this was inſcribed the name of the ſhip, which was uſually taken from the figure painted on the flag. Hence comes the frequent mention of ſhips called *Pegaſi*, *Scyllæ*, *bulls*, *rams*, *tigers*, &c. which the poets took the liberty to repreſent as living creatures that tranſported their riders from one country to another.

The whole fabric being completed, it was fortified with pitch, and ſometimes a mixture of roſin, to ſecure the wood from the waters; whence it comes that Homer's ſhips are everywhere mentioned with the epithet of μελαιναι, or "black." The firſt that made uſe of pitch were the inhabitants of Phæacia, ſince called Corſica; ſometimes wax was employed in the ſame uſe; whence Ovid.

Cærulea ceratas accipit unda rates.

The azure waves receive the waxed ſhips.

After all, the ſhip being bedecked with garlands and flowers, the mariners alſo adorned with crowns, ſhe was launched into the ſea with loud acclamations and other expreſſions of joy; and being purified by a prieſt with a lighted torch, an egg and brimſtone, or after ſome other manner, was conſecrated to the god whoſe image ſhe bore.

The ſhips of war of the ancients were diſtinguiſhed from other kinds of veſſels by various turrets and acceſſions of building, ſome to defend their own ſoldiers, and others to annoy the enemy; and from one another, in latter ages, by ſeveral degrees or ranks of oars, the moſt uſual number of which was four or five, which appear not to have been arranged, as ſome imagine, on the ſame level in different parts of the ſhip; nor yet, as others have ſuppoſed, directly above one another's heads; but their ſeats being placed one behind another, aſcended gradually, like ſtairs. Ptolemy Philopater, urged by a vain-glorious deſire of exceeding all the world beſides in naval architecture, is ſaid to have farther enlarged the number of banks to 40; and the ſhip being otherwiſe in equal proportion, this raiſed her to ſuch an enormous bulk, that ſhe appeared at a diſtance like a floating mountain or iſland; and, upon a nearer view, like a prodigious caſtle on the ocean. She was 280 cubits long, 38 broad, and 48 high (each cubit being 1 Engliſh foot 5½ inches), and carried 400 rowers, 400 ſailors, and 3000 ſoldiers. Another which the ſame prince made to ſail on the Nile, we are told, was half a ſtadium long. Yet theſe were nothing in compariſon of Hiero's ſhip, built under the direction of Archimedes; on the ſtructure whereof Moſchion wrote a whole volume. There was wood enough employed in it to make 50 galleys; it had all the variety of apartments of a palace; ſuch as banqueting-rooms, galleries, gardens, fiſh-ponds, ſtables, mills, baths, and a temple to Venus. The floors of the middle apartment were all inlaid, and repreſented in various colours the ſtories of Homer's Iliad. The ceilings, windows, and all other parts, were finiſhed with wonderful art, and embelliſhed with all kinds of ornaments. In the uppermoſt apartment there was a ſpacious gymnaſium, or place for exerciſe, and water was conveyed to the garden by pipes, ſome

History.

ſome of hardened clay, and others of lead. The floors of the temple of Venus were inlaid with agates and other precious ſtones; the inſide lined with cypreſs wood; the windows adorned with ivory paintings and ſmall ſtatues. There was likewiſe a library. This veſſel was adorned on all ſides with fine paintings. It had 20 benches of oars, and was encompaſſed with an iron rampart, eight towers, with walls and bulwarks, furniſhed with machines of war, particularly one which threw a ſtone of 300 pounds, or a dart 12 cubits long, the ſpace of half a mile, with many other particulars related by Athenæus. Caligula likewiſe built a veſſel adorned with jewels in the poop, with ſails of many colours, and furniſhed with large porticoes, bagnios, and banqueting-rooms, beſides rows of vines, and fruit-trees of various kinds. But theſe, and all ſuch monſtrous fabrics, ſerved only for ſhow and oſtentation, being rendered by their vaſt bulk unwieldy and unfit for ſervice. Athenæus informs us, the common names they were known by, were *Cyclades*, or *Ætna*, i. e. "iſlands, or mountains," to which they ſeemed nearly equal in bigneſs; conſiſting, as ſome report, of as many materials as would have compoſed 50 triremes, or ſhips of three banks.

The veſſels employed by the northern nations appear to have been ſtill more imperfect than thoſe of the Romans; for a law was enacted in the reign of the emperor Honorius, 24th September, A. D. 418, inflicting capital puniſhment on any who ſhould inſtruct the barbarians in the art of ſhip-building; a proof at once of the great eſtimation in which this ſcience was then held, and of the ignorance of the barbarians with regard to it.

The fleet of Richard I. of England, when he weighed anchor for the holy war from Meſſina, in Sicily, where he had paſſed the winter, A. D. 1190-1, is ſaid to have conſiſted of 150 great ſhips and 53 galleys, beſides barks, tartans, &c. What kinds of ſhips theſe were is not mentioned. To the cruſades, however pernicious in other reſpects, this ſcience ſeems to owe ſome improvements; and to this particular one we are indebted for Richard's marine code, commonly called the *Laws of Oleron*, from the name of a ſmall iſland on the coaſt of France, where he compoſed them, and which moſt of the nations in Europe have made the baſis of their maritime regulations. Thoſe ſhips, if they merited the name of ſhips, were probably very ſmall, as we find that ſo long after as the time of Edward I. *anno* 1304, 40 men were deemed ſufficient to man the beſt and largeſt veſſels in England; and that Edward the Third, *anno* 1335, ordained the mayor and ſheriffs of London to "take up all ſhips in their port, and all other ports in the kingdom, of the burden of 40 tons and upwards, and to furniſh the ſame with armed men and other neceſſaries of war, againſt the Scots his enemies, confederated with certain perſons of foreign nations." Edward the Third's fleet before Calais, *anno* 1347, conſiſted of 738 Engliſh ſhips, carrying 14,956 mariners, being on an average but 20 men to each ſhip; 15 ſhips and 459 mariners, from Bayonne in Guienne, being 30 men to each ſhip; 7 ſhips and 184 men from Spain, which is 26 men to each ſhip; one from Ireland, carrying 25 men; 14 from Flanders, with 133 men, being ſcarcely 10 men to each ſhip; and one from Guelderland, with 24 mariners. Fifteen of theſe were called the king's own ſhips, manned with 419 mariners, being ſomewhat under 17 to each ſhip.

Fœdera, vol. ii. p. 943.

Ib. vol. iv, p. 664.

Hiſtorians repreſent the veſſels of Venice and Genoa as the largeſt and the beſt about this time, but they were ſoon exceeded in ſize by the Spaniſh veſſels called *carricks*, ſome of which carried cannon; and theſe again were exceeded by the veſſels built by the northern people, particularly thoſe belonging to the Hanſe-towns.—In the 14th century, the Hanſiatics were the ſovereigns of the northern ſeas, as well without as within the Baltic; and their ſhips were ſo large, that foreign princes often hired them in their wars. According to Hakluyt, an Engliſh ſhip from Newcaſtle, of 200 tons burden, was ſeized in the Baltic by thoſe of Wiſmar and Roſtock, *anno* 1394; and another Engliſh veſſel of the ſame burden was violently ſeized in the port of Liſbon, *anno* 1412.

Fœdera, vol. viii. p. 727.

Soon after ſhips of a much larger ſize were conſtructed. It is mentioned that a very large ſhip was built, *anno* 1449, by John Taverner of Hull; and in the year 1455, king Henry IV, at the requeſt of Charles king of Sweden, granted a licence for a Swediſh ſhip of the burden of a thouſand tons or under, laden with merchandize, and having 120 perſons on board, to come to the ports of England, there to diſpoſe of their lading, and to relade back with Engliſh merchandize, paying the uſual cuſtoms. The inſcription on the tomb of William Canning, an eminent merchant, who had been five times mayor of Briſtol, in Ratcliff-church at Briſtol, *anno* 1474, mentions his having forfeited the king's peace, for which he was condemned to pay 300 merks; in lieu of which ſum, king Edward IV. took of him 2470 tons of ſhipping, amongſt which there was one ſhip of 900 tons burden, another of 500 tons, and one of 400 tons, the reſt being ſmaller.

Ib. vol. xi. p. 358.

Ib. vol. xi. p. 364.

In the year 1506, king James IV. of Scotland built the largeſt ſhip which had hitherto been ſeen, but which was loſt in her way to France in the year 1512, owing probably to a defective conſtruction, and the unſkilfulneſs of the crew in managing ſo large a ſhip—About this time a very large ſhip was likewiſe built in France. In the fleet fitted out by Henry VIII. *anno* 1512, there was one ſhip, the Regent, of 1000 tons burden, one of 500, and three of 400 each. A ſhip ſtill larger than the Regent was built ſoon after, called *Henri Grace Dieu!* In the year 1522 the firſt voyage round the globe was finiſhed.

The Engliſh naval hiſtorians think that ſhips carried cannon on their upper decks only, and had not gunports before the year 1545: and it is certain that many of the largeſt ſhips in former times were fitted out from harbours, where ſhips of a moderate ſize now would not have water enough to float them. In 1575 the whole of the royal navy did not exceed 24 ſhips, and the number of merchant-ſhips belonging to England amounted to no more than 135 veſſels above 100 tons, and 656 between 40 and 100 tons. At queen Elizabeth's death, *anno* 1603, there were not above four merchant-ſhips in England of 400 tons burden each.—The largeſt of queen Elizabeth's ſhips of war was 1000 tons burden, carrying but 340 men, and 40 guns, and the

Monſon's Naval Tracts, p. 294.

the ſmalleſt 600 tons, carrying 150 men and 30 guns. Smaller veſſels were occaſionally hired by her from private owners.

In the memorable ſea-fight of Lepanto between the Turks and Chriſtians, *anno* 1571, no veſſels were employed but galleys; and it would appear from the carcaſes of ſome of them, which are ſtill preſerved in the arſenal at Venice, that even theſe were not ſo large or ſo well conſtructed as thoſe of our times. The Invincible Armada, as Spaniſh vanity ſtyled it, once the terror and admiration of nations, in the pompous and exaggerated deſcriptions of which the Spaniſh authors of thoſe times dwelt with ſo much apparent pleaſure, conſiſted of 130 ſhips, near 100 of which were the ſtatelieſt that had yet been ſeen on the ocean. The largeſt of theſe, however, would be no more than a third rate veſſel in the Britiſh navy, and they were ſo ill conſtructed, that they would neither move eaſily, ſail near the wind, nor be properly worked in tempeſtuous weather. The whole of the naval force collected by Queen Elizabeth to oppoſe this formidable fleet, including hired veſſels, tenders, ſtore-ſhips, &c. amounted to no more than 143.

Ship-building began now to make a conſiderable progreſs in Britain. Both war and trade required an increaſe of ſhipping; ſo that, in the year 1670, the annual charge of the navy was reported to be L. 500,000; and in 1678 the navy conſiſted of 83 ſhips, of which 58 were of the line. At this time the exports amounted to ten millions *per annum;* and the balance of trade was two millions. In 1689 there were 173 ſhips, great and ſmall, in the royal navy, and it has been conſtantly increaſing; ſo that in 1761 the ſhips in the navy amounted to 372, of which 129 were of the line; and in the beginning of the year 1795, the total amount was above 430.

3 Ships of the common form found defective,

4 And improvements propoſed.

As ſhips of the common conſtruction are found to be very defective in many particulars, various methods have therefore from time to time been propoſed to remove ſome of the bad qualities they poſſeſſed.—As it would be an endleſs taſk to enumerate the different inventions for this purpoſe, therefore a few of them only will be mentioned.

5 Double ſhips introduced by Sir William Petty, European Magazine for Auguſt 1782.

In 1663 Sir William Petty conſtructed a double ſhip, or rather a ſingle ſhip with a double bottom, which was found to ſail conſiderably faſter than any of the ſhips with which it had an opportunity of being tried. Her firſt voyage was from Dublin to Holyhead; and in her return "ſhe turned into that narrow harbour againſt wind and tide, among rocks and ſhips, with ſuch dexterity as many ancient ſeamen confeſſed they had never ſeen the like." This veſſel with 70 more were loſt in a dreadful tempeſt.

6 And again propoſed by Mr Gordon, p. 54.

This ſubject was again revived by Mr Gordon, in his Principles of Naval Architecture, printed at Aberdeen *anno* 1784; where, having delivered his ſentiments on the conſtruction of large maſts, he ſays: "Theſe experiments likewiſe point out to us methods by which two veſſels may be laterally connected together, though at a conſiderable diſtance from each other, in a manner ſufficiently ſtrong, with very little increaſe of weight or expence of materials, and without expoſing much ſurface to the action or influence of the wind or the waves, or obſtructing their motion in any conſiderable degree, and conſequently without being much oppoſed by them on that account under any circumſtances; and if veſſels are judiciouſly conſtructed with a view to ſuch a junction, it would be no eaſy matter to enumerate all the advantages that may be obtained by this means." He then enumerates the advantages that double veſſels would have over thoſe of the common conſtruction. Soon after double ſhips were actually built by Mr Miller of Dalſwinton.

7 And lately conſtructed by Mr Miller.

Principles of Naval Architecture, p. 76.

8 Draught of water propoſed to be diminiſhed in order to obtain velocity, &c.

Another plan was propoſed by Mr Gordon to make a ſhip ſail faſt, draw little water, and to keep a good wind. For this purpoſe, "the bottom (he ſays) ſhould be formed quite flat, and the ſides made to riſe perpendicular from it, without any curvature; which would not only render her more ſteady, as being more oppoſed to the water in rolling, but likewiſe more convenient for ſtowage, &c. while the ſimplicity of the form would contribute greatly to the eaſe and expedition with which ſhe might be fabricated. Though diminiſhing the draught of water is, *cæteris paribus*, undoubtedly the moſt effectual method of augmenting the velocity with which veſſels go before the wind; yet, as it proportionally diminiſhes their hold of the water, it renders them extremely liable to be driven to leeward, and altogether incapable of keeping a good wind. This defect may, however, be remedied, in a ſimple and effectual manner, by proportionally augmenting the depth of keel, or, as ſo large a keel would be inconvenient on many accounts, proportionally increaſing their number; as, in place of adding a keel eight feet deep to a veſſel drawing ſix feet water, to affix to different parts of her flat bottom, which would be well adapted for receiving them, ſix different keels of two feet deep each at equal diſtances from each other, with proper intervals between; which will be found equally effectual for preventing theſe pernicious effects. Four ſuch, indeed, would have anſwered the purpoſe as well as the eight feet keel, were it not for the ſuperior preſſure or reſiſtance of the lower water (A).

9 Inconveniency of this plan.

10 Remedied by augmenting the depth of the keel.

11 Or by increaſing the number of keels.

Thus then it appears, that a veſſel drawing eight feet water only, keels and all, may be made to keep as good a wind, or be as little liable to be driven to leeward, as the ſharpeſt built veſſel of the ſame length drawing 14, nay 20 or upwards, if a few more keels are added, at the ſame time that ſhe would be little more reſiſted in moving in the line of the keels than a veſſel drawing ſix feet water only. Theſe keels, beſides, would ſtrengthen the veſſel conſiderably, would render her more ſteady, and leſs liable to be overſet, and thereby enable

(A) This is frequently repeated on the authority of Mr Gordon and others. Theory ſays otherwiſe; and the experiments of Sir Iſaac Newton ſhow in the moſt unexceptionable manner, that the reſiſtance of a ball deſcending through the water is the ſame at all depths; nay, the heaping up of the water on the bow, occaſioning a hydroſtatical preſſure in addition to the real reſiſtance, will make the whole oppoſition to an equal ſurface, but of greater horizontal dimenſions, greater, becauſe it bears a greater proportion to the reſiſtance.

History.

enable her to carry more sail; and Mr. Gordon then enumerates the several advantages that a ship of this construction will possess.

12 The plan further improved by the adoption of sliding keels.

This plan has lately been put into execution by Captain Schank, with this difference only, that instead of the keels being fixed as proposed by Mr. Gordon, Captain Schank constructed them so as to slide down to a certain depth below the bottom, or to be drawn up within the ship as occasion might require.

Captain Schank having communicated his plans to the Navy Board, two vessels were in consequence ordered to be built of 13 tons each, and similar in dimensions, one on the old construction, and the other flat-bottomed, with sliding keels. In 1790 a comparative trial in presence of the commissioners of the navy was made on the river Thames, each having the same quantity of sail; and although the vessel on the old construction had leeboards, a greater quantity of ballast, and two Thames pilots aboard, yet Captain Schank's vessel with three sliding keels beat the other vessel, to the astonishment of all present, one half of the whole distance sailed; and no doubt she would have beat her much more had she been furnished with a Thames pilot.

13 The utility of sliding keels proved by experiment.

This trial gave so much satisfaction, that a king's cutter of 120 tons was immediately ordered to be built on the same construction, and Captain Schank was requested to superintend its building. This vessel was launched at Plymouth in 1791, and named the *Trial*. The length of this vessel is 66 feet, breadth 21 feet, and depth of the hold seven feet: her bottom is quite flat, and draws only six feet water, with all her guns, stores, &c. whereas all other vessels of her tonnage on the old construction draw 14 feet; so that she can go with safety into almost any harbour or creek. She has three sliding keels inclosed in a case or well; they are each 14 feet in length; the fore and the after keels are three feet broad each, and the middle keel is six feet broad. The keels are moveable by means of a winch, and may be let down seven feet below the real keel; and they work equally well in a storm as in still water. Her hold is divided into several compartments, all water-tight, and so contrived, that should even a plank or two start at sea in different parts of the vessel, she may be navigated with the greatest security to any place. If she should be driven on shore in a gale of wind, she will not soon become a wreck, as her keels will be driven up into their cases, and the ship being flat-bottomed, will not be easily overset; and being able to go into such shallow water, the crew may all be easily saved. By means of her sliding keels she is kept steady in the greatest gale; she is quite easy in a great sea, does not strain in the least, and never takes in water on her deck; and when at anchor, she rides more upright and even than any other ship can do: she sails very fast either before or upon a wind; no vessel she has ever been in company with, of equal size, has been able, upon many trials, to beat her in sailing; and yet her sails seem too small.

14 And actually put in practice upon a larger scale.

It has also been proposed to construct vessels of other materials than wood; and lately a vessel was built whose bottom, instead of being plank, was copper.

Book I. *Containing the Method of delineating the several Sections of a Ship.*

Properties of Ships.

Chap. I. *Of the Properties of Ships.*

A ship ought to be constructed so as to answer the particular purpose for which she is intended. It would be an easy matter to determine the form of a ship intended to sail by means of oars; but, when sails are used, a ship is then acted upon by two elements, the wind and water: and therefore it is much more difficult than is commonly imagined to ascertain the form of a ship so as to answer in an unfavourable as well as a favourable wind; the ship at the same time having a cargo of a certain weight and magnitude. 15 General principles of ship-building

Every ship ought to sail well, but particularly when the wind is upon the beam; for this purpose a considerable length in proportion to the breadth is necessary, and the plane of resistance should be the least possible. The main frame should also be placed in a proper situation; but according to the experiments of Mr. Chapman*, its plane is variable with the velocity of the ship: the mean place of the main frame has, however, been generally estimated to be about one-twelfth of the length of the keel before the middle. Without a sufficient degree of stability a ship will not be able to carry a press of sail: a great breadth in proportion to the length and low upper-works will augment the stability. The following particulars being attended to, the above property will be gained, and the ship will also steer well. The wing transom should be carried pretty high; the fashion-pieces well formed, and not full below the load water-line: the lower part of the stem to be a portion of a circle, and to have a considerable rake: the sternpost to be nearly perpendicular to the keel; and all the upper works kept as low as possible. 16 Properties that a ship must possess to be a good sailer.

* Traité de la Construction des Vaisseaux, p. 40.

Many ships from construction are liable to make much leeway. This may in a great measure be avoided by giving the ship a long keel, little breadth, and a considerable depth in the hold; whence the bow will meet with little resistance in comparison to the side, and therefore the ship will not fall much to the leeward. 17 To make a ship keep a good wind.

Another very great retardation to the velocity of a ship is her pitching. The principal remedy for this is to increase the length of the keel and floor, to diminish the rising afore and abaft, and to construct the hull in such a manner that the contents of the fore-body may be duly proportioned to the contents of the after-body. 18 And to sail smoothly without pitching hard.

In a ship of war the lower tier of guns ought to be of a sufficient height above the water, otherwise it will be impossible to work the lee-guns when it blows hard. This property will be obtained by giving her a long floor-timber, little rising, a full midship frame, light upper works, and the wing transom not too high: And in every ship the extreme breadth ought always to be higher afore and abaft than at midships. 19 In ships of war the lower deck guns to be sufficiently high above the water.

A merchant ship, besides being a fast sailor, ought to carry a considerable cargo in proportion to its length, to sail with little ballast, and to be navigated with few hands. 20 Properties of a merchant ship.

That a ship may take in a considerable cargo, it should 21 To take in a great cargo, Properties of Ships. should have a great breadth and depth in proportion to its length, a full bottom, and a long and flat floor. But a ship of this construction will neither sail fast, nor carry much sail.

22
And to have stability.

If a ship be filled out much towards the line of floatation, together with low upper works, she will require little ballast: and that ship which is stiff from construction is much better adapted for sailing fast than one which, in order to carry the same quantity of canvas, is obliged to be loaded with a much greater weight: for the resistance is as the quantity of water to be removed, or nearly as the area of a transverse section of the immersed part of the body at the midship frame; and a body that is broad and shallow is much stiffer than one of the same capacity that is narrow and deep.

Principles of naval Architecture, p. 100.

23
Advantages of a ship of a small draught of water.

"The advantages (says Mr Gordon) are numerous, important, and obvious. For it is evident, that by enlarging, perhaps doubling, the breadth of vessels, and forming their bottoms flat and well furnished with keels, they must, in the *first* place, become much steadier, roll little, if any, and be enabled to carry greatly more sail, and that in a better direction, at the same time that they would be in no danger of being dismasted or overset, unless the masts were of a most extraordinary height indeed. *Secondly*, They would have little or no occasion for ballast, and if any was used, could incur less danger from its shifting. *Thirdly*, That there would be much more room upon deck, as well as accommodation below; the breadth being so much increased without any diminution of the height above the load-water line. *Fourthly*, That they would deviate much less from the intended course, and penetrate the water much easier in the proper direction: for doubling the breadth, without any increase of weight, would diminish the depth or draught of water one half; and though the extent of the directly opposing surface would be the same as before, yet the vessel in moving would meet with half the former resistance only: for so great is the difference between the pressure, force, or reaction, of the upper and the under water. *Fifthly*, That they would by this means be adapted for lying unsupported in docks and harbours when dry, be rendered capable of being navigated in shallow water, and of being benefited by all the advantages attending that very important circumstance; and it is particularly to be observed, that making vessels which may be navigated in shallow water, may, in many respects, justly be regarded as a matter of equal importance with increasing the number of harbours, and improving them, as having identically the same effects with regard to navigation; at the same time, that the benefits which would result from such circumstances are obtained by this means without either expence, trouble, or inconveniency: besides, it would not only enable vessels to enter many rivers, bays, and creeks, formerly inaccessible to ships of burden, but to proceed to such places as are most land-locked, where they can lie or ride most secure, and with least expence of men and ground tackle. As ships of war would carry their guns well by being so steady, there could be but little occasion for a high topside, or much height of hull above water; and as little or no ballast would be required, there would be no necessity, as in other vessels, for increasing their weight on that account, and thereby pressing them deeper into the water. These are very important circumstances, and would contribute much to improve the sailing of such vessels." From whence it appears, that there would be united, what has hitherto been deemed irreconcileable, the greatest possible stability, which is nearly as the area of a tranverse section of the immersed part of the body at the midship frame: and a body that is broad and shallow is much stiffer than one of the same capacity that is narrow and deep. A ship of this construction may take in a considerable cargo in proportion to her size; but if deeply loaded will not sail fast, for then the area of a section of the immersed part at the midship frame will be very considerable; and as the sails of such a ship must necessarily be large, more hands will therefore be required.

The less the breadth of a ship, the fewer hands will be necessary to work her; as in that case the quantity of sail will be less, and the anchors also of less weight. We shall gain much (says M. Bouguer) by making the extreme breadth no more than the fifth or sixth part of the length, if, at the same time, we diminish the depth proportionally; and likewise this most surprising circumstance, that by diminishing these two dimensions, or by increasing the length, a ship may be made to go sometimes as fast as the wind.

24
And to be navigated with few hands.
Traité du Navire.

In order to obtain the preceding properties, very opposite rules must be followed; and hence it appears to be impossible to construct a ship so as to be possessed of them all. The body, however, must be so formed, that as many of these properties may be retained as possible, always observing to give the preference to those which are most required. If it is known what particular trade the ship is to be employed in, those qualities are then principally to be adhered to which are most essentially necessary for that employment.

25
Impossible to unite all the qualities in the same ship.

It may easily be demonstrated that small ships will not have the same advantages as large ones of a similar form, when employed in the same trade: for a large ship will not only sail faster than a small one of a similar form, but will also require fewer hands to work her. Hence, in order that a small ship may possess the same advantages as a large one, the correspunding dimensions will not be proportional to each other. The reader will see in Chapman's *Architectura Navalis Mercatoria* ample tables of the several dimensions of ships, of different classes and sizes, deduced from theory combined with experiments. Tables of the dimensions of the principal ships of the British navy, and of other ships, are contained in the Ship-builder's Repository, and in Murray's Treatise on Ship-building.

26
Small ships inferior to large ones in point of sailing, &c.

CHAP. II. *Of the different Plans of a Ship.*

When it is proposed to build a ship, the proportional size of every part of her is to be laid down; from whence the form and dimensions of the timbers, and of every particular piece of wood that enters into the construction, is to be found. As a ship has length, breadth, and depth, three different plans at least are necessary to exhibit the form of the several parts of a ship: these are usually denominated the *sheer plan*, the *half breadth* and *body plans*.

The *sheer plan* or *draught*, otherwise called the *plan of elevation*, is that section of the ship which is made by a vertical plane passing through the keel. Upon this plan are laid down the length of the keel; the height and rake of the stem and sternpost; the situation and

27
Sheer draught, or elevation.

Different Plans of a Ship.

and height of the midship and other frames; the place of the masts and channels; the projection of the head and quarter gallery, and their appendages; and in a ship of war the positions and dimensions of the gun-ports. Several imaginary lines, namely, the upper and lower height of breadth lines, water lines, &c. are also drawn in this plan.

28 Half breadth plan or horizontal plane.

The *half-breadth* or *floor-plan*, or, as it is frequently called the *horizontal* plane, contains the several half-breadths of every frame of timbers at different heights; ribbands, water lines, &c. are also described on this plane.

29 Body plan, or projection.

The *body* plan, or *plane of projection*, is a section of the ship at the midship frame or broadest place, perpendicular to the two former. The several breadths, and the particular form of every frame of timbers, are described on this plane. As the two sides of a ship are similar to each other, it is therefore unnecessary to lay down both; hence the frames contained between the main frame and the stem are described on one side of the middle line, commonly on the right hand side, and the after frames are described on the other side of that line.

30 The various lines laid down on these plans.

Several lines are described on these planes, in order the more readily to assist in the formation of the timbers; the principal of which are the following:

The *top-timber line*, is a curve limiting the height of the ship at each timber.

The *top-timber half-breadth line*, is a section of the ship at the height of the top-timber line, perpendicular to the plane of elevation.

The *height of breadth lines*, are two lines named the *upper* and *lower* heights of breadth. These lines are described on the plane of elevation to determine the height of the broadest part of the ship at each timber; and being described in the body plan, limits the height and breadth of each frame at its broadest part.

Main half breadth, is a section of the ship at the broadest part, perpendicular to the sheer plan, and represents the greatest breadth at the outside of every timber.

Water lines, are lines supposed to be described on the bottom of a ship when afloat by the surface of water; and the uppermost of these lines, or that described by the water on the ship's bottom when sufficiently loaded, is called the *load water line*. According as the ship is lightened, she will rise higher out of the water; and hence new water lines will be formed. If she be lightened in such a manner that the keel may preserve the same inclination to the surface of the water, these lines will be parallel to each other; and if they are parallel to the keel, they will be represented by straight lines parallel to each other in the body plan; otherwise by curves. In the half-breadth plan, these lines are curves limiting the half-breadth of the ship at the height of the corresponding lines in the sheer plan. In order to distinguish the lines, they are usually drawn in green.

Ribband lines, are curves on a ship's bottom by the intersection of a plane inclined to the plane of elevation; and are denominated *diagonal* or *horizontal*, according as they are measured upon the diagonal, or in a direction perpendicular to the plane of elevation. Both these answer to the same curve on the ship's bottom, but give very different curves when described on the half-breadth plan.

Different Plans of a Ship.

Frames, are circular pieces of timber bolted together, and raised upon the keel at certain distances, and to which the planks are fastened. A frame is composed of one floor-timber, two or three futtocks, and a top-timber on each side: which being united together, form a circular inclosure, and that which incloses the greatest space is called the *midship* or *main* frame. The arms of the floor-timber of this frame form a very obtuse angle; but in the other frames this angle decreases with the distance of the frame from midships. Those floor timbers which form very acute angles are called *crutches*. The length of the midship floor timber is in general about half the length of the mainframe. 31 Frames, composed of a floor timber, futtocks, and top timber.

32 Sweeps of the several parts of a frame.

A frame of timbers is commonly formed by arches of circles called *sweeps*. There are generally five sweeps: *1st*, The *floor sweep*; which is limited by a line in the body plan perpendicular to the plane of elevation, a little above the keel; and the height of this line above the keel at the midship frame is called the *dead rising*. The upper part of this arch forms the head of the floor timber. *2d*, The *lower breadth sweep*; the centre of which is in the line representing the lower height of breadth. *3d*, The *reconciling sweep*. This sweep joins the two former, without intersecting either; and makes a fair curve from the lower height of breadth to the rising line. If a straight line is drawn from the upper edge of the keel to touch the back of the floor sweep, the form of the midship frame below the lower height of breadth will be obtained. *4th*, The *upper breadth sweep*; the centre of which is in the line representing the upper height of breadth of the timber. This sweep described upwards forms the lower part of the top timber. *5th*, The *top timber sweep* is that which forms the hollow of the top-timber. This hollow is, however, very often formed by a mould, so placed as to touch the upper breadth sweep, and pass through the point limiting the half breadth of the top timber.

33 Names of frames.

The main frame, or as it is usually called *dead-flat*, is denoted by the character ⊕. The timbers before dead-flat are marked A, B, C, &c. in order; and those abaft dead-flat by the figures 1, 2, 3, &c. The timbers adjacent to dead-flat, and of the same dimensions nearly, are distinguished by the characters (A), (B), &c. and (1), (2), &c. That part of the ship abaft the main frame is called the *after body*; and that before it the *fore body*.

All timbers are perpendicular to the half-breadth plan. Those timbers whose planes are perpendicular to the sheer plan, are called *square timbers*; and those whose planes are inclined to it are called *canted timbers*.

The *rising line*, is a curve drawn in the sheer plan, at the heights of the centres of the floor sweeps in the body plan. As, however, this line, if drawn in this manner, would extend beyond the upper line of the figure, it is therefore usually so drawn that its lower part may touch the upper edge of the keel. This is performed by taking the heights of each of the centres in the body plan, from the height of the centre of the sweep of dead-flat, and setting them off on the corresponding timbers in the sheer plan from the upper edge of the keel.

Half-breadth of the rising, is a curve in the floor plan, which limits the distances of the centres of the floor sweeps from the middle line of the body plan.

The

Different Plans of a Ship.

The rising of the floor, is a curve drawn in the sheer plan, at the height of the ends of the floor timbers. It is limited at the main frame or dead flat by the dead rising, and in flat ships is nearly parallel to the keel for some timbers afore and abaft the midship frame; for which reason these timbers are called *flats*: but in sharp ships it rises gradually from the main frame, and ends on the stem and post.

Cutting down line, is a curve drawn on the plane of elevation. It limits the depth of every floor timber at the middle line, and also the height of the upper part of the dead wood afore and abaft.

Timber and room, or *room and space*, is the distance between the moulding edges of two timbers, which must always contain the breadth of two timbers and an interval of about two or three inches between them. In forming the timbers, one mould serves for two, the foreside of the one being supposed to unite with the aftside of the other, and so make only one line, which is called the *joint of the timbers*.

34 Principal pieces that compose a ship.

In order to illustrate the above, and to explain more particularly the principal pieces that compose a ship, it will be necessary to give a description of them. These pieces are for the most part represented according to the order of their disposition in fig. 1. Plate CCCCLIV.

A, Represents the pieces of the keel to be securely bolted together and clinched.

B, The sternpost, which is tenanted into the keel, and connected to it by the knee G.

E, The back of the post, which is also tenanted into the keel, and securely bolted to the post; the intention of it is to give sufficient breadth to the post, which seldom can be got broad enough in one piece. C is the false post, which is fayed (B) to the fore part of the sternpost.

C, The stem, in two pieces, to be scarfed together. The stem is joined to the fore foot, which makes a part of both.

H, The apron in two pieces, to be scarfed together, and fayed on the inside of the stem, to support the scarf thereof; and therefore the scarf of the apron must be at some distance from that of the stem.

I, The stemson, in two pieces, to support the scarf of the apron.

D, The beams which support the deck; and F the knees by which the beams are fastened to the sides of the ship.

K, The wing transom: it is fayed across the sternpost, and bolted to the head of it, and its extremities are fastened to the fashion pieces. L, is the deck transom, parallel to the wing transom. M, N, Two of the lower transoms: these are fastened to the sternpost and fashion pieces in the same manner as the wing transom. Q, The knee which fastens the transom to the ship's side. And, O, The fashion-piece, of which there is one on each side. The keel of the fashion piece is connected with the dead-wood, and the head is fastened to the wing transom.

R, S, Breast-hooks: these are fayed in the inside to the stem, and to the bow on each side of it, to which they are fastened with proper bolts. There are generally four or five in the hold, in the form of that marked R, and one in the form of that marked S, into which the lower deck planks are rabbeted: There is also one immediately under the hause holes, and another under the second deck.

T, The rudder, which is joined to the sternpost by the rudder irons, upon which it turns round in the googings, fastened to the sternpost for that purpose. There is a mortise cut in the head of the rudder, into which a long bar is fitted called the *tiller*, and by which the rudder is turned.

U, A floor timber; it is laid across the keel, to which it is fastened by a bolt through the middle. V, V, V, V, The lower, the second, third, and fourth futtocks. W, W, The top timbers. These represent the length and scarf of the several timbers in the midship frame.

X, The pieces which compose the kelson. They are scarfed together in the same manner as the keel, and placed over the middle of the floor-timbers, being scored about an inch and a half down upon each side of them, as represented in the figure.

Y, The several pieces of the knee of the head; the lower part of which is fayed to the stem, and its keel is scarfed on the head of the forefoot It is fastened to the bow by two knees, called *cheeks*, in the form of that represented by Z; and to the stem, by a knee called a *standard*, in the form of that marked ⊕.

a, The cathead, of which there is one on each side of the bow, projecting so far as to keep the anchor clear of the ship when it is hove up.

b, The bits, to which the cable is fastened when the ship is at anchor.

d, The side counter-timbers, which terminate the ship abaft within the quarter gallery.

e, *e*, Two pieces of dead wood, one afore and the other abaft, fayed on the keel.

Fg. 2. is a perspective representation of a ship framed and ready for the planking; in which A, A is the keel; B, the sternpost; C, the stem; K, L, M, the transoms; F, F, F, F, F, F, the ribbands.

Chap. III. *Containing Preliminary Problems*, &c.

The general dimensions of a ship are the *length*, *breadth* and *depth*.

35 Proportional dimensions of a ship.

To ascertain those dimensions that will best answer the intended purpose is, no doubt, a problem of considerable difficulty; and, from theory, it may be shown, that there are no determinate proportions subsisting between the length, breadth and depth, by which these dimensions may be settled; yet, by combining theory and practice, the proportional dimensions may be approximated to pretty nearly.

36 To be inferred from theory combined with practice;

As ships are constructed for a variety of different purposes, their principal dimensions must therefore be altered accordingly, in order to adapt them as nearly as possible to the proposed intention; but since there is no fixed standard whereby to regulate these dimensions, the methods therefore introduced are numerous, and in a great measure depend upon custom and fancy.

With regard, however, to the proportional dimensions,

(B) To *fay*, is to join two pieces of timber together.

sions, they perhaps may be inferred from the circle. Thus, if the extreme breadth be made equal to the diameter, the length at the load water line, or the distance

37 And also from the circle.

between the rabbets at the stem and post at that place, may be made equal to the circumference of the same circle; and the depth of the hold equal to the radius, the upper works being continued upwards according to circumstances. A ship formed from these dimensions, with a bottom more or less full according as may be judged necessary, will no doubt answer the proposed intention. Nevertheless, one or other of these dimensions may be varied in order to gain some essential property, which the trade that the vessel is intended for may require.

The following hints are given by Mr Hutchinson † towards fixing rules for the best construction of ships bottoms.

† Practical Seamanship page 25.

1. "I would recommend (says he), to prevent ships bottoms from hogging* upwards amidship, to have the fore and after part of their keels deep enough, that the upper part may be made to admit a rabbet for the garboard streak, that the main body and bearing part of the ships bottoms may be made to form an arch downwards in their length, suppose with the same sheer as their bends, at the rate of about 2 inches for every 30 feet of the extreme length of the keel towards the midship or main frame, which may be reckoned the crown of the arch; and the lower part of the keel to be made straight, but laid upon blocks so that it may form a regular convex curve downwards at the rate of an inch for every 30 feet of the extreme length of the keel, the lowest part exactly under the main frame; which curve, I reckon, is only a sufficient allowance for the keel to become straight below, after they are launched afloat, by the pressure of the water upwards against their floors amidship, which causes their tendency to hog. And certainly a straight keel is a great advantage in sailing, as well as to support them when laid upon level ground or on straight blocks in a repairing dock, without taking damage.

* See Book ii. Chap. 2.

2. "As square sterned ships, from experience, are found to answer all trades and purposes better than round or pink sterned ships, I would recommend the fore part of the sternpost on account of drawing the water lines in the draught, only to have a few inches rake, that the after part may stand quite upright perpendicular to the keel: and for the rake of the stem I would propose the rabbet for the hudding ends for the entrance, and bows from the keel upwards, to form the same curve as the water line from the stem at the harpin towards the main breadth, and the bows at the harpin to be formed by a sweep of a circle of half the three-fourths of the main breadth; and the main transom to be three-fourths of the main-breadth; and the buttocks, at the load or sailing mark aft, to be formed, in the same manner as the bows at the harpin, with a sweep of a circle of half the three-fourths of the main breadth, to extend just as far from the stem and stern post as to admit a regular convex curve to the main frame, and from these down to the keel to form regular convex water-lines, without any of those unnatural, hollow, concave, ones, either in the entrance or run; which rules, in my opinion, will agree with the main body of the ship, whether she is designed to be built full for burden or sharp below for sailing.

3. "This rule for raking the stem will admit all the water-lines in the ship's entrance to form convex curves all the way from the stem to the midship or main frame, which answers much better for sailing as well as making a ship more easy and lively in bad weather. And the bows should flange off, rounding in a circular form from the bends up to the gunwale, in order to meet the main breadth the sooner, with a sweep of half the main breadth at the gunwale amidships; which will not only prevent them greatly from being plunged under water in bad weather, but spread the standing fore-rigging the more, to support these material masts and sails forward to much greater advantage than in those over sharp bowed ships, as has been mentioned. And as the sailing trim of ships in general is more or less by the stern, this makes the water-lines of the entrance in proportion the sharper to divide the particles of water the easier, so that the ship may press through it with the least resistance.

4. "The run ought to be formed shorter or longer, fuller or sharper, in proportion to the entrance and main body, as the ship is designed for burden or sailing fast. The convex curves of the water lines should lessen gradually from the load or sailing mark aft, as has been mentioned, downwards, till a fair straight taper is formed from the after part of the floor to the sternpost below, without any concavity in the water lines; which will not only add buoyancy and burden to the after body and run of the ship, but, in my opinion, will help both her sailing and steering motions; for the pressure of the water, as it closes and rises upon it to come to its level again, and fill up that hollow which is made by the fore and main body being pressed forward with sail, will impinge, and act with more power to help the ship forward in her progressive motion, than upon those unnatural concave runs, which have so much more flat dead wood, that must, in proportion, be a hindrance to the stern being turned so easily by the power of the helm to steer the ship to the greatest advantage."

Many and various are the methods which are employed to describe the several parts of a ship. In the following problems, however, those methods only are given which appear to be most easily applied to practice, and which, at the same time, will answer any proposed purpose.

Prob. I. To describe in the plane of elevation the sheer or curvature of the top-timbers.

Plate CCCCLV.

Let QR (fig. 3.) be the length of the ship between the wing transom and the rabbet of the stem. Then since it is generally agreed, especially by the French constructors, that the broadest part of the ship ought to be about one-twelfth of the length before the main frame or dead flat; therefore make R⊕ equal to five-twelfths of QR, and ⊕ will be the station of the main frame: space the other frames on the keel, and from these points let perpendiculars be drawn to the keel. Let ⊗P be the height of the ship at the main frame, VF the height at the aftermost frame, and RK the height at the stem. Through P draw EPL parallel to the keel; describe the quadrants PGI, PMN, the radius being P⊕; make PH equal to EF, and PO equal KL, and draw the parallels GH, OM: Divide GH similar to ⊕C, and OM similar to ⊕R. Through these points of division draw lines perpendicular to EL, and the several portions of these perpendiculars contained between EL and the arch will be the risings of the top-

38 The place of the main frame about one-twelfth before the middle of the ship.

39 Method of describing the top-timber line.

Fig. 1.

PIESES of the HULL.

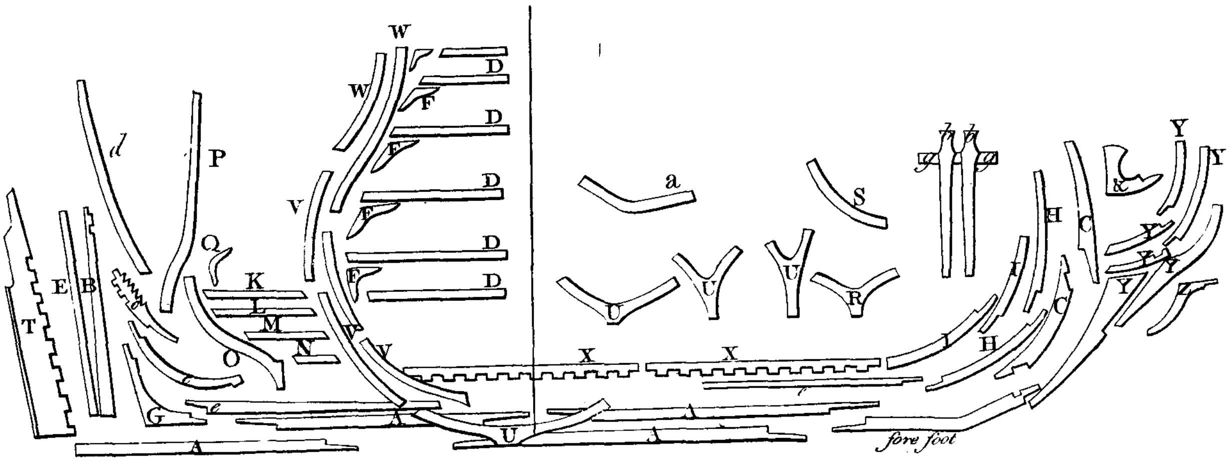

Fig. 2.

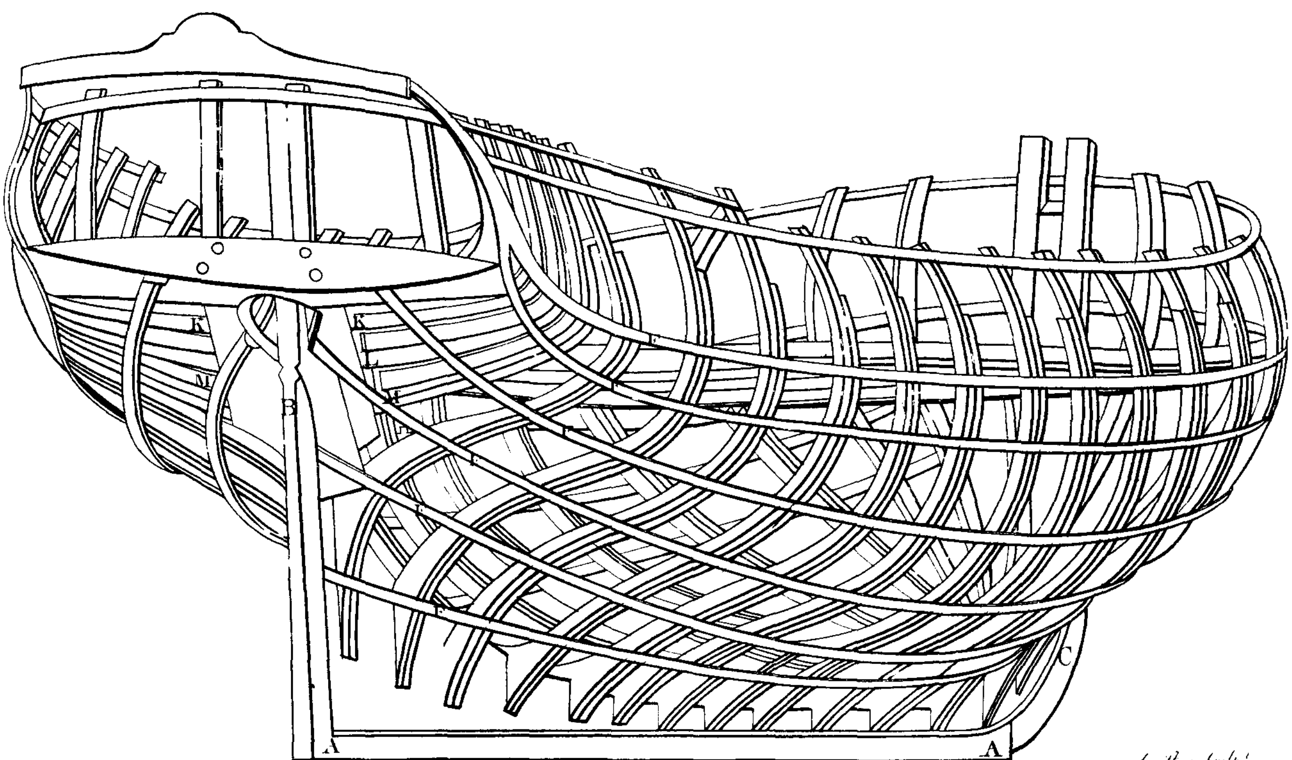
FRAMES of a SHIP.



Smither Sculp.

top timber line above EL. A curve drawn through theſe points will form the top-timber line.

This line is more eaſily drawn by means of a curved or bent ruler, ſo placed that it may touch the three points F, P, and K.

Prob. II. To deſcribe the ſtem.

40 The ſtem, Let K (fig. 3.) be the upper part of the ſtem, thro' which draw KS parallel to the keel, and equal to twice KR: Through the termination of the wales on the ſtem draw TW parallel to QR. Then from the centre S, with the diſtance SK, deſcribe an arch: Take an extent equal to the neareſt diſtance between the parallels WT, QR; and find the point W, ſuch that one point of the compaſs being placed there, the other point will juſt touch the neareſt part of the above arch; and from this point as a centre deſcribe an arch until it meets the keel, and the ſtem will be formed.

Prob. III. To deſcribe the ſternpoſt.

41 And poſt. Set off QV (fig. 3.) for the rake of the poſt: draw VX perpendicular to the keel, and equal to the height of the wing tranſom, join QX, and it will repreſent the aft ſide of the poſt.

Prob. IV. To deſcribe the half breadth line.

42 Main half breadth line. Let MN (fig. 4.) be the given length: Make N$\otimes$ equal to five-twelfths of MN; draw the line $\oplus$P perpendicular to MN, and equal to the propoſed extreme half breadth. Let ME be the round aft of the ſtern or wing tranſom; make EO perpendicular to MN, and equal to the given half breadth at the ſtern, which is generally between two thirds and three-fourths of the main half breadth; and deſcribe the arch MO, the centre of which is in the middle line. Space the frames (A), A, B, &c. and (1), 1, 2, &c. From the centre $\oplus$, with the radius $\oplus$P, deſcribe the quadrant PRS; deſcribe alſo the quadrant PCT. Through the point O draw ORU parallel to MN; divide the ſtraight line RU ſimilar to M$\otimes$; and through theſe points of diviſion draw lines perpendicular to MN, and meeting the arch. Transfer theſe lines to the correſpondent frames each to each, and a curve drawn through the extremities will repreſent that part of the ſide contained between the main frame and the ſtern. Again, thro' Q, the extremity of the foremoſt frame, draw QV parallel to MN. Or make PV a fourth or third part of PU, according as it is intended to make the ſhip more or leſs full towards the bow. Divide VC ſimilar to $\otimes$C; through theſe points draw lines perpendicular to MN, and terminating in the quadrantal arch: Transfer theſe lines to the correſponding timbers in the fore part, and a curve drawn through the extreme points will limit that part of the ſhip's ſide contained between P and Q. Continue the curve to the next timber at X. From Q draw QZ perpendicular to QX; make the angle ZNQ equal to ZQN, and the point Z will be the centre of the arch forming the bow. Remark, if it is propoſed that the breadth of the ſhip at the frames adjacent to the main frame ſhall be equal to the breadth at the main frame; in this caſe, the centres of the quadrantal arches will be at the points of interſection of theſe frames with the line MN; namely at (A) and (1). Alſo, if the height of the ſhip at the frames (A) and (1) is to be the ſame as at dead flat, the quadrantal arches in fig. 3. are to be deſcribed from the points of interſection of theſe frames with the line EL.

Theſe rules, it is evident, are variable at pleaſure; and any perſon acquainted with the firſt principles of mathematics may apply calculation to find the radii of the ſeveral ſweeps.

Prob. V. To deſcribe the main frame or dead-flat.

This frame is that which contains the greateſt ſpace, and the particular form of each of the other frames depends very much on it. If the ſhip is intended to carry a great burden in proportion to her principal dimenſions, this frame is made very full; but if ſhe is intended to ſail faſt, it is uſually made ſharp. Hence ariſes diverſity of opinions reſpecting its form; each conſtructor uſing that which to him appears preferable. In order to ſave repetition, it is judged proper to explain certain operations which neceſſarily enter into all the different methods of conſtructing this frame. 43 Of the midſhip frame.

In the plane of the upper ſide of the keel produced, draw the line AB (fig. 5.) equal to the propoſed breadth of the ſhip; biſect AB in C, and draw AD, CE, and BF, perpendicular to AB. Then, ſince the two ſides of a ſhip are ſimilar, it is therefore thought ſufficient to deſcribe the half of each frame between the main frame and the ſtern on one ſide of the middle line CE, and the half of each of thoſe before the main frame on the other ſide of it. The firſt half is called the *after-body*, and the other the *fore-body*. The after-body is commonly deſcribed on the left ſide of the middle line; and the fore-body on the right ſide of it: hence the line AD is called the *ſide line* of the *after* body, and BF the ſide line of the *fore* body. Make AD and BF each equal to the height of the ſhip at the main frame. Make AG, BG, and AH, BH, equal to the lower and upper heights of breadth reſpectively, taken from the ſheer plan. Let I I be the load-water line, or line of floatation when the ſhip is loaded, and KK the height of the riſing line of the floor at this frame. Make CN, CO, each equal to half the length of the floor timber, and N, O, will be the heads of the floor timber, thro' which draw perpendiculars to AB. Make C *m*, E *m*, each equal to half the thickneſs of the ſternpoſt, and C *n*, E *n*, equal to half the thickneſs of the ſtern, and join *m m*, *n n*. 44 General precepts for deſcribing it.

Method I. *Of deſcribing a main frame.*—From the centre *a* (fig. 5.), in the lower breadth line, deſcribe the lower breadth ſweep G *e*; make N *b* equal to the propoſed radius of the floor ſweep, and from the centre *b* deſcribe the floor ſweep N *f*. Let the radius of the reconciling ſweep be A *g*, equal to about the half of AC; then make A *h* equal to N *b*, and A *m*, equal to G *a*. Now from the centre *a*, with an extent equal to *g m*, deſcribe an arch, and from the centre *b*, with the extent *g h*, deſcribe an arch interſecting the former in *c*, which will be the centre of the reconciling ſweep *e f*. Join N *m*, by an inverted curve, the centre of which may be in the line *b* N produced downwards; or it may be joined by two curves, or by a ſtraight line if there is little riſing; and hence the lower port of the main frame will be deſcribed.

In order to form the top timber, make F *k* equal to ſuch part of the half breadth, agreeable to the propoſed round of the ſide, as one-ſeventh; join H *k*, and make *k i* equal to about two-thirds of H *k*: make the angle H *i l* equal to *i* H *l*; and from the centre *l* at the diſtance

distance l H describe the arch H i; and from the centre o, the intersection of $l\,i$ and k F produced, describe the arch $i\,k$, and the top timber will be formed.

II. *To describe a main frame of an intermediate capacity, that is, neither too flat nor too sharp.*—Divide the line AX (fig. 6), which limits the head of the floor timber, into three equal parts; and make $a\,b$ equal to one of them. Divide the line d B, the perpendicular distance between the load water line and the plane of the upper side of the keel, into seven equal parts; and set off one of these parts from d to c, and from c to m. Let GH be the lower deck, join G m, and produce it to q. Draw the straight line V a, bisect it in n, and from the points n, a, describe arches with the radius G q intersecting each other in P, which will be the centre of the arch $n\,a$. The centre of the arch V n is found by describing arches downwards with the same radius.

With an extent equal to once and a half of B e, describe arches from the points h, e, intersecting each other in A, and from this point as a centre describe the arch $e\,b$; make $a\,l$ equal to $d\,m$, and join A m, A l. Then, in order to reconcile two arches so as to make a fair curve, the centres of these arches, and of the points of contact must be in the same straight line. Hence the point k will be the centre of the arch $d\,m$, and o the centre of the arch $a\,l$. The arch $l\,m$ is described from the centre A.

To form the top timber, set back the tenth part of the half breadth from K to S upon the line of the second deck; then with an extent equal to two-thirds of the whole breadth describe an arch through the points S and H, the upper height of breadth. Again, make MI equal to the fifth part of the half breadth; describe an arch of a circle through the points S and T, taking the diagonal GB for the radius. As this arch is inverted in respect of the arch d S, the centre will be without the figure. Hence one-half of the main frame is formed, and the other half is described by similar operations.

Remark. This frame may be made more or less full by altering the several radii.

III. *To describe a main frame of a circular form.*—Let the several lines be drawn as before: Then make O a (fig. 7.) equal to the half breadth G a, and from the centre a, with the radius G a, describe the arch b G c O. Let d be the head of the floor-timber, and $d\,x$ the rising. Assume the point f in the arch, according to the proposed round of the second futtock, and describe the arch $d\,f$; the centre of which may be found as in the former method: from the centre a, with the distance $a\,d$, describe the arch $d\,c$ O; make $d\,c$ equal to one-third of d O, and the angle $d\,c\,h$ equal to $c\,d\,h$, and from the centre h describe the arch $d\,c$. The inverted arch c O may be described as before.

Plate CCCCLVI.

IV. *To describe a very full main frame.*—Let the vertical and horizontal lines be drawn as before: let b, fig. 8. be the floor-head, and $b\,x$ the rising. Divide G c into two equal parts in the point d, and upon $c\,d$ describe the square $d\,b\,a\,c$, in which inscribe the quadrant $d\,e\,a$. Divide the line $b\,d$ into any number of equal parts in the points O, N, M, L, and draw the lines Lm, Me, Nn, O b, perpendicular to $d\,b$. Divide the line G C, the depth of the hold, the rising being deducted, into the same number of equal parts in the points E, F, I, K, and make the lines E p, F q, I r, K s, in the frame, equal to the lines O b, Nn, Me, Lm, in the squares each to each respectively; and through the points G, p, q, r, s, b, describe a curve. The remaining parts of the frame may be described by the preceding methods.

V. *To describe the main frame of a ship intended to be a fast sailer.* The principal lines being drawn as before, let the length of the floor-timber be equal to half the breadth of the ship, and the rising one-fifth or one-sixth of the whole length of the floor-timber, which lay off from x to E, fig. 9. Through the point E draw the line T x perpendicular to GC, and d E perpendicular to A G. Join T d, which bisect in B, and draw BF perpendicular thereto, and meeting CG produced in F, from the centre F, at the distance F T, describe the semicircle T d D. Divide GT into any number of parts, VW, &c. and bisect the intervals D V, DW, &c. in the points X, Z, &c; then from the centre X, with the extent XV, describe the semicircle D b V, intersecting AG in b. Let VP be drawn perpendicular to GT, and b P, perpendicular to AG, and the point of intersection P will be one point through which the curve is to pass. In like manner proceed for the others, and a curve drawn through all the points of intersection will be part of the curve of the main frame. The remaining part of the curve from E to Y will be composed of two arches, the one to reconcile with the former part of the curve at E, and the other to pass through the point Y, the centre of which may be found by any of the preceding methods. In order to find the centre of that which joins with the curve at E, make TR equal to the half of GD, and join ER, in which a proper centre for this arch may be easily found.

The portion G b E of the curve is a parabola, whose vertex is G and parameter GD.

For G D : G b : : G b : GV by construction.

Hence DG $\times$ GV = G b^2, which is the equation for a parabola.

VI. *To describe a main frame of a middling capacity.*—Let the length of the floor timber be equal to one-half of the breadth of the ship. Make O d, fig. 10. equal to one-fourth of the length of the floor timber, and draw the perpendicular $d\,c$ equal to the rising, and divide it into two equal parts in the point e. Describe an arch through e, and the extremity a of the floor timber, the radius being equal to the half breadth, or more or less according to the proposed round of the floor head.—Then with the radius O l, half the length of the floor timber, describe the arch e Y.

Draw $l\,m$ perpendicular to OA: bisect A n in p, and draw the perpendicular $p\,q$. From the middle of A p draw the perpendicular $r\,s$, and from the middle of A r draw the perpendicular $t\,u$. Make $n\,z$, $p\,g$, each equal to $l\,n$: make the distances $p\,y$, $r\,b$, each equal to $a\,g$; r F, t E, each equal to $a\,b$; and $t\,x$ equal to aE. Then a curve drawn through the points a, z, y, F, x, T, will form the under part of the midship frame.

We shall finish these methods of describing the main frame of a ship with the following remark from M. Vial du Clairbois†. "It seems (says he) that they have affected to avoid straight lines in naval architecture; yet, geometrically speaking, it appears that a main frame formed of straight lines will have both the advantage and simplicity over others." To illustrate this, draw the straight line M N (fig. 9.) in such a manner that the mixtilineal space M $a\,d$ may be equal to the mix-

† Architecture Navale, p. 22.

Preliminary Problems.

mixtilineal space DNY. Hence the capacity of the main frame formed by the straight lines MN, NY will be equal to that of the frame formed by the curve M a D Y; and the frame formed by the straight lines will for the most part be always more susceptible of receiving a bow that will easily divide the fluid. It is also evident, that the cargo or ballast, being lower in the frame formed of straight lines than in the other, it will therefore be more advantageously placed, and will enable the ship to carry more sail (c); so that having a bow equally well or better formed, she will sail faster.

Traité du Navire de Bouguer, p. 601.

Prob. VI. To describe a stern having a square tuck.

Let AB (fig. 11.) be the middle line of the post, and let CD be drawn parallel thereto at a distance equal to half the thickness of the post. Make CE equal to the height of the lower part of the fashion-piece above the keel: make CT equal to the height of the extremity G of the transom above the plane of the keel produced, and CH equal to the height of the transom on the post, HT being equal to above one-ninth or one-tenth of GT, and describe the arch GH, the centre of which will be in BA produced: make EK equal to five-twelfths of ET: through K draw KL perpendicular to CD, and equal to EK; and with an extent equal to EL describe the arch EL. Make GI equal to the half of ET, and from the centre I describe the arch GM, and draw the reconciling curve ML.—Let the curve of the fashion-piece be produced upwards to the point representing the upper height of breadth, as at O. Make ON equal to the height of the top-timber, and BN equal to the half-breadth at that place, and join ON. Through N and the upper part of the counter, let arches be described parallel to GH. The tafferel, windows, and remaining part of the stern, may be finished agreeable to the fancy of the artist.

In fig. 12. the projection of the stern on the plane of elevation is laid down, the method of doing which is obvious from inspection.

If the transom is to round aft, then since the fashion pieces are always sided straight, their planes will intersect the sheer and floor planes in a straight line. Let Gg (fig. 14.) be the intersection of the plane of the fashion-piece with the floor plane. From the point g draw g W perpendicular to g M: make $y\,k$ equal to the height of the tuck, and W k being joined will be the intersection of the plane of the fashion-piece with the sheer plane. Let the water lines in the sheer plane produced meet the line kW in the points a, s, h, and draw the perpendiculars aa, ss, hh. From the points a, s, h, (fig. 14.) draw lines parallel to Gg to intersect each corresponding water line in the floor plane in the points 3, 2, 1. From the points G, 3, 2, 1 in the floor plane draw lines perpendicular to g M, intersecting the water lines (fig. 13) in the points G, 3, 2, 1; and through these points describe the curve G 3 2 1 k; and WG 3 2, 1 k will be the projection of the plane of the fashion-piece on the sheer plane. Through the points G, 3, 2, 1 (fig. 13) draw the lines GF, 3 A, 2 S, 1 H, perpendicular to W k; and make the lines WF, a A, s S,

Plate CCCCLVII.

h H, equal to the lines g G, a 3, s 2, h 1 (fig. 14.) respectively, and WFASH k will be the true form of the plane of the aft side of the fashion-piece. When it is in its proper position, the line WF will be in the same plane with the sheer line; the line a A in the same plane with the water line a 3; the line s S in the same plane with the water line s 2; and the line h H in the same plane with the water line h1. If lines be drawn from the several points of intersection of the water lines with the rabbet of the port (fig. 13.), perpendicular to g M, and curved lines being drawn from these points to G, 3, 2, 1 (fig. 14.) respectively, will give the form and dimensions of the tuck at the several water lines,

Prob. VII. To bevel the fashion-piece of a square tuck by water-lines.

As the fashion-piece both rakes and cants, the planes of the water-lines will therefore intersect it higher on the aft than on the fore-side: but before the heights on the fore-side can be found, the breadth of the timber must be determined; which let be $b\,n$ (fig. 15.) Then as it cants, the breadth in the direction of the water-line will exceed the true breadth. In order to find the true breadth, from the aft-side of the fashion-piece as directed in the last problem.

Let t 5 (fig. 13.) be the aft-side of the rabbet on the outside of the post, WM the common section of the plan of the fashion-piece and the sheer-plan. Before this last line can be determined, the several water-lines 1, 2, 3, 4, and 5, must be drawn parallel to the keel, which may represent so many transoms — Let these water lines be formed and ended at the aft-side of the rabbet, as in fig. 14. where the rounds aft of the several transoms are described, limiting the curves of the water lines. Now the line WM must rake so as to leave room for half the thickness of the post, at the tuck: in order to which, produce Wg to r; make $r\,g$ half the thickness of the post; through r draw a line parallel to g M to intersect g G in b: then with the radius $r\,b$, from x the point of the tuck as a centre, describe an arch, and draw the line WM just to touch the back of that arch.

The line WM being drawn, let any point k in it be assumed at pleasure: from k draw $k\,y$ perpendicular to g M: through y draw $y\,f$ (fig. 14.) parallel to g G, intersecting the line Mf drawn perpendicular to g M in the point f. From M draw M i perpendicular to $y\,f$, and from y draw $y\,n$ perpendicular to WM (fig. 13.) Make Mn (fig. 15.) equal to M i (fig. 14.); then MI (fig. 15.) being equal to $y\,k$ (fig. 13), join n 1, and the angle 1nM will be the bevelling to the horizontal plane. Again, make Mz Mf (fig. 15.) respectively equal to $y\,n$ (fig. 13.) and M f (fig. 14.), and join $z\,f$; and the angle M $z\,f$ will be the bevelling to the sheer plane.

The bevelling being now found, draw the line $a\,b$ (fig. 15.) parallel to $z\,n$, $a\,z$ or $b\,n$ being the scantling of the timber. Then $n\,x$ will be the breadth of the timber on the horizontal plane, and $z\,e$ its breadth on the sheer plane, and $a\,c$ what it is within a square.

Now as the lines g G, a 3, s 2, h 1, y i, represent the

(c) It is not a general rule, that lowering the cargo of a ship augments her stability. This is demonstrated by the Chevalier de Borda, in a work published by M. de Goimpy upon this subject. See also *L'Architecture Navale per M. Vial du Clairbois.* p. 23.

Preliminary Problems.

the aft side of the fashion-piece on the horizontal plane (fig. 14.), dotted lines may be drawn parallel to them to represent the fore-side, making *n x* (fig. 15.) the perpendicular distance between the lines representing fore and aft sides of the fashion-piece. By these lines form the fore-side of the fashion-piece in the same manner as the aft-side was formed. The water lines on the fore-side of the plane of the fashion-piece must, however, be first drawn in fig. 13. thus: Draw the lines *e b*, *c d* parallel to W M, and whose perpendicular distances therefore may be equal to *a c* and *z e* (fig. 15.) respectively. Draw a line parallel to W F (fig. 13.) through the point where the line *c d* intersects the fifth water line. Draw a line parallel to *a* A through the point where the fourth water line intersects the line *c d*; in like manner proceed with the other water lines. The fore-side of the fashion-piece is now to be described by means of these new water lines, observing that the distances in the floor plane must be set off from the line *e b*, and not from WM, as in the former case; and a curve described through the points 5, 3, 2, 1, where these distances reach to, will represent the fore-side of the fashion-piece.

The nearest distance between the points 5, 3, 2, 1, and the aft side of the fashion-piece is what the bevelling is beyond the square when both stock and tongue of the bevel are perpendicular to the timber. Make M *p* (fig. 16.) equal to the breadth of the timber, and M 5 equal to the perpendicular distance of the point 5 (fig. 13.) from the aft side of the fashion-piece, and join 5 *p*. In like manner proceed with the others, and the bevellings at these parts will be obtained; but, in order to avoid confusion, the perpendiculars 4, 3, 2, (fig. 13.), instead of being laid off from M (fig. 16.), were set off from points as far below M as the other extremities of the lines draw from these points are below the point *p*.

Prob. VIII. To describe the transoms of a round poop.

The transoms are fastened to the stern-post in the same manner that the floor timbers are fastened to the keel, and have a rising called the *flight* similar to the rising of the floor-timbers. The upper transom is called the *wing* transom, the next the *deck* transom, and the others the *first*, *second*, and *third* transoms, in order. The wing transom has a round aft and a round up: the round up of the deck transom is the same as that of the beams.

The fashion-piece of a square tuck must be first described, together with the three adjacent frames, by the method to be explained. The part of the stern above the wing transom is to be described in the same manner as before, and may therefore be omitted in this place. The part below the keel of the fashion-piece is also the same in both cases. Let fig 17. represent the fashion-piece of a square tuck, and the three adjoining frames. Divide the interval A B into four equal parts in the points C, D, E, and draw the perpendiculars AF, CG, D H, E I, and B K: these will be portions of water lines answering to the several transoms.

Plate CCCCLVIII.

Let these water lines be described on the floor plan (fig. 18.), in which ABC represents the wing transom. Describe the arch *b* C to reconcile the curves A *b* and CE. Let LFG be the water-line answering to the lower part of the fashion-piece, the distance between the points L and A being equal to the excess of the projection of the point A beyond that of B (fig. 20.). Draw C K (fig. 18.) perpendicular to AM, and make the angle KCM equal to about 25 degrees, and CN will be the projection of the fashion-piece on the floor-plane. Make AB (fig. 19.) equal to AB (fig. 17.) Divide it into four equal parts, and draw the perpendiculars AF, CH, DI, EK, and BG. Make AF equal to CM, and BG equal to MN, and draw the curve FHIKG, having a less curvature than the fashion-piece of the square tuck *s c p g n*. Make MO, MP, MQ, equal to CH, DI, and EK respectively. Divide AL (fig. 18) into four equal parts, and to these points of division draw curves through the points O, P, Q, so as to partake partly of the curvature of A *b* C E and partly of that of LNF, but most of the curvature of that to which the proposed curve is nearest; and hence the form of the several transoms will be obtained.

In order to represent the curve of the fashion-piece on the plane of projection, make the lines AF, CG, DH, EI, and BK (fig. 17.) respectively equal to the perpendicular distance of the points C, O, P, Q, and N. From the line AN (fig. 18.), and through the extremities of these lines, draw the curve FGHIK.

It remains to lay down the projection of the fashion-piece on the plane of elevation. In order to which, divide the line AB, fig. 20. (equal to AB, fig. 17.) into four equal parts, and through the points of division draw the perpendiculars AF, CG, DH, EI, and BK; make AF (fig. 20.) equal to the perpendicular distance of the point C from the line BL (fig. 18.) In like manner make the lines CG, DH, EI, and B K (fig. 20.) respectively equal to the perpendicular distances of the points O, P, Q, and N, from the line BL (fig. 18.); and a curve drawn through these points will be the projection of the fashion-piece on the plane of elevation.

Prob. IX. To describe the intermediate frames in the after body.

For this purpose the midship and stern frames must be drawn in the plane of projection. As the main frame contains the greatest capacity, and the stern frame is that having the least, it hence follows that the form and dimensions of the intermediate frames will be between these; each frame, however, partaking most of the form of that to which it is nearest.

Let ACDE (fig. 21.) be the main frame on the plane of projection, and FGH the stern frame; and let there be any convenient number of intermediate frames, as *nine*. Draw the floor ribband CF, and the breadth ribband GD. Divide the curves CD, FG, each into the same number of equal parts, as three, in the points K, M; L, N; and draw the second and third ribbands KL, MN. In order to divide these ribbands so as to form fair curves in different sections, various methods have been proposed. One of the best of these, being that which is chiefly employed by the French constructors, is by means of an equilateral triangle, which is constructed as follows.

Draw the line ME (fig. 22.), limited at M, but produced towards E: take M 1 equal to any convenient extent; make 1, 2 equal to thrice that extent, 2, 3 equal to five times, and 3, 4 equal to seven times the above extent; and continue this division to E, always increasing by two, until there be as many points as there are

are frames, including the main and stern frames. Upon ME describe the equilateral triangle MSE, and draw lines from the vertex S to each point of division; then the line SM will be that answering to the main frame, and SE that corresponding to the post; and the other lines will be those answering to the intermediate frames in order.

Let fig. 23. be the projection of part of the stern on the plane of elevation, together with the eighth and ninth frames. From the points L, N, G, (fig. 21.) draw the lines LO, NP, GQ, perpendicular to the plane of the upper edge of the keel. Make AB (fig. 23.) equal to AF (fig. 21.), and draw the water line BCD. Draw the line BC (fig. 22.) so that it may be parallel to the base of the triangle, and equal to CD (fig. 23), which produce indefinitely towards H. Make BD equal to BC (fig. 23.), and draw the dotted line SD (fig. 22.) The ribband FC (fig. 21.) is to be applied to the triangle, so that it may be parallel to the base, and contained between the line MS and the dotted line SD. Let *cf* represent this line; then transfer the several divisions from *cf* to the ribband CF (fig. 21.), and number them accordingly. Again, make EF (fig. 23.) equal to LO (fig. 21.), and draw the water line FGH; make BF (fig. 22.) equal to FG (fig. 23.), and draw the dotted line SF; apply the second ribband LK to the triangle, so that the extremity K may be on the line SM, and the other extremity L on the dotted line SF, and making with SM an angle of about $62\frac{1}{2}$ degrees. Let *kl* be this line, and transfer the divisions from it to the ribband KL. In like manner make IK (fig. 23.) equal to NP (fig. 21.), and draw the water line KLM. Make BG (fig. 22.) equal to KL (fig. 23.), and draw the dotted line SG; then the ribband MN is to be applied to the triangle in such a manner that its extremities M and N may be upon the lines SM, SG respectively, and that it may make an angle of about 68 degrees with the line SM; and the divisions are to be transferred from it to the ribband MN. The same process is to be followed to divide the other ribbands, observing to apply the fourth ribband to the triangle, so that it may make an angle of 86 degrees with the line SM; the fifth ribband to make an angle of 65 degrees, and the sixth an angle of 60 degrees with the line SM.

The quantities of these angles are, however, far from being precisely fixed. Some constructors, in applying the ribbands to the triangle, make them all parallel to its base; and others vary the measures of these angles according to fancy. It may also be remarked, that a different method of dividing the base of the triangle is used by some. It is certainly proper to try different methods; and that is to be preferred which best answers the intended purpose.

Beside the frames already mentioned, there are other two laid down by some constructors in the several plans, called *balance frames*. The after balance frame is placed at one fourth of the length of the ship before the stern-post; and the other, commonly called the *loof frame*, at one fourth of the ship's length aft of a perpendicular to the keel from the rabbet of the stem. Let the dotted line at X, between the fifth and sixth frames, (fig. 23.) be the place of the after balance frame in the plane of elevation. Then, in order to lay down this frame in the plane of projection, its representation must be previously drawn in the triangle. To accomplish this, draw the line SV (fig. 22.) so that the internal 5V may have the same ratio to 5 6 (fig. 22.) that 5 X has to 5 6 (fig. 23.) (D). Then the several points in the ribbands in the plane of projection answering to this frame are to be found by means of the triangle in the same manner as before.

The loof frame is nearly of the same dimensions as the after balance frame, or rather of a little greater capacity, in order that the centre of gravity of that part of the ship may be nearly in the plane of the midship frame. Hence the loof frame may be easily drawn in the plane of projection, and hence also the other frames in the fore body may be readily described.

Prob. X. To describe the frames in the fore body.

Draw the middle line of the stem AB (fig. 24.); make AC, BD each equal to half the thickness of the stem, and draw the line CD; describe also one half of the main frame CEFGHI. Let *e*E, *f*F, *g*G, *h*H, be water lines at the heights of the ribbands on the main frame; also let *a* be the termination of the floor ribband, and *b* that of the breadth ribband on the stem. Divide the interval *a b* into three equal parts in the points *c*, *d*, and draw the ribbands *a*E, *c*F, *d*G, and *b*H. Make *ei*, *fk*, *gl*, *hm* (fig. 24.) equal to *ei*, *fk*, *gl*, *hm* (fig. 21.) respectively, and draw the curve C*iklm*, which will be the projection of the loof frame. Or since it is necessary that the capacity of the loof frame should be a little greater than that of the after balance frame, each of the above lines may be increased by a proportional part of itself, as one tenth or one-twentieth, as may be judged proper.

Construct the triangle (fig. 25.) in the same manner as fig. 22. only observing, that as there are fewer frames in the fore than in the after body, its base will therefore be divided into fewer parts. Let there be eight frames in the fore body, then there will be eight divisions in the base of the triangle beside the extremes.

Let fig. 26. represent the stem and part of the fore-body in the plane of elevation, and let O be the place of the loof frame. Divide the interval 4, 5 (fig. 25.) so that 4, 5 may be to 4Z as 4, 5 to 4, 0 (fig. 26.), and draw the dotted line SZ, which will be the line denoting the loof frame in the triangle.

Draw the lines AB, CD, EF, GH (fig. 26.) parallel to the keel, and whose perpendicular distances therefrom may be equal to C*a*, C*c*, C*d*, C*b*, (fig. 24.) the intersections of these lines with the rabbet of the stem, namely, the points I, K, L, M will be the points of termination of the several ribbands on the stem in the plane of elevation. Divide 8 A (fig. 25.) so that 8 B, 8 C, 8 D, and 8 E, may be respectively equal to BI, DK, FL, and HM (fig. 26.), and draw the dotted lines SB, SC, SD, SE (fig. 25.) Apply the edge of a slip of card to the first ribband (fig. 24.), and mark thereon

(D) It is evident, from the method used to divide the base of the triangle, that this proportion does not agree exactly with the construction: the difference, however, being small, is therefore neglected in practice.

Preliminary Problems.

thereon the extremities of the ribband *a*, E, and also the point of intersection of the loof frame. Then apply this slip of card to the triangle in such a manner that the point *a* may be on the dotted line SB, the point E on the line SM, and the point answering to the loof frame on the dotted line SZ; and mark upon the card the several points of intersection of the lines S1, S2, &c. Now apply the card to the ribband *a*E (fig. 24.) as before, and transfer the several points of division from it to the ribband. In like manner proceed with the other ribbands; and lines drawn through the corresponding points in the ribbands will be the projection of the lower part of the frames in the fore body. The projections of the top-timbers of the several frames may be taken from the half breadth plan; and hence each top-timber may be easily described.

In large ships, particularly in those of the French navy, a different method is employed to form the top-timbers in the fore body, which is as follows:

Plate CCLIX.

Let BI (fig. 27.) be one fourth of the breadth of the ship, and draw IK parallel to AB. Take the height of the foremost frame from the plane of elevation, and lay it off from A to B: from the point B draw BH perpendicular to AB, and equal to half the length of the wing transom. Let E be the place of the breadth ribband on the main frame, and F its place on the stem at the height of the wing transom. With a radius equal to five-sixths of half the greatest breadth of the ship describe the quadrant EFG (fig. 28.): Make EH equal to FG (fig. 27.), the point F being at the height of the wing transom. Through H draw HO perpendicular to EH, and intersecting the circumference in O; then draw OL parallel to HE, and EL parallel to HO. Divide EL into as many equal parts as there are frames in the fore body, including the main frame, and from these points of division draw the perpendiculars 11, 22, &c. meeting the circumference as in the figure. Take the distance 11, and lay it off from G (fig. 27.) towards F to the point 1; and from the same point G lay off towards F the several perpendiculars contained between the straight line and the curve to the points 2, 3, &c. and through these points draw lines parallel to EG.

Take any line AB (fig. 29.) at pleasure: divide it equally in two in the point 8; divide 8 B in two parts in the point 7, and continue this method of division until there are as many points as there are frames in the fore body, including the main frame. Upon AB construct the equilateral triangle ACB, and draw the lines C8, C7, &c. Place a slip of card on the parallel *a*K8 (fig. 27.), and mark thereon the points opposite to *a*, K, and 8; and let them be denoted accordingly. Then apply this slip of card to the triangle, so that the point *a*, which is that answering to the rabbet of the stem, may be on the line AC; that the point answering to K may be on C8, and the extremity 8 on the line CB; and mark on the card the points of intersection of the lines C7, C6, &c. and number them accordingly. Now apply this slip of card to the seventh parallel (fig. 23.), the point *a* being on the line CD, and mark on this parallel the point of intersection 7; slide the card down to the sixth parallel, to which transfer the point n° 6. In like manner proceed with the other parallels.

The point K, at the intersection of the line IK with the eighth parallel, is one point through which the eighth frame passes. From this point upwards a curve is to be described so as to reconcile with the lower part of this frame already described, and the upper part, forming an inverted arch, which is to terminate at H. This top-timber may be formed by two sweeps, whose radii and centres are to be determined partly from circumstances and partly according to fancy. It however may be more readily formed by hand.

Let LM (fig. 27.) be the line of the second deck at the main frame, and let LN be the difference of the draught of water, if any. Make GN (fig. 28.) equal to LN; draw NM perpendicular to GN, meeting the circle in M; and through the points G and M draw the parallels GV and MV; divide GN as before, and from the several points of division draw perpendiculars terminating in the curve. Transfer these perpendiculars from L upwards (fig. 27.), and through the points thus found draw the lines 11, 22, &c. parallel to LM. Apply a slip of card to the eighth parallel, and mark upon it the point answering to the stem, the eighth and main frames: carry this to the triangle, and place it so that these points may be on the corresponding lines. Then the points of intersection of the lines C7, C6, &c. are to be marked on the card, which is now to be applied first to the eighth parallel (fig. 27.), then to the seventh, &c. transferring the several points of division in order as before.

Draw the line HO (fig. 27.); mark its length on a slip of card, and apply it to the triangle, so that it may be parallel to its base, and its extremities one on the eighth and the other on the main frame: mark on the card the points of intersection of the several intermediate lines as before; then apply the card to HO, and transfer the divisions.

There are now three points determined through which each top-timber must pass, namely, one in the breadth ribband, one in the fifth, and one in the upper ribband. Through these curves are to be described, so as to reconcile with the lower part of the frame, and partake partly of the curvature of the eighth frame, and partly of that of the main frame, but most of that of the frame to which it is nearest: and hence the plane of projection is so far finished, that it only remains to prove the several frames by water lines.

Another method of describing the frames in the body plan is by sweeps. In this method it is necessary, in the first place, to describe the height of the breadth lines, and the rising of the floor, in the plane of elevation. The half breadth lines are next to be described in the floor plan. The main frame is then to be described by three or more sweeps, and giving it such a form as may be most suitable to the service the ship is designed for. The lower, upper, and top-timber heights of breadth, and the risings of the floor, are to be set upon the middle line in the body plan, and the several half breadths are then to be laid off on lines drawn through these points perpendicular to the middle line. A mould may then be made for the main frame, and laid upon the several risings, as in whole mouldings, explained in Chapter V. with this difference, that here an under breadth sweep is described to pass through the point which limits the half breadth of the timber, the centre of which will be in the breadth line of that timber. The proper centres for all the frames being found, and the

Preliminary Problems.

the arches described, the bend mould must be so placed on the rising line of the floor, that the back of it may touch the back of the under breadth sweep. But the general practice is, to describe all the floor sweeps with compasses, as well as the under breadth sweeps, and to reconcile those two by a mould which is an arch of a circle, its radius being the same with that of the reconciling sweep by which the midship frame was formed. It is usual for all the floor sweeps to be of the same radius; and in order to find their centres a line is formed on the floor plan for the half breadth of the floor. As this line cannot be described on the surface of a ship, it is therefore only an imaginary line. Instead of it some make use of a diagonal in the body plane to limit the half breadth of the floor upon every rising line, and to erect perpendiculars at the several intersections, in the same manner as for the midship frame.

After the sweeps are all described, recourse is had to moulds, or some such contrivance, to form the hollow of the timbers, much in the same manner as in whole moulding; and when all the timbers are formed, they must be proved by ribband and water lines, and altered, if necessary, to make fair curves.

The preceding methods of describing the several planes or sections of a ship being well understood, it will be a very easy matter to construct draughts for any proposed ship: and as the above planes were described separately and independent of each other, it is therefore of little consequence which is first described. In the following application, however, the plane of elevation will be first drawn, then part of the floor plan, and lastly the body plan: and in connecting these plans the most rational and simple methods will be employed.

Chap. IV. *Application of the foregoing Rules to the Construction of Ships.*

Sect. I. *To construct a Ship intended to carry a considerable Burden in Proportion to her general Dimensions, and to draw little Water.*

Dimensions.

	F.	*In.*
Length between the wing transom and a perpendicular from the rabbet of the stem at the height of breadth line	80	0
Main half breadth moulded	11	0
Half breadth at the height of breadth line at the stern	7	6
Top-timber half breadth	0	6

Height of top-timber at midships	14	0
——— at stern	18	0

Application of the foregoing Rules to the Construction of Ships.

Plate CCCCLX

Draw the line *a b* (fig. 37.) equal to 80 feet, from a convenient scale: divide it into as many equal parts plus one as there are to be frames, which let be 16, and through each point of division draw perpendicular. Make *b c* equal to 17 feet, the perpendicular height of the top of the stem above the upper edge of the keel, and describe the stem by Prob. II. Make *a d* equal to $10\frac{1}{2}$ feet, the height of the middle line of the wales at the stern, and *a e* equal to the proposed rake of the post, which may be about 2 feet; join *d e*; and draw the line *f g* representing the aft-side of the post. Describe the counter and stern by Problem VI. and VII. Make ⊕*h* equal to 14 feet, the top-timber height at the main frame, and *i k* equal to 18 feet, the height at the stern; and through the three points *c*, *h*, *k*, describe the curve limiting the top-timbers by Problem I. Make *b d* equal to 10 feet, the height of the middle line of the wales at the stem, and ⊕H equal to 6 feet 10 inches, the height at the main frame; and the curve *d* H *d* being described will represent the middle line of the wales. At the distance of $10\frac{1}{2}$ inches on each side of this line draw two curves parallel thereto, and the wales will be completed in this plan. Make *b l* equal to $13\frac{1}{2}$ feet, the height of the breadth line at the stem; *a m* equal to $12\frac{1}{4}$ feet, the height at the stern; and I⊕ K⊕ equal to 5 feet 10 inches and 7 feet 4 inches respectively; and draw the upper breadth line *l* K *m* and lower breadth line *l* I *m*. From the line *a b* lay downwards the breadth of the keel, which may be about one foot, and draw the line L*t* parallel to *a b*.

Let the line L *r*, which is the lower edge of the keel, represent also the middle line of the floor plan. Produce all the perpendiculars representing the frames: make ⊗ M (fig. 31) equal to 11 feet, the main half breadth at midships; through *m* (fig. 30.) draw the line *m* N perpendicular to *a b*, and make *p* N equal to $7\frac{1}{2}$ feet, and draw the main half breadth line NM *r* by Problem IV. Describe also the top-timber half breadth line PO *r*, ⊕ O being equal to $10\frac{1}{2}$ feet, and form the projecting part of the stem *q r s t*.

In order that the top-timber line may look fair on the bow, and to prevent the foremost top-timbers from being too short, it is necessary to lift or raise the sheer from the round of the bow to the stem. For this purpose the following method is usually employed: Produce the circular sheer before the stem in the plane of elevation at pleasure; then place a batton to the round of the bow in the half breadth plan, and mark on it the stations of the square timbers and the side of the stem; apply the batton to the sheer plan, and place it to the sheer of the ship, keeping the stations of the timbers on the batton well with those on the sheer plan for several timbers before dead-flat, where they will not alter; then mark the other timbers and the stem on the sheer line produced; through these points draw lines parallel to the keel, to intersect their corresponding timbers and the stem in the sheer plan: then a curve described these last points will be the sheer of the ship round the bow, lifted as required: and the heights of the timbers thus lengthened are to be transferred to the body plan as before.

Draw the line AB (fig. 32.) equal to 22 feet, the whole breadth; from the middle of which draw the perpendicular CD: make CE equal to half the thickness

Application of the foregoing Rules to the Conſtruction of Ships.

of the poſt, and CF equal to half that of the ſtem, and from the points A, E, F, B, draw lines parallel to CD. Make AG, BG each equal to 14 feet, the height at the main frame, and draw the line GG parallel to AB. Make GH, GH each equal to half a foot, the difference between the main and top timber half breadths. From A and B ſet up the heights of the lower and upper breadth lines to I and K, and draw the ſtraight lines IK, IK. Let CL be the riſing at the main frame, and ⊕, ⊕ the extremities of the floor timber. Hence, as there are now five points determined in each half of the main frame, it may be very eaſily deſcribed.

Make CM equal to L⊕, join M⊕, and draw the other ribbands NO, PQ. In order, however, to ſimpliſy this operation, the rectilineal diſtance ⊕I was triſected, and through the points of diviſion the lines NO, PQ were drawn parallel to the floor ribband M⊕.

Take the diſtance *b c* (fig. 30.), and lay it off from F to (fig. 32.); alſo make F*b* (fig. 32.) equal to F*u* (fig. 30.); through *b* draw *bc* parallel to AB, and equal to FR (fig. 31). In like manner take the heights of each top-timber from fig, 30. and lay them off from C towards D (fig. 32); through theſe points draw lines parallel to AB, and make them equal each to each, to the correſponding half breadth lines taken from the floor plan: Then through the ſeveral points *a*, *c*, &c. thus found, draw a line *a c* H, which will be the projection of the top-timber line of the fore body in the body plan. Proceed in the ſame manner to find the top-timber line in the after body.

Transfer the height of the main-breadth line on the ſtem *b l* (fig. 30.) from F to *d* (fig. 32). Transfer alſo the heights of the lower and upper breadth lines at timber F (fig. 30.), namely, FW, FX, from F to *e* and *f* (fig. 32.); through which draw the parallel *eg*. *fh*; make them equal to FS (fig. 31.), and draw the ſtraight line *g h*. In this manner proceed to lay down the portions of the extreme breadth at each frame, both in the fore and in the after body in the body plan, and draw the upper and lower breadth lines *dh*K, *dg* I in the fore body and K*i*, I*i* in the after body. Hence the portions of the ſeveral top-timbers contained between the top-timber and main breadth lines may be eaſily deſcribed. It was before remarked that their forms were partly arbitrary. The midſhip top-timber has generally a hollow, the form of which is left entirely to the artiſt, though in ſome ſhips, eſpecially ſmall ones, it has none. It is the common practice to make a mould for this hollow, either by a ſweep or ſome other contrivance, which is produced conſiderably above the top-timber line, in a ſtraight line or very near one: The midſhip top-timber is formed by this mould, which is ſo placed that it breaks in four with the back of the upper breadth ſweep. The other top-timbers are formed by the ſame mould, obſerving to place it ſo that the ſtraight part of it may be parallel to the ſtraight part of the midſhip timber, and moved up or down, ſtill keeping it in that direction till it juſt touches the back of the upper breadth ſweep. Some conſtructors begin at the after timber, after the mould is made for the midſhip top-timber, becauſe they think it eaſier to keep the ſtraight part of the mould parallel to this than to the midſhip timber: and by this means the top ſide is kept from winding. Others, again, make a mark upon the mould where the breadth line of the midſhip timber croſſes it, and with the ſame mould they form the after timber: this will occaſion the mark that was made on the mould when at the main frame to fall below the breadth line of the after timber, and therefore another mark is made at the height of the breadth line at the after timber; the ſtraight part of the mould is then laid obliquely acroſs the breadth lines of the top-timbers, in ſuch a manner that it may interſect the breadth line of the midſhip timber at one of theſe marks and the breadth line of the after timber at the other mark; then the ſeveral interſections of the breadth lines of the timbers are marked upon the mould; which muſt now be ſo placed in forming each timber, that the proper mark may be applied to its proper breadth, and it muſt be turned about ſo as juſt to touch the upper breadth ſweep. Any of theſe methods may make a fair ſide, and they may be eaſily proved by forming another intermediate half breadth line.

Application of the foregoing Rules to the Conſtruction of Ships.

The remaining parts of the frames may be deſcribed by either of the methods laid down in Problems IX. and X. In order, however, to illuſtrate this ſtill farther, it is thought proper to ſubjoin another method of forming the intermediate frames, the facility of which will recommend it.

Take FZ (fig. 30.), and lay it from F to *k* (fig. 32.); then deſcribe the lower part of the foremoſt frame, making it more or leſs full according as propoſed; and interſecting the ribbands in the points *l*, *m*, *n*. Deſcribe alſo the aftermoſt frame *o*, *p*, *q*. Make α β (fig. 30.) equal to F *r* (fig, 32.), and produce it to *a* (fig. 31.): alſo draw γ δ, and ε ζ (fig. 30.) equal to E *r* and E *s* (fig. 32.) reſpectively; and produce them to *b* and *c*: Make F *e*, F *f*, F R (fig. 31.) equal to M *l*, N *m*, P *n* (fig 32.) each to each. Let alſo ⊕*h*, ⊕*i*, ⊕*k*, and 9 *l*, 9 *m*, 9 *n* (fig. 31.) be made equal to M ⊕, NO, PQ, and M *o*, N *q*, P*p* (fig. 32); then through theſe points trace the curves *a e n b l b*, *r f i m c*, and *r* R *k n p*, and they will be the projections of the ribbands in the floor plane. Now transfer the ſeveral intervals of the frames contained between the middle line and the ribbands (fig. 31.) to the correſponding ribbands in the body plan (fig. 32). Hence there will be five points given in each frame, namely, one at the lower breadth line, one at each ribband, and one at the keel; and conſequently theſe frames may be eaſily deſcribed. In order to exemplify this, let it be required to lay down the frame E in the plane of projection. Take the interval E *n* (fig. 31.), and lay it from M to *u* (fig. 32). Lay off alſo E *v*, E *e* (fig. 31.) from N to *v* and from P to *n* (fig. 32.); then through the points F, *u*, *v*, *n* and the lower breadth line deſcribe a curve, and it will be the repreſentation of the frame E in the body plan. In like manner the other frames may be deſcribed.

The ribbands may now be transferred from the body plan to the plane of elevation, by taking the ſeveral heights of the interſection of each ribband with the frames, and laying them off on the correſponding frames in the floor plan; and if the line drawn through theſe points make a fair curve, it is preſumed that the curves of the frames are rightly laid down in the body plan. Only one of theſe ribbands, namely, the firſt, is laid down in fig. 30. Theſe curves may alſo be farther proved, by drawing water lines in the plane of elevation,

Application of the foregoing Rules to the Conſtruction of Ships.

vation, and in the body plan, at equal diſtances from the upper edge of the keel. Then the diſtances between the middle line of the body plan, and the ſeveral points of interſection of theſe lines with the frames, are to be laid off from the middle line in the floor plan upon the correſponding frames; and if the line drawn through theſe points form a fair curve, the frames are truly drawn in the body plan.

In figs. 30. and 32. there are drawn four water lines at any equal diſtances from the keel, and from each other. Theſe lines are then transferred from fig. 32. to fig. 31.; and the lines paſſing through theſe points make fair curves.

The tranſoms are deſcribed by Problem VIII. it is therefore unneceſſary to repeat the proceſs. A riſing line of the floor timbers is commonly drawn in the plane of elevation.

As this is intended only as an introductory example, ſeveral particulars have therefore been omitted; which, however, will be exemplified in the following ſection.

Sect. IV. *To deſcribe the ſeveral Plans of a Ship of War propoſed to carry 80 Guns upon two Decks.*

As it is propoſed in this place to ſhow the method of deſcribing the plans of a ſhip of a very conſiderable ſize, it therefore ſeems proper to give the dimenſions of every particular part neceſſary in the delineation of theſe plans. The ſeveral plans of this ſhip are contained in Plate CCCCLXI. figs 33, and 34. But as it would very much confuſe the figures to have a reference to every operation, and as the former example is deemed a ſufficient illuſtration, the letters of reference are upon theſe accounts omitted in the figures.

I. *Of the Sheer Draught or Plane of Elevation.*

Draw a straight line (fig. 53.) to represent the upper edge of the keel, erect a perpendicular on that end to the right, and from thence set off 182 feet, the length on the gun deck, and there erect another perpendicular; that to the right is called the *foremost* perpendicular, and the other the *after* one: upon these two perpendiculars all the formost and aftermost heights must be set off, which are expressed in the dimensions.

Then set off the distance of the main frame or dead flat from the foremost perpendicular, and at that place erect a third perpendicular, which must be distinguished by the character ⊕. From dead flat the room and space of all the timbers must be set off; but it will only be necessary to erect a perpendicular at every frame timber; which in the fore body are called *dead flat*, A, C, E, &c. and in the after body (2), 1, 3, 5, &c.: hence the distance between the frame perpendiculars will be double the room and space expressed in the dimensions. Then set off the heights of the gun deck afore at midship or dead flat, and abaft from the upper side of the keel; and a curve described through these three points will be the upper side of the gun-deck. Set off the thickness of the gun-deck plank below that; and another curve being drawn parallel to the former, the gun-deck will then be described at the middle line of the sheer plan.

The centre of the stem is then to be laid down by means of the table of dimensions; from which centre, with an extent equal to the nearest distance of the upper edge of the keel, describe a circle upwards: describe also another circle as much without the former as the stem is moulded. Then set off the height of the head of the stem, with the distance afore the perpendicular, and there make a point; and within that set off the moulding of the stem, and there make another point: from this last mentioned point let a line pass downwards, intersecting the perpendicular at the height of the gun-deck, and breaking in fair with the inner circle, and the after part of the stern is drawn. Draw another line from the foremost point downwards, parallel to the former, and breaking in fair with the outer circle; then the whole stem will be formed, except the after or lower end, which cannot be determined till hereafter.

The stern-post must be next formed. Set off on the upper edge of the keel a spot for the aft part of the rabbet taken from the dimensions, and from that forward set off another point at the distance of the thickness of the plank of the bottom, which is 4½ inches; and from this last mentioned point draw a line upwards intersecting the perpendiculars at the height of the lower deck;

Application of the foregoing Rules to the Construction of Ships.

deck; then set up the perpendicular the height of the wing transom, and draw a level line, and where that line intersects, the line first drawn will be the aft side of the wing transom; on the upper part of the middle line set off from that place the distance of the aft side of the stern-post; set off also the distance of the after part from the rabbet on the upper edge of the keel, and a line drawn through these two points will be the aft side of the post. A line drawn parallel to the first drawn line at the distance of $4\frac{1}{2}$ inches, the thickness of the plank on the bottom, will be the aft side of the rabbet: and hence the stern-post is described, except the head, which will be determined afterwards.

From the dimensions take the several heights of the upper-deck above the gun-deck, afore, at midship, and abaft, and set them off accordingly; through these points describe a curve, which will be the under side of the upper deck; describe also another curve parallel thereto, at the distance of the thickness of the plank, and the upper deck will be then represented at the middle line of the ship.

Set off the height of the lower counter, at the middle line, from the upper edge of the keel, and draw a horizontal line with a pencil; then on the pencil line set off the distance the touch of the lower counter is abaft the aft side of the wing transom: from this point to that where the fore part of the rabbet of the stern-post intersects the line drawn for the upper part of the wing transom, draw a curve at pleasure, which curve will represent the lower counter at the middle line. The height of the upper counter is then to be set off from the upper edge of the keel, and a horizontal line is to be drawn as before, setting off the distance the touch of the upper counter is abaft the aft side of the wing transom; and a curve described from thence to the touch of the lower counter will form the upper counter at the middle line.

Both counters being formed at the middle line, the upper part of the stern timber above the counters is to be described as follows: On the level line drawn for the upper side of the wing transom set off the distance of the aft side of the stern timber at the middle line from the aft side of the wing transom, at the height of the top-timber line, and erect a perpendicular: then upon this perpendicular, from the upper edge of the keel, set off the height at the middle line of the top timber line at the after side of the stern timber; through this point draw a straight line to the touch of the upper counter, and the upper part of the stern timber will be described.

As the stern rounds two ways, both up and aft, the stern timber at the side will consequently alter from that at the middle line, and therefore remains to be represented. Take the round up of the upper counter from the dimensions, and set it below the touch at the middle, and with a pencil draw a level line; take also the round aft, and set it forward from the touch on the touch line, and square it down to the pencil line last drawn, and the point of intersection will be the touch of the upper counter at the side. In the same manner find the touch of the lower counter; and a curve, similar to that at the middle line, being described from the one touch to the other, will form the upper counter at the side.

Take the round up of the wing transom, and set it off below the line before drawn for the height of the wing transom, and draw another horizontal line in pencil: then take the round aft of the wing transom, and set it forward on the upper line from the point representing the aft side of the wing transom; square it down to the lower line, and the intersection will be the touch of the wing transom: then a curve, similar to that at the middle line, being drawn from the touch of the wing transom to the touch of the lower counter at the side, will be the lower counter at the side. Draw a line from the upper counter upwards, and the whole stern timber at the side will be represented. But as the straight line drawn for the upper part of the side timber should not be parallel to that at the middle line, its rake is therefore to be determined as follows.

Draw a line at pleasure, on which set off the breadth of the stern at the upper counter; at the middle of this line set off the round aft of the upper counter, then through this point and the extremities of the stern describe a curve. Now take the breadth of the stern at the top-timber line, and through the point where that breadth will intersect the curve for the round aft of the stern draw a line parallel to that first drawn, and the distance from the line last drawn to the curve at the middle of the line is the distance that the side timber must be from the middle line at the height of the top-timber line.

The sheer is to be described, which is done by setting off the heights afore, at midships, and abaft, and a curve described through these three points will be the sheer. But, in order that the sheer may correspond exactly with the dimensions laid down, it will be necessary to proceed as follows: The perpendicular representing timber dead flat being already drawn, set off from that the distances of the other frame timbers, which is double the room and space, as the frames are only every other one; and erect perpendiculars, writing the name under each: then on each of these perpendiculars set off the corresponding heights of the top-timber line taken from the table of dimensions for constructing the bodies; and through these points a curve being described, will represent the sheer of the ship or top timber line agreeable to the dimensions.

The quarter-deck and forecastle are next to be described, which may be done by taking their respective heights and lengths from the dimensions, and describing their curves. In the same manner also, the round-house may be drawn. The decks being described representing their heights at the middle, it is then necessary to represent them also at the side. For this purpose take the round of the decks from the dimensions, and set them off below the lower line drawn for the middle, and a curve described both fore and aft, observing to let it be rather quicker than the former, will be the representation of the decks at the side.

The ports come next under consideration. In the placing of them due attention must be paid, so as to preserve strength; or that they shall be so disposed as not to weaken the ship in the least, which is often done by cutting off principal timbers, placing them in too large openings, having too short timbers by the side of them, &c. The frames represented by the lines already drawn must be first consulted. Then with a pencil draw two curves, for the lower and upper parts of the lower deck posts, parallel to the line representing the lower deck; the distances of these lines from the

Scale of Feet to Fig. 30, 31 and 32.

Application of the foregoing Rules to the Construction of Ships.

the deck are to by taken from the dimensions, observing, however, to add to these heights the thickness of the deck, as the deck line at the side represents the under part of the deck.

The foremost port is then to be described, observing to place it as far aft as to give sufficient room for the manger; the most convenient place will therefore be to put it between the frames R and T, and equally distant from each. It will then be placed in the most conspicuous point of strength, as it will have a long top-timber on the aft side and a long fourth futtock on the fore side of it. The second port may be placed in like manner between the next two frames, which will be equally well situated for strength as the former; and by proceeding in this manner, the ports on the gun-deck may also be placed, taking care to have two frames between every two ports, all fore and aft.

The upper deck ports are then to be described; and in order to dispose of them in the strongest situation possible, they must be placed over the middle between the gun-deck ports, so that every frame in the ship will run up to the top of the side, by their coming between a gun and upper deck port; and every port will be between the frames, which will in a great measure contribute towards the strength of the ship. With regard to the ports on the quarterdeck, it is not of such material consequence if they cut the head of the frame, as in placing them the situation of the dead eyes must be considered, placing a port where there is a vacancy between the dead eyes large enough to admit of one; observing always to place them as nearly as possible at equal distances from each other; and where it happens that they do not fall in the wake of a frame, then that frame must by all means be carried up to the top of the side.

The necessary length of the round-house being determined in the dimensions, it may be set off; observing however, to let it be no longer than is just sufficent for the necessary accommodations, as the shorter the round-house the works abaft may be kept lower, and a low snug stern is always accounted the handsomest. Then set off the round of the deck at the foremost end, below the line drawn; the deck at the side may be described by another curve drawn quite aft. Now, from the point for the round of the deck to the stern timber, draw a curve parallel to the top-timber line, and that will be the extreme height of the top of the side abaft, which height continues to range fair along to the foremost end of the round-house, and at that place may have a fall about 14 inches, which may be turned off with a drift scroll. At the fore part of the quarter-deck, the topside may have a rise of 14 inches, which may also be turned off with a scroll. But as the raising of the topside only 14 inches at that place will not be sufficient to unite with the heights abaft, it will therefore be necessary to raise 14 inches more upon that, and break it off with a scroll inverted on the first scroll, and continue these two lines, parallel to the top-timber line, to the distance of about seven feet aft. At the foremost end of the round-house there is a break of 14 inches already mentioned, and in order to make that part uniform with the breaks at the foremost end of the quarter-deck, there must be set down 14 inches more below the former; land at these two heights continue two curves parallel to the top-timber line, from the aft part of the stern to the ends of the two curves already drawn at the foremost end of the quarter-deck. If they should happen not to break in fair with them, they must be turned off with a round; but to make them appear more handsome, the lower line may be turned off with a scroll. These lines being drawn will represent the upper edges of the rails.

The height of the top side at the fore part of the ship must next be considered; which, in order to give proper height for the forecastle, must have a rise there of 14 inches, the break being at the after end of the forecastle, and turned off as before. But as this part of the ship is still considerably lower than the after part, it will be necessary to give another of eight inches upon the former, and turn it off with a scroll inverted. Hence this part of the ship will appear more uniform to the after part

The finishing parts, namely the wales, stern, head, rails, &c. remain to be described. The wales may be first drawn; and as the strength of the ship depends very much on the right placing of them, great care must therefore be taken that they may be as little as possible wounded by the lower deck ports, and so placed that the lower deck bolts shall bolt in them, and also that they come as near as possible on the broadest part of the ship. In the first place, therefore, the height of breadth lines must be chosen for our guide. These heights of breadth are to be taken from the dimensions, and set off on the respective frames, and curves drawn through these points will be the upper and lower heights of the breadth lines. The height of the wales may now be determined; which in general is in such a manner that the upper height of breadth line comes about six inches below their upper edge, and the wales are then placed right upon the breadth lines. Take the heights and breadths of the wales afore, at midships, and abaft from the table of dimensions; draw curves through the points thus found, and the wales will be represented.

The channel wales are then to be described. They are principally intended to strengthen the top side, and must be placed between the lower and upper deck ports; and the lower edge of them at midships should be placed as low as possible, in order to prevent them from being cut by the upper deck ports afore and abaft. Take their heights and breadths from the dimensions; lay them off, and describe curves through the corresponding points, and the channel wales will be represented.

Lay off the dimensions of the waste rail found in the table; and through the points draw a line parallel to the top-timber line all fore and aft. This rail terminates the lower part of the paint work in the top side, as all the work above this rail is generally painted, and the work of the top side below it payed with a varnish, except the main wales, which are always payed with pitch.

Take the draught of water from the dimensions, and draw the load water-line, which is always done in green. Divide the distance between the load water-line and the upper edge of the keel into five equal parts, and through these points draw four more water-lines

Set off the centres of the masts on the gun-deck; their rake may likewise be taken from the dimensions. Set off also the centre of the bowsprit, letting it be four

Application of the foregoing Rules to the Construction of Ships.

four feet from the deck at the after part of the stem, which will give sufficient height for a light and airy figure.

Draw the knight-heads so as to be sufficiently high above the bowsprit to admit of a chock between them for the better security of the bowsprit. The timber heads may also be drawn above the forecastle, observing to place the most convenient for the timbers of the frame, being those which come over the upper deck ports, as they may be allowed long enough to form handsome heads. There should be one placed abaft the cat-head, to which the foremost block is to be bolted, and there may be two ports on the forecastle formed by them, and placed where it is most convenient to the dead eyes.

Describe the channels, taking their lengths and thicknesses from the dimensions, and place their upper edges well with the lower edge of the sheer rail. The dead eyes may then be drawn, observing to place them in such a manner that the chains may not interfere with the ports; and the preventer plates must all be placed on the channel wales, letting them be of such a length that the preventer bolt at each end may bolt on each edge of the channel wales. It must also be observed to give each of the chains and preventer plates a proper rake, that is, to let them lie in the direction of the shrouds, which may be done in the following manner: Produce the mast upwards, upon which set off the length of the mast to the lower part of the head; these straight lines drawn from that point through the centre of each dead eye will give the direction of the chains and preventer braces.

The fenders may be then drawn, observing to place them right abreast of the main hatchway, in order to prevent the ship's side from being hurt by whatever may be hoisted on board. The proper place for them will therefore be at timber 3; and the distance between them may be regulated by the distance between the ports. The chest-tree may also be drawn, which must be placed at a proper distance abaft the foremast, for the conveniency of hauling home the fore tack. It may therefore be drawn at the aft side of timber C, from the top of the side down to the upper edge of the channel wales; and the fenders may reach from the top of the side down to the upper edge of the main wales. As the fenders and chest-tree are on the outside of the planks, wales, &c. the lines representing the wales, &c. should not be drawn through them.

Draw the steps on the side, which must be at the fore part of the main drift or break, making them as long as the distance between the upper and lower deck ports will admit of. They may be about six inches asunder, and five inches deep, and continued from the top of the side down to the middle of the main wales.

In order to describe the head, the height of the beak-head must be first determined, which may be about two feet above the upper deck. At that place draw a horizontal line, upon which set off the length of the beak-head, which may be $7\frac{1}{2}$ feet abaft the fore part of the stem, and from thence square a line up to the forecastle deck; which line will represent the aft part of the beak-head, and will likewise terminate the foremost end of the forecastle. The length of the head may now be determined, which by the proportions will be found to be 15 feet six inches from the fore part of the stem. Set it off from the fore part of the stem, and erect a perpendicular, which will be the utmost limits of the figure forward: then take the breadth of the figure from the proportions, which is four feet four inches, and set it off forward; and another perpendicular being drawn will shew the utmost extent of the hair bracket forward, or aft part of the figure. Then draw the lower cheek, letting the upper edge be well with the upper edge of the main wales, and the after end ranging well with the beak-head line; set off the depth of it on the stem; which is about 11 inches, and let a curved line pass from the after end through the point on the stem, and to break in fair with the perpendicular first drawn for the length of the head, the fore part of the curve will then represent the position of the figure.

The upper cheek may be next drawn; but, in order to know the exact place of it on the stem, the place of the main rail must first be set off on the stem, the upper edge of which may be kept on a level with the beak-head; then setting off the depth of it below that, the place for the upper cheek may be determined, letting it be exactly in the middle between that and the lower cheek: then, by drawing curves for the upper and lower edges of the cheek from the after end parallel to the lower cheek, to break in fair with the perpendicular, drawn for the back of the figure: then the upper cheek will be formed. The upper part may run in a serpentine as high as where the shoulder of the figure is supposed to come, at which place it may be turned off with a scroll. The distance from the scroll to the heel of the figure is called the hair-bracket.

The head of the block may be formed by continuing the line at the breast round to the top of the hair-bracket, observing to keep the top of it about six inches clear of the under side of the bowsprit.

Having the distance set off on the stem for placing the main rail, it may next be described, keeping the bag of it as level as possible for the conveniency of the gratings, and letting the foremost end rise gradually according to the rise of the upper cheek and hair-bracket, and may turn off on the round of the scroll before drawn for the hair-bracket. To form the after end, set off the size of the head of the rail abaft the beak-head line, and erect a perpendicular; then describe the arch of a circle from that perpendicular to break in fair with the lower side of the rail in the middle, and also another from the beak-head perpendicular, to break in fair with the upper side of the rail at the middle, observing to continue the head of it sufficiently high to range with the timber heads above the forecastle.

The head timbers are next to be drawn, placing the stem timber its own thickness abaft the stem, and the foremost must be so placed that the fore side may be up and down with the heel of the block or figure, which has not yet been set off. Take therefore the distance from the breast to the heel on a square which is seven feet, and erect a perpendicular from the lower part of the lower cheek to the lower part of the upper cheek; which perpendicular will terminate the foremost end of the lower cheek and the heel of the figure, and will also terminate the lower end of the hair-bracket: then, by continuing the same perpendicular from the upper part of the lower deck to the under part of the main rail, the fore side of the foremost head timber will be described; and by setting off its thickness aft, the other side may be drawn. The middle head timber may be spaced between the two former ones; and there may also be one timber

Application of the foregoing Rules to the Construction of Ships.

timber placed abaft the ftem, at a diftance from the ftem, equal to that between the others, and the lower end of it may ftep on the upper edge of the lower rail.

To defcribe the middle and lower rails, divide the diftance between the lower part of the main rail and the upper part of the upper cheek equally at every head timber; and curves being defcribed through thefe points will form the middle and lower rails. The after end of the lower rail muft terminate at the after edge of the after head timber.

The cat-head ought to be reprefented in fuch a manner as to come againft the aft fide of the head of the main rail, to rake forward four inches in a foot, and to fteeve up $5\frac{1}{2}$ inches in a foot, and about one foot fix inches fquare. The lower part of it comes on the plank of the deck at the fide, and the fupporter under it muft form a fair curve to break in with the after end of the middle rail.

The hawfe holes muft come between the cheeks, which is the moft convenient place for them; but their place fore and aft cannot be exactly determined until they are laid down in the half-breadth plan.

The knee of the head is to project from the breaft of the figure about two inches; and particular care muft be taken that in forming it downwards it be not too full, as it is then liable to rub the cable very much: it may therefore have no more fubftance under the lower cheek at the heel of the figure than is juft fufficient to admit of the bobftay holes, and may be $3\frac{1}{2}$ feet diftant from the ftem at the load water-line, making it run in an agreeable ferpentine line from the breaft down to the third water line, where it may be $1\frac{1}{2}$ feet from the ftem. By continuing the fame line downwards, keeping it more diftant from the ftem as it comes down, the *gripe* will be formed. The lower part of it muft break in fair with the under part of the falfe keel; and the breadth of the gripe at the broadeft place will be found by the proportions to be $4\frac{1}{2}$ feet. As the aft part of the gripe is terminated by the fore foot, or foremoft end of the keel, it will now be proper to finifh that part as follows: From the line reprefenting the upper edge of the keel fet down the depth of the keel, through which draw a line parallel to the former, and it will be the lower edge of the keel. From that point, where the aft fide of the ftem is diftant from the upper edge of the keel by a quantity equal to the breadth of the keel at midfhips, erect a perpendicular, which will limit the foremoft end of the keel; and the after or lower end of the ftem may be reprefented by fetting off the length of the fcarf from the foremoft end of the keel, which may be fix feet. Set down from the line reprefenting the lower edge of the keel the thicknefs of the falfe keel, which is feven inches; and a line drawn through that point parallel to the lower edge of the keel will be the under edge of the falfe keel, the foremoft end of which may be three inches afore the foremoft end of the main keel.

The head being now finifhed, proceed next to the ftern, the fide and middle timbers of which are already drawn. From the fide timber fet off forward 14 feet, the length of gallery, and draw a pencil line parallel to the fide timber; draw alfo a line to interfect the touch of the upper counter at the fide, producing it forwards parallel to the fheer as far as the pencil line firft drawn; and this line will reprefent the upper edge of the gallery rim. From which fet down eight inches, the breadth of the gallery rail, and draw the lower edge of the rail. At the diftance of eight inches from the fore fide of the fide timber draw a line parallel thereto; and from the point of interfection of this line with the upper edge of the gallery rim, draw a curve to the middle timber parallel to the touches of the upper counter, which line will reprefent the upper edge of the upper counter rail as it appears on the fheer draught. The lower edge of this rail may be formed by fetting off its depth from the upper edge. In the fame manner the lower counter rail may be defcribed: then take the diftance between that and the upper counter rail, and fet it off below the rim rail; and hence the rail that comes to the lower ftool may be drawn, keeping it parallel to the rim rail. Underneath that, the lower finifhing may be formed, making it as light and agreeable as poffible.

Set off from the middle timber on the end of the quarter-deck the projection of the balcony, which may be about 2 feet, and draw a line with a pencil parallel to the middle timber. On this line fet off a point $1\frac{1}{2}$ inches below the under fide of the quarter-deck, from which draw a curve to the fide timber parallel to the upper counter rail, which curve will reprefent the lower fide of the foot fpace rail of the balcony as it appears in the fheer draught.

Take the diftance between the point of interfection of the upper edge of the upper counter with the middle line, and the point of interfection of the under fide of the foot fpace rail with the middle line, which fet up on a perpendicular from the upper edge of the rim rail at the foremoft end. Through this point draw a line parallel to the rim rail to interfect the lower part of the foot fpace rail, and this line will reprefent the lower edge of the rail that comes to the middle ftool, and will anfwer to the foot fpace rail. Then between this line and the rim rail three lights or fafhes may be drawn, having a muntin or pillar between each light of about 14 inches broad, and the lower gallery will be finifhed. Set off the depth of the middle ftool rail above the line already drawn for the lower edge, and the upper edge may be drawn. Then fet off the fame depth above the curve drawn for the lower edge of the foot fpace rail, and the upper edge of that rail may then be drawn.

The quarter-piece muft be next defcribed, the heel of which muft ftep on the after end of the middle ftool. Draw a line with a pencil parallel to the middle timber, and at a diftance therefrom, equal to the projection of the balcony. Upon this line fet up from the round houfe deck the height of the upper part of the ftern or taff rail, which may be four feet above the deck. At that height draw with a pencil a horizontal line, and from its interfection with the line firft drawn defcribe a curve to the middle ftool rail, obferving to make the lower part of this curve run nearly parallel to the fide timber, and the lower part about three inches abaft the fide timber; and this curve will reprefent the aft fide of the quarter-piece at the outfide. There fet off the thicknefs of the quarter-piece, which is one foot fix inches, afore the curve already drawn; and another curve being defcribed parallel to it from the lower part to the top of the fheer, and the quarter-piece

Application of the foregoing Rules to the Construction of Ships.

at the outside will be repreſented. On the horizontal line drawn for the upper part of the taff-rail ſet off forward the thickneſs of the taff-rail, which is one foot; then draw a curve down to the head of the quarter-piece parallel to the firſt, and that part of the taff-rail will be deſcribed. Inſtead of a fair curve, it is cuſtomary to form the upper part of the taff-rail with one or two breaks, and their curves inverted. Either way may, however, be uſed according to fancy.

Set off the depth of the taff-rail, which may be about $3\frac{1}{2}$ feet, on the line drawn for the projection; from the upper part, and from this point, deſcribe a curve as low as the heel of the quarter-piece, and about five inches abaft it at that place; obſerving to make it run nearly parallel to the after edge of the quarter-piece; and the after part of the quarter-piece, which comes neareſt to the ſide, will be repreſented.

Set up on the line drawn for the projection of the balcony the height of the upper part of the balcony or breaſt rail, which is $3\frac{1}{2}$ feet from the deck; ſet off the thickneſs of the rail below that, and deſcribe the balcony, keeping it parallel to the foot ſpace rail, and terminating it at the line drawn for the after part of the quarter-piece neareſt the ſide; and the whole balcony will then be repreſented.

The upper gallery is then to be deſcribed. In order to this, its length muſt be determined, which may be 11 feet. Set off this diſtance from the ſide timber forward with the ſheer; and at this point draw a line parallel to the ſide timber, which line will repreſent the fore part of the gallery. Then take the diſtance between the upper part of the foot ſpace rail and the upper part of the breaſt rail on a perpendicular, and ſet it off on a perpendicular from the upper part of the middle ſtool rail on the line drawn for the fore part of the gallery, from which to the fore part of the quarter piece draw a ſtraight line parallel to the rail below, which line will be the upper edge of the upper rim rail; and its thickneſs being ſet off, the lower edge may alſo be drawn. From the upper edge of that rail ſet up an extent equal to the diſtance between the lower rim rail and middle ſtool rail, and deſcribe the upper ſtool rail, the after end of which will be determined by the quarter piece, and the fore end by the line for the length of the gallery. There may be three ſaſhes drawn between theſe two rails as before; and hence the upper gallery will be formed.

The upper finiſhing ſhould be next drawn, the length of which may be $1\frac{1}{2}$ foot leſs than the upper gallery. Draw a line parallel to the rake of the ſtern for the fore end of it, and let the upper part of the top ſide be the upper part of the upper rail, from which ſet down three inches for the thickneſs of the rail, and deſcribe it. Deſcribe alſo another rail of the ſame length and thickneſs as the former, and eight inches below; from the end of which a ſerpentine line may be drawn down to the upper ſtool rail, and the upper finiſhing will be completed.

The ſtern being now finiſhed, the rudder only remains to be drawn. The breadth of the rudder at the lower part is to be determined from the proportions, and ſet off from the line repreſenting the aſt part of the ſtern poſt; which line alſo repreſents the fore part of the rudder. Then determine on the lower hance, letting it be no higher than is juſt ſufficient, which may be about one foot above the load water-line, and ſet off its breadth at that place taken from the proportions. Then a line drawn from thence to the breadth ſet off at the lower part will be the aſt ſide of the rudder below the lower hance. There may alſo be another hance about the height of the lower deck. The uſe of theſe breaks or hances is to reduce the breadth as it riſes toward the head. The aſt part may be drawn above the lower hance, the break at the lower hance being about ten inches, and the break at the upper hance ſix inches.—The back may be then drawn. It is of elm, about four inches thick on the aſt part. That thickneſs being ſet off, and a line drawn from the lower hance to the lower end, will repreſent the back. The head of the rudder ſhould be as high as to receive a tiller above the upper deck. Therefore ſet off the ſize of the head above the upper deck, and draw a line from thence to the break at the upper hance, and the aſt part of the rudder will be repreſented all the way up. The bearding ſhould be drawn, by ſetting off the breadth of it at the keel from the fore ſide of the rudder, which may be nine inches. Set off alſo the breadth at the head of the wing tranſom, which may be a foot. Then a line being drawn through theſe two points, from the lower part of the rudder to about a foot above the wing tranſom, and the bearding will be repreſented. As the bearding is a very nice point, and the working of the rudder depending very much upon it, it ſhould always be very particularly conſidered. It has been cuſtomary to beard the rudder to a ſharp edge at the middle line, by which the main piece is reduced more than neceſſary. The rudder ſhould, however, be bearded from the ſide of the pintles, and the fore ſide made to the form of the pintles.

The pintles and braces may next be drawn. In order to which determine the place of the upper one, which muſt be ſo diſpoſed that the ſtraps ſhall come round the head of the ſtandard, which is againſt the head of the ſtern-poſt on the gun-deck, and meet at the middle line. By this means there is double ſecurity both to the brace and ſtandard. To obtain thoſe advantages, it muſt therefore be placed about four inches above the wing tranſom; the ſecond muſt be placed juſt below the gun-deck ſo as to bolt in the middle of the deck tranſom, and the reſt may be ſpaced equally between the lower one, which may be about ſix inches above the upper edge of the keel. The number of them are generally ſeven pair upon this claſs of ſhips; but the number may be regulated by the diſtance between the ſecond and upper one, making the diſtance between the reſt nearly the ſame. The length of all the braces will be found by ſetting off the length of the lower one, which may be eight feet afore the back of the ſtern-poſt, and alſo the length of the third, which is four feet and a half afore the back of the ſtern-poſt; and a line drawn from the one extremity to the other will limit the intermediate ones, as will appear on the ſheer draught. The braces will ſeem to diminiſh in length very much as they go up; but when meaſured or viewed on the ſhape of the body, they will all be nearly of an equal length. The length of the ſtraps of the pintles which come upon the rudder may all be within four inches of the aſt ſide of the rudder; and the rudder being a flat ſurface, they will appear of the proper lengths.

II. *Of the half-breadth and body plans.*——The half-breadth

Application of the foregoing Rules to the Construction of Ships.

breadth plan must be first drawn. Then produce the lower edge of the keel both ways, and let it also represent the middle line of the half-breadth plan. Produce all the frames downwards, and also the fore and after perpendiculars. Then from the place in the sheer-plan, where the height of breadth-lines intersect the stem, square down to the middle line the fore and aft part of the rabbet and the fore part of the stem. Take from the dimensions what the stem is sided at that place, and set off half of it from the middle line in the half-breadth plan, through which draw a line parallel to the middle line through the three lines squared down, and the half-breadth of the stem will be represented in the half-breadth plan. Take the thickness of the plank of the bottom, which is $4\frac{1}{2}$ inches, and describe the rabbet of the stem in the half-breadth plan.

From the points of intersection of the height of breadth lines with the counter timber at the side, and with the counter timber at the middle line, draw lines perpendicular to the middle line of the half-breadth plan, from which set off the half breadth of the counter on the line first drawn; and from this point to the intersection of the line last drawn, with the middle line draw a curve, and the half breadth of the counter will be represented at the height of breadth, which will be the broadest part of the stern.

Take the main half breadth of timber dead flat from the dimensions, and lay it off from the middle line on dead flat in the half-breadth plan. Take also from the dimensions the main half breadth of every timber, and set off each from the middle line on the corresponding timbers in the half-breadth plain. Then a curve drawn from the end of the line representing the half breadth of the counter though all the points, set off on the timbers, and terminating at the aft part of the stern, will be the main half breadth line. Take from the dimensions the top-timber half-breadth, and describe the top-timber half-breadth line in the half-breadth plan, in the same manner as the main half-breadth line.

Take from the dimensions the half breadth of the rising, and set it off from the middle line on the corresponding timbers in the half-breadth plan, observing, where the word *outside*, is expressed in the tables, the half breadth for that timber must be set off above or on the outside of the middle line. Then a curve drawn through these points will be the half breadth of rising in the half-breadth plan.

It will now be necessary to proceed to the body plan. Draw a horizontal line (fig. 35.), which is called the *base line*, from the right hand extremity of which erect a perpendicular. Then set off on the base line the main half-breadth at dead flat, and erect another perpendicular, and from that set off the half breadth again, and erect a third perpendicular. The first perpendicular, as already observed, is called the side line of the fore body; the second the middle line; and the third the side line of the after body.

Plate CCCCLXII.

Take from the dimensions the heights of the diagonals up the middle line, and set them from the base up the middle line in the body plan. Take also their distances from the middle line on the base, and set them off. Set off also their heights up the side lines, and draw the diagonals. Then take from the sheer plan the heights of the lower height of breadth line, and set them off upon the middle line in the body plan; through these points lines are to be drawn parallel to the base, and terminating at the side lines. In like manner proceed with the upper height of breadth line.

The rising is next to be set off on the body plan; it must, however, be first described in the sheer plan: Take, therefore, the heights from the dimensions, and set them off on the corresponding timbers in the sheer plan, and a curve described through these points will be the rising line in the sheer plan. Then take from the dimensions the rising heights of dead flat. Set it off in the body plan, and draw a horozontal line. Now take all the rising heights from the sheer plan, and set them off in the body plan from the line drawn for the rising height of dead flat, and draw horizontal lines through these points. Take from the half-breadth plan the half-breadths of the rising, and set them off from the middle line in the body plan, and the centres of the floor sweeps of the corresponding timbers will be obtained.

From the half-breadth plan take the main half-breadth lines, and set them off from the middle line in the body plan on the corresponding lines before drawn for the lower height of breadth; and from the extremities of these lines set off towards the middle line the lengths of the lower breadth sweeps respectively.

Take from the dimensions the distance of each frame from the middle line on the diagonals, and set them off from the middle line on their respective diagonal lines. Now these distances being set off, and the lower breadth and floor sweeps described, the shape of the frames below the breadth line may easily be drawn as follows: Place one point of a compass in the distance set off for the length of the lower breadth sweep, and extend the other to the point which terminates the breadth, and describe an arch of a circle downwards, which will intersect the points set off on the upper diagonal lines, letting it pass as low as convenient. Then fix one point of the compasses in the centre of the floor sweep, and extend the other to the point set off on the fourth diagonal, which is the floor head; and describe a circle to interfect as many of the points set off on the diagonals as it will. Then draw a curve from the back of the lower breadth sweep, through the points on the diagonals, to the back of the floor-sweep. Describe also another curve from the back of the floor-sweep through the points on the lower diagonals, and terminating at the upper part of the rabbet of the keel, and that part of the frame below the breadth will be formed. In like manner describe the other frames.

Through the extremities of the frames at the lower height of breadth draw lines parallel to the middle line, and terminating at the upper height of breadth line and from thence set off the upper breadth sweeps; now fix one point of the compass in the centre of the upper breadth sweeps successively, and the other point to the extremities of the frames, and describe circles upwards. Then from the sheer plan take off the heights of the top-timber lines, and set them off in the body plan, drawing horizontal lines; upon which set off the top-timber half-breadths taken from the corresponding timbers in the half-breadth plan; and by describing curves from the back of the upper breadth sweeps through the points set off on the seventh or upper diagonal; and intersecting the top-timber half-breadths, the timbers will then be formed from the keel

Application of the foregoing Rules to the Construction of Ships.

keel to the top of the side. The upper end of the timbers may be determined by taking the several heights of the upper part of the top side above the top-timber line, and setting them off above the top-timber line on the corresponding timbers in the body plan. The lower parts of the timbers are ended at the rabbet of the keel as follows: With an extent of $4\frac{1}{2}$ inches, the thickness of the bottom, and one leg of the compasses at the place where the line for the thickness of the keel intersects the base line; with the other leg describe an arch to intersect the keel line and the base. Then fix one point at the intersection of the arch and keel, and from the point of intersection of the keel and base describe another arch to intersect the former. Then from the intersection of these arches draw one straight line to the intersection of the keel and base, and another to the intersection of the lower arch and the keel, and the rabbet of the keel will be described at the main frame. All the timbers in the middle part of the ship which have no rising terminate at the intersection of the upper edge of the rabbet with the base line; but the lower part of the timbers, having a rising, end in the centre of the rabbet, that is, where the two circles intersect. Those timbers which are near the after end of the keel must be ended by setting off the half-breadth of the keel at the port in the half-breadth plan, and describe the tapering of the keel. Then at the corresponding timbers take off the half-breadth of the keel; set it off in the body plan, and describe the rabbet as before, letting every timber end where the two circles for its respective rabbet intersect.

To describe the side counter or stern timber, take the height of the wing transom, the lower counter, upper counter, and top-timber line at the side; from the sheer plan transfer them to the body plan, and through these points draw horizontal lines. Divide the distance between the wing transom and lower counter into three equal parts, and through the two points of division draw two horizontal lines. Draw also a horizontal line equidistant from the upper counter and the top-timber line in the sheer plan, and transfer them to the body plan.

Now, from the point of intersection of the aft side of the stern timber at the side, with the wing transom at the side in the sheer plan, draw a line perpendicular to the middle line in the half-breadth plan. Draw also perpendicular lines from the points where the upper and lower transoms touch the stern-post; from the points of intersection of the stern timber with the two horizontal lines drawn between, and from the intersection of the stern timber with the horizontal line drawn between the upper counter and top-timber line. Then curves must be formed in the half-breadth plan for the shape of the body at each of these heights. In order to which, begin with the horizontal or level line representing the height of the wing transom in the body plan. Lay a slip of paper to that line, and mark on it the middle line and the timbers 37, 35, 33, and 29; transfer the slip to the half-breadth plan, placing the point marked on it for the middle line exactly on the middle in the half-breadth plan, and set off the half-breadths on the corresponding timbers 37, 35, 33, and 29, and describe a curve through these points, and to intersect the perpendicular drawn from the sheer plan. In like manner proceed with the horizontal lines at the heights of the counters, between the lower counter and wing transom, above the upper counter and top-timber line; and from the intersections of the curve drawn in the half-breadth plan, with the perpendicular lines drawn from the sheer plan, take the distances to the middle line, and set them off on the corresponding lines in the body plan; then a curve described through the several points thus set off will be the representative of the stern timber.

The round-up of the wing transom, upper and lower counter, may be taken from the sheer draught, and set off at the middle line above their respective level lines in the body plan, by which the round-up of each may be drawn. The round aft of the wing transom may also be taken from the sheer plan, and set off at the middle line, abaft the perpendicular for the wing transom in the half-breadth plan, whence the round aft of the wing transom may be described.

The after body being now finished, it remains to form the fore body; but as the operation is nearly the same in both, a repetition is therefore unnecessary, except in those parts which require a different process.

The foremost timbers end on the stem, and consequently the method of describing the ending of them differs from that used for the timbers used in the after body. Draw a line in the body plan parallel to the middle line, at a distance equal to the half of what the stem is sided. In the sheer plan take the height of the point of intersection of the lower part of the rabbet of the stem with the timber which is required to be ended, and set it off on the line before drawn in the body plan. Then take the extent between the points of intersection of the timber with the lower and upper parts of the rabbet, and with one leg of the compasses at the extremity of the distance laid off in the body plan describe a circle, and the timbers may then pass over the back of this circle. Now, by applying a small square to the timber, and letting the back of it intersect the point set off for the lower part of the rabbet, the lower part of the rabbet and the ending of the timbers will be described.

The foremost timbers differ also very much at the head from those in the after body: For since the ship carries her breadth so far forward at the top-timber line, it therefore occasions the two foremost frames to fall out at the head beyond the breadth, whence they are called *knuckle* timbers. They are thus described; The height of the top-timber line being set off in the body plan, set off on it the top half breadth taken from the half-breadth plan, and at that place draw a perpendicular; then from the sheer plan take the height of the top of the side, and set it off on the perpendicular in the body plan: Take also the breadth of the rail at the top-timber line in the sheer plan, and set it off below the top-timber line at the perpendicular line in the body plan, and the straight part of the knuckle timber to be drawn will be determined. Then from the last mentioned point set off describe a curve through the points set off for the timber down to the upper breadth, and the whole knuckle timber will be formed. It will hence be seen that those timbers forward will fall out beyond the main breadth with a hollow, contrary to the rest of the top side, which falls within the main breadth with a hollow.

The fore and after bodies being now formed, the water lines must next be described in the half-breadth plan, in order to prove the fairness of the bodies. In this draught the water lines are all represented parallel to

th

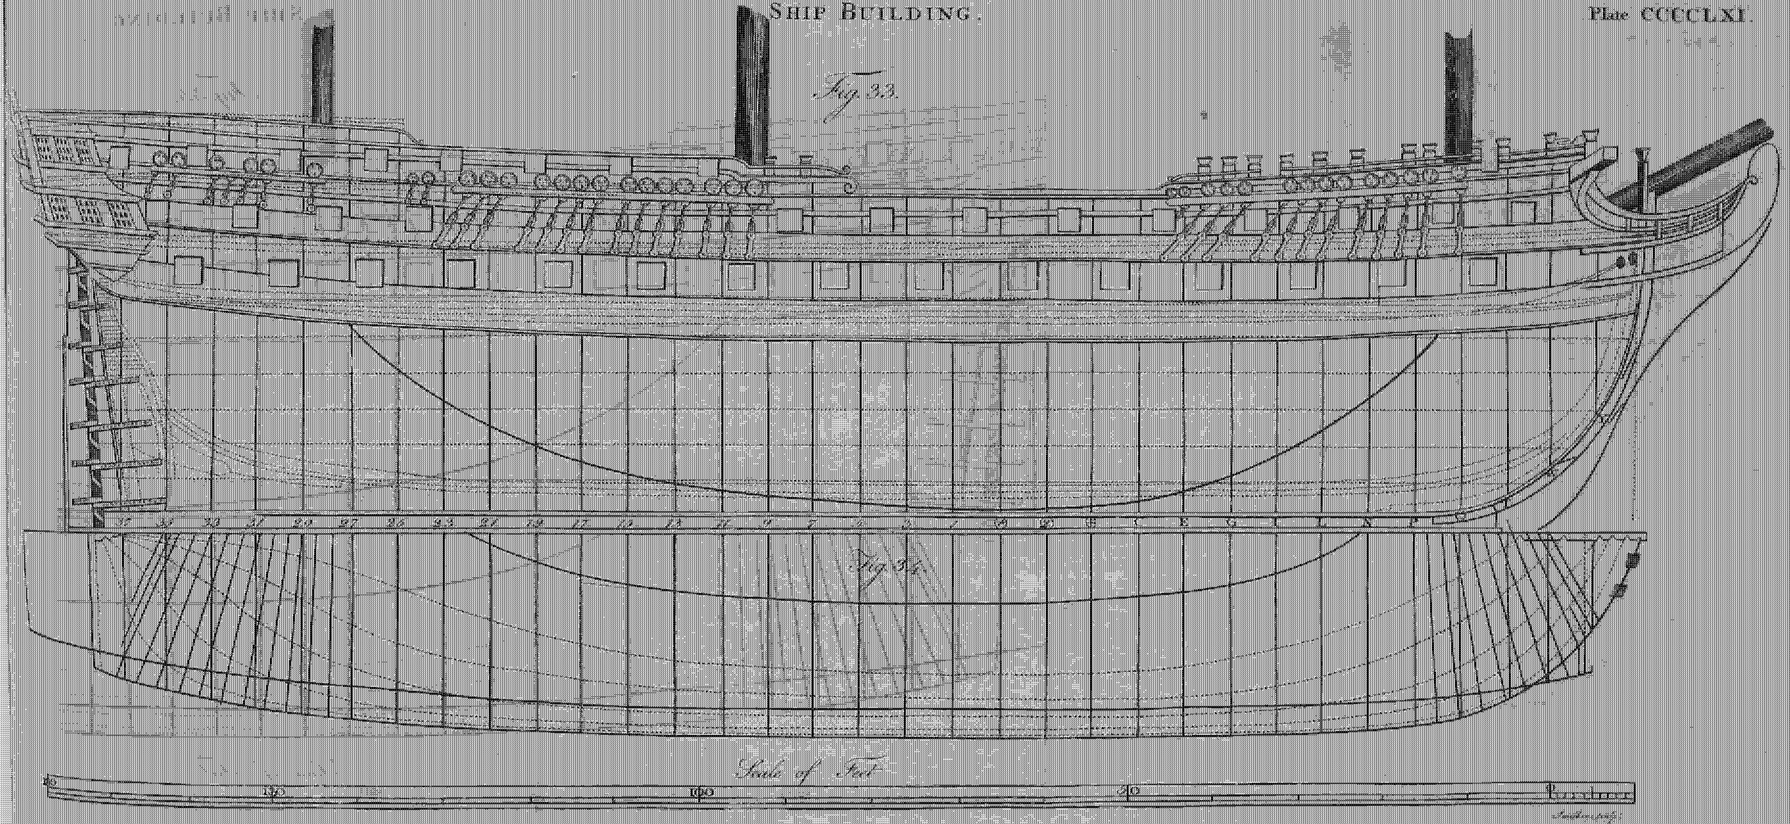

Fig. 33.
Fig. 34.
Scale of Feet

Application of the foregoing Rules to the Construction of Ships.

the keel; their heights may, therefore, be taken from the sheer plan, and transferred to the body plan, drawing horizontal lines, and the water lines will be represented in the body plan. In ships that draw more water abaft than afore, the water lines will not be parallel to the keel; in this case, the heights must be taken at every timber in the sheer plan, and set off on their corresponding timbers in the body plan; and curves being described through the several points, will represent the water lines in the body plan.

Take the distance from the middle line to the points where the water lines intersect the different timbers in the body plan, and set them off on their corresponding timbers in the half-breadth plan. From the points where the water lines in the sheer plan intersect the aft part of the rabbet of the sternpost draw perpendiculars to the middle line of the half-breadth plan, and upon these perpendiculars set off from the middle line the half thickness of the sternpost at its corresponding water line; which may be taken from the body plan, by setting off the size of the post at the head and the keel, and drawing a line for the tapering of it; and where the line so drawn intersects the water lines, that will be the half thickness required: then take an extent in the compasses equal to the thickness of the plank, and fix one point where the half thickness of the post intersects the perpendicular, and with the other describe a circle, from the back of which the water lines may pass through their respective points set off, and end at the fore part of the half breadth plan, proceeding in the same manner as with the after part. A line drawn from the water line to the point set off for the half thickness of the post will represent the aft part of the rabbet of the post; and in like manner the rabbet of the stem may be represented. The water lines being all described, it will be seen if the body is fair; and if the timbers require any alteration, it should be complied with.

The cant timbers of the after body may next be described in the half-breadth plan; in order to which the cant of the fashion-piece must first be represented. Having therefore the round aft of the wing transom represented in the half-breadth plan, and also the shape of a level line at the height of the wing transom; then set off the breadth of the wing transom at the end, which is one foot four inches, and that will be the place where the head of the fashion-piece will come: now to determine the cant of it, the shape of the body must be considered; as it must be canted in such a manner as to preserve as great a straightness as is possible for the shape of the timber, by which means the timber will be much stronger than if it were crooked; the cant must also be considered, in order to let the timber have as little bevelling as possible. Let, therefore, the heel of the timber be set off on the middle line, two feet afore timber 35; and then drawing a line from thence to the point set off on the level line for the wing transom, the cant of the fashion-piece will be described, and will be found situated in the best manner possible to answer the before mentioned purposes.

The cant of the fashion-piece being represented, the cant of the other timbers may now be easily determined. Let timber 29 be the foremost cant timber in the after body, and with a pencil draw timber 28; then observe how many frames there are between timber 28 and the fashion-piece, which will be found to be nine, namely, 29, 30, 31, 32, 33, 34, 35, 36, and 37. Now divide the distance between timber 28 and the fashion-piece on the middle line into 10 equal parts: Divide also the corresponding portion of the main half breadth lines into the same number of equal parts; and straight lines joining the corresponding points as the middle line with those in the half-breadth line will represent the cant timbers in the after body.

Application of the foregoing Rules to the Construction of Ships.

The line drawn for the cant of the fashion-piece represents the aft side of it, which comes to the end of the transoms; but in order to help the conversion with regard to the lower transoms, there may be two more fashion-pieces abaft the former; therefore the foremost fashion-piece, or that which is already described in the half-breadth plan, may only take the ends of the three upper transoms, which are, the wing, filling, and deck; the middle fashion-piece may take the four next, and the after fashion-piece the lower ones: therefore set off in the half-breadth plan the siding of the middle and after fashion-piece, which may be 13 inches each; then by drawing lines parallel to the foremost fashion-piece, at the aforesaid distance from each other, the middle and after fashion-piece will be represented in the half-breadth plan.

The fashion-piece and transoms yet remain to be represented in the sheer plan; in order to which, let the number of transoms be determined, which, for so large a buttock, may be seven below the deck transom: draw them with a pencil, beginning with the wing, the upper side of which is represented by a level line at its height; set off its siding below that, and draw a level line for the lower edge. The filling transom follows; which is merely for the purpose of filling the vacancy between the under edge of the wing and the upper part of the deck plank: it may therefore be represented by drawing two level lines for the upper and lower edge, leaving about two inches between the upper edge and lower edge of the wing transom, and four inches between the lower edge of the gun-deck plank; then the deck transom must be governed by the gun-deck, letting the under side of the gun deck plank represent the upper side of it, and setting off its siding below that; the under edge may also be drawn: the transoms below the deck may all be sided equally, which may be 11 inches; they must also have a sufficient distance between to admit the circulation of the air to preserve them, which may be about three inches.

The transoms being now drawn with a pencil, the fashion-piece must next be described in the sheer plan, by which the length of the transoms as they appear in that plan will be determined. As the foremost fashion-piece reaches above the upper transom, it may therefore be first described: in order to which, draw a sufficient number of level lines in the sheer plan; or, as the water lines are level, draw therefore one line between the upper water line and the wing transom, and one above the wing transom at the intended height of the head of the fashion-piece, which may be about five feet: then take the height of these two level lines, and transfer them to the body plan; and take off two or three timbers and run them in the half-breadth plan, in the same manner as the water lines were done; then from the point where the line drawn for the cant of the fashion-piece, in the half-breadth plan, intersects the le-

Application of the foregoing Rules to the Construction of Ships.

vel line drawn for the head of the fashion-piece, draw up a perpendicular to the said line in the sheer plan, making a point. Again, from the intersection of the cant line, with the level line for the wing transom in the half-breadth plan draw a perpendicular to the wing transom in the sheer plan. Also draw perpendiculars from the points where the cant line in the half-breadth plan intersects the level line below the wing transom, and also the water lines to the corresponding lines in the sheer plan; then a curve described through these points will be the representation of the foremost fashion-piece in the sheer plan. In the same manner the middle and after fashion-pieces may be described; observing to let the middle one run up no higher than the under part of the deck transom, and the after to the under side of the fourth transom under the deck. The transoms may now be drawn with ink, as their lengths are limited by the fashion-pieces.

Neither the head nor the foreside of the sternpost are yet described; take, therefore, from the dimensions, the breadth of the post on the keel, and set it off on the upper edge of the keel from the aft side of post. The head of the post must next be determined, which must just be high enough to admit of the helm-post transom and the tiller coming between it and the upper deck beam; the height therefore that is necessary will be one foot nine inches above the wing transom. Now draw a level line at that height, upon which set off the breadth of the sternpost at that place, taken from the dimensions, and a line drawn from thence to the point set off on the keel will be the foreside of the sternpost; observing, however, not to draw the line through the transoms, as it will only appear between them. The inner post may be drawn, by setting off its thickness forward from the sternpost, and drawing a straight line as before, continuing it no higher than the under side of the wing transom.

The cant-timbers in the after body being described, together with the parts dependent on them, those in the fore body may be next formed; in order to which, the foremost and aftermost cant-timbers must be first determined, and also the cant of the foremost ones. The foremost cant-timber will extend so far forward as to be named &c; the cant on the middle line may be one foot four inches afore square timber W, and on the main half-breadth line one foot nine inches afore timber Y; in which situation the line may be drawn for the cant; the aftermost may be timber Q. The cant timbers may now be described in the same manner as those in the after body, namely, by spacing them equally between the cant timber &c and the square timber P, both on the main half breadth and middle lines, and drawing straight lines between the corresponding points, observing to let them run out to the top-timber half-breadth line, where it comes without the main half-breadth line.

The hawse pieces must next be laid down in the half-breadth plan; the sides of which must look fore and aft with the ship upon account of the round of the bow. Take the siding of the apron, which may be about four inches more than the stem, and set off half of it from the middle line, drawing a line from the main half-breadth to the foremost cant timber, which will represent the foremost edge of the knight-head; then from that set off the siding of the knight-head, which may be one foot four inches, and draw the aft side of it. The hawse pieces may then be drawn, which are four in number, by setting off their sidings, namely, one foot six inches parallel from the knight-head and from each other; and straight lines being drawn from the main half-breadth line to the foremost cant timber will represent them.

The hawse holes should be described in such a manner as to wound the hawse pieces as little as possible; they may therefore be placed so that the joint of the hawse pieces shall be in the centre of the holes, whence they will only cut half the hawse pieces. Take the dimensions of the hawse holes, which is one foot six inches, and set off the foremost one, or that next the middle line, on the joint between the first and second hawse piece; then set off the other on the joint between the third and fourth hawse piece; and small lines being drawn across the main half-breadth at their respective places will represent the hawse holes in the half-breadth plan.

The hawse holes should next be represented in the sheer plan. In this class of ships they are always placed in the middle between the cheeks; therefore set off their diameter, namely, one foot six inches, between the cheeks, and draw lines parallel to the cheeks for their upper and lower part. Then to determine their situation agreeable to the half-breadth plan, which is the fore and aft way, draw perpendiculars from their intersections with the main half-breadth line to the lines drawn between the cheeks, and their true situations, the fore and aft way, will be obtained; and, by describing them round or circular, according to the points set off, they will be represented as they appear in the sheer plan.

The apron may be drawn in the sheer plan, setting off its bigness from the stem, and letting it come so low that the scarf may be about two feet higher than the foremost end of the fore foot; by which it will give ship to the scarfs of the stem. It may run up to the head of the stem.

The cutting down should next be drawn. Take therefore from the tables of dimensions the different heights there expressed, and set them off from the upper edge of the heel on the corresponding timbers in the sheer plan; then a curve described through the points set off, from the inner post aft to the apron forward, will be the cutting down. Next set off from the cutting down the thickness of the timber strake, which is $8\frac{1}{2}$ inches, and a curve described parallel to the former will represent the timber strake, from which the depth of the hold is always measured.

The kelson is drawn, by taking its depth from the dimensions, and setting it off above the cutting down line; and a curve described parallel to the cutting down will represent the kelson.

The cutting down line being described, the knee of the dead wood abaft timber 27, being the after floor timber, may then be represented. Set off the siding of the floor abaft it, and erect a perpendicular in the sheer plan, which will terminate the foremost end of the dead wood: then the fore and aft arm of the knee may be half the length of the whole dead wood, and the up and down arm may reach to the under part of the lower transom; and the whole knee may be placed in such a manner that the upper piece of the dead

4 wood

Application of the foregoing Rules to the Construction of Ships.

wood ſhall bolt over it, and be of as much ſubſtance as the knee itſelf: therefore the knee muſt conſequently be placed its whole thickneſs below the cutting down line repreſenting the upper part of the dead wood.

The ſheer draught, the body, and half-breadth plans are now finiſhed, from whence the ſhip may be laid down in the mould loft, and alſo the whole frame erected. As, however, the uſe of the diagonal lines in the body plan has not been ſufficiently explained, it is therefore thought proper to ſubjoin the following illuſtration of them.

45
Nature and uſe of diagonal lines.

The diagonal lines in the body plan are mentioned in the tables of dimenſions merely for the purpoſe of forming the body therefrom; but after the body is formed, they are of very principal uſe, as at their ſtations the ribbands and harpins which keep the body of the ſhip together while in her frames are all deſcribed, and the heads of the different timbers in the frame likewiſe determined.

The lowermoſt diagonal, or nº 1. which is named the *lower ſirmark*, at which place the bevellings are taken for the hollow of the floors; its ſituation is generally in the middle between the keel and the floor ſirmark.

Second diagonal is placed in the midſhips, about 18 inches below the floor head, and is the ſtation where the floor ribband is placed in midſhips, and likewiſe the floor harpin forward; there is alſo a bevelling taken at this diagonal all the way fore and aft, from which it is termed the *floor ſirmark*.

Third diagonal, terminates the length of the floors, and is therefore called the *floor head*. There are likewiſe bevellings taken at this diagonal as far forward and aft as the floor extends. The placing of this diagonal is of the utmoſt conſequence to the ſtrength of the ſhip, it being ſo near to that part of the bulge which takes the ground, and of conſequence is always liable to the greateſt ſtrain; it ſhould therefore be placed as much above the bearing of the body in midſhips as could be conveniently allowed by converſion of the timber; but afore and abaft it is not of ſo much conſequence.

Fourth diagonal is placed in the middle between the floor head and the fifth diagonal, at which place a ribband and harpin are ſtationed for the ſecurity of the firſt or lower futtock, from whence it is named the *firſt futtock ſirmark*. There are alſo bevellings taken at this diagonal all afore and aft, which being part of the body where the timbers moſt vary, occaſions them to be the greateſt bevellings in the whole body.

Fifth diagonal terminates the heads of the firſt futtocks, and is therefore called the *firſt futtock head*. It ſhould be placed at a convenient diſtance above the floor head, in order to give a ſufficient ſcarf to the lower part of the ſecond futtocks. There are likewiſe bevellings for the timbers taken at this diagonal, all fore and aft.

Sixth diagonal ſhould be placed in the middle between the firſt futtock head and the ſeventh diagonal; at which place the ribband and harpin are ſtationed for the ſupport of the ſecond futtocks. Bevellings are taken at this diagonal all fore and aft. It is named the *ſecond futtock ſirmark*.

Seventh diagonal terminates the ſecond futtock heads from the fore to the aftermoſt floors, and afore and abaft them it terminates the double futtock heads in the fore and aft cant bodies. It ſhould be placed in midſhips, as much above the firſt futtock head as the firſt futtock is above the floor head: by which it gives the ſame ſcarf to the lower part of the third futtock as the firſt futtock does to the ſecond. There are bevellings taken all fore and aft at this diagonal. It is named the *ſecond futtock head*.

Eighth diagonal is the ſtation for the ribband and harpin which ſupports the third futtocks, and is therefore placed between the ſecond futtock head and ninth diagonal. It is alſo a bevelling place, and is named the *third futtock ſirmark*.

Ninth and laſt diagonal is placed the ſame diſtance above the ſecond futtock head as that is above the firſt, and terminates all the heads of the third futtocks which are in frames, as they come between the ports; but ſuch as are between the frames, and come under the lower deck ports, muſt run up to the under part of the ports, as no ſhort timbers ſhould by any means be admitted under the ports, which require the greateſt poſſible ſtrength. This diagonal is likewiſe a bevelling place for the heads of the third futtocks, and is therefore called the *third futtock head*.

The fourth futtock heads are terminated by the under part of the upper deck ports all fore and aft, and a ribband is placed fore and aft at the height of the upper breadth line, another between the lower and upper deck ports, and one at the top-timber line; which, with the ribbands and harpins before-mentioned, keep the whole body of the ſhip together, and likewiſe in its proper form and ſhape.

It muſt be obſerved, that the diagonal lines laid down in the dimenſions will not correſpond to what has been ſaid above the diagonals, as they were drawn diſcretionally upon the body for the purpoſe of giving the true dimenſions of it. Therefore, when the body is drawn in fair, the firſt diagonals (which ſhould only be in pencil) are to be rubbed out, and the proper diagonals drawn with red ink, ſtrictly adhering to what has been ſaid above.

Sect. III. *Of the inboard Works of the Ship deſcribed in the preceding Section.*

Draughts of the outboard works being now conſtructed, in which every part is deſcribed that is neceſſary to enable the artiſt to put the ſhip in her frames, we muſt now proceed to form another draught of the cavity of the ſhip or inboard works, which muſt be ſo contrived that every thing within the ſhip may be arranged in the moſt commodious manner and to the beſt advantage.

Ship-builder's Repoſitory.

It is uſual to draw the inboard works in the ſheer-draught; but as this generally occaſions much confuſion, it is therefore the beſt and eaſieſt method to appropriate a draught to this particular purpoſe.

Take from the ſheer draught the ſtem, ſtern-poſt, counter timbers, and keel, and deſcribe them on another paper; draw in alſo the cutting down, kelſon, apron, tranſoms, faſhion-pieces, and decks, and the upper line of the ſheer all fore and aft, alſo the timbers and ports.

The beams come firſt under conſideration, and ſhould be ſo diſpoſed as to come one under and one between each port, or as near as can be to anſwer other works of the ſhip; but where it happens that a beam cannot poſſibly be placed under the port, then a beam arm ſhould

Application of the foregoing Rules to the Construction of Ships.

should be introduced to make good the deficiency. Every beam, and also the beam arms, should be kneed at each end with one lodging and one hanging knee; and in those parts of the ship which require the knees to be very acute, such as the after beams of the gun-deck, and in some ships, whose bodies are very sharp, the foremost beams of the gun-deck, there should be knees of iron. Care should be taken always to let the upper side of the knees be below the surface of the beams in large ships one inch and a half, and in small ships an inch, by which means the air will have a free passage between the knees and under part of the deck.

In the conversion of the beams the side next the lodging knee should be left as broad at the end of the beam as can possibly be allowed by the timber, the beam retaining its proper scantling at the end of the lodging knee: by so doing the lodging knees will be more without a square, which consequently makes them the more easy to be provided.

In ships where the beams can be got in one piece, they should be so disposed as to have every other one with the butt end the same way; for this reason, that the butts will decay before the tops. In large ships the beams are made in two or three pieces, and are therefore allowed to be stronger than those that are in one piece. The beams in two pieces may have the scarf one-third of the length, and those in three pieces should have the middle piece half the length of the whole beam. The customary way of putting them together is to table them; and the length of the tablings should be one-half more than the depth of the beam. It is very common to divide the tablings in the middle of the beam, and that part which is taken out at the upper side to be left at the lower side, and then kersey or flannel is put into the scarf: but in this case the water is liable to lie in the scarf, and must be the means of rotting the beams. If, however, the beams were tabled together in dovetails, and taken through from side to side, putting tar only between them, which hardens the wood; then the water occasioned by the leaking of the decks would have a free passage, and the beam would dry again; and this method would not be found inferior in point of strength to the other. The length of the fore and aft arm of the lodging knee should extend to the side of the hanging knee next to it; but there is no necessity for that arm to be longer than the other. In fastening the knees, care should be taken to let one bolt pass exactly through the middle of the throat, one foot six inches from each end, and the rest divided equally between; observing always to have the holes bored square from the knee. The bolts for the thwartship arms of both hanging and lodging knees may go through the arms of each knee, and drive every one the other way.

In order to draw the beams in the draught, take the moulding of the lower deck beams, and set it off below the line representing the deck at the side, and draw a line in pencil parallel thereto, which will represent the under side of the beams. In like manner represent the under side of the beams for the upper deck, quarter deck, forecastle, and roundhouse. Then take the siding of the lower deck beams, and place one under and one between each port, all fore and aft, drawing them in pencil. Determine the dimensions of the well fore and aft, which is ten feet, and set it off abaft the beam under the eighth port, placing the beam under the ninth port at that distance: those two beams may then be drawn in ink, and will terminate the extent of the well the fore and aft way; and as a beam cannot go across the ship at that place upon account of its being the well and mast room, there must therefore be a beam arm between these two beams.

Application of the foregoing Rules to the Construction of Ships.

The main hatchway should then be determined, letting the beam that forms the fore part of the well form the aft part of it, and the beam under the next part may form the fore side of it, which beam may also be now drawn in ink: there should also be another beam arm introduced in the wake of the main hatchway.

The fore hatchway may be next determined; the fore side of which should range well up and down with the after end of the forecastle, and it may be fore and aft about four-sevenths of the main hatchway. At the fore side of the fore hatchway there must be a ladder-way down to the orlop, which may be as much fore and aft as the beams will allow. The rest of the beams afore the fore hatchway may remain as first placed, there being nothing in the way to alter the ship. Then determine on the after hatchway, the foreside of which comes to the aft side of the mainmast room.

There should also be a hatchway, the fore side of which may be formed by the aft side of the beam under the twelfth port; which is for the conveniency of the spirit and fish rooms: and there should be a ladder-way abaft it to lead down to the cockpit. There may be also another hatchway, the foreside of it to be formed by the aft side of the beam under the eleventh port. The size of the ladder and hatchways must be governed by the beams, as when there is a good shift of beams they should not be altered for ladder and hatchways, unless it is the three principal hatchways, which must always be of a proper size, according to the size of the ship.

The after capstan must be placed between the two hatchways last described, and the beams abaft may stand as they are already shifted, observing only the mizenmast. There should be a small scuttle placed afore the second beam from aft, for the convenience of the bread room: it must be on one of the middle lines, as there is a calling at the middle under the four or five after beams to receive the pillars for the support thereof.

The bits may be placed, letting the foreside of the after ones come against the aft side of the beam abaft the third port, and the foreside of the foremost ones against the next beam but one forward; then at the foreside of each bit there should be drawn a small scuttle for the conveniency of handing up the powder from the magazine. The breast hook should also be drawn, which may be three feet the moulding away, and sided nine-tenths of the beams of the lower deck.

The gun-deck, beams, knees, &c. being described; in which, as well as all the decks having ports, the same precautions are to be used as in the gun-deck; and observing to keep the beams upon one deck as nearly as possible over the beams of the other, for the conveniency of pillaring, as they will then support each other.

The hatchways are to be placed exactly over those

on

Application of the foregoing Rules to the Construction of Ships.

on the lower deck, each over each; and therefore, where there is a beam arm in the lower deck there muſt alſo be one above it in the upper deck, and the ſame in the middle deck in three-deck ſhips. It commonly happens in ſhips of the line that there cannot be a whole beam between the deek breaſt hook and the beam that ſupports the ſtep of the bowſprit, becauſe the bowſprit paſſes through that place: in this caſe, there muſt be a beam arm placed, letting the end come equally between the beam and the breaſt hook: but in ſhips that the bowſprit will allow of a whole beam, then the ports and the reſt of the beams muſt be conſulted in order to ſpace it; and when it ſo happens that the foremaſt comes in the wake of a port, then a beam arm muſt be neceſſarily introduced.

Having placed the beams according to the diſpoſition of the other beams below, the ladder-ways ſhould be contrived: there ſhould be one next abaft the fore hatchway, which is a ſingle ladder-way; and one next afore the main hatch, which is a double ladder-way; the ladders ſtanding the fore and aſt way. There ſhould alſo be another next abaſt the after hatch, and one over the cockpit correſponding with that on the lower deck.

The capſtans are next to be conſidered; the after one is already placed on the lower deck, the barrel of which muſt paſs through the upper deck to receive the whelps and drumhead there, it being a double capſtan. In ſhips having three decks, the upper part of each capſtan is in the middle deck; but in ſhips with one deck there is only this one capſtan, the upper part of which is placed on the quarter deck. The foremoſt capſtan ſhould be placed in the moſt convenient ſpot, to admit of its being lowered down to the orlop out of the way of the long boat: it may therefore be placed between the main and fore hatchways; the beam under the ſixth port of the lower deck may form the aſt ſide of its room, and the beams on each ſide of it ſhould be placed exactly over or under the beams on the other decks, and they ſhould be at a diſtance from each other ſufficient to let the drumheads paſs between them. The centre of the capſtan ſhould then be placed in the middle between the beams which compoſe its room; and the partners ſhould be fitted in ſuch a manner as to ſhift occaſionally when wanted, which is by letting them be in two pieces fitted together. The partners on the lower deck, wherein the capſtan ſteps, muſt be ſupported by a pillar on the orlop deck, the lower part of which may be fitted in an oak chock; ſo that when the pillar is taken away, and the capſtan lowered down, that chock ſerves as a ſtep for the capſtan. Thoſe two beams on the orlop, by having the pillar and chock upon them, have therefore the whole weight of the capſtain preſſing downwards: for the ſupport of them, there ſhould be a carling placed underneath the fore and aft way, with three pillars, one under each beam, and one between; all of them being ſtept in the kelſon, by which the orlop deck will be well ſupported in the wake of the capſtan, and the other decks will feel no ſtrain from it.

The fire hearth is next to be diſpoſed; which is placed differently according to the ſize of the ſhip. In three-deckers it is found moſt convenient to place it on the middle deck; whence there is much more room under the forecaſtle than there would have been had it been placed there. In all two-deck ſhips it is placed under the forecaſtle, becauſe on the deck underneath the bits are in the way. It is alſo under the forecaſtle in one-deck ſhips, though confined between the bits: in this caſe it ſhould be kept as near as poſſible to the after bits, that there may be more room between it and the foremoſt bits to make a good galley.

The poſitions of the main-top-ſail-ſheet bits are next to be determined; the foremoſt of which muſt be ſo placed as to let its foreſide come againſt the aft ſide of the beam abaft the main hatchway, and to paſs down to the lower deck, and there ſtep in the beams: admitting it to be a ſtraight piece, it would come at the aſt ſide of the lower deck beam the ſame as it does at the upper deck beam, in conſequence of thoſe two beams ranging well up and down with each other: it muſt therefore have a caſt under the upper deck beam, by which the lower part may be brought forward ſufficient to ſtop in the lower deck beam. The aftermoſt muſt be placed againſt the foreſide of the beam abaft the maſt, and ſtep on the beam below; but there is no neceſſity to provide a crooked piece as before, for the beam of the upper deck may be moved a little farther aft, till it admit of the bit ſtopping on the lower deck beam, unleſs the beam comes under a port, as in that caſe it muſt not by any means be moved. The croſs pieces to the bits ſhould be on the foreſide, and in height from the upper deck about one-third of the height between it and the quarter deck. With regard to the heads of the bits, the length of the ſhip's waſte ſhould be conſidered; and if there is length enough from the forecaſtle to the foremoſt bits to admit of the ſpare geer being ſtowed thereon without reaching farther aft, the quarter deck may then run ſo far forward that the head of the foremoſt bits ſhall tenon in the foremoſt beam; this gives the mainmaſt another deck, and admits of the quarter deck being all that the longer; but if there is not the room before mentioned, then the quarter deck muſt run no further forward than the after bits, which will then tenon in the foremoſt beam; and the foremoſt bits muſt have a croſs piece let on their heads, which is termed a *horſe*, and will be for the purpoſe of receiving the ends of the ſpare geer.

The length of the quarter deck being now determined, the beams are then to be placed. For this purpoſe the ſeveral contrivances in the quarter deck muſt be previouſly conſulted. It is neceſſary to obſerve, that there are neither carlings nor lodges, the carlings of the hatches excepted, in the quarter deck, round-houſe, and forecaſtle; as they would weaken inſtead of ſtrengthening the beams, which ſhould be as ſmall as the ſize of the ſhip will permit, in order that the upper works may be as light as poſſible. Hence, as there are to be neither carlings nor lodges, the deck will require a greater number of beams, and a good round up, as on the contrary the deck would be apt to bend with its own weight. The moſt approved rule is therefore to have double the number of beams in the quarter deck as there are in a ſpace of the ſame length in the upper deck.

Then proceed to ſhift the beams to the beſt advantage, conſulting the hatchways, ladder-ways, maſts, bits, wheel, &c With reſpect to the ladder-ways on the quarter decks of all ſhips, there ſhould be one near the fore part of the great cabin for the officers, and an-

Application of the foregoing Rules to the Construction of Ships.

other near the foremost end of the quarter deck consisting of double ladders for the conveyance of the men up from the other decks in cases of emergency; and likewise one on each side of the fore part of the quarter deck from the gangway: and in every ship of the line all the beams from the foremost ladder-way to the after one should be open with gratings, both for the admission of air, and for the greater expedition of conveying different articles in the time of action.

Two scuttles are to be disposed one on each side of the mainmast, if it happens to come through the quarter deck, for the top tackles to pass through, to hook to the eye bolts drove in the upper deck for that purpose.

The steering wheel should be placed under the forepart of the roundhouse, and the two beams of the quarter deck, which come under it, should be placed conformable to the two uprights, so that they may tenon in them. The quarter deck beams, should be kneed at each end with one hanging and one lodging knee; which adds greatly to the strength of the side. The hanging knees which come in the great cabin may be of iron; their vertical arms to be two-thirds of the length of that of wood, and to reach the spirketing. It should be observed, that the beam abaft, which comes under the screen bulkhead, should round aft agreeable to the round of the bulkhead, for the support of the same.

The forecastle beams should be placed according as the works of the deck will admit. The hatchways are therefore to be considered first. There should be one for the funnel of the fire hearth to pass through, and one for the copper to admit of vent for the steam; and also one or two over the galley as the forecastle will admit of. The fore-top-sail-sheet bits should be so disposed as to come one pair on the fore and one on the aft side of the mast, to let into the side of the forecastle beams, and step on the upper deck beams below: there should also be a ladder-way at the fore part of the forecastle for the conveniency of the fore part of the ship.

The beams may now be placed agreeable thereto, their number being four more than there are in a space in the upper deck equal in length to the forecastle; and where there happens to be a wide opening between the beams, as in the case of a hatchway, mast room, &c. then half a beam of fir may be introduced to make good the deficiency. The foremost beam should be of a breadth sufficient to take the aft side of the inboard arms of the catheads, as they are secured upon this beam by being bolted thereto. Every beam of the forecastle should be kneed at each end with one hanging and one lodging knee: the vertical arms of the hanging knees should reach the spirketing, and the knees well bolted and carefully clenched.

Proceed to the roundhouse; the same things being observed with respect to the beams as in the quarter deck: for as the roundhouse beams are sided very small, it hence follows that they must be near to each other. Let therefore the number of beams on the roundhouse be four more than in the same length of the quarter deck; every other beam being of fir for lightness, and every oak beam may be kneed at each end with one hanging and one lodging knee; the hanging knees abaft may be of iron, their vertical arms to be in length two thirds of those of wood. The round-house should always have a great round up, both for strength and conveniency. There must be on the roundhouse a small pair of knee-bits on each side of the mizenmast, turned round and scarfed over each other, and bolted through the mast carlings. There must also be a companion on the roundhouse placed over the middle of the coach in order to give light thereto.

Application of the foregoing Rules to the Construction of Ships.

With regard to placing the roundhouse beams, the uprights of the steering wheel and the mizenmast are to be observed; as when the beams which interfere with those parts are properly spaced, the rest may be disposed of at discretion, or at an equal distance from each other, and letting the beam over the screen bulkhead have a proper round aft, agreeable to the quarter deck beam underneath.

The upper parts of the inboard works being now described, proceed next to the lower parts, or to those which come below the lower deck. Draw in the orlop, by taking the heights afore, at midships, and abaft, between that and the gun-deck, from the dimensions, and a curve described through these points will represent the upper part of the deck. Set off the thickness of the plank below, and the under side of the plank will be represented. As this deck does not run quite forward and aft as the other decks, the length of it must be therefore determined; for this purpose let the after beam be placed at a sufficient distance from aft to admit of the bread rooms being of a proper size for the ship, which will be under that beam of the gun-deck that comes at the second part from aft. The after beam being drawn in, proceed to space the other beams, placing them exactly under those of the gun-deck; and that which comes under the foremost beam of the gun-deck may terminate the fore part of the orlop. Draw the limber strake, by setting off its thickness above the cutting down line, and a line drawn parallel thereto will represent the limber strake. That part of the orlop which is over the after magazine, spirit room, and fish room, and also that which is over the fore magazine, is laid with thicker planks than the rest of the deck; which is for the better security of those places, the planks being laid over the beams; but in the midships, from the fore part of the spirit room to the aft part of the fore magazine, the beams are laid level with the surface of the deck, and the planks are rabbeted in from one beam to the other.

In order to represent the orlop as just described, the dimensions of the different apartments above mentioned must be determined: Let the aft side of the after beam be the aft side of the after magazine, and from thence draw the bulkhead down to the limber strake; and the foreside of the third beam may be the foreside of the after magazine, drawing that bulkhead likewise, which will also form the aft side of the fish room; the foreside of the fish room may be drawn from the aft side of the fifth beam, which will also represent the aft side of the spirit room; then the foreside of the spirit room may be drawn from the foreside of the sixth beam. Hence from the foreside of the sixth beam quite aft the deck will be represented by the two lines already drawn, and the upper side of the beams will be represented by the lower line.

Proceed next to the forepart of the orlop, letting the fore-

foreside of the after bits be the aft part of the foremost magazine, drawing the bulkhead thereof which will come to the aft side of the sixth beam; therefore, from the sixth beam to the foremost end of the orlop, the plank and beams will be represented just in the same manner as before mentioned for the after part of the orlop: then the midship part of the deck will be represented by letting the upper line be the upper side of the plank, and likewise the upper side of the beams; and the lower line will represent the lower edge of the plank, only drawing it from beam to beam, and observing not to let it pass through them.

The hatchways, &c. may now be represented on the orlop, letting the main, fore, and after hatchway, be exactly under those of the gun-deck: there must be one over the fish room, and one over the spirit room. There must be two scuttles over the after magazine for the passage to the magazine and light room. There should also be one afore the fourth beam from forward for the passage to the fore magazine, and one abaft the second beam for the passage to the light room.

The bulkheads for the fore and after parts of the well may be drawn from the lower deck beams to the orlop, and from thence to the limber strake in the hold. The shot lockers may also be represented, having one afore and one abaft the well: there should also be one abaft the foremost magazine, the ends of which may be formed by the after bits. The steps of the masts may be drawn in by continuing their centres down to the limber strake; and likewise two crutches abaft the mizen step divided equally between that and the after part of the cutting down: the breast hooks may also be drawn letting them be five in number below the lower deck hook, and all equally divided between that and the fore step. Hence every part of the inboard is described as far as necessary.

Chap. V. *Of the Method of Whole-moulding.*

46 Method of whole-moulding. Murray's Ship-Building.

Having now finished the methods of laying down the several plans of a ship, any farther addition on this subject might appear unnecessary. We cannot, however, with propriety, omit to describe the method called *whole-moulding*, used by the ancients, and which still continues in use among those unacquainted with the more proper methods already explained. This method will be illustrated by laying down the several plans of a long-boat; the length of the keel being 29 feet, and breadth moulded nine feet.

47 Applied to a long boat. Plate CCCCLXIII.

Draw the straight line PO (fig. 37.) equal to 29 feet, the extreme length of the boat, and also to represent the upper edge of the keel. Let ⊕ be the station of the midship frame. From the points P, ⊕, and O, draw the lines PT, ⊕M, and OS, perpendicular to PO. Make ⊕M, ⊕N, equal to the upper and lower heights of breadth respectively at the main frame, PT the height of breadth at the transom, and OS the height at the stem. Describe the curve TMS to represent the sheer or extreme height of the side, which in a ship would be called the *upper height of breadth line*, or upper edge of the wale. Through the point N draw a curve parallel to TMS, to represent the breadth of the upper strake of a boat, or lower edge of the wale if in a ship. The dotted line TNS may also be drawn to represent the lower height of breadth.

Set off the rake of the port from P to p, and draw the line pt to represent the aft side of the port; then Tt will represent the round up of the transom. Set off the breadth of the port from p to r, and from T to s, and draw the line rs to represent the foreside of the port, which may either be a curve or a straight line at pleasure. Set up the height of the tuck from p to k. Let k X be the thickness of the transom, and draw the line ZX to represent the foreside of the transom.

There is given the point S, the height of the sheer on the foreside of the stem; now that side of the stem is to be formed either by sweeps or some other contrivance. Set off the breadth of the stem, and form the aft side of it.

Set up the dead-rising from ⊕ to d, and form the rising line r i s. Draw the line KL parallel to PO to represent the lower edge of the keel, and another to represent the thickness of the plank or the rabbet. The rabbet on the post and stem may also be represented; and the stations of the timbers assigned, as ⊗, (1), 1, 2, 3, 4, 5, 6, 7, 8, 9; and ⊕, (A), A, B, C, D, E, F, G, H; and the sheer plan will be completed.

The half-breadth plan is to be formed next; for this purpose the perpendiculars TP, 9, 8, &c. must be produced. Upon M⊕ produced set off the half breadth from the line KL to R (fig. 38.); set off also the half breadth at the transom from K to b, and describe the extreme half breadth line b RX, making the forepart of the curve agreeable to the proposed round of the transom.

We may next proceed to form the timbers in the body plan. Let AB (fig. 39.) be the breadth moulded at ⊕. Erect the perpendicular CD in the middle of the line AB; draw the line mn distant therefrom the half thickness of the post, and xy the half thickness of the stern. Then take off the several portions of the perpendiculars ⊕, 1, 2, &c. intercepted between the upper edge of the keel and the rising line in the sheer plan, and set them up from C upon the line CD; through these points draw lines parallel to AC; take off also the several lower heights of breadth at ⊕, 1, 2, &c. from the sheer plan; and set them up from C upon the middle line in the body plan; and draw lines parallel to AC through these points: Then take off the several half breadths corresponding to each from the floor plan; and set them off on their proper half-breadth lines from the middle line in the body plan.

Construct the midship frame by Problem V. the form of which will in some measure determine the form of the rest. For if a mould be made on any side of the middle line to fit the curve part of it, and the rising line, or that marked *bend mould* (fig. 40.), and laid in such a manner that the lower part of it, which is straight, may be set upon the several rising lines, and the upper part just touch the point of the half breadth in the breadth line corresponding to that rising upon which the mould is placed, a curve may then be drawn by the mould to the rising line. In this manner we may proceed so far as the rising line is parallel to the lower height of the breadth line. Then a hollow mould must be made, the upper end of which is left straight, as that

Method of Whole-moulding.

that marked *hollow mould* (fig. 40.). This is applied in such a manner, that some part of the hollow may touch the side of the keel and the straight part touch the back of the curve before described by the bend mould; and, beginning abaft, the straight part will always come lower on every timber, till we come to the midship timber, when it comes to the side of the keel. Having thus formed the timbers, so far as the whole mouldings will serve, the timbers abaft them are next formed. Their half-breadths are determined by the sheer and floor plans, which are the only fixed points through which the curves of these timbers must pass. Some form these after timbers before the whole is moulded, and then make the hollow mould, which will be straighter than the hollow of either of these timbers. It is indifferent which are first formed, or what methods are used; for after the timbers are all formed, though every timber may appear very fair when considered by itself, it is uncertain what the form of the side will be. In order to find which, we must form several ribband and water lines; and if these do not make fair curves, they must be rectified, and the timbers formed from these ribbands and water lines. In using the hollow mould, when it is applied to the curve of each timber, if the straight part is produced to the middle line, we shall have as many points of intersection as there are timbers; and if the heights above the base be transferred to the corresponding timbers in the sheer plan, a curve passing through these points is what is called a *rising strait*. This may be formed by fixing a point for the aftermost timber that is whole moulded, and transferring that height to the sheer plan. The curve must pass through this point, and fall in with the rising line somewhere abaft dead flat; and if the several heights of this line be transferred from the sheer to the middle line in the body plan, these points will regulate what is called the *hauling down* of the hollow mould.

The timbers in the after body being all formed, those in the fore body are formed in the same manner, by transferring the several heights of the rising and breadth lines from the sheer to the body plan; the half-breadths corresponding to each height must also be transferred from the floor to the body plan. The same hollow mould will serve both for the fore and after body; and the level lines, by which the water lines to prove the after body were formed, may be produced into the fore body, and by them, the water lines to prove the fore body, may be described.

Another method of proving the body is by ribband lines, which are formed by sections of planes inclined to the sheer plan, and intersecting the body plan diagonally, as before observed, of which there may be as many as may be judged necessary. As this has been already explained, we shall therefore lay down only one, represented in the body plan by the lines marked d i a. These are drawn in such a manner as to be perpendicular to as many timbers as conveniently may be. After they are drawn in the body plan, the several portions of the diagonal intercepted between the middle line and each timber must be transferred to the floor plan. Thus, fix one foot of the compasses in the point where the diagonal intersects the middle line in the body plan; extend the other foot to the point where the diagonal intersects the timber; for example, timber 9: Set off the same extent upon the perpendicular representing the plane of timber 9 from the point where it intersects the line KL on the floor plan: in like manner proceed with all the other timbers both in the fore and after body; and these shall have the points thro' which the curve must pass. If this should not prove a fair curve, it must be altered, observing to conform to the points as nearly as the nature of the curve will admit: so it may be carried within one point, and without another, according as we find the timbers will allow. For after all the ribband lines are formed, the timbers must, if needful, be altered by the ribband lines: this is only the reverse of forming the ribband lines; for taking the portions of the several perpendiculars intercepted between the line KL and the curve of the ribband line in the floor plan, and setting them off upon the diagonal from the point where it intersects the middle line, we shall have the points in the diagonal through which the curves of the timbers must pass. Thus the distance between the line KL and the ribband at timber 3 on the floor plan, when transferred to the body plan, will extend on the diagonal from the middle line to the point where the curve of timber 3 intersects that diagonal. The like may be said of all the other timbers; and if several ribband lines be formed, they may be so contrived that their diagonals in the body plan shall be at such distances, that a point for every timber being given in each diagonal, will be sufficient to determine the form of all the timbers.

In stationing the timbers upon the keel for a boat, there must be room for two futtocks in the space before or abaft ⊗; for which reason, the distance between these two timbers will be as much more than that between the other as the timber is broad. Here it is between ⊕ and (A); which contains the distances between ⊕ and (1), and the breadth of the timber besides.

The timbers being now formed, and proved by ribband and water lines, proceed then to form the transom, fashion-pieces, &c. by Problem VI.

This method of whole moulding will not answer for the long timbers afore and abaft. They are generally canted in the same manner as those for a ship. In order to render this method more complete, we shall here describe the manner of moulding the timbers after they are laid down in the mould loft, by a rising square, bend, and hollow mould.

It was shown before how to form the timbers by the bend and hollow mould on the draught. The same method must be used in the loft; but the moulds must be made to their proper scantlings in real feet and inches. Now when they are set, as before directed, for moulding each timber, let the middle line in the body plan be drawn across the bend mould, and draw a line across the hollow mould at the point where it touches the upper edge of the keel; and let them be marked with the proper name of the timber, as in fig. 40. The graduations of the bend mould will therefore be exactly the same as the narrowing of the breadth. Thus, the distance between ⊗ and 7 on the bend mould is equal to the difference between the half breadth of timber 7 and that of ⊕. The height of the head of each timber is likewise marked on the bend mould, and also the floor and breadth sirmarks. The floor sirmark is in that point where a straight edged batten touches the back of the bend mould, the batten being so placed as

Method of whole Moulding.

as to touch the lower edge of the keel at the same time. The several risings of the floor and heights of the cutting down line are marked on the rising square, and the half breadth of the keel set off from the side of it.

The moulds being thus prepared, we shall apply them to mould timber 7. The timber being first properly sided to its breadth, lay the bend mould upon it, so as may best answer the round according to the grain of the wood; then lay the rising square to the bottom of the bend mould, so that the line drawn across the bend mould at timber 7 may coincide with the line representing the middle of the keel upon the rising square; and draw a line upon the timber by the side of the square, or let the line be scored or cut by a tool made for that purpose, called a *raseing knife* (E); this line so rased will be the side of the keel. Then the square must be moved till the side of it comes to 7 on the bend mould, and another line must be rased in by the side of it to represent the middle of the keel. The other side of the keel must likewise be rased after the same manner, and the point 7 on the rising square be marked on each side of the keel, and a line rased across at these points to represent the upper edge of the keel. From this line the height of the cutting down line at 7 must be set up, and then the rising square may be taken away, and the timber may be rased by the bend mould, both inside and outside, from the head to the floor sirmark; or it may be carried lower if necessary. After the sirmarks and head of the timbers are marked, the bend mould may likewise be taken away, and then the hollow mould applied to the back of the sweep in such a manner that the point 7 upon it may intersect the upper side of the keel, before set off by the rising square; and when in this position the timber may be rased by it, which will complete the outside of the timbers. The inside of the timbers may likewise be formed by the hollow mould. The scantling at the keel is given by the cutting down before set off. The mould must be so placed as to touch the sweep of the inside of the timber formed before by the bend mould, and pass through the cutting down point.

The use of the sirmarks is to find the true places of the futtocks; for as they are cut off three or four inches short of the keel, they must be so placed that the futtock and floor sirmarks may be compared and coincide. Notwithstanding which, if the timbers are not very carefully trimmed, the head of the futtock may be either within or without its proper half breadth; to prevent which a half breadth staff is made use of.

The half breadth staff may be one inch square, and of any convenient length. Upon one side of it are set off from one end the several half breadths of all the timbers in the after body, and those of the fore body upon the opposite side. On the other two sides are set off the several heights of the sheer, the after body on one side, and the fore body on its opposite. Two sides of the staff are marked *half breadths*, and the other two sides *heights of the sheer*.

The staff being thus prepared, and the floor-timbers fastened on the keel, and levelled across, the futtocks must next be fastened to the floor timbers; but they must be set first to their proper half breadth and height. The half breadth staff, with the assistance of the ramline §, serves to set them to the half breadth: for as the keel of a boat is generally parallel to the horizon, therefore the line at which the plummet is suspended and which is moveable on the ram line, will be perpendicular to the keel. Whence we may by it set the timbers perpendicular to the keel, and then set them to their proper half breadths by the staff: and when the two sirmarks coincide, the futtock will be at its proper height, and may be nailed to the floor timbers, and also to the breadth ribband, which may be set to the height of the sheer by a level laid across, taking the height of the sheer by the staff from the upper side of the keel; by which means we shall discover if the ribband is exactly the height of the sheer; and if not, the true height may be set off by a pair of compasses from the level, and marked on the timbers.

Practice of Ship-building.

§ See next Chapter.

Chap. VI. *Of the Practice of Ship-building.*

The elevation, projection, and half-breadth plans, of a proposed ship being laid down on paper, we must next proceed to lay down these several plans on the mould loft of the real dimensions of the ship proposed to be built, and from which moulds for each separate part are to be made. The method of laying down these plans, from what has been already said, will, it is, presumed, be no very difficult task to accomplish, as it is no more than enlarging the dimensions of the original draughts; and with respect to the moulds, they are very easily formed agreeable to the figure of the several parts of the ship laid down in the mould loft.

Blocks of wood are now to be prepared upon which the keel is to be laid. These blocks are to be placed at nearly equal distances, as of five or six feet, and in such a manner that their upper surfaces may be exactly in the same plane, and their middle in the same straight line. This last is easily done by means of a line stretched a little more than the proposed length of the keel; and the upper planes of these blocks may be verified by a long and straight rule; and the utmost care and precaution must be taken to have these blocks properly bedded. Each block may be about six or eight inches longer than the keel is in thickness; their breadth from 12 to 14 inches, and their depth from a foot to a foot and half.

The dimensions of the keel are to be taken from the mould loft, and the keel is to be prepared accordingly. As, however, it is seldom possible to procure a piece of wood of sufficient length for a keel, especially if for a large ship, it is, therefore, for the most part necessary to compose it of several pieces, and these pieces are to be scarfed together, and securely bolted, so as to make one entire piece. It must, however, be observed, that the pieces which compose the keel ought to be of such lengths, that a scarf may not be opposite to the step of any of the masts. Rabbets are to be formed on each side of the keel to receive the edge of the planks next to

(E) The term *raseing* is used when any line is drawn by such an instrument instead of a pencil.

Practice of Ship-building.

to it, or garboard strake, and the keel is to be laid on the blocks (F).

The stem, and the post, and the several transoms belonging to it, are to be prepared from the moulds, and rabbeted in like manner as the keel, to receive the ends of the plank. The transoms are to be bolted to the post at their middle, each at its respective height, taken from the elevation in the mould loft, and the extremities of the transoms are to be firmly connected with the fashion-pieces. Both stem and post are then to be erected, each at its respective extremity of the keel. The tenons at the heel of each being let into mortoises prepared to receive them, and being set to their proper rakes or angles with the keel, are to be supported by props or shores. Pieces of wood called *dead wood* are to be laid upon and fixed to the upper side of the keel towards the fore and aft parts of it; the deepness of the dead wood increasing with its distance from the middle, agreeable to the proposed form of the cutting down line.

A line is to be stretched from the middle of the head of the stem to that of the post, called the *ram line*, upon which is a moveable line with a plummet affixed to it. The midship and other frames are to be erected upon the keel at their proper stations. The extremities of each frame are set at equal distances from the vertical longitudinal section of the ship, by moving the frame in its own plane until the plumb-line coincides with a mark at the middle between the arms of each frame; and although the keel is inclined to the horizon, yet the frames may also be set perpendicular to the keel by means of the plumb-line. The shores which are supporting the frames are now to be securely fixed, that the position of the frames may not be altered. The ribbands are now to be nailed to the frames at their proper places, the more effectually to secure them; and the intermediate vacancies between the frames filled up with filling timbers. For a perspective view of a ship framed, see Plate CCCCLIV. fig. 2.

The frames being now stationed, proceed next to fix on the planks, of which the wales are the principal, being much thicker and stronger than the rest, as is represented in the midship frame, Plate CCCXIV. The harpins, which may be considered as a continuation of the wales at their fore ends, are fixed across the hawse pieces, and surround the fore part of the ship. The planks that inclose the ship's sides are then brought about the timbers; and the clamps, which are of equal thickness with the wales, fixed opposite to the wales within the ship. These are used to support the ends of the beams, and accordingly stretch from one end of the ship to the other. The thick stuff or strong planks of the bottom within board are then placed opposite to the several scarfs of the timbers, to reinforce them throughout the ship's length. The planks employed to line the ship, called the *ceiling* or *foot-waling*, is next fixed in the intervals between the thick stuff of the hold. The beams are afterwards laid across the ship to support the decks, and are connected to the side by lodging and hanging knees: the former of which are exhibited at F, Plate CLVI. See also the article Deck; and the hanging-knees, together with the breadth, thickness, and position of the keel, floor timbers, futtocks, top-timbers, wales, clamps, thick stuff, planks within and without, beams, decks, &c. are seen in the midship frame, Plate CCCXIV. and in that article these several parts have already been explained.

The cable-bits being next erected, the *carlings* and *ledges*, represented in Plate CLVI. are disposed between the beams to strengthen the deck. The *water-ways* are then laid on the ends of the beams throughout the ship's length, and the spirketing fixed close above them.— The upper deck is then planked, and the *string* placed under the *gunnel*, or *plansheer*, in the waist. The disposition of those latter pieces on the timbers, viz. the water-ways, spirketing, upper deck, string, and gunnel, are also represented in the midship frame, Plate CCCIV.

Then proceed next to plank the quarter-deck and forecastle, and to fix the *partners* of the masts and capsterns with the *coamings* of the hatches. The *breast-hooks* are then bolted across the stem and bow within-board, the step of the foremast placed on the kelson, and the *riders*, exhibited in the Midship Frame, fayed to the inside of the timbers, to reinforce the sides in different parts of the ship's length. The *pointers*, if any, are afterwards fixed across the hold diagonally to support the beams; and the crotches stationed in the after hold to unite the half timbers. The *steps* of the mainmast and capsterns are next placed; the planks of the lower decks and orlop laid; the *navel-hoods* fayed to the hawse holes; and the *knees of the head*, or cut-water, connected to the stem. The figure of the head is then erected, and the *trail-board* and cheeks fixed on the side of the knee.

The *taffarel* and *quarter-pieces*, which terminate the ship abaft, the former above and the latter on each side, are then disposed, and the stern and quarter galleries framed and supported by their brackets. The *pumps*, with their well, are next fixed in the hold; the *limber boards* laid on each side of the kelson, and the *garboard strake* fixed on the ship's bottom next to the heel without.

The hull being thus fabricated, proceed to separate the apartments by bulkheads or partitions, to frame the port-lids, to fix the catheads and chess-trees; to form the hatchways and scuttles, and fit them with proper covers or gratings. Next fix the ladders at the different hatchways, and build the manger on the lower deck, to carry off the water that runs in at the hawse-holes when the ship rides at anchor in a sea. The bread-room and magazines are there lined; and the gunnel, rails, and gangways fixed on the upper part of the ship. The cleats, kevels, and ranges, by which the ropes are fastened, are afterwards bolted or nailed to the sides in different places.

The rudder, being fitted with its irons, is next hung to the stern-post, and the tiller or bar, by which it is managed, let into a mortise at its upper end. The *scuppers*,

4.

(F) In ships of war, which are a long while in building, it has been found that the keel is often apt to rot before they are finished. Upon this account, therefore, some builders have begun with the floor timbers, and added the keel afterwards.

Improvements in the Maſts and Rudder.

ſcuppers, or leaden tubes, that carry the water off from the decks, are then placed in holes cut through the ſhip's ſides; and the *ſtandards* repreſented in the Midship Frame, Plate CCCXIV. bolted to the beams and ſides above the deck to which they belong. The poop lanthorns are laſt fixed upon their cranes over the ſtern, and the *bilge-ways* or *cradles* placed under the bottom to conduct the ſhip ſteadily into the water whilſt launching.

As the various pieces which have been mentioned above are explained at large in their proper places, it is therefore ſuperfluous to enter into a more particular deſcription of them here.

Chap. VII. *Of Improvements in the Maſts and Rudder.*

48 Improvements in maſts.

Since the article Mast was printed, an account of a method for reſtoring maſts of ſhips when wounded, or otherwiſe injured, in an eaſy cheap, and expeditious manner, by Captain Edward Pakenham of the royal navy, has been publiſhed in the tenth volume of the Tranſactions of the Society for the Encouragement of Arts, &c. Captain Pakenham introduces his invention with the following obſervations:

49 Of wounded maſts by Captain Pakenham. Page 209.

"Among the various accidents which ſhips are liable to at ſea, none call more for the attention and exertion of the officer than the ſpeedy refitting of the maſts; and having obſerved, in the courſe of laſt war, the very great deſtruction made among the lower maſts of our ſhips from the enemy's mode of fighting, as well as the very great expence and delay in refitting a fleet after an action, particularly acroſs the Atlantic—a very ſimple expedient has ſuggeſted itſelf to me as a reſource in part; which appears ſo very ſpeedy and ſecure, that the capacity of the meaneſt ſailor will at once conceive it. I therefore think it my duty to ſtate my ideas of the advantages likely to reſult from it; and I ſhall feel myſelf exceedingly happy ſhould they in anywiſe contribute to remedy the evil.

"My plan, therefore, is, to have the heels of all lower maſts ſo formed as to become the heads; but it is not the intention of the above plan to have the ſmalleſt alteration made in the heels of the preſent lower maſts; for as all line-of-battle ſhips maſts are nine inches in diameter larger at the heel than at the head, it will follow, that by letting in the treſſel-trees to their proper depth, the maſt will form its own checks or hounds; and I flatter myſelf the following advantages will reſult from the above alteration.

"Firſt, I muſt beg to obſerve, that all line-of-battle ſhips bury one-third of their lower maſts, particularly three-deckers; it therefore follows, that if the wounds are in the upper third, by turning the maſt ſo as to make the heel the head, it will be as good as new; for, in eight actions I was preſent in laſt war, I made the following obſervations:

"That in the ſaid actions fifty-eight lower maſts were wounded, and obliged to be ſhifted, thirty-two of which had their wounds in the upper third, and of courſe the ſhips detained until new maſts were made. And when it is conſidered that a lower maſt for a 90 or 74 ſtands government in a ſum not leſs, I am informed, than 2000 l. to 2300 l. the advantages acroſs the Atlantic reſulting from the aforeſaid plan will be particularly obvious; not to mention the probability of there being no fit ſpars in the country, which was the caſe in the inſtances of the Iſis and Princeſs Royal: and as I was one of the lieutenants of the Iſis at that time, I am more particular in the circumſtance of that ſhip. The Iſis had both her lower maſts wounded above the cather pins in her action with the Cæſar, a French 74; and as there were no ſpars at New York, the Iſis was detained five weeks at that place.—Now, if her maſts had been fitted on the plan I have propoſed, I am confident ſhe would have been ready for ſea in 48 hours; and as a further proof, I beg leave to add, that the whole fleet, on the glorious 12th of April, had not the leaſt accident of any conſequence except what befel their lower maſts, which detained them between eight and ten weeks at Jamaica.

"The delay of a ſhip while a new maſt is making, and probably the fleet being detained for want of that ſhip, which frequently occurred in the courſe of laſt war, the taking of ſhipwrights from other work, with a variety of inconveniences not neceſſary to mention here, muſt be obvious to every officer that has made the ſmalleſt obſervations on ſea actions.

"You will further obſerve, that this ſubſtitute is formed on the moſt ſimple principle, fitted to the meaneſt capacity, and calculated to benefit all ſhips, from a firſt-rate down to the ſmalleſt merchantman, in caſes of an accident by ſhot, a ſpring, or a rottenneſs, particularly as theſe accidents generally happen in the upper third of the maſt and above the cheeks.

"It might probably be objected, that a difficulty and ſome danger might ariſe from the wounded part of the maſt being below; but this will at once be obviated, when it is remembered, that as the wounded part is below the wedges, it may with eaſe be both fiſhed, caſed, and ſecured, to any ſize or degree you pleaſe, with the addition of its being wedged on each deck."

Fig. 41. repreſents a maſt of a firſt-rate in its proper ſtate, the figures repreſenting its thickneſs at the different diviſions.

Fig. 42. the ſame maſt inverted, the heel forming the head, and the treſſel-trees let into their proper depth, the additional thickneſs of the maſt forming its own cheeks.

Fig. 43. the propoſed maſt, the figures repreſenting the thickneſs of the maſt in the propoſed alteration; *a*, the heel made ſquare: *b*, the letting in of the treſſel-trees; *c*, the third proportion of thickneſs continued up to where the fourth is in the preſent maſt, or at leaſt ſome little diſtance above the lower part of the cheeks, which is always looked upon as the weakeſt part of the maſt; and by its being ſo proportioned, the maſt, when turned, will be nearly as ſtrong in the partners as before.

As the expence of a maſt is much greater than is generally imagined, it is therefore thought proper to ſubjoin the following ſtatement of the ſeveral articles uſed in making a 74 gun ſhip's mainmaſt.

Principles of Naval Architecture, p. 50.

50 Mr Gordon's plan of buildig masts.

In order to lessen the enormous expence of masts, a proposal was made some years ago to construct them hollow; and the author having premised several experiments which he had made, proceeds as follows:

"Galileo taught us, that the resistance or strength of a hollow cylinder is to that of a full cylinder, containing the same quantity of matter, as the total diameter of the hollow one is to the diameter of the full one; and these experiments show us, that the strength or resistance of two or more pieces of wood, fastened together at each end, and connected by a pillar, pillars, or framing, increases, at least to a certain degree, *cæteris paribus*, as the distance between them and number of pillars, provided the force is applied in the line or direction of the pillars.

"It is surprising that this discovery of Galileo has not been made subservient to more useful purposes. It is particularly applicable to the construction of masts, as not requiring that the hollow cylinder should be made of one solid piece of wood (G).

"However, the foregoing experiments teach us, that the same advantages may be obtained by other forms besides that of a cylinder; and that perhaps not only in a superior degree, but likewise with greater facility of execution; as by adopting a square figure, but more particularly by constructing them of separate pieces of wood, placed at proper distances from each other, in the following or any other manner that may be found most convenient. Fig. 44, 45, and 46, exhibit each the transverse section of a mast, in which the small circles represent the trees or upright pieces of wood, and the lines the beams or framing of wood, which are employed at proper places and at proper distances from each other, for connecting them together. Perhaps solid frames of wood, placed at proper distances from each other, and filling up the whole dotted space, would answer better; in which event, the mast could be strongly hooped with iron at those places, and the upright trees formed square, or of any other convenient form.

"It will be evident to those acquainted with this subject, that such masts would be greatly stronger than common ones containing the same quantity of materials. It is likewise evident that they would be less apt to spring, as being supported on a more extended base, and affording many conveniences for being better secured; and that they might be constructed of such wood as at present would be deemed altogether improper for masts: a circumstance of importance to Britain at all times, but more particularly now, when there is such difficulty in procuring wood proper for the kind of masts in common use."

51 An improvement in the rudder.

An improvement in the rudder has lately taken place in several ships, particularly in some of those in the service of the East India company. It will, however, be necessary previously to describe the usual form of the rudder, in order to show the advantages it possesses when constructed agreeably to the improved method.

Papers on Naval Architecture, part I.

N° 1. (fig. 47.) represents the rudder according to the common method of construction; in which AB is the axis of rotation. It is hence evident that a space considerably greater than the transverse section of the rudder at the counter must be left in the counter for the rudder to revolve in. Thus, let CAB (N° 2.) be the section of the rudder at the counter; then there must be a space similar to CDE in the counter, in order that the rudder may be moveable as required. Hence, to prevent the water from washing up the rudder case, a rudder coat, that is, a piece of tarred canvas, is nailed in such a manner to the rudder and counter as to cover the intermediate space: but the canvas being continually washed by the sea, soon becomes brittle, and unable to yield to the various turns of the rudder without breaking; in which case the ship is of course left pervious to the waves, even of three or four feet high; in fact, there are few men bred to the sea who have not been witnesses to the bad effects of such a space being left so ill guarded against the stroke of the waves; and many ships have, with great probability, been supposed to founder at sea from the quantity of water shipped between the rudder and counter.

It was to remedy this defect that the alteration above alluded to took place; which consists in making the upper part AFG (fig. 48, n° 1.) of the rudder ABD cylindrical, and giving that part at the same time a cast forward, so that the axis of rotation may by that means be the line AD, passing as usual from E to D, through the centres of the braces which attach the rudder to the stern-post, and from E to A through the axis

(G) The strength of these cylinders would be still further augmented by having solid pieces of wood placed within them at proper distances, and securely fastened to them, in the same manner, and on the same principles, that nature has furnished reeds with joints; and for answering, in some respects, the same purpose as the pillars in the experiments alluded to.

Load-water Line and Ship's Capacity.

axis the cylinder AFG, in order that the transverse section KH (nº 2.) at the counter may be a circle revolving upon its centre; in which case the space of half an inch is more than sufficient between the rudder and the counter, and consequently the necessity of a rudder coat entirely done away. But as it was foreseen, that if the rudder by any accident was unshipped, this alteration might endanger the tearing away of the counter, the hole is made much larger than the transverse section of the cylindric part of the rudder, and the space between filled up with pieces of wood so fitted to the counter as to be capable of withstanding the shock of the sea, but to be easily carried away with the rudder, leaving the counter, under such circumstances, in as safe a state as it would be agreeable in the present form of making rudders in the navy.

Chap. VIII. *Upon the Position of the Load water Line, and the Capacity of a Ship.*

See Hydrostatics.

The weight of the quantity of water displaced by the bottom of a ship is equal to the weight of the ship with its rigging, provisions, and every thing on board. If therefore the exact weight of the ship when ready for sea be calculated, and also the number of cubic feet in the ship's bottom below the load-water line, and hence the weight of the water she displaces; it will be known if the load-water line is properly placed in the draught.

Ship-Builder's Repository.

The position of the ship in the draught may be either on an even keel, or to draw most water abaft; but an even keel is judged to be the best position in point of velocity, when the ship is constructed suitable thereto, that is, when her natural position is such. For when a ship is constructed to swim by the stern, and when brought down to her load-water made to swim on an even keel (as is the case with most ships that are thus built), her velocity is by that means greatly retarded, and also her strength greatly diminished: for the forepart being brought down lower than it should be, and the middle of the ship maintaining its proper depth in the water, the after part is by that means lifted, and the ship is then upon an even keel: but in consequence of her being out of her natural position, the after part is always pressing downwards with a considerable strain, which will continue till the ship's sheer is entirely broke, and in time would fall into its natural position again: for which reason we see so many ships with broken backs, that is, with their sheers altered in such a manner that the sheer rounds up, and the highest part is in the midships.

Such are the disadvantages arising from not paying a due attention to those points in the construction of a draught; therefore, when the load-water line is found to be so situated at a proper height on the draught, according to the weight given for such a ship, and also drawn parallel to the keel, as supposing that to be the best sailing trim, the next thing is to examine whether the body is constructed suitable thereto, in order to avoid the above-mentioned ill consequences.

In the first place, therefore, we must divide the ship equally in two lengthwise between the fore and after perpendiculars; and the exact number of cubic feet in the whole bottom beneath the load-water line being known, we must find whether the number of cubic feet in each part so divided are the same; and if they are found to be equal, the body of the ship may then be said to be constructed in all respects suitable to her swimming on an even keel, let the shape of the body be whatever it will; and which will be found to be her natural position at the load-water line. But if either of the parts should contain a greater number of cubic feet than the other, that part which contains the greatest will swim the most out of the water, and consequently the other will swim deepest, supposing the ship in her natural position for that construction. In order, therefore, to render the ship suitably constructed to the load-water line in the draught, which is parallel to the keel, the number of cubit feet in the less part must be subtracted from the number contained in the greater part, and that part of the body is to be filled out till it has increased half the difference of their quantities, and the other part is to be drawn in as much: hence the two parts will be equal, that is, each will contain the same number of cubic feet, and the ship's body will be constructed in a manner suitable to her swimming on an even keel.

If it is proposed that the ship laid down on the draught shall not swim on an even keel, but draw more water abaft then afore, then the fore and after parts of the ship's body below the load-water line are to be compared; and if these parts are unequal, that part which is least is to be filled out by half the difference, and the other part drawn in as much as before.

It will be necessary, in the first place, to calculate the weight of a ship ready equipped for sea, from the knowledge of the weight of every separate thing in her and belonging to her, as the exact weight of all the timber, iron, lead, masts, sails, rigging, and in short all the materials, men, provisions, and every thing else on board of her, from which we shall be able afterwards to judge of the truth of the calculation, and whether the load-water line in the draught be placed agreeable thereto. This is indeed a very laborious task, upon account of the several pieces of timber, &c. being of so many different figures, and the specific gravity of some of the timber entering the construction not being precisely determined.

In order to ascertain the weight of the hull, the timber is the first thing which comes under consideration: the number of cubic feet of timber contained in the whole fabric must be found; which we shall be able to do by help of the draught and the principal dimensions and scantling; observing to distinguish the different kinds of timber from each other, as they differ considerably in weight; then the number of cubic feet contained in the different sorts of timber being reduced into pounds, and added, will be the weight of the timber. In like manner proceed to find the weight of the iron, lead, paint, &c. and the true weight of the whole will be found.

In reducing quantity to weight, it may be observed that a cubic foot of oak is equally to 66 pounds, and the specific gravity of the other materials are as follow: See Hydrostatics.

Water being	1000	Oak is	891.89
Lead is -	11345	Dry elm	702.70
Iron	7643	Dry fir	648.64

Load-water Line and Ship's Capacity.

Weight of the men and ballast	1795361	801	1121
Sum -	8182463	3652	1983

Agreeable to the above estimate, we find that the eighty gun ship, with every thing on board and fit for sea, when brought down to the load water line, weighs 8,182,463 pounds, or nearly 3653 tons. It may now be known if the load water line in the draught be properly placed, by reducing the immersed part of the body into cubic feet. For if the eighty gun ship, when brought down to the load water line, weighs 3653 tons, the quantity of water displaced must also be 3653 tons: now a cubic foot of salt-water being supposed to weigh 74 pounds, if therefore 8182463 be divided by 74, the quotient is 110573, the number of cubical feet which she must displace agreeable to her weight.

It is now necessary to find the number of cubic feet contained in the ship's bottom below the load water line by calculation. If the bottom was a regular solid, this might be very easily done; but as it is otherwise, we must be satisfied with the following method by approximation, first given by M. Bouguer.

53 Method of calculating the content of the bottom of a ship.

Take the lengths of every other of the lines that represent the frames in the horizontal plane upon the upper water line; then find the sum of these together, with half the foremost and aftermost frames. Now multiply that sum by the distance between the frames, and the product is the area of the water line contained between the foremost and aftermost frames: then find the area of that part abaft the after frame, which forms a trapezium, and also the post and rudder; find also the area of that part afore the foremast frame, and also of the stem and gripe; then these areas being added to that first found, and the sum doubled will be the area of the surface of the whole water line. The reason of this rule will be obvious to those acquainted with the first principles of mathematics.

The areas of the other water line may be found in the same manner: then the sum of all these areas, except that of the uppermost and lowermost, of which only one half of each must be taken, being multiplied by the distance between the water lines (these lines in the plane of elevation being equidistant from each other), and the product will be the solid content of the space contained between the lower and load water lines.

Add

Load water Line and Ship's Capacity.

Add the area of the lower water line to the area of the upper side of the keel; multiply half that sum by the distance between them, the product will be the solid content of that part between the lower water line and upper edge of the keel, supposing them parallel to each other. But if the lower water line is not parallel to the keel, the above half sum is to be multiplied by the distance between them at the middle of the ship.

The solid contents of the keel must be next found, by multiplying its length by its depth, and that product by the breadth. Then the sum of these solid contents will be the number of cubic feet contained in the immersed part of the ship's bottom, or that part below the load water line.

Determination of the number of Cubic Feet contained in the Bottom of the Eighty Gun Ship. See Plates CCCCLX. and CCCCLXI.

54 Applied to the eighty gun ship.

THE fore body is divided into five, and the after body into ten, equal parts in the horizontal plane; besides the parts contained between the foremost timber and the stem, and the aftermost timber and the post. The plane of elevation is also divided into five equal parts by water lines drawn parallel to the keel. These water lines are also described upon the horizontal plane.

It is to be observed that there must be five inches added to each line that represents a frame in the horizontal plane for the thickness of the plank, that being nearly a mean between the thickness of the plank next the water and that on the lower part of the bottom.

Tonnage of a ship.

	Ft.	In.
Cubic feet contained between the lower and load water lines	33634	2¾
Cubic feet contained between lower water line and keel	2692	7½
Content of the keel and false keel	196	6
Content afore midship frame under water when loaded	36523	4
Content abaft midship frame	74050	6
Content under water	110573	10
Weight of a cubic foot of salt water	74 lbs.	
Weight of the whole ship with every thing on board	8182463.8 lbs.	

As the weight of the ship, with every thing on board, found by this calculation, is equal to that found by estimate; it hence appears that the water line is properly placed in the draught. It now only remains to find whether the body is constructed suitably thereto, that is, whether the ship will be in her natural position when brought down to that line. For this purpose a perpendicular must be erected 27 feet ¼ inch abaft dead flat, which will be the middle between the two perpendiculars and the place where the centre of gravity should fall, that the ship may swim on an even keel. The solidity of that part of the bottom contained between the said perpendicular and dead flat is then to be calculated, which will be found to be 25846 feet 7 inches.

	f.	in.
Solidity of the bottom afore dead flat	36523	4
——— between the middle and dead flat	25846	7
Solid content of the fore part of the bottom	62369	11
Solidity of the bottom abaft dead flat	74050	6
——— between the middle and dead flat	25846	7
Solid content of the aft part of the bot.	48203	11
———fore part of the bottom	62369	11
Difference	14166	
Half	7083	

Hence the after part of the ship's bottom is too lean by 7083 cubic feet, and the fore part as much too full. The after part must therefore be filled out until it has received an addition of 7083 feet, and the fore part must be drawn in till it has lost the same quantity, and the bottom will then be constructed suitable to the ship's swimming on an even keel.

Chap. IX. *Of the Tonnage of a Ship.*

This is a question of equal importance and difficulty. By the tonnage of a ship is meant the weight of every thing that can with safety and expediency be taken on board that ship for the purpose of conveyance: it is also called the *ship's burthen;* and it is totally different from the weight of the whole as she floats in the water. It is perhaps best expressed by calling it the *weight of the cargo.* It is of importance, because it is by this that the merchant or freighter judges of the fitness of

55 Proper method of calculating the tonnage of a ship.

Tonnage of a ship.

of the ship for his purpose. By this government judge of the ships requisite for transport service, and by this are all revenue charges on the ship computed. It is no less difficult to answer this question by any general rule which shall be very exact, because it depends not only on the cubical dimensions of the ship's bottom, but also on the scantling of her whole frame, and in short on the weight of every thing which properly makes part of a ship ready to receive on board her cargo. The weight of timber is variable; the scantling of the frame is no less so. We must therefore be contented with an average value which is not very remote from the truth; and this average is to be obtained, not by any mathematical discussion, but by observation of the burthen or cargo actually received, in a great variety of cases. But some sort of rule of calculation must be made out. This is and must be done by persons not mathematicians. We may therefore expect to find it incapable of being reduced to any principle, and that every builder will have a different rule. Accordingly the rules given for this purpose are in general very whimsical, measures being used and combined in a way that seems quite unconnected with stercometry or the measurement of solids. The rules for calculation are even affected by the interests of the two parties oppositely concerned in the result. The calculation for the tonnage by which the customs are to be exacted by government are quite different from the rule by which the tonnage of a transport hired by government is computed; and the same ship hired as a transport will be computed near one half bigger than when paying importation duties.

Yet the whole of this might be made a very simple business and very exact. When the ship is launched, let her light-water line be marked, and this with the cubical contents of the immersed part be noted down, and be engrossed in the deed by which the property of the ship is conveyed from hand to hand. The weight of her masts, sails, rigging, and sea-stores, is most easily obtained; and every builder can compute the cubical contents of the body when immersed to the load-water line. The difference of these is unquestionably the burthen of the ship.

It is evident from what has been already said in the last chapter, that if the number of cubic feet of water which the ship displaces when light, or, which is the same, the number of cubic feet below the light water line, found by the preceding method of calculation, be subtracted from the number of cubic feet contained in the bottom below the load water line, and the remainder reduced to tons by multiplying by 74, the number of pounds in a cubic foot of sea water, and divided by 2240, the number of pounds in a ton, the quotient will be the tonnage.

But as this method is very troublesome, the following rule for this purpose is that which is used in the British king's and merchant's service.

56 Common rule.

Let fall a perpendicular from the foreside of the stem at the height of the hawse holes (H), and another perpendicular from the back of the main post at the height of the wing transom. From the length between these two perpendiculars deduct three-fifths of the extreme breadth (I), and also as may times $2\frac{1}{2}$ inches as there are feet in the height of the wing transom above the upper edge of the keel; the remainder is the length of the keel for tonnage. Now multiply this length by the extreme breadth, and the product by half the extreme breadth, and this last product divided by 94 is the tonnage repuired.

Or, multiply the length of the keel for tonnage by the square of the extreme breadth, and the product divided by 188 will give the tonnage.

Calculation of the Tonnage of an Eighty Gun Ship.

I. According to the true method.

57 Calculation of the tonnage of the eighty gun ship.

58 The common rule gives the tonnage of ships of war greater, and of merchant ships less, than the truth.

Hence an eighty gun ship will not carry the tonnage she is rated at by about 95 tons. As the body of this ship is fuller than in ships of war in general, there is therefore a nearer agreement between the tonnages found by the two different methods. It may be observed that ships of war carry less tonnage than they are rated at by the common rule, and that most merchant ships carry a great

(H) In the merchant service this perpendicular is let fall from the fore side of the stem at the height of the wing transom, by reason of the hawse-holes being generally so very high in merchant ships, and their stems also having a great rake forward.

(I) The breadth understood in this place is the breadth from outside to outside of the plank.

Tonnage of a Ship.

a great deal more. In confirmation of this, it is thought proper to subjoin the dimensions of several ships, with the tonnage calculated therefrom.

Real tonnage	110	1131
Difference	148	2133

The impropriety of the common rule is hence manifest, as there can be no dependence on it for ascertaining the tonnage of vessels.

We shall now subjoin the following experimental method of finding the tonnage of a ship.

59 Experimental method of determining the tonnage of vessels.

Construct a model agreeable to the draught of the proposed ship, to a scale of about one-fourth of an inch to a foot, and let the light and load water lines be marked on it. Then put the model in water, and load it until the surface of the water is exactly at the light water line; and let it be suspended until the water drains off, and then weighed. Now since the weights of similar bodies are in the triplicate ratio of their homologous dimensions, the weight of the ship when light is, therefore, equal to the product of the cube of the number of times the ship exceeds the model by the weight of the model, which is to be reduced to tons. Hence, if the model is constructed to a quarter of an inch scale, and its weight expressed in ounces; then to the constant logarithm 0.4893556, add the logarithm of the weight of the model in ounces, and the sum will be the logarithm of the weight of the ship in tons.

Again, the model is to be loaded until the surface of the water coincides with the load water line. Now the model being weighed, the weight of the ship is to be found by the preceding rule: then the difference between the weights of the ship when light and loaded is the tonnage required.

Tonnage of a ship.

It will also be worth while to add the following exact rule of Mr Parkins, who was many years foreman of the shipwrights in Chatham dockyard.

1. *For Men of War.*

Take the length of the gun-deck from the rabbet of the stem to the rabbet of the stern-post. $\frac{23}{24}$ of this is to be assumed as the *length for tonnage*, = L.

Take the extreme breadth from outside to outside of the plank; add this to the length, and take $\frac{1}{23}$ of the sum; call this the *depth for tonnage*, = D.

Set up this height from the limber strake, and at that height take a breadth also from outside to outside of plank in the timber when the extreme breadth is found, and another breadth in the middle between that and the limber strake; add together the extreme breadth and these two breadths, and take $\frac{1}{3}$ of the sum for the breadth for tonnage, = B.

Multiply L, D, and B together, and divide by 49. The quotient is the burthen in tons.

The following proof may be given of the accuracy of this rule. Column 1. is the tonnage or burthen by the king's measurement; col. 2. is the tonnage by this rule; and, col. 3. is the weight actually received on board these ships at Blackstakes:

Victory	100 guns.	2162	1839	1840
London	90	1845	1575	1677
Arrogant	74	1614	1308	1314
Diadem	64	1369	1141	965
Adamant	50	1044	870	886
Dolphin	44	879	737	758
Amphion	32	667	554	549
Daphne	20	429	329	374

2. *For Ships of Burthen.*

Take the length of the lower deck from the rabbet of the stem to the rabbet of the stern-post; then $\frac{31}{32}$ of this is the length for tonnage, = L.

Add the length of the lower deck to the extreme breadth from outside to outside of plank; and take $\frac{3}{55}$ of the sum for the depth for tonnage, = D.

Set up that depth from the limber strake, and at this height take a breadth from outside to outside. Take another at $\frac{2}{3}$ of this height, and another at $\frac{1}{3}$ of the height. Add the extreme breadth and these three breadths, and take the 4th of the sum for the breadth for tonnage, = B.

Multiply L, D, and B, and divide by $36\frac{2}{3}$. The quotient is the burthen in tons.

This rule rests on the authority of many such trials, as the following:

	King's Measm.	Rule.	Actually recd. on bd.
Northington Indiaman	676	1053	1064
Granby Indiaman	786	1179	1179
Union coallier	193	266	289
Another coallier	182	254	277

CHAP. X. *Of the Scale of Solidity.*

Scale of Solidity.

By this scale the quantity of water displaced by the bottom of the ship, for which it is constructed, answering to a given draught of water is easily obtained; and also the additional weight necessary to bring her down to the load water line.

In order to construct this scale for a given ship, it is necessary to calculate the quantity of water displaced by the keel, and by that part of the bottom below each water line in the draught. Since the areas of the several water lines are already computed for the eighty gun ship laid down in Plates CCCCLX. and CCCCLXI. the contents of these parts may hence be easily found for that ship, and are as follow.

Draught of water.			*Water displaced in* Cubic feet.	tons.	lbs.
Keel and false keel	2 f.	3 in.	660.9	21	1855
Dist. bet. keel and 5th w. line	4	1	$8583.1\frac{1}{4}$	283	1233
Sum	6	4	$9243.10\frac{1}{4}$	305	848
Dist. 5th and 4th w. line	4	1	$18657.8\frac{11}{48}$	616	828
Sum	10	5	$27901.7\frac{47}{48}$	921	1676
Dist. 4th and 3d w. line	4	1	$23574.6\frac{17}{48}$	778	1795
Sum	14	6	$51476\ 2\frac{1}{4}$	1700	1231
Dist. 3d and 2d w. line	4	1	$27812.1\frac{3}{24}$	918	1775
Sum	18	7	$79288.3\frac{21}{24}$	2619	766
Dist. 2d and 1st w. line	4	1	$31285.7\frac{19}{24}$	1033	1218
Sum	22	8	$110573.11\frac{1}{3}$	3652	1984

Construct any convenient scale of equal parts to represent tons, as scale n° 1. and another to represent feet, as n° 2.

Plate CCCCLXII. 60 Construction of the scale of solidity for the ship of eighty guns.

Draw the line AB (fig. 36.) limited at A, but produced indefinitely towards B. Make AC equal to the depth of the keel, 2 feet 3 inches from scale n° 2, and through C draw a line parallel to AB, which will represent the upper edge of the keel; upon which set off C *c* equal to 21 tons 1855 lbs, taken from scale n° 1. Again, make AD equal to the distance between the lower edge of the keel and the fifth water line, namely, 6 feet 4 inches, and a line drawn through D parallel to AB will be the representation of the lower water line; and make D *b* equal to 305 tons 848 lbs, the corresponding tonnage. In like manner draw the other water lines, and lay off the corresponding tonnages accordingly: then through the points A, *c*, *b*, *e*, *f*, *g*, *h*, draw the curve A *c b e f g h*. Through *h* draw *h* B perpendicular to AB, and it will be the greatest limit of the quantity of water expressed in tons displaced by the bottom of the ship, or that when she is brought down to the load water line. And since the ship displaces 1788 tons at her light water mark, take therefore that quantity from the scale n° 1, which being laid upon AB from A to K, and KL drawn perpendicular to AB, will be the representation of the light water line for tonnage. Hence the scale will be completed.

Let

Scale of Solidity.

61

Uſe of the above ſcale.

Let it now be required to find the number of cubic feet diſplaced when the draught of water is 17 feet, and the number of additional tons neceſſary to bring her down to the load water mark.

Take the given draught of water 17 feet from the ſcale n° 2, which laid from it will reach to I; through which draw the line IMN parallel to AB, and interſecting the curve in AC; then the diſtance IM applied to the ſcale n° 1. will meaſure about 2248 tons, the diſplacement anſwerable to that draught of water; and MN applied to the ſame ſcale will meaſure about 1405 tons, the additional weight neceſſary to bring her down to the load water mark. Alſo the neareſt diſtance between M and the line KL will meaſure about 460 tons, the weight already on board.

It will conduce very much to facilitate this operation to divide KB into a ſcale of tons taken from the ſcale n° 1, beginning at B, and alſo *b* L, beginning at *b*. Then when the draught of water is taken from the ſcale n° 2, and laid from it to I, as in the former example; and IMN drawn parallel to AB, and interſecting the curve in M. Now through M draw a line perpendicular to AB, and it will meet KB in a point repreſenting the number of tons aboard, and alſo *b* L in a point denoting the additional weight neceſſary to load her.

Again, if the weight on board be given, the correſponding draught of water is obtained as follows.

Find the given number of tons in the ſcale KB, through which draw a line perpendicular to AB; then through the point of interſection of this line with the curve draw another line parallel to AB. Now the diſtance between A and the point where the parallel interſected AH being applied to the ſcale n° 2, will give the draught of water required.

Any other caſe to which this ſcale may be applied will be obvious.

Book II. *Containing the Properties of Ships, &c.*

Chap. I. *Of the Equilibrium of Ships.*

See Hydroſtatics.

Since the preſſure of fluids is equal in every direction, the bottom of a ſhip is therefore acted upon by the fluid in which it is immerſed; which preſſure, for any given portion of ſurface, is equal to the product of that portion by the depth and denſity of the fluid: or it is equal to the weight of a column of the fluid whoſe baſe is the given ſurface, and the altitude equal to the diſtance between the ſurface of the fluid and the centre of gravity of the ſurface preſſed. Hence a floating body is in equilibrio between two forces, namely, its gravity and the vertical preſſure of the fluid; the horizontal preſſure being deſtroyed.

Plate CCCCLXIV.

Let ABC (fig. 49.) be any body immerſed in a fluid whoſe line of floatation is GH: hence the preſſure of the fluid is exerted on every portion of the ſurface of the immerſed part AFCH. Let EF, CD be any two ſmall portions contained between the lines ED, FC, parallel to each other, and to the line of floatation GH; then the preſſure exerted upon EF is expreſſed by EF × IK, IK being the depth of EF or CD; the denſity of the fluid being ſuppoſed equal to 1. In like manner the preſſure upon CD is equal to CD × IK. Now ſince the preſſure is in a direction perpendicular to the ſurface, draw therefore the line EL, perpendicular to EF, and DM perpendicular to DC, and make each equal to the depth IK, below the ſurface. Now the effect or preſſure of the fluid upon EF will be expreſſed by EF × EL, and that upon CD by CD × DM. Complete the parallelograms ON, QS, and the preſſure in the direction EL, is reſolved into EN, EO, the firſt in a horizontal, and the ſecond in a vertical direction. In like manner, the preſſure in the direction DM is reſolved into the preſſures DS, DQ. Hence the joint effect of the preſſures in the horizontal and vertical directions, namely, EF × EN, and EF × EO, will be equal to EF × EL: For the ſame reaſon, CD × DP + CD × DQ = CD × DM. But the parts of the preſſures in a horizontal direction EF × EN, and CD × DP, are equal. For, becauſe of the ſimilar triangles ENL, ERF, and DPM, DSC, we have $\frac{EL}{EN} = \frac{EF}{FR}$ and $\frac{DM}{DP} = \frac{DC}{CS}$: Hence DM × CS = DP × DC, and EL × FR = EN × EF. Now ſince EL = DM, and FR = CS, therefore EL × FR = DM × CS = DP × DC = EN × EF. Hence, ſince EF × EN = DP × CD, the effects of the preſſures in a horizontal direction are therefore equal and contrary, and conſequently deſtroy each other.

Equilibrium of Ships.

The preſſure in a vertical direction is repreſented by EO × EF, DQ × DC, &c. which, becauſe of the ſimilar triangles EOL, ERF, and DLM, DSC, become EL × ER, DM × DS, &c. or IK × ER, IK × DS, &c. By applying the ſame reaſoning to every other portion of the ſurface of the immerſed part of the body, it is hence evident that the ſum of the vertical preſſures is equal to the ſum of the correſponding diſplaced columns of the fluid. 62

Hence a floating body is preſſed upwards by a force equal to the weight of the quantity of water diſplaced; and ſince there is an equilibrium between this force and the weight of the body, therefore the weight of a floating body is equal to the weight of the diſplaced fluid (K). Hence alſo the centre of gravity of the body and the centre of gravity of the diſplaced fluid are in the ſame vertical, otherwiſe the body would not be at reſt.

The weight of a ſhip equal to that of the quantity of water diſplaced.

63

And the centre of gravity of both are in the ſame vertical.

Chap. II. *Upon the Efforts of the Water to bend a Veſſel.*

Theorie complette, &c. par Euler, tranſlated by Watſon.

When it is ſaid that the preſſure of the water upon the immerſed part of a veſſel counterbalances its weight, it is ſuppoſed that the different parts of the veſſel are ſo cloſely connected together, that the forces which act upon its ſurface are not capable of producing any change. For we may eaſily conceive, if the connection of the parts were not ſufficiently ſtrong, the veſſel would run the riſk either of being broken in pieces, or of ſuffering ſome alteration in its figure.

The veſſel is in a ſituation ſimilar to that of a rod AB (fig. 50.), which being acted upon by the forces A*a*, C*c*, D*d*, B*b*, may be maintained in equilibrio, pro-

(K) Upon this principle the weight and tonnage of the 80 gun ſhip laid down was calculated.

Efforts of the Water to bend a Vessel.

provided it has a sufficient degree of stiffness: but as soon as it begins to give way, it is evident it must bend in a convex manner, since its middle would obey the forces C c and D d, while its extremities would be actually drawn downwards by the forces A a and B b.

The vessel is generally found in such a situation; and since similar efforts continually act whilst the vessel is immersed in the water, it happens but too often that the keel experiences the bad effect of a strain. It is therefore very important to inquire into the true cause of this accident.

For this purpose, let us conceive the vessel to be divided into two parts by a transverse section through the vertical axis of the vessel, in which both the centre of gravity G (fig. 51.) of the whole vessel and that of the immersed part are situated: so that one of them will represent the head part, and the other that of the stern, each of which will be considered separately. Let g be the centre of gravity of the entire weight of the first, and o that of the immersed part corresponding. In like manner, let γ be the centre of gravity of the whole after part, and ω that of its immediate portion.

Plate CCCCLXV.

Now it is plain, that the head will be acted upon by the two forces $g\,m$ and $o\,n$, of which the first will press it down, and the latter push it up. In the same manner, the stern will be pressed down by the force, $\gamma\mu$, and pushed up by the force $\omega\,\nu$. But these four forces will maintain themselves in equilibrium, as well as the total forces reunited in the points G and O, which are equivalent to them; but whilst neither the forces before nor those behind fall in the same direction, the vessel will evidently sustain efforts tending to bend the keel upwards, if the two points $o\,\omega$ are nearer the middle than the two other forces $g\,m$ and $\gamma\,\mu$. A contrary effect would happen if the points o and ω were more distant from the middle than the points g and γ.

64 The cause of a ship's hogging,

65 And sagging.

But the first of these two causes usually takes place almost in all vessels, since they have a greater breadth towards the middle, and become more and more narrow towards the extremities; whilst the weight of the vessel is in proportion much more considerable towards the extremities than at the middle. From whence we see, that the greater this difference becomes, the more also will the vessel be subject to the forces which tend to bend its keel upwards. It is therefore from thence that we must judge how much strength it is necessary to give to this part of the vessel, in order to avoid such a consequence.

If other circumstances would permit either to load the vessel more in the middle, or to give to the part immersed a greater capacity towards the head and stern, such an effect would no longer be apprehended. But the destination of most vessels is entirely opposite to such an arrangement: by which means we are obliged to strengthen the keel as much as may be necessary, in order to avoid such a disaster.

We shall conclude this chapter with the following practical observations on the hogging and sagging of ships by Mr Hutchinson of Liverpool:

Practical Seamanship, p. 13.

"When ships with long floors happen to be laid adry upon mud or sand, which makes a solid resistance against the long straight floors amidships, in comparison with the two sharp ends, the entrance and run meet with little support; but are pressed down lower than the flat of the floor, and in proportion hogs the ship amidships; which is too well known from experience to occasion many total losses, or do so much damage by hogging them, as to require a vast deal of trouble and expence to save and repair them, so as to get the hog taken out and brought to their proper sheer again: and to do this the more effectually, the owners have often been induced to go to the expence of lengthening them; and by the common method, in proportion as they add to the burden of these ships, by lengthening their too long straight floors in their main bodies amidships, so much do they add to their general weakness to bear hardships either on the ground or afloat; for the scantling of their old timber and plank is not proportionable to bear the additional burden that is added to them.

Efforts of the Water to bend a Vessel.

"But defects of this kind are best proved from real and incontestable facts in common practice. At the very time I was writing upon this subject, I was called upon for my advice by the commander of one of these strong, long, straight floored ships, who was in much trouble and distraction of mind for the damage his ship had taken by the pilot laying her on a hard, gentle sloping sand, at the outside of our docks at Liverpool, where it is common for ships that will take the ground to lie for a tide, when it proves too late to get into our wet docks. After recommending a proper ship carpenter, I went to the ship, which lay with only a small keel, yet was greatly hogged, and the butts of her upper works strained greatly on the lee-side; and the seams of her bottom, at the lower futtock heads, vastly opened on the weather side: all which strained parts were agreed upon not to be caulked, but filled with tallow, putty, or clay, &c. with raw bullocks hides, or canvas nailed with battons or her bottom, which prevented her sinking with the flow of the tide, without hindering the pressure of water from righting and closing the seams again as she floated, so as to enable them to keep her free with pumping. The vessel, like many other instances of ships of this construction that I have known, was saved and repaired at a very great expence in our dry repairing docks. And that their bottoms not only hog upwards, but sag (or curve) downwards, to dangerous and fatal degrees, according to the strain or pressure that prevails upon them, will be proved from the following facts:

"It has been long known from experience, that when ships load deep with very heavy cargoes or materials that are stowed too low, is makes them so very laboursome at sea, when the waves run high, as to roll away their masts; and after that misfortune causes them to labour and roll the more, so as to endanger their working and straining themselves to pieces: to prevent which, it has been long a common practice to leave a great part of their fore and after holds empty, and to stow them as high as possible in the main body at midships, which causes the bottoms of these long straight floored ships to sag downwards, in proportion as the weight of the cargo stowed there exceeds the pressure of the water upwards, so much so as to make them dangerously and fatally leaky.

"I have known many instances of those strong ships of 500 or 600 tons burdens built with long straight floors, on the east coast of England, for the coal and timber trade, come loaded with timber from the Baltic

to

Efforts of the Water to bend a Vessel.

to Liverpool, where they commonly load deep with rock salt, which is too heavy to fill their holds, so that for the above reasons they stowed it high amidships, and left large empty spaces in their fore and after holds, which caused their long straight floors to sag downwards, so much as to make their hold staunchions amid ships, at the main hatchway, settle from the beams three of four inches, and their mainmasts settle so much as to oblige them to set up the main rigging when rolling hard at sea, to prevent, the masts being rolled away; and they were rendered so leaky as to be obliged to return to Liverpool to get their leaks stopped at great expence. And in order to save the time and expence in discharging them, endeavours were made to find out and stop their leaks, by laying them ashore dry on a level sand; but without effect: for though their bottoms were thus sagged down by their cargoes when afloat, yet when they came a-dry upon the sand, some of their bottoms hogged upwards so much as to raise their mainmasts and pumps so high as to tear their coats from their decks; that they have been obliged to discharge their cargoes, and give them a repair in the repairing dock, and in some to double their bottoms, to enable them to carry their cargoes with safety, stowed in this manner. From this cause I have known one of these strong ships to founder.

"Among the many instances of ships that have been distressed by carrying cargoes of lead, one sailed from hence bound to Marseilles, which was soon obliged to put back again in great distress, having had four feet water in the hold, by the commander's account, owing to the ship's bottom sagging down to such a degree as made the hold staunchions settle six inches from the lower deck beams amidships; yet it is common with these long straight floored ships, when these heavy cargoes are discharged that makes their bottom sag down, then to hog upwards: so that when they are put into a dry repairing dock, with empty holds, upon straight blocks, they commonly either split the blocks close fore and aft, or damage their keels there, by the whole weight of the ship lying upon them, when none lies upon the blocks under the flat of their floors amidships, that being hogged upwards; which was the case of this ship's bottom; though sagged downwards six inches by her cargo, it was now found hogged so much that her keel did not touch the blocks amidships, which occasioned so much damage to the after part of the keel, as to oblige them to repair it; which is commonly the case with these ships, and therefore deserving particular notice."

In order to prevent these defects in ships, "they should all be built with their floors or bottoms lengthwise, to form an arch with the projecting part downwards, which will naturally not only contribute greatly to prevent their taking damage by their bottoms hogging and straining upwards, either aground or afloat, as has been mentioned, but will, among other advantages, be a help to their sailing, steering, staying, and waring."

Chap. III. *Of the Stability of Ships.*

When a vessel receives an impulse or pressure in a horizontal direction, so as to be inclined in a small degree, the vessel will then either regain its former position as the pressure is taken off, and is in this case said to be possessed of stability; or it will continue in its inclined state; or, lastly, the inclination will increase until the vessel is overturned. With regard to the first case, is is evident that a sufficient degree of stability is necessary in order to sustain the efforts of the wind; but neither of the other two cases must be permitted to have place in vessels.

Stability of Ships.

Let CED (fig. 52.) be the section of a ship passing through its centre of gravity, and perpendicular to the sheer and floor plans; which let be in equilibrium in a fluid; AB being the water line, G the centre of gravity of the whole body, and g that of the immersed part AEB. Let the body receive now a very small inclination, so that aEb becomes the immersed part, and γ its centre of gravity. From γ draw γ M perpendicular to ab, and meeting g G, produced, if necessary, in M. If, then, the point M thus found is higher than G the centre of gravity of the whole body, the body will, in this case, return to its former position, the pressure being taken off. If the point M coincides with G, the vessel will remain in its inclined state; but if M be below G, the inclination of the vessel will continually increase until it is entirely overset.

The point of intersection M is called the *metacenter*, and is the limit of the altitude of the centre of gravity of the whole vessel. Whence it is evident, from what has already been said, that the stability of the vessel increases with the altitude of the metacenter above the centre of gravity: But when the metacenter coincides with the centre of gravity, the vessel has no tendency whatever to move out of the situation into which it may be put. Thus, if the vessel be inclined either to the right or left side, it will remain in that position until a new force is impressed upon it: in this case, therefore, the vessel would not be able to carry sail, and is hence unfit for the purposes of navigation. If the metacenter is below the common centre of gravity, the vessel will instantly overset.

As the determination of the metacenter is of the utmost importance in the construction of ships, it is therefore thought necessary to illustrate this subject more particularly.

Let AEB (fig. 52.) be a section of a ship perpendicular to the keel, and also to the plane of elevation, and passing through the centre of gravity of the ship, and also through the centre of gravity of the immersed part, which let be g.

Now let the ship be supposed to receive a very small inclination, so that the line of floatation is a, b, and γ the centre of gravity of the immersed part a E b. From γ draw γ M perpendicular to ab, and intersecting GM in M, the metacenter, as before. Hence the pressure of the water will be in the direction γ M.

In order to determine the point M, the metacenter, the position of γ with respect to the lines AB and g G, must be previously ascertained. For this purpose, let the ship be supposed to be divided into a great number of sections by planes, perpendicular to the keel, and parallel to each other, and to that formerly drawn, these planes being supposed equidistant. Let AEB (fig. 53.) be one of these sections, g the centre of gravity of the immersed part before inclination, and γ the centre of gravity of the immersed part when the ship is in its inclined state; the distance $g\ \gamma$ between the two centres of of gravity in each ſection is to be found. Let AB be the line of the floatation of the ſhip when in an upright ſtate, and $a\,b$ the water line when inclined. Then, becauſe the weight of the ſhip remains the ſame, the quantity of water diſplaced will alſo be the ſame in both caſes, and therefore $AEB = a\,E\,b$, each ſuſtaining the ſame part of the whole weight of the ſhip. From each of theſe take the part $AE\,b$, which is common to both, and the remainders $AO\,a$, $BO\,b$ will be equal; and which, becauſe the inclination is ſuppoſed very ſmall, may be conſidered as rectilineal triangles, and the point O the middle of AB.

Now, let H, I, K, be the centres of gravity of the ſpaces $AO\,a$, $AE\,b$, and $BO\,b$, reſpectively. From theſe points draw the lines $H\,b$, $I\,i$, and $K\,k$, perpendicular to AB, and let IL be drawn perpendicular to EO. Now to aſcertain the diſtance $\gamma\,q$ of the centre of gravity γ of the part $a\,E\,b$ from the line AB, the momentum of $a\,E\,b$ with reſpect to this line muſt be put equal to the difference of the momentums of the parts $AE\,b$, $AO\,a$, which are upon different ſides of AB †. Hence $a\,E\,b \times \gamma\,q$, or $AEB \times \gamma\,q = AE\,b \times I\,i - AO\,a \times H\,b$. But ſince g is the common centre of gravity of the two parts $AE\,b$, $BO\,b$, we have therefore $AEB \times g\,O = AE\,b \times I\,i + BO\,b \times K\,k$. Hence by expunging the term $AE\,b \times I\,i$ from each of theſe equations, and comparing them, we obtain $AEB \times \gamma\,q = AEB \times g\,O - BO\,b \times K\,k - AO\,a \times H\,b$.

† Bezout's Mechanique, art. 263.

Now, ſince the triangles $AO\,a$, $BO\,b$, are ſuppoſed infinitely ſmall, their momentums or products, by the infinitely little lines $H\,b$, $K\,k$, will alſo be infinitely ſmall with reſpect to $AEB \times g\,O$; which therefore being rejected, the former equation becomes $AEB \times \gamma\,q = AEB \times g\,O$, and hence $\gamma\,q = g\,O$. Whence the centres of gravity γ, g, being at equal diſtances below AB, the infinitely little line $\gamma\,g$ is therefore perpendicular to EO. For the ſame reaſon $g\,\gamma$, fig. 52. may be conſidered as an arch of a circle whoſe centre is M.

To determine the value of $g\,\gamma$, the momentum of $a\,E\,b$ with reſpect to EO muſt be taken, for the ſame reaſon as before, and put equal to the momentums of the two parts $AO\,a$, $AE\,b$; and we ſhall then have $a\,E\,b \times g\,\gamma$, or $AEB \times g\,\gamma = AEB \times IL + AO\,a \times O\,b$. But ſince g is the common centre of gravity of the two ſpaces $AE\,b$, $BO\,b$, we ſhall have $AE\,b \times IL - BO\,b \times O\,k = O$, or $AE\,b \times IL = BO\,b \times O\,k$. Hence $AEB \times g\,\gamma = BO\,b \times O\,k + AO\,a \times O\,b = 2\,BO\,b \times O\,k$; becauſe the two triangles $AO\,a$, $BO\,b$ are equal, and that the diſtances $O\,k$, $O\,b$, are alſo evidently equal.

Let x be the thickneſs of the ſection repreſented by ABC. Then the momentum of this ſection will be $2\,BO\,b \times x \times O\,k$, which equation will alſo ſerve for each particular ſection.

Now let $\int$ repreſent the ſum of the momentums of all the ſections. Hence $\int, AEB \times x \times g\,\gamma = \int, 2.\ BO\,b \times x \times O\,k$. Now the firſt member being the ſum of the momentums of each ſection, in proportion to a plane paſſing through the keel, ought therefore to be equal to the ſum of all the ſections, or to the volume of the immerſed part of the bottom multiplied by the diſtance $g\,\gamma$. Hence V repreſenting the volume, we ſhall have $V \times g\,\gamma = \int, 2\,BO\,b \times x\,O\,k$.

In order to determine the value of the ſecond number of this equation, it may be remarked, that when the ſhip is inclined, the original plane of floatation CBPQ (fig. 54.) becomes $C\,b\,p\,Q$. Now the triangles $NI\,n$, $BO\,b$, being the ſame as thoſe in figures 52. and 53.; and as each of theſe triangles have one angle equal, they may, upon account of their infinite ſmallneſs, be conſidered as ſimilar; and hence $B\,O\,b : NI\,n :: \overline{OB}^2 : \overline{IN}^2$; whence $BO\,b = \dfrac{\overline{OB}^2}{\overline{IN}^2} \times N\,I\,n$. Moreover, we have (fig. 53.) $O\,k = \frac{2}{3}\,O\,B$, for the points K and k may be conſidered as equidiſtant from the point O: whence $BO\,b \times O\,k = \dfrac{\frac{2}{3}\overline{OB}|^3}{\overline{IN}^2} \times NI\,n$.

Hence $V \times g\,\gamma = \int, \dfrac{\frac{3}{4}\overline{OB}^3}{\overline{IN}^2} \times x \times NI\,n$. From this equation the value of $g\,\gamma$ is obtained.

To find the altitude g M (fig. 55.) of the metacenter above the centre of gravity of the immerſed part of the bottom, let the arc NS be deſcribed from the centre I with the radius IN; then $NI\,n = \dfrac{IN \times NS}{2}$. Now ſince the two ſtraight lines $\gamma\,M$, $g\,M$ are perpendicular to $a\,n$ and AN reſpectively, the angles M and $NI\,n$ are therefore equal: and the infinitely little portion $g\,\gamma$, which is perpendicular to $g\,M$, may be conſidered as an arch deſcribed from the centre M. Hence the two ſectors NIS, $g\,M\,\gamma$ are ſimilar; and therefore $g\,M : g\,\gamma :: IN : NS$. Hence $NS = \dfrac{IN \times g\,\gamma}{g\,M}$; and conſequently $NI\,n = \dfrac{\overline{IN}^2 \times g\,\gamma}{2\,g\,M}$. Now this being ſubſtituted in the former equation, and reduced, we have $V \times g\,\gamma = \int \dfrac{\frac{2}{3}\,\overline{OB}^3 \times x \times g\,\gamma}{g\,M}$. But ſince g M and $g\,\gamma$ are the ſame, whatever ſection may be under conſideration, the equation may therefore be expreſſed thus, $V \times g\,\gamma = \dfrac{\frac{2}{3}\,g\,\gamma}{g\,M} \cdot \int, \overline{OB}^3 \times x$. Hence $g\,M = \dfrac{\frac{2}{3}\int, \overline{OB}^3 \times x}{V}$. Let $y = OB$, and the equation becomes $g\,M = \dfrac{\frac{2}{3}\int, y^3\,x}{V}$. Whence to have the altitude of the metacenter above the centre of gravity of the immerſed part of the bottom, the length of the ſection at the water-line muſt be divided by lines perpendicular to the middle line of this ſection into a great number of equal parts, ſo that the portion of the curve contained between any two adjacent perpendiculars may be conſidered as a ſtraight line. Then the ſum of the cubes of the half perpendiculars or ordinates is to be multiplied by the diſtance between the perpendiculars, and two thirds of the product is to be divided by the volume of the immerſed part of the bottom of the ſhip.

It is hence evident, that while the ſector at the water line is the ſame, and the volume of the immerſed part of the bottom remains alſo the ſame, the altitude of the metacenter will remain the ſame, whatever may be the figure of the bottom.

Chap. IV. *Of the Centre of Gravity of the immerſed Part of the Bottom of a Ship.*

The centre of gravity * of a ſhip, ſuppoſed homogenous, and in an upright poſition in the water, is in a ver-

* See Mechanics.

Centre of Gravity.

vertical ſection paſſing through the keel, and dividing the ſhip into two equal and ſimilar parts, at a certain diſtance from the ſtern, and altitude above the heel.

In order to determine the centre of gravity of the immerſed part of a ſhip's bottom, we muſt begin with determining the centre of gravity of a ſection of the ſhip parallel to the keel, as ANDFPB (fig. 56.), bounded by the parallel lines A B, DF, and by the equal and ſimilar curves AND, BPF.

66 Diſtance of the centre of gravity from the ſtem or ſtern.

If the equation of this curve were known, its centre of gravity would be eaſily found: but as this is not the caſe, let therefore the line C E be drawn through the middle C, E, of the lines AB, DF, and let this line C E be divided into ſo great a number of equal parts by the prependiculars T H, KM, &c. that the arches of the curves contained between the extremities of any two adjacent perpendiculars may be conſidered as ſtraight lines. The momentums of the trapeziums DTHF, TKMH, &c. relative to the point E, are then to be found, and the ſum of theſe momentums is to be divided by the ſum of the trapeziums, that is, by the ſurface ANDFPB.

The diſtance of the centre of gravity of the trapezium THED from the point E is $= \frac{\frac{1}{3}\text{IE} \times (\text{DF}+2\text{TH})}{\text{DF}+\text{TH}}$ ‡.

For the ſame reaſon, and becauſe of the equalty of the lines IE, IL. the diſtance of the centre of gravity of the trapezium TKMH from the ſame point E will be

$$\frac{\frac{1}{3}\text{IE} \times (\text{TH}+2\text{KM})}{\text{TH}+\text{KM}}+\text{IE}, \text{or} = \frac{\frac{1}{3}\text{IE} \times (4\text{TH}+5\text{KM})}{\text{TH}+\text{KM}}$$

In like manner the diſtance of the centre of gravity of the trapezium NKMP from the point E will be

$$\frac{\frac{1}{3}\text{IE} \times (\text{KM}+2\text{NP})}{\text{KM}+\text{NP}}+2\,\text{IE}, \text{or} \frac{\frac{1}{3}\text{IE} \times (7\text{KM}+8\text{NP})}{\text{KM}+\text{NP}},$$

&c.

‡ Bezout's Mechanique, art. 279.

Now, if each diſtance be multiplied by the ſurface of the correſponding trapezium, that is, by the product of half the ſum of the two oppoſite ſides of the trapezium into the common altitude IE, we ſhall have the momentums of theſe trapeziums, namely, $\frac{1}{6}\overline{\text{IE}}|^2 \times (\text{DF}+2\text{TH})$, $\frac{1}{6}\overline{\text{IE}}|^2 \times (4\text{TH}+5\text{KM})$ $\frac{1}{6}\overline{\text{IE}}|^2 \times (7\text{KM}+8\text{NP})$, &c. Hence the ſum of theſe momentums will be $\frac{1}{6}\overline{\text{IE}}|^2 \times (\text{DF}+6\text{TH}+12\text{KM}+18\text{NP}+24\text{QS}+14\text{AB})$. Whence it may be remarked that if the line C E be divided into a great number of equal parts, the factor or coefficient of the laſt term, which is here 14, will be $= 2+3(n-2)$ or $3n-4$, n being the number of perpendiculars. Thus the general expreſſion of the ſum of the momentums is reduced to $\overline{\text{IE}}|^2 \times (\frac{1}{6}\text{DF} + \text{TH} + 2\text{KM} + 3\text{NP} + 4\text{QS} +, \&c. - + \frac{3n-4}{6} \times \text{AB})$.

The area of the figure A N D F P B is equal to $\text{IE} \times (\frac{1}{2}\text{DF} + \text{TH} + \text{KM} + \text{NP} +, \&c. \ldots + \frac{1}{2}\text{AB})$; hence the diſtance E G of the centre of gravity G from one of the extreme ordinates DF is equal to

67 Rule for the diſtance of the centre of gravity from one of the extreme ordinates.

$$\frac{\text{IE} \times (\frac{1}{6}\text{DF}+\text{TH}+2\text{KM}+3\text{NP}+, \&c. + \frac{3n-4}{6} \times \text{AB})}{\frac{1}{2}\text{DF}+\text{TH}+\text{KM}+\text{NP}+, \&c. + \frac{1}{2}\text{AB}}$$

Whence the following rule to find the diſtance of the centre of gravity G from one of the extreme ordinates DF. To the ſixth of the firſt ordinate add the ſixth of the laſt ordinate multiplied by three times the number of ordinates minus four; then the ſecond ordinate, twice the third, three times the fourth, &c. the ſum will be the firſt term. Then to half the ſum of the extreme ordinates add all the intermediate ones, and the ſum will be a ſecond term. Now the firſt term divided by the ſecond, and the quotient multiplied by the interval between two adjacent perpendiculars, will be the diſtance ſought.

Thus, let there be ſeven perpendiculars, whoſe values are 18, 23, 28, 30, 30, 21, 0, feet reſpectively, and the common interval between theſe perpendiculars 20 feet. Now the ſixth of the firſt term 18 is 3; and as the laſt term is 0, therefore to 3 add 23, twice 28 or 56, thrice 30 or 90, four times 30 or 120, five times 21 or 105; and the ſum is 397. Then to the half of 18+0, or 9, add the intermediate ordinates, and the ſum will be 141. Now $\frac{397 \times 20}{141}$, or $\frac{7940}{141}$, = 59 feet 4 inches nearly, the diſtance of the centre of gravity from the firſt ordinate.

Now, when the centre of gravity of any ſection is determined, it is eaſy from thence to find the centre of gravity of the ſolid, and conſequently that of the bottom of a ſhip.

68 Height of the centre of gravity above the keel.

The next ſtep is to find the height of the centre of gravity of the bottom above the keel. For this purpoſe the bottom muſt be imagined to be divided into ſections by planes parallel to the keel or water-line, (figs. 57, 58.) Then the ſolidity of each portion contained between two parallel planes will be equal to half the ſum of the two oppoſed ſurfaces multiplied by the diſtance between them; and its centre of gravity will be at the ſame altitude as that of the trapezium *a b c d*, (fig. 58.), which is in the vertical ſection paſſing through the keel. It is hence obvious, that the ſame rule as before is to be applied to find the altitude of the centre of gravity, with this difference only, that the word perpendicular or ordinate is to be changed into ſection. Hence the rule is, to the ſixth part of the loweſt ſection add the product of the ſixth part of the uppermoſt ſection by three times the number of ſections minus four; the ſecond ſection in aſcending twice the third, three times the fourth, &c. the ſum will be a firſt term. To half the ſum of upper and lower ſections add the intermediate ones, the ſum will be a ſecond term. Divide the firſt term by the ſecond, and the quotient multiplied by the diſtance between the ſections will give the altitude of the centre of gravity above the keel.

With regard to the centre of gravity of a ſhip, whether it is conſidered as loaded or light, the operation becomes more difficult. The momentum of every different part of the ſhip and cargo muſt be found ſeparately with reſpect to a horizontal and alſo a vertical plane. Now the ſums of theſe two momentums being divided by the weight of the ſhip, will give the altitude of the centre of gravity, and its diſtance from the vertical plane; and as this centre is in a vertical plane paſſing through the axis of the keel, its place is therefore determined. In the calculation of the momentums, it muſt be obſerved to multiply the weight, and not the magnitude of each piece, by the diſtance of its centre of gravity.

A more eaſy method of finding the centre of gravity of a ſhip is by a mechanical operation, as follows; Conſtruct a block

Centre of Gravity.

69
A mechanical method for ascertaining the centre of gravity of a ship.

a block of as tight wood as possible, exactly similar to the parts of the proposed draught or ship, by a scale of about one-fourth of an inch to a foot. The block is then to be suspended by a silk-thread or very fine line, placed in different situations until it is found to be in a state of equilibrium, and the centre of gravity will be pointed out. The block may be proved by fastening the line which suspends it to any point in the line joining the middles of the stem and post, and weights are to be suspended from the extremities of this middle line at the stem and post. If, then, the block be properly constructed, a plane passing through the line of suspension, and the other two lines, will also pass through the keel, stem, and post. Now, the block being suspended in this manner from any point in the middle line, a line is to be drawn on the block parallel to the line of suspension, so that the plane passing through these two lines may be perpendicular to the vertical plane of the ship in the direction of the keel. The line by which the block is suspended is then to be removed to some other convenient point in the middle line; and another line is to be drawn on the block parallel to the line suspending it, as before. Then the point of intersection of this line with the former will give the position of the centre of gravity on the block, which may now be laid down in the draught.

Chap. V. *Application of the preceding Rules to the Determination of the Centre of Gravity and the Height of the Metacenter above the Centre of Gravity of a Ship of 74 Guns.*

In fig. 59 are laid down the several sections in a horizontal direction, by planes parallel to the keel, and at equal distances from each other, each distance being 10 feet 0 inches 4 parts.

I. *Determination of the Centre of Gravity of the upper Horizontal Section.*

To find the distance of the centre of gravity of the plane $8\,g\,o\,G$ from the first ordinate $8\,g$.

Ordinates. Feet.	In.	P.	Double Ord. Feet.	In.	P.	1st Factors.	1st Products. Feet.	In.	P.	2d Factors.	2d Products. Feet.	In.	P.
14	9	0	29	6	0	$0\frac{1}{6}$	4	11	0	$0\frac{1}{2}$	14	9	0
17	1	6	34	3	0	1	34	3	0	1	34	3	0
18	9	0	37	6	0	2	75	0	0	1	37	6	0
19	10	0	39	8	0	3	119	0	0	1	39	8	0
20	7	6	41	3	0	4	165	0	0	1	41	3	0
21	1	9	42	3	6	5	211	5	6	1	42	3	6
21	6	3	43	0	6	6	258	3	0	1	43	0	6
21	7	9	43	3	6	7	303	0	6	1	43	3	6
21	7	9	43	3	6	8	346	4	0	1	43	3	6
21	7	6	43	3	0	9	389	3	0	1	43	3	0
21	4	0	42	8	0	10	426	8	0	1	42	8	0

291	1	3	582	2	6		3897	3	1		554	4	3

$$\text{Now } \frac{3897\ \ 3\ \ \frac{1}{3}}{554\ \ 4\ \ 3} \times 10\ \ 0\ \ 4 = \frac{3897 \cdot 25}{554 \cdot 25} \times 10.03 = 70.5.$$

	Feet.
Hence the distance of the centre of gravity of double the plane $8\,g\,o\,G$ from the first ordinate $8\,g$, is - - - -	70.5
Distance of this ordinate from the aft side of stern-post, - -	13.5
Distance of the centre of gravity from the aft side of post, - -	84.0
Distance of the centre of gravity of double the trapezium $A R g 8$ from its ordinate $A R$,	8.42
Distance of this ordinate from the aft side of the stern-post, - -	0.58
Distance of the centre of gravity of this plane from the aft side of the stern-post, -	9.0
Distance of the centre of gravity of double the trapezium $G o \gamma \gamma$ from its ordinate $G o$,	5.44
Distance of this ordinate from the aft side of the post, - -	153.78
Distance of the centre of gravity of this trapezium from the aft side of the post, -	159.22
Distance of the centre of gravity of the section of the stern-post from the aft part of the post,	0.29
Distance of the centre of gravity of the section of the stern from the aft side of the post, -	169.76

Centre of Gravity.

The areas of these several planes, calculated by the common method, will be as follow:

5558.90 for that of the plane, and its momentum 5558.9 × 84 =	466947.6000
199.13 for that of double the trapezium A R g 8, and its momentum 199.13 × 9 =	1792.1700
214.59 for that of double the trapezium G o γ γ, and its momentum 214.59 × 159.22 =	34167.0236
0.77 for that of the section of the stern-post, and its momentum 0.77 × 0.29 =	0.2233
0.77 for that of the section of the stem, and its momentum 0.77 × 169.76 =	130.7152
5974.16 Sum	503037.7321

Now $\frac{503037.7321}{5974.16} = 84.2$, the distance of the centre of gravity of the whole section from the aft side of the stern-post.

II. *Determination of the Centre of Gravity of the second Horizontal Section.*

To find the distance of the centre of gravity of double the plane 8 f n G from its first ordinate 8 f.

Ordinates.			Double Ord.			1. Factors.	1. Products.			2. Fact.	2. Products.		
Feet.	In.	Pts.	Feet.	In.	Pts.		Feet.	In.	Pts.		Feet.	In.	Pts.
11	2	3	22	4	6	$0\frac{1}{6}$	3	8	9	$0\frac{1}{2}$	11	2	3
15	3	0	30	6	0	1	30	6	0	1	30	6	0
17	5	0	34	10	0	2	69	8	0	1	34	10	0
18	10	3	37	8	6	3	113	1	6	1	37	8	6
19	10	6	39	9	0	4	159	0	0	1	39	9	0
20	7	0	41	2	0	5	205	10	0	1	41	2	0
21	0	3	42	0	6	6	252	3	0	1	42	0	6
21	2	0	42	4	0	7	296	4	0	1	42	4	0
21	0	6	42	1	0	8	336	8	0	1	42	1	0
20	10	9	41	9	6	9	376	1	6	1	41	9	6
20	6	6	41	1	0	10	410	10	0	1	41	1	0
19	10	0	39	8	0	11	436	4	0	1	39	8	0
18	6	0	37	0	0	12	444	0	0	1	37	0	0
15	9	6	31	7	0	13	410	7	0	1	31	7	0
11	2	9	22	5	6	$((3\times 15)-4)\times\frac{1}{6}$	153	5	6	$0\frac{1}{2}$	11	2	9
273	2	3	546	4	6		3698	5	3		523	11	6

Hence the distance of the centre of gravity of double the plane 8 f n G from its first ordinate 8 n is $\frac{3698\ \ 5\ \ 3}{523\ \ 11\ \ 6}$ × 10.0.4 = $\frac{3698.43}{523.95}$ × 10.03 = - - 70.79

Distance of this ordinate from the aft side of the stern-post - -	13.5
Distance of the centre of gravity of the above plane from the aft side of post -	84.29
Distance of the centre of gravity of double the trapezium A R f 8 from its ordinate A R -	8.38
Distance of this ordinate from aft side of stern-post - -	0.57
Distance of the centre of gravity of the trapezium from the aft side of the post -	8.95
Distance of the centre of gravity of the trapezium before the ordinate G n from that ordinate	5.74
Distance of that ordinate from the aft side of the post - -	153.78
Distance of the centre of gravity of the trapezium from the aft side of the post -	159.52
Distance of the centre of gravity of the section of the stern-post from the aft side of the post -	0.29
Distance of the centre of gravity of the section of the stem from the aft side of the post -	169.76

The areas of these several plans being calculated, will be as follow:

5255.22 for that of the plan 8 f n G, and its momentum 5255.22 × 84.29 = -	442962.4938
153.11 for that of double the trapezium A R f 8, and its momentum 153.11 × 8.95 = -	1370.3345
182.40 the area of the trapezium before, and its momentum 182.40 × 159.52 = -	29096.4480
0.77 the area of the section of the sternpost, and its momentum 0.77 × 0.29 = -	0.2233
0.77 the area of the section of the stem, and its momentum 0.77 × 169.76 = -	130.7152
5592.27 Sum	473560.2148

Centre of Gravity.

Now $\frac{473560.2148}{5952.27} = 84.68$, the diſtance of the centre of gravity of the whole ſection from the aft ſide of the ſtern-poſt.

Centre of Gravity.

III. *Determination of the Centre of Gravity of the third Horizontal Section.*

Diſtance of the centre of gravity of double the plan 8 *e m* G from its firſt ordinate 8 *e*.

Ordinates.			Double Ord.			1. Factors.	1. Products.			2. Fact.	2. Products.		
Feet.	In.	Pts.	Feet.	In.	Pts.		Feet.	In.	Pts.		Feet.	In.	Pts.
6	7	6	13	3	0	$0\frac{1}{6}$	2	2	6	$0\frac{1}{2}$	6	7	6
11	7	6	23	3	0	1	23	3	0	1	23	3	0
15	1	0	30	2	0	2	60	4	0	1	30	2	0
17	1	3	34	2	6	3	102	7	6	1	34	2	6
18	3	0	36	6	0	4	146	0	0	1	36	6	0
19	3	0	38	6	0	5	192	6	0	1	38	6	0
19	9	0	39	6	0	6	237	0	0	1	39	6	0
20	0	0	40	0	0	7	280	0	0	1	40	0	0
20	0	0	40	0	0	8	320	0	0	1	40	0	0
19	8	3	39	4	6	9	354	4	6	1	39	4	6
19	1	3	38	2	6	10	382	1	0	1	38	2	6
18	1	0	36	2	0	11	397	10	0	1	36	2	0
16	3	9	32	7	6	12	391	6	0	1	32	7	6
13	2	3	26	4	6	13	342	10	6	1	26	4	6
8	4	6	16	9	0	$((3\times15)-4)\times\frac{1}{6}=$	114	5	6	$0\frac{1}{2}$	8	4	6
242	5	3	484	10	6		3347	0	6		469	10	6

Hence the diſtance of the centre of gravity of double the plane 8 *e m* G from its firſt ordinate 8 *e* is $= \frac{3347\ \ 0\ \ 6}{469\ \ 10\ \ 6} \times 10\ \ 0\ \ 4 = \frac{3347.04}{469.87} \times 10.03 =$ - - 71.44

Diſtance of this ordinate from the aft ſide of the poſt - - 13.5

Hence the diſtance of the centre of gravity of this plan from the aft ſide of the poſt is - 84.94

Diſtance of the centre of gravity of double the trapezium AR *e* 8, from its ordinate AR, - 8.03

Diſtance of this ordinate from the aft ſide of the poſt - - 0.58

Diſtance of the centre of gravity of this trapezium from the aft ſide of the poſt - 8.61

Diſtance of the centre of gravity of the foremoſt trapezium from its ordinate G *m* - 5.19

Diſtance of this ordinate from the aft ſide of the poſt - - 153.78

Diſtance of the centre of gravity of this trapezium from the aft ſide of the poſt - 158.97

Diſtance of the centre of gravity of the ſection of the poſt from the aft ſide of the poſt - 0.29

Diſtance of the centre of gravity of the ſection of the ſtem from the aft ſide of the poſt - 169.76

The areas of theſe ſeveral planes will be found to be as follow:

4712.7961	for that of double the plan 8 *e m* G, and its momentum 4712.7961 × 84.94 =	400304.9007
93.84	the area of double the trapezium AR 3 *e* 88, and its momentum 93.84 × 8.61 =	807.9624
131.1	for the area of foremoſt trapezium, and its momentum 131.1 × 158.97 = -	20840.967
0.77	the area of the ſection of the poſt, and its momentum 0.77 × 0.29 = -	0.2233
0.77	the area of the ſection of the ſtem, and its momentum 0.77 × 169.76 = -	130.7152
4939.2761	Sum - -	422084.7706

Now $\frac{422084.7706}{4939.2761} = 85.45$, the diſtance of the centre of gravity of the whole ſection from the aft ſide of the poſt

IV. De-

IV. *Determination of the Centre of Gravity of the Fourth Horizontal Section.*

Distance of the centre of gravity of double the plan 8 *d l* G from its first ordinate 8 *d*.

Ordinates. Feet.	In.	Pts.	Double Ord. Feet.	In.	Pts.	1. Factors.	1. Products. Feet.	In.	Pts.	2. Fact.	2. Products. Feet.	In.	Pts.
3	3	6	6	7	0	$0\frac{1}{6}$	1	1	2	$0\frac{1}{2}$	3	3	6
7	9	0	15	6	0	1	15	6	0	1	15	6	0
11	11	0	23	10	0	2	47	8	0	1	23	10	0
14	8	9	29	5	6	3	88	4	6	1	29	5	6
16	3	0	32	6	0	4	130	0	0	1	32	6	0
17	4	9	34	9	6	5	173	11	5	1	34	9	6
18	1	9	36	3	6	6	217	9	0	1	36	3	6
18	5	0	36	10	0	7	257	10	0	1	36	10	0
18	3	0	36	6	0	8	292	0	0	1	36	6	0
17	10	9	35	9	6	9	322	1	6	1	35	9	6
17	2	6	34	5	0	10	340	10	0	1	34	5	0
15	10	3	31	8	6	11	348	9	6	1	31	8	6
13	6	0	27	0	0	12	324	0	0	1	27	0	0
9	7	6	19	3	0	13	250	3	0	1	19	3	0
5	4	9	10	9	6	$\left((3\times15)-4\right)\times\frac{1}{6}$	73	8	11	$0\frac{1}{2}$	5	4	9
205	7	6	411	3	0		2883	11	0		402	6	9

Hence the distance of the centre of gravity of double the plane 8 *d l* G from its first ordinate 8 *d*, is $=\frac{2883\ 11\ 0}{402\ 6\ 9}\times 10\ 0\ 4=\frac{2883.916}{402.56}\times 10.03=$ - - 71.85

Distance of this ordinate from the aft side of the post - - 13.5

Distance of the centre of gravity of the plan from the aft side of the post - 85.35

Distance of the centre of gravity of double the trapezium A R *d* 8 from its ordinate A R - 7.89
Distance of this ordinate from aft side of the post - - 0.58

Distance of the centre of gravity of the trapezium from the aft side of the post - 8.47

Distance of the centre of gravity of the foremost trapezium from its ordinate G *l* - 4.83
Distance of this ordinate from aft side of the post - - 153.78

Distance of the centre of gravity of the trapezium from the aft side of the post - 158.61

Distance of the centre of gravity of the section of the post from its aft side - - 0.29
Distance of the centre of gravity of the section of the stem from the aft side of the post - 169.76

The areas of these several plans being calculated, will be as follow:

4037.6768	for that of double the plan 8 *d l* G, and its momentum 4037.6768 × 85.35 =	344615.7149
51.12	the area of double the trapezium A R *d* 8, and its momentum 51.12 × 8.47 =	432.9864
79.16	the area of the foremost trapezium, and its momentum 79.16 × 158.61 = -	12555.5676
0.77	the area of the section of the post, and its momentum 0.77 × 0.29 = -	0.2233
0.77	the area of the section of the stem, and its momentum 0.77 × 169.76 = -	130.7152
4169.4968	Sum	357735.2074

Then $\frac{357735.2074}{4169.4968}=85.80$, the distance of the fourth horizontal section from the aft side of the stern-post.

V. *Determination of the Centre of Gravity of the fifth Horizontal Section.*

Distance of the centre of gravity of double the plan 8 *c k* G from its first ordinate 8 *c*.

	Ordinates. Feet.	In.	L.	Double Ord. Feet.	In.	L.	1. Factors.	1. Products. Feet.	In.	L.	2. Fact.	2. Products. Feet.	In	L.
	1	9	0	3	6	0	$0\frac{1}{6}$	0	7	0	$0\frac{1}{2}$	1	9	0
	4	6	0	9	0	0	1	9	0	0	1	9	0	0
Over	6	3	0	12	6	0		9	7	0		10	9	0

Centre of Gravity.

	Feet.	In.	L.	Feet.	In.	L.		Feet.	In.	L.		Feet.	In.	L.
Brought over	6	3	0	12	6	0		9	7	0		10	9	0
	8	3	0	16	6	0	2	33	0	0	1	16	6	0
	11	8	3	23	4	6	3	70	1	6	1	23	4	6
	13	10	3	27	8	6	4	110	10	0	1	27	8	6
	15	3	0	30	6	0	5	152	6	0	1	30	6	0
	16	0	3	32	0	6	6	192	3	0	1	32	0	6
	16	5	0	32	10	0	7	229	10	0	1	32	10	0
	16	3	0	32	6	0	8	260	0	0	1	32	6	0
	15	9	0	31	6	0	9	283	6	0	1	31	6	0
	14	10	0	29	8	0	10	296	8	0	1	29	8	0
	12	10	3	25	8	6	11	282	9	6	1	25	8	6
	9	8	9	19	5	6	12	233	6	0	1	19	5	6
	6	1	6	12	3	0	13	159	3	0	1	12	3	0
	3	3	0	6	6	0	$((3\times15)-4)\times\frac{1}{8}$	44	5	0	$0\frac{1}{2}$	3	3	0
	166	6	3	333	0	6		2358	3	0		328	0	6

Hence the distance of the centre of gravity of double the plane 8 *c k* G from its first ordinate is $\frac{2358\ 3\ 0}{328\ 0\ 6}$

$\times$ 10 0 4 $= \frac{2358.25}{328.04} \times 10.03 =$ - - 72.10

Distance of this ordinate from the aft side of the post - - 13.50

Distance of the centre of gravity of the plan from the aft side of the post - 85.60

Distance of the centre of gravity of double the trapezium AR *c* 8 from its ordinate AR - 7.42
Distance of this ordinate from aft side of post - - 0.58

Distance of the centre of gravity of trapezium from aft side of the post - 8 00

Distance of the centre of gravity of the foremost trapezium from its ordinate G *k* - 4.22
Distance of this ordinate from aft side of post - - 153.78

Distance of the centre of gravity of the foremost trapezium from the aft side of the post - 158.00

Distance of the centre of gravity of the section of the post from the aft side of post - 0.29
Distance of the centre of gravity of the section of the stem from the aft side of post - 169.76

The areas of these several planes being calculated, will be as follow.

3290.2412	for the area of double the plan 8 *c k* G, and its momentum $3290.2412 \times 85.6 =$	281644.6467
31.21	the area of double the trapezium AR *c* 8, and its momentum $31.21 \times 8 =$ -	249.68
42.43	the area of the foremost trapezium, and its momentum $42.43 \times 158 =$ -	6703.94
0.77	the area of the section of the post, and its momentum $0.77 \times 0.29 =$ -	0.2233
0.77	the area of the section of the stem, and its momentum $0.77 \times 169.76 =$	130.7152
3365.4212	Sum - -	288729.2052

Now $\frac{288729.2052}{3365.4212} = 85.79$, the distance of the centre of gravity of the whole section from the aft side of the stern.

VI. *Determination of the Centre of Gravity of the sixth Horizontal Section.*

Distance of the centre of gravity of double the plan 8 *b i* G from its first ordinate 8 *b*.

Ordinates.			Double Ord.			1st Factors.	1st Products.			2d Factors.	2d Products.		
Feet.	In.	L.	Feet.	In.	L.		Feet.	In.	L.		Feet.	In.	L.

Over 37	4	6	74	9	0		268	9	6		73	9	0

Centre of Gravity.

	Feet.	In.	L.	Feet.	In.	L.		Feet.	In.	L.		Feet.	In.	L.
Brought over	37	4	6	74	9	0		268	9	6		73	9	0
	13	3	0	26	6	0	6	159	0	0	1	26	6	0
	13	9	9	27	7	6	7	193	4	6	1	27	7	6
	13	7	0	27	2	0	8	217	4	0	1	27	2	0
	12	8	0	25	4	0	9	228	0	0	1	25	4	0
	10	6	6	21	1	0	10	210	10	0	1	21	1	0
	7	1	0	14	2	0	11	155	10	0	1	14	2	0
	4	7	3	9	2	6	12	110	6	0	1	9	2	6
	2	10	6	5	9	0	13	74	9	0	1	5	9	0
	1	6	9	3	1	6	$\times\left((3\times15)-4\right)\times\frac{1}{6}$	21	4	3	$0\frac{1}{2}$	1	6	9
	117	4	3	234	8	6		1639	9	3		232	1	9

Hence the diſtance of the centre of gravity of double the plane 8 *b v* G from its firſt ordinate 8 *b*, is $\frac{1639 \quad 9 \quad 3}{232 \quad 1 \quad 9}$

$\times 10 \quad 0 \quad 4 = \frac{1639 \cdot 77}{232 \cdot 14} \times 10.03 =$ - 70.84

Diſtance of this ordinate from aft ſide of poſt, - - 13.50

Hence the diſtance of the centre of gravity of the plan from the aft ſide of the poſt is - - 84.34

Diſtance of the centre of gravity of the trapezium AR *b* 8 from its ordinate AR - 6.88

Diſtance of this ordinate from the aft ſide of the poſt - - 0.58

Diſtance of the centre of gravity of the trapezium from the aft ſide of the poſt, - 7.46

Diſtance ot the centre of gravity of the foremoſt trapezium from the ordinate G *i* - 2.92

Diſtance of this ordinate from the aft ſide of poſt - - 153.78

Diſtance of the centre of gravity of this trapezium from the aft ſide of the poſt - 156.70

Diſtance of the centre of gravity of the ſection of the poſt from its aft ſide - 0.29

Diſtance of the centre of gravity of the ſection of the ſtem from the aft ſide of the poſt - 169.76

The areas of theſe plans will be found to be as follow:

2328.3642	for that of double the plan 8 *b i* G, and its momentum 2328.3642 × 84.34 =	196374.2366
21.52	for the area of double the trapezium AR *b* 8, and its momentum 21.52 × 7.46 =	160.5392
15.04	the area of the foremoſt trapezium, and its momentum 15.04 × 156.7 = -	2356.7680
0.77	the area of the ſection of the poſt, and its momentum 0.77 × 0.29 = -	0.2233
0.77	the area of the ſection of the ſtem, and its momentum 0.77 × 169.76 = -	130.7152
2366.4642	Sum - -	199022.4823

Now $\frac{199022.4823}{2366.4642} = 84.1$, the diſtance of the centre of gravity of the whole from the aft ſide of the poſt.

VII. *Determination of the Centre of Gravity of the ſeventh Horizontal Section.*

Diſtance of the centre of gravity of double the plan 8 *a b* G from its firſt ordinate 8 *a*.

	0	8	0	1	4	0	$((3\times15)-4)\times\frac{1}{6}$	9	1	4	$0\frac{1}{2}$	0	8	0
	18	2	9	36	5	6		205	4	6		35	1	6

Hence the diſtance of the centre of gravity of double the plane from its firſt ordinate is $\frac{205\ 4\ 6}{35\ 1\ 6} \times 10\ 0\ 4$

$= \frac{205.37}{35.12} \times 10.83 =$ - 58.65

The diſtance of this ordinate from aft ſide of poſt = - - 13.50

Hence the diſtance of the centre of gravity of this plane from the aft ſide of the poſt is 72.15

Diſtance of the centre of gravity of double the rectangle AR *a* 8 from its ordinate AR 6.45

Diſtance of this ordinate from the aft ſide of the poſt - - 0.58

Diſtance of the centre of gravity of this rectangle from the aft ſide of the poſt 7.03

Diſtance of the centre of gravity of the foremoſt rectangle from its ordinate 7′ 7 *e* 7′ - 1.25

Diſtance of this ordinate from the aft ſide of the poſt - - 153.78

Diſtance of the centre of gravity of this rectangle from the aft ſide of the poſt 155.03

Diſtance of the centre of gravity of the ſection of the poſt from its aft ſide 0.29

Diſtance of the centre of gravity of the ſection of the ſtem from the aft ſide of the poſt - - 169.76

Now the areas of theſe ſeveral plans being calculated will be as follows.

352.2536, the area of double the plan 8 *a b* G, and its momentum $352.2536 \times 72.15 =$ 25415.0972

17.1570, the area of double the rectangle AR *a* 8, and its momentum $17.1570 \times 7.03 =$ 120.6137

3.3250, the area of the foremoſt rectangle, and its momentum $3.3250 \times 155.03 =$ 515.4747

0.77 the area of the ſection of the port, and its momentum $0.77 \times 0.29 =$ 0.2233

0.77 the area of the ſection of the ſtem, and its momentum $0.77 \times 169.76 =$ 130.7152

374.2756 Sum 26182.1242

Then $\frac{26182.1242}{374.2756} = 69.95$, the diſtance of the centre of gravity of the whole ſection from the aft ſide of the poſt.

VIII. *Determination of the Centre of Gravity of the eighth Plane.*

This plane is equal in length to the ſeventh horizontal plane, and its breadth is equal to that of the keel. The diſtance between the ſeventh and eighth planes is three feet, but which is here taken equal to 2 feet $11\frac{1}{2}$ inches.

Diſtance between the aft ſide of the poſt and the firſt ordinate - 13.5

Fourteen intervals between the fifteen ordinates, each interval being 10.03 feet 140.42

Diſtance of the laſt ordinate from the fore foot 2.2

Hence the length of the eighth plane is 156.12

Which multiplied by the breadth - 1.33

The product is the area of this plane 208.

The diſtance of its centre of gravity from the aft ſide of the poſt, being equal to half its length, is - - 78.06

The centres of gravity of theſe eight planes being found, the diſtance of the centre of gravity of the bottom of the ſhip from the aft ſide of the poſt, and alſo its altitude, may from thence be eaſily determined.

From the principles already explained, the diſtance of the centre of gravity of the bottom from the aft ſide of the poſt, is equal to the ſum of the momentums of an infinite number of horizontal planes, divided by the ſum of theſe planes, or, which is the ſame, by the ſolidity of the bottom. As, however, we have no more than eight planes, we muſt therefore conceive their momentums as the ordinates of a curve, whoſe diſtances may be the ſame as that of the horizontal planes. Now the ſum of theſe ordinates minus half the ſum of the extreme ordinates being multiplied by their diſtance, gives the ſurface of the curve; of which any ordinate whatever repreſents the momentum of the horizontal plane at the ſame altitude as theſe ordinates; and the whole ſurface will repreſent the ſum of the momentums of all the horizontal planes.

Hor. Planes.	Fact.	Products.	Momentums.	Fact.	Products.
5974.16	$0\frac{1}{2}$	2987.08	503037.73	$0\frac{1}{2}$	251518.86
5592.27	1	5592.27	473560.21	1	473560.21
4939.27	1	4939.27	422084.77	1	422084.77
4169.50	1	4169.50	357735.21	1	357735.21
3365.42	1	3365.42	288729.20	1	288729.20
2366.46	1	2366.46	199022.48	1	199022.48
374.27	1	374.27	21682.12	1	21682.12
208.00	$0\frac{1}{2}$	104.00	16236.48	$0\frac{1}{2}$	8118.24
		23898.27			2022451.09

Now $\frac{2022451.09}{23898.27} = 84.63$, the diſtance of the

centre

centre of gravity of the bottom of the ſhip from the aft ſide of the poſt.

The height of the centre of gravity of the bottom above the lower edge of the keel may be determined by the ſame principles. Thus,

To one ſixth of the lowermoſt horizontal ſection add the product of one ſixth of the uppermoſt ſection by three times the number of ſections minus four the ſecond ſection in aſcending, twice the third, three times the fourth, &c.; and to half the ſum of the extreme planes add all the intermediate ones. Now the firſt of theſe ſums, multiplied by the diſtance between the planes or ſections, and divided by the ſecond ſum, gives the altitude of the centre of gravity of the bottom of the ſhip above the lower edge of the keel as required.

Hor. Planes.	1ſt Fact.	1ſt Products.	2d Fact.	2d Products.
208.00	$0\frac{1}{6}$	34.67	$0\frac{1}{2}$	104.00
374.27	1	374.27	1	374.27
2366.46	2	4732.92	1	2366.46
3365.42	3	10096.26	1	3365.42
4169.50	4	16678.00	1	4169.50
4939.27	5	24696.35	1	4939.27
5592.27	6	33553.62	1	5592.27
5974.16	$((3\times 8)-4)\times\frac{1}{6}$	19913.87	$0\frac{1}{2}$	2987.08
		110079.96		23898.27

Now $\frac{110079.96}{23898.27}\times 2.95 = 13.588$, the height of the centre of gravity of the bottom of the ſhip above the lower edge of the keel.

We have now found the diſtance of the centre of gravity of the bottom of the ſhip from the aft ſide of the poſt, and its altitude above the lower edge of the keel. Hence the ſhip being ſuppoſed in an upright poſition, this centre of gravity will neceſſarily be in the vertical longitudinal ſection which divides the ſhip into two equal and ſimilar parts; the poſition of this centre is therefore determined.

70 Determination of the height of the metacenter above the centre of gravity.

It now remains to find the height of the metacenter above the centre of gravity; the expreſſion for this altitude, as found in Chap. III. is $\frac{\frac{2}{3}\int y^3 x}{V}$; which we ſhall now apply to determine the metacenter of the ſhip of 74 guns, whoſe centre of gravity we have already found.

$2\int y^3 x$ - -		2325522.78652
$\frac{2}{3}\int y^3 x$ - -		775174.26217

The ſolidity of the bottom is $2527\frac{3}{4}$ tons = 70018.67 cubic feet: hence $\frac{\frac{2}{3}\int y^3 x}{V} = \frac{775174.26}{70018.67} = 11.07$ feet, the altitude of the metacenter above the centre of gravity of the bottom of the ſhip.

APPENDIX.

When a ſhip is built, ſhe muſt be fitted with maſts, yards, ſails, ropes, and blocks, or, in other words, ſhe muſt be *rigged* before ſhe can go to ſea. To complete this article, it may therefore be thought neceſſary to treat of the art of rigging veſſels; but we have elſewhere (ſee *Mast-Rigging*, Rope-Making, and Sail) ſhown how the ſeveral parts of a ſhip's rigging are made; and the art of putting them properly together, ſo as to make the ſhip beſt anſwer the purpoſe for which ſhe is intended, depends upon a juſt knowledge of the impulſe and reſiſtance of fluids, and of the theory and practice of ſeamanſhip. (See *Resistance of Fluids* and Seamanship). Nothing, therefore, of the ſubject is left to us here, except we were to ſtate in few words the progreſſive method of rigging ſhips; but there is no one undeviating mode which is purſued, as the nature of the operation is ſuch that all the parts of it may be advancing at the ſame time. We ſhall therefore take our leave of *ſhips* and *ſhip-building* with a few general obſervations on *ſail-making*, which were omitted under the article Sail, referring our readers for farther information to the very elegant work lately publiſhed, in

two

two volumes 4to, on *the Elements and Practice of Rigging and Seamanship*.

Sails are made of canvas, of different textures, and are extended on or between the masts, to receive the wind that forces the vessel through the water. They are quadrilateral or triangular, as has been elsewhere described, and are cut out of the canvas cloth by cloth. The width is governed by the length of the yard, gaff, boom, or stay; the depth by the height of the mast. In the valuable work to which we have just referred, the following directions are given for cutting sails. "The width and depth being given, find the number of cloths the width requires, allowing for seams, tabling on the leeches, and slack cloth; and, in the depth, allow for tabling on the head and foot. For sails cut square on the head and foot, with gores only on the leeches, as some topsails, &c. the cloths on the head, between the leeches, are cut square to the depth; and the gores on the leeches are found by dividing the depth of the sail by the number of cloths gored, which gives the length of each gore. The gore is set down from a square with the opposite selvage; and the canvas being cut diagonally, the longest gored side of one cloth makes the shortest side of the next; consequently, the first gore being known, the rest are cut by it. In the leeches of topsails cut hollow, the upper gores are longer than the lower ones; and in sails cut with a roach leech, the lower gores are longer than the upper ones. This must he regulated by judgment, and care taken that the whole of the gores do not exceed the depth of the leech. Or, by drawing on paper the gored side of the sail, and delineating the breadth of every cloth by a convenient scale of equal parts of an inch to a foot, the length of every gore may be found with precision. Sails, gored with a sweep on the head or the foot, or on both, have the depth of their gores marked on the selvage, from the square of the given depth on each cloth, and are cut as above; the longest selvage of one serving to measure the shortest selvage of the next, beginning with the first gored cloth next the middle in some sails, and the first cloth next the mast leech in others. For those gores that are irregular no strict rule can be given; they can only be determined by the judgement of the sail-maker, or by a drawing.

Elements and practice of Rigging and Seamanship, vol. i. p. 91.

"In the royal navy, mizen topsails are cut with three quarters of a yard hollow in the foot; but, in the merchant service, top and topgallant sails are cut with more or less hollow in the foot. Flying jibs are cut with a roach-curve on the stay, and a three-inch gore in each cloth, shortening from the tack to the clue. Lower studding-sails are cut with square leeches, and topmast and topgallant-mast studding sails with goring leeches.

"The length of reef and middle bands is governed by the width of the sail at their respective places; the leech-linings, buntline-cloths, top-linings, mast-cloths, and corner-pieces, are cut agreeably to the depth of the sail; each cloth and every article should be properly marked with charcoal, to prevent confusion or mistake. Sails that have bonnets are cut out the whole depth of the sail and bonnet included, allowing enough for the tablings on the foot of the sail and head and foot of the bonnet. The bonnet is cut off after the sail is sewed together. If a drabler is required, it is allowed for in the cutting out the same as the bonnet."

4

When the cloth is thus properly cut, the different pieces are to be joined together in the form of a sail; and for doing this properly we have the following directions in the work already quoted. "Sails have a double flat seam, and should be sewed with the best English-made twine of three threads, spun 360 fathoms to the pound, and have from one hundred and eight to one hundred and sixteen stitches in every yard in length. The twine for large sails, in the royal navy, is waxed by hand, with genuine bees-wax, mixed with one-sixth part of clear turpentine; and, for small sails, in a mixture made with bees wax, 4 lb; hogs lard 5 lb; and clear turpentine 1 lb. In the merchant service, the twine is dipped in tar (L), softened with a proper proportion of oil.

"It is the erroneous practice of some sailmakers not to sew the seams any farther than where the edge is creased down for the tabling; but all sails should be sewed quite home to the end, and, when finished, should be well rubbed down with a rubber. In the merchant service seams are sometimes made broader at the foot than at the head, being stronger. Broad seams are not allowed to be made on courses, in the royal navy, but goring leeches are adopted in lieu of them. Boom-mainsails and the sails of sloops generally have the seams broader at the foot than at the head. The seams of courses and topsails are stuck or stitched up, in the middle of the seams, along the whole length, with double seaming-twine; and have from 68 to 72 stitches in a yard. In the merchant service it is common to stick the seams with two rows of stitches, when the sail is half worn, as they will then last till the sail is worn out.

"The breadth of the seams of courses, topsails, and other sails, in the royal navy, to be as follow, viz. courses and topsails, for 50 gun ships and upwards, one inch and a half, and, for 44 gun ships and under, one inch and a quarter, at head and foot; all other sails, one inch at head and foot.

"The tablings of all sails are to be of a proportionable breadth to the size of the sail, and sewed at the edge, with 68 to 72 stitches in a yard. Those for the heads of main and fore courses to be four to six inches wide; for sprit courses and mizens, drivers, and other boom sails, 3 to 4 inches wide; for topsails, 3 inches to 4 inches and a half; topgallant and sprit topsails, 3 inches; royal sails, 2 inches and a half; jib and other staysails, 3 inches to 4 inches and a half, on the stay or hoist; and for studding sails, 3 inches to 4 inches on the head. Tablings on the foot and leeches of main and fore courses to be 3 inches to 5 inches broad; sprit course and topsails, 3 inches; topgallant and sprit topsails, 2 inches and a half; royals, 2 inches; fore leeches of mizen, driver, and other boomsails, 3 inches and a half to 4 inches; after leech, 3 inches; and on the foot 2 or 3 inches. Tablings on the after leech of jibs and other staysails to be from 2 to 3 inches broad; and, on the foot, 2 to 2 inches and a half: on studding sail leeches one inch and a half to two inches and a half; and on the foot, from one to two inches.

"Main

(L) The dipping of the twine in tar, we are persuaded, is a very bad practice, for the reason assigned in ROPE-MAKING. See that article, n° 32.

"Main and fore courſes are lined on the leeches, from clue to earing, with one cloth ſeamed on and ſtuck or ſtitched in the middle, and have a middle band half way between the lower reef band and the foot, alſo four buntline cloths, at equal diſtances between the leeches, the upper ends of which are carried under the middle band, that the lower ſide of the band may be tabled upon or ſewed over the end of the buntline pieces. They have likewiſe two reef bands; each in breadth one third of the breadth of the canvas; the upper one is one ſixth of the depth of the ſail from the head, and the lower band is at the ſame diſtance from the upper one; the ends go four inches under the leech linings, which are ſeamed over the reef bands. All linings are ſeamed on, and are ſtuck with 68 to 72 ſtitches in a yard.

"Main, fore, and mizen, topſails have leech linings, maſt and top linings, buntline cloths, middle bands and reef bands. The leech linings are made of one breadth of cloth, ſo cut and ſewed as to be half a cloth broad at the head, and a cloth and a half broad at the foot; the piece cut out being half the breadth of the cloth at the one end, and tapering to a point at the other. The middle bands are put on half way between the lower reef and foot, the buntline cloths join the top-linings, and the buntline cloths and top-linings are carried up to the lower ſide of the middle band, which is tabled on them. The maſt lining is of two cloths, and extends from the foot of the ſail to the lower reef, to receive the beat or chaſe of the maſt. The middle band is made of one breadth of canvas, of the ſame number as the top-lining. It is firſt folded and rubbed down, to make a creaſe at one third of the breadth; then tabled on the ſelvage, and ſtuck along the creaſe; then turned down, and tabled and ſtuck through both the double and ſingle parts, with 68 to 72 ſtitches in a yard. It is the opinion of many, that middle bands ſhould not be put on until the ſail is half worn.

"Main and fore topſails have three and ſometimes four reef bands from leech to leech, over the leech linings; the upper one is one eighth of the depth of the ſail from the head, and they are the ſame diſtance aſunder in the royal navy, but more in the merchant ſervice. The reef bands are each of half a breadth of canvas put on double; the firſt ſide is ſtuck twice, and the laſt turned over, ſo that the reef holes may be worked upon the double part of the band, which is alſo ſtuck with 68 to 72 ſtitches in a yard.

"The top-lining of topſails is of canvas n° 6 or 7. The other linings of this, and all the linings of other ſails, ſhould be of the ſame quality as the ſails to which they belong.

"Top-linings and maſt cloths are put on the aft ſide, and all other linings on the fore ſide, of ſails. Mizens are lined with one breadth of cloth from the clue five yards up the leech, and have a reef band ſewed on, in the ſame manner as on other ſails, at one fifth the depth of the ſail from the foot; they have alſo a neck-piece and a peek-piece, one cut out of the other, ſo that each contains one yard. Mizen topſails of 50 gun ſhips and upwards have three reefs, the upper one is one eighth of the depth of the ſail from the head, and the reefs are at the ſame diſtance aſunder. Mizen topſails of ſhips of 44 guns and under have two reefs one ſeventh part of the depth of the ſail aſunder, the upper one being at the ſame diſtance from the head. Main and main top ſtudding ſails have each one reef, at one eighth of the depth of the ſail from the head. Reef bands ſhould not be put on until the ſail is ſewed up, a contrary practice being very erroneous. Lower ſtayſails, fore top and main top ſtayſails, and flying jibs, have clue-pieces two yards long. Square tack ſtayſails have half a breadth of cloth at the fore part, with a clue-piece containing two yards, and a peek-piece, containing one yard.

"Sails have two holes in each cloth, at the heads and reefs of courſes, topſails, and other ſquare ſails; one hole in every yard in the ſtay of flying jibs, and one in every three quarters of a yard in the ſtays of ſquare tack and other ſtayſails. Theſe are made by an inſtrument called a *Pegging awl*, or a ſtabber, and are fenced round by ſtitching the edge to a ſmall grommet, made with log or other line; when finiſhed, they ſhould be well ſtretched or rounded up by a pricker or a marline-ſpike. Reef and head holes of large ſails have grommets of twelve-thread line, worked round with 18 to 21 ſtitches; ſmaller ſails have grommets of nine-thread line, with 16 to 18 ſtitches, or as many as ſhall cover the line, and ſmaller holes in porportion. The holes for marling the clues of ſails and the top-brims of topſails have grommets; of log-line, and ſhould have from 9 to 11 ſtitches; twelve holes are worked in each cloth. Main courſes have marling holes from the clue to the lower bow line cringle up the leech, and from the clue to the firſt buntline cringle on the foot. Fore courſes have marling holes one eighth of the depth of the ſail up the leech, and from the clue to the firſt buntline cringle at the foot. Main and fore topſails have marling holes three feet each way from the clue and at the top-brims. Spritſails, mizen topſails, lower ſtayſails, main and fore top ſtayſails, and jibs, have marling holes two feet each way from the clues. All other ſails are ſewed home to the clues. Marling holes of courſes are at three fourths of the depth of the tablings at the clues from the rope, and thoſe of topſails are at half the depth of the tablings at the clues and top-brim from the rope."

The rope, which is ſewed on the edges of ſails to prevent their rending, and which is called *bolt rope*, ſhould be well made of fine yarn, ſpun from the beſt Riga rhine hemp well topt, and ſewed on with good Engliſh made twine of three threads, ſpun 200 fathom to the pound; the twine in the royal navy is dipped in a compoſition made with bees-wax, 4 lbs; hogs lard 5 lbs; and clear turpentine one pound; and in the merchant ſervice, in tar ſoftened with oil. They ſhould be ſtoved in a ſtove by the heat of a flue, and not in a baker's oven or a ſtove tub; and tarred in the beſt Stockholm tar. The flexibility of them ſhould be always conſidered, in taking in the ſlack, which muſt reſt on the judgment of the ſailmaker.

"Bolt-ropes of courſes, topſails, and all other ſails, ſhould be neatly ſewed on through every buntline of the rope; and, to avoid ſtretching, the rope muſt be kept tightly twiſted while ſewing on, and care taken that neither too much nor too little ſlack is taken in; they are to be croſs-ſtitched at the leeches every twelve inches in length; at every ſeam, and in the middle of every cloth at the foot, with three croſs-ſtitches: four croſs ſtitches ſhould be taken at all beginnings and faſtenings off; the firſt ſtitch giving twice, and the laſt three times. Small ſails have two croſs ſtitches at every ſeam, and three at every faſtening off.

"On main and fore courses two inches slack cloth should be allowed in the head and foot, and one inch and a half in the leeches, in every yard in length. Topsails are allowed 3 inches slack in every cloth in the foot, one inch and a half in every yard in the leech, and two inches in every cloth left open in the top-brim. Mizen courses have two inches slack in every yard in the foremost leech, but none in the after leech or foot. Spritsail courses have no slack cloth. Jibs have four inches slack in every yard in the stay, one inch in every cloth in the foot, and none in the leech. Staysails have three inches slack in every yard in the stay, one inch in every cloth in the foot, but none in the leech. Topgallant sails have two inches slack in every cloth in the foot, and one inch in every yard in the leech. Studding sails have an inch and a half slack in every yard in goring leeches, but no slack in square leeches, and one inch in every cloth in the head and foot."

These directions for sailmaking, we trust may be useful. They are indeed very general, but the limits prescribed us will not permit of a more minute detail. The sailmaker will find every instruction that he can want in the *Elements of Rigging and Seamanship*, a work which we therefore recommend to his attention.

Ship.

Ship's Form Gauge, an instrument recommended by Mr Hutchinson as fit to ascertain any alteration in the bottom of a ship, by its hogging or sagging; and also to regulate the stowage of a ship.

"All ships (says he) of any consequence are built with staunchions fixed from the kelson to the middle of all the lower-deck beams fore and aft, in order to support them in their exact, regular height, as well as the whole frame of the ship in the regular form in which she was built upon the stocks; yet notwithstanding these staunchions, it is proved from experience that our ships bottoms, hitherto, by the pressure of water, and improper stowage, have generally been hogged upwards, or sagged downwards, and most about the midship frame or main body of the ship, which is commonly about the fore part of the main hatchway; which naturally makes it the best place at which to fix the ship's form guage, where either the hogging or sagging of her bottom may be observed and seen soonest and best, to regulate the stowage of heavy materials to the greatest advantage, so as to keep her bottom nearly in the same form in which she was built.

"The guage I recommend is nothing more than a narrow plate of iron divided into inches and quarters like the slide of a carpenter's rule. Let this be fixed to the after side of the staunchion now mentioned, with its upper end projecting two or three inches above the staunchion; a groove being cut out for it in the after side of the lower-deck beam, and a mark being made (when the ship is on the stocks) at the part of the beam which corresponds to the o on the guage. When the ship alters in her shape, the guage will slide up and down in this groove, and the quantity of hogging or sagging will be pointed out on the guage by the mark on the beam. The stowage may then be so managed as to bring this mark to coincide again with the o, or to approach it as near as we see necessary."

Ship-Money, was an imposition charged upon the ports, towns, cities, boroughs, and counties of England, in the reign of king Charles I. by writs, commonly called *ship-writs*, under the great seal of the realm, in the years 1635 and 1636, for the providing and furnishing of certain ships for the king's service, &c. which was declared to be contrary to the laws and statutes of that realm, the *petition of right* and liberty of the subject, by stat. 17 Car. I. c. 14. See *Blackstone's Commentaries*, vol. iv. p. 30.

Ship-Shape, according to the fashion of a ship, or in the manner of an expert sailor; as, The mast is not rigged ship-shape; Trim your sails ship-shape.

Stowing and Trimming of Ships, the method of disposing of the cargo in a proper and judicious manner in the hold of a ship.

A ship's sailing, steering, staying, and wearing, and being lively and comparatively easy at sea in a storm, depends greatly on the cargo, ballast, or other materials, being properly stowed, according to their weight and bulk, and the proportional dimensions of the built of the ship, which may be made too crank or too stiff to pass on the ocean with safety. These things render this branch of knowledge of such consequence, that rules for it ought to be endeavoured after, if but to prevent, as much as possible, the danger of a ship oversetting at sea, or being so laboursome as to roll away her masts, &c. by being improperly stowed, which is often the case.

When a ship is new, it is prudent to consult the builder, who may be supposed best acquainted with a ship of his own planning, and most likely, to judge what her properties will be, to advise how the cargo or materials, according to the nature of them, ought to be disposed of to advantage, so as to put her in the best sailing trim; and at every favourable opportunity afterwards it will be proper to endeavour to find out her best trim by experiment.

Ships must differ in their form and proportional dimensions; and to make them answer their different purposes, they will require different management in the stowage, which ought not to be left to mere chance, or done at random, as goods or materials happen to come to hand, which is too often the cause that such improper stowage makes ships unfit for sea: therefore the stowage should be considered, planned, and contrived, according to the built and properties of the ship, which if they are not known should be inquired after. If she is narrow and high-built in porportion, so that she will not shift herself without a great weight in the hold, it is a certain sign such a ship will require a great part of heavy goods, ballast, or materials, laid low in the hold, to make her stiff enough to bear sufficient sail without being in danger of oversetting. But if a ship be built broad and low in porportion, so that she is stiff and will support herself without any weight in the hold, such a ship will require heavy goods, ballast, or materials, stowed higher up, to prevent her from being too stiff and laboursome at sea, so as to endanger her masts being rolled away, and the hull worked loose and made leaky.

In order to help a ship's sailing, that she should be lively and easy in her pitching and ascending motions,

Ship.

it ſhould be contrived by the ſtowage, that the principal and weightieſt part of the cargo or materials ſhould lie as near the main body of the ſhip and as far from the extreme ends, fore and aft, as things will admit of. For it ſhould be conſidered, that the roomy part of our ſhips lengthwiſe forms a ſweep or curve near four times as long as they are broad; therefore thoſe roomy parts at and above the water's edge, which are made by a full harping and a board tranſom to ſupport the ſhip ſteady and keep her from plunging into the ſea, and alſo by the entrance and run of the ſhip having little or no bearing body under for the preſſure of the water to ſupport them, of courſe ſhould not be ſtowed with heavy goods or materials, but all the neceſſary vacancies, broken ſtowage, or light goods, ſhould be at theſe extreme ends fore and aft; and in proportion as they are kept lighter by the ſtowage, the ſhip will be more lively to fall and riſe eaſy in great ſeas; and this will contribute greatly to her working and ſailing, and to prevent her from ſtraining and hogging; for which reaſon it is a wrong practice to leave ſuch a large vacancy in the main hatchway, as is uſual, to coil and work the cables, which ought to be in the fore or after hatchway, that the principal weight may be more eaſily ſtowed in the main body of the ſhip, above the flatteſt and loweſt floorings, where the preſſure of the water acts the more to ſupport it.

Machine for meaſuring a Ship's *Way.* We have already deſcribed a variety of machines or inſtruments which have been propoſed for this purpoſe under the article Log. In this place, therefore, we ſhall confine ourſelves to the machine invented by Francis Hopkinſon, Eſq; Judge of the Admiralty in Pennſylvania.— After having ſhown the fallacies to which the common log, and alſo that particular kind of inſtrument invented by M Saumarez, are liable, he proceeds to deſcribe his own machine as follows:

Tranſact. of the American Philoſophical Society, vol. ii. p. 160.

This machine, in its moſt ſimple form, is repreſented by fig. 5. Plate CCCCLIII. wherein A B is a ſtrong rod of iron moveable on the fulcrum C. D is a thin circular palate of braſs rivetted to the lower extremity of the rod. E an horizontal arm connected at one end with the top of the rod A B by a moveable joint F, and at the other end with the bottom of the index H, by a like moveable joint G. H is the index turning on its centre I, and travelling over the graduated arch K; and L is a ſtrong ſpring, bearing againſt the rod A B, and conſtantly counteracting the preſſure upon the palate D. The rod A B ſhould be applied cloſe to the cut water or ſtem, and ſhould be of ſuch a length that the palate D may be no higher above the keel than is neceſſary to ſecure it from injury when the veſſel is aground, or ſails in ſhoal water. As the bow of the ſhip curves inwards towards the keel M, the palate D will be thrown to a diſtance from the bottom of the veſſel, although the prependicular rod to which it is annexed lies cloſe to the bow above; and therefore the palate will be more fairly acted upon. The arm E ſhould enter the bow ſomewhere near the hawſe hole, and lead to any convenient place in the forecaſtle, where a ſmooth board or plate may be fixed, having the index H, and graduated arch K, upon it.

It is evident from the figure, that as the ſhip is urged forward by the wind, the palate D will be preſſed upon by the reſiſting medium, with a greater or leſs force, according to the progreſſive motion of the ſhip; and this will operate upon the levers ſo as to immediately affect the index, making the leaſt increaſe or diminution of the ſhip's way viſible on the graduated arch; the ſpring L always counteracting the preſſure upon the palate, and bringing back the index, on any relaxation of the force impreſſed.

This machine is advantageouſly placed at the bow of the ſhip, where the current firſt begins, and acts fairly upon the palate, in preference to the ſtern, where the tumultuous cloſing of the waters cauſes a wake, viſible to a great diſtance. The palate D is ſunk nearly as low as the keel, that it may not be influenced by the heaping up of the water and the daſhing of the waves at and near the water line. The arch K is to aſcertain how many knots or miles ſhe would run in one hour at her then rate of ſailing. But the graduations on this arch muſt be unequal; becauſe the reſiſtance of the ſpring L will increaſe as it becomes more bent, ſo that the index will travel over a greater ſpace from one to five miles than from five to twelve. Laſtly, the palate, rod, ſpring, and all the metallic parts of the inſtrument, ſhould be covered with a ſtrong varniſh, to prevent ruſt from the corroſive quality of the ſalt water and ſea air.

This machine may be conſiderably improved as follows: Let the rod or ſpear A B (fig. 5.) be a round rod of iron or ſteel, and inſtead of moving on the fulcrum or joint, as at C, let it paſs through and turn freely in a ſocket, to which ſocket the moveable joint muſt be annexed, as repreſented in fig. 6. The rod muſt have a ſhoulder to bear on the upper edge of the ſocket, to prevent its ſlipping quite down. The rod muſt alſo paſs through a like ſocket at F, fig. 5. The joint of the lower ſocket muſt be fixed to the bow of the ſhip, and the upper joint or ſocket muſt be connected with the horizontal arm E. On the top of the uppermoſt ſocket let there be a ſmall circular plate, bearing the 32 points of the mariner's compaſs; and let the top of the rod AB come through the centre of this plate, ſo as to carry a ſmall index upon it, as is repreſented in fig. 7. This ſmall index muſt be fixed to the top of the rod on a ſquare, ſo that by turning the index round the plate, the rod may alſo turn in the ſockets, and of courſe carry the palate D round with it; the little index always pointing in a direction with the face of the palate. The ſmall compaſs plate ſhould not be faſtened to the top of the ſocket, but only fitted tightly on, that it may be moveable at pleaſure. Suppoſe then the intended port to bear S. W. from the place of departure, the palate muſt be turned on the ſocket till the ſouth-weſt point thereon looks directly to the ſhip's bow; ſo that the ſouth-weſt and north-eaſt line on the compaſs plate may be preciſely parallel with the ſhip's keel, and in this poſition the plate muſt remain during the whole voyage. Suppoſe, then, the ſhip to be ſailing in the direct courſe of her intended voyage, with her bowſprit pointing ſouth-weſt. Let the little index be brought to the ſouth-weſt point on the compaſs plate, and the palate D will neceſſarily preſent its broad face toward the port of deſtination; and this it muſt always be made to do, be the ſhip's courſe what it may. If, on account of unfavourable winds, the ſhip is obliged to deviate from her intended courſe, the little index muſt be moved ſo many points from the ſouth-weſt

line

Ship. line of the compass plate as the compass in the binnacle shall show that she deviates from her true course; so that in whatever direction the ship shall sail, the palate D will always look full to the south-west point of the horizon, or towards the port of destination, and consequently will present only an oblique surface to the resisting medium, more or less oblique as the ship deviates more or less from the true course of her voyage. As, therefore, the resistance of the water will operate less upon the palate in an oblique than in a direct position, in exact proportion to its obliquity, the index H will not show how many knots the vessel runs in her then course, but will indicate how many she gains in the direct line of her intended voyage—Thus, in fig. 9. if the ship's course lies in the direction of the line A B, but she can sail by the wind no nearer than A C; suppose, then, her progressive motion such as to perform A C equal to five knots or miles in an hour, yet the index H will only point to four knots on the graduated arch, because she gains no more than at that rate on the true line of her voyage, viz. from A to B. Thus will the difference between her real motion and that pointed out by the index be always in proportion to her deviation from her intended port, until she fails in a line at right angles therewith, as A D; in which case the palate would present only a thin sharp edge to the resisting medium, the pressure of which should not be sufficient to overcome the friction of the machine and the bearing of the spring L. So that at whatever rate the ship may sail on that line, yet the index will not be affected, showing that she gains nothing on her true course. In this case, and also when the vessel is not under way, the action of the spring L should cause the index to point at O, as represented by the dotted lines in fig. 5. and 8.

As the truth of this instrument must depend on the equal pressure of the resisting medium upon the palate D, according to the ship's velocity, and the proportionable action of the spring L, there should be a pin or screw at the joints C and F, so that the rod may be readily unshipped and taken in, in order to clean the palate from any foulness it may contract, which would greatly increase its operation on the index H, and thereby render the graduated arch false and uncertain.

Further, the spring L may be exposed too much to injury from the salt water, if fixed on the outside of the ship's bow. To remedy this, it may be brought under cover, by constructing the machine as represented by fig. 8. where A B is the rod, C the fulcrum or centre of its motion, D the palate, E the horizontal arm leading through a small hole into the forecastle; M is a strong chain fastened at one end to the arm E, and at the other to a rim or barrel on the wheel G, which by means of its teeth gives motion to the semicircle I and index H. The spring L is spiral, and enclosed in a box or barrel, like the main spring of a watch. A small chain is fixed to, and passing round the barrel, is fastened by the other end to the fuzee W. This fuzee is connected by its teeth with the wheel G, and counteracts the motion of the palate D. N, N, are the two sockets through which the rod A B passes, and in which it is turned round by means of the little index R. S is the small compass plate, moveable on the top of the upper socket N. The plate S hath an upright rim round its edge, cut into teeth or notches, so that when the index R is a little raised up, in order to bring it round to any intended point, it may fall into one of these notches, and be detained there; otherwise the pressure of the water will force the palate D from its oblique position, and turn the rod and index round to the direction in which the ship shall be then sailing.—Should it be apprehended that the palate D, being placed so far forward, may affect the ship's steerage or obstruct her rate of sailing, it should be considered that a very small plate will be sufficient to work the machine, as one of three or four inches in diameter would probably be sufficient, and yet not large enough to have any sensible effect on the helm or ship's way. Ship.

The greatest difficulty, perhaps, will be in graduating the arch K, (if the machine is constructed as in fig. 5.); the unequal divisions of which can only be ascertained by actual experiment on board of each ship respectively, inasmuch as the accuracy of these graduations will depend on three circumstances, viz. the position of the fulcrum C with respect to the length of the rod, the size of the palate D, and the strength or bearing of the spring L. When these graduations, however, are once ascertained for the machine on board of any one vessel, they will not want any future alterations, provided the palate D be kept clean, and the spring L retains its elasticity.

But the unequal divisions of the graduated arch will be unnecessary, if the machine is constructed as in fig. 8.; for as the chain goes round the barrel L, and then winds through the spiral channel of the fuzee W, the force of the main spring must operate equally, or nearly so, in all positions of the index, and consequently the divisions of the arch K may in such case be equal.

After all, it is not expected that a ship's longitude can be determined to a mathematical certainty by this instrument. The irregular motions and impulses to which a ship is continually exposed, make such an accuracy unattainable perhaps by any machinery: But if it should be found, as we flatter ourselves it will on fair experiment, that it answers the purpose much better than the common log, it may be considered as an acquisition to the art of navigation.

It should be observed, that in ascertaining a ship's longitude by a time-piece, this great inconvenience occurs, that a small and trifling mistake in the time makes a very great and dangerous error in the distance run: Whereas the errors of this machine will operate no farther than their real amount; which can never be great or dangerous, if corrected by the usual observations made by mariners for correcting the common log.

A like machine, made in its simple form (as at fig. 5.), so constructed as to ship and unship, might occasionally be applied alongside about midships, in order to ascertain the leeway; which, if rightly shown, will give the ship's precise longitude. As to sea-currents, this and all other machines hitherto invented must be subject to their influence; and proper allowances must be made according to the skill and knowledge of the navigator.

Lastly, some discretion will be necessary in taking observations from the machine to be entered on the log-book: that is, the most favourable and equitable moment should be chosen for the observation; not whilst the ship is rapidly descending the declivity of a wave, or is suddenly checked by a stroke of the sea, or is in the very act of plunging. In all cases, periods may be found in which a ship proceeds with a true average velocity;

velocity; to discover which, a little experience and attention will lead the skilful mariner (A).

SHIRAUZ. See SCHIRAS.

SHIRE, is a Saxon word signifying a division; but a county, *comitatus*, of the same import, is plainly derived from *comes*, "the count of the Franks;" that is, the earl or alderman (as the Saxons called him) of the shire, to whom the government of it was entrusted. This he usually exercised by his deputy, still called in Latin *vice-comes*, and in English the *sheriff, shrieve*, or *shire reeve*, signifying the "officer of the shire;" upon whom, in process of time, the civil administration of it totally devolved. In some counties there is an intermediate division between the shire and the hundred; as lathes in Kent and rapes in Sussex, each of them containing about three or four hundreds a-piece. These had formerly their lathe-reeves and rape-reeves, acting in subordination to the shire-reeve. Where a county is divided into three of these intermediate jurisdictions, they are called *trithings*, which were anciently governed by a trithing reeve. These trithings still subsist in the large county of York, where, by an easy corruption, they are denominated *ridings;* the north, the east, and the west riding.

SHIRL, or COCKLE, in mineralogy. See COCKLE.

SHIRT, a loose garment, commonly of linen, worn next the body.—Some doubt the propriety of changing the linen when a person is sick. Clean linen promotes perspiration; and it may be renewed as often as the patient pleases, whether the disorder be of the acute or the chronical kind. Except during a crisis in fevers, whilst the patient is in a sweat, a change of linen, if well dried and warmed, may be daily used.

Shirts were not worn by Jews, Greeks, or Romans, but their place was supplied by thin *tunicæ* of wool. The want of linen among the ancients made frequent washings and ablutions necessary.

SHIVER. See SCHISTUS and SHALE.

SHIVERS, in the sea language, names given to the little rollers, or round wheels of pulleys.

SHOAD, among miners, denotes a train of metalline stones, serving to direct them in the discovery of mines.

Shoad-Stones, a term used by the miners of Cornwall and other parts of Great Britain, to express such loose masses of stone as are usually found about the entrances into mines, sometimes running in a straight course from the load or vein of ore to the surface of the earth.

These are stones of the common kinds, appearing to have been pieces broken from the strata or larger masses; but they usually contain mundic, or marcasitic matter, and more or less of the ore to be found in the mine. They appear to have been at some time rolled about in water, their corners being broken off, and their surface smoothed and rounded.

The antimony mines in Cornwall are always easily discovered by the shoad-stones, these usually lying up to the surface, or very nearly so; and the matter of the stone being a white spar, or debased crystal, in which the native colour of the ore, which is a shining bluish black, easily discovers itself in streaks and threads.

Shoad-stones are of so many kinds, and of such various appearances, that it is not easy to describe or know them: but the miners, to whom they are of greatest use in the tracing or searching after new mines, distinguish them from other stones by their weight; for if very ponderous, though they look ever so much like common stones, there is great reason to suspect that they contain some metal. Another mark of them is their being spongy and porous; this is a sign of especial use in the tin countries; for the tin shoad-stones are often so porous and spongy, that they resemble large bodies thoroughly calcined. There are many other appearances of tin shoads, the very hardest and firmest stones often containing this metal.

When the miners, in tracing a shoad up hill, meet with such odd stones and earths that they know not well what to make of them, they have recourse to vanning, that is, they calcine and powder the stone, clay or whatever else is supposed to contain the metal; and then washing it in an instrument, prepared for that purpose, and called a *vanning shovel*, they find the earthy matter washed away, and of the remainder, the stony or gravelly matter lies behind, and the metalline matter at the point of the shovel. If the person who performs this operation has any judgment, he easily discovers not only what the metal is that is contained in the shoad, but also will make a very probable guess at what quantity the mine is likely to yield of it in proportion to the ore.

SHOAL, in the sea-language, denotes a place where the water is shallow; and likewise a great quantity of fishes, such as *a shoal of herrings*.

SHOCK, in electricity. The effect of the explosion of a charged body, that is, the discharge of its electricity on any other body, is called the *electric shock*.

SHOE, a covering for the foot, usually of leather.

SHOES, among the Jews, were made of leather, linen, rush, or wood; those of soldiers were sometimes of brass or iron. They were tied with thongs which passed under the soles of the feet. To put off their shoes was an act of veneration; it was also a sign of mourning and humiliation: to bear one's shoes, or to untie the latchet of them, was considered as the meanest service.

Among the Greeks shoes of various kinds were used. Sandels were worn by women of distinction. The Lacedemonians wore red shoes. The Grecian shoes generally reached to the middle of the leg. The Romans used two kinds of shoes; the *calceus*, which covered the whole foot somewhat like our shoes, and was tied above with latchets or strings; and the *solea* or slipper, which covered only the sole of the foot, and was fastened with leathern thongs. The calceus was always worn along

(A) An ingenious mechanic would probably construct this machine to better advantage in many respects. The author only meant to suggest the principle; experiment alone can point out the best method of applying it. He is sensible of at least one deficiency, viz. that the little index R, fig. 4. will not be strong enough to retain the palate D in an oblique position when the ship is sailing by the wind; more especially as the compass plate S, in whose notched rim the index R is to fall, is not fixed to, but only fitted tight on the socket N. Many means, however, might not be contrived to remedy this inconvenience.

along with the *toga* when a person went abroad: slippers were put on during a journey and at feasts, but it was reckoned effeminate to appear in public with them. Black shoes were worn by the citizens of ordinary rank, and white ones by the women. Red shoes were sometimes worn by the ladies, and purple ones by the coxcombs of the other sex. Red shoes were put on by the chief magistrates of Rome on days of ceremony and triumphs. The shoes of senators, patricians, and their children, had a crescent upon them which served for a buckle; these were called *calcei lunati*. Slaves wore no shoes; hence they were called *cretati* from their dusty feet. Phocion also and Cato Uticensis went without shoes. The toes of the Roman shoes were turned up in the point; hence they were called *calcei rostrati, repandi*, &c.

In the 9th and 10th centuries the greatest princes of Europe wore wooden shoes, or the upper part of leather and the sole of wood. In the reign of William Rufus, a great beau, Robert, surnamed *the horned*, used shoes with long sharp points, stuffed with tow, and twisted like a ram's horn. It is said the clergy, being highly offended, declaimed against the long-pointed shoes with great vehemence. The points, however, continued to increase till, in the reign of Richard II. they were of so enormous a length that they were tied to the knees with chains, sometimes of gold, sometimes of silver. The upper parts of these shoes in Chaucer's time were cut in imitation of a church window. The long-pointed shoes were called *crackowes*, and continued in fashion for three centuries in spite of the bulls of popes, the decrees of councils, and the declamations of the clergy. At length the parliament of England interposed by an act A. D. 1463, prohibiting the use of shoes or boots with pikes exceeding two inches in length, and prohibiting all shoemakers from making shoes or boots with longer pikes under severe penalties. But even this was not sufficient: it was necessary to denounce the dreadful sentence of excommunication against all who wore shoes or boots with points longer than two inches. The present fashion of shoes was introduced in 1633, but the buckle was not used till 1670.

In Norway they use shoes of a particular construction, consisting of two pieces, and without heels: in which the upper leather fits close to the foot, the sole being joined to it by many plaits or folds.

The shoes or slippers of the Japanese, as we are informed by Professor Thunberg, are made of rice-straw woven, but sometimes for people of distinction of fine slips of ratan. The shoe consists of a sole without upper leather or hind-piece; forwards it is crossed by a strap, of the thickness of one's finger, which is lined with linen; from the tip of the shoe to the strap a cylindrical string is carried, which passes between the great and second toe, and keeps the shoe fast on the foot. As these shoes have no hind-piece, they make a noise, when people walk in them like slippers. When the Japanese travel, their shoes are furnished with three strings made of twisted straw, with which they are tied to the legs and feet, to prevent them from falling off. Some people carry one or more pairs of shoes with them on their journeys, in order to put on new, when the old ones are worn out. When it rains, or the roads are very dirty, these shoes are soon wetted through, and one continually sees a great number of worn out shoes lying on the roads, especially near the brooks, where travellers have changed their shoes after washing their feet. Instead of these, in rainy or dirty weather they wear high wooden clogs, which underneath are hollowed out in the middle, and at top have a band across like a stirrup, and a string for the great toe; so that they can walk without soiling their feet. Some of them have their straw shoes fastened to these wooden clogs. The Japanese never enter their houses with their shoes on; but leave them in the entry, or place them on the bench near the door, and thus are always barefooted in their houses, so as not to dirty their neat mats. During the time that the Dutch live at Japan, when they are sometimes under an obligation of paying visits at the houses of the Japanese, their own rooms at the factory being likewise covered with mats of this kind, they wear, instead of the usual shoes, red, green, or black slippers, which on entering the house they pull off: however, they have stockings on, and shoes made of cotton stuff with buckles in them, which shoes are made at Japan, and can be washed whenever they are dirty. Some have them of black sattin, in order to avoid washing them.

Shoe of an Anchor, a small block of wood, convex on the back, and having a small hole, sufficient to contain, the point of the anchor fluke, on the foreside. It is used to prevent the anchor from tearing or wounding the planks on the ship's bow, when ascending or descending; for which purpose the shoe slides up and down along the bow between the fluke of the anchor and the planks, as being pressed close to the latter by the weight of the former.

To Shoe an Anchor, is to cover the flukes with a broad triangular piece of plank, whose area or superficies is much larger than that of the flukes. It is intended to give the anchor a stronger and surer hold of the bottom in very soft and oozy ground.

Horse-Shoe. See Farriery, Sect. 47.

SHOOTING, in the military art. See Artillery, Gunnery, and Projectiles.

Shooting, in sportsmanship, the killing of game by the gun, with or without the help of dogs. 1 Shooting in sportsman ship.

Under this article we shall lay down all the rules which are necessary to be observed in order to render one accomplished and successful in the art of shooting.

The first thing which the sportsman ought to attend to is the choice of his fowling-piece. Conveniency requires that the barrel be as light as possible, at the same time it ought to possess that degree of strength which will make it not liable to burst. Experience, has proved, that a thin and light barrel, which is of equal thickness in every part of its circumference, is much less liable to burst than one which is considerably thicker and heavier, but which, from being badly filed or bored, is of unequal strength in different places. 2 Directions for choosing a fowling-piece.

It is also of importance to determine of what length the barrel ought to be, in order to acquire that range which the sportsman has occasion for. On this subject we have received the following information from an experienced sportsman. We have, at different times, compared barrels of all the intermediate lengths betwen 28 and 40 inches, and of nearly the same caliber, that is to say, from 22 to 26; and these trials were made

Shooting. made both by firing the pieces from the shoulder, and from a firm block, at an equal distance, and with equal weights of the same powder and of the same shot.

To avoid every possibility of error, the quires of paper at which we fired were fixed against planks instead of being placed against the wall. From these trials frequently repeated, we found that the shot pierced an equal number of sheets, whether it was fired from a barrel of 28, 30, 32, 34, 36, 38, or 40, inches in length. Nay more, we have compared two barrels of the same caliber, but one of them 33, and the other 66 inches long, by repeatedly firing them in the same manner as the others, at different distances, from 45 to 100 paces, and the results have always been the same, *i. e.* the barrel of 33 inches drove its shot through as many sheets of paper as that of 66 did. The conclusion from all this is, that the difference of 10 inches in the length of the barrel, which seems to be more than is ever insisted upon among sportsmen, produces no sensible difference in the range of the piece; and therefore, that every one may please himself in the length of his barrel, without either detriment or advantage to the range.

It may appear as an objection to this, that a duck-gun which is five or six feet long kills at a greater distance than a fowling-peice; but this is not owing to its length, but to its greater weight and thickness, which give it such additional strength, that the shot may be increased, and the charge of powder doubled, trebled, and even quadrupled. But a barrel of five or six feet length would be very inconvenient for fowling. Those who consult the appearance of the piece, lightness, and the ease with which it is managed, will find that a barrel from 32 to 38 inches will answer best.

3 Proper length of the barrel.

4 Caliber.

The next thing to be considered is, of what dimensions the caliber or bore of a fowling-piece ought to be. This matter has been subjected to experiment, and it has been found, that a barrel of 22 or 24, which is the largest caliber usually employed in fowling-pieces, throws its shot as closely as one of the smallest caliber, viz. of 30 or 32 (A).

5 Length and form of the stock.

As to the length and form of the stock, it may be laid down as a principle, that a long stock is preferable to a short one, and at the same time rather more bent than usual; for a long stock fits firmer to the shoulder than a short one, and particularly so when the shooter is accustomed to place his left hand, which principally supports the piece, near to the entrance of the ramrod into the stock.

It is certain, however, that the stock may be so formed as to be better suited to one man than another. For a tall, long-armed man, the stock of a gun should be longer than for one of a less stature and shorter arm. That a straight stock is proper for him who has high shoulders and a short neck; for, if it be much bent, it would be very difficult for him, especially in the quick motion required in shooting at a flying or running object, to place the butt of the gun-stock firmly to the shoulder, the upper part alone would in general be fixed; which would not only raise the muzzle, and consequently shoot high, but make the recoil much more sensibly felt, than if the whole end of the stock were firmly placed on his shoulder. Besides, supposing the shooter to bring the butt home to his shoulder, he would scarcely be able to level his piece at the object. On the contrary, a man with low shoulders, and a long neck, requires a stock much bent; for if it is straight, he will, in the act of lowering his head to that place of the stock at which his cheek should rest in taking aim, feel a constraint which he never experiences, when by the effect of the proper degree of bent, the stock lends him some assistance, and, as it were, meets his aim half way.

Having now described the fowling-piece which has been found to answer best, it will next be proper to give some instructions for the choice of gunpowder, shot, and wadding.

6 Best gunpowder.

The various kinds of gunpowder are well known; but, in the opinion of some experienced sportsmen, Hervey's battle powder is the best. Those who wish to examine the strength of powder, may determine it by drying some of it very well, and then trying how many sheets of paper it will drive the shot through, at the distance of 10 or 12 yards. In this trial we should be careful to employ the same sized shot in each experiment, the quantity both of the shot and the powder being regulated by exact weight; otherwise we cannot, even in this experiment, arrive to any certainty in comparing the strength of different powders, or of the same powder at different times.

7 To be kept dry.

Powder ought to be kept very dry, for every degree of moisture injures it; and if considerable, the saltpetre is dissolved, and the intimate combination of the several ingredients is entirely destroyed. It is observed, that after firing with damp powder the piece becomes very foul, which seems to arise from the diminution of the activity of the fire in the explosion. Flasks of copper or tin are much better for keeping powder in than those made of leather, or than small casks. Their necks ought to be small and well stopped with cork.

8 Size of shot.

The *patent milled shot* is now very generally used, and is reckoned superior to any other. The size of the shot must vary according to the particular species of game which is the object of the sportsman's pursuit, as well as be adapted to the season. In the first month of partridge shooting, N° 1. is most proper; for since at this time the birds spring near at hand, and we seldom fire at more than the distance of 40 paces, if the shooter takes his aim but tolerably well, it is almost impossible for a bird at this distance to escape in the circle which the shot forms.

As hares sit closer, and are thinly covered with fur at this season, they may easily be killed with this shot at 30 or 35 paces. N° 1. is equally proper for shooting snipes or quails. About the beginning of October, when the partridges are stronger, N° 3. is the most proper shot to be used. Many sportsman use no other during the whole season. The directions which have now been given refer only to the patent shot.

We shall now subjoin a table, which will show at one view the number of pellets composing an ounce weight of each sort of shot, the patent and the common, beginning with the smallest size.

PATENT

(A) In speaking of the size of the caliber, we mean by 22 or 24, that so many balls exactly fitting it weigh just one pound; and every caliber is marked in the same way.

PATENT SHOT.

9 Proportion of powder and shot in the charge.

For a fowling piece of a common caliber, which is from 24 to 30 balls to the pound weight, a dram and a quarter, or at most a dram and a half, of good powder; and an ounce, or an ounce and a quarter of shot, is sufficient. But when shot of a larger size is used, such as N° 5. the charge of shot may be increased one-fourth, for the purpose of counterbalancing in some degree what the size of the shot loses in the number of pellets, and also to enable it to garnish the more. For this purpose the sportsman will find a measure marked with the proper gauges very convenient to him. An instrument of this nature has been made by an ingenious artist of London, Egg, of the Haymarket.

A consequence of overloading with shot, is the powder has not sufficient strength to throw it to its proper distance; for if the object fired at be distant, one-half of the pellets composing the charge, by their too great quantity and weight, will strike against each other, and fall by the way; and those which reach the mark will have small force, and will produce but little or no effect.

10 Wadding.

The use of the *wadding* is to carry the shot in a body to a certain distance from the muzzle of the piece. It ought to be of soft and pliable materials. The best kind of wadding, in the opinion of an experienced fowler, is a piece of an old hat; but this cannot be obtained in sufficient quantity. Next to it nothing is better than soft brown paper, which combines suppleness with consistence, moulds itself to the barrel, and never falls to the ground within 12 or 15 paces from the muzzle of the piece. Tow answers very well, and cork has been extolled for possessing the peculiar virtue of increasing the range and closeness of the shot.

The wadding ought to be quite close in the barrel, but not rammed too hard; for if it be rammed too close, or be of a rigid substance, the piece will recoil, and the shot will spread too much. On the other hand, if the wadding be very loose, or is composed of too soft materials, such as wool or cotton, the discharge will not possess proper force.

11 Powder and shot to be slightly rammed down.

In loading a piece, the powder ought to be slightly rammed down by only pressing the ramrod two or three times on the wadding, and not by drawing up the ramrod and then returning it into the barrel with a jerk of the arm several times. For when the powder is violently compressed, some of the grains must be bruised, which will prevent the explosion from being quick, and will spread the shot too wide. In pouring the powder into the barrel, the measure ought to be held so as that the powder may fall most readily to the bottom. That no grains may adhere to the sides of the barrel, the butt end of the piece may be struck against the ground. The shot ought never to be rammed down with force: it is sufficient to strike the butt-end of the gun against the ground as before. Then the wadding is to be put down gently. A sportsman ought never to carry his gun under his arm with the muzzle inclined downwards, for this practice loosens the wadding and charge too much.

12 Directions for loading and firing.

Immediately after the piece is fired it ought to be reloaded; for while the barrel is still warm, there is no danger of any moisture lodging in it to hinder the powder from falling to the bottom. As it is found that the coldness of the barrel, and perhaps the moisture condensed in it, diminishes the force of the powder in the first shot; it is proper to fire off a little powder before the piece is loaded. Some prime before loading, but this is not proper unless the touch-hole be very large. After every discharge the touch-hole ought to be pricked, or a small feather may be inserted to clear away any humidity or foulness that has been contracted.

The sportsman having loaded, his piece, must next prepare to fire. For this purpose he ought to place his hand near the entrance of the ramrod, and at the same time grasp the barrel firmly. The muzzle should be a little elevated, for it is more usual to shoot low than high. This direction ought particularly to be attended to when the object is a little distant; because shot as well as ball only moves a certain distance point blank, when it begins to describe the curve of the parabola.

13 Distance at which the sportsman ought to kill.

Practice soon teaches the sportsman the proper distance at which he should shoot. The distance at which he ought infallibly to kill any kind of game with patent shot, N° 3. provided the aim be well taken, is from 25 to 35 paces for the footed, and from 40 to 45 paces for the winged, game. Beyond this distance even to 50 or 55 paces, both partridges and hares are sometimes killed; but in general the hares are only slightly wounded, and carry away the shot; and the partridges at that distance present so small a surface, that they frequently escape untouched between the spaces of the circle. Yet it does not follow that a partridge may not be killed with N° 3. patent shot at 60 and even 70 paces distance, but then these shots are very rare.

14 How the aim is to be taken.

In shooting at a bird flying, or a hare running across, it is necessary to take aim before the object in proportion to its distance at the time of firing. If a partridge flies across at the distance of 30 or 35 paces, it will be sufficient to aim at the head, or at most but a small space before it. If it be 50, 60, or 70 paces distant, it is then requisite to aim at least half a foot before the head. The same practice ought to be observed in shooting at a hare, rabbit, or fox, when running in a cross direction; at the same time making due allowance for

(B) The reader will observe, that the patent shot has no N° 6. the × being substituted in in its place, and that the numbers do not follow each other in the order of progression: the reason of this we cannot assign.

Shooting.

for the distance and swiftness of the pace. Another thing to be attended to is, that the shooter ought not involuntarily to stop the motion of the arms at the moment of pulling the trigger; for the instant the hand stops in order to fire, however inconsiderable the time be, the bird gets beyond the line of aim, and the shot will miss it. A sportsman ought therefore to accustom has hand while he is taking aim to follow the object. When a hare runs in a straight line from the shooter, he should take his aim between the ears, otherwise he will run the hazard either of missing, or at least not of killing dead, or as it is sometimes called *clean*.

15 Every part of the piece to be kept clean and dry.

A fowling-piece should not be fired more than 20 or 25 times without being washed; a barrel when foul neither shoots so ready, nor carries the shot so far as when clean. The flint, pan, and hammer, should be well wiped after each shot; this contributes greatly to make the piece go off quick, but then it should be done with such expedition, that the barrel may by reloaded whilst warm, for the reasons we have before advanced. The flint should be frequently changed, without waiting until it misses fire, before a new one is put in. Fifteen or eighteen shots, therefore, should only be fired with the same flint; the expence is too trifling to be regarded, and by changing it thus often much vexation will be prevented.

A gun also should never be fired with the prime of the preceding day; it may happen that an old priming will sometimes go off well, but it will more frequently contract moisture and fuze in the firing; then the object will most probably be missed, and that because the piece was not fresh primed.

16 When and how game's to be sought for.

For the information of the young sportsman we shall add a few more general directions. In warm weather he ought to seek for game in plains and open grounds, and in cold weather he may search little hills exposed to the sun, along hedges among heath, in stubbles, and in pastures where there is much furze and fern. The morning is the best time of the day, before the dew is exhaled, and before the game has been disturbed. The colour of the shooter's dress ought to be the same with that of the fields and trees; in summer it ought to be green, in winter a dark grey. He ought to hunt as much as possible with the wind, not only to prevent the game from preceiving the appreach of him and his dog, but also to enable the dog to scent the game at a greater distance.

He should never be discouraged from hunting and ranging the same ground over and over again, especially in places covered with heath, brambles, high grass, or young coppice wood. A hare or rabbit will frequently suffer him to pass several times within a few yards of its form without getting up. He should be still more patient when he has marked partridges into such places, for it often happens, that after the birds have been sprung many times, they lie so dead that they will suffer him almost to tread upon them before they will rise. Pheasants, quails, and woodcocks do the same.

He ought to look carefully about him, never passing a bush or tuft of grass without examination; but he ought never to strike them with the muzzle of his gun for it will loosen his wadding. He who patiently beats and ranges his ground over again, without being discouraged, will always kill the greatest quantity of game; and if he is shooting in company, he will find game where others have passed without discovering any.

When he has fired he should call in his dog, that he may not have the mortification to see game rise which he cannot shoot. When he has killed a bird, instead of being anxious about picking it up, he ought to follow the rest of the covey with his eye till he see them settle.

17 Dogs fit for sport.

Three species of dogs are capable of receiving the proper instruction, and of being trained. These are the smooth pointer, the spaniel, and the rough pointer. The last is a dog with long curled hair, and seems to be a mixed breed of the water-dog and the spaniel. The smooth pointer is active and lively enough in his range, but in general is proper only for an open country.

The greatest part of these dogs are afraid of water, brambles, and thickets; but the spaniel and the rough pointer are easily taught to take the water, even in cold weather, and to range the woods and rough places as well as the plain. Greater dependence may therefore be had on these two last species of dogs than on the smooth pointer.

18 Directions for training a pointer.

The education of a pointer may commence when he is only five or six months old. The only lessons which he can be taught at this time are to *fetch* and *carry* any thing when desired; to come in when he runs far off, and to go behind when he returns; using, in the one case, the words *here, come in*, and in the other *back* or *behind*. It is also necessary at this period to accustom him to be tied up in the kennel or stable; but he ought not at first to be tied too long. He should be let loose in the morning, and fastened again in the evening. When a dog is not early accustomed to be chained, he disturbs every person in the neighbourhood by howling. It is also of importance that the person who is to train him should give him his food.

When the dog has attained the age of 10 or 12 months, he may be carried into the field to be regularly trained. At first he may be allowed to follow his own inclination, and to run after every animal he sees. His indiscriminating eagerness will soon abate, and he will pursue only partridges and hares. He will soon become tired of following partridges in vain, and will content himself after having flushed them to follow them with his eyes. It will be more difficult to prevent him from following hares.

All young dogs are apt to *rake*; that is, to hunt with their noses close to the ground, to follow birds rather by the track than by the wind. But partridges lie much better to dogs that *wind* them, than to those that follow them by the track. The dog that winds the scent approaches the birds by degrees and without disturbing them; but they are immediately alarmed when they see a dog tracing their footsteps. When you preceive that your dog is committing this fault, call to him in an angry tone *hold up*: he will then grow uneasy, and agitated, going first to the one side and then to the other, until the wind brings him the scent of the birds. After finding the *game* four or five times in this way, he will take the wind of himself, and hunt with his nose high. If it be difficult to correct this fault, it will be necessary to put the *puzzle peg* upon him. This is of very simple construction, consisting only of a piece of oak or deal inch board, one foot in length, and an inch and a half in breadth, tapering a little to one end; at the broader end are two holes running longitudinally, through which the collar of the dog is put, and the whole is buckled round his neck; the piece of wood being projected beyond his nose, is then fastened with a piece of leather thong to his under jaw. By this means the peg advancing seven or eight inches beyond his snout, the dog is prevented from putting his nose to the ground and raking.

As soon as the young dog knows his game you must bring him under complete subjection. If he is tractable, this will be easy; but if he is stubborn, it will be necessary to use the *trash cord*, which is a rope or cord of 20 or 25 fathoms in length fastened to his collar. If he refuse to come back when called upon, you must check him smartly with the cord, which will often bring him upon his haunches. But be sure you never call to him except when you are within reach of the cord. After repeating this several times he will not fail to come back when called; he ought then to be caressed, and a bit of bread should be given him. He ought now constantly to be tied up, and never unchained, except when you give him his food, and even then only when he has done something to deserve it.

The next step will be to throw down a piece of bread on the ground, at the same moment taking hold of the dog by the collar, calling out to him, "take heed,—softly." After having held him in this manner for some space of time, say to him, "seize—lay hold." If he is impatient to lay hold of the piece of bread before the signal is given, correct him gently with a small whip. Repeat this lesson until he "takes heed" well, and no longer requires to be held fast to prevent him from laying hold of the bread. When he is well accustomed to this manége, turn the bread with a stick, holding it in the manner you do a fowling-piece, and having done so, cry *seize*. Never suffer the dog to eat either in the house or field without having first made him take heed in this manner.

Then, in order to apply this lesson to the game, fry small pieces of bread in hogs lard, with the dung of partridge; take these in a linen bag into the fields, stubbles, ploughed grounds, and pastures, and there put the pieces in several different places, marking the spots with little cleft pickets of wood, which will be rendered more distinguishable by putting pieces of card in the nicks. This being done, cast off the dog and conduct him to these places, always hunting in the wind. After he has caught the scent of the bread, if he approaches too near, and seems eager to fall upon it, cry to him in a menacing tone, "take heed;" and if he does not stop immediately, correct him with a whip. He will soon comprehend what is required of him, and will stand.

At the next lesson, take your gun charged only with powder, walk gently round the piece of bread once or twice, and fire instead of crying *seize*. The next time of practising this lesson, walk round the bread four or five times, but in a greater circle than before, and continue to do this, until the dog is conquered of his impatience, and will stand without moving until the signal is given him. When he keeps his point well, and stands steady in this lesson, you may carry him to the birds; if he runs in upon them, or barks when they spring up, you must correct him; and if he continues to do so, you must return to the fried bread; but this is seldom necessary.

When the dog has learned by this use of the bread to take heed, he may be carried to the fields with the trash-cord dragging on the ground. When he springs birds for the first time, if he runs after them or barks, check him by calling out to him, *take-heed*. If he point properly, caress him; but you ought never to hunt without the cord until he point staunch.

19 And preventing his running after sheep

If the dog runs after sheep, and it be difficult to cure him, couple him with a ram, and then whip the dog as long as you can follow him. His cries will at first alarm the ram; he will run with all his speed, and drag the dog along with him; but he will at length take courage, turn upon the dog, and butt him severely with his horns. When you think the dog is sufficiently chastised, untie him: he will never run at sheep again.

Having now given a few general instructions concerning the best method of training pointers, we shall subjoin a few observations respecting the most common species of game, the partridge, pheasant, grouse, woodcock, snipe, and wild duck.

20 Observations concerning the partridge.

Partridges pair in the spring, and lay their eggs (generally from 15 to 20) during May and part of June. The young begin to fly about the end of June, and their plumage is complete in the beginning of October. The male has a conspicuous horseshoe upon his breast, and an obtuse spur on the hinder part of the leg, which distinguishes him from the female. He is also rather larger.

When a sportsman is shooting in a country where the birds are thin, and he no longer chooses to range the field for the bare chance of meeting with them, the following method will show him where to find them on another day. In the evening, from sun-set to night-fall, he should post himself in a field, at the foot of a tree or a bush, and there wait until the partridges begin to call or juck, which they always do at that time; not only for the purpose of drawing together when separated, but also when the birds composing the covey are not dispersed. After calling in this manner for some little space of time, the partridges will take to flight; then, if he mark the place where they alight, he may be assured they will lie there the whole night, unless disturbed. Let him return to the same post the next morning by break of day, and there watch a while; being careful to keep his dog in a string, if he is not under perfect command.

As soon as the dawn begins to peep, the partridges will begin to call, and soon afterwards will perform the same manœuvre as on the preceding evening; that is, after having called a while, they will take their flight, and will most commonly settle at a little distance. There in a few minutes they will call again, and sometimes take a second flight, but that will be to no great distance. Then as soon as the sun is risen, and the sportsman can see to shoot, he may cast off his dog and pursue them.

21 Pheasant.

The *pheasant* is of the size of a common dunghill cock, and lays its eggs generally in the woods, the number of which is 10 or 12.

Pheasants are accounted stupid birds; for when they are surprised they will frequently squat down like a rabbit, supposing themselves to be in safety as soon as their heads

heads are concealed; and in this way they will ſometimes ſuffer themſeves to be killed with a ſtick. They love low and moiſt places, and haunt the edges of thoſe pools which are found in woods, as well as the high graſs of marſhes that are near at hand; and above all, places where there are clumps of alders.

22 Grouſe. *Grouſe*, or muir-game, are found in Wales, in the northern counties of England, and in great abundance in Scotland. The chiefly inhabit thoſe mountains and muirs which are covered with heath, and ſeldom deſcend to the low grounds. They fly in companies of four or five braces, and love to frequent moſſy places, particularly in the middle of the day or when the weather is warm. In purſuing this game, when the pointer ſets, and the ſportſman perceives the birds running with their heads erect, he muſt run after them as faſt as he can, in the hope that he may get near enough to ſhoot when they riſe upon the wing; for he may be pretty certain they will not lie well that day. As theſe birds are apt to grow ſoon putrid, they ought to be drawn carefully the inſtant they are ſhot and ſtuffed with any heath, and if the feathers happen to be wetted they muſt be wiped dry.

23 Woodcock. The *woodcock*, is a bird of paſſage; it commonly goes ſouthward about the end of October, and remains until the middle of March. Woodcocks are fatteſt in December and January, but from the end of February they are lean. At their arrival they drop any where, but afterwards take up their reſidence in copſes of nine or ten years growth. They ſeldom, however, ſtay in one place longer than 12 or 15 days. During the day they remain in thoſe parts of the woods where there are void ſpaces or glades, picking up earth-worms and grubs from the fallen leaves. In the evening they go to drink and waſh their bills at pools and ſprings, after which they repair to the open fields and meadows for the night. It is remarkable, that when a woodcock ſprings from a wood to go into the open country, he always endeavours to find ſome glade or opening, which he follows to the boundaries of the wood. At his return he purſues the ſame path a good way, and then turns to the right or left oppoſite to ſome glade, in order to drop into a thick part of the wood, where he may be ſheltered from the wind. He may therefore be watched with advantage in theſe narrow paſſes and little alleys on the edges of woods which lead to a pool or ſpring, or he may be watched in the duſk of the evening near the pools which he frequents.

24 Snipe. The *ſnipe* is a bird of paſſage as well as the woodcock. This bird is ſcarcely worth ſhooting till the froſt commences. In the month of November they begin to grow fat. Snipes, like woodcocks, frequent ſprings, bogs, and marſhy places, and generally fly againſt the wind. The ſlant and croſs ſhots are rather difficult, as the birds are ſmall and fly very quickly. The ſportſman ought to look for them in the direction of the wind; becauſe then they will fly towards him, and preſent a fairer mark.

25 Wild duck. The *wild duck* is alſo a bird of paſſage, and arrives here in great flocks from the northern countries in the beginning of winter. Still, however, a great many remain in our marſhes and fens during the whole year, and breed.

The wild duck differs little in plumage from the tame duck, but is eaſily diſtinguiſhed by its ſize, which is leſs; by the neck, which is more ſlender; by the foot, which is ſmaller; by the nails, which are more black; and above all, by the web of the foot, which is much finer and ſofter to the touch.

In the ſummer ſeaſon, when it is known that a team of young ducks are in a particular piece of water, and juſt beginning to fly, the ſportſman is ſure to find them early in the morning dabbling at the edges of the pool, and amongſt the long graſs, and then he may get very near to them: it is uſual alſo to find them in thoſe places at noon.

In the beginning of autumn almoſt every pool is frequented by teams of wild ducks, which remain there during the day, concealed in the ruſhes. If theſe pools are of ſmall extent, two ſhooters, by going one on each ſide, making a noiſe, and throwing ſtones into the ruſhes, will make them fly up; and they will in this way frequently get ſhots, eſpecially if the pool is not broad, and contracts at one end. But the ſureſt and moſt ſucceſsful way, is to launch a ſmall boat or trow on the pool, and to traverſe the ruſhes by the openings which are found; at the ſame time making as little noiſe as poſſible. In this manner the ducks will ſuffer the ſportſmen to come ſufficiently near them to ſhoot flying; and it often happens that the ducks, after having flown up, only make a circuit, return in a little time, and again alight upon the pool. Then the ſportſmen endeavour a ſecond time to come near them. If ſeveral ſhooters are in company, they ſhould divide, two ſhould go in the boat, whilſt the others ſpread themſelves about the edge of the pool, in order to ſhoot the ducks in their flight. In pools which will not admit a trow, water ſpaniels are abſolutely neceſſary for this ſport.

In winter they may be found on the margins of little pools; and when pools and rivers are frozen up, they muſt be watched for in places where there are ſprings and waters which do not freeze. The ſport is then much more certain, becauſe the ducks are confined to theſe places in order to procure aquatic herbs, which are almoſt their only food at this period.

SHOP-LIFTERS, are thoſe that ſteal goods privately out of ſhops; which, being to the value of 5s. though no perſon be in the ſhop, is felony without the benefit of clergy by the 10 and 11 W. III. c. 23.

SHORE, a place waſhed by the ſea, or by ſome large river.

Count Marſigli divides the ſea-ſhore into three portions: the firſt of which is that track of land which the ſea juſt reaches in ſtorms and high tides, but which it never covers; the ſecond part of the ſhore is that which is covered in high tides and ſtorms, but is dry at other times; and the third is the deſcent from this, which is always covered with water.

The firſt part is only a continuation of the continent, and ſuffers no alteration from the neighbourhood of the ſea, except that it is rendered fit for the growth of ſome plants, and wholly unfit for that of others, by the ſaline ſteams and impregnations: and it is ſcarce to be conceived by any, but thoſe who have obſerved it, how far on land the effects of the ſea reach, ſo as to make the earth proper for plants which will not grow without this influence; there being ſeveral plants frequently found on high hills and dry places, at three, four, and more miles from the ſea, which yet would not grow unleſs in the neighbourhood of it, nor will ever be found elſewhere.

The second part or portion of the shore is much more affected by the sea than the former, being frequently washed and beaten by it. Its productions are rendered salt by the water, and it is covered with sand, or with the fragments of shells in form of sand, and in some places with a tartarous matter deposited from the water; the colour of this whole extent of ground is usually dusky and dull, especially where there are rocks and stones, and these covered with a slimy matter.

The third part of the shore is more affected by the sea than either of the others; and is covered with an uniform crust of the true nature of the bottom of the sea, except that plants and animals have their residence in it, and the decayed parts of these alter it a little.

SHORE (Jane), the celebrated concubine of the licentious king Edward IV. was the wife of Mr Matthew Shore, a goldsmith in Lombard street, London. Kings are seldom unsuccessful in their amorous pursuits; therefore there was nothing wonderful in Mrs Shore's removing from Lombard-street to shine at court as the royal favourite. Historians represent her as extremely beautiful, remarkably cheerful, and of most uncommon generosity. The king, it is said, was no less captivated with her temper than with her person: she never made use of her influence over him to the prejudice of any person; and if ever she importuned him, it was in favour of the unfortunate. After the death of Edward, she attached herself to the lord Hastings; and when Richard III. cut off that nobleman as an obstacle to his ambitious schemes, Jane Shore was arrested as an accomplice, on the ridiculous accusation of witchcraft. This, however, terminated only in a public penance; excepting that Richard rifled her of all her little property: but whatever severity might have been exercised towards her, it appears that she was alive, though sufficiently wretched, under the reign of Henry VIII. when Sir Thomas More saw her poor, old, and shrivelled, without the least trace of her former beauty. Mr Rowe, in his tragedy of Jane Shore, has adopted the popular story related in the old historical ballad, of her perishing by hunger in a ditch where Shoreditch now stands. But Stow assures us that street was so named before her time.

SHORL. See SCHORL.

SHORLING and MORLING, are words to distinguish fells of sheep; *shorling* being the fells after the fleeces are shorn off the sheep's back; and *morling*, the fells flead off after they die or are killed. In some parts of England they understand by a *shorling*, a sheep whose fleece is shorn off; and by a *morling*, a sheep that dies.

SHORT (James), an eminent optician, was born in Edinburgh on the 10th of June, O S. in the year 1710. At ten years of age, having lost his father and mother, and being left in a state of indigence, he was received into Heriot's Hospital, (see *EDINBURGH Public Buildings*, n° 16.), where he soon displayed his mechanical genius in constructing, for himself, little chests, bookcases, and other conveniences, with such tools as fell in his way. At the age of twelve he was removed from the Hospital to the High School, where he showed a considerable taste for classical literature, and generally kept at the head of his forms. In the year 1726 he was entered into the university, where he passed through the usual course of education, and took his master's degree with great applause.

By his friends he was intended for the church; but after attending a course of theological lectures, his mind revolted from a profession which he thought little suited to his talents; and he devoted his whole time to mathematical and mechanical pursuits. He had been fortunate enough to have the celebrated M'Laurin for his preceptor, who having soon discovered the bent of his genius, and made a proper estimate of the extent of his capacity, encouraged him to prosecute those studies in which nature had qualified him to make the greatest figure. Under the eye of that eminent master, he began in 1732 to construct Gregorian telescopes; and, as the professer observed in a letter to Dr Jurin, "by taking care of the figure of his specula, he was enabled to give them larger apertures, and to carry them to greater perfection, than had ever been done before him." See OPTICS, n° 97.)

In the year 1736 Mr Short was called to London, at the desire of Queen Caroline, to give instructions in mathematics to William duke of Cumberland; and immediately on his appointment to that very honourable office, he was elected a fellow of the royal society, and patronised by the earls of Morton and Macclesfield. In the year 1739 he accompained the former of those noble lords to the Orkney isles, where he was employed in adjusting the geography of that part of Scotland; and happy it was for him that he was so employed, as he might otherwise have been involved in a scuffle which took place between the retainers of Sir James Stewart of Barra and the attendants of the earl, in which some of the latter were dangerously wounded.

Mr Short having returned to London, and finally established himself there in the line of his profession, was in 1743 employed by lord Thomas Spencer to make for him a reflector of twelve feet focus, for which he received 600 guineas. He made several other telescopes of the same focal distance with greater improvements and higher magnifiers; and in 1752 finished one for the king of Spain, for which, with its whole apparatus, he received 1200 l. This was the noblest instrument of the kind that had then been constructed, and perhaps it has never yet been surpassed except by the astonishing reflectors of Herschel. See TELESCOPE.

Mr Short was wont to visit the place of his nativity once every two or three years during his residence in London, and in 1766 he visited it for the last time. On the 15th of June 1768 he died, after a very short illness, at Newington Butts, near London, of a mortification in his bowels, and was buried on the 22d of the same month, having completed, within a few days, his fifty-eighth year. He left a fortune of about 20,000 l. of which 15,000 l. was bequeathed to two nephews, and the rest in legacies to his friends. In gratitude for the steady patronage of the earl of Morton, he left to his daughter the Lady Mary Douglas, afterwards countess of Aboyne, 1000 l. and the reversion of his fortune, should his nephews die without issue; but this reversionary legacy the lady, at the desire of her father, generously relinquished by a deed in favour of Mr Short's brother Mr Thomas Short and his children. Mr Short's eminence as an artist is universally known, and we have often heard him spoken of by those who had

known

Short ‖ Shot.

known him from his youth, as a man of virtue and of very amiable manners.

Short-Hand Writing. See Stenography.

Short-jointed, in the manege. A horse is said to be short-jointed that has a short pastern; when this joint, or the pastern is too short, the horse is subject to have his fore legs from the knee to the cornet all in a straight line. Commonly your short-jointed horses do not manege so well as the long-jointed; but out of the manege the short-jointed are the best for travel or fatigue.

Short-Sightedness, a certain defect in vision, by which objects cannot be distinctly seen unless they are very near the eye. See Optics, nº 155.

SHORTFORD, q. d. *fore-close*, an ancient custom in the city of Exeter, when the lord of the fee cannot be answered rent due to him out of his tenement, and no distress can be levied for the same. The lord is then to come to the tenement, and there take a stone, or some other dead thing off the tenement, and bring it before the mayor and bailiff, and this he must do seven quarter days successively; and if on the seventh quarter day the lord is not satisfied of his rent and arrears, then the tenement shall be adjudged to the lord to hold the same a year and a day; and forthwith proclamation is to be made in the court, that if any man claims any title to the said tenement, he must appear within the year and day next following, and satisfy the lord of the said rent and arrears: but if no appearance be made, and the rent not paid, the lord comes again to the court, and prays that, according to the custom, the said tenement be adjudged to him in his demesne as of fee, which is done accordingly, so that the lord hath from thenceforth the said tenement, with the appurtenances to him and his heirs.

SHOT a denomination given to all sorts of balls for fire-arms; those for cannon being of iron, and those for guns, pistols, &c. of lead. See Shooting.

Case Shot formerly consisted of all kinds of old iron, nails, musket-balls, stones &c. used as above.

Shot of a cable, on ship-board, is the splicing of two cables together, that a ship may ride safe in deep waters and in great roads; for a ship will ride easier by one shot of a cable, than by three short cables out ahead.

Grape Shot. See *Grape-Shot*.

Patent milled Shot is thus made: Sheets of lead, whose thickness corresponds with the size of the shot required, are cut into small pieces, or cubes, of the form of a die. A great quantity of these little cubes are put put into a large hollow iron cylinder, which is mounted horizontally and turned by a winch; when by their friction against one another and against the sides of the cylinder, they are rendered perfectly round and very smooth. The other patent shot is cast in moulds, in the same way as bullets are.

Shot-Flaggon, a sort of flaggon somewhat bigger than ordinary, which in some counties, particularly Derbyshire, it is the custom for the host to serve his guests in, after they have drank above a shilling.

Small Shot, or that used for fowling, should be well sized, and of a moderate bigness: for should it be too great, then it flies thin, and scatters too much; or if too small, then it hath not weight and strength to penetrate far, and the bird is apt to fly away with it. In order, therefore, to have it suitable to the occasion, it not being always to be had in every place fit for the purpose, we shall set down the true method of making all sorts and sizes under the name of *mould-shot*. Its principal good properties are to be round and solid.

Shot.

Take any quantity of lead you think fit, and melt it down in an iron vessel; and as it melts keep it stirring with an iron ladle, skimming off all impurities whatsoever that may arise at the top: when it begins to look of a greenish colour, strew on it as much auripigmentum or yellow orpiment, finely powdered, as will lie on a shilling to every 12 or 14 pound of lead; then stirring them together, the orpiment will flame.

The ladle should have a notch on one side of the brim, for more easily pouring out the lead; the ladle must remain in the melted lead, that its heat may be the same with that of the lead, to prevent inconveniences which otherwise might happen by its being either too hot or too cold: then, to try your lead, drop a little of it into water, and if the drops prove round, then the lead is of a proper heat; if otherwise, and the shot have tails, then add more orpiment to increase the heat, till it be found sufficient.

Then take a plate of copper, about the bigness of a trencher, which must be made with a hollowness in the middle, about three inches compass, within which must be bored about 40 holes according to the size of the shot which you intend to cast: the hollow bottom should be thin; but the thicker the brim, the better it will retain the heat. Place this plate on a frame of iron, over a tub or vessel of water, about four inches from the water, and spread burning coals on the plate, to keep the lead melted upon it: then take some lead and pour it gently on the coals on the plate, and it will make its way through the holes into the water, and form itself into shot; do this till all your lead be run through the holes of the plate taking care, by keeping your coals alive, that the lead do not cool, and so stop up the holes.

While you are casting in this manner, another person with another ladle may catch some of the shot, placing the ladle four or five inches underneath the plate in the water, by which means you will see if they are defective, and rectify them.

Your chief care is to keep the lead in a just degree of heat, that it be not so cold as to stop up the holes in your plate, nor so hot as to cause the shot to crack: to remedy the heat, you must refrain working till it is of a proper coolness; and to remedy the coolness of your lead and plate, you must blow your fire; observing, that the cooler your lead is, the larger will be your shot; as the hotter it is, the smaller they will be.

After you have done casting, take them out of the water, and dry them over the fire with a gentle heat, stirring them continually that they do not melt; when dry, you are to separate the great shot from the small, by the help of a sieve made for that purpose, according to their several sizes. But those who would have very large shot, make the lead trickle with a stick out of the ladle into the water, without the plate.

If it stop on the plate, and yet the plate be not too cool, give but the plate a little knock, and it will run again; care must be had that none of your implements be greasy, oily, or the like; and when the shot, being separated, are found too large or too small for your purpose,

pose, or otherwise imperfect, they will serve again at the next operation.

The sizes of common shot for fowling are from N° 1 to 6, and smaller, which is called mustard seed, or dust shot; but N° 5 is small enough for any shooting whatsoever. The N° 1 may be used for wild geese; the N° 2 for ducks, widgeons, and other water-fowl; the N° 3 for pheasants, partridges after the first month, and all the fen-fowl: the N° 4 for partridges, woodcocks, &c.; and the N° 5 for snipes and all the smaller birds.

Tin-Case Shot, in artillery, is formed by putting a great quantity of small iron shot into a cylindrical tin-box called a cannister, that just fits, the bore of the gun. Leaden bullets are sometimes used in the same manner; and it must be observed, that whatever number or sizes of the shots are used, they must weigh with their cases nearly as much as the shot of the piece.

SHOVEL (Sir Claudesly), was born about the year 1650 of parents rather in the lower rank of life. He was put apprentice to a shoemaker; but disliking this profession, he abandoned it a few years after, and went to sea. He was at first a cabin boy with Sir Christopher Mynns, but applying to the study of navigation with indefatigable industry, his skill as a seaman soon raised him above that station.

The corsairs of Tripoli having committed great outrages on the English in the Mediterranean, Sir John Narborough was sent in 1674 to reduce them to reason. As he had received orders to try the effects of negociation before he proceeded to hostilities, he sent Mr Shovel, who was at that time a lieutenant in his fleet to demand satisfaction. The Dey treated him with a great deal of disrespect, and sent him back without an answer. Sir John dispatched him a second time, with orders to remark particularly the situation of things on shore. The behaviour of the Dey was worse than ever. Upon Mr Shovel's return, he informed Sir John that it would be possible, notwithstanding their fortifications, to burn all the ships in the harbour. The boats were accordingly manned, and the command of them given to Lieut. Shovel, who seized the guardship, and burnt four others, without losing a man. This action so terrified the Tripolins, that they sued for peace.—Sir John Narborough gave so favourable an account of this exploit, that Mr Shovel was soon after made captain of the Sapphire, a fifth rate ship.

In the battle of Bantry-Bay, after the revolution, he commanded the Edgar, and, for his gallant behaviour in that action, was soon after knighted by king William. Next year he was employed in transporting an army into Ireland; a service which he performed with so much diligence and dexterity, that the king raised him to the rank of rear-admiral of the blue, and delivered his commission with his own hands. Soon after he was made rear-admiral of the red, and shared the glory of the victory at La Hogue. In 1694, he bombarded Dunkirk. In 1703, he commanded the grand fleet in the Mediterranean, and did every thing in his power to assist the Protestants who were in arms in the Cevennes.

Soon after the battle off Malaga, he was presented by prince George to Queen Anne, who received him graciously, and next year employed him as commander in chief.

In 1705 he commanded the fleet, together with the earls of Peterborough and Monmouth, which was sent into the Mediterranean; and it was owing to him chiefly that Barcelona was taken. After an unsuccessful attempt upon Toulon, he sailed for Gibraltar, and from thence homeward with a part of the fleet. On the 22d of October, at night, his ship, with three others, was cast away on the rocks of Scilly. All on board perished. His body was found by some fishermen on the island of Scilly, who stripped it of a valuable ring, and afterwards buried it. Mr Paxton, the purser of the Arundel, hearing of this, found out the fellows, and obliged them to discover where they had buried the body. He carried it on board his own ship to Portsmouth, from whence it was conveyed to London, and interred with great solemnity in Westminster abbey. A monument was afterwards erected to his memory by the direction of the Queen. He married the widow of his patron, Sir John Narborough, by whom he left two daughters, co-heiresses.

SHOVELER, in ornithology, a species of Anas.

SHOULDER-blade, a bone of the shoulder, of a triangular figure, covering the hind part of the ribs, called by anatomists the *scapula* and *omoplata*. See Anatomy.

SHOUT, clamour, in antiquity, was frequently used on ecclesiastical, civil, and military occasions, as a sign of approbation, and sometimes of indignation.—Thus as Cicero, in an assembly of the people, was exposing the arrogance of L. Antony, who had had the impudence to cause himself to be inscribed the patron of the Romans, the people on hearing this raised a shout to show their indignation. In the ancient military discipline, shouts were used, 1. Upon occasion of the general's making a speech or harangue to the army from his tribunal. This they did in token of their approving what had been proposed. 2. Before an engagement, in order to encourage and spirit their own men, and fill the enemy with dread. This is a practice of great antiquity; besides which, it wants not the authority of reason to support it; for as mankind are endowed with two senses, hearing and seeing, by which fear is raised in the mind, it may be proper to make use of the ear as well as the eye for that purpose. Shouts were also raised in the ancient theatre, when what was acted pleased the spectators. It was usual for those present at the burning of the dead to raise a great shout, and call the dead person by his name before they set fire to the pile.

SHOWER, in meteorology, a cloud condensed into Rain.

SHREWMOUSE. See Sorex.

SHREWSBURY, the capital of Shropshire in England. This town, the metropolis of the county, grew up out of the ruins of Uriconium, anciently a city, now a village called *Wroxeter*, about four miles from it. The Saxons called it *Scrobbes Berig*, from the shrubs that grew about it; and from thence the present name of *Shrewsbury* is supposed to have been formed. It is pleasantly situated upon a hill near the Severn, over which there are two handsome bridges. It was a place of note in the Saxon times; after which it was granted by William the Conqueror, together with the title of *earl* and most of the county, to Roger de Montgomery, who built a castle upon the north side of it, where the Severn, that encompasses it on all other sides, leaves an opening. His son Robert built also a wall across this neck of land, when he revolted from

from Henry I. We learn from doomsday book, that at that time, when a widow of this town married, she paid 20 shillings to the king, and a virgin 10. The abovementioned Roger founded also, and endowed here, a Benedictine monastery and a collegiate church. When old age came upon him, he quitted the world, and spent the rest of his days as a monk in the abbey, and when he died was interred in its church. From the history of this church and monastery, it appears, that ecclesiastical benefices about that time were hereditary. The abbey became so rich afterwards, that the abbot was mitred, and sat in parliament. Besides this abbey, in after times there were there others, viz. a Franciscan, Dominican, and Augustinian, and likewise two collegiate churches; one dedicated to St Chad and the other to St Mary. In the contest between the empress Maud and Stephen, this town, and its governor William Fitz-Allan, sided with the empress. In Henry III.'s time, a part of it was burnt down by the Welch; and in Richard II.'s reign a parliament was held in it. At a place called *Battlefield*, near this town, Henry Percy the younger, surnamed *Hotspur*, was killed in an engagement with Henry IV. against whom he had rebelled. The king afterwards built a chapel upon the spot, and endowed it for the support of two priests to pray for the souls of the slain. Two of Edw. IV.'s sons were born here: namely, Richard, duke of York, whom Perkin Warbeck afterwards personated, and who was murdered in the Tower; and George Plantagenet, who died before his brothers. Here first broke out the sweating-sickness, which carried off great numbers, so suddenly, that those who were seized with it either died or recovered in the space of 24 hours. In the beginning of the civil wars, king Charles I. came hither, and formed an army, with which he marched towards London; but was met by the parliament's forces at Edgehill. He continued here from the 20th of September to the 12th of October, during which time he was joined by prince Rupert, and many of the gentry and nobility of these parts. This town anciently gave title of earl to the Montogmeries, and afterwards to the Talbots, by whom it is still retained. Here is a free grammar-school, with three masters, and several ushers, well endowed by Edward VI. and queen Elizabeth, and not inferior to many colleges in the universities. It has a good library and chapel, and there are several scholarships appropriated to it in the university of Cambridge. Here are also several hospitals, alms-houses, and charity-schools. This town is one of the most flourishing in England, having two great weekly markets for corn, cattle, and provisions; and another for Welch cottons and flannels, of which great quantities are sold. A great trade is carried on with the Welch, who bring their commodities hither, as to the common mart of both nations. The town in large and well-built, and the situation extremely pleasant. There is a very beautiful walk called the *quarry*, between the town walls and the Severn, delightfully shaded with rows of lime-trees, so that it is not inferior to the Mall in St James's Park. The town is also noted for its gallantry and politeness, being full of gentry, for whom there are always balls and assemblies once a-week all the year round.—Here is a fine house and gardens, which belonged to the earl of Bradford; and in the neighbourhood, as Wroxeter, the Roman highway, called Watling-street, may be seen for several miles, where Roman coins are frequently found. In Shrewsbury are 12 incorporated trading companies; and the corporation has a power to try even capital causes of itself, except high treason. It is said that thigh-bones of dead men have been found here a yard long, and teeth three inches round and three long.

SHRIKE. See LANIUS.

SHRIMP, in ichthyology. See CANCER, n° 5. and 6.

SHRINE, in ecclesiastical history, a case or box to hold the relics of some saint.

SHROPSHIRE, a county of England, bounded on the south by Worcestershire, Herefordshire, and Radnorshire; on the north, by Cheshire; on the east, by Staffordshire; on the west, by Montgomeryshire and Denbighshire, in Wales. Its length is between 49 and 50 miles, its breadth about 38, and its circumference about 210. It is an inland county, containing 890,000 acres, 113,680 inhabitants, and 15 hundreds, in which are 170 parishes, and 15 market towns. It makes a part of three bishoprics, viz. Hereford, Coventry and Litchfield, and St Asaph. Some part of it lies on the north, and some on the south side of the Severn. Besides the Severn, it is also watered by the *Temd* or *Tesidiauc*, as it is called in Welch, which flows from the mountains of Radnorshire; and by the Tern, which has its rise and name from one of those pools called *tearnes*, in Staffordshire. All these abound with fish, especially trouts, pikes, lampreys, graylings, carp, and eels. The air, especially upon the hills, with which the county abounds, is very wholesome. There is as great a diversity of soil as in most other counties. On the hills, where it is poor, is very good pasture for sheep; and in the low grounds, were it is very rich, along the Severn in particular, there is plenty of grass for hay and black cattle, with all sorts of corn. No county is better provided with fuel than this, having in it many inexhaustible pits of coal, and also mines of lead and iron. Over most of the coal-pits in this county lies a stratum or layer of blackish porous rock, of which, by grinding and boiling, they make pitch and tar, which are rather better than the common sort for caulking ships, as they do not crack, but always continue close and smooth. Quarries of lime-stone and iron-stone are common enough in the county, and the soil in many places is a reddish clay. As it lies, upon the borders of Wales, it was anciently full of castles and walled towns. On the side next that country there was an almost continued line of castles, to guard the county against the inroads and depredations of the Welch. The borders here, as those between England and Scotland, were called *marches*, and there were certain noblemen intitled *barones marchiæ, marchiones de marchia Walliæ*, "lords of the marches, or marquisses of the marches of Wales," who were vested with a sort of palatine jurisdiction, held courts of justice to determine controversies, and enjoyed many privileges and immunities, the better to enable and encourage them to protect the county against the incursions of the Welch, and to maintain order amongst the borderers; but they often abused their power, and were the greatest of tyrants.

As to the ecclesiastical government of the county, the far greater part, namely, all that belongs to the bishoprics of Hereford, and of Litchfield and Coventry, is is under the jurisdiction and visitation of the archdeacon of Shrewsbury or Salop, and is divided into several deanries.

The Oxford circuit includes in it this county, which sends 12 members to parliament, viz. two for the shire, and two for each of the following towns, Shrewsbury, Ludlow, Wenlock, and Bishop's Castle.

SHROVE-TUESDAY, is the Tuesday after Quinquagesima Sunday, or the day immediately preceding the first of Lent; being so called from the Saxon word *shrive*, which signifies "to confess." Hence Shrove-Tuesday signifies Confession-Tuesday; on which day all the people in every parish throughout England (during the Romish times) were obliged to confess their sins, one by one, to their own parish-priests, in their own parish-churches; and, that this might be done the more regularly, the great bell in every parish was rung at ten o'clock (or perhaps sooner), that it might be heard by all, and that they might attend, according to the custom then in use. And though the Romish religion has now given way to the Protestant religion, the custom of ringing the great bell in the ancient parish-churches, at least in some of them, still remains, and obtains in and about London the name of Pancake bell; perhaps, because after the confession it was customary for the several persons to dine on pancakes or fritters. Most churches, indeed, have rejected that custom of ringing the bell on Shrove-Tuesday; but the usage of dining on pancakes or fritters, and such like provision, still continues.

SHROUDS (*scrud* Sax.), a range of large ropes extending from the mast-heads to the right and left side of the ship, to support the masts, and enable them to carry sail, &c.

The shrouds as well as the sails are denominated from the masts to which they belong. Thus they are the main, fore, and mizen shrouds; the main-top-mast, fore-top-mast, or mizen-top-mast shrouds; and the main-top-gallant, fore-top-gallant or mizen-top-gallant shrouds. The number of shrouds by which a mast is sustained, as well as the size of rope of which they are formed, is always in proportion to the size of the mast and the weight of the sail it is intended to carry.

Bowsprit shrouds are those which support the bowsprit. Bumkin shrouds are those which support the bumkins. Futtock shrouds are shrouds which connect the efforts of the topmast shrouds to the lower shrouds. Bentinck-shrouds are additional shrouds to support the masts in heavy gales. Preventer shrouds are similar to bentinck-shrouds, and are used in bad weather to ease the lower rigging. See MAST and SAIL.

SHRUB, *frutex*, a little, low, dwarf tree, or a woody vegetable, of a size less than a tree; and which, instead of one single stem, frequently from the same root puts forth several sets or stems. See PLANT and TREE. Such are privet, phillyrea, holly, box, honeysuckle, &c. Shrubs and trees put forth in autumn a kind of buttons, or gems, in the axis of the leaves; these buttons are as so many little ova, which, coming to expand by the warmth of the following spring, open into leaves and flowers. By this, together with the height, some distinguish shrubs from *suffrutices*, or under shrubs, which are low bushes, that do not put forth any of these buttons, as sage, thyme, &c.

The two hardiest shrubs we are possessed of are the ivy and box; these stand the severity of our sharpest winters unhurt, while other shrubs perish, and trees have their solid bodies split and torn to pieces. In the hard winter of the year 1683, these two shrubs suffered no injury any where; though the yews and hollies, which are generally supposed very hardy, were that winter in some places killed, and in others stripped of their leaves, and damaged in their bark. Furze-bushes were found to be somewhat hardier than these, but they sometimes perished, at least down to the root. The broom seemed to occupy the next step of hardiness beyond these. This lived where the others died, and where even this died, the juniper shrubs were sometimes found unhurt. This last is the only shrub that approaches to the hardiness of the box and ivy, but even it does not quite come up to them; for while they suffer nothing in whatever manner they are exposed, the juniper, though it bears cold well under the shelter of other trees, yet cannot bear the vicissitudes of heat and cold; insomuch that some juniper shrubs were found half dead and half vigorous: that side which faced the mid-day sun having perished by the successive thawing and freezings of its sap; while that which was not exposed to the vicissitudes of heat had borne the cold perfectly well. Such shrubs as are not hardy enough to defy the winter, but appear half dead in the spring, may often be recovered by Mr Evelyn's method of beating their branches with a slender hazel-wand, to strike off the withered leaves and buds, and give a free passage to the air to the internal parts. Where this fails, the method is to cut them down to the quick, and if no part of the trunk appears in a growing condition, they must be taken off down to the level of the ground. Philosophical Transactions, n° 165.

SHUCKFORD (Samuel), curate of Shelthon in Norfolk, prebendary of Canterbury, and chaplain in ordinary to the king, was a learned Englishman. His manners were those of a philosopher, uncorrupted by the manners of the world. He wrote a history of the world, sacred and profane, to serve as an introduction to Prideaux, in 3 vols 8vo. It is heavily written, but displays a great deal of erudition. His death, which happened in 1756, prevented him from carrying it down to the year 747 before Christ, where Prideaux begins. He wrote also a treatise on the Creation and Fall of Man, to serve as a supplement to the preface to his history.

SHUTTLE, in the manufactures, an instrument used by the weavers, which guides the thread it contains, either of woollen, silk, flax, or other matter, so as to make it form the woofs of stuffs, cloths, linens, ribbands, &c. by throwing the shuttle alternately from left to right, and from right to left, across between the threads on the warp, which are stretched out lengthwise on the loom.

In the middle of the shuttle is a kind of cavity, called the *eye* or *chamber* of the shuttle; wherein is inclosed the spoul, which is a part of the thread destined for the woof; and this is wound on a little tube of paper, rush or other matter.

The ribband-weaver's shuttle is very different from that of most other weavers, though it serves for the same purpose: it is of box, six or seven inches long, one broad, and as much deep; shod with iron at both ends, Sialogogues, Siam.

ends, which terminate in points, and are a little crooked, the one towards the right, and the other towards the left, reprefenting the figure of an ∞ horizontally placed. See Weaving.

SIALOGOGUES, medicines which promote the falivary difcharge.

1 Boundaries and extent.

SIAM Proper by fome called *Upper*, (to diftinguifh it from the *Lower* Siam under which are often included Laos, Cambodia, and Malacca), is bounded on the north by the kingdoms of Pegu and Laos; on the eaft by Cambodia and Cochin-China; on the fouth by Malacca and the bay of Siam; and on the weft by the ocean. But as the opinions of geographers are extremely various concerning the fituation and extent of moft of the inland countries of Afia and Africa, neither the extent not boundaries of Siam are yet accurately known. By fome it is fuppofed to extend 550 miles in length, and 250 miles in breadth; in fome places it is not above 50 miles broad.

2 Weather.

The winds blow here from the fouth upon the coaft of Siam, in March, April, and May, in April the rains begin, in May and June they fall almoft without ceafing. In July, Auguft, and September, the winds blow from the weft, and the rains continuing, the rivers overflow their banks nine or ten miles on each fide, and for more than 150 miles up the ftream. At this time, and more particularly in July, the tides are fo ftrong as to come up the river Menan as far as the city of Siam, which is fituated 60 miles from its mouth; and fometimes as far as Louvo, which is 50 miles higher. The winds blow from the weft and north in October, when the rain ceafes. In November and December the winds blow dry from the north, and the waters being in a few days reduced to their ancient channels, the tides become fo infenfible, that the water is frefh at the mouth of the river. At Siam there is never more than one flood and one ebb in the fpace of 24 hours. In January the winds blow from the eaft, and in February from the eaft and fouth. When the wind is at the eaft, the current fets to the weft; and, on the contrary, when the wind is at weft, the currents run to the eaftward.

As this country is fituated near the tropic, it muft neceffarily be very hot; but yet, as in other places nearly of the fame latitude, when the fun is vertical and fhines with a moft intenfe heat, the inhabitants are fo fkreened by the clouds, and the air is fo refrefhed by a deluge of rain that overflows the plains which the people chiefly inhabit, that the heat is very fupportable. The cooleft wind blows in December and January.

3 Vegetable drouctions.

The vegetable produce of this country is chiefly rice and wheat, befides tropical and a few European fruits. The Siamefe prepare the land for tillage as foon as the earth is fufficiently moiftened by the floods. They plant the rice before the waters rife to any confiderable height, and, as they rife flowly, the rice keeps pace with them, and the ear is always above the water, They reap their corn when the water retires, and fometimes go in boats to cut it while the waters are upon the ground. They alfo fow rice in feveral parts of the kingdom that are not overflowed, and this is thought better tafted, and will keep longer, that the other; but they are forced to fupply thefe fields conftantly with water, while the rice is growing, from bafins and ponds that lie about them.

Siam.

They have no European fruits except oranges, lemons, citrons, and pomegranates. They have bananas, Indian figs, jaques, durions, mangoes mangoftans, tamarinds, ananas, and cocoa-nuts; they have alfo abundance of pepper and fugar-canes. The mountains are covered with trees which make good mafts. The vegetable of greateft ufe in the country is the bamboo, which grows chiefly in marfhy foils, and is often found of a prodigious fize. Cotton trees are found in great numbers; and others that yield *capoc*, a very fine cotton wool, but fo fhort as to be unfit for fpinning, though it anfwers very well for ftuffing mattreffes and pillows.

There is no country where elephants abound more than in Siam, or where they are held in greater veneration. They have a few horfes, fheep, and goats, befides oxen and buffaloes; but they have no good animal food except the flefh of hogs, their beef and mutton being of a very indifferent quality. 4 Animals.

The Siamefe are of fmall ftature, but well proportioned; their complexions are fwarthy; the faces of both the men and women are broad, and their foreheads, fuddenly contracting, terminate in a point, as well as their chins. They have fmall black eyes, hollow jaws, large mouths, and thick pale lips. Their teeth are dyed black, their nofes are fhort and round at the end, and they have large ears, which they think very beautiful. Their hair is thick and lank, and both fexes cut it fo fhort that it reaches no lower than their ears; the women make it ftand up on their foreheads; and the men fhave their beards, 5 Defcription of the inhabitants.

People of diftinction wear a piece of calico tied about their loins, that reaches down to their knees.—The men bring up this cloth between their legs, and tuck it into their girdles, which gives it the appearance of a pair of breeches. They have alfo a muflin fhirt without a collar, with wide fleeves, no wriftbands, and the bofom open. In winter they wear a piece of ftuff or painted linen over their fhoulders, like a mantle, and wind it about their arms. 6 Drefs.

The king of Siam is diftinguifhed by wearing a veft of brocaded fatin, with ftraight fleeves that reach down to the wrift, under fuch a fhirt as we have juft defcribed, and it is unlawful for any fubject to wear this drefs unlefs he receives it from the king. They wear flippers with piked toes turned up, but no ftockings. The king fometimes prefents a military veft to the generals; this is buttoned before, and reaches to the knees; but the fleeves are wide, and come no lower than the elbows. All the retinue of the king, either in war or in hunting, are clothed in red. The king wears a cap in the form of a fugar-loaf, encompaffed by a coronet or circle of precious ftones, and thofe of his officers have a circle of gold, filver, or of vermilion gilt, to diftinguifh their quality; and thefe caps are faftened with a ftay under the chin; they are only worn when they are in the king's prefence, or when they prefide in courts of juftice, and on other extraordinary occafions. They have alfo hats for travelling; but, in general, few people cover their heads notwithftanding the fcorching heat of the fun.

The women alfo wrap a cloth about their middle, which hangs down to the calf of their legs. They cover their breafts with another cloth the ends of which hang over their fhoulders. But they have no garment corresponding to a shift, nor any covering for their heads but their hair. The common people are almost naked, and wear neither shoes nor slippers. The women wear as many rings on the three last fingers of each hand as they can keep on, and bracelets upon their wrists and ancles, with pendants in their ears shaped like a pear.

7 Manners and customs.

For an inferior to stand before a superior is deemed insolent; and therefore slaves and people of inferior rank sit upon their heels, with their heads a little inclined, and their joined hands lifted up to their foreheads. In passing by a superior they bend their bodies, joining their hands, and lifting them towards their heads in proportion to the respect they would show. When an inferior pays a visit, he enters the room stooping, prostrates himself, and then remains upon his knees, sitting upon his heels without speaking a word till he is addressed by the person whom he visits; for he that is of the highest quality must always speak first. If a person of rank visits an inferior, he walks upright, and the master of the house receives him at the door, and waits on him so far when he goes away, but never farther.

The highest part of the house is esteemed the most honourable, and no person cares to lodge under another's feet. The Siamese indeed have but one story, but the rooms rise gradually, and the innermost, which are the highest, are always the most honourable. When the Siamese ambassador came to the French court, some of his retinue were lodged in a floor over the ambassador's head; but they no sooner knew it, than they were struck with the greatest consternation, and ran down tearing their hair at the thoughts of being guilty of what they considered as so unpardonable a crime.

The Siamese never permit such familiarities as are practised by gentlemen in Europe. Easiness of access, and affability to inferiors, is in that part of the world thought a sign of weakness, and yet they take no notice of some things which would be looked upon as ill breeding among us; such as belching in company, which no man endeavours to prevent, or so much as holds his hands before his mouth. They have an extraordinary respect for the head, and it is the greatest affront to stroke or touch that of another person; nay, their cap must not be used with too much familiarity; for when a servant carries it, it is put on a stick and held above his head; and when the master stands still the stick is set down, it having a foot to stand upon. They also show their respect by lifting their hands to the head; and therefore, when they receive a letter from any one for whom they have a great respect, they immediately hold it up to their heads, and sometimes lay it upon their heads.

8 Genius and dispositions.

They are esteemed an ingenious people, and though rather indolent than active in disposition, they are not addicted to the voluptuous vices which often accompany a state of ease, being remarkably chaste and temperate, and even holding drunkenness in abhorrence.—They are, however, accounted insolent towards their inferiors, and equally obsequious to those above them; the latter of which qualities appears to be particularly inculcated from their earliest youth. In general, their behaviour is extremely modest, and they are averse to loquacity. Like the Chinese, they avoid speaking in the first person; and when they address a lady, it is always with some respectful epithet, insinuating personal accomplishments.

No man in this country learns any particular trade, but has a general knowledge of all that are commonly practised, and every one works six months for the king by rotation; at which time, if he should be found perfectly ignorant of the business he is set about, he is doomed to suffer the bastinado. The consequence of this burdensome service is, that no man endeavours to excel in his business, lest he should he obliged to practise it as long as he lives for the benefit of the crown.

9 Government.

The government of this country is extremely oppressive, the king being not only sovereign but proprietor of all the lands, and chief merchant likewise; by which means he monopolizes almost the whole traffic, to the great prejudice of his subjects. The crown is said to be hereditary, but it is often transferred by revolutions, on account of the exorbitant abuse of power in those who exercise the royal office. In his palace, the king is attended by women, who not only prepare his food, and wait on him at table, but even perform the part of valets, and put on all his clothes, except his cap, which is considered as too sacred to be touched by any hand but his own. He shows himself to the people only twice a-year, when he distributes his alms to the talapoins or priests; and on those occasions he always appears in an elevated situation, or mounted on the back of an elephant. When he takes the diversion of hunting, he is as usual attended by his women on foot, preceded by a guard of 200 men, who drive all the people from the roads through which they are to pass; and when the king stops, all his attendants fall upon their faces on the ground.

10 Forms of procei

All their proceedings in law are committed to writing, and none is suffered to exhibit a charge against another, without giving security to prosecute it, and answer the damages if he does not prove the fact against the person accused. When a person intends to prosecute another, he draws up a petition, in which he sets forth his complaint, and presents it to the *nai*, or head of the band to which he belongs, who transmits it to the governor; and if the complaint appears frivolous, the prosecutor, according to the laws of the country, should be punished; but the magistrates generally encourage prosecutions on account of the perquisites they bring to their office.

Every thing being prepared for hearing, the parties are several days called into court, and persuaded to agree; but this appears to be only a matter of form. At length the governor appoints a day for all parties to attend; and being come into court, the clerk reads the process and opinion of his associates, and then the governor examines upon what reasons their opinions are founded; which being explained to him, he proceeds to pass judgment.

11 Trial by ordeal.

When sufficient proofs are wanting, they have recourse to an ordeal trial, like that of our Saxon ancestors: both the plaintiff and the defendant walk upon burning coals, and he that escapes unhurt is adjudged to be in the right: sometimes the proof is made by putting their hands in boiling oil; and in both these trials, by some peculiar management, one or the other is said to remain unhurt. They have also a proof by water,

in,

Siam. in which he who remains longest under it is esteemed innocent. They have another proof, by swallowing pills, which their priests administer with severe imprecations; and the party who keeps them in his stomach without vomiting is thought to be innocent.

All these trials are made in the presence of the magistrates and people; and the king himself frequently directs them to be performed, when crimes come before him by way of appeal. Sometimes he orders both the informer and prisoner to be thrown to the tigers: and the person that escapes by his not being seized upon by those beasts, is sufficiently justified.

12 Religious opinions. They maintain the doctrine of transmigration, believing in a pre-existent state, and that they shall pass into other bodies till they are sufficiently purified to be received into paradise. They believe likewise that the soul is material, but not subject to the touch; that it retains the human figure after quitting a body of that species; and that when it appears to persons with whom it was acquainted, which they suppose it to do, the wounds of one that has been murdered will then be visible. They are of opinion that no man will be eternally punished; that the good, after several transmigrations, will enjoy perpetual happiness; but that those who are not reformed will be doomed to transmigration to all eternity. They believe in the existence of a Supreme Being; but the objects of their adoration are departed saints, whom they consider as mediators or intercessors for them; and to the honour of this numerous tribe both temples and images are erected.

13 Marriage. The men of this country are allowed a plurality of women; but excepting one, who is a wife by contract, the other, are only concubines, and their children deemed incapable of any legal inheritance. Previous to every nuptial contract, an astrologer must be consulted, who calculates the nativity of the parties, and determines whether their union is likely to prove fortunate or otherwise. When his prognostication is favourable, the lover is permitted to visit his mistress three times, at the last of which interviews the relations being present, the marriage portion is paid, when, without any religious ceremony performed, the nuptials are reckoned complete, and soon after consummated. A few days after the talapoin visits the married couple, sprinkles them with water, and repeats a prayer for their prosperity.

14 Funerals. The practice in Siam respecting funerals, is both to burn and bury the dead. The corpse being laid upon the pile, it is suffered to burn till a considerable part is consumed, when the remainder is interred in a burying-place contiguous to some temple. The reason which they give for not burning it entirely to ashes is, that they suppose the deceased to be happy when part of his remains escapes the fire. Instead of a tombstone, they erect a pyramid over the grave. It formerly was the custom to bury treasure with the corpse; but longer experience evincing, that the sacrilegious light in which robbing the graves was considered did not prevent the crime, they now discontinue the ancient practice, and instead of treasure bury only painted papers and other trifles.

15 Rivers. The two principal rivers are the Menan and the Mecon, which rise in the mountains of Tartary, and run to the south; the former passing by the city of Siam, falls into the bay of the same name, in the 13th degree of north latitude; and the latter running through Laos and Cambodia, discharges itself into the Indian ocean in the 9th degree of north latitude. Siam ‖ Siberia.

The capital of the country is Siam, called by the natives *Siyothoya*, situated in the 101st degree of east longitude; and in the 14th degree of north latitude, being almost encompassed by the branches of the river Menan. It is about 10 miles in circumference within the walls, but not a sixth part of the ground is occupied by buildings. In the vacant spaces there are near 300 pagodas or temples, round which are scattered the convents of the priests and their burying-places. The streets of the city are spacious, and some have canals running through them, over which is a great number of bridges. The houses stand on pillars of the bamboo cane, and are built of the same materials; the communication between different families, during the winter season, being carried on as in other tropical countries by means of boats. The grounds belonging to the several tenements are separated by a pallisado, within which the cattle are housed in barns, erected likewise upon pillars, to preserve them from the annual inundation. 16 Description of the capital.

SIBBALDIA, in botany: A genus of plants belonging to the class of pentandria, and to the order of pentagynia; and in the natural system arranged under the 35th order, *Senticosæ*. The calyx is divided into ten segments. The petals are five, and are inserted into the calyx. The styles are attached to the side of the germens. The seeds are five. There are three species belonging to this genus, the *procumbens*, *erecta*, and *altaica*. The procumbens, or reclining sibbaldia, is a native of North Britain, having never been discovered in the southern parts of the island. It grows on Ben-Lomond and Ben-Mor, within a mile of the summit. It is distinguished by a procumbent or trailing stem; by three leaves growing on the top of a small footstalk, which are trifid at the extremity, and somewhat hairy. The flowers are yellow, and blossom in July or August.

SIBENICO, or SEBENICO, the name of a city and province of Dalmatia. The province of Sibenico runs along the sea for more than 30 miles; reaches in some places above 20 miles within land, and comprehends above 70 islands. The city of Sibenico is situated near the mouth of the river Cherca, in the Gulf of Venice, 35 miles north of Spalatto, and 25 south-east of Zara. E. Long. 16° 46′, N. Lat. 44° 17′. It belongs to the Venetians. It is defended on one side by a castle, which held out against repeated attacks of the Turks, and towards the sea by a fort.

SIBERIA, a large country, comprehending the most northerly parts of the Russian empire in Asia. It is bounded on the east by the eastern ocean; on the south by Great Tartary; on the west by Russia; and on the north by the Frozen Ocean. It is about 2000 miles in length from east to west, and 750 miles in breadth from north to south. 1 Boundaries and extent.

At what time this country was first inhabited, or by whom it was peopled, we are entirely ignorant; but writings have been found in it when it was discovered, which shows that it must have been early known to a civilized people†. The Russians, from whom we have received our knowledge, knew nothing of it before the middle of the 16th century. In the reign of John Basilowitz I. indeed, an incursion had been made into Siberia, and 2 Conquered by the Russians.

† Bell's Travels.

and some Tartar tribes subdued: but these conquests were not permanent; and we hear of no further communication between Russia and Siberia till the time of John Basilowitz II. It was opened again at that time by means of one Anika Strogonoff, a Russian merchant who had established some salt-works at a town in the government of Archangel. This man carried on a trade with the inhabitants of the north west parts of Siberia, who brought every year to the town abovementioned large quantities of the finest furs. Thus he acquired a very considerable fortune in a short time; when at last the czar, perceiving the advantages which would accrue to his subjects from having a regular intercourse with Siberia, determined to enlarge the communication which was already opened. With this view he sent into Siberia a body of troops, which crossed the Yugorian mountains, that form part of the north-eastern boundary of Europe. They seem, however, not to have passed the Irtish, or to have penetrated farther than the western branch of the river Oby. Some Tartar tribes were laid under contribution, and a chief named *Yediger* consented to pay an annual tribute of 1000 sables. But this produced no lasting advantage to Russia; for, soon after, Yediger was defeated and taken prisoner by Kutchum Khan, a descendant of the great Jenghiz Khan: and thus the allegiance of this country to Russia was dissolved.

For some time we hear of no further attempts made by the Russians on Siberia; but in 1577 the foundation of a permanent conquest was laid by one Yermac Temofeeff, a Cossack of the Don. This man was at first the head of a party of banditti who infested the Russians in the province of Casan; but being defeated by the troops of the czar, he retired with 6000 of his followers into the interior parts of that province. Continuing his course still eastward, he came to Oral, the most easterly of all the Russian settlements. Here he took up his winter-quarters: but his restless genius did not suffer him to continue for any length of time in a state of inactivity; and from the intelligence he procured concerning the situation of the neighbouring Tartars of Siberia, he turned his arms towards that quarter.

3
State of Siberia at the time of the Russian conquest.

Siberia was at that time partly divided among a number of separate princes, and partly inhabited by the various tribes of independent Tartars. Of the former Kutchum Khan was the most powerful sovereign. His dominions consisted of that tract of country which now forms the south-western part of the province of Tobolsk; and stretched from the banks of the Irtish and Oby to those of the Tobol and Tura. His principal residence was at Sibir, a small fortress upon the river Irtish, not far from the present town of Tobolsk, and of which some ruins are still to be seen. After a course of unremitted fatigue, and a series of victories which almost exceed belief, but of which we have not room to give the detail, our intrepid adventurer dispossessed this prince of his dominions, and seated himself on the throne of Sibir. The number of his followers, however, being greatly reduced, and preceiving he could not depend on the affections of his new subjects, he had recourse to the czar of Muscovy, and made a tender of his new acquisition to that monarch, upon condition of receiving immediate and effectual support. This proposal was received with the greatest satisfaction by the czar; who granted him a pardon for all former offences, and sent him the required succours. Yermac, however, being soon after drowned in an unsuccessful excursion, the Russians began to lose their footing in the country. But fresh reinforcements being seasonably sent, they not only recovered their ground, but pushed their conquests far and wide; wherever they appeared, the Tartars were either reduced or exterminated. New towns were built, and colonies were planted on all sides. Before a century had well elapsed, all that vast tract of country now called *Siberia*, which stretches from the confines of Europe to the Eastern Ocean, and from the Frozen Sea to the present frontiers of China, was annexed to the Russian dominions.

4
Climate.

The air of Siberia is in general, extremely piercing, the cold there being more severe than in any other part of the Russian dominions. The Siberian rivers are frozen very early, and it is late in the spring before the ice is thawed (A). If the corn does not ripen in August, there is little hope of a harvest in this country; and in the province of Jeniseisk it is sometimes covered with snow before the peasants can reap it. To defend the inhabitants against this extreme severity of the climate, Providence seems more liberally to have dealt out to them wood for fuel and furs for clothing. As the winter's day in the north parts of Siberia lasts but a few hours, and the storms and flakes of snow darken the air so much, that the inhabitants, even at noon, cannot see to do any thing without artificial lights, they sleep away the greatest part of that season.

These

(A) M. Gmelin, M. Muller, and two other philosophers, set out in the 1733, to explore the dreary regions of Siberia, by desire of the empress Anne of Russia. After spending nine years and a half in observing every thing that was remarkable, they returned to Petersburgh; and an account of this journey was published by M. Gmelin. In order to examine how far the frost had penetrated into the ground M. Gmelin, on the 18th of June, at a place called Jacutia, ordered the earth to be dug in high ground; they found mould to the depth of 11 inches, under which they met with loose sand to two feet and a half further, after which it grew harder, and at half a foot deeper so hard as scarce to give way to the tools; so that the ground still remained unthawed at not less than the depth of four feet. He made the same experiment in a lower situation; the soil was 10 inches deep, after that a loose sand for two feet and ten inches, below which all was frozen and hard. At Jacutia the inhabitants preserve in cellars several sorts of berries, which they reckon among their dainties, perfectly good and fresh the whole year, though these cellars are scarce a fathom deep. At the fortress of Argun, in little more than 50 degrees of latitude, the inhabitants relate that the earth in many places is never thawed above a yard and half, and that the internal cold of the earth will scarce permit a well to be dug, of which they bring an instance that happened not long before the author's arrival at that place. They designed to sink a well near a house at some

These severe winters are rapidly succeeded by summers, in which the heat is so intense that the Tungusians, who live in the province of Jakutsk, go almost naked. Here is scarcely any night during that season; and towards the Frozen Ocean the sun appears continually above the horizon. The vegetables and fruits of the earth are here extremely quick in their growth.

5 Soil and produce. The whole tract of land beyond the 60th degree of north latitude is a barren waste; for the north part of Siberia yields neither corn nor fruits; though barley is known frequently to come to perfection in Jakutsk.—For this reason, the inhabitants of the northern parts are obliged to live on fish and flesh, but the Russians are supplied with corn from the southern parts of Siberia, where the soil is surprising fertile. The countries beyond the lake of Baikal, especially towards the east, as far as the river Argun, are remarkably fruitful and pleasant; but such is the indolence of the inhabitants, that several fine tracts of land, which would make ample returns to the peasant for cultivating them, lie neglected. The pastures are excellent in this country, which abounds in fine horned cattle, horses, goats, &c. on which the Tartars chiefly depend for subsistence. However, there are several steppes, or barren wastes, and unimprovable tracts in these parts; and not a single fruit tree is to be seen. There is great variety of vegetables, and in several places, particularly near Krasnaia Sloboda, the ground is in a manner overrun with asparagus of an extraordinary height and delicious flavour. The bulbs of the Turkish bundes, and other sorts of lilies, are much used by the Tartars instead of bread. This want of fruit and corn is richly compensated by the great quantities of wild and tame beasts, and fowls, and the infinite variety of fine fish which the country affords (B.)

In that part of Siberia which lies near the Ice Sea, as well as in several other places, are woods of pine, larch, and other trees; besides which, a considerable quantity of wood is thrown ashore by the waves of the Ice Sea; but whence it comes is not yet ascertained.

6 Wild beasts. Besides the wild fowl with which Siberia abounds, there is a prodigious number of quadrupeds, some of which are eatable, and others valuable for their skins or furs.

The animals most valued for their skins are the black fox,

---

some distance from the river Argun, for which purpose they thawed the earth by degrees, and dug some fathoms till they had penetrated a fathom and a half below the level of the river, but found no spring. Hence perhaps we may venture to assert, that besides the great elevation of the earth in these countries, there is another cause, perhaps latent in the earth itself, of this extraordinary cold, naturally suggested to us by considering the cavity of an old silver mine at Argun, which being exhausted of its ore, now serves the inhabitants in summer time for a cellar to keep their provisions: this place is so extremely cold as to preserve flesh meats from putrefaction in the hottest summers, and to sink the mercury in de Lisle's themometer to 146 and 147. The author travelling from Nerschoi towards Argun, to visit the works of the silver mines in that place, August 1735, came to the river Orkija, near Solonischaia, on July the 1st, from whence he arrived a little before dark at the village of Seventua, distant from the river 27 leagues. In this journey he and his fellow travellers for more than four leagues felt it vastly cold soon after they came into a warm air, which continued some leagues; after which the cold returned; and thus are travellers subjected to perpetual vicissitudes of warmth and cold. But it is observed, in general, that the eastern parts are colder than the western, though situated in the same latitude; for as in those eastern regions some tracts of land are much colder than the rest, their effects must be felt by the neighbouring parts. And this conjecture is favoured by the thermometrical observations made with M. de L'Isle's instrument in all parts of Siberia, in which the mercury was depressed to the 226th degree, even in those parts that lie very much towards the south, as in the territory of Selinga, which said degree answers in Fahrenheit's themometer to about 55.5 below 0, but the same thermometer sometimes indicated a much greater cold. At the fort of Kiringa, on Feb. 10. 1738, at 8 in the morning, the mercury stood at 240, which answers nearly to 72 below 0 in Fahrenheit's. On the 23d of the same month it was a degree lower. At the same place, December 11. at three in the afternoon, it stood at 254 in De Lisle's themometer, and very near 90 in Fahrenheit's; on December 29. at four in the afternoon, at 263; on November 27. at noon, at 270; January 9. at 275, which several depressions answer in Fahrenheit's to 99.44, 107.73 and 113.65; on January 5. at 5 in the morning, at 262, an hour after at 281, but at eight o'clock it returned to 250, and there remained till 6 in the afternoon; and then rose by degrees till an hour before midnight, when it stood at 202. So that the greatest depression of the mercury answers in Fahrenheit's thermometer to 120.76 degrees below 0, which is indeed very surprising, and what no body ever imagined before. While this cold lasted at Jenisea, the sparrows and magpies fell to the ground, struck dead, as it were, with the frost, but revived if they were soon brought into a warm room. The author was told also that numbers of wild beasts were found in the woods dead and stiff with the frost, and several travellers had their blood and juices quite frozen in their vessels. The air itself at that time was so dismal, that you would think it changed to ice, as it was a thick fog, which was not dissipable by any exhalations, as in the spring and autumn, and the author could scarce stand three minutes in the porch of his house for the cold.

(B) The oak, though frequent in Russia, it is said, is not to be found through this vast region nearer than the banks of the Argun and Amur, in the dominions of China. The white poplar, the aspen, the black poplar, the common sallow, and several species of the willow, are very common. The Norway and silver fir form great forests; but the former does not grow beyond the 60th degree of north latitude, and the latter not beyond 58 degrees. To this dreary region of Siberia, Europe is indebted for that excellent species of oats called *Avena Sibirica*, and our gardens are enlivened with the gay and brilliant flowers brought from the same country.

Siberia. fox, the sable, the hyæna, the ermine, the squirrel, the beaver, and the lynx. The skin of a real black fox is more esteemed than even that of a sable. In the country near the Frozen Ocean are also blue and white foxes. The finest sables come from Nertshinsk and Jakutsk, the inhabitants of which places catch them in the mountains of Stannowoi Krebet. The tributary nations were formerly obliged to pay their taxes in the skins of foxes and sables only. But now the skins of squirrels, bears, rein-deer, &c. and sometimes money, are received by way of tribute; and this not only from those who live near the Lena, but also in the governments of Ilinsk, Irkutzk, Selinginsk, and Nertshinsk. When the Tartars first became tributary to Russia, they brought their furs indiscriminately as they caught them, and among them were often sables of extraordinary value; and formerly, if any trader brought with him an iron kettle, they gave him in exchange for it as many sables as it would hold. But they are now better acquainted with their value. They sell their sables to smugglers at a very high price, and pay only a ruble instead of a skin to the revenue officers, who now receive more ready money than sables, by way of tribute. The subjects plead the scarcity of furs, and indeed not without some appearance of truth.

7 Minerals. Siberia has still other and more valuable treasures than those we have yet mentioned. The silver mines of Argun are extremely rich; the silver they produce yields some gold, and both of these are found among the copper ore of Koliwan. This country is also particularly rich in copper and iron ore. The former lies even upon the surface of the earth; and considerable mines of it are found in the mountains of Pictow, Koliwan, Plofkau, Woskeresensk, Kuswi, Alepaik, and several others, and in the government of Krasnoiarsk (c). Iron is still more plentiful in all these places, and very good; but that of Kamenski is reckoned the best. Several hundred thousand puds of these metals are annually exported from the smelting houses, which belong partly to the crown, and partly to private persons. Most of them lie in the government of Catharinenburg. The Tartars also extract a great quantity of iron from the ore.

8 Precious stones. The topazes of Siberia have a fine lustre, and in open sandy places, near the river Argun, as well as on the banks of other rivers and lakes, are found single small pieces of agate. Here are also cornelians and green jasper with red veins. The latter is chiefly met with in the deserts of Gobiskoi.

9 Marienglas. The famous marienglas, or lapis specularis, great quantities of which are dug up in Siberia, is by some called Muscovy or Russian glass; and by others, though with less propriety, isinglass. It is a particular species of transparent stone, lying in strata like so many sheets of paper. The matrix, or stone in which it is found, is partly a light yellow quartz, or marcassia, and partly a brown indurated fluid; and this stone contains in it all the species of the marienglas. To render the marienglas fit for use, it is split with a thin two-edged knife; but care is taken that the laminæ be not too thin. It is used for windows and lanterns all over Siberia, and indeed in every part of the Russian empire, and looks very beautiful; its lustre and clearness surpassing that of the finest glass, to which it is particularly preferable for windows and lanterns of ships, as it will stand the explosion of cannon. It is found in the greatest plenty near the river Witim.

10 Magness. Siberia affords magnets of an extraordinary size, and even whole mountains of loadstone. Pit-coal is also dug up in the northern parts of this country. The kamennoe maslo, a yellowish kind of alum, unctuous and smooth to the touch, like tophus, is found in the mountains of Krasnoiarsk, Ural, Altaish, Jenisea, Baikal, Bargusik, Lena, and several others in Siberia.

11 Salt lakes and springs. In this country are not only a great number of fresh water lakes, but likewise several whose waters are salt; and these reciprocally change their nature, the salt sometimes becoming fresh, and the fresh changing into saline. Some lakes also dry up, and others appear where none were ever seen before. The salt lake of Yamusha, in the province of Tobolsk, is the most remarkable of all, for it contains a salt as white as snow, consisting entirely of cubic crystals. One finds also in Siberia saline springs, salt water brooks, and a hill of salt.

12 Curiosities. Siberia affords many other things which deserve notice. That useful root called rhubarb grows in vast quantities near the city of Seleginsk. The curious mamuth's bones and horns, as they are called, which are found along the banks of the Oby, Jenesei, Lena, and Irtish, are unquestionably the teeth and bones of elephants. But whether these elephants teeth and bones were conveyed to these northern regions by the general deluge, or by any other inundation, and were by degrees covered with earth, is a point which might lead us into long and very fruitless disquisitions; we shall therefore only observe, that such bones have likewise been found in Russia, and even in several parts of Germany. A kind of bones of a still larger size than these have also been dug up in Siberia, and seem to have belonged to an animal of the ox kind. The horn of the whale called *narwhal* has been found in the earth near the rivers Indigirka and Anadir; and the teeth of another species of whales, called Wolross, about Anadirskoi. The latter are larger than the common sort, which are brought from Greenland, Archangel, and Kola.

13 Mountains. The chain of Siberian mountains reaches from that of Werchoturie towards the south as far as the neighbourhood of the city of Orienburg, in a continued ridge, under the name of the Uralian mountains; but from thence it alters its direction westward. These mountains are a kind of boundary between Russia Proper and Siberia. Another chain of hills divides Siberia from the country of the Calmucks and Mongalians.—These mountains, between the rivers Irtish and Oby, are called the Altaic or Golden Mountains, which name they afterwards lose, particularly between the river Jenesei and the Baikal lake, where they are called the Sayanian mountains.

The

(c) The copper mines of Koliwan, from which gold and silver are extracted, employ above 40,000 people. The silver mines of Nertshinsk, beyond lake Baikal, employ above 14,000. The whole revenue arising from these mines, according to Mr Coxe, is not less than L. 697,182,13 s.

14 Inhabitants. The inhabitants of Siberia conſiſt of the Aborigines or ancient inhabitants, the Tartars, and Ruſſians.

Some of theſe nations have no other religion but that of nature; others are Pagans or Mahometans, and ſome of them have been converted to Chriſtianity, or rather only baptiſed by the Ruſſian miſſionaries.

SIBTHORPIA, in botany: A genus of plants belonging to the claſs of didynamia, and to the order of angioſpermia; and in the natural ſyſtem claſſed with thoſe the order of which is doubtful. The calyx is ſpreading, and divided into five parts, almoſt to the baſe. The corolla is divided into five parts in the ſame manner, which are rounded, equal, ſpreading, and of the length of the calyx. The ſtamina grow in pairs at a diſtance from each other. The capſule is compreſſed, orbicular, bilocular, the partition being tranſverſe.—There are two ſpecies, the *europæa* and *evolvulacea*. The *europæa*, or baſtard money-wort, is a native of South Britain. The ſtems of it are ſlender, and creeping. The leaves are ſmall, round, and notched. The flowers grow under the wings of the leaves, are ſmall, and of a pale red colour. It bloſſoms from July to September, and is found in Cornwall on the banks of rivulets.

SIBYLS, in pagan antiquity, certain women ſaid to have been endowed with a prophetic ſpirit, and to have delivered oracles, ſhowing the fates and revolutions of kingdoms. Their number is unknown. Plato ſpeaks of one, others of two, Pliny of three, Ælian of four, and Varro of ten; an opinion which is univerſally adopted by the learned. Theſe ten Sibyls generally reſided in the following places, Perſia, Libya, Delphi, Cumæ in Italy, Erythræa, Samos, Cumæ in Æolia, Marpeſſa on the Helleſpont, Ancyra in Phrygia, and Tiburtis. The moſt celebrated of the Sibyls is that of Cumæ in Italy, whom ſome have called by the different names of Amalthæa, Demiphile, Herophile, Daphne, Manto, Phemonoe, and Deiphobe. It is ſaid, that Apollo became enamoured of her, and that to make her ſenſible of his paſſion he offered to give her whatever ſhe ſhould aſk. The Sibyl demanded to live as many years as ſhe had grains of ſand in her hand, but unfortunately forgot to aſk for the enjoyment of the health, vigour, and bloom, of which ſhe was then in poſſeſſion. The god granted her requeſt, but ſhe refuſed to gratify the paſſion of her lover, though he offered her perpetual youth and beauty. Some time after ſhe became old and decrepit, her form decayed, melancholy paleneſs and haggard looks ſucceeded to bloom and cheerfulneſs. She had already lived about 700 years when Æneas came to Italy, and, as ſome have imagined, ſhe had three centuries more to live before her years were as numerous as the grains of ſand which ſhe had in her hand. She gave Æneas inſtructions how to find his father in the infernal regions, and even conducted him to the entrance of hell. It was uſual for the Sibyl to write her prophecies on leaves, which ſhe placed at the entrance of her cave; and it required particular care in ſuch as conſulted her to take up theſe leaves before they were diſperſed by the wind, as their meaning then became incomprehenſible. According to the moſt authentic hiſtorians of the Roman republic, one of the Sibyls came to the palace of Tarquin the Second, with nine volumes, which ſhe offered to ſell for a very high price. The monarch diſregarded her, and ſhe immediately diſappeared, and ſoon after returned, when ſhe had burned three of the volumes. She aſked the ſame price for the remaining ſix books; and when Tarquin refuſed to buy them, ſhe burned three more, and ſtill perſiſted in demanding the ſame ſum of money for the three that were left.—This extraordinary behaviour aſtoniſhed Tarquin; he bought the books, and the Sibyl inſtantly vaniſhed, and never after appeared to the world. Theſe books were preſerved with great care by the monarch, and called the Sibyline verſes. A college of prieſts was appointed to have the care of them; and ſuch reverence did the Romans entertain for theſe prophetic books, that they were conſulted with the greateſt ſolemnity, and only when the ſtate ſeemed to be in danger. When the capitol was burnt in the troubles of Sylla, the Sibylline verſes which were depoſited there periſhed in the conflagration; and to repair the loſs which the republic ſeemed to have ſuſtained, commiſſioners were immediately ſent to different parts of Greece to collect whatever verſes could be found of the inſpired writings of the Sibyls. The fate of theſe Sibylline verſes which were collected after the conflagration of the capitol is unknown. There are now many Sibylline verſes extant, but they are reckoned univerſally ſpurious; and it is evident that they were compoſed in the ſecond century by ſome of the followers of Chriſtianity, who wiſhed to convince the heathens of their error, by aſſiſting the cauſe of truth with the arms of pious artifice.

Lempriere's Dictionary.

SICERA, a name given to any inebriating liquor by the Helleniſtic Jews. St Chryſoſtom, Theodoret, and Theophilus of Antioch, who were Syrians, and who therefore ought to know the ſignification and nature of "ſicera," aſſure us, that it properly ſignifies palm-wine. Pliny acknowledges, that the wine of the palm tree was very well known through all the eaſt and that it was made by taking a buſhel of the dates of the palm tree, and throwing them into three gallons of water; then ſqueezing out the juice, it would intoxicate like wine. The wine of the palm tree is white: when it is drunk new, it has the taſte of the cocoa, and is ſweet as honey. When it is kept longer, it grows ſtrong, and intoxicates. After long keeping, it becomes vinegar.

SICILIAN, in muſic, denotes a kind of gay ſprightly air, or dance, probably invented in Sicily, ſomewhat of the nature of an Engliſh jig; uſually marked with the characters $\frac{6}{8}$, or $\frac{12}{8}$. It conſiſts of two ſtrains; the firſt of four, and the ſecond of eight, bars or meaſures.

SICILY, is a large iſland in the Mediterranean Sea, adjoining to the ſouthern extremity of Italy, and extends from latitude 36° 25′ to latitude 38° 25′, and from longitude 12° 50′ to longitude 16° 5′ eaſt from London. Its greateſt length 210 miles, breadth 133, circumference 600; its form triangular, the three angles being the promontories of Pelorum, Pachynum, and Lilybæum, or as they are now called the Faro, Capo Paſſaro, and Capo Boco. It is divided from Italy by the ſtraits of Meſſina, reaching from the Tower of Faro, which is the moſt northerly part of the iſland, to the *Capo dell' Armi*, or the Cape of Arms, the moſt ſouthern part of Calabria. Theſe ſtraits, by the Latins called *Fretum Siculum*, by the Italians *Il Fare di Meſſina*, and by us the *Fare of Meſſina*, are between 12 and 15 miles over in the broadeſt places, and in the narroweſt about a mile and an half; inſomuch that when 1 Boundaries and extent.

Meſſina

Sicily. Messina was taken by the Carthaginians, many of the inhabitants are said to have saved themselves by swimming to the opposite coasts of Italy. Hence has arisen an opinion that the island of Sicily was originally joined to the continent, but afterwards separated by an earthquake or some other natural cause. This separation, however, is reckoned by the most judicious among the ancients to be fabulous; and they content themselves with speaking of it as a thing said to have happened.

2 History during the fabulous ages.

Anciently this island was called *Sicania, Sicilia,* and *Trinacria* or *Triquetra;* the two former it had from the Sicani and Siculi, who peopled a considerable part of the country; the two latter from its triangular figure. Its first inhabitants, according to the most respectable ancient authors, were the Cyclopes and Læstrigones, who are said to have settled in the countries adjoining to Mount Etna; but of their origin we know nothing, except what is related by the poets. After them came the Sicani, who called themselves the original inhabitants of the country; but several ancient historians inform us that they came from a country in Spain watered by the river Siconus. Diodorus, however, is of opinion, that the Sicani were the most ancient inhabitants of this island. He tells us that they were in possession of the whole, and applied themselves to cultivate and improve the ground in the neighbourhood of Etna, which was the most fruitful part of the island: they built several small towns and villages on the hills to secure themselves against thieves and robbers; and were governed, not by one prince, but each city and district by its own king. Thus they lived till Etna began to throw out flames, and forced them to retire to the western parts of the island, which they continued to inhabit in the time of Thucydides. Some Trojans, after the destruction of their city, landed in the island, settled among the Sicani, and built the cities of Eryx and Egesta, uniting themselves with them, and taking the general name of Elymi or Elymæi. They were afterwards joined by some Phocenses, who settled here on their return from the siege of Troy.

After the Sicani had for many ages enjoyed an undisturbed possession of the whole of Sicily, or such parts of it as they chose to inhabit, they were visited by the Siculi, who were the ancient inhabitants of Ausonia, properly so called; but being driven out from thence by the Opici, they took refuge in the island of Sicily. Not being contented with the narrow bounds allowed them by the Sicani, they began to encroach upon their neighbours; upon which a war ensuing, the Sicani were utterly defeated, and confined to a corner of the island, the name of which was now changed from *Sicania* into that of *Sicilia*.

About 300 years after the arrival of the Siculi, the island first began to be known to the Greeks, who established various colonies, and built many cities in different parts of the island; and it is only from the time of their arrival that we have any history of the island. The first of the Greeks that came into Sicily were the Chalcidians of Eubœa, under the conduct of Thucles, who built Naxus, and a famous altar of Apollo, which, as Thucydides tells us, was still standing in his time without the city. The year after, which was, according to Dionysius Halicarnassensis, the third of the 17th Olympiad, Archias the Corinthian, one of the Heraclidæ, laid the foundations of Syracuse. Seven years after, a new colony of Chalcidians founded Leontini and Catana, after having driven out the Siculi, who inhabited that tract. About the same time Lamis, with a colony from Megara, a city of Achaia, settled on the river Pantacius, at a place called *Trotilum,* where his adventurers lived some time in common with the Chalcidians of Leontini; but, being driven from thence by the Leontines, he built the city of Thapsus, where he died. Upon his death, the colony left Thapsus; and under the conduct of Hyblon king of the Siculi, founded Megara Hyblæa, where they resided 245 years, till they were driven out by Gelon tyrant of Syracuse. During their abode at Megara, they sent one Pamilus, who was come from Megara in Achaia, their original city, to build Selinus. This city was founded about 100 years after the foundation of Megara. Antiphemus and Entimus, the former a Rhodian, the other a Cretan, led each a colony of their countrymen, and jointly built the city of Gela on a river of the same name, establishing in their new settlement the Doric customs, about 45 years after the founding of Syracuse. The inhabitants of Gela founded Arigentum 108 years after their arrival in Sicily, and introduced the same customs there. A few years after, Zancle was built by the pirates of Cumæ in Italy; but chiefly peopled by the Chalcidians, Samians, and Ionians, who chose rather to seek new settlements than live under the Persian yoke. Some time after, Anaxales, tyrant of Rhegium, drove out the ancient proprietors; and, dividing his lands amongst his followers, called the city *Messana* or *Messene,* which was the name of his native city in Peloponnesus. The city of Himera was founded by the Zancleans under the direction of Euclides, Simus, and Sacon; but peopled by the Chalcidians and some Syracusan exiles, who had been driven out by the contrary faction.

The Syracusans built Acræ, Chasmenæ, and Camarina; the first 70 years, the second 90, and the third 135, after the foundation of their own city. This is the account which Thucydides, a most judicious and exact writer, gives us of the various nations, whether Greeks or Barbarians, who settled in Sicily. Strabo counts among the ancient inhabitants of Sicily the Morgetes, who being driven out of Italy by the Oenotrians, settled in that part of the island where the ancient city of Morgantium stood. The Campani, who assumed the name of *Mamertini,* that is, *invincible warriors,* and the Carthaginians, who settled very early in Sicily, ought likewise to be counted among the ancient inhabitants of the island.

Before this period the history of Sicily is blended with fables like the early history of almost every other country. After the settlement of the Greeks in the island, its various revolutions have been traced from their several sources by many writers; but by none with greater accuracy than Mr Swinburne. From his account of his Travels in the Two Sicilies, we have therefore taken the following concise history of this kingdom, which will at once gratify such of our readers as interest themselves in the fate of a generous people who long struggled in vain for freedom; and at the same time afford them a specimen of the entertainment they may receive from the very elegant work of the author.

"Ari-

Sicily.

Swinburne's Travels in the Two Sicilies, vol. ii. p. 176.

3 Grecian colonies in Sicily.

"Aristocracy prevailed at first in the Greek settlements, but soon made way for tyranny; which in its turn was expelled by democracy. One of the earliest destroyers of common liberty was Phalaris of Agrigentum, who reigned 600 years before Christ: his example was contagious; a legion of tyrants sprang up, and not a commonwealth in the island escaped the lash of an usurper. Syracuse was most oppressed and torn to pieces by dissention; as its wealth and preponderance in the general scale held out a greater temptation than other cities to the ambition of wicked men. It requires the combined testimony of historians to enforce our belief of its wonderful prosperity, and the no less extraordinary tyranny of some of its sovereigns. These Grecian colonies attained to such excellence in arts and sciences as emboldened them frequently to vie with the learned and ingenious in the mother country; nay, often enabled them to bear away the palm of victory: there needs no stronger proof of their literary merits than a bare recital of the names of Archimedes, Theocritus Gorgias, and Charondas.

4 Carthaginians conquer great part of it.

"But the Sicilian Greeks were not destined to enjoy the sweets of their situation without molestation. Very soon after their arrival, the inhabitants of the neighbouring coast of Africa began to aspire to a share of Sicily. Carthage sent large bodies of forces at different times to establish their power in the island, and about 500 years before the Christian era had made themselves masters of all the western parts of it. The Siculi retained possession of the midland country, and the southern and eastern coasts were inhabited by the Greeks.

5 Gelo chosen king.

"About that time Gelo was chosen prince of Syracuse on account of his virtues, which grew still more conspicuous after his exaltation: had the example he set been followed by his successors, the advantages of freedom would never have been known or wished for by the Syracusans. The Carthaginians found in him a vigorous opponent to their project of enslaving Sicily, a project invariably pursued but never accomplished.

6 Is succeeded by Hiero.

"Hiero succeeded his brother Gelo, and, contrary to the usual progression, began his reign by a display of bad qualities. Sensible of his error, and improved by experience, he afterwards adopted more equitable measures. At his death the Syracusans threw off the yoke, and for sixty years revelled in all the joys of freedom. Their peace was, however, disturbed by the Athenians and the Carthaginians. The latter plundered Agrigentum, and threatened ruin to the rest of the Grecian states; but a treaty of peace averted that storm. The Athenians, under pretence of supporting their allies the people of Segesta, but in reality from a thirst of dominion, invested Syracuse with a formidable land and naval armament under the command of Nicias; in consequence of a rash indigested plan, ill conducted attacks, and inadequate supplies, their whole host was cut to pieces or led away into captivity.

7 Dionysius the elder and younger.

"Syracuse had scarce time to breathe after her victory ere intestine wars broke out, and raised Dionysius to supreme command. Avarice, despotism, and cruelty, marked every day of his reign; but his military enterprises were crowned with constant success. He died in peace, and bequeathed a powerful sovereignty to a son of his name tainted with the same and worse vices, but not endowed with equal capacity and martial ability; in such hands the rod of tyranny ceased to be formidable, and the tyrant was driven out of Sicily by the patriotic party; but matters were not sufficiently settled for popular government, and Dionysius resumed the sceptre for a while, till Timoleon forced him into perpetual exile."

8 Agathocles the tyrant.

Liberty seemed now to be established on a permanent basis; but in Syracuse such prospects always proved illusory. Agathocles, a tyrant more inhuman than any preceding usurper, seized the throne, and deluged the country with blood. He was involved in a perilous contest with the Carthaginians, who obtained many advantages over him, drove his troops from port to port, and at last blocked up his capital. In this desperate situation, when all foreign helps were precluded, and hardly a resource remained at home, the genius of Agathocles compassed his deliverance by a plan that was imitated among the ancients by Hannibal, and among the moderns by the famous Cortes. He embarked with the flower of his army; forced his way through innumerable obstacles; landed in Africa; and, having burnt his fleet, routed the Carthaginians in a pitched battle, and laid their territory waste. Carthage seemed to be on the brink of ruin, and that hour might have marked her downfal had the Sicilian host been composed of patriotic soldiers, and not of ungovernable assassins; discord pervaded the victorious camp, murder and riot ensued; and the tyrant, after beholding his children and friends butchered before his face, escaped to Sicily, to meet a death as tragical as his crimes deserved.

9 Pyrrhus king of Epirus deceives the Sicilians.

Anarchy now raged throughout the island, and every faction was reduced to the necessity of calling in the assistance of foreign powers; among whom Pyrrhus king of Epirus took the lead, and reduced all parties to some degree of order and obedience. But ambition soon prompted him to invade those rights which he came to defend; he cast off the mask, and made Sicily feel under his sway as heavy a hand as that of its former oppressors; but the Sicilians soon assumed courage and strength enough to drive him out of the island.

10 The Mamertini surprise Messina, and are assisted by the Romans.

About this period the Mamertini, whom Mr Swinburne indignantly styles a crew of miscreants, surprised Messina, and, after a general massacre of the citizens, established a republican from of government. Their commonwealth became so troublesome a neighbour to the Greeks, that Hiero II. who had been raised to the chief command at Syracuse in consideration of his superior wisdom and warlike talents, found himself necessitated to form a league with Carthage, in order to destroy this nest of villains. In their distress the Mamertini implored the assistance of Rome, though the senate had recently punished with exemplary severity one of their own legions for a similar outrage committed at Rhegium. The virtue of the Romans gave way to the temptation, and the desire of extending their empire beyond the limits of Italy, cast a veil over every odious circumstance attending this alliance. A Roman army crossed the Faro, relieved Messina, defeated the Carthaginians, and humbled Hiero into an ally of the republic.

11 Which gives rise to the first Punic war.

Thus began the first Punic war, which was carried on for many years in Sicily with various success. The genius of Hamilcar Barcas supported the African cause under numberless disappointments, and the repeated overthrows of his colleagues; at last, finding his exertions

Sicily. tions ineffectual, he advised the Carthaginian rulers to purchase peace at the price of Sicily. Such a treaty was not likely to be observed longer than want of strength should curb the animosity of the vanquished party: when their vigour was recruited, Hannibal son of Hamilcar easily persuaded them to resume the contest, and for 16 years waged war in the heart of the Roman territories. Meanwhile Hiero conducted himself with so much prudence, that he retained the friendship of both parties, and preserved his portion of Sicily in perfect tranquillity. He died in extreme old age, beloved and respected both at home and abroad.

12 The second Punic war raised by Hannibal.

His grandson Hieronymus, forsaking this happy line of politics, and contracting an alliance with Carthage, fell an early victim to the troubles which his own folly had excited. Once more, and for the last time, the Syracusans found themselves in possession of their independence: but the times were no longer suited to such a system; dissensions gained head, and distracted the public councils. Carthage could not support them, or prevent Marcellus from undertaking the siege of Syracuse, immortalized by the mechanical efforts of Archimedes, and the immensity of the plunder. See SYRACUSE.

13 Sicily conquered by the Saracens, and afterwards by the Normans.

The Sicilians after this relinquished all martial ideas and during a long series of generations turned their attention solely to the arts of peace and the labours of agriculture. Their position in the centre of the Roman empire preserved them both from civil and foreign foes, except in two instances of a servile war. The rapacity of their governors was a more constant and insupportable evil. In this state of apathy and opulence Sicily remained down to the 7th century of our era, when the Saracens began to disturb its tranquillity. The barbarous nations of the north had before invaded and ravaged its coasts, but had not long kept possession. The Saracens were more fortunate. In 827 they availed themselves of quarrels among the Sicilians to subdue the country. Palermo was chosen for their capital, and the standard of Mahomet triumphed about 200 years. In 1038 George Maniaces was sent by the Greek emperor with a great army to attack Sicily. He made good his landing, and pushed his conquests with vigour: his success arose from the valour of some Norman troops, which were at that time unemployed and ready to sell their services to the best bidder. Maniaces repaid them with ingratitude; and by his absurd conduct gave the Mussulmen time to breathe, and the Normans a pretext and opportunity of invading the Imperial dominions in Italy. Robert and Roger of Hauteville afterwards conquered Sicily on their own account, not as mercenaries; for having substantially settled their power on the continent, they turned their arms against this island in obedience to the dictates of zeal and ambition. After ten years struggle, the Saracens yielded up the rich prize, and Robert ceded it to his brother Roger, who assumed the title of Great Earl of Sicily, ruled the state with wisdom, and ranks deservedly among the greatest characters in history. He raised himself from the humble station of a poor younger son of a private gentleman, to the exalted dignity of a powerful monarch, by the sole force of his own genius and courage; he governed a nation of strangers with vigour and justice, and transmitted his possessions undisputed to his posterity. Such an assemblage of great qualities is well intitled to our admiration.

He was succeeded by his son Simon, whose reign was short, and made way for a second son called Roger. In 1127 this prince joined to his Sicilian possessions the whole inheritance of Robert Guiscard (see NAPLES, n° 23.), and assumed the regal style. The greatest part of his reign was taken up in quelling revolts in Italy, but Sicily enjoyed profound peace. In 1154 his son William ascended the throne, and passed his life in war and confusion. William II. succeeded his father, and died without issue. Tancred, though basely born, was elected his successor, and after him his son William III. who was vanquished by Henry of Swabia. During the troubles that agitated the reign of his son the emperor Frederic, peace appears to have been the lot of Sicily. A short lived sedition, and a revolt of the Saracens, are the only commotions of which we read. For greater security, the Saracens were removed to Puglia 400 years after the conquest of Sicily by their ancestors. Under Conrad and Manfred Sicily remained quiet; and from that time the history of Sicily is related under the article NAPLES, n° 26, &c.

Sicily. 14 Under the dominion of different monarchs.

15 Is at length conquered by the Spaniards.

At the death of Charles II. of Spain, his spoils, became an object of furious contention; and at the peace of Utrecht, Sicily was ceded to Victor duke of Savoy, who, not many years after, was forced by the emperor Charles VI. to relinquish that fine island, and take Sardinia as an equivalent. But as the Spaniards had no concern in these bargains, they made a sudden attempt to recover Sicily, in which they failed through the vigilance of the English admiral Byng. He destroyed their fleet in 1718, and compelled them to drop their scheme for a time. In 1734 the Spanish court resumed their design with success. The infant Don Carlos drove the Germans out, and was crowned king of the two Sicilies at Palermo. When he passed into Spain to take possession of that crown, he transferred the Sicilian diadem to his son Ferdinand III. of Sicily and IV. of Naples, and it has ever since remained in the possession of the same family.

16 Account of the Straits of Messina.

Sicily is separated, as we have already observed, from Italy by a narrow strait called the *Faro of Messina*. This strait is still remarkable for the rapidity of its currents and the irregular ebbing and flowing of the sea, which sometimes rushes in with such violence as to endanger ships riding at anchor. Anciently it was much more remarkable for Scylla and Charybdis, the one a rock, and the other a whirlpool, between which it was very dangerous to steer, and concerning which so many fables have been related by the ancients. Scylla is a rock on the Italian side, opposite to Cape Pylores, which runs out into the sea on the Sicilian side. Mr Brydone informs us, that the navigation of the straits is not even yet performed without danger. He informs us, that the noise of the current which sets through the straits may be heard for several miles, like the roaring of some large impetuous river confined between narrow banks. In many places the water rose into whirlpools and eddies, which are dangerous to shipping. The current set exactly for the rock of Scylla, and would certainly have carried any thing thrown into it against that point. Our author, however, is by no means of opinion that the strait is so dangerous as the ancients have represented it; though he thinks that the strait is now probably much wider than formerly, which may have diminished the danger. See SCYLLA. There are many small rocks,

which

Sicily.

which show their heads near the base of the large ones. These are probably the dogs described by the ancient poets as howling round Scylla. The rock is near 200 feet high, and has a kind of castle or fort built on its summit with a town called *Scylla* or *Sciglio*, containing 300 or 400 inhabitants on its south side, which gives the title of prince to a Calabrese family.

Charybdis is now so much diminished, that it seems almost reduced to nothing in comparison of what it was, though even yet it is not to be passed without danger. See CHARYBDIS.

In the straits, Mr Brydone informs us, a most surprising phenomenon is to be observed. In the heat of summer, after the sea and air have been much agitated, there appears in the heavens over the straits a great variety of singular forms, some at rest and others moving with great velocity. These forms, in proportion as the light increases, seem to become more aerial, till at last, some time before sun-rise, they totally disappear. The Sicilians represent this as the most beautiful sight in nature. Leonti, one of their best and latest writers, says, that the heavens appear crowded with a variety of objects, such as palaces, woods, gardens, &c. besides the figures of men and other animals that appear in motion among them. Some treatises have been written concerning this phenomenon; but nothing satisfactory has been delievered concerning its cause.

17 Climate and produce.

Watkin's Travels through Switzerland, Italy, Sicily, &c.

Though Sicily lies in a warm climate, the air is healthful, being refreshed with sea-breezes on every side. It has at all times been remarkably fertile; but the era of its greatest prosperity was from the siege of Syracuse by the Athenians to the Carthaginian conquests. Then and long after it supplied with grain in years of scarcity all the countries upon the Mediterranean except Egypt and the coasts of Asia, and Rome and Carthage continually. Even now, under all the impediments of superstition and bad government, its productions are, in quantity and quality, the best in Europe. Of the vegetable are grain, wines, oil, fruits, tobacco, mulberry trees for the silkworm, cotton, medicinal roots, and sugar canes. The last of these flourish near Avola and Merilli. They are of an inferior quality to those of the West Indies, but their sugar is sweeter than any other. The animal production is simliar to that of Italy, but the horned cattle are a smaller breed. The coasts abound with fish, particularly with tunney and anchovies; the export of which forms a very lucrative branch of commerce. There are mines of silver, copper, and lead, but none are worked. Near Palma are beds of the best sulphur: at the mouth of the river Giaretta is found a yellow amber, preferable to that of the Baltic; and in every part of the island quarries of marbles, that have furnished materials for all the noble edifices of Sicily. The most beautiful are in the neighbourhood of Palermo, particularly the yellow, and these that resemble the verdeantique, porphyry, and lapis lazuli. The population of the island amounts to 1,300,000 souls; not as much again as the single city of Syracuse formerly contained.

18 Rivers and mountains.

Here are several rivers and good springs; but few of the rivers are navigable, having but a short course, and descending precipitately from the mountains. The chief are the Cantera, the Jarretta, and the Salso; of which the two former run from west to east, and the third from north to south.

Of the mountains in this island the most noted is Mount Etna, now called *Monte Gibello* or *Mongibello*, a volcano whose eruptions have often proved fatal to the neighbouring country. See ETNA.

19 Constitution and government.

Munter's Memors relative to Naples and Sicily.

Were the Sicilians a cultivated people, among whom those arts were encouraged which not only promote the wealth and comfort of a nation, but also exercise the nobler faculties and extend the views of mankind, the circumstances of their government are such, that it might gradually be improved into a free constitution: but to this, the ignorance, superstition, and poverty, of the people seem to be invincible obstacles. The monarchical power in Sicily is far from being absolute; and the parliament claims a share of public authority independently of the will of the king, deduced from a compact made between Roger and the Norman barons after the expulsion of the Saracens. This claim is denied by the king, who wishes the nobles to consider their privileges as derived solely from his favour. Hence the government is in a situation which greatly resembles that of England and the other kingdoms of Europe in the feudal times; there are continual jealousies and oppositions between the king and the barons, of which an enlightened people might easily take advantage, and obtain that share in the constitution which might secure them from future oppression. In these disputes, the king has the advantage at least of power if not of right; and several works, in which the claims of the Sicilian barons have been asserted, were publicly burned a few years ago.

As the sovereign holds his court at Naples, Sicily is governed by a viceroy, who is appointed only for three years, though at the end of that term his commission is sometimes renewed. He lives in great state, and, as the representative of the king, his power is very considerable. He presides in all the courts and departments of government, and is commander in chief of all the forces: he calls or dissolves the parliament when he pleases; and by him all orders, laws, and sentences, must be signed: but his office is far from being desirable, as it generally renders him the object either of the jealousy of the court of Naples, or of the hatred of the Sicilians.

The parliament consists of the nobles, the bishops, and abbots, and the representatives of 43 cities, which are immediately subject to the crown. Those cities which are subject to any of the nobles send no members to the parliament; in these the king has not much authority, and derives little advantage from them. According to the laws, the parliament ought to be assembled at the end of every three years: but the government pays little attention to this rule. The common people are in general very much attached to the nobles, and are inclined to take their part in all their differences with the court: but the magistrates and principal inhabitants of the cities which belong to these feudal lords, wish to get rid of their authority, and imagine that they should be less oppressed, if immediately subject to the king: these inclinations are not disagreeable to the court, and are encouraged by most of the lawyers, who are of great service to government in contesting the privileges of the nobles. Many of these privileges are now abridged; and the power of the barons, with respect to the administration of justice in their domains, was very properly limited by the viceroy Ca-

 raccioli,

20 Inquisition. racciolo, in the year 1785. The government of this nobleman was very beneficial to Sicily, as he, in a great measure, cleared the island of the banditti that used to infest it, and made several excellent regulations for the establishment of social order and personal security. He deserves the thanks of every well-wisher to mankind for having abolished the court of inquisition, which had been established in this country by Ferdinand the Catholic, and made dependent on the authority of the grand inquisitor of Spain. Its last *auto da fe* was held in the year 1724, when two persons were burned. At length Charles III. rendered it independent of the Spanish inquisitor, and abridged its power, by forbidding it to make use of the torture, and to inflict public punishments. The Marchese Squillace, and his successor the Marchese Tanucci, were both enemies to the hierarchy; and, during their viceroyalties, took care to appoint sensible and liberal men to the office of inquisitor: the last of whom was Ventimiglia, a man of a most humane and amiable character, who heartily wished for the abolition of this diabolical court, and readily contributed toward it. While he held the office of inquisitor, he always endeavoured to procure the acquittal of the accused; and when he could succeed no other way, would pretend some informality in the trial. The total annihilation of this instrument of the worst of tyranny was reserved for Caraccioli. A priest being accused to the inquisition, was dragged out of his house and thrown into the dungeon. He was condemned; but, on account of informality, and a violation of justice in the trial, he appealed to the viceroy, who appointed a committee of jurists to examine the process. The inquisitor refused to acknowledge the authority of this commission; pretending that to expose the secrets of the holy office, and to submit its decisions to the examination of lay judges, would be
21 Abolished by Caraccioli. so inconsistent with his duty, that he would see the inquisition abolished rather than consent to it. Caraccioli took him at his word, and procured a royal mandate by which the holy office was at once annihilated. He assembled all the nobility, judges, and bishops, on the 27th of March 1782, in the palace of the inquisition, and commanded the king's order to be read; after which he took possession of the archives, and caused all the prisons to be set open: in these were at that time only two prisoners, who had been condemned to perpetual confinement for witchcraft. The papers relating to the finances were preserved; but all the rest were publicly burned. The possessions of the holy office were assigned to the use of churches and charitable institutions: but the officers then belonging to it retained their salaries during their lives. The palace itself is converted into a customhouse, and the place where heretics were formerly roasted alive for the honour of the Catholic faith, is now changed into a public garden. The cognizance of offences against orthodoxy is committed to the bishops: but they cannot cite any one to appear before them without permission from the viceroy; neither can they confine any person to a solitary prison, nor deny him the privilege of writing to his friends, and conversing freely with his advocate. The nobility are so numerous in this island, that Labat says it is paved with noblemen. The general assembly of parliament is composed of 66 archbishops, bishops, abbots, and priors, which form the Bracchio ecclesiastico. Fifty-eight princes, 27 dukes, 37 marquisses, 27 counts, 1 viscount, and 79 barons, form the militaire; and the demaniale consists of 43 representatives of free towns. Out of each bracchio four deputies are chosen to conduct public business. But the viceroy, the prince of Butera, and the prætor of Palermo, are always the three first. *N. B.* There are many titled persons that have no seat in the assembly, viz. 62 princes, 55 dukes, 87 marquisses, 1 count, and 282 other feudatories. There are three archbishoprics and seven bishoprics; and the island, ever since it was conquered by the Saracens, has been divided into three parts or valleys; namely, the *Val di Demone*, *Val di Noto*, and *Val di Mazzara*.

SICINNIUS (Dentatus), a tribune of the people, lived a little after the expulsion of the kings from Rome. He was in 120 battles and skirmishes, besides single combats, in all of which he came off conqueror. He served under nine generals, all of whom triumphed by his means. In these battles he received 45 wounds in the fore-part of his body, and not one in his back. The senate made him great presents, and he was honoured with the name of the Roman Achilles.

SICYOS, in botany: A genus of plants belonging to the class of monœcia, and to the order of syngenesia; and in the natural system arranged under the 34th order, *Cucurbitaceæ*. The male flowers have their calyx quinquedentated, their corolla quinquepartite, and there are three filaments. The female flowers have their calyx and corolla similar; but their style is trifid, and their drupa monospermous. There are three species, the *angulata*, *laciniata*, and *garcini*, which are all foreign plants.

SIDA, *Yellow* or *Indian Mallow*, in botany: A genus of plants belonging to the class of monadelphia, and to the order of polyandria; and in the natural system ranging under the 37th order, *Columniferæ*. The calyx is simple and angulated; the style is divided into many parts; there are several capsules, each containing one seed. There are 27 species. 1. The Spinosa; 2. Angustifolia; 3. Alba; 4. Rhombifolia; 5. Almifolia; 6. Ciliaris; 7. Retusa; 8. Triquetra; 9. Jamaicensis; 10. Carpinifolia; 11. Viscosa; 12. Cordifolia; 13. Umbellatæ; 14. Paniculata; 15. Atrosanguinea; 16. Periplocifolia; 17. Urens; 18. Arborea; 19. Occidentalis; 20. Americana; 21. Abutilon; 22. Mauritiana; 23. Asiatica; 24. Indica; 25. Crispa; 26. Cristata; 27. Ternata. The first 18 species have 15 capsules; the rest are multicapsular. They are all natives of warm climates; and most of them are found in the East or West Indies.

The Chinese make cords of the sida abutilon. This plant loves water, and may be advantageously planted in marshes and ditches, where nothing else will grow. From experiments made by the Abbé Cavanilles, a Spaniard, which are inserted in the *Mem. de l' Acad. Royale*, it appears that the plants succeed best when sown in May, and they arrive at perfection in three months and a half. The maceration of the smaller stalks is finished in about 15 days; of the larger in a month. The strength and goodness of the thread appeared to be in proportion to the perfection of the vegetation, and to the distance the plant was kept at from other plants. The fibres lie in strata, of which there are sometimes six: they are not quite straight, but preserve an undulating direction, so as to form a network in their natural

ral positions. Their smell resembles that of hemp; the fibres are whiter, but more dry and harsh than those of hemp. The harshness is owing to a greenish gluten which connects the fibres; and the white colour must always be obtained at the expence of having this kind of thread less supple: when of its natural hue, it is very soft and flexible. This description belongs chiefly to the sida; but it will also apply to the malva crispa, Peruviana, and Mauritiana. The malva crispa gave, however, the greatest quantity of fibres, and its gluten was most copious. The fibres of the sida abutilon, and the malva crispa, are the longest and the strongest; those of the Peruviana and Mauritiana are the shortest and weakest. The fibres of those plants which had lost their leaves are less strong, though of equal length with those which had preserved them.

SIDDEE, or Sedee; an Arabic title, by which the Abyssinians or Habashys are always distinguished in the courts of Hindostan; where, being in great repute for firmness and fidelity, they are generally employed as commanders of forts or in posts of great trust.

SIDEREAL year. See *Astronomy-Index*.

SIDERIA, in natural history, the name of a genus of crystals, used to express those altered in their figure by particles of iron. These are of a rhomboidal figure, and composed only of six planes. Of this genus there are four known species. 1. A colourless, pellucid, and thin one; found in considerable quantities among the iron ores of the forest of Dean in Gloucestershire, and in several other places. 2. A dull, thick, and brown one; not uncommon in the same places with the former. And, 3. A black and a very glossy kind, a fossil of great beauty; found in the same place with the others, as also in Leicestershire and Sussex.

SIDERITE, a substance discovered by Mr Meyer, and by him supposed to be a new metal; but Messrs Bergman and Kirwan have discovered that it is nothing else than a natural combination of the phosphoric acid with iron. Mr Klaproth of Berlin also came to the same conclusion, without any communication with Mr Meyer. It is extremely difficult to separate this acid from the metal; however, he found the artificial compound of phosphoric acid and iron to agree in its properties with the calx sideri alba obtained by Bergman and Meyer from the cold-short iron extracted from the swampy or marshy ores. The discovery of this substance, however, may be accounted an important affair in chemistry, as we are thus furnished with an immense quantity of phosphoric acid, which might be applied to useful purposes if it could be separated from the metal.

SIDERITIS, Ironwort, in botany: A genus of plants belonging to the class of didynamia, and to the order of gymnospermia; and in the natural system ranging under the 42d order, *Verticillatæ*. The stamina are within the tube of the corolla. There are two stigmas, one of which is cylindrical and concave; the other, which is lower, is membranous, shorter, and sheathing the other. The species are 13. 1. The Canariensis, or Canary ironwort, which is a native of Madeira and the Canary islands; 2. The Candicans, which is also a native of Madeira; 3. The Syriaca, a native of the Levant; 4. The Perfoliata, a native of the Levant; 5. The Montana, a native of Italy and Austria; 6. The Elegans; 7. The Romana, a native of Italy; 8. The Incana, a native of Spain; 9. The Hyssopifolio, a native of Italy and the Pyrenees; 10. The Scordioides, a native of the south of France; 11. The Hirsuta, which is indigenous in the south of Europe; 12. The Ciliata; 13. The Lanata.

SIDEROXYLON, Iron-wood, in botany; A genus of plants belonging to the class of pentandria, and to the order of monogynia; and in the natural system ranging under the 43d order, *Dumosæ*. The corolla is cut into 10 parts, the lasciniæ or segments being incurvated alternately; the stigma is simple; the berry contains five seeds. There are ten species: 1. Mite; 2. Inerme, smooth iron-wood; 3. Melanophleum, laurel-leaved iron-wood; 4. Fœtidissimum; 5. Cymosum—both natives of the Cape of Good Hope; 6. Sericeum, silky iron-wood, a native of New South Wales; 7. Tenax, silvery-leaved iron-wood, a native of Carolina; 8. Lycioides, willow-leaved iron-wood, a native of North America; 9. Spinosum, thorny iron-wood or argan, a native of Morocco; 10. Decandrum.

The wood of these trees being very close and solid, has given occasion for this name to be applied to them, it being so heavy as to sink in water. As they are natives of warm countries, they cannot be preserved in this country unless they are placed, the two former in a warm stove, the others in a green house. They are propagated by seeds, when these can be procured from abroad.

SIDNEY (Sir Philip), was born, as is supposed, at Penshurst in Kent in the year 1554: His father was Sir Henry Sidney, an Irish gentlemen, and his mother Mary the eldest daughter of John Dudley duke of Northumberland. He was sent when very young to Christchurch college at Oxford, but left the university at 17 to set out on his travels. After visiting France, Germany, Hungary, and Italy, he returned to England in 1575, and was next year sent by Queen Elizabeth as her ambassador to Randolph emperor of Germany. On his return he visited Don John of Austria, governor of the Netherlands, by whom he was received with great respect. In 1579, when Queen Elizabeth seemed on the point of concluding her long projected marriage with the duke of Anjou, Sir Philip wrote her a letter, in which he dissuaded her from the match with unusual elegance of expression, as well as force of reasoning. About this time a quarrel with the earl of Oxford occasioned his withdrawing from court; during which retirement he is supposed to have written his celebrated romance called *Arcadia*.

In 1585, after the queen's treaty with the United States, he was made governor of Flushing and master of the horse. Here he distinguished himself so much both by his courage and conduct, that his reputation rose to the highest pitch. He was named, it is pretended, by the republic of Poland as one of the competitors for that crown, and might even have been elected had it not been for the interference of the queen. But his illustrious career was soon terminated; for in 1586 he was wounded at the battle of Zutphen, and carried to Arnheim, where he soon after died. His body was brought to London, and buried in St Paul's cathedral. He is described by the writers of that age as the most perfect model of an accomplished gentleman that could be formed even by the wanton imagination of poetry or fiction. Virtuous conduct, polite conversation, heroic valour, Sidney.

lour, and elegant erudition, all concurred to render him the ornament and delight of the English court; and as the credit which he enjoyed with the queen and the earl of Leicester was wholly employed in the encouragement of genius and literature, his praises have been transmitted with advantage to posterity. No person was so low as not to become an object of his humanity. After the battle of Zutphen, while he was lying on the field mangled with wounds, a bottle of water was brought him to relieve his thirst; but observing a soldier near him in a like miserable condition, he said, *This man's necessity is still greater than mine*; and resigned to him the bottle of water. Besides his *Arcadia*, he wrote several smaller pieces both in prose and verse, which have been published.

Sidney (Algernon), was the second son of Robert earl of Leicester, and of Dorothy eldest daughter of the earl of Northumberland. He was born about the year 1617. During the civil wars he took part against the king, and distinguished himself as a colonel in the army of the parliament. He was afterwards appointed one of king Charles's judges, but declined appearing in that court. During the usurpation of Cromwel, Sidney, who was a violent republican, retired to the country, and spent his time in writing those discourses on government which have been so deservedly celebrated. After the death of the Protector, he again took part in the public transactions of his country, and was abroad on an embassy to Denmark when king Charles was restored. Upon this he retired to Hamburgh, and afterwards to Francfort, where he resided till 1677, when he returned to England and obtained from the king a pardon. It has been affirmed, but the story deserves no credit, that during his residence abroad king Charles hired ruffians to assassinate him. After his return he made repeated attempts to procure a seat in parliament but all of them proved unsuccessful. After the intention of the commons to seclude the duke of York from the throne had been defeated by the sudden dissolution of parliament, Sidney joined with eagerness the councils of Russel, Essex, and Monmouth, who had resolved to oppose the duke's succession by force of arms. Frequent meetings were held at London; while, at the same time, a set of subordinate conspirators, who were not, however, admitted into their confidence, met and embraced the most desperate resolutions. Keiling, one of these men, discovered the whole conspiracy; and Algernon Sidney, together with his noble associates, was immediately thrown into prison, and no art was left unattempted in order to involve them in the guilt of the meaner conspirators.

Howard, an abandoned nobleman, without a single spark of virtue or honour, was the only witness against Sidney; but as the law required two, his discourses on government, found unpublished in his closet, were construed into treason, and declared equivalent to another witness. It was in vain for Sidney to plead that papers were no legal evidence; that it could not be proved they were written by him; and that if they were, they contained nothing treasonable. The defence was over-ruled; he was declared guilty, condemned, and executed! His attainder was reversed in the first year of king William.

He was a man of extraordinary courage; steady even to obstinacy; of a sincere but rough and boisterous temper. Though he professed his belief in the Christian religion, he was an enemy to an established church, and even, according to Burnet, to every kind of public worship. In his principles he was a zealous republican: government was always his favourite study; and his essays on that subject are a proof of the progress which he made.

Sidon, Sidus.

SIDON (anc. geog.), a city of Phœnicia in Asia, famous in Scripture for its riches, arising from the extensive commerce carried on by its inhabitants. Heavy judgments were denounced against the Sidonians in account of their wickedness, which were accomplished in the time of Ochus king of Persia: for that monarch having come against them with an army on account of their rebellion, the city was betrayed by its king; upon which the wretched inhabitants were seized with despair; they set fire to their houses, and 40,000, with their wives and children, perished in the flames.

This city is now called *Saide*, and, according to Mr Bruce's account, not only its harbour is filled up with sand, but the pavement of the ancient city stood $7\frac{1}{2}$ feet lower than the ground on which the present city stands. Volney describes it as an ill-built dirty city. Its length along the sea-shore is about 600 paces, and its breadth 150. At the north-west side of the town is the castle, which is built in the sea itself, 80 paces from the main land, to which it is joined by arches. To the west of this castle is a shoal 15 feet high above the sea, and about 200 paces long. The space between this shoal and the castle forms the road, but vessels are not safe there in bad weather. The shoal, which extends along the town, has a bason inclosed by a decayed pier. This was the ancient port; but it is so choaked up by sand, that boats alone can enter its mouth near the castle. Fakr-el-din, emir of the Druses, destroyed all these little ports from Bairout to Acre, by sinking boats and stones to prevent the Turkish ships from entering them. The bason of Saide, if it were emptied, might contain 20 or 25 small vessels. On the side of the sea, the town is absolutely without any wall; and that which encloses it on the land side is no better than a prison wall. The whole artillery does not exceed six cannons, and these are without carriages and gunners. The garrison scarcely amounts to 100 men. The water comes from the river Aoula, through open canals, from which it is fetched by the women. These canals serve also to water the orchards of mulberry and lemon trees.

Saide is a considerable trading town, and is the chief emporium of Damascus and the interior country. The French, who are the only Europeans to be found there, have a consul, and five or six commercial houses. Their exports consist in silks, and particularly in raw and spun cottons. The manufacture of this cotton is the principal art of the inhabitants, the number of whom may be estimated at about 5000. It is 45 miles west from Damascus. E. Long. 36. 5. N. Lat. 37.

SIDUS Georgium, in astronomy, a new primary planet, discovered by Dr Herschell in the year 1781. By most foreign, and even by some British philosophers, it is known by the name of *Herschell*, an honour which is due to the discoverer. As the other planets are distinguished by marks or characters, the planet Herschell is distinguished by an H, the initial letter of the discoverer's name, and a cross to show that it is a Christian planet. From many calculations of our best astronomers

mers and mathematicians, says Dr Herschell, I have collected the following particulars, as most to be depended upon.

Place of the node - -	$2^s\ 11^d\ 49'\ 30''$
Inclination of the orbit - -	$43'\ 35''$
Place of the perihelion -	$172^d\ 13'\ 17''$
Time of the perihelion passage	Sep 7. 1799
Eccentricity of the orbit	,82034
Half the greater axis	19,07904
Revolution - -	83,3364 siderial years.

From my own observations on this planet's apparent diameter, which I have found cannot well be less than 4″, nor indeed much greater, we infer, that its real diameter is to that of the earth as 4,454 to 1; and hence it appears to be of very considerable bulk, and, except Saturn and Jupiter, by far the largest of the remaining planets. Its light is of a bluish-white colour, and in brilliancy between that of the Moon and of Venus. With a telescope which magnifies about 300 times, it appears to have a very well defined visible disk; but with instruments of a small power, it can hardly be distinguished from a fixed star of between the sixth and seventh magnitude. In a very fine clear night, when the moon is absent, it may also be seen by the naked eye.

SIEGE, in the art of war, is to sorround a fortified place with an army, and approach it by passages made in the ground, so as to be covered against the fire of the place.

SIEGEN, a town of Germany in Wetteravia, with a castle and the title of a principality, which it gives to a branch of the house of Nassau. It is seated on a river of the same name in E. Long. 8. 5. N. Lat. 50. 53.

SIENNA, a large, ancient, and celebrated city of Tuscany in Italy; capital of the Siennese, with an archbishop's see, a famous university, and a citadel. It is about four miles in circumference, and surrounded with an old wall. The metropolitan church is much esteemed by travellers; and though it is a Gothic structure, the architecture is admirable. It is built with black and white marble, and the pavement is of Mosaic work. The town is adorned with a great number of palaces, fountains, and superb churches, as also a magnificent hospital. The great area is round, and the houses about it are of the same height, supported by piazzas, under which people may walk in hot or rainy weather; in the middle is a bason, which can be filled with water at any time, to represent a sea-fight with small vessels. The Italian language is taught here with such purity, that a great many foreigners frequent it in that account. It is seated on three eminences, in fertile soil, in E. Long. 11. 11. N. Lat. 43. 10.

SIENNESE, a duchy in Italy; bounded on the north by the Florentino, on the south by the Mediterranean sea and the duchy of Castro, on the east by the Perugino and Orvietano, and on the west by the Florentino and the Tuscan sea; being about 55 miles in length, and as much in breadth. The soil is pretty fertile, especially in mulberry trees, which feed a great number of silk-worms; and there are several mineral springs. Sienna is the capital town.

SIERRA LEONA, a large country on the west coast of Africa, which some extend from the Grain Coast on the south east to Cape Verga or Vega on the north-west, *i. e.* between 7° and 10° N. Lat. Others, however, confine the country between Cape Verga and Cape Tagrin. There runs through it a great river of the same name, of which the source is unknown, but the mouth is in longitude 12. 30. west. lat. 8. 5. north, and is nine miles wide. The climate and soil of this tract of country appear to be, on both sides of the river, among the best in Africa, or at least the most favourable to European constitutions. The heat is much the same as that of the West Indies; but on the higher grounds there is a cool sea breeze, and in the mountainous parts the air is very temperate. According to Lieutenant Matthew, "Sierra Leona, if properly cleared and cultivated, would be equal in salubrity and superior in produce to any of the islands in the West Indies;" and others have affirmed, that "the air is better for a man's health than in many places of Europe." These advantages of climate induced the English to establish a factory at Sierra Leona; but they chose not the most healthful situation. For the benefit of a spring of good water they fixed their residence in a low valley, which is often overspread with mists and noisome vapours, while the air is clear and serene on the summits of the hills, to which water from the well might be easily carried.

The animal productions of this country are lions, from which it has its name; leopards, hyænas, musk cats, and many kinds of weasels; the japanzee or chimpanzee, a species of simia, which has a still more striking resemblance to the human figure than even the ourang outang; porcupines, wild hogs, squirrels, and antelopes. Besides these, which are natives of the country, oxen thrive in it, and even grow fat; asses too are employed in labour, and do not suffer by the climate; but sheep suffer much from the heat, change their wool into hair, grow lean and increase very little; while the hardy goat is here as prolific and large as in any other country. Of the birds which frequent the woods of Sierra Leona we can give no perfect account. A species of crane in mentioned as easily tamed; common poultry multiply fast; ducks thrive well, but geese and turkeys seem not to agree with the climate. Turtles of all kinds are very common, and sometimes of a large size. Crocodiles or alligators of a non-descript species have been found ten or twelve feet in length, and lizards of six different species. Snakes, which are almost innumerable, haunt the houses in the night in search of poultry; and one was observed with measured 18 feet, but was happily found not to be venomous. Fishes are in great variety both in the sea and in the rivers. Besides the whale, the shark, stinging ray, and porpoise, there are eels, horse-mackarel, tarpoons, cavillos, mullets, snappers, yellow-tails, old-maids, ten-pounders, and some other fishes; all of which, except the eels and ten-pounders, are esteemed fine eating. Oysters are found in great abundance, and another shellfish, which the natives eat. Among the zoophites, none is more worthy of notice than the common sponge, which covers all the sandy beaches of the river, particularly on the Bullom shore, and would fetch a high price in Great Britain.

Of the numerous vegetable productions of Sierra Leona, our limits will permit us only to mention the following. Rice, which is the plant chiefly cultivated, as the natives subsist almost entirely upon it, grows both in

Sierra.

in the high and low grounds. It prospers indeed best in swamps, though the grain is better in a drier soil. Next to rice the cassado constitutes the chief food of the inhabitants, and is cultivated with great care. The country likewise produces yams, various kinds of potatoes, eddoes, or the *arum esculentum.* Oil-palm, plantains, and bananas; papaw, guava, oranges and limes; pompions, melons, and cucumbers; pine-apples, pigeon-peas, which dressed like English peas are a good pulse; maize or Indian corn; millet, cocoa-nut trees; okra; the tallow-tree; a great variety of tamarinds; different kinds of fig-trees and plums; a kind of fruit resembling grapes, but more acid and acrid; cherries resembling a fine nectarine in taste; a species of the bread fruit-tree; the cream fruit, so called because when wounded it yields a fine white juice resembling sugar or the best milk, of which the natives are very fond; the malaguetta pepper, or grains of paradise; a new species of nutmeg, but whether so good as the common sort has not yet been ascertained; a new species of the Peruvian bark, which it is hoped will prove as useful as the other; and cola, a fruit highly esteemed by the natives for the same virtues with that bark; the ricinus, cassia, dye-stuffs, and gums, of great value; cotton, tobacco, and sugar-canes, which, it is thought, would thrive exceedingly well under proper cultivation.

Considering the ardour of the maritime nations of Europe for settling colonies in distant regions of the globe, it is somewhat surprizing that a climate so temperate and a soil so productive as that of Sierra Leona did not long ago attract their notice. But it was left to be colonized for a better purpose than that which first drew the natives of Europe to the West Indies and the American continent. Being thinly inhabited, Sierra Leona appeared to some benevolent gentlemen in England a place where, without incommoding the natives, a sufficient quantity of ground might be bought on which to settle a great number of free negroes, who in 1786 swarmed in London in idleness and want. About 400 of these wretches, together with 60 whites, mostly women of bad character and in ill health, were accordingly sent out, at the charge of government, to Sierra Leona. Necessity, it was hoped, would make them industrious and orderly; and Captain Thomson of the navy, who conducted them, obtained, for their use, a grant of land to his majesty from king Tom, the neighbouring chief, and afterwards from Naimbanna, the king of the country. The colony, however, soon went to ruin; but the land which they occupied being about 20 miles square his majesty was enabled to grant by act of parliament to another colony founded on better principles and for a still nobler purpose.

The most intelligent members of that society, which has laboured so strenuously to procure an abolition of the slave-trade, justly concluding that the natives of Guinea would reap very little benefit from the attainment of their object, unless they should be taught the principles of religion and the arts of civil life, which alone can render them really free, conceived the plan of a colony at Sierra Leona to be settled for the truly generous purpose of civilizing the Africans by maintaining with them a friendly intercourse, and a commerce in every thing but men. This plan could not be carried into effect but at a very great expence. Subscriptions were therefore opened upon rational and equitable terms, and a sum deemed sufficient was speedily raised. An act of parliament was passed in favour of the subscribers, by which they were incorporated by the denomination of the *Sierra Leona Company;* and in pursuance of that act they held their first meeting at London on the 19th of October 1791, when the following gentlemen were chosen directors for that year.

"Henry Thornton, Esq; M. P. chairman—Philip Sansom, Esq; deputy chairman—Sir Charles Middleton, Bart.—Sir George Young, Knt.—William Wilberforce, Esq; M. P.—Rev. Thomas Clarkson, A. M. —Joseph Hardcastle, Esq;—John Kingston, Esq;—Samuel Parker, Esq;—Granville Sharp, Esq;—William Sandford, Esq;—Vickeris Taylor, Esq;—George Wolf, Esq."

The directors having stated the natural advantages of Sierra Leona, and its present miserable condition, observed, that they had not merely to establish a commercial factory, but that, to introduce civilization, cultivation, and a safe trade, the company must provide for the security of the persons and property of the colonists. The directors therefore resolved, that three or four vessels should sail at once, with such a number of people as would be able to protect and assist each other; with goods both for trade and for the supply of the colony. Accordingly several vessels sailed, having on board a council for the government of the colony and the management of the company's affairs; a number of artificers and other servants of the company; some soldiers, and a very few English settlers. The directors were laudably cautious in the choice of colonists. They admitted into the society no white man of bad character, or who was not a declared enemy to the slave-trade; and as the chief object of their enterprise was the civilization of the natives, it was with great propriety that they chose more than three-fourths of their settlers from the free negroes in Nova Scotia, who had borne arms for the British government during the American war. The superintendant and council were particularly instructed to secure to all blacks and people of colour, at Sierra Leona, equal rights and equal treatment, in all respects, with whites. They were to be tried by jury, as well as others; and the council was desired to allot to the blacks employments suited to their present abilities, and to afford them every opportunity of cultivating their talents. All practicable means of maintaining subordination were directed to be used; and the council was especially instructed to promote religion and morals, by supporting public worship and the due observance of the Sabbath, and by the instruction of the people, and the education of children. But no person was to be prevented from performing or attending religious worship in whatever place, time, or manner, he might think fit, or from peaceably inculcating his own religious opinions. Orders were given in choosing the scite of a town, to consider health as the first object; and the first town was directed to be called *Free Town.* Articles for building and cultivation were sent out, besides the cargoes for prosecuting the company's commerce; and schools for reading, writing, and accounts were ordered to be set up for the purpose of instructing the children of such natives as should be willing to put them under the company's care.

The leading object of the company was to substitute, for that disagraceful traffic which has too long subsisted

Sierra.

a fair commerce with Africa, and all the blessings which might be expected to attend it. Considerable advantages appeared hereby likely to result to Great Britain, not only from its obtaining several commodities cheaper, but also from opening a market for British manufactures, to the increasing demands of which it is difficult to assign a limit. From this connection, Africa was likely to derive the still more important benefits of religion, morality, and civilization. To accomplish these purposes, it was necessary for the company to possess a tract of land, as a repository for their goods, and which the Africans might cultivate in peace, secure from the ravages of the slave trade. It had been ascertained, beyond a doubt, that the climate and soil of Africa were admirably suited to the growth of sugar, spices, coffee, cotton, indigo, rice, and every other species of tropical produce. The company proposed to instruct the natives to raise these articles, and to set them the example, by a spirited cultivation, on its own account. Directions were given to the company's commercial agent to push forward a trade, in a mode prescribed, in the present produce of Africa. Measures were taken for cultivating, on the company's account, the most profitable tropical produce; and in particular, a person of long experience in the West Indies was ordered to begin a sugar plantation. A mineralogist and botanist were likewise engaged to go out and explore the country for new articles of commerce.

"Every thing being thus settled upon the most equitable and benevolent principles, the ships sailed with the British colonists, to whom, in March 1792, were added 1131 blacks from Nova Scotia. The native chiefs being reconciled to the plan, and made to understand its beneficent tendency towards their people, the colony proceeded to build *Free-Town*, on a dry and rather elevated spot on the south side of the river. It occupied between 70 and 80 acres, its length being about one third of a mile, and its breadth nearly the same; and it contained near 400 houses, each having one-twelfth of an acre annexed, on which a few vegetables were raised. There were nine streets running from north-west to south-east, and three cross streets, all 80 feet wide, except one of 160 feet, in the middle of which were all the public buildings. These consisted of a governor's house and offices; a large store-house; a large hospital; six or eight other houses, offices, and shops, occupied by the company's servants; and a church capable of containing 800 people. The colonists at first suffered much from the rainy season, against which it was not in their power to provide sufficient protection; but at the end of it they recovered in a great measure their health and spirits, and proceeded with alacrity to execute the various purposes of their settlement. To excite emulation in culture, the government gave premiums to those colonists who raised the greatest quantities of rice, yams, eddoes, cabbages, Indian corn, and cotton, respectively. To limit the excesses of the slave-trade, and gain the favour of the neighbouring chiefs, the directors instructed the governor and council to redeem any native from the neighbourhood, who should be unjustly sold either to or by a British subject. The servants of the company conducted themselves with the utmost propriety, being sober, moral, and exemplary; and from the labours of the clergymen were derived services highly important in every point of view. Before the end of two years from the institution of the colony, order and industry had begun to show their effects in an increasing prosperity. The woods had been cut down to the distance of about three English miles all round the town. By these means the climate had become healthier, and sickness had diminished. The fame of th colony had spread not only along the whole western coast of Africa, but also to parts far distant from the coast; embassies had been received of the most friendly nature from kings and princes several hundred miles distant; and the native chiefs had begun to send their children to the colony, with full confidence, to be taught reading, writing, and accounts, and to be brought up in the Christian religion. In a word, in was not without grounds that the directors looked forward to that joyful period when, by the influence of the company's measures, the continent of Africa should be rescued from her present state of darkness and misery, and exhibit a delightful scene of light and knowledge, of civilization and order, of peaceful industry and domestic comfort. On their beneficent exertions they hoped with confidence for the blessing of Providence; they were countenanced and supported by the British government; and upon the breaking out of the present war, the French Convention authorised one of their agents to write to the directors, requesting a full account of the design of the institution, and the names of the ships employed in their service, and assuring them of the good wishes of the French government to so noble an undertaking. How completely that government fulfilled its promise is very generally known. Having vindicated the rights of man in Europe by the violation of every principle of truth and justice, they determined by the same means to give light and liberty to the Africans; and that they have fully carried their determination into effect will be seen by the following extract of a letter from Mr Afzelius, the company's botanist, dated Sierra Leona, 15th November 1794. "The French have been here and have ruined us. They arrived on the 28th of September last, early in the morning, with a fleet consisting of one large ship, two frigates, two armed brigs, and one cutter, together with two large armed merchant ships, taken by them at the Isles de Los, an English slave factory to the north of our colony, and which they have also destroyed and burnt. So well had they concealed their nation, that we took them at first for English. They had English-built vessels, which were rigged in the English way. They showed the English flag, and had their sailors, at least those we saw on deck, dressed like English. In short, we did not perceive our mistake till we observed them pointing their guns. We had not strength sufficient to resist, and therefore our governor gave orders, that as soon as they should begin to fire, the British flag should be struck, and a flag of truce hoisted. Accordingly this was done, but still they continued firing, and did much damage, both within and without the town. They killed two people and wounded three or four. But, as we did not understand the meaning of this proceeding, we asked them for an explanation; and they answered us, that we should display the flag of liberty, as a proof of our submission. We assured them that it should already have been done, if we had had any, which terminated the hostilities from the ships. In the mean time, most of the inhabitants had fled from the town, having taken with them as much of their

Wadstrom Part II. p. 280.

Sierra.

property as they conveniently could in such a hurry. I was with the governor, together with a number of others; but as soon as I was certain they were enemies, I went towards my own house with a view to save as much as possible of my property and natural collections; but was received in such a manner, that I could not venture to proceed. My house was situated near the shore, and unfortunately just opposite the frigate which fired. I saw the balls passing through the house, and heard them whizzing about my ears. I saw that I should lose all my property; but life was dearer to me, and I hastened to the woods.

"In the afternoon the enemy landed, finding the town almost destitute of people, but rich in provisions, clothing, and other stores. They began immediately to break open the houses and to plunder. What they did not want, they destroyed, burnt, or threw into the river. They killed all the cattle and animals they found in the fields or streets, yards, or elsewhere, not sparing even asses, dogs, and cats. These proceedings they continued the whole succeeding week, till they had entirely ruined our beautiful and prospering colony; and when they found nothing more worth plundering, they set fire to the public buildings and all the houses belonging to the Europeans; and burnt, as they said, by mistake nine or ten houses of the colonists. In the mean time, they were not less active on the water. They sent three of their vessels to Bance island, an English slave factory higher up the river, which they plundered and burnt, together with some slave ships lying there. They took besides about 10 or 12 prizes, including the company's vessels. Most of these they unloaded and burnt. They took along with them also two of our armed vessels, one of which was a large ship, laden with provisions, and which had been long expected; but she unfortunately arrived a few days too soon, and was taken with her whole cargo. We expected at least to receive our private letters, but even this was refused, and they were thrown overboard. At last, after inflicting on us every hardship we could suffer, only sparing our lives and the houses of the colonists, they sailed on the 13th of October last, at noon, proceeding downwards to the Gold Coast, and left us in the most dreadful situation, without provisions, medicines, clothes, houses, or furniture, &c. &c. and I feared much, that most of us should have perished, had not our friends in the neighbourhood, both natives and Europeans, who were so happy as to escape the enemy, been so kind as to send us what they could spare. In the mean time, most of us have either been, or still are, very sick, and many have died for want of proper food and medicine. The worst, however, is now past. At least we are not in any want of provision, although of the coarsest kind, but are destitute of the most necessary articles and utensils for the house, the table, and the kitchen."

"The Sierra Leona colony was established for no other end than to abolish the slave-trade, to enlighten the Africans, and to render them virtuous rational, free, and happy; and those powerful patrons of the rights of man destroyed that colony with many circumstances of the most wanton cruelty. Though Mr Afzelius is a Swede, and ought therefore to have been protected by the laws of neutrality, they burnt his house with the rest; deprived him of his trunks, his clothes, and his bed; destroyed the natural curiosities which he had collected at the hazard of his life; and carried away the instruments by means of which only he could collect more. It is with pleasure, however, that we learn from the proceedings of the general court held on the 25th of February 1795, that the directors do not yet despair of the colony; and that they have adopted the most prudent measures to avert all such calamities in future. That their benevolent labours may be finally crowned with success is our earnest prayer, in which we shall, doubtless, be joined by every good Christian."

Sierra ‖ Si-fans.

SIERRA MORENA, mountains of Andalusia in Spain.

SIEUR, a title of respect among the French, like that of *master* among us. It is much used by lawyers, as also by superiors in their letters to inferiors.

SIFANTO, or SIPHANTO, an island of the Archipelago, to the west of Paros, to the north east of Milo, and to the south-west of Serphanto. The air is so good here, that many of the inhabitants live to the age of 120; and their water, fruits, wild fowl, and poultry, are excellent, but more especially the grapes. It abounds with marble and granite, and is one of the most fertile and best cultivated of these islands. The inhabitants employ themselves in cultivating olive-trees and capers; and they have very good silk. They trade in figs, onions, wax, honey, and straw-hats; and may be about 8000 in all. E. Long. 25. 15. N. Lat. 37. 9.

SI-FANS, or TOU-FANS, a people inhabiting the country on the west of China. Their country is only a continued ridge of mountains, inclosed by the rivers Hoang-ho on the north, Ya-long on the west, and Yang-tse-kiang on the east, between the 30th and 35th degrees of north latitude.

Grosier's General Description of China, vol. i. p. 203.

The Si-fans are divided into two kinds of people; the one are called by the Chinese *Black Si-fans*, the other *Yellow*; names which are given them from the different colours of their tents. The black are the most clownish and wretched; they live in small bodies, and are governed by petty chiefs, who all depend upon a greater.

The yellow Si-fans are subject to families, the oldest of which becomes a lama, and assumes the yellow dress. These lama princes, who command in their respective districts, have the power of trying causes, and punishing criminals; but their government is by no means burdensome; provided certain honours are paid them, and they receive punctually the dues of the god Fo, which amount to very little, they molest none of their subjects. The greater part of the Si-fans live in tents; but some of them have houses built of earth, and even brick. Their habitations are not contiguous; they form at most but some small hamlets, consisting of five or six families. They feed a great number of flocks, and are in no want of any of the necessaries of life. The principal article of their trade is rhubarb, which their country produces in great abundance. Their horses are small; but they are well shaped, lively, and robust.

These people are of a proud and independent spirit, and acknowledge with reluctance the superiority of the Chinese government, to which they have been subjected: when they are summoned by the mandarins, they rarely appear; but the government, for political reasons, winks

winks at this contempt, and endeavours to keep these intractable subjects under by mildness and moderation: it would, besides, be difficult to employ rigorous means in order to reduce them to perfect obedience; their wild and frightful mountains (the tops of which are always covered with snow, even in the month of July) would afford them places of shelter, from which they could never be driven by force.

The customs of these mountaineers are totally different from those of the Chinese. It is, for example, an act of great politeness among them to present a white handkerchief of taffety or linen, when they accost any person whom they are desirous of honouring. All their religion consists in their adoration of the god Fo, to whom they have a singular attachment: their superstitious veneration extends even to his ministers, on whom they have considered it as their duty to confer supreme power and the government of the nation.

SIGAULTIAN OPERATION, a method of delivery in cases of difficult labour, first practised by M. Sigault. It consists in enlarging the dimensions of the pelvis, in order to procure a safe passage to the child without injuring the mother. See MIDWIFERY, chap. vii.

SIGESBECKIA, in botany: A genus of plants belonging to the class of syngenesia, and to the order of polygamia superflua; and in the natural system ranging under the 49th order, *Compositæ*. The receptacle is paleaceous; the pappus is wanting; the exterior calyx is pentaphyllous, proper, and spreading; the radius is halved. There are three species: 1. The *orientalis*, which is a native of India and China. 2. The *occidentalis*, which is a native of Virginia. 3. The *flosculosa*, a native of Peru.

SIGETH, a town of Lower Hungary, and capital of a county of the same name. It is seated in a morass, and has a triple wall, with ditches full of water; and is defended by a citadel, being one of the strongest places in Hungary. It now belongs to the house of Austria, and was retaken from the Turks in 1669, after it had been blocked up two years. In some maps it is called *Zigat*. E. Long. 18. 58. N. Lat. 46. 17.

SIGHING, an effort of nature, by which the lungs are put into greater motion, and more dilated, so that the blood passes more freely, and in greater quantity, to the left auricle, and thence to the ventricle. Hence we learn, says Dr Hales, how sighing increases the force of the blood, and consequently proportionably cheers and relieves nature, when oppressed by its too slow motion, which is the case of those who are dejected and sad.

SIGHT, or VISION. See ANATOMY, n° 142. and *Index* subjoined to OPTICS.

Imperfections of SIGHT *with regard to Colours.* Under the article COLOURS, is given an instance of a strange deficiency of sight in some people who could not distinguish between the different colours. In the Phil. Trans. Vol. LXVIII. p. 611. we have an account of a gentleman who could not distinguish a claret colour from black. These imperfections are totally unaccountable from any thing we yet know concerning the nature of this sense.

Second SIGHT. See *Second* SIGHT.

SIGN, in general, the mark or character of something absent or invisible. See CHARACTER.

Among physicians, the term *sign* denotes some appearance in the human body which serves to indicate or point out the condition of the patient with regard to health or disease.

SIGN, in algebra. See ALGEBRA, Part I.

SIGN, in astronomy, a constellation containing a 12th part of the zodiac. See ASTRONOMY, n° 318.

NAVAL SIGNALS. When we read at our fireside the account of an engagement, or other interesting operation of an army, our attention is generally so much engaged by the results, that we give but little to the movements which led to them, and produced them, and we seldom form to ourselves any distinct notion of the conduct of the day. But a professional man, or one accustomed to reflection, and who is not satisfied with the mere indulgence of eager curiosity, follows every regiment in its movements, endeavours to see their connection, and the influence which they have had on the fate of the day, and even to form to himself a general notion of the whole scene of action at its different interesting periods. He looks with the eye of the general, and sees his orders succeed or fail.

But few trouble themselves farther about the narration. The movement is ordered; it is performed; and the fortune of the day is determined. Few think how all this is brought about; and when they are told that during the whole of the battle of Custrin, Frederic the Great was in the upper room of a country inn, from whence he could view the whole field, while his aids de camp, on horseback, waited his orders in the yard below, they are struck with wonder, and can hardly conceive how it can be done: but, on reflection, they see the possibility of the thing. Their imagination accompanies the messenger from the inn yard to the scene of action; they hear the General's orders delivered, and they expect its execution.

But when we think for a moment on the situation of the commander of a fleet, confined on board one ship, and this ship as much, or more closely, engaged, than any other of the fleet; and when we reflect that here are no messengers ready to carry his orders to ships of the squadron at the distance of miles from him, and to deliver them with precision and distinctness, and that even if this were possible by sending small ships or boats, the vicissitudes of wind and weather may render the communication so tedious that the favourable moment may be irretrievably lost before the order can be conveyed.—When we think of all these circumstances, our thoughts are bewildered, and we are ready to imagine that a sea-battle is nothing but the unconnected struggle of individual ships; and that when the admiral has once "cried havoc, and let slip the dogs of war," he has done all that his situation empowers him to do, and he must leave the fate of the day to the bravery and skill of his captains and sailors.

1 Signals a language to the eye.

Yet it is in this situation, apparently the most unfavourable, that the orders of the commander can be conveyed, with a dispatch that is not attainable in the operations of a land army. The scene of action is unincumbered, so that the eye of the General can behold the whole without interruption. The movements which it is possible to execute are few, and they are precise. A few words are sufficient to order them, and then the mere fighting the ships must always be left to their respective commanders. This simplicity in the duty to be performed has enabled us to frame a language fully adequate to the business in hand, by which a correspondence can be kept up as far as the eye can see. This is the language of SIGNALS, a language by writing, addreſſed to the eye, and which he that runneth may read. As in common writing certain arbitrary marks are agreed on to expreſs certain ſounds uſed in ſpeech, or rather, as in hieroglyphics certain arbitrary marks are agreed on to expreſs certain thoughts, or the ſubjects of theſe thoughts; ſo here certain exhibitions are made, which are agreed on to expreſs certain movements to be executed by the commander to whom they are addreſſed, and all are enjoined to keep their eyes fixed on the ſhip of the conductor of the fleet, that they may learn his will.

2 Uſed in ancient times.

It is ſcarcely poſſible for any number of ſhips to act in concert, without ſome ſuch mode of communication between the general and the commanders of private ſhips. We have no direct information of this circumſtance in the naval tactics of the ancient nations, the Greeks and Romans; yet the neceſſity of the thing is ſo apparent, that we cannot ſuppoſe it to have been omitted by the moſt ingenious and the moſt cultivated people who have appeared on the great theatre of the world; and we are perſuaded that Themiſtocles, Conon, and other renowned ſea commanders of Athens, had ſignals by which they directed the movements of their fleets. We read, that when Ægeus ſent his ſon Theſeus to Crete, it was agreed on, that if the ſhip ſhould bring the young prince back in ſafety, a white flag ſhould be diſplayed. But thoſe on board, in their joy for reviſiting their country after their perilous voyage, forgot to hoiſt the concerted ſignal. The anxious father was every day expecting the ſhip which ſhould bring back his darling ſon, and had gone to the ſhore to look out for her. He ſaw her, but without the ſignal agreed on. On which the old man threw himſelf into the ſea. We find, too, in the hiſtory of the Punic wars by Polybius, frequent alluſions to ſuch a mode of communication; and Ammianus Marcellinus ſpeaks of the *ſpeculatores* and *vexillarii*, who were on board the ſhips in the Adriatic. The coins both of Greece and Rome exhibit both flags and ſtreamers. In ſhort, we cannot doubt of the ancients having practiſed this hieroglyphical language. It is ſomewhat ſurpriſing that Lord Dudley, in his *Arcano del Mare*, in which he makes an oſtentatious diſplay of his knowledge of every thing connected with the ſea ſervice, makes no expreſs mention of this very eſſential piece of knowledge, although he muſt, by his long reſidence in Italy, have known the marine diſcipline of the Venetians and Genoeſe, the greateſt maritime powers then in Europe.

3 As well as in modern;

"In the naval occurrences of modern Europe, mention is frequently made of ſignals. Indeed, as we have already obſerved, it ſeems impoſſible for a number of ſhips to act in any kind of concert, without ſome method of communication. Numberleſs ſituations muſt occur, when it would be impoſſible to convey orders or information by meſſengers from one ſhip to another, and coaſt and alarm ſignals had long been practiſed by every nation. The idea was, therefore, familiar. We find, in particular, that Queen Elizabeth, on occaſion of the expedition to Cadiz, ordered her ſecretaries to draw up inſtructions, which were to be communicated to the admiral, the general, and the five counſellors of war, and by them to be copied and tranſmitted to the ſeveral ſhips of the navy, not to be opened till they ſhould arrive in a certain latitude. It was on this occaſion, (ſays the hiſtorian Guthrie), "*that we meet with the firſt regular ſets of ſignals and orders to the commanders of the Engliſh fleet.*" But, till the movements of a fleet have attained ſome ſort of uniformity, regulated and connected by ſome principles of propriety, and agreed on by perſons in the habit of directing a number of ſhips, we may with confidence affirm that ſignals would be nothing but a parcel of arbitrary marks, appropriated to particular pieces of naval ſervice, ſuch as attacking the enemy, landing the ſoldiers, &c.; and that they would be conſidered merely as referring to the final reſult, but by no means pointing out the mode of execution, or directing the movements which were neceſſary for performing it.

4 But firſt formed into a ſyſtem by James II. when duke of York.

"It was James II. when duke of York, who firſt conſidered this practice as capable of being reduced into a ſyſtem, and who ſaw the importance of ſuch a compoſition. He, as well as the king his brother, had always ſhowed a great predilection for the ſea ſervice; and, when appointed admiral of England, he turned his whole attention to its improvement. He had ſtudied the art of war under Turenne, not as a paſtime, but as a ſcience, and was a favourite pupil of that moſt accompliſhed general. Turenne one day pointed him out, ſaying, "Behold one who will be one of the firſt princes and greateſt generals of Europe." When admiral of England, he endeavoured to introduce into the maritime ſervice all thoſe principles of concert and arrangement which made a number of individual regiments and ſquadrons compoſe a great army. When he commanded in the Dutch war, he found a fleet to be little better than a collection of ſhips, on board of each of which the commander and his ſhip's company did their beſt to annoy the enemy, but with very little dependence on each other, or on the orders of the General; and in the different actions which the Engliſh fleet had with the Dutch, every thing was confuſion as ſoon as the battle began. It is remarkable that the famous penſionary De Witt, who from a ſtateſman became a navigator and a great ſea commander in a few weeks, made the ſame repreſentation to the States General on his return from his firſt campaign.

"In the memoirs of James II. written by himſelf, we have the following paſſage: "1665. On the 15th of March the duke of York went to Gunfleet, the general rendezvous of the fleet, and haſtened their equipment. He ordered all the flag officers on board with him every morning, to agree on the order of battle and rank. In former battles, no order was kept, and this under the duke of York was the firſt in which fighting in a line and regular form of battle was obſerved."

"This muſt be conſidered as full authority for giving the duke of York the honour of the invention. For whatever faults may be laid to the charge of this unfortunate prince, his word and honour ſtand unimpeached. And we are anxious to vindicate his claim to it, becauſe our neighbours the French, as uſual, would take the merit of this invention, and of the whole of naval tactics, to themſelves. True it is, that Colbert, the great and juſtly celebrated miniſter of Lous XIV. created a navy for his ambitious and vain-glorious maſter, and gave it a conſtitution which may be a model for other nations to copy. By his encouragement, men of the greateſt ſcientific eminence were engaged to contribute to its improvement: and they gave us the firſt treatiſes of naval evolutions. But it muſt ever be remembered, that our accompliſhed, though miſguided ſovereign, was then reſiding

residing at the court of Louis; that he had formerly acted in concert with the French as a commander and flag officer, and was at this very time aiding them with his knowledge of sea affairs. In the memorable day at La Hogue, the gallant Russel, observing one of Tourville's movements, exclaimed, "There! they have got Pepy's † among them." This anecdote we give on the authority of a friend, who heard an old and respectable officer (Admiral Clinton) say, that he had it from a gentleman who was in the action, and heard the words spoken; and we trust that our readers will not be displeased at having this matter of general opinion established on some good grounds.

† Pepys was secretary to the duke of York.

5 Wonderful simplicity of his system;

"It was on this occasion, then, that the duke of York made the movements and evolutions of a fleet the object of his particular study, reduced them to a system, and composed that "System of Sailing and Fighting Instructions," which has ever since been considered as the code of discipline for the British navy, and which has been adopted by our rivals and neighbours as the foundation of their naval tactics. It does great honour to its author, although its merit will not appear very eminent to a careless surveyor, on account of that very simplicity which constitutes its chief excellence. It is unquestionably the result of much sagacious reflection and painful combination of innumerable circumstances, all of which have their influence; and it is remarkable, that although succeeding commanders have improved the subject by several subordinate additions, no change has to this day been made in its general principles or maxims of evolution.

"Till some such code be established, it is evident that signals can be nothing but arbitrary and unconnected hieroglyphics, to be learned by rote, and retained by memory, without any exercise of the judgment; and the acquisition of this branch of nautical skill must be a more irksome task than that of learning the Chinese writing. But such a code being once settled, the character in which it may be expressed becomes a matter of rational discussion.

"Accordingly, the sailing and fighting instructions of the duke of York were accompanied by a set of signals for directing the chief or most frequent movements of the fleet. These also were contrived with so much judgment, and such attention to distinctness, simplicity, and propriety, that there has hardly been any change found necessary; and they are still retained in the British navy as the usual signals in all cases when we are not anxious to conceal our movements from an enemy.

6 Yet as an art has since his time received considerable improvements.

"Notwithstanding this acknowledged merit of the duke of York's signals, it must be admitted that great improvements have been made on this subject, considered as an art. The art military has, in the course of a century past, become almost an appropriate calling, and has therefore been made the peculiar study of its professors. Our rivals the French were sooner, and more formally, placed in this situation, and the ministers of Louis XIV. took infinite and most judicious pains to make their military men superior to all others by their academical education. A more scientific turn was given to their education, and the assistance of scientific men was liberally given them; and all the nations of Europe must acknowledge some obligations to them for information on every thing connected with the art of war. They have attended very much to this subject, have greatly improved it, and have even introduced a new principle into the art; and by this means have reduced it to the most simple form of reference to the code of sailing and fighting instructions, by making the signals immediately expressive, not of orders, but of simple numbers. These numbers being prefixed to the various articles of the code of instructions, the officer who sees a signal thrown out by the admiral reads the number, and reports it to his captain, perhaps without knowing to what it relates. Thus simplicity and secrecy, with an unlimited power of variation, are combined. We believe that M. de la Bourdonnois, a brave and intelligent officer, during the war 1758, was the author of this ingenious thought.

"We do not propose to give a system of British signals. This would evidently be improper. But we shall show our readers the practicability of this curious language, the extent to which it may be carried, and the methods which may be practised in accomplishing this purpose. This may make it an object of attention to scientific men, who can improve it; and the young officer will not only be able to read the orders of the commander in chief, but will not be at a loss, should circumstances place him in a situation where he must issue orders to others."

Signals may be divided into,

I. Day Signals.

II. Night Signals; and,

III. Signals in a Fog.

They must also be distinguished into, 1. Signals of Evolution, addressed to the whole Fleet, or to Squadrons of the fleet, or to Divisions of these squadrons. 2. Signals of Movements to be made by particular ships; and, 3. Signals of Service, which may be either general or particular. 7

7 During an engagement the signals of the Admiral are repeated by frigates stationed out of the line.

The great extent of a large fleet, the smoke in time of battle, and the situation of the commander in chief, who is commonly in the midst of the greatest confusion and hottest fire, frequently makes it very difficult for the officers of distant ships to perceive his signals with distinctness. Frigates, therefore, are stationed out of the line, to windward or to leeward, whose sole office it is to observe the admiral's signals, and instantly to repeat them. The eyes of all the signal officers in the private ships of war are directed to the repeating frigates, as well as to the admiral; and the officers of the repeating frigate, having no other duty, observe the admiral incessantly, and, being unembarrassed by the action, can display the signal with deliberation, so that it may be very distinctly seen. Being minutely acquainted with the substitutions, which must be made on board the admiral when his masts and rigging are in disorder, his (perhaps imperfect) signal is exhibited by the repeating frigate in its proper form, so as to be easily understood. And to facilitate this communication, the commanders of the different squadrons repeat the signals of the commander in chief, and the commanders of division repeat the signals of the commanders of their squadron. 8

8 Evolution signals are preceded by a signal of advertisement, and accompanied with a directive signal.

"Every evolution signal is preceded by a signal of advertisement and preparation, which is general, and frequently by a gun, to call attention; and when all the signals have been made which direct the different parts of that evolution, another signal is made, which marks the close of the complex signal, and divides it from others which may immediately follow it: and as the orders of the commander in chief may relate either to the movements of the whole fleet, those of a single division, or

those

Naval Signals.

thoſe of certain private ſhips, the EXECUTIVE SIGNAL, which dictates the particular movement, is accompanied by a DIRECTIVE SIGNAL, by which theſe ſhips are pointed out, to which the order is addreſſed.

9 Anſwered by the commander to whom they are addreſſed.

The commander of the ſhip to which any ſignal is addreſſed, is generally required to ſignify by a ſignal (which is general) that he has obſerved it. And if he does not thoroughly underſtand its meaning, he intimates this by another general ſignal. And here it is to be obſerved, that as ſoon as the ſignal is anſwered by the ſhips to which it is addreſſed, it is uſual to haul it down, to avoid the confuſion which might ariſe from others being hoiſted in the ſame place. The order remains till executed, notwithſtanding that the ſignal is hauled down.

10 Annulling ſignal.

It may happen that the commander who throws out the ſignal for any piece of ſervice, ſees reaſons for altering his plan. He intimates this by a general ANNULLING ſignal, accompanying the ſignal already given. This will frequently be more ſimple than to make the ſignals for the movements which would be required for re-eſtabliſhing the ſhips in their former ſituation.

All theſe things are of very eaſy comprehenſion, and require little thought for their contrivance. But when we come to the particular evolutions and movements, and to combine theſe with the circumſtances of ſituation in which the fleet may be at the time, it is evident, that much reflection is neceſſary for framing a body of ſignals which may be eaſily exhibited, diſtinctly perceived, and well underſtood, with little riſk of being miſtaken one for another. We ſhall take notice of the circumſtances which chiefly contribute to give them theſe qualities as we proceed in deſcribing their different claſſes.

I. *Of* DAY SIGNALS.

THESE are made by means of the ſhip's ſails, or by colours of various kinds.

Thoſe made with ſails are but few in number, and are almoſt neceſſarily limited to the ſituation of a fleet at anchor. Thus,

The following Signals	*uſually ſignify.*
Main top-gallant ſtayſail hoiſted	Officers and men belonging to the ſhip to come on board.
Fore top-ſail looſe	To prepare for ſailing.
Main top-ſail looſe	To unmoor.
Main top-ſail ſheets hauled home	To weigh.
Main top-ſail ſheets clewed up, and the yard hoiſted	Annul the former ſignal, and the ſhip to come to an anchor.
Top-gallant ſails looſe, and the ſheets flying	Diſcovering ſtrange ſails.
Main top-gallant ſail looſe and hoiſted. Topſail-yard down	Recal ſhips in chaſe.
Mizen top-ſail hoiſted, and the ſheets clewed up	Moor.

Before we proceed to the deſcription of the ſignals by means of colours, ſuch as FLAGS, BANNERS (or triangular flags), PENDANTS or VANES, we muſt take notice of the oſtenſible diſtinctions of the various diviſions and ſubdiviſions of a fleet, ſo that we may underſtand how the ſame ſignal may be addreſſed to a ſquadron, diviſion, or ſingle ſhip or ſhips. We ſuppoſe it known that a fleet of ſhips of war is diſtributed into three grand diviſions (which we ſhall term *ſquadrons*), called the *van*, *centre*, and *rear*. Theſe denominations have not always a relation to the one being more advanced than the other, either towards the enemy, or in the direction of their courſe.

11 Meaning of the terms van, centre, and rear, in the line of battle at ſea.

In a land army, the poſition of every part is conceived from its reference to the enemy; and the reader, conceiving himſelf as facing the enemy, eaſily underſtands the terms *van*, *centre*, and *rear*, the *right* and *left wing*, &c. But the movements of a ſea army having a neceſſary dependence on the wind, they cannot be comprehended unleſs expreſſed in a language which keeps this circumſtance continually in view. The ſimpleſt and moſt eaſily conceived diſpoſition of a fleet, is that in which it is almoſt indiſpenſably obliged to form in order to engage an enemy. This is a ſtraight line, each ſhip directly a-head of its neighbour, and cloſe hauled. This is therefore called the *line of battle*. In this poſition, the two extremities of the fleet correſpond to the right and left wings of an army. Suppoſe this line to be in the direction eaſt and weſt, the wind blowing from the north-north-weſt, and therefore the fleet on the ſtarboard tack; the ſhips heads are to the weſt, and the weſtermoſt diviſion is undoubtedly the van of the fleet, and the eaſtermoſt diviſion is the rear. And it is in conformity to this arrangement and ſituation that the LIST OF THE FLEET is drawn up. But the ſhips may be on the ſame eaſt and weſt line, cloſe hauled, with their heads to the weſt, but the wind blowing from the ſouth-ſouth-weſt. They muſt therefore be on the larboard tack. The ſame ſhips, and the ſame diviſion, are ſtill, in fact, the van of the fleet. But ſuppoſe the ſhips heads to be to the eaſtward, and that they are cloſe hauled, having the wind from the ſouth-ſouth-eaſt or the north-north-eaſt, the ſhips which were the real van on both tacks in the former ſituation are now, in fact, the rear on both tacks; yet they retain the denomination of the *van ſquadron* of this fleet, and are under the immediate direction of the officer of the ſecond rank, while the other extremity is under the direction of the third officer. This ſubordination therefore is rather an arrangement of rank and precedence than of evolution. It is, however, conſidered as the NATURAL ORDER to which the general ſignals muſt be accommodated. For this reaſon, the diviſion which is denominated *van* in the liſt of this fleet, is *generally* made to lead the fleet when in the line of battle on the ſtarboard tack, and to form the *weathermoſt* column in *the order of ſailing in columns;* and, in general, it occupies that ſtation from which it can moſt eaſily paſs into the place of the leading diviſion on the ſtarboard line of battle ahead. Although this is a technical nicety of language, and may frequently puzzle a landſman in reading an account of naval operations, the reflecting and intelligent reader will ſee the propriety of retaining this mode of conceiving the ſubordinate arrangement of a fleet, and will comprehend the employment of the ſignals which are neceſſary for re-eſtabliſhing this arrangement, or directing the movements while another arrangement is retained.

This being underſtood, it is eaſy to contrive various methods

Naval Signals.

methods of distinguishing every ship by the place which she occupies in the fleet, both with respect to the whole line, with respect to the particular squadron, the particular division of that squadron, and the particular place in that division. This may be done by a combination of the position and colour of the pendants and vanes of each ship. Thus the colour of the pendants may indicate the squadron, their position or mast on which they are hoisted may mark the division of that squadron, and a distinguishing vane may mark the place of the private ship in her own division. The advantages attending this method are many. In a large fleet it would hardly be possible for the commander in chief to find a sufficient variety of single signals to mark the ship to which an order is addressed, by hoisting it along with the signal appropriated to the intended movement. But by this contrivance one third part of these signals of address is sufficient. It also enables the commander in chief to order a general change of position by a single signal, which otherwise would require several. Thus, suppose that the fore, main, and mizen masts, are appropriated (with the proper modifications) for exhibiting the signals addressed to the van, the centre, and the rear squadrons of the fleet, and that a red, a white, and a blue flag, are chosen for the distinguishing flags of the officers commanding these squadrons; then, if the commander in chief shall hoist a red flag at his mizen top-gallant mast head, it must direct the van squadron to take the position then occupied by the rear squadron the evolution necessary for accomplishing this end being supposed known by the commander of the squadron, who will immediately make the necessary signals to the squadron under his particular direction. In the same manner the distinguishing signal for the leading ship of a squadron being hoisted, along with the signal of address to the whole fleet, and the signal for any particular service, will cause the three or the nine leading ships to execute that order, &c. &c.

12 How signals are addressed to each of these divisions.

All that has been said hitherto may be considered as so many preparations for the real issuing of orders by the commander in chief. The most difficult part of the language remains, viz. to invent a number of signals which shall correspond to that almost infinite variety of movements and services which must be performed.

13 Essential qualities of signals are distinctness,

Distinctness, simplicity, and propriety, are the three essential qualities of all signals. A signal must be some object easily seen, strongly marked, so that it may be readily understood, with little risk of its being mistaken for another. When made by flags, banners, or pendants, they must be of the fullest colours, and strongest contrasts. The ships are frequently at a very great distance, so that the intervening air occasions a great degradation of colour. They are seen between the eye and a very variable sky; and in this situation, especially in the morning or evening, or a dark day, it is not easy to distinguish one full colour from another, all of them approaching to the appearance of a black. At the distance of a very few miles hardly any full colours can be distinguished but a scarlet and a blue. Red, blue, yellow, and white, are the colours which can be distinguished at greater distances than any others, and are therefore the only colours admitted as signals. Even these are sometimes distinguished with difficulty. A yellow is often confounded with a dirty white, and a blue with a red. All other dark colours are found totally unfit. But as these afford but a small variety, we must combine them in one flag, by making it striped, spotted, or chequered, taking care that the opposition of colour may be as great as possible, and that the pieces of which the flags are made up may not be too minute. Red must never be striped nor spotted with blue, and the stripes, spots, or chequers, should never be less than one-third of the breadth of the flag. Plate CCCCLXVI. is a selection by an officer of experience as a set very easily recognised, and little liable to be confounded. Their colours are reresented by hatching, in the same manner as in heraldry (See HERALDRY).

Difference of shape, as flags, banners, or pendants, is another distinction by which the expression may be varied. And in doing this, we must recollect, that in light winds it may be difficult to distinguish a flag from a banner as neither are fully displayed for want of wind to detach the fly from the staff.

And lastly signals may be varied by their position, which may be on any lofty and well detached part of the masts, yards, or rigging.

14 Simplicity.

Simplicity is an eminent property in all signals. They are addressed to persons not much accustomed to combinations, and who are probably much occupied by other pressing duties. It were to be wished that every piece of service could be indicated by a single flag. This is peculiarly desirable with respect to the signals used in time of battle. The rapid succession of events on this occasion call for a multitude of orders from the commander in chief, and his ship is frequently clad over with flags and pendants, so that it is exceedingly difficult for the signal officer of a private ship to distinguish the different groups, each of which make a particular signal.

15 And propriety.

These considerations are the foundation of a certain *propriety* in signals, which directs us to a choice among marks which appear altogether arbitrary. Signals which run any risk of being confounded, on account of some resemblance, or because their position hinders us from immediately perceiving their difference, should be appropriated to pieces of service which are hardly possible to be executed, or can hardly be wanted, in the same situation. No bad consequence could easily result though the signal for *coming to closer action* should resemble that for *unmooring*, because the present situation of the ships makes the last operation impossible or absurd. Such considerations direct us to select for battle signals, those which are of easiest exhibition, are the most simple, and have the least dependence on the circumstance of position; so that their signification may not be affected by the damages sustained in the masts or rigging of the flag ship. Such signals as are less easily seen at a distance, should be appropriated to orders which can occur only in the middle of the fleet, &c. &c. Signals which are made to the admiral by private ships may be the same with signals of command from the flag ship, which will considerably diminish the number of signals perfectly different from each other.

16 By what means signals are distinctly conveyed,

With all these attentions and precautions a system of signals is at last made up, fitted to the code of sailing and fighting instructions. It is accompanied by another small set for the duty of convoys. It must be engrossed in two books; one for the officer of the flag ship, who is to make the signals, and the other is

deli-

delivered to every private ship. In the first, the evolutions, movements, and other operations of service, are set down in one column, and their corresponding signals in another. The first column is arranged, either alphabetically, by the distinguishing phrase, or systematically, according to the arrangement of the sailing and fighting instructions. The officer whose duty it is to make the signals, turns to this column for the order which he is to communicate, and in the other column he finds the appropriated signal.

17 And understood.

In the other book, which is consulted for the interpretation of the signals, they are arranged in the leading column, either by the flags, or by the places of their exhibition. The first is the best method, because the derangement of the flag ship's masts and rigging in time of action may occasion a change in the place of the signal.

18 The art of signals much improved since the publication of the Tactique Navale.

"The *Tactique Navale* of the Chevalier de Morogues contains a very full and elaborate treatise on signals. We recommend this work to every sea-officer, as full of instruction. The art of signals has been greatly simplified since the publication of this work, but we cannot but ascribe much of the improvements to it. We believe that the author is the inventor of that systematic manner of addressing the order or *effective signal* to the different squadrons and divisions of the fleet, by which the art of signals is made more concise, the execution of orders is rendered more systematic, and the commanders of private ships are accustomed to consider themselves as parts of an army, with a mutual dependence and connection. We are ready enough to acknowledge the superiority of the French in manœuvring, but we affect to consider this as an imputation on their courage. Nothing can be more unjust; and dear-bought experience should long ere now have taught us the value of this superiority. What avails that courage which we would willingly arrogate to ourselves, if we cannot come to action with our enemy, or must do it in a situation in which it is almost impossible to succeed, and which needlessly throws away the lives of our gallant crews? Yet this must happen, if our admirals do not make evolutions their careful study, and our captains do not habituate themselves, from their first hoisting a pendant, to consider their own ship as connected with the most remote ship in the line. We cannot think that this view of their situation would in the least lessen the character which they have so justly acquired, of fighting their ship with a courage and firmness unequalled by those of any other nation. And we may add, that it is only by such a rational study of their profession, that the gentleman can be distinguished from the mercenary commander of a privateer."

II. Night Signals.

It is evident, that the communication of orders by night must be more difficult and more imperfect than by day. We must, in general, content ourselves with such orders as are necessary for keeping the fleet together, by directing the more general movements and evolutions which any change of circumstances may render necessary. And here the division and subordinate arrangement of the fleet is of indispensable necessity, it being hardly possible to particularise every ship by a signal of address, or to see her situation. The orders are therefore addressed to the commanders of the different divisions, each of whom is distinguished by his poop and top-lights, and is in the midst of, and not very remote from, the ships under his more particular charge. Yet even in this unfavourable situation, it is frequently necessary to order the movements of particular ships. Actions during the night are not uncommon. Pursuits and rallyings are still oftener carried on at this time. The common dangers of the sea are as frequent and more disastrous. The system of signals therefore is very incomplete till this part be accomplished.

Night signals must be made by guns, or by lights, or by both combined.

19 How gun-signals may be varied.

Gun-signals are susceptible of variety both in number and in disposition. The only distinct variation which can be made in this disposition, is by means of the time elapsed between the discharges. This will easily admit of three varieties, slow, moderate, and quick.—Half-minute guns are as slow as can easily be listened to as appertaining to one signal. Quarter-minute guns are much better, and admit of two very distinct subdivisions. When the gunners, therefore, are well trained to this service (especially since the employment of firelocks for cannon), intervals of 15 or 12 seconds may be taken for slow firing, 8 or 10 seconds for moderate, and 4 or 5 seconds for quick firing. If these could be reduced one half, and made with certainty and precision, the expression would be incomparably more distinct. A very small number of firings varied in this way will give a considerable number of signals. Thus five guns, with the variety of only quick and moderate, will give 20 very distinguishable signals. The same principle must be attended to here as in the flag signals. The most simple must be appropriated to the most important orders, such as occur in the worst weather, or such as are most liable to be mistaken. Quick firing should not make part of a signal to a very distant ship, because the noise of a gun at a great distance is a lengthened sound, and two of them, with a very short interval, are apt to coalesce into one long continued sound. This mode of varying gun-signals by the time must therefore be employed with great caution, and we must be very certain of the steady performance of the gunners.

Note, that a preparatory signal or advertisement that an effective signal is to be made, is a very necessary circumstance. It is usual (at least in hard weather) to make this by a double discharge, with an interval of half a second, or at most a second.

Gun-signals are seldom made alone, except in ordinary situations and moderate weather; because accident may derange them, and inattention may cause them to escape notice, and, once made, they are over, and their repetition would change their meaning. They are also improper on an enemy's coast, or where an enemy's cruisers or fleets may be expected.

20 Signals by lights.

Signals by lights are either made with LIGHTS simply so called, *i. e.* lanthorns shown in different parts of the ship, or by rockets. Lights may differ by number, and by position, and also by figure. For the flag ship always carrying poop or top-lights, or both, presents an object in the darkest night, so that we can tell whether the additional lights are exhibited about the mainmast, the foremast, the mizenmast, &c. And if the lights shown from any of these situations are arranged in certain distinguishable situations in respect to each other, the number

number of ſignals may be greatly increaſed. Thus three lights may be in a vertical line, or in a horizontal line, or in a triangle, and the point of this triangle may be up, or down, or forward, or aſt, and thus may have many ſignifications.

Lights are alſo exhibited by falſe fires or rockets: Theſe can be varied by number, and by ſuch differences of appearance as to make them very diſtinguiſhable. Rockets may be with ſtars, with rain fire, or ſimple ſquibs.

21 These two ſpecies of ſignals may be combined.

By varying and combining theſe, a very great number of ſignals may be produced, fully ſufficient to direct every general movement or evolution, or any ordinary and important ſervice. The Chevalier de Morogues has given a ſpecimen of ſuch a ſyſtem of night ſignals, into which he has even introduced ſignals of addreſs or direction to every ſhip of a large fleet; and has alſo given ſignals of number, by which depths of ſoundings, points of the compaſs, and other things of this kind, may be expreſſed both eaſily and diſtinctly. He has made the ſignals by rockets perfectly ſimilar in point of number to thoſe by lanthorns, ſo that the commander can take either; a choice which may have its uſe, becauſe the ſignals by rockets may cauſe the preſence of a fleet to be more extenſively known than may be convenient.

22 General obſervations concerning night ſignals.

The commander in chief will inform the fleet by ſignal, that guns, or perhaps rockets, are not to be uſed that night. This ſignal, at the ſame time, directs the fleet to cloſe the line or columns, that the light ſignals may be better obſerved.

It is indeed a general rule to ſhow as few lights as poſſible; and the commander frequently puts out his own poop and top-lights, only ſhowing them from time to time, that his ſhips may keep around him.

The ſignal lanthorns on board the flag ſhip, and a lanthorn kept in readineſs on board of every private ſhip, to anſwer or acknowledge ſignals from the commander in chief, are all kept in bags, to conceal their lights till the moment they are fixed in their places, and the preparatory or advertiſing ſignal has been made.

The commander in chief ſometimes orders by ſignal every ſhip to ſhow a light for a minute or two, that he may judge of the poſition of the fleet; and the admiral's ſignal muſt always be acknowledged by theſe to whom it is addreſſed.

It is of particular importance that the fleet be kept together. Therefore the leading ſhips of the fleet, on either tack, are enjoined to acknowledge the ſignals of the commander in chief by a ſignal peculiar to their ſtation. Thus the commander in chief learns the poſition of the extremities of his fleet.

In framing a ſet of night ſignals, great attention muſt be given to their poſition, that they be not obſcured by the ſails. The nature of the order to be given will frequently determine this. Thus, an order for the rear ſhips to make more ſail, will naturally direct us to exhibit the ſignal at the mizen peek; and ſo of other pieces of ſervice. Lanthorns expoſed in groups, ſuch as triangles, lozenges, &c. are commonly ſuſpended at the corners of large frames of laths, at the diſtance of a fathom at leaſt from each other. Attempts have been made to ſhow lights of different colours; but the riſk of miſtake or failure in the compoſition at the laboratory, makes this rather hazardous. Coloured lanthorns are more certain; but when the glaſſes are made of a colour ſufficiently intenſe, the vivacity of the light (which at no time is very great) is too much diminiſhed. Beſides, the very diſtance changes the colour exceedingly and unaccountably.

III. *Of* Signals *in a* Fog.

These can be made only by noiſes, ſuch as the firing of cannon and muſkets, the beating of drums and ringing of bells, &c. Fog ſignals are the moſt difficult to contrive of any, and are ſuſceptible of the leaſt variety. The commander in chief is principally concerned to keep his fleet together; and unleſs ſomething very urgent requires it, he will make no change in his courſe or rate of ſailing. But a ſhift of wind or other cauſes may make this neceſſary. The changes which he will order, it will be prudent to regulate by ſome fixed rule, which is in general convenient. Thus, when a fleet is in the order of ſailing upon a wind, and a fog comes on, the fleet will hold on the ſame courſe. If the wind ſhould come a little more on the beam, the fleet will ſtill keep cloſe to the wind. Certain general rules of this kind being agreed on, no ſignals are neceſſary for keeping the fleet together; and the ſhips can ſeparate or run foul of each other only by difference in their rate of ſailing, or by inaccurate ſteerage. To prevent this, the commander in chief fires a gun from time to time, and the ſhips of the fleet judge of his ſituation and diſtance by the ſound. The commanders of diviſions fire guns, with ſome diſtinction from thoſe of the commander in chief. This both informs the commander in chief of the poſition of his ſquadrons, and enables the private ſhips of each diviſion to keep in the neighbourhood of their own flag ſhip. On board of every private ſhip the drum is beaten, or the bell is chimed, every quarter of an hour, according as the ſhip is on the ſtarboard or larboard tack. By ſuch contrivances, it is never difficult keep a fleet in very good order when ſailing on a wind. The wind is almoſt always moderate, and the ſhips keep under a very eaſy ſail. It is much more difficult when going large, and ſeparation can be prevented only by the moſt unwearied attention. The greateſt riſk is the falling in with ſtrange ſhips ſteering another courſe.

23 By obſerving certain general rules ſignals during a fog are in many caſes unneceſſary.

But evolutions and other movements are frequently indiſpenſable. The courſe muſt be changed by tacking or wearing, and other ſervices muſt be performed. None, however, are admitted but the moſt probable, the moſt ſimple, and the moſt neceſſary.

24 How they are given when neceſſary.

The commander in chief firſt informs the fleet by the *preparatory fog ſignal*, that he is about to order an evolution, and that he is to direct it by *fog ſignals*. This precaution is indiſpenſable to prevent miſtakes. Along with this advertiſing ſignal he makes the ſignal of the movement intended. This not only calls the attention of the fleet, but makes the ſhips prepare for the preciſe execution of that movement. The commanders of diviſions repeat the advertiſing ſignal, which informs their ſhips of their ſituation, and the private ſhips beat their drums or chime their bells. Thus the whole ſhips of the fleet cloſe a little, and become a little better acquainted with their mutual poſition. It is now underſtood that a movement is to be made preciſely a quarter of an hour after the advertiſement. At

Naval Signals. the expiration of this time, the effective signal for this movement is made by the commander in chief, and must be instantly repeated by the commanders of divisions, and then the movement must be made by each ship, according to the sailing and fighting instructions. This must be done with the utmost attention and precision, because it produces a prodigious change in the relative position of the ships; and even although the good sense of the commander in chief will select such movements for accomplishing his purpose as produce the smallest alterations, and the least risk of separation or running foul of each other; it is still extremely difficult to avoid these misfortunes. To prevent this as much as possible, each ship which has executed the movement, or which has come on a course thwarting that of the fleet, intimates this by a signal properly adapted, often adding the signal of the tack on which it is now standing, and even its particular signal of recognizance. This is particularly incumbent on the flag ships and the leading ships of each division.

After a reasonable interval, the commander in chief will make proper signals for bringing the fleet to a knowledge of their reunion in this new position.

25 Improper to publish a particular account of signals.

This must serve for a general account of the circumstances which must be attended to in framing a code of signals. The arbitrary characters in which the language is written must be left to the sagacity of the gentlemen of the profession. It must be observed, that the stratagems of war make secrecy very necessary. It may be of immense hazard if the enemy should understand our signals. In time of battle it might frequently frustrate our attempts to destroy them, and at all times would enable them to escape, or to throw us into disorder. Every commander of a squadron, therefore, issues private signals, suited to his particular destination; and therefore it is necessary that our code of signals be susceptible of endless variations. This is exceedingly easy without any increase of their number. The commander needs only intimate that such and such a signal is so and so changed in its meaning during his command.

26 Signals may be made the immediate expressions of numbers.

We cannot leave this article without returning to an observation which we made almost in the beginning, viz. that the system of signals, or, to speak more properly, the manner of framing this system, has received much improvement from the gentlemen of the French navy, and particularly from the most ingenious thought of M. de la Bourdonnais, of making the signals the immediate expressions of *numbers* only, which numbers may be afterwards used to indicate any order whatever. We shall present our readers with a scheme or two of the manner in which this may be done for all signals, both day, night, and fog. This alone may be considered as a system of signals, and is equally applicable to every kind of information at a distance. Without detracting in the smallest degree from the praise due to M. de la Bourdonnais, we must observe, that this principle of *notation* is of much older date. Bishop Wilkins, in his Secret and Swift Messenger, expressly recommends it, and gives specimens of the manner of execution; so does Dr Hooke in some of his proposals to the Royal Society. Gaspar Schottus also mentions it in his *Technica Curiosa;* and Kircher, among others of his Curious Projects.

M. de la Bourdonnais's method is as follows: Naval Signals.

27 M. de la Bourdonnais's method for doing this

He chooses pendants for his effective signals, because they are the most easily displayed in the proper order. Several pendants, making part of one signal, may be hoisted by one hallyard, being stopped on it at the distance of four or six feet from each other. If it be found proper to throw out another signal at the same time and place, they are separated by a red pendant without a point. His colours are chosen with judgement, being very distinctly recognised, and not liable to be confounded with the addressing signals appropriated to the different ships of the fleet. They are,

For N° 1.	Red.	For N° 6.	Red, with blue tail.
2.	White.	7.	White, with blue tail.
3.	Blue.	8.	White, with red tail.
4.	Yellow.	9.	Blue, with yellow tail.
5.	Red, with white tail.	0.	Yellow, with blue tail.

Three sets of such pendants will express every number under a thousand, by hoisting one above the other, and reckoning the uppermost hundreds, the next below it tens, and the lowest units. Thus the number 643 will be expressed by a pendent red with blue tail, a yellow pendant below it, and a blue one below the last.

This method has great advantages. The signals may be hoisted in any place where best seen, and therefore the signification is not affected by the derangement of the flag ship's masts and rigging. And by appropriating the smaller numbers to the battle signals, they are more simple, requiring fewer pendants.

28 Might be rendered much simpler by using fewer colours.

As this method requires a particular set of colours, it has its inconveniences. An admiral is often obliged to shift his flag, even in time of action. He cannot easily take the colours along with him. It is therefore better to make use of such colours as every private ship is provided with. One set of 11 will do with the addition of three, at most of four pendants, of singular make, to mark 100, 200, 300, 400. Two of these flags, one above the other, will express any number under 100, by using the 11th as a substitute for any flag that should be repeated. Thus the 11th flag, along with the flag for eight or for six, will express the number of 88 or 66, &c. Thus we are able to express every number below 500, and this is sufficient for a very large code of signals.

And in order to diminish as much as possible the number of these compound signals, it will be proper that a number of single flag signals be preserved, and even varied by circumstances of position, for orders which are of very frequent occurrence, and which can hardly occur in situations where any obstructions are occasioned by loss of masts, &c. And farther, to avoid all chance of mistake, a particular signal can be added, intimating that the signals now exhibited are numerary signals; or, which is still better, all signals may be considered as numerary signals; and those which we have just now called *single flag signals* may be set down opposite to, or as expressing, the largest numbers of the code.

This method requires the signal of advertsement, the annulling signal, the signal of address to the particular ship or division, the signal of acknowledgment, the signal of indistinctness, of distress, of danger, and one

Naval Signals. one or two more which, in every method, muſt be employed.

Another method of expreſſing numbers with fewer colours is as follows; Let the flags be A, B, C, D, E, F, and arrange them as follows:

29 Another method of expreſſing numbers by fewer colours.

	A	B	C	D	E	F
	1	2	3	4	5	6
A	7	8	9	10	11	12
B	13	14	15	16	17	18
C	19	20	21	22	23	24
D	25	26	27	28	29	30
E	31	32	33	34	35	36
F	37	38	39	40	41	42

The number expreſſed by any pair of flags is found in the interſection of the horizontal and perpendicular columns. Thus the flag D, hoiſted along with and above the flag F, expreſſes the number 40, &c. In order to expreſs a greater number (but not exceeding 84) ſuppoſe 75, hoiſt the flags $\frac{C}{E}$, which expreſſes 33, or 75 wanting 42, and above them a flag or ſignal G, which alone expreſſes 42.

30 Which may be alſo improved. This method may be ſtill farther improved by arranging the flags thus:

	A	B	C	D	E	F
	1	2	3	4	5	6
A	7	8	9	10	11	12
B	—	13	14	15	16	17
C	—	—	18	19	20	21
D	—	—	—	22	23	24
E	—	—	—	—	25	26
F	—	—	—	—	—	27

In this laſt method the ſignification of the ſignal is totally independent of the poſition of the flags. In whatever parts of the ſhip the flags D and E are ſeen, they expreſs the number 23. This would ſuit battle ſignals.

31 A third method. Another method ſtill may be taken. Flags hoiſted any where on the foremaſt may be accounted units, thoſe on the mainmaſt tens, and thoſe on the mizenmaſt hundreds. Thus numeral ſignals may be made by a ſhip diſmaſted, or having only poles in their place.

Many other ways may be contrived for expreſſing numbers by colours, and there is great room for exerciſing the judgment of the contriver. For it muſt always be remembered, that theſe ſignals muſt be accompanied with a ſignal by which it is addreſſed to ſome particular ſhip or diviſion of the fleet, and it may be difficult to connect the one with the other, which is perhaps ſhown in another place, and along with other executive ſignals.

32 Advantages of numeral ſignals. One great advantage of theſe numeral ſignals is, that they may be changed in their ſignification at pleaſure. Thus, in the firſt method, it can be ſettled, that on Sundays the colours A, B, C, D, &c. expreſs the cyphers 1, 2, 3, 4, &c. but that on Mondays they expreſs the cyphers 0, 1, 2, 3, &c. and on Tueſdays the cyphers 9, 0, 1, 2, &c.; and ſo on through all the days of the week. This mean of ſecrecy is mentioned by Dr Hooke for the coaſt and alarm ſignals, where, by the by, he ſhews a method for conveying intelligence over land very ſimilar to what is now practiſed by the French with their telegraph.

It is equally eaſy to expreſs numbers by night ſignals. Thus M. de la Bourdonnais propoſes, that one diſcharge of a great gun ſhall expreſs 7, and that 1, 2, 3, 4, 5, 6 ſhall be expreſſed by lights. Therefore, to expreſs 24, we muſt fire three guns, and ſhow three lights. This is the moſt perfect of all forms of night and fog ſignals. For both the manner of firing guns and of exhibiting lights may be varied to a ſufficient extent with very few guns or lights, and with great diſtinctneſs. 33 Numbers may be alſo expreſſed by night ſignals.

Thus, for guns. Let F mark the firing of a ſingle gun at moderate intervals, and *ff* a double gun, that is, two diſcharged at the interval of a ſecond. We may expreſs numbers thus:

1	F.
2	F, F.
3	F, F, F.
4	F, F, F, F.
5	F, *ff*.
6	F, F, *ff*.
7	F, *ff*, F.
8	F, *ff*, F, F.
9	F, *ff*, F, *ff*.
10	*ff*.
100, &c.	*ff*, *ff*, or *fff*.

It might be done with fewer guns if the *ff* were admitted as the firſt firing. But it ſeems better to begin always with the ſingle gun, and thus the double gun beginning a ſignal diſtinguiſhes the tens, &c.

In like manner, a ſmall number of lights will admit of a great variety of very diſtinct poſitions, which may ſerve for all ſignals to ſhips not very remote from the commander in chief. For orders to be underſtood at a very great diſtance, it will be proper to appropriate the numbers which are indicated by ſignals made with rockets. Theſe can be varied in number and kind to a ſufficient extent, ſo as to be very eaſily diſtinguiſhed and underſtood. It is ſufficient to have ſhown how the whole, or nearly the whole, notation of ſignals may be limited to the expreſſion of numbers.

We have taken little notice of the ſignals made by private ſhips to the commander in chief. This is a very eaſy buſineſs, becauſe there is little riſk of confounding them with other ſignals. Nor have we ſpoken of ſignals from the flag ſhips whoſe ultimate interpretation is number, as when ſhips are directed to change their courſe ſo many points. Thoſe alſo are eaſily contrived in any of the methods already deſcribed: alſo when a private ſhip wiſhes to inform the commander in chief that ſoundings are found at ſo many fathoms. In like manner, by numbering the points of the compaſs, the admiral can direct to chace to any one of them, or may be informed of ſtrange ſhips being ſeen in any quarter, and what is their number. 34 Concluding remarks.

SIGNALS *by the Drum*, made uſe of, in the exerciſe of the army, inſtead of the word of command, viz.

SIGNALS.	*Operations.*
A ſhort roll, -	To caution.
A flame, -	To perform any diſtinct thing.
To arms, -	To form the line or battalion
The march, -	To advance, except when intended for a ſalute.
The quick march,	To advance quick.
The point of war,	To march and charge.

The retreat,	To retreat.
Drum ceasing, -	To halt.
Two short rolls, -	To perform the flank firing.
The dragoon march, -	To open the battalion.
The grenadier march,	To form the column.
The troop, -	To double divisions.
The long roll, -	To form the square.
The grenadier march,	To reduce the square to the column.
The preparative, -	To make ready and fire.
The general, -	To cease firing.
Two long rolls, -	To bring or lodge the colours.

SIGNATURE, a sign or mark impressed upon any thing, whether by nature or art. Such is the general signification of the word; but in the plural number it has been used, in a particular sense, to denote those external marks by which physiognomists and other dabblers in the occult sciences pretend to discover the nature and internal qualities of every thing on which they are found. According to Lavater, every corporeal object is characterized by signatures peculiar to itself.

The doctrine of signatures, like alchemy and astrology, was very prevalent during the 15th and 16th centuries; and was considered as one of the occult sciences which conferred no small degree of honour on their respective professors. Some of these philosophers, as they thought fit to style themselves, maintained that plants, minerals, and animals, but particularly plants, had signatures impressed on them by the hand of nature, indicating to the adept the *therapeutic* uses to which they might be applied. Others, such as the mystic theosophists and chemists of that day, proceeded much farther in absurdity, maintaining that every substance in nature had either *external* signatures immediately discernible, or *internal* signatures, which, when brought into view by fire or menstrua, denoted its connection with some siderial or celestial archetype. Of the doctrine of signatures, as it relates merely to the therapeutic uses of plants and minerals, traces are to be found in the works of some of the greatest authors of antiquity; but the celestial signatures, we believe, were discovered only by the moonlight of the monkish ages. Pliny informs us*, that the marble called *aphites*, from its being spotted like a serpent, was discovered by those spots to be a sovereign remedy for the bite of that animal; and that the colour of the *hæmatites* or blood-stone intimated that it was fit to be employed to stop an hemorrhagy; but we do not recollect his attributing the virtues of these minerals to a siderial or celestial influence.

* Hist Nat. lib. 34.

Signature, a signing of a person's name at the bottom of an act or deed written by his own hand.

Signature, in printing, is a letter put at the bottom of the first page at least, in each sheet, as a direction to the binder in folding, gathering, and collating, them. The signatures consist of the capital letters of the alphabet, which change in every sheet: if there be more sheets than letters in the alphabet, to the capital letter is added a small one of the same sort, as A a, B b; which are repeated as often as necessary. In large volumes it is easy to distinguish the number of alphabets, after the first three or four, by placing a figure before the signature, as 5 B, 6 B, &c.

SIGNET, one of the king's seals, made use of in sealing his private letters, and all grants that pass by bill signed under his majesty's hand: it is always in the custody of the secretaries of state.

Signet, in Scots law. See Law, Part III. § 17.

SILENE, Catchfly, or *Viscous Campion*, in botany: A genus of plants belonging to the class of *decandria*, and order of *trigynia*; and in the natural system arranged under the 22d order, *caryophylleæ*. The calyx is ventricose; the petals are five in number, bifid and unguiculated, and crowned by a nectarium; the capsule is cylindrical, covered, and trilocular. There are 26 species, of which 7 are natives of Britain and Ireland. 1. *Anglica*, the small corn campion or catchfly. The stem is weak, hairy, and above a foot high; the leaves are oblong, and grow in pairs at the joints; the flowers are small, white, and entire; they stand on footstalks which issue from the alæ of the leaves; they are erect, alternate, single, and lateral. It grows in corn-fields, and flowers in June and July. 2. *Nutans*, Nottingham catchfly. The stem is about two feet high, and firm: the radical leaves are broad, obtuse, and grow in a tuft; those on the stem are narrow and acute: the flowers are white, and grow in lateral panicles; the petals are bifid and curled; the calyx is long, bellying a little, with ten longitudinal striæ. It grows in pastures, and flowers in June and July. 3. *Amœna*, sea campion. The stem is two or three feet long, slender, procumbent, and branched alternately: the leaves are long and narrow: the flowers are white, and grow on opposite footstalks, three on each, in unilateral bunches: the calyx is hairy and purplish, and has ten angles. It grows on the south coast, and flowers in June and July. 4. *Conoidea*, greater corn catchfly, or campion. The leaves are narrow and soft; the calyx is conical, with 30 striæ; the flowers proceed from the divarications of the stem; the petals are entire. It grows in corn fields, and flowers in June. 5. *Noctiflora*, night flowering catchfly. The stem is about two feet high, and forked; the calyx has ten angles, is somewhat clammy, and oval, with longer teeth than the other species; the petals are of a reddish white. 6. *Armeria*, broad-leaved catchfly. The stem is about 18 inches high, and erect, with few branches; the leaves are smooth, sessile, and broad at the base; the flowers terminal, in fastigiate bundles, small and red. It may be seen on the banks of rivers, and is in flower in July and August. 7. *Acaulis*, moss campion. The radical leaves are spread on the ground like a tuft of moss; the stalks are about an inch long, and naked, bearing each a single purple flower. This last species grows on mountains, and has been found, in Wales and Scotland, within half a mile from their top. It is in flower in July.

SILESIA, a duchy of Germany, bounded on the east by Poland; on the west, by Bohemia and Lower Lusatia; on the south, by a chain of mountains, and a thicket of considerable extent which separates it from Hungary; and to the north, by the marquisate of Brandenburg and Poland. From north-west to south-east it is about 274 miles, and about 100 where broadest: but it is much contracted at both ends. Upon the frontiers of this country, to the west and south, are very high mountains, and some likewise in other parts of it. One of the ridges upon the frontiers is styled the *Riphæan mountains*, another the *Moravian*, another the *Bohemian*, and another the *Hungarian*, *Crapack*, or *Carpathian*.

pathian. A branch of the Bohemian is called the *Giant Mountains*. The winter on thefe hilly tracks is more fevere, fets in fooner, and lafts longer, than in the low lands. The inhabitants ufe a kind of fkates when the fnow is deep, as they do in Carniola. Little or no grain is raifed in the mountains and fome fandy tracks; but the reft of the country is abundantly fruitful, not only in grain, but fruits, roots, pafture, flax, hops, madder, tobacco, and hemp, yielding alfo fome wine, with confiderable quantities of filk and honey. In many places are great woods of pines, fir, beech, larch, and other trees, affording tar, pitch, rofin, turpentine, lamp-black, and timber for all ufes. In this country alfo is found marble of feveral forts, fome precious ftones, lime-ftone, millftone, pitcoal, turf, vitriol, fome filver ore, copper, lead, iron, and mineral fprings. Great numbers of black cattle and horfes are brought hither from Poland and Hungary for fale, thofe bred in the country not being fufficient; but of fheep, goats, game, and venifon, they have great plenty. As for wild beafts, here are lynxes, foxes, weafels, otters, and beavers. The rivers, lakes, and ponds, yield fifh of feveral forts, particularly fturgeons feveral ells in length, and falmon. Befides a number of fmaller ftreams to water this country, there is the Oder, which traverfes it almoft from one end to the other; and the Viftula, which after a pretty long courfe through it enters Poland. The number of the cities and market-towns is faid to be about 200, the county of Glatz included, and that of the villages 5000. The inhabitants, who are computed to be about a million and an half, are a mixture of Germans, Poles, and Moravians. The language generally fpoken is German; but in fome places the vulgar tongue is a dialect of the Sclavonic. The ftates confift of the princes and dukes, and thofe called *ftate-lords*, with the nobility, who are immediately fubject to the fovereign, and the reprefentatives of the chief cities; but fince the country fell under the dominion of the king of Pruffia, no diets have been held. The king, however, when he took poffeffion of the country, confirmed all the other privileges of the inhabitants. With refpect to religion, not only Proteftants, but Papifts, Jews, and Greeks, enjoy full liberty of confcience. The greateft part of Silefia lies in the diocefe of Breflaw, but fome part of it in the Polifh diocefes of Pofen and Cracow. The bifhop of Breflaw ftands immediately under the pope with regard to fpirituals: but all ecclefiaftical benefices, not excepting the fee of Breflaw, are in the king's gift. Befides Latin fchools, colleges, and feminaries, at Breflaw is an univerfity, and at Lignitz an academy for martial exercifes. The principal manufactures here are woollens, linens, and cottons of feveral forts, with hats, glafs-ware, gunpowder, and iron manufactures. Of thefe there is a confiderable exportation. Accounts are generally kept in rix-dollars, filver grofchens, and ducats. With refpect to its revolutions and prefent government, it was long a part of the kingdom of Poland; afterwards it had feveral dukes and petty princes for its fovereigns, who by degrees became fubject to the kings of Bohemia, until at laft king Charles IV. incorporated the whole duchy with Bohemia; and thus it continued in the poffeffion of the houfe of Auftria, until the king of Pruffia in 1742, taking advantage of the troubles that enfued upon the death of the emperor Charles VI. and pretending a kind of claim, wrefted a great part of it, together with the county of Glatz, from his daughter and heirefs Maria Therefa, the late emprefs-dowager; fo that now only a fmall part of it is poffeffed by the houfe of Auftria, and connected with the empire, the reft being governed by the king of Pruffia, without acknowledging any fort of dependence on the crown of Bohemia or the empire. For the adminiftration of juftice in all civil, criminal, and feudal cafes, and fuch as relate to the revenue, the king of Pruffia has eftablifhed three fupreme judicatories, to which an appeal lies from all the inferior ones, and from which, when the fum exceeds 500 rix-dollars, caufes may be moved to Berlin. The Lutheran churches and fchools are under the infpection of the upper confiftories, and thofe of the Papifts under that of the bifhop's court at Breflaw; but from both an appeal lies to the tribunal at Berlin. As to the revenue, the excife here is levied only in the walled towns, being on the fame footing as in the marquifate of Brandenburg; but in the reft of the country the contributions are fixed, and the fame both in peace and war. The feveral branches of the revenue are under the management of the war and domain officers of Breflaw and Glogau. The whole revenue arifing to the king of Pruffia from Silefia and the county of Glatz amounts to about four millions of rix-dollars *per annum*.

Silefia is divided into Upper and Lower, and each of thefe again into principalities and lordfhips; of fome of which both the property and jurifdiction belong immediately to the fovereign, but of others to his fubjects and vaffals. In regard to the character of the people, the boors are accounted very dull and ftupid; but of thofe of a higher rank, many have diftinguifhed themfelves by their wit and learning, as well as by their military and political talents. However, in general, like their neighbours the Germans and Bohemians, they have more of Mars than Mercury in their compofition, and their parts are more folid than fhining.

SILESIAN EARTH, in the materia medica, a fine aftringent bole. It is very heavy, of a firm compact texture, and in colour of a brownifh yellow. It breaks eafily between the fingers, and does not ftain the hands; is naturally of a fmooth furface, is readily diffufible in water, and melts freely into a butter-like fubftance in the mouth. It leaves no grittinefs between the teeth, and does not ferment with acid menftrua. It is found in the perpendicular fiffures of rocks near the gold-mines at Strigonium in Hungary, and is fuppofed to be impregnated with the fulphur of that metal. It is a good aftringent, and better than moft of the boles in ufe.

SILICERNIUM, among the Romans, was a feaft of a private nature, provided for the dead fome time after the funeral. It confifted of beans, lettuces, bread, eggs, &c. Thefe were laid upon the tomb, and they foolifhly believed that the dead would come out for the repaft. What was left was generally burnt on the ftone. The word *filicernium* is derived from *filex* and *cœna*, i. e. "a fupper upon a ftone." Eating what had thus been provided for the dead, was efteemed a mark of the moft miferable poverty. A fimilar entertainment was made by the Greeks at the tombs of the deceafed; but it was ufual among them to treat the ghofts with the fragments from the feaft of the living. See FUNERAL and INFERIÆ.

SILEX. See Flint.

SILICEOUS earths. See Mineralogy, Part II. Order 4.

SILIUS (Italicus Caius), an ancient Roman poet, and author of an epic poem in 17 books, which contains an history of the second Punic war, so famous for having decided the empire of the world in favour of the Romans. He was born in the reign of Tiberius, and is supposed to have derived the name of *Italicus*, from the place of his birth; but whether he was born at Italica in Spain, or at Corfinium in Italy, which, according to Strabo, had the name of *Italica* given it during the Social war, is a point which cannot be known: though, if his birth had happened at either of these places, the grammarians would tell us, that he should have been called *Italicensis*, and not *Italicus*. When he came to Rome, he applied himself to the bar; and, by a close imitation of Cicero, succeeded so well, that he became a celebrated advocate and most accomplished orator. His merit and character recommended him to the highest offices in the republic, even to the consulship, of which he was possessed when Nero died. He is said to have been aiding and assisting in accusing persons of high rank and fortune, whom that wicked emperor had devoted to destruction: but he retrieved his character afterwards by a long and uniform course of virtuous behaviour. Vespasian sent him as proconsul into Asia, where he behaved with clean hands and unblemished reputation. After having thus spent the best part of his life in the service of his country, he bade adieu to public affairs, resolving to consecrate the remainder to polite retirement and the muses. He had several fine villas in the country: one at Tusculum, celebrated for having been Cicero's; and a farm near Naples said to have been Virgil's, at which was his tomb, which Silius often visited. Thus Matial compliments him on both these accounts:

Silius hæc magni celebrat monumenta Maronis,
Jugera facundi qui Ciceronis habet.
Hæredem Dominumque sui tumulique larisque
Non alium mallet nec Maro nec Cicero.

Epigr. 49. lib. xi.

Of Tully's seat my Silius is possess'd,
And his the tomb where Virgil's ashes rest.
Could those great shades return to choose their heir,
The present owner they would both prefer.

In these retirements he applied himself to poetry: led not so much by any great force of genius, which would certainly not have suffered him to stay till life was in the wane and his imagination growing cold, as by his exceeding great love of Virgil, to whose memory he paid the highest veneration. He has imitated him in his poem; and though he falls infinitely short of him, yet he has discovered a great and universal genius, which would have enabled him to succeed in some degree in whatever he undertook.

Having been for some time afflicted with an imposthume, which was deemed incurable, he grew weary of life, to which, in the language of Pliny, he put an end with determined courage.

There have been many editions of Silius Italicus. A neat and correct one was published at Leipsic in 1696, in 8vo, with short and useful notes by Cellarius: but the best is that *cum notis integris variorum et Arnoldi Drakenborch.* Traject. ad Rhen. 1717, in 4to.

SILK, a very soft, fine, bright thread, the work of an insect called *bombyx*, or the silk worm.

As the silk worm is a native of China, the culture of silk in ancient times was entirely confined to that country. We are told that the empresses, surrounded by their women, spent their leisure hours in hatching and rearing silk worms, and in weaving tissues and silk veils. That this example was soon imitated by persons of all ranks, we have reason to conclude; for we are informed that the Chinese, who were formerly clothed in skins, in a short time after were dressed in vestments of silk. Till the reign of Justinian, the silk worm was unknown beyond the territories of China, but silk was introduced into Persia long before that period. After the conquest of the Persian empire by Alexander the Great, this valuable commodity was brought into Greece, and thence conveyed to Rome. The first of the Roman writers extant by whom silk is mentioned, are Virgil and Horace; but it is probable that neither of them knew from what country it was obtained, nor how it was produced. By some of the ancients it was supposed to be a fine down adhering to the leaves of certain trees or flowers. Others imagined it to be a delicate species of wool or cotton; and even those who had learned that it was the work of an insect, show by their descriptions that they had no distinct idea of the manner in which it was formed. Among the Romans, silk was deemed a dress too expensive and too delicate for men, and was appropriated wholly to women of eminent rank and opulence. Elagabulus is said to have been the first man among the Romans who wore a garment of fine silk. Aurelian complained that a pound of silk was sold at Rome for 12 ounces of gold; and it is said he refused to give his wife permission to wear it on account of its exorbitant price.

1 Opinions of the ancients concerning the nature of silk.

For several centuries the Persians supplied the Roman empire with the silks of China. Caravans traversed the whole latitude of Asia, in 243 days, from the Chinese ocean to the sea-coast of Syria, carrying this commodity. Sometimes it was conveyed to the ports of Guzerat and Malabar, and thence transported by sea to the Persian Gulph. The Persians, with the usual rapacity of monopolists, raised the price of silk to such an exhorbitant height, that Justinian, eager not only to obtain a full and certain supply of a commodity which was become of indispensable use, but solicitous to deliver the commerce of his subjects from the exactions of his enemies, endeavoured by means of his ally, the Christian monarch of Abyssinia, to wrest some portion of the silk trade from the Persians. In this attempt he failed; but when he least expected it, he, by an unforeseen event, attained, in some measure, the object which he had in view. Two Persian monks having been employed as missionaries in some of the Christian churches, which were established (as we are informed by Cosmas) in different parts of India, had penetrated into the country of the Seres, or China. There they observed the labours of the silk worm, and became acquainted with all the arts of man in working up its productions into such a variety of elegant fabrics. The prospect of gain, or perhaps an indignant zeal, excited by seeing this lucrative branch of commerce engrossed by unbelieving nations,

2 Brought from China by the Persians till the time of Justinian.

Robertson's Disquisition concerning India. p. 88.

3 Silk worms introduced into Europe by two monks.

Silk. nations, prompted them to repair to Constantinople. There they explained to the emperor the origin of silk, as well as the various modes of preparing and manufacturing it, mysteries hitherto unknown, or very imperfectly understood in Europe; and encouraged by his liberal promises, they undertook to bring to the capital a sufficient number of those wonderful insects, to whose labours man is so much indebted. This they accomplished, by conveying the eggs of the silk worm in a hollow cane. They were hatched by the heat of a dunghill, fed with the leaves of a wild mulberry tree, and they multiplied and worked in the same manner as in those climates where they first became objects of human attention and care. Vast numbers of these insects were soon reared in different parts of Greece, particularly in the Peloponnesus. Sicily afterwards undertook to breed silk worms with equal success, and was imitated, from time to time, in several towns of Italy. In all these places extensive manufactures were established and carried on with silk of domestic production. The demand for silk from the east diminished of course, the subjects of the Greek emperors were no longer obliged to have recourse to the Persians for a supply of it, and a considerable change took place in the nature of the commercial intercourse between Europe and India.

As silk is the production of a worm, it will be first necessary to give a description of its nature and mode of manufacturing. But before we give any account of the most approved methods of managing silk worms in Europe, it will be proper to present a short description of the method practised in China, the original country of the silk worm. These are two: they either permit them to remain at liberty on mulberry trees, or keep them in rooms. As the finest silk is produced by worms confined in rooms, and as the first method is very simple, it will suffice to describe the second.

Payne's Geography.

4
Method of rearing silk worms in China.

To begin with the eggs, which are laid on large sheets of paper, to which they firmly adhere. The sheets are hung up on a beam of the room, with the eggs inward, and the windows are opened in the front to admit the wind; but no hempen ropes must ever come near the worms or their eggs. After some days the sheets are taken down, rolled up loosely with the eggs inward, and then hung up again, during the summer and autumn. At the end of December, or the beginning of January, the eggs are put into cold water, with a little salt dissolved in it. Two days after they take them out, hang them up again, and when dry roll them a little tighter, and enclose each separately, standing on one end in an earthen vessel. Some put them into a lye made of mulberry tree ashes, and then lay them some moments in snow-water, or else hang them up three nights on a mulberry tree to receive the snow or rain, if not too violent. The time of hatching them is when the leaves of the mulberry trees begin to open, for they are hastened or impeded according to the different degrees of heat or cold to which they are exposed. When they are ready to come forth, the eggs swell, and become a little pointed.

The third day before they are hatched, the rolls of paper are taken out of the vessel, stretched out, and hung up with their backs toward the sun, till they receive a kindly warmth; and then being rolled up close, they are set upright in a vessel in a warm place. This is repeated the next day, and the eggs change to an ash-grey. They then put two sheets together, and rolling them close tie the ends.

The third day, towards night, the sheets are unrolled and stretched on a fine mat, when the eggs appear blackish. They then roll three sheets together, and carry them into a pretty warm place, sheltered from the south wind. The next day the people taking out the rolls, and opening them, find them full of worms like small black ants.

The apartment chosen for silk worms is on a dry ground, in a pure air, and free from noise. The rooms are square, and very close, for the sake of warmth; the door faces the south, and is covered with a double mat, to keep out the cold; yet there should be a window on every side, that when it is thought necessary the air may have a free passage. In opening a window to let in a refreshing breeze, care must be taken to keep out the gnats and flies. The room must be furnished with nine or ten rows of frames, about nine inches one above the other. On these they place rush hurdles, upon which the worms are fed till they are ready to spin; and, to preserve a regular heat, stove fires are placed at the corners of the room, or else a warming pan is carried up and down it; but it must not have the least flame or smoke. Cow dung dried in the sun is esteemed the most proper fuel.

The worms eat equally day and night. The Chinese give them on the first day forty-eight meals that is, one every half hour; the next thirty; and third day they have still less. As cloudy and rainy weather takes away their stomach, just before their repast a wisp of very dry straw, the flame of which must be all alike, is held over the worms to free them from the cold and moisture that benumbs them, or else the blinds are taken from the windows to let in the full day-light.

Eating so often hastens their growth, on which the chief profit of the silk worm depends. If they come to maturity in 23 or 25 days, a large sheet of paper covered with worms, which at their first coming from the eggs weigh little more than a drachm, will produce 25 ounces of silk; but if not till 28 days, they then yield only 20 ounces; and if they are a month or 40 days in growing, they then produce but ten.

They are kept extremely clean, and are often removed; and when they are pretty well grown, the worms belonging to one hurdle are divided into three, afterwards they are placed on six, and so on to the number of 20 or more; for being full of humours, they must be kept at a due distance from each other. The critical moment for removing them is when they are of a bright yellow and ready to spin; they must be surrounded with mats at a small distance, which must cover the top of the place to keep off the outward air; and because they love to work in the dark. However, after the third day's labour, the mats are taken away from one o'clock till three, but the rays of the sun must not shine upon them. They are at this time covered with the sheets of paper that were used on the hurdles.

The cocoons are completed in seven days, after which the worm is metamorphosed into a chrysalis; the cocoons are then gathered, and laid in heaps, having first set apart those designed for propagation upon a hurdle, in a cool airy place. The next care is to kill the moths in these cones which are not to be bored. The best way of doing this is to fill large earthen vessels with cones.

cones in layers of ten pounds each, throwing in four ounces of ſalt with every layer, and covering it with large dry leaves like thoſe of the water-lily, and cloſely ſtopping the mouth of the veſſels. But in laying the cones into the veſſels, they ſeparate the long, white, and glittering ones, which yield a very fine ſilk, from thoſe that are thick, dark, and of the colour of the ſkin of an onion, which produce a coarſer ſilk.

5 Deſcription and hiſtory of the ſilk worm.

The ſilk worm is a ſpecies of caterpillar, which, like all others of the ſame claſs, undergoes a variety of changes, that, to perſons who are not acquainted with objects of this kind, will appear to be not a little ſurpriſing.

The Bee, n° 72.

It is produced from a yellowiſh coloured egg, about the ſize of a ſmall pin head, which has been laid by a kind of greyiſh coloured moth, which the vulgar confound with the butterfly.

Theſe eggs, in the temperature of this climate, if kept beyond the reach of the fire and ſun ſhine, may be preſerved during the whole of the winter and ſpring months without danger of hatching: and even in ſummer they may eaſily be prevented from hatching if they be kept in a cool place; but in warmer climates it is ſcarcely poſſible to preſerve them from hatching, even for a few days, or from drying ſo much as to deſtroy them. Hence it is eaſy in this country to keep the eggs till the food on which the worm is to feed be ready for that purpoſe. When this food is in perfection, the eggs need only be expoſed to the ſun for a day or two, when they will be hatched with great facility.

When the animal is firſt protruded from the egg, it is a ſmall black worm, which is active, and naturally aſcends to the top of the heap in ſearch of food. At this ſtage of his growth the ſilk worm requires to be fed with the youngeſt and moſt tender leaves. On theſe leaves if good, he will feed very freely for about eight days, during which period he increaſes in ſize to about a quarter of an inch in length. He is then attacked with his firſt ſickneſs, which conſiſts in a kind of lethargic ſleep for about three days continuance; during which time he refuſes to eat, and changes his ſkin, preſerving the ſame bulk. This ſleep being over, he begins to eat again, during five days, at which term he is grown to the ſize of full half an inch in length; after which follows a ſecond ſickneſs in every reſpect like the former.

He then feeds for other five days; during which time he will have increaſed to about three quarters of an inch in length, when he is attacked with his third ſickneſs. This being over, he begins to eat again, and continues to do ſo for five days more, when he is attacked by his fourth ſickneſs, at which time he is arrived at his full growth. When he recovers this ſickneſs, he feeds once more during five days with a moſt voracious appetite; after which he diſdains his food, becomes tranſparent, a little on the yellowiſh caſt, and leaves his ſilky traces on the leaves where he paſſes. Theſe ſigns denote that he is ready to begin his cocoon, and will eat no more.

Thus it appears that the whole duration of the life of the worm, in this ſtate of its exiſtence, in our climate, is uſually about 46 days; 28 of which days he takes food, and remains in his ſick or torpid ſtate 18; but it is to be obſerved, that during warm weather the periods of ſickneſs are ſhortened, and in cold weather lengthened, above the terms here ſpecified. In very hot climates it may be ſaid to live faſter, and ſooner to attain maturity, than in thoſe that are colder. Dr Anderſon informs us, that at Madras the worm undergoes its whole evolutions in the ſpace of 22 days. It appears, however, that it feeds fully as many days in India as in Europe, the difference being entirely occaſioned by ſhortening the period of ſickneſs. The longeſt ſickneſs he had ſeen them experience there did not exceed two days; and during ſummer it only laſts a few hours.

When the worm has attained its full growth, it ſearches about for a convenient place for forming its cocoon, and mounts upon any branches or twigs that are put in its way for that purpoſe. After about two days ſpent in this manner, it ſettles in its place, and forms the cocoon, by winding the ſilk which it draws from its bowels round itſelf into an oblong roundiſh ball.

During this operation it gradually loſes the appearance of a worm; its length is much contracted, and its thickneſs augmented. By the time the web is finiſhed, it is found to be transformed into an oblong roundiſh ball, covered with a ſmooth ſhelly ſkin, and appears to be perfectly dead. In this ſtate of exiſtence it is called an *aurelia*. Many animals in this ſtate may be often ſeen ſticking on the walls of out-houſes, ſomewhat reſembling a ſmall bean.

In this ſtate it remains for ſeveral days entirely motionleſs in the heart of the cocoon, after which it burſts like an egg hatching, and from that comes forth a heavy dull looking moth with wings; but theſe wings it never uſes for flying; it only crawls ſlowly about in the place it has been hatched. This creature forces its way through the ſilk covering which the worm had woven, goes immediately in queſt of its mate, after which the female lays her eggs; and both male and female, without taſting food in this ſtage of their exiſtence, die in a very ſhort time.

The ſilk worm, when at its full ſize, is from an inch and a quarter to an inch and a half in length, and about half an inch in circumference. He is either of a milk or pearl colour, or blackiſh; theſe laſt are eſteemed the beſt. His body is divided into ſeven rings, to each of which are joined two very ſhort feet. He has a ſmall point like a thorn exactly above the anus. The ſubſtance which forms the ſilk is in his ſtomach, which is very long, wound up, as it were, upon two ſpindles, as ſome ſay, and ſurrounded with a gum, commonly yellowiſh, ſometimes white, but ſeldom greeniſh. When the worm ſpins his cocoon, he winds off a thread from each of his ſpindles, and joins them afterwards by means of two hooks which are placed in his mouth, ſo that the cocoon is formed of a double thread. Having opened a ſilk worm, you may take out the ſpindles, which are folded up in three plaits, and, on ſtretching them out, and drawing each extremity, you may extend them to near two ells in length. If you then ſcrape the thread ſo ſtretched out with your nail, you ſcrape off the gum, which is very like bees wax, and performs the ſame office to the ſilk it covers as gold leaf does to the ingot of ſilver it ſurrounds, when drawn out by the wire drawer. This thread, which is extremely ſtrong and even, is about the thickneſs of a middling pin.

6 Particular attention ought to be paid to the breed of ſilk worms.

Of ſilk worms, as of moſt other animals, there is a conſiderable variety of breeds, ſome of which are much more hardy, and poſſeſs qualities conſiderably different from others. This is a particular of much importance

Silk.

to be adverted to at the time of beginning to breed these creatures in any place; for it will make a great difference in the profit on the whole to the undertaker if he rears a good or a bad sort (A). This is a department in respect to the economy of animals that has been in every case much less adverted to than it deserves; and in particular with regard to the silk worm it has been almost entirely overlooked. A few eggs of the silk worm can be easily transported by post in a letter from any part of Europe to another, especially during the winter season. It would therefore be an easy matter for any patriotic society, such as the Society of Arts in London, to obtain a specimen of the eggs from every country in which silk is now reared, to put these under the care of a person who could be depended upon, and who understood the management of them, with orders to keep each kind distinct from another, and advert to every particular that occurred in their management, so as to make a fair estimate of their respective merits. By these means the best might be selected, and those of inferior value rejected. Forty or fifty of each sort might be enough for the experiment; but it ought to be repeated several times before conclusions could be drawn from it that might be altogether relied upon; for it is well known that a variation of circumstances will make a change in the result; and it is by no means certain that the same particular would affect those of one breed exactly in the same manner as it would do those of a different breed. One may be more hardy with regard to cold, another more delicate in respect to food, and so on. It is experience alone that can ascertain the circumstances here inquired for.

7 The management of silk worms must be different in different climates;

From the abovementioned particulars, it is evident, that the management of silk worms must be very different in hot climates from what is required in those that are colder. At Madras, it appears from Dr Anderson's experiments that it is very difficult to prevent the eggs from hatching for a very few days, so that many generations of them must be propagated in one year. "In this hottest season," says he, in a letter to Sir Joseph Banks, dated July 6. 1791, "the shortest time I have been able to remark for the whole evolutions of the silk worm is 40 days; that is to say, six days an egg, 22 a worm, 11 a grub in the cocoon, and one a moth or butterfly." Fortunately, where the climate forces forward their production so rapidly, nature hath been equally provident of food for their subsistence; for in these regions the mulberry continues to grow and push out leaves throughout the whole year.

8 But may be easily reared in temperate climes.

Though the silk worm be a native of China, there is no doubt but it might easily be propagated perhaps in most parts of the temperate zones. The eggs of this insect, indeed, require a considerable degree of warmth to hatch them, but they can also endure a severe frost. No less than 5400 lbs of silk was raised in 1789 in the cold, sandy territories of Prussia. In the province of Pekin, in China, where great quantities of silk are fabricated, the winter is much colder than even in Scotland. From the information of some Russians who were sent thither to learn the Chinese language, we find that Reaumur's thermometer was observed from 10 to 15, and even 20 degrees below the freezing point. Nor is it difficult to rear the food of the silk worm in a temperate clime. The mulberry-tree is a hardy vegetable, which bears, without injury, the winters of Sweden, and even of Siberia. Of the seven species of the mulberry (see MORUS) enumerated by Linnæus, four of these (viz. the white, red, black, and Tartarian), there is every reason to believe could be reared both in Britain and Ireland. The *white* grows in Sweden; the *red* is abundant round Quebec; the *black* delights in bleak situations, exposed to wind on the sea shore; and the *Tartarian* mulberry is represented as growing in the chilly regions of Siberia. Bee, No 156.

9 Whether any species of mulberry tree be superior to others.

As to the superior qualities of the different species, probably there is very little to be pointed out amongst the four just mentioned with regard to nourishment, except what may be drawn from the following fact: that if the first three are laid down together, the silk worm will first eat the white, then the red, and next the black, in the order of the tenderness of the leaves. The Tartarian seems to hold as high a place in its esteem as either the red or black; but all must yield to the white, which seems to be its natural food.

In Calabria the red mulberry is used; in Valencia the white; and in Granada, where excellent silk is produced, the mulberries are all black. The white seems to prosper very well in a moist stiff soil: the black agrees well with a dry, sandy, or gravelly soil; and the white is most luxuriant in a moist rich loam.

10 Britain possesses some advantages over warmer countries for raising silk.

It may justly be asserted, that Britain possesses some advantages in the raising of raw silk which are not enjoyed by warmer countries. Even in the south of France, Mr Arthur Young informs us, the mulberry leaves are often nipped by frost in the bud; but this is scarcely ever the case in Britain. It is well known that thunder and lightning are hurtful to the silk worm. Now that climate can boast that it is almost wholly exempted from those dreadful storms of thunder and lightning which prevail so much in hot climates. Nature has then furnished us with every thing requisite for the silk manufacture; it remains only for us to improve the advantages which we possess. Let mulberry trees be planted by proprietors of lands, and let a few persons of

(A) As the success of the silk manufacture must depend on the breed of worms, it is of great consequence to bring them from those countries where they are reckoned best.

Mr Andrew Wright, an ingenious silk manufacturer of Paisley, has given the following directions for conveying the eggs of the silk worm from distant countries by sea: As soon as the moth has laid her eggs, dry them immediately, and put them into glass vials; seal them so close that damp air or water will not penetrate into them. Put these phials that contain the eggs into earthen pots filled with cold water; and as often as the water becomes warm renew it. Place the earthen vessels in the coldest place of the ship, and let them remain until the end of the voyage. It must be observed, that the ship chosen for this purpose ought to be one that would arrive in Britain in the months of June or July.

Silk.

of skill and attention devote their time to the raising of silk worms. This is an employment that will not interfere with any manufacture already established; on the contrary, it would afford a respectable, a lucrative, and agreeable employment to ladies, or to females in general, who have at present too few professions to which they can apply. The society instituted at London for the encouragement of arts, manufactures, and commerce, much to their honour, have offered premiums to those who shall plant a certain number of mulberry trees.

11 Method of raising mulberry-trees in the south of France. Letters on the Culture of Raw Silk on the Coast of Coromandel.

The following method of raising mulberry trees from seed is practised in the south of France, and has been repeated with success in the East Indies by Dr Anderson of Madras. "Take the ripe berries of the mulberry when it is full of juice and of seeds. Next take a rough horse hair line or rope, such as we dry linen on, and with a good handful of ripe mulberries run your hand along the line bruising the berries and mashing them as much as possible as your hand runs along, so that the pulp and seeds of the berries may adhere in great abundance to the rope or hair line. Next dig a trench in the ground where you wish to plant them, much like what is practised in kitchen gardens in England for crops of various kinds. Next cut the rope or hair line into lengths according to the length of the trench you think fit to make, and plunge the line full of mashed berries into the trench, and then cover it over well with earth, always remembering afterwards to water it well, which is essential to success. The seeds of the berries thus sown will grow, and soon shoot out young suckers, which will bear young leaves, which are the best food for the silk worm.

"The facility and rapidity with which young leaves may by this means be produced is evident, for as many rows of trenches may thus be filled as can be wished; and it can never be necessary to have mulberry trees higher than our raspberries, currants, or gooseberry bushes. Whenever they get beyond that, they lose their value; and if these trenches succeed, you may have a supply coming fresh up day after day, or any quantity you please." Thus abundance of these trees might be reared. But as mulberry trees are not yet found in abundance in Britain it were to be wished that some other food could be substituted in their place: attempts have accordingly been made by those who have reared silk worms, and it has been found possible to support the silk worm upon lettuce (B).

Bee, N° 70. 12 Miss Rhodes fed silk worms on lettuce for some time.

Miss Henrietta Rhodes, a lady who has made some successful experiments on raising silk worms in England had found that the silk worm could with safety be kept on lettuce for some time. This is pretty generally known by ladies who have turned their attention to this subject; but she found that in general they could not with safety be kept upon that food above three weeks. If longer fed upon that plant, the worms for the most part die without spinning a web at all. She found, however, that they did not always die, but that in some cases they produced very good cocoons, even when fed entirely on lettuce. She therefore with reason suspected that the death of the animal must be occasioned by some extraneous circumstance, and not from the poisonous quality of the food itself; the circumstance she suspected, from some incidental observations, was the coldness of that food; and therefore she thought it was not impossible, but if they were kept in a very warm place, while fed on lettuce, they might attain, in all cases, a due perfection.

13 General Mordaunt still more successful.

General Mordaunt having been informed of this conjecture, resolved to try the experiment. He got some silk worms eggs, had them hatched in his hot-house, and caused them to be all fed upon lettuce and nothing else. They prospered as well as any worms could do, few or none of them died; and they afforded as fine cocoons as if they had been fed upon mulberry leaves. As far as one experiment can go, this affords a very exhilarating prospect in many points of view. If one kind of food has been noxious, merely on account of an improper temperature, others may be found which have been hurtful only from a similar cause; so that it is not impossible but we may at last find that this delicate creature may be supported by a variety of kinds of food. Few, however, could be more easily obtained than lettuce; and this plant, when cabbaged (the cos, or ice lettuce especially, would possess one quality that the mulberry leaf never can possess, from the want of which many millions of worms die in those countries where silk is now reared; for it is observed, that when the leaves are gathered wet, it is scarcely possible to preserve the worms alive for any length of time; so that during a continuance of rainy weather many of them are unavoidably cut off; but a lettuce, when cabbaged, resists moisture. If gathered, even during rain, the heart of it is dry; so that if the outer leaves be thrown aside at that time, the worms would be continued in perfect health. The expence, too, of cultivating and gathering lettuce, would be so much less than that of gathering mulberry leaves, as to occasion a saving that would be much more than sufficient to counterbalance the expence of heating the conservatory, as a little reflection will show.

But the great point to be now ascertained is, whether it is a fact that worms fed on lettuce, if kept in a due temperature, will continue in good health, in general, till they shall have perfected their cocoon? One experiment is too little to establish this fact with perfect certainty. It would therefore be necessary that more experiments should be made on this subject.

14 Silk worms said to be fed on dried mulberry leaves.

It is said that Dr Lodovico Bellardi, a learned and ingenious botanist of Turin, has, after a number of experiments, discovered a new method of feeding silk worms, when they are hatched before the mulberry trees have produced leaves, or when it happens that the frost destroys the tender branches. This new method consists in giving the worms dried leaves of the mulberry-tree. One would think that this dry nourishment

(B) It is not improbable, says Dr Anderson, to whose valuable work entitled the *Bee*, we have been much indebted in the drawing up of this article, that other kinds of food may be found which will answer the same purpose. The chicorium intybus and common endive might be tried, as they have the same lactescent quality with the lettuce.

Silk.

ment would not be much relished by these insects; but repeated experiments made by our author, prove that they prefer it to any other, and eat it with the greatest avidity. The mulberry leaves must be gathered about the end of autumn, before the frosts commence, in dry weather, and at times when the heat is greatest. They must be dried afterwards in the sun, by spreading them upon large cloths, and laid up in a dry place after they have been reduced to powder. When it is necessary to give this powder to the worms, it should be gently moistened with a little water, and a thin coat of it must be placed around the young worms, which will immediately begin to feed upon it.

15 Proper experiments ought to be made on various vegetables.

We have mentioned all the different kinds of food, which, as far as we have heard, have been tried with any success to nourish the silk worm; not, however, with great confidence, but as experiments which it might be worth while carefully to consider and perform. We must not omit to mention that one person, who has had much experience in the managing of silk worms, assures us, that the silk produced from any other food than mulberry leaves is of an inferior quality, and that the worms are sickly. We think, however, that there is reason to suspect that the experiment has not been skilfully performed; and therefore, before every other food except mulberry leaves is discarded, the experiment ought to be performed with more attention and care. We know that many animals in a domestic state can live upon food very different from that which supported them when running wild in the fields. Certain it is, however, that every animal, in its state of nature, partakes of a food peculiar to itself, which is rejected by other animals as if it were of a poisonous quality; and it may be mentioned as a curious fact, as well as an admirable instance of the care of that Being who feeds the fowls of heaven, that notwithstanding the numberless insects that prey upon animals and vegetables, the mulberry tree is left untouched by them all, as the exclusive property of the silk worm, the chief of the insect tribe, which toils and spins for the use of man.

16 What situation and apartments proper for these insects.

Having now considered the food proper for the silk worm, we shall next consider what situation is most favourable to them. In the opinion of some persons in Britain who have been in the practice of rearing silk worms, they ought always to be kept in a dry place, well sheltered, and possessing a considerable degree of warmth, and which is not exposed to sudden transitions from heat to cold. If the weather be too cold, a small fire must be made: this is of most importance when the worms are ready for spinning. A southern exposure is therefore preferable. Some think light is of great utility to silk worms, others think that they thrive better in the dark. As to what apartments are best accommodated for promoting the health of silk worms, and most convenient for those who have the care of them, they may be various according to the extent of the manufacture or the wealth of the proprietors. Silk worms may be kept in boxes or in shelves. When shelves are to be used, they may be constructed in the following manner: The shelves may be of wicker, ranged at the distance of a foot and a half, and fixed in the middle of the room: their breadth ought to be such, that any person can easily reach to the middle from either side. This is perhaps the simplest and cheapest apparatus for rearing silk worms; but there is another apparatus which may be recommended to those who are anxious to unite some degree of elegance with convenience. This apparatus is the invention of the Rev. George Swayne of Puckle-church, a gentlemen who, greatly to his honour, has studied this subject much, in order to find out the way for promoting the culture of silk among the poor. This apparatus, with the description of it, we have borrowed from that valuable and patriotic work, the Transactions of the Society for encouraging Arts, Manufactures, and Commerce, Vol. VII. p. 148. The apparatus consists of a wooden frame four feet two inches high, each side 16 inches and a half wide, divided into eight partitions by small pieces of wood which form grooves, into which the slides run, and are thus easily thrust into or drawn out of the frame. The upper slide (*a*) in the model sent to the society by Mr Swayne is of paper only, and designed to receive the worms as soon as hatched; the two next (*b*, *b*) are of catgut, the threads about one-tenth of an inch distant from each other: these are for the insects when a little advanced in size: the five lower ones, marked *c*, *c*, *c*, *c*, *c*, are of wicker work; but, as Mr Swayne afterwards found, netting may be substituted with advantage instead of wicker bottoms. Under each of these, as well as under those of catgut, are sliders made of paper, to prevent the dung of the worms from falling on those feeding below them.

17 Mr Swayne's apparatus described.

Plate CCCCXXIV.

18 Proper time for hatching silk worms.

The management of silk worms is next to be attended to. The proper time for hatching them is when the leaves of the mulberry are full grown, or nearly so; that as soon as these insects are capable of receiving food they may obtain it in abundance. To attempt to hatch them sooner would be hurtful, as the weather would not be sufficiently warm. Besides, as leaves are necessary to the life of a vegetable, if the young leaves of the mulberry-tree are cropped as soon as they are unfolded, the tree will be so much weakened as to be incapable of producing so many leaves as it would otherwise have done; and if this practice be frequently repeated, will inevitably be destroyed.

19 How they ought to be hatched and fed.

When the proper season is arrived, the eggs may be hatched either by the heat of the sun, when it happens to be strong enough, or by placing them in a small room moderately heated by a stove or fire; and after being exposed for six or seven days to a gentle heat, the silk worm issues from the egg in the form of a small black hairy caterpillar. When Mr Swayne's apparatus is used, the worms are to be kept on the drawers with paper bottoms till they are grown so large as not readily to creep through the gauze-bottomed drawers: they are then to be placed on those drawers, where they are to remain till their excrements are so large as not readily to fall through; when this is the case, they must be removed to the drawers with the wicker or netting bottoms, and fed thereon till they show symptoms of being about to spin. It is scarcely necessary to mention, that the paper slides beneath the gauze and wicker drawers are intended to receive the dung, which should be emptied as often as the worms are fed, at least once a-day; or to direct, that when the worms are fed, the slides are to be first drawn out a considerable way, and the drawers to rest upon them.

20 Wet or damp food produces contagious diseases.

It has been already mentioned, that wet or damp food is exceedingly prejudicial to these insects. It produces contagious and fatal diseases. To prevent the necessity of giving them wet or damp food, attention

Silk.

ought to be paid to the weather, so that when there is an immediate prospect of rain, a sufficient quantity of leaves may be gathered to serve the worms two or three days. In this country, the leaves of the black or red mulberry tree may be preserved good for food, although kept four or five days, by the following method: When new gathered, lay them loosely in glazed earthen vessels, place these in a cold place, well aired, not exposed to drought.

21 Ought to be kept as clean as possible.

The utmost attention must be paid to preserve the place where silk worms are kept as clean as possible: the house or room must be well ventilated, that no noxious vapours be accumulated. By some experiments of M. Faujas de St Fond, which are recorded in his history of Languedoc, it appears that the silk worm is much injured by foul air. All decayed leaves must be removed from them, as it is now well known that they emit bad air in great abundance.

One of the most difficult branches of the management of silk worms has hitherto been the cleaning without bruising them. To avoid this inconvenience, the peasants in France and Italy frequently allow the whole litter to remain without ever cleaning them, which is the cause of that unwholesome stench that has been so often remarked by those who visit the places for rearing silk worms in these countries. This difficulty may be effectually removed by providing a net, or, what would be still better, a wire bottomed frame, wrought into large meshes like a riddle. Have that made of a size exactly sufficient to cover the wooden box in which the worms are kept. When you mean to shift them, spread fresh leaves into the wire basket; and let it down gently over the worms till it comes within their reach. They no sooner perceive the fresh food than they abandon the rubbish below, and creep through the meshes, so as to fix themselves upon the leaves; then by gently raising the fresh basket, and drawing out the board below (which ought to be made to slip out like the slip bottom of a bird's cage), you get off all the excrements and decayed leaves, without incommoding the worms in the smallest degree; and along with the litter you will draw off an inch or two in depth of the foulest mephitic vapours. To get entirely rid of these, the board, when thus taken out, should be carried without doors, and there cleaned; and the slip board immediately replaced to receive all the excrements and offals. After it is replaced, the wire frame that had been elevated a little, may be allowed to descend to a convenient distance above the board without touching it. Thus will there be left a vacant space for the mephitic air to fall below the worms, so as to allow them to inhabit a wholesome region of the atmosphere.

Bee, N° 93.

22 How they may be cleaned without bruising them.

When a fresh supply of food is to be given before cleaning, the wire frame ought to be let down as close to the board as can be safely done, and another wire-bottomed frame put over it, with fresh leaves, as before described. When the worms have abandoned that in their turn, let the slip-board, together with the lower wire frame, be drawn out and removed, and so on as often as necessary. To admit of this alternate change, every table, consisting of one slip-board, ought to have two sets of wire-bottomed frames of the same size; the slip-board to be always put into its place immediately after it is cleaned, and the wire frames reserved to be afterwards placed over the other. By this mode of management, it is probable that the worms would be saved from the diseases engendered by the mephitic air, and the numerous deaths that are the consequence of it avoided.

23 Quick lime would absorb all the bad air which surrounds them.

Dr Anderson, to whom we have already acknowledged our obligations, and to whom Britain has been much indebted for valuable works on agriculture, the fisheries, &c. advises those who have the management of silk worms to strew a thin stratum of fresh slaked quicklime upon the slip-board each time it is cleaned, immediately before it is put into its place. This would absorb the mephitic gas, for as soon as it is generated it would descend upon the surface of the quicklime. Thus would the worms be kept continually in an atmosphere of pure air (c). Were the walls of the apartments to be frequently washed with quicklime and water, it would tend much to promote cleanliness at a small expence, and augment the healthiness of the worms as well as that of the persons who attend them.

24 Mr Swayne's receptacle for the worms when going to spin.

When the silk worm refuses its food, and leaves silky traces on the leaves over which it passes it is a proof that it is ready to begin its cocoon. It is now necessary to form a new receptacle, which is commonly done by pinning together papers in the shape of inverted cones with broad bases. "This method (says Mr Swayne), where there are many worms, is exceedingly tedious, wastes much paper, and uses a large number of pins; besides, as the silk worm always weaves an outer covering or defensive web before it begins the cocoon or oval ball, I apprehended that it caused a needless waste of silk in forming the broad web at the top. The method I make use of is, to roll a small piece of paper (an uncut octavo leaf, such as that of an old magazine, is sufficient

Transactions of the Society for the Encouragement of Arts, vol. vii. p 123.

(c) To put this question beyond a doubt, Mr Blancard made the following comparative experiments, which were several times repeated. "I procured (says he) four glass jars nine inches high and five in diameter, closing the mouth with cork stoppers. After which I placed in each of them, in their second life (so *mue* may be translated which means the stage between the different sicknesses), twelve silk worms, which were fed four times a-day; and which I confined in this kind of prison all their life, without taking away either their dead companions or their ordure or litter. I sprinkled with chalk the worms of only two of these jars, and kept the two others to compare with them.

"In those without lime, I never obtained neither more nor less than three small and imperfect cocoons (*chiques ou bouffard*), and in the two that were sprinkled with lime, I had very often twelve, and never less than nine fine full sized firm cocoons."

This experiment affords the most satisfactory proof of the utility of this process. From a number of trials he found, that even when the worms were covered with a very large proportion of lime, they never were in any way incommoded by it.

sufficient for three), round my fore-finger, and to give it a twist at the bottom; which is done with the utmost expedition, and gives no occasion for the use of pins. These rolled paper-cases being likewise of a form more nearly resembling that of a cocoon, with a much narrower opening on the top than the others, takes away the necessity of wasting much silk in the outer web, and consequently leaves more to be employed in forming the ball. The silk is readily taken out of these cases by untwisting the bottom; and if this be done with moderate care, and the papers are preserved, they will serve several times for the like purpose."

25 Others recommend bushes of heath.

Others advise, that when the silk worms are preparing to spin, little bushes of heath, broom, or twigs, should be stuck upright near the shelf or box in which they are inclosed: the worms mount these, and attach their web to them.

26 How silk worms may be revived when affected by thunder. Transactions of the American Philosophical Society, vol. ii.

When the worms are ready to mount, in order to spin, if the weather be hot, attended with thunder, you will see them in a languishing condition; your care must then be to revive them, which is effected thus: Take a few eggs and onions, and fry them in a pan with some stale hog's lard, the ranker the better, and make pancake; which done, carry it smoaking hot into the room where they are kept, and go round the chamber with it. You will be surprised to see how the smell revives them, excites those to eat who have not done feeding, and makes the others that are ready to spin climb up the twigs.

27 Different kinds of cocoons.

In about ten or twelve days, according to the accounts which we have received from Mr Andrew Wright of Paisley, it may be safely concluded, that if the worms have finished their work, the cocoons may be collected.

We shall now distinguish the cocoons from one another according to their value or their use, and consider the method of managing each. They may be distinguished into the good and bad. The good cocoons may be known by these marks: they are little, strong, and firm; have a fine grain, both ends are round, and they are free from spots. Among the good cocoons also may be arranged those which are called *calcined* cocoons, in which the worm, in consequence of sickness, is petrified or reduced to a fine powder. These cocoons produce more silk than others, and are sold in Piedmont at half as much again. They may be distinguished by the noise which the worm makes when the cocoon is shaken. Of the bad cocoons there are six species: 1. The *pointed cocoons*, one extremity of which ends in a point; the silk which covers the point is weak, and soon breaks or tears. 2. The *cocalons*, which are bigger, but the contexture is weak. 3. The *dupions*, or double cocoons, which have been formed by the joint labour of two and sometimes of three worms. 4. The *soufflons*, which have a loose contexture, sometimes so loose that they are transparent. 5. The *perforated cocoons*, which have a hole at one end. 6. The *bad choquette*, which is composed of defective cocoons, spotted or rotten. Besides these there is the *good choquette*, which does not properly belong to either of these two classes: it is formed of those cocoons in which the worm dies before the silk is brought to perfection. The worms adhere to one side of the cocoon, and therefore when the cocoon is shaken will not rattle: the silk is as fine, but is not of so bright a colour, nor is so strong and nervous, as that which is obtained from good cocoons.

28 Mr Wright's instructions for selecting and preserving the royal cocoons.

The cocoons which are kept for breeding are called *royal* cocoons. For selecting and preserving these, we have been favoured with some valuable instructions by Mr Wright of Paisley, which we shall present to our readers.—The largest and best cocoons ought to be kept for breed, about an equal number of males and females; the cocoons that contain the former are sharper pointed at the ends than those that contain the latter. Although it should happen that there are more females than males, little inconvenience or ill consequences can arise from it, as one male will serve two or three females, if the time of their coming out of the cocoons answer. About 12 or 15 days after they begin to spin, the cocoons for breed may be laid on sheets of white paper; about this time the moth opens for itself a passage through the end of its cocoon, and issues out. When the female has laid her eggs, which on an average may amount to 250, they are spread upon sheets of paper and hung up to dry in some place where they may not be exposed to the heat of the sun: after being dried they must be kept in a cool well-aired place, where neither vapours nor moisture can reach them. That they may be preserved from external accidents, as insects of different kinds will destroy them, and mice is their enemy in all the stages of their existence, they should be kept in stone pots or glass bottles with their mouths stopped, and there remain until brought out next season to be hatched.

29 How to prepare the cocoons for being wound.

The cocoons from which the silk is to be immediately wound must be exposed to the heat of an oven, in order to kill the chrysalis or aurelia, which would otherwise eat its way through the cocoon, and render it useless. The following directions are given for managing this process by one of the first silk manufacturers in Italy.

Transactions of the American Philosophical Society, vol. ii.

Put your cocoons in long shallow baskets, and fill them up within an inch of the top. You then cover them with paper, and put a wrapper over that. These baskets are to be disposed in an oven, whose heat is as near as can be that of an oven from which the bread is just drawn after being baked. When your cocoons have remained therein near an hour, you must draw them out; and to see whether all the worms are dead, draw out a dupion from the middle of your basket and open it: if the worm be dead, you may conclude all the rest are so; because the contexture of the dupion being stronger than that of the other cocoons, it is consequently less easily to be penetrated by the heat. You must observe to take it from the middle of the basket, because in that part the heat is least perceptible. After you have drawn your baskets from the oven, you must first cover each of them with a woollen blanket or rug, leaving the wrapper besides, and then you pile them above one another. If your baking has succeeded, your woollen cover will be all over wet with a kind of dew, the thickness of your little finger. If there be less, it is a sign your cocoons have been too much or too little baked. If too much baked, the worm, being over-dried, cannot transpire a humour he no longer contains, and your cocoon is then burnt. If not enough baked, the worm has not been sufficiently penetrated by the heat to distil the liquor he contains, and in that case is not dead.

You must let your baskets stand thus covered five or six hours if possible, in order to keep in the heat, as this makes an end of stifling those worms which might have avoided the first impression of the fire. You are likewise wife to take great care to let your cocoons ſtand in the oven the time that is neceſſary: for if they do not ſtand long enough, your worms are only ſtunned for a time and will afterwards be revived. If, on the other hand, you leave them too long in the oven, you burn them: many inſtances of theſe two caſes are frequently to be met with. It is a good ſign when you ſee ſome of the butterflies ſpring out from the cocoons which have been baked, becauſe you may be certain they are not burnt. For if you would kill them all to the laſt worm, you would burn many cocoons which might be more expoſed to the heat than that particular worm.

30 How the ſilk is to be wound from the cocoons.

The next operation is the winding of the ſilk. Before you begin to wind, you muſt prepare your cocoons as follows:

1. In ſtripping them of that waſte ſilk that ſurrounds them, and which ſerved to faſten them to the twigs. This burr is proper to ſtuff quilts, or other ſuch uſes; you may likewiſe ſpin it to make ſtockings, but they will be coarſe and ordinary.

2. You muſt ſort your cocoons, ſeparating them into different claſſes in order to wind them apart. Theſe claſſes are, the good white cocoons; the good cocoons of all the other colours; the dupions; the cocalons, among which are included the weak cocoons; the good choquette; and, laſtly, the bad choquette. In ſorting the cocoons, you will always find ſome perforated cocoons amongſt them, whoſe worm is already born; thoſe you muſt ſet apart for fleuret. You will likewiſe find ſome foufflons, but very few; for which reaſon you may put them among the bad choquette, and they run up into waſte.

The good cocoons, as well white as yellow, are the eaſieſt to wind; thoſe which require the greateſt care and pains are the cocalons; you muſt wind them in cooler water than the others, and if you take care to give them to a good windſter, you will have as good ſilk from them as the reſt. You muſt likewiſe have a careful windſter for the dupions and choquettes. Theſe two ſpecies require hotter water than the common cocoons.

The good cocoons are to be wound in the following manner: Firſt, chooſe an open convenient place for your filature, the longer the better, if you intend to have many furnaces and coppers. The building ſhould be high and open on one ſide, and walled on the other, as well to ſcreen you from the cold winds and receive the ſun, as to give a free paſſage to the ſteam of your baſons or coppers.

Theſe coppers or baſons are to be diſpoſed (when the building will admit of it) in a row on each ſide of the filature, as being the moſt convenient method of placing them, for by that means in walking up and down you ſee what every one is about. And theſe baſons ſhould be two and two together, with a chimney between every couple.

Having prepared your reels (which are turned by hands, and require a quick eye), and your fire being a light one under every baſon, your windſter muſt ſtay till the water is as hot it can be without boiling. When every thing is ready, you throw into your baſons two or three handfuls of cocoons, which you gently bruſh over with a wiſk about ſix inches long, cut ſtumpy like a broom worn out: by theſe means the threads of the cocoons ſtick to the wiſk. You muſt diſengage theſe threads from the wiſk, and purge them by drawing theſe ends with your fingers till they come off entirely clean. This operation is called *la Battue*. Silk.

When the threads are quite clear, you muſt paſs four of them (if you will wind fine ſilk) through each of the holes in a thin iron bar that is placed horizontally at the edge of your baſon; afterwards you twiſt the two ends (which conſiſt of four cocoons each) twenty or twenty-five times, that the four ends in each thread may the better join together in croſſing each other, and that your ſilk may be plump, which otherwiſe would be flat.

Your windſter muſt always have a bowl of cold water by her, to dip her fingers in, and to ſprinkle very often the ſaid bar, that the heat may not burn the thread.

Your threads, when thus twiſted, go upon two iron hooks called rampins, which are placed higher, and from thence they go upon the reel. At one end of the axis of the reel is a cog-wheel, which catching in the teeth of the poſt-rampin, moves it from the right to the left, and conſequently the thread that is upon it; ſo that your ſilk is wound on the reel croſsways, and your threads form two hanks of about four fingers broad.

As often as the cocoons you wind are done, or break or diminiſh only, you muſt join freſh ones to keep up the number requiſite, or the proportions; becauſe, as the cocoons wind off, the thread being finer, you muſt join two cocoons half wound to replace a new one: Thus you may wind three new ones and two half wound, and your ſilk is from four to five cocoons.

When you would join a freſh thread, you muſt lay one end on your finger, which you throw lightly on the other threads that are winding, and it joins them immediately, and continues to go up with the reſt. You muſt not wind off your cocoons too bare or to the laſt, becauſe when they are near at an end, the *biarré*, that is, the huſk, joins in with the other threads, and makes the ſilk foul and gouty.

When you have finiſhed your firſt parcel, you muſt clean your baſons, taking out all the ſtriped worms, as well as the cocoons, on which there is a little ſilk, which you firſt open and take out the worm, and then throw them into a baſket by you into which you likewiſe caſt the looſe ſilk that comes off in making the battue.

You then proceed as before with other two or three handfuls of cocoons; you make a new battue; you purge them, and continue to wind the ſame number of cocoons or their equivalent, and ſo to the end.

As was already mentioned, the windſter muſt always have a bowl of cold water by her, to ſprinkle the bar, to cool her fingers every time ſhe dips them in the hot water, and to pour into her baſon when neceſſary, that is, when her water begins to boil. You muſt be very careful to twiſt your threads a ſufficient number of times, about 25, otherwiſe your ſilk remains flat, inſtead of being round and full; beſides, when the ſilk is not well croſſed, it never can clean, becauſe a gout or nub that comes from a cocoon will paſs through a ſmall number of theſe twiſts, though a greater will ſtop it. Your thread then breaks, and you paſs what foulneſs there may be in the middle of your reel be-

tween

tween the two hanks, which ſerves for a head-band to tie them.

You muſt obſerve that your water be juſt in a proper degree of heat. When it is too hot, the thread is dead, and has no body; when it is too cold, the ends which form the thread do not join well, and form a harſh ill-qualified ſilk.

You muſt change the water in your baſon four times a-day for your dupions and choquette, and twice only for good cocoons when you wind fine ſilk; but if you wind coarſe ſilk, it is neceſſary to change it three or four times. For if you were not to change the water, the ſilk would not be ſo bright and gloſſy, becauſe the worm contained in the cocoons foul it very conſiderably. You muſt endeavour as much as poſſible to wind with clear water, for if there are too many worms in it, your ſilk is covered with a kind of duſt which attracts the moth, and deſtroys your ſilk.

You may wind your ſilk of what ſize you pleaſe, from one cocoon to 1000; but it is difficult to wind more than 30 in a thread. The nicety, and that in which conſiſts the greateſt difficulty, is to wind even; becauſe as the cocoon winds off, the end is finer, and you muſt then join other cocoons to keep up the ſame ſize. This difficulty of keeping the ſilk always even is ſo great, that (excepting a thread of two cocoons, which we call ſuch) we do not ſay a ſilk of three, of four, or of ſix cocoons; but a ſilk of three to four, of four to five, of ſix to ſeven cocoons. If you proceed to a coarſer ſilk, you cannot calculate ſo nicely as to one cocoon more or leſs. We ſay, for example, from 12 to 15, from 15 to 20, and ſo on.

31
What number of worms produce a certain quantity of ſilk.

What number of worms are neceſſary to produce a certain quantity of ſilk has not been aſcertained. And as different perſons who wiſhed to determine this point have had different reſults, the truth ſeems to be, that from various circumſtances the ſame number of worms may produce more ſilk at one time than at another. It is related in the ſecond volume of the Tranſactions of the Society for encouraging Arts, &c. that Mrs Williams obtained nearly an ounce and a half of ſilk from 244 cocoons. Mr Swayne from 50 cocoons procured 100 grains. Miſs Rhodes obtained from 250 of the largeſt cocoons, three quarters of an ounce and a dram. From a paper in the ſecond volume of the American Tranſactions, which we have before referred to in the courſe of this article, we are informed that 150 ounces of good cocoons yield about 11 ounces of ſilk from five to ſix cocoons: if you wind coarſer, ſomething more. But what appears aſtoniſhing, Mr Salvatore Bertezen, an Italian, to whom the Society for encouraging Arts, &c. adjudged their gold medal, raiſed five pounds of excellent ſilk from 12,000 worms.

32
Length of the threads.

The cocoons produce a thread of very unequal length; you may meet with ſome that yield 1200 ells, whilſt others will ſcarcely afford 200 ells. In general, you may calculate the production of a cocoon from 500 to 600 ells in length.

33
Advantages of Mr Sholl's improved ſilk loom.

As there is every reaſon to hope that the ſilk manufacture will ſoon be carried on with ardour in Great Britain, and to a great extent, we are happy to learn that the ſilk-loom has been much improved lately by Mr Sholl of Bethnal-Green. It appears from the evidence of ſeveral gentlemen converſant in that branch of ſilk weaving to which this loom is particularly adapted, that the advantages of this conſtruction are, the gaining light, a power of ſhortening the porry occaſionally, ſo as to ſuit any kind of work, being more portable, and having the gibbet firmly fixed, together with the diminution of price; which, compared with the old loom, is as five pounds, the price of a loom on the old conſtruction, to three pounds ten ſhillings, the price of one of theſe contrived by Mr Sholl; and that, as the proportion of light work is to ſtrong work as nine to one, this ſort of loom promiſes to be of very conſiderable advantage, particularly in making modes, or other black work.

Tranſactions of the Society, for encouraging Arts, &c. vol. viii.

34
Deſcription of it.

As a plate of this loom, with proper references, will render its advantages moſt intelligible, we ſhall ſubjoin theſe: Plate CCCCLXVI. A, A, The ſills; B, B, The breaſt-roll poſts; C, The cut tree; D, D, The uprights; E, The burdown; F, The batton; G, The reeds; H, The harneſs; I, The breaſt-roll; K, The cheeſe; L, The gibbet; M, The treddles; N, The tumblers; O, Short counter-meſhes; P, Long counter-meſhes; Q, The porry; R, R, Cane-roll poſts; S, The cane-roll; T, The weight bar and weight; U, U, Counter-weights; W, The breaking rod; X, X, Croſs rods.

Silk-Worm. See Silk.

SILPHA, Carrion-beetle, in natural hiſtory; a genus of animals belonging to the claſs of *inſectæ*, and to the order of *coleopteræ*. The antennæ are clavated; the clava are perfoliated; the elytra marginated; the head is prominent; and the thorax marginated. There are 94 ſpecies, of which ſeven only are natives of Britain and Ireland. 1. The *veſpillo.* The margin of the thorax broad. The ſhells abbreviated, black, with two yellow belts. The thighs of the hind legs large, with a ſpine near their origin. Length near one inch. It infeſts dead bodies. 2. The *biphuſtulata*, is black; the antennæ are long and ſmall, and there are two red ſpots on the middle of each ſhell. The length is one-third of an inch. 3. The *puſtulata*, is black and oblong: there are four brown ſpots on the ſhells: the length is one-fifth of an inch. It lives on trees. 4. The *quadripunctata.* The head, antennæ, and legs black. Margin of the thorax and ſhells are of a pale yellow, with four black ſpots. The length half an inch. It is found in Cain-wood, near Hampſtead. 5. The *ſabuloſa*, is black; the antennæ are ſhort and globular; there are five ſtriæ on each ſhell. The ſhells and wings are ſhort. There are five joints on the two firſt feet, four on the reſt. It lives in ſand. 6. The *aquatica*, is brown, with a green bronze tinge. There are four ribs on the thorax. On each ſhell there are 10 ſtriæ. The length is one-fifth of an inch. 7. The *pulicaria*, is black and oblong; the ſhells are abbreviated; the abdomen is rounded at the extremity; the thorax and ſhells are ſcarce marginated; the length is one line. It is found frequently running on flowers.

Berkenhout, vol. i.

SILPHIUM, in botany: A genus of plants belonging to the claſs of ſyngeneſia, and to the order of polygamia neceſſaria; and in the natural ſyſtem arranged under the 49th order, *compoſitæ*. The receptacle is paleaceous; the pappus has a two-horned margin, and the calyx is ſquarroſe. There are eight ſpecies; the laciniatum, terebinthinum, perfoliatum, connatum, aſteriſcum, trifoliatum, ſoldaginoides, and trilobatum. The firſt ſix of theſe are natives of North America.

Silver.

SILVER, one of the perfect metals, and the whitest and most brilliant amongst them all, is of the specific gravity, according to Bergman, of 10.552; but according to Kirwan, of 11.095. Its ductility is not greatly inferior to that of gold, as a grain of silver leaf measures somewhat more than 51 square inches; and the silver wire used for astronomical purposes measures only the 750th part of an inch in diameter; which is no more than half the thickness of the hair of the human head. It is harder and more elastic than lead, tin, or gold; but less so than copper, platina, or iron: like other metals it grows hard by hammering, but is easily reduced to its former state by annealing. It is more destructable than gold, and is particularly acted upon by sulphureous vapours: hence its surface tarnishes in the air, and assumes a dark brown colour.

Cronsted's Mineralogy, vol. ii. p. 536.

"It has been long thought (says Mr Fourcroy) that silver is indestructible by the combined action of heat and air. It is certain, that this metal kept in fusion, without contact of air, does not appear to be sensibly altered; yet Junker had affirmed, that by treating it a long time in the reverberatory furnace, in the manner of Isaac Hollandus, silver was changed into a vitreous calx. This experiment has been confirmed by Macquer. That learned chemist exposed silver 20 times successively in a porcelain crucible to the fire of the furnace at Seves; and at the 20th fusion he obtained a vitriform matter of an olive green, which appeared to be a true glass of silver. This metal, when heated in the focus of a burning glass, has always exhibited a white pulverulent matter on its surface, and a greenish vitreous covering on the support it rested upon. These two facts remove all doubt respecting the alteration of silver: though it is much more difficult to calcine than other metallic matters, yet it is capable of being converted after a long time into a white calx, which, treated in a violent fire, affords an olive coloured glass. It may be possible perhaps to obtain a calx of silver by heating this metal when reduced into very fine laminæ, or into leaves, for a very long time in a matrass, as is done with mercury."

Magellan informs us, that by melting in a due proportion with gold or steel, silver becomes greenish or bluish; so that it is capable of producing the white, yellow, red, green, blue, and olive colours, more or less conspicuously according to the various circumstances of heat and proportions of the mixture. Though he makes mention of the vitrifications by Macquer already taken notice of, he denies that it can be calcined by heat alone. "Silver (says he) is so fixed by itself in the fire, that, after being kept a whole month in fusion, it had only lost one 60th part of its weight, which might be on account of some alloy. It is therefore incapable of being calcined by mere heat; and the calx of silver, which can only be made by means of its solution in acids, is reducible to its metallic form without the addition of any oxigenous substance. But when silver is exposed to the violent heat of the solar rays collected by a powerful lens, a kind of smoke is seen surrounding it, which proves at last to be the minute particles of the metal raised and dispersed by heat, as is evident if a thin plate of gold be exposed to it; for then the particles of silver are seen upon the gold in the same manner as those of gold are seen upon silver in a similar experiment."

By slow cooling after it has been melted, silver crystallizes into quadrangular pyramids. M. Baumé observes, that, in cooling, it assumes a symmetrical form, observable on the surface by small fibres resembling the feathers of a pen. M. Fourcroy observes, that the fine button obtained by cupellation, often presents on its surface five or six sides arranged amongst each other like a pavement; but the crystallization in tetrahedral pyramids has not been observed particularly excepting by Messrs Tillet and Mongez. It has been supposed that silver melts with a smaller degree of heat than copper; but the late improved thermometer of Mr Wedgewood shows that this is a mistake; silver requiring 130° of Fahrenheit more than copper to bring it into fusion. It is found in the earth.

1. *Native*, generally of the fineness of 16 carats; and of this there are several varieties. 1. Thin plated or leaved. 2. Capillary silver, of fine or coarse fibres or arborescent, from Potosi in America and Kunsberg in Norway. 3. A kind is also met with resembling coarse linen in the surface, which in Saxony is called *knit cobalt*. Abundance of this kind is to be met with in Potosi, but more rarely in Saxony and Norway. 4. Sometimes native silver is met with in a crystalline or regularly figured state with shining surfaces. This is found at Kunsburg, but is very scarce. There appears likewise a kind of crystallization on the thin plates of native silver, their surfaces being full of minute pyramidal crystals. Most of the American silver is of the native kind; so is that at Kunsburg in Norway. It is not, however, met with native so commonly in other European mines. A very small quantity of it is found in the mines of Salberg in Westmanland, and of Lofasen in Dalarne, and several other places in Sweden. It has been found in pretty large lumps in clay mixed with nickel, partly decayed or withered; in which situation it formed the compound called the *stercus anserinum*, or goose dung ore. 5. A piece of native silver in coal is shown in the mineralogical academy at Freyberg; and Lahman, quoted by Le Camus, speaks also of a similar silver ore found in a mine of pit-coal †. The capillary silver, according to the observations of Henckel and Rome de Lisle, seems to have been produced by a decomposition of red silver ore; and Wallerius affirms, that if sulphur is mixed in a gentle heat with silver, the latter takes a capillary form. 6. Native silver is likewise sometimes found in the form of spider's webs, and for that reason called by the Spaniards *arane*. 7. It is met with in branches formed by octaedrons inserted into one another. Some of these show the mark of a leaf of fern or of a tree; others are cubes or single octaedrons, whose angles are truncated, though, these last are but rare. 8. It is often found dispersed through sand and ochre, as well as in grey limestone in Lower Austria, and in a greenish clay near Schemnitz, or mixed with ochre, clay, and calciform nickel. It is generally alloyed with copper, sometimes with gold, iron, or regulus of antimony; and sometimes it contains even five per cent. of arsenic. That found near Kunsberg contains so much gold, that the colour of it is yellow.

† Cronsted's Mineralogy, p. 542.

Wallerius distinguishes seven species of native silver; viz. 1. In irregular masses and lumps, at Kunsburg in Norway and other places, in a bed of clay. 2. In a granular and jagged form in America and Norway. 3. Arborescent, in the places already mentioned. 4. In thin

Silver.

thin leaves, between the fiſſures of ſtones, in Norway and Germany. In a capillary form, in the places already mentioned, including the cobweb ſilver of the Spaniards already mentioned. 6. Cryſtallized. 7. Superficial. Mr Daubenton enumerates eight varieties of native white ſilver, of different forms, moſt of which have been already enumerated. The materials in which this metal is moſt commonly found in its native ſtate are, baro-ſelenite, limeſtone, ſelenite, quartz, chert, flint, ſerpentine, gneiſs, agate, mica, calcareous ſpar, pyrites, ſchiſtus, clay, &c. Sometimes it is met with in large maſſes, of the weight of 60 pounds or more, in or near the veins of moſt metallic ores, particularly in Peru and in various parts of Europe, of a white, brown, or yellowiſh colour. In Norway and at Alſace it is found in the form of ſolitary cubes and octahedral lumps, of 50 and 60 pounds weight.

2. *Native ſilver alloyed with other metals.* 1. With gold, as in Norway, where it contains ſo much as to appear of a yellow colour. 2. With copper. 3. With gold and copper. 4. Amalgamated with mercury, as in the mines of Salberg. M. Rome de Liſle mentions a native amalgam of ſilver and mercury found at Muſchel Landſberg in the duchy of Deux Ponts, in a ferruginous matrix, mixed with cinnabar, and cryſtallized in a hexagonal form, and of a large ſize. It was before the French revolution preſerved in the king's cabinet at Paris. 5. With iron. According to Bergman, this ore contains two per cent. of iron; but Mongez informs u, that it often does not exceed one per-cent. 6. With lead, "Silver (ſays Mr Magellan) is always contained in lead, though the quantity is generally inſufficient to defray the expence of ſeparating it. In the reign of Edward I. of England, however, near 1600 pounds weight of ſilver were obtained, in the courſe of three years, from a lead mine in Devonſhire, which had been diſcovered about the year 900. The lead mines in Cardiganſhire have at different periods afforded great quantities of ſilver; ſo that Sir Hugh Middleton is ſaid to have cleared from them L. 2000 in a month. The ſame mines in the year 1745 yielded 80 ounces of ſilver out of every ton of lead. The lead in only one of the ſmelting houſes at Holywell in Flintſhire produced no leſs than 37521 ounces, or 3126¾ pounds of ſilver from the year 1754 to 1756, and from 1774 to 1776. There are ſome lead ores in England, which, though very poor in that metal, contain between 300 and 400 ounces of ſilver in a ton of lead; and it is commonly obſerved, that the pooreſt lead ores are the richeſt in ſilver; ſo that a large quantity of ſilver is probably thrown away in England by not having the pooreſt ſort of lead ores properly eſſayed." 7. Mr Monnet found ſilver united with arſenic among the ores which came from Guadanal canal in Spain, and an ore of the ſame kind is furniſhed by the Samſon mine near Andreaberg in the Hartz: but Mr Mongez very properly remarks, that theſe ores muſt be diſtinguiſhed from ſuch as have the arſenic in the form of an acid; for in this caſe they are properly mineralized by it, whilſt there can only be a mixture of native ſilver, or ſome of its calces with arſenic in its reguline form. 8. Bergman mentions ſilver in a ſtate of union with antimony. The ore yields ſome ſmoke when roaſted, but has not the garlic ſmell obſervable in the arſenical ores. 9. The white ſilver ore, found in the mines near Freyberg, has the metal united to the regulus of arſenic and iron, the three metallic ingredients being nearly in equal proportions. All the extraneous matters with which the ſilver is united are ſometimes in exceedingly ſmall proportion, but not to be neglected where they exceed the hundredth part of the whole maſs. 10. A particular kind of ſtony ſilver ores is mentioned by Wallerius under the title of *lapis deæ*, and which contain the following varieties, viz. the calcareous ſilver ore at Annaberg in Auſtria, when the metal is mixed with an alkaline limeſtone; the ſpathoſe ore, either white, variegated, or yellowiſh, found at Schemnitz in Hungary; the quartzoſe white ore in a powdery form, mixed with ferruginous ſcoria, found at Potoſi in America; the dark and variegated quartzoſe ſilver ores, with many other ſubdiviſions diſtinguiſhed from one another by little elſe than their colour.

Id. p. 544. Watſon's Eſſays, vol. iii.

Silver is found mineralized by various ſubſtances; as,

1. With ſulphur in the glaſſy or vitreous ſilver ore; though this name ſeems rather to belong to the minera argenti cornea or horn ſilver ore, to be afterwards taken notice of more particularly. It is ductile, and of the ſame colour with lead, but quickly becomes very black by expoſure to the air; though ſometimes it is grey or black even when firſt broken. It is found either in large lumps, or inhering in quartz, gypſum, gneiſs, pyrites, &c. Its ſpecific gravity, according to Kirwan, is 7,200. An hundred parts of it contain from 72 to 77 of ſilver, and it is rarely contaminated with any other metal.

Profeſſor Brunnich ſays that it contains 180 merks of ſilver in the hundred weight. The medium between the glaſs ore and the red gilder ore is called *roſch-gewachs* in Hungary, and *brittle glaſs ore* in Saxony. It is black, and affords a powder of the ſame colour when pounded. In the mines of Himmelfurſt near Freyberg, it is ſaid to have held 140 merks, but theſe pieces are very ſcarce at preſent; and indeed the Hungarian glaſs ores in general are now very ſcarce, as Profeſſor Brunnich informs us, though they are now and then found in the windſhafts, which are frequently covered with a thin membrane or rather cruſt, of the colour of pyrites. Mr Magellan ſays that this ore is nothing elſe but native ſilver penetrated by ſulphur: for, on being expoſed to a ſlow heat, the latter flies off, and the ſilver ſhoots into filaments. There are nine varieties of it. 1. Like *blacklead*, or plumbago, the moſt common kind of any. 2. Bruckman mentions a kind *brown* on the outſide and greeniſh within. 3. The *yellow ore* has its colour from ſome arſenic contained in it, which forms an orpiment with the ſulphur. 4. It is alſo found of a *greeniſh*, and 5. *bluiſh* colour; the latter is friable, like the ſcoria of metals, and is called at Freyberg *Schlarekenerz*, or the ore of ſcoria. 6. It is found alſo in the *arboreſcent*. 7. *Lamellated* 8. *Cryſtallized* into octaedral or hexaedral priſms, and into ten pyramids with ten ſides. 9. Laſtly, it is found *ſuperficial*, or covering the ſtones or maſſes of other ores.

2. The pyrites argenteus of Henckel contains ſilver and iron mineralized with arſenic. There are three varieties of it. 1. Hard, white, and ſhining ore, of a compact, lamellar, or fibrous texture. The brighteſt kind has leaſt ſilver, only giving 6 or 8 ounces per quintal, and the richeſt about ten per cent. It is found in Germany and Spain. It contains no ſulphur. 2. Of a yellowiſh white colour, and ſtriated texture reſembling biſmuth, but much harder. It is found in Spain, and yields about 60 per cent. of ſilver. 3. In another kind

Cronſtedt, p. 550.

Silver.

the quantity of arsenic is so great, that it would scarcely deserve the name of silver ore if the arsenic were not very easily dissipated. It is soft and easily cut; has a brilliant metallic appearance, and consists of conchoidal laminæ. A quintal contains only from four to six ounces of silver, but it is easily reduced by evaporating the arsenic, after which the silver is left behind slightly contaminated with iron.

3. The red or ruby silver ore, the *rothgulden* of the Germans, has the metal combined with sulphur and arsenic. It is a heavy shining substance, sometimes transparent and sometimes opaque; the colour generally crimson, though sometimes grey or blackish. It is found in shapeless masses, or crystallized in pyramids or polygons, sometimes dendritical or plated, or with radiated incrustations. It is found in quartz, flint, spar, pyrites, sparry iron ore, lead ore, cobalt ore, jasper, baro-selenite, gneiss, &c. When radiated or striated, it is called *rothgulden bluth*. It cracks in the fire, and detonates with nitre. Its specific gravity is from 5,400 to 5,684. Bergman informs us, that this kind contains, in the hundred, 60, sometimes 70, pounds of silver, 27 of arsenic, and 13 of sulphur. The darkest coloured ores are the richest, the yellow kinds much poorer; but the most yellow do not belong to this species, being in fact an orpiment with 6 or 7 per cent. of silver. This last kind is brought chiefly from Potosi in America, and is called *rosi-cler* by the Spaniards.

4. The *schwartz gulden*, or *silver mulm*, contains the metal mineralized by sulphur and a small quantity of arsenic and iron. It is of a black sooty colour, and was supposed by Cronstedt to contain a good quantity of copper, to which its colour was owing; but later experiments have evinced, that there is no copper at all in it.

Kirwan's Mineralogy.

It is either of a solid or brittle consistence, and of a glassy appearance when broken, or of a looser texture, and sooty or deep black colour; or it is found like moss, or thin leaves, lying on the surface of other silver ores, or those of lead and cobalt, or in clays, ponderous spar, gneiss, &c. It contains from 25 to 60 per cent. of silver.

5. The *minera argenti alba*, the *Weissgulden ore* of the Germans, is a heavy, soft, opaque substance, fine grained or scaly, bright and shining in its fractures, of a whitish, steely, or lead colour; sometimes crystallized in pyramidical or cylindrical forms, but often in amorphous grains, or resembling moss, or in the form of thin laminæ incrustating other bodies, found in quartz, spar, stelstein, pyrites, blend, lead-ore, cobalt ore, sparry iron ore, fluors, &c. It is very fusible. Its specific gravity is from 5 to 5,300. Its proportion of silver from 10 to 30 per cent. It is found, though not commonly, in Saxony, Hungary, the Hartz, and St Marie aux Mines.

6. The *weisertz*, or white silver ore, is an arsenical pyrites, containing silver. It is met with in the Saxon mines so exactly resembling the common arsenical pyrites, that it cannot be distinguished from it by inspection. Cronstedt supposes that the silver it contains may exist in a capillary form; but Professor Brunnich thinks this is not altogether the case. It is very scarce, but met with near Freyberg. There is likewise a brown mulm having the appearance of rags, met with in the crevices and upon the lumps of cubic lead ore in a mine near Clausthal and other places, which contains a great quantity of silver. It is of a whitish shining colour; hard, granulated, and solid, sometimes striking fire with steel. It discovers a mixture of arsenic, by emitting a garlic smell when heated.

Silver.

7. The *leberertz* of the Germans has the metal combined with sulphurated antimony. It is of a dark grey and somewhat brownish colour. A variety of a blackish blue colour is found in the form of capillary crystals, and called *federertz* or plumose silver ore. It is met with in Saxony, and contains sometimes a mark or half a pound, sometimes only two, three, or four ounces, and sometimes only a mere trifle of silver, per cent. There is another silver ore, also called *leberertz* by the Germans, which contains arsenic and regulus of antimony. This ore is sometimes also found of a dark grey colour; for the most part amorphous, but sometimes crystallized into pyramids. It appears red when scraped, and contains from one to five per cent. of silver. The greatest part of this ore is copper, and the next arsenic. According to Bergman, the copper amounts to 24 per cent. It is found in Transylvania; and a kind was lately discovered in Spain, of a hard solid consistence, and of a greyish blue colour.

8. The *goose dung* ores contain silver mineralized with sulphur in combination with iron, arsenic, and cobalt. It looks like the *weissgulden*, excepting that the cobalt, by its decomposition, gives it a rosy appearance. There are two varieties; one of a dull tarnished surface and ferruginous look; the other has a shining appearance like the *leberertz*. It contains from 10 to 40 or 50 per cent. of silver. The arsenic is in an acid state, and united to the cobalt.

9. The *dal fahlertz* contains silver mineralized with sulphurated copper and antimony, and resembles the dark-coloured *weissgulden*, giving a red powder when rubbed. It is found either solid or crystallized, and is met with in the province of Dal, where it is melted by a very difficult process, calculated to preserve the different metals it contains. There is another kind which has arsenic united to the rest of the ingredients. It is only the grey copper ore impregnated with silver, of which it contains from one to twelve per cent. the quantity of copper being from 12 to 24 per cent. and the remainder consisting either of sulphur or arsenic, with a little iron. It is the most common of all silver ores; and M. Monnet remarks, that where copper is united to arsenic, silver is always to be found. A variety has been found at Schemnitz, containing a portion of gold also.

10. The *pecheblende* is an ore of zinc containing silver, and is met with in the Saxon and Hungarian mines among the rich gold and silver ores. It is either of a metallic changeable colour or black. Of these there were formerly two varieties, viz. either in the form of fine scales or in balls, but the latter is now entirely unknown. A black blend is found in Bohemia, which is very heavy, with the surface somewhat elevated like some kinds of hæmatites, but no silver has yet been extracted from it.

11. The *bleyganz*, potters ore, or galena, contains silver mineralized with sulphurated lead. It is also called *pyritous silver*, and is of a brown colour, yielding but a very small portion of metal. It is met with at Kunsberg;

berg in Norway. When the silver is combined with sulphurated lead and antimony, the ore is called *stri-perz*.

12. The *marcasite* containing silver has the metal united with sulphurated iron. There are great varieties of this ore holding different proportions of the metal; some produce only half an ounce of silver per cent. A liver-coloured marcasite is found at Kunsberg in Norway, containing from three to three ounces and a half of silver per cent.

13. Silver is found mineralized with sulphurated and arsenical cobalt; the stone sometimes containing *dendrites*. These kinds keep well in water, but generally decay in the air, and lose the silver they contain. It is found at Morgenstern near Freyberg and Annaberg.

14. The *butter-milk ore* cotnains silver mineralized by sulphur, with regulus of antimony and barytes. It is found in the form of thin particles or granular spar. Wallerius says that it is soft like mud, and feels like butter. He suspects it to be produced from other silver ores washed away by running waters. Bomare adds, that the miners look upon it as a certain sign of other ores in the neighbourhood, though some are persuaded that it is only an unripened silver ore, which would soon become perfect.

15. The *combustible* silver ore is a black brittle substance, leaving about six per cent. of silver in its ashes. It is in fact a perfect coal in which silver is found.

16. The *hornertz*, or horn silver ore, in which the silver is united with the muriatic acid, is the scarcest of all the silver ores. It is sometimes found in snowy cubical crystals, but is met with of many different colours. Its principal characteristic is to change to a violaceous brownish colour when exposed to the sunbeams, as happens also to the artificial luna cornea. It is frequently crystallized in a cubic form, though not always of a white colour. Sometimes it resembles an earth easily fusible without smoke. There is a black kind, friable, and easily reducible to powder; the other is in some degree malleable, may be cut with a knife, and takes a sort of polish when rubbed. The vitreous silver ore, which is sometimes mixed with the horn silver, is soluble in nitrous acid; and this affords a method of separating them, the horn silver ore being insoluble in that menstruum. When the horn silver is free from iron, it generally contains 70 per cent. of silver at least; but these ores mostly contain some portion of iron, a small part of which is even united to the marine acid. This kind of ore was first analysed by Mr Woule, who discovered the presence of the vitriolic acid in it.

Phil.Trans. for 1776.

17. Another kind of horn silver ore is mentioned by Mr Bergman, in which the metal is mineralized by the vitriolic and marine acids, along with some sulphur. He doubts, however, whether the mineralization be perfect in this case, as the salt and sulphur do not admit of any other than a mechanical union. But since iron is often found in these ores, a marcasite may thus be sometimes formed.

18. The *silver goose dung ore* is of a greenish colour, with a mixture of yellow and red. Some think it is a mixture of red silver ore and calx of nickel.

19. The *foliaceous* silver ore. The colour of this ore is *mortdoré*. Some imagine it to be a native silver ore; others that it is a mixture of galena, ochre, and silver. It is sometimes found in the mountain cork, and is so light that it will swim upon water. It contains but one ounce of silver per quintal.

These are all the varieties hitherto observed in which silver is met with in the earth, though it may perhaps occur in various other forms. It would be worth while to examine whether, in those countries where gold and silver are found in large quantities, the precious metals may not be contained in some proportion in the most common ores, more especially when the particles of gold and silver have not been able to extricate themselves in such a manner as to lie separate in fissures, veins, or hollow places of the mine. A mineralization of silver with alkali is said to have been lately met with at Annaberg in Austria; but the account of it as yet can scarcely be depended upon. Professor Brunnich says, that the silver contained in the limestone at that place appears to be native when the stone is polished.

The purest silver is that which is extracted from luna cornea, and is the only kind that ought to be trusted in the nice operations of chemistry. The process, however, is very tedious, and presents a very unexpected phenomenon, as this metal, though one of the most fixed, is nevertheless volatilized in the operation in such a manner that it exhales though the pores of the crucible; and small globules of silver are afterwards found in the cover, and even in the support of the crucible. According to Cramer, this loss may be prevented by smearing the crucible with black soap, and mixing with the luna cornea half its weight of oil or tallow, which last must also be added by little and little during the operation.

Cronstedt, p. 537.

M. Magellan takes notice of a remarkable appearance observable in dissolving silver in the nitrous acid. He observes, that this acid is its specific menstruum, attacking it even when cold with considerable effervescence, growing hot, and emitting a considerable quantity of orange-coloured fumes, which diminish in proportion as the saturation advances. The metal appears of a pale brown colour in the conflict, and the solution becomes quite black. This last appearance, however, is owing to a thin, black, fuliginous substance like smut, which is at once formed into a crust on the surface of the thin plates of silver in the first attack of the acid upon them. This is a very singular phenomenon, and hitherto unaccounted for, these black crusts being comminuted into smaller and smaller particles by the action of the acid; and, when the effervescence is over, they are seen distinctly to fall to the bottom of the vessel, and to form a black sediment, leaving the liquid solution quite transparent, but of a blue colour inclining to green.—This colour might be attributed to some small mixture of copper, though the silver used in the experiment was of the purer kind. The chemists of Dijon say, that the nitrous solution of silver looks of a fine blue colour, if the acid be pure and well concentrated; but if it has any mixture of vitriolic or marine, a precipitation of vitriolated silver or luna cornea takes place. Afterwards the solution becomes as colourless as water, but gives a lasting black tinge to animal substances. This solution is of great use in chemistry, serving to form the lunar caustic, to purify the common aquafortis from a mixture of the vitriolic and marine acids, and is a very nice test of the existence of these acids in mineral waters.

Silver does not combine with earths, even by the most violent heat, though Mr Fourcroy supposes that its calx might give an olive green to glass. Mr Magellan informs us, that its calx, precipitated by volatile alkali, gives a yellow colour to glass, and that he has seen it stained in this manner so high as almost to appear of a red colour. It unites with most metals, even with iron. The nature of this alloy has been but little inquired into, though Fourcroy is of opinion that it may probably be of the greatest utility in the arts. It combines in all proportions with copper, by which it is not deprived of its ductility, but renders it harder and more sonorous; by which means it is often used in bells. It is otherwise highly useful, on account of its indestructibility by fire and air, and its extreme ductility. Its fine colour renders it extremely proper for ornamental purposes, and it is applied like gold on the surface of different bodies, and even on copper. It likewise enters the texture of rich silks; but its most considerable use is that of being employed as money of an inferior value to gold. In this case, it is alloyed with one-twelfth part of copper. It is likewise often employed in making household utensils of all kinds, though its great price renders it less common than it would otherwise be for this purpose. For plate, it is usually alloyed with one twenty-fourth of copper, which gives it a greater degree of hardness and coherence, without rendering it in the least noxious.

Silver also has been used in medicine; but its extreme causticity, when dissolved in the nitrous acid, and its inactivity otherwise, have brought it into disuse. The crystals of silver have been recommended in very small quantity in dropsical cases; but they are by no means superior, or even equal in efficacy, to much safer medicines. The solution of silver, under the name of *Greek water*, has been used for the purpose of dying hair of a dark colour; and the same solution evaporated to a consistence, and fused, forms the lunar caustic of the shops.

Shell SILVER, is prepared of the shreds of silver leaf, or of the leaves themselves, for the use of painters, after the same manner as shell gold. See *Shell-Gold*.

SILVERING, the covering of any thing with silver. It is usual to silver metals, wood, paper, &c. which is performed either with fire, oil, or size. Metal gilders silver by the fire; painter-gilders all the other ways. See GILDING.

To silver copper or brass. 1. Cleanse the metal with aquafortis, by washing it lightly, and immediately throwing it into pure water; or by heating it red-hot, and scouring it with salt and tartar and pure water with a small wire brush. 2. Dissolve some silver in aquafortis, in a broad-bottomed glass vessel, or of glazed earth; then evaporate away the aquafortis over a chaffing dish of coals. 3. Put five or six times its quantity of water, or as much as will be necessary to dissolve it perfectly, on the remaining dry calx; evaporate this water with the like heat; then put more fresh water, and evaporate again; and, if need be, the third time, making the fire towards the latter end so strong as to leave the calx perfectly dry, which, if your silver is good, will be of a pure white. 4. Take of this calx, common salt, crystal of tartar, of each a like quantity or bulk, and mixing well the whole composition, put the metal into pure water, and take of the said powder with your wet fingers, and rub it well on, till you find every little cavity of the metal sufficiency silvered over. 5. If you would have it richly done, you must rub on more of the powder; and in the last place wash the silvered metal in pure water, and rub it hard with a dry cloth.

SILVERING *of Glasses*. See FOLIATING *of Looking-glasses*.

SILURIS, in ichthyology, a genus belonging to the order of pisces abdominales. The head is naked; the mouth set round with hairy filaments; the bronchiæ have from 4 to 14 rays, the rays of the pectoral fins, or the first dorsal one, is prickly, and dentated backwards.—There are 21 species, most of them natives of the Indian and American seas. Mr Hasselquist mentions one called the *clarias* by Linnæus, and *scheilan* by the Arabians. If it pricks one with the bone of the breast-fin, it is dangerous; and our author saw the cook of a Swedish merchant ship die of the poison communicated by the prick of one of these fish. See ELECTRICITY, n° 261.

SIMEON *of* DURHAM, the cotemporary of William of Malmsbury, took great pains in collecting the monuments of British history, especially in the north of England, after they had been scattered by the Danes. From these he composed a history of the kings of England, from A. D. 616 to 1130; with some smaller historical pieces. Simeon both studied and taught the sciences, and particularly the mathematics at Oxford; and became precentor of the church at Durham, where he died, probably soon after the conclusion of his history, which was continued by John, prior of Hexham, to A. D. 1156.

SIMIA, the MONKEY, a genus of quadrupeds belonging to the class of mammalia, and order of primates, in the Linnæan system, but by Mr Pennant arranged under the digitated quadrupeds. According to the Linnæan system, the characteristics of this genus are these; There are four close set fore teeth on each jaw; single tusks on each side in both jaws, which are longer than the rest, and somewhat remote from them. The grinders are obtuse, and the feet are formed like hands. Mr Pennant gives the following generic description of the simia. There are four cutting teeth in each jaw, and two canine. Each of the feet are formed like hands, generally with flat nails, and, except in one instance, have four fingers and a thumb. There are eyebrows both above and below.

They are a numerous race; but almost all confined to the torrid zone. They fill the woods of Africa from Senegal to the Cape, and from thence to Æthiopia. They are found in all parts of India, and its islands; in Cochin-China, in the south of China, and in Japan; (and one is met with in Arabia); and they swarm in the forests of South America, from the isthmus of Darien as far as Paraguay. They are lively, agile, full of frolic, chatter, and grimace. From the structure of their members, they have many actions in common with the human kind. Most of them are fierce and untameable; some are of a milder nature, and will show a degree of attachment; but in general they are endowed with mischievous intellects; and are filthy, obscene, lascivious, and thieving. They inhabit the woods, and live on trees; feeding on fruits, leaves, and insects. In general they are gregarious, going in vast companies; but the different species never mix with each other, always keeping apart and in different quarters. They leap with vast activity from tree to tree, even when loaded with their young, which cling to them. They are the prey of leopards and others of the feline race: and of serpents, which pursue them to the summits of the trees, and swallow them entire. They are not carnivorous, but for mischief's sake will rob the nests of birds of the eggs and young. In the countries where they most abound, the sagacity of the feathered tribe is more marvellously shown in their contrivances to fix the nest beyond the reach of these invaders.

The simiæ being more numerous in their species than any other animals, and differing greatly in their appearances, it seemed necessary to methodize and subdivide the genus. Accordingly Mr Ray first distributed them into three classes.

Simiæ, Apes, such as wanted tails.

Cercopitheci, Monkeys, such as had tails.

Papiones, Baboons, those with short tails; to distinguish them from the common monkeys, which have very long ones.

Gmelin's Edition of the Animal Kingdom of Linnæus, by Ker.

The principal marks by which the species of this genus are distinguishable from each other, are derived, 1st, from the tail, which is either long, short, or altogether wanting, or is straight, or prehensile; 2dly, from the buttocks, which are naked, and furnished with callosities, or are covered with hair; 3dly, from the nails, which are flat and rounded like those of man, or sharp pointed like the claws of beasts in general; 4thly, from the presence or absence of a beard on the chin; and, 5thly, from the cheeks being provided with, or wanting, pouches in their under parts. For greater convenience, the species of this genus, which are very numerous, are arranged under five subordinate divisions, considered as distinct genera by some authors, and not without reason. Three of these subdivisions were adopted by Linnæus; but Dr Gmelin, following Buffon, has added other two taken from the third division of his great precursor. These subdivisions are the *simiæ, papiones, cercopitheci, sapaji*, and *sagoini*.

I. The Simiæ, or Apes. They have no tails. The visage is flat; the teeth, hands, fingers, feet, toes, and nails, resemble those of man, and they walk naturally erect. This division includes the simiæ, or apes properly so called, which are not found in America.

1. The chimpanzee, the simia troglodytes of Linnæus, common in the mountains of Sierra Leona, resembles man more than the orang-outang. This animal was first brought to Europe in 1738, when it was exhibited as a show in London. The following description of one that was kept some months at the colony of Sierra Leona is given by Wadstrom, in his Essay on Colonization †. He was nearly two feet high; but the full stature is nearly five feet. He was covered with black hair, long and thick on the back, but short and thin on the breast and belly. His face was bare; his hands and his head resembled those of an old black man, except that the hair on his head was straight. He ate, drank, slept, and sat at table, like a human being. At first he crept on all fours, on the outside of his hands; but, when grown larger, he endeavoured to go erect, supporting himself by a stick. He was melancholy, but always good natured.

† Part ii. p. 272.

Plate CCCCLXVII. fig. 1.

2. The satyrus, orang-outang, or great ape, has a flat face, and a deformed resemblance of the human; ears like those of a man; the hair on the head longer than on the body. The body and limbs are covered with reddish and shaggy hair; longest on the back, thinnest on the fore parts. The face and paws are swarthy; the buttocks covered with hair. They inhabit the interior parts of Africa, the isles of Sumatra, Borneo, and Java. Are solitary, and live in the most desert places. They grow to the height of six feet; have prodigious strength, and will overpower the strongest man. The old ones are shot with arrows, the young alone can be taken alive. They live entirely on fruits and nuts. They will attack and kill the negroes who wander in the woods; will drive away the elephants, and beat them with their fists or pieces of wood; and will throw stones at people that offend them. They sleep in trees; and make a sort of shelter from the inclemency of the weather. They are of a grave appearance and melancholy disposition, and even when young not inclined to frolic. They go erect, and are vastly swift and agile. These accounts are chiefly taken from Andrew Battel, an English sailor, who was taken prisoner 1589, and lived many years in the inner parts of Congo; his narrative is plain, and seems very authentic. It is preserved in Purchas's collection. Froger * informs us, "that those along the banks of the river Ganges are larger and more mischievous than in any part of Africa: the negroes dread them, and cannot travel alone in the country without running the hazard of being attacked by these animals, who often present them with a stick, and force them to fight. I have heard the Portuguese say, that they have often seen them hoist up young girls, about seven or eight years old, into trees, and that they could not be wrested from them without a great deal of difficulty. The most part of the negroes imagine them to be a foreign nation come to inhabit their country, and that they do not speak for fear of being compelled to work." When taken young, they are capable of being tamed, and taught to perform many menial offices. Francis Pyrard † relates, "that in the province of Sierra Leona, there is a species so strong limbed, and so industrious, that, when properly trained and fed, they work like servants; that they generally walk on the two hind feet; that they pound any substances in a mortar; that they go to bring water from the river in small pitchers, which they carry full on their heads. But when they arrive at the door, if the pitchers are not soon taken off, they allow them to fall; and when they perceive the pitchers overturned and broken, they weep and lament." Father Jarric ¶, quoted by Nieremberg, says the same thing, nearly in the same terms. With regard to the education of these animals, the testimony of Shoutten § accords with that of Pyrard. "They are taken (he remarks) with snares, taught to walk on their hind feet, and to use their fore feet as hands in performing different operations, as rinsing glasses, carrying drink round the company, turning a spit, &c." "I saw at Java (says Guat ‡) a very extraordinary ape. It was a female. She was very tall, and often walked erect on her hind feet. On these occasions, she concealed with her hands the parts which distinguish the sex. Except the eye-brows, there was no hair on her face, which pretty much resembled the grotesque female faces I saw among the Hottentots at the Cape. She made her bed very neatly every day, lay upon her side, and covered herself with the bed cloaths. When her head ached, she bound it up with a handkerchief; and it was amusing to see her

Simia. her thus hooded in bed. I could relate many other little articles which appeared to be extremely singular. But I admired them not so much as the multitude; because, as I knew the design of bringing her to Europe to be exhibited as a show, I was inclined to think that she had been taught many of these monkey tricks, which the people considered as being natural to the animal.—She died in our ship, about the latitude of the Cape of Good Hope. The figure of this ape had a very great resemblance to that of man, &c." Gmelli Carreri tells us, that he saw one of these apes, which cried like an infant, walked upon its hind-feet, and carried a matt under his arm to lie down and sleep upon.

Buffon's Nat. Hist. by Smellie, vol. viii. p. 86. An orang-outang which Buffon saw, is described by him as mild, affectionate, and good-natured. His air was melancholy, his gait grave, his movements measured, his dispositions gentle, and very different from those of other apes. He had neither the impatience of the Barbary ape, the maliciousness of the baboon, nor the extravagance of the monkeys. "It may be alleged, (says our author), that he had the benefit of instruction; but the other apes which I shall compare with him, were educated in the same manner. Signs and words were alone sufficient to make our orang-outang act; but the baboon required a cudgel, and the other apes a whip; for none of them would obey without blows. I have seen this animal present his hand to conduct the people who came to visit him, and walk as gravely along with them as if he had formed a part of the company. I have seen him sit down at table, unfold his towel, wipe his lips, use a spoon or a fork to carry the victuals to his mouth, pour his liquor into a glass, and make it touch that of the person who drank along with him. When invited to take tea, he brought a cup and a saucer, placed them on the table, put in sugar, poured out the tea, and allowed it to cool before he drank it. All these actions he performed without any other instigation than the signs or verbal orders of his master, and often of his own accord. He did no injury to any person: he even approached company with circumspection, and presented himself as if he wanted to be caressed. He was very fond of dainties, which every body gave him: And as his breast was diseased, and he was afflicted with a teazing cough, this quantity of sweetmeats undoubtedly contributed to shorten his life. He lived one summer in Paris, and died in London the following winter. He eat almost every thing; but preferred ripe and dried fruits to all other kinds of food. He drank a little wine; but spontaneously left it for milk, tea, or other mild liquors." This was only two feet four inches high, and was a young one. There is great possibility that these animals may vary in size and in colour, some being covered with black, others with reddish hairs.—They are not the satyrs of the ancients; which had tails (A), and were a species of monkey. Linnæus's *homo nocturnus*, an animal of this kind, is unnecessarily separated from his *simia satyrus*. Simia.

To enable the reader to form a judgment of this animal, which has so great a resemblance to man, it may not be unacceptable to quote from Buffon the differences and conformities which make him approach or recede from the human species. "He differs from man externally by the flatness of his nose, by the shortness of his front, and by his chin, which is not elevated at the base. His ears are proportionally too large, his eyes too near each other, and the distance between his nose and mouth is too great. These are the only differences between the face of an orang-outang and that of a man. With regard to the body and members, the thighs are proportionally too short, the arms too long, the fingers too small, the palm of the hands too long and narrow, and the feet rather resemble hands than the human foot. The male organs of generation differ not from those of man, except that the prepuce has no frænum. The female organs are extremely similar to those of a woman. Id. p. 95.

"The orang-outang differs internally from the human species in the number of ribs: man has only 12, but the orang-outang has 13. The vertebræ of the neck are also shorter, the bones of the pelvis narrow, the buttocks flatter, and the orbits of the eyes sunk deeper. He has no spinal process on the first vertebra of the neck. The kidneys are rounder than those of man, and the ureters have a different figure, as well as the bladder and gall-bladder, which are narrower and longer than in the human species. All the other parts of the body, head, and members, both external and internal, so perfectly resemble those of man, that we cannot make the comparison without being astonished that such a similarity in structure and organization should not produce the same effects. The tongue, and all the organs of speech, for example, are the same as in man; and yet the orang-outang enjoys not the faculty of speaking; the brain has the same figure and proportions; and yet he possesses not the power of thinking. Can there be a more evident proof than is exhibited in the orang-outang, that matter alone, though perfectly organized, can produce neither language nor thought, unless it be animated by a superior principle? Man and the orang-outang are the only animals who have buttocks and the calf of the legs, and who, of course, are formed for walking erect; the only animals who have a broad chest, flat shoulders, and vertebræ of the same structure; and the only animals whose brain, heart, lungs, liver, spleen, stomach, and intestines, are perfectly similar, and who have an appendix vermiformis, or blind-gut. In fine, the orang-outang has a greater resemblance to man than even to the baboons or monkeys, not only in all the parts we have mentioned, but in the largeness of the face, the figure of the cranium, of the jaws, of the teeth, and of the other bones of the head and

(A) Ælian gives them tails, *lib.* xvi. c. 21. Pliny says they have teeth like dogs, *lib.* vii. *c.* 2. circumstances common to many monkeys. *Ptolemy, lib.* 7. *c.* 2. speaks of certain islands in the Indian ocean inhabited by people with tails like those with which satyrs are painted, whence called the *isles of satyrs*. Kœping, a Swede, pretended to have discovered these *homines caudati*; that they would have trafficked with him, offering him live parrots; that afterwards they killed some of the crew that went on shore, and eat them, &c. &c. *Amœn. Acad.* vi. 71.

Simia.

and face; in the thickness of the fingers and thumb, the figure of the nails, and the number of vertebræ; and, lastly, in the conformity of the articulations, the magnitude and figure of the rotula, sternum, &c. Hence, as there is a greater similarity between this animal and man, than between those creatures which resemble him most, as the Barbary ape, the baboon, and monkey, who have all been designed by the general name of *apes*, the Indians are to be excused for associating him with the human species, under the denomination of *orang-outang*, or *wild man*. In fine, if there were a scale by which we could descend from human nature to that of the brutes, and if the essence of this nature consisted entirely in the form of the body, and depended on its organization, the orang-outang would approach nearer to man than any other animal. Placed in the second rank of beings, he would make the other animals feel his superiority, and oblige them to obey him. If the principle of imitation, by which he seems to mimic human actions, were a result of thought, this ape would be still farther removed from the brutes, and have a greater affinity to man. But the interval which separates them is immense. Mind, reflection, and language, depend not on figure or the organization of the body. These are endowments peculiar to man. The orang-outang, though, as we have seen, he has a body, members, senses, a brain, and a tongue, perfectly similar to those of man, neither speaks nor thinks. Though he counterfeits every human movement, he performs no action that is characteristic of man, no action that has the same principle or the same design. With regard to imitation, which appears to be the most striking character of the ape kind, and which the vulgar have attributed to him as a peculiar talent, before we decide, it is necessary to inquire whether this imitation be spontaneous or forced. Does the ape imitate us from inclination, or because, without any exertion of the will, he feels the capacity of doing it? I appeal to all those who have examined this animal without prejudice; and I am convinced that they will agree with me, that there is nothing voluntary in this imitation. The ape, having arms and hands, uses them as we do, but without thinking of us. The similarity of his members and organs necessarily produces movements, and sometimes successions of movements, which resemble ours. Being endowed with the human structure, the ape must move like man; but the same motions imply not that he acts from imitation. Two bodies which receive the same impulse, two similar pendulums or machines, will move in the same manner; but these bodies or machines can never be said to imitate each other in their motions. The ape and the human body are two machines similarly constructed, and necessarily move nearly in the same manner; but parity is not imitation. The one depends on matter, and the other on mind. Imitation presupposes the design of imitating. The ape is incapable of forming this design, which requires a train of thinking; consequently man, if he inclines, can imitate the ape; but the ape cannot even incline to imitate man."

Fig. 2. 3. Pongo, or Jocko, are considered as one species by Pennant and Gmelin. It inhabits the island of Java, and the interior parts of Guinea. Has no pouches within his checks, no tail, and no callosities on the buttocks; which last are plump and fleshy. All the teeth are similar to those of man. The face is flat, naked, and tawny: the ears, hands, feet, breast, and belly, are likewise naked; the hair of the head descends on both temples in the form of tresses; the hair on the back and loins is in small quantities. It is five or six feet high, and walks always erect on the two hind feet. It has not been ascertained whether the females, of this species or variety, are subject to periodical discharges; but analogy renders this almost unquestionable. This animal is, by Dr Gmelin, considered only as a variety of the orang-outang.

4. The great gibbon, long-armed ape, or simia lar, with a flat swarthy face surrounded with grey hairs: hair on the body black and rough; buttocks bare; nails on the hands flat; on the feet long; arms of a most disproportioned length, reaching quite to the ground when the animal is erect, its natural posture; of a hideous deformity.—Inhabits India, Malacca, and the Molucca isles; a mild and gentle animal; grows to the height of four feet. The great black ape of Mangsi, a province in China, seems to be of this kind. Fig. 3.

5. The lesser gibbon, or simia lar minor, but is much less, being only about a foot and a half high; the body and face are of a brown colour, resembles the former. The simia lar argentea is probably a variety of this species. Fig. 4.

6. The pigmy, or simia silvanus, has no tail; the buttocks are naked; the head roundish, and the arms shorter than the body. It inhabits Africa; and is not uncommon in our exhibitions of animals; is very tractable and good-natured, and was most probably the pigmy of the ancients. It abounds in Æthiopia, one seat of that imaginary nation; was believed to dwell near the fountains of the Nile, whence it descended annually to make war on the cranes, *i. e.* to steal their eggs, which the birds may be supposed naturally to defend; whence the fiction of their combats. Fig. 5.

7. The magot, simia inuus, or Barbary ape, has a long face, not unlike that of a dog; canine teeth, long and strong; ears like the human; nails flat; buttocks bare; colour of the upper part of the body a dirty greenish brown; belly, of a dull pale yellow; grows to above the length of four feet.—They inhabit many parts of India, Arabia, and all parts of Africa except Egypt, where none of this genus are found. A few are found on the hill of Gibraltar, which breed there; probably from a pair that had escaped from the town; as they are not found in any other part of Spain.—They are very ill-natured, mischievous, and fierce; agreeing with the character of the ancient Cynocephali. They are a very common kind in exhibitions. By force of discipline they are made to play some tricks; otherwise they are more dull and sullen than the rest of this genus. They assemble in great troops in the open fields in India, and will attack women going to market, and take their provisions from them. The females carry the young in their arms, and will leap from tree to tree with them. Apes were worshipped in India, and had magnificent temples erected to them. When the Portuguese plundered one in Ceylon, they found in a little golden casket the tooth of an ape; a relic held by the natives in such veneration, that they offered 700,000 ducats to redeem it, but in vain; for it was burnt by the viceroy, to stop the progress of idolatry. Fig. 6. and 7.

II. Papiones, or Baboons. These have short tails, a long face; a broad high muzzle; longish dog-like tusks, or canine teeth; and naked callosities on the buttocks. They are only found in the old world, and are the papiones and κυνοκεφαλα of the ancients.

8. The maimon, simia papio nemestrina, or pig-tailed baboon, Plate CCCCLXVIII. fig. 8.

baboon, with a pointed face, which is naked, of a swarthy redness; two sharp canine teeth; ears like the human; hair on the limbs and body brown inclining to ash-colour, palest on the belly; fingers black; nails long and flat; thumbs on the hind feet very long, connected to the nearest toe by a broad membrane; tail four inches long, slender, exactly like a pig's, and almost naked; the bare spaces on the rump red, and but small: length, from head to tail, 22 inches. Inhabits the isles of Sumatra and Japan; is very docile. In Japan it is taught several tricks, and carried about the country by mountebanks. Kempfer was informed by one of these people, that the baboon he had was 102 years old.

Fig. 9. 9. The great baboon, or simia papio sphinx, with hazel irides; ears small and naked; face canine, and very thick; middle of the face and fore-head naked; and of a bright vermilion colour; tip of the nose of the same, and ending truncated like that of a hog; sides of the nose broadly ribbed, and of a fine violet hue; the opening of the mouth very small; cheeks, throat, and goat-like beard yellow; hair on the fore-head very long, turns back, is black, and forms a kind of pointed crest. Head, arms, and legs, covered with short hair, yellow and black intermixed; the breast with long whitish yellow hairs, the shoulders with long brown hair. Nails flat; feet and hands black; tail four inches long, and very hairy; buttocks bare, red, and filthy; but the space about them is of a most elegant purple colour, which reaches to the inside of the upper part of the thighs.

Pennant's Quadrupe ls, vol. i. p. 172. This was described by Mr Pennant from a stuffed specimen in Sir Ashton Lever's museum. In August 1779, a live animal of this species was shown at Edinburgh, and in October following at Chester, where being seen by Mr Pennant, that inquisitive naturalist has described it in his History of Quadrupeds. "It differed little (he observes) in colour from the above, being in general much darker. Eyes much sunk in the head, and small. On the internal side of each ear was a white line, pointing upwards. The hair on the fore-head turned up a like a toupee. Feet black; in other respects resembling the former. In this I had an opportunity of examining the teeth. The cutting teeth were like those of the rest of the genus; but, in the upper and lower jaw, were two canine, or rather tusks, near three inches long, and exceedingly sharp and pointed. This animal was five feet high, of a most tremendous strength in all its parts, was excessively fierce, libidinous, and strong."

Mr Schreber says, that this species lives on succulent fruits, and on nuts; is very fond of eggs, and will put eight at once into its pouches, and, taking them out one by one, break them at the end, and swallow the yolk and white; rejects all flesh-meat, unless it be dressed; would drink quantities of wine or brandy; was less agile than other baboons; very c'e in'y; for it would immediately fling its excrements out of its hut. That which was shown at Chester was particularly fond of cheese. Its voice was a kind of roar, not unlike that of a lion, but low and somewhat inward. It went upon all fours, and never stood on its hind legs, unless forced by the keeper; but would frequently sit on its rump in a crouching manner, and drop its arms before the belly. Inhabits the hotter parts of Africa.

Fig. 10. 10. The little baboon, or simia papio apedia, has a roundish head, with a projecting muzzle, and roundish naked ears; the hair on the body is yellow, tipt with black; the face is brown, and almost naked, having only a few scattered hairs; the nails are all compressed and oblong, except on the thumbs and great toes, the nails of which resemble man; the tail is very short, being hardly an inch long; the body is about the size of a cat. It is uncertain, saye Gmelin, if this animal should he considered as a distinct species, or only as a variety of the simia sciurea.

11. The mantegar, or simia papio mermon, commonly called the *tufted ape*, but it is improperly named an *ape*, as it has a tail. It is described in the abridgment of the Philosophical Transactions, n° 290. It had a nose and head 14 inches in length; the nose of a deep red, face blue, both naked; black eye-brows; ears like the human; on the top of the head a long upright tuft of hair; on the chin another; two long tusks in the upper jaw; fore feet exactly resembling hands, and the nails on the fingers flat; the fore-part of the body, and the inside of the legs and arms, naked; the outside covered with mottled brown and olive hair. Length, from the nose to the rump, three feet two inches. It was very fierce and salacious; went on all fours, but would sit up on its rump, and support itself with a stick; in this attitude, it would hold a cup in its hand, and drink out of it. Its food was fruits. Fig. 11.

12. The mandril, simia papio maimon, or ribbed nose baboon, has a short tail, and a thin beard on the chin; the cheeks are blue and striped, and the buttocks are naked. This species of baboon is found on the Gold Coast, and in the other southern provinces of Africa, where he is called *boggo* by the negroes, and *mandril* by the Europeans. Next to the orang-outang, he is the largest of all the apes or baboons. Smith relates, that he had a present of a female mandril, which was only six months old, and that it was as large as an adult baboon. He adds, that these mandrils walk always on two feet; that they weep and groan like men; that they have a violent passion for women, which they never fail to gratify when they find a woman at a distance from relief. We have given figures both of the male and female, which may be easily distinguished by their size and appearance. Fig. 12. and 13.

13. The wood-baboon, or simia papio sylvatica, with a long dog-like face, covered with a small glossy black skin; hands and feet naked, and black like the face; hair on all parts long, elegantly mottled with black and tawny; nails white: about three feet high when erect; tail not three inches, and very hairy on the upper top. Inhabits Guinea, where it is called by the English the *man of the wood*. Fig. 14.

14. The brown baboon, or simia papio platypygos, with pointed ears; face of a dirty white; nose large and broad; hairs round the face short and straight; colour of the upper part of the body brown; of the under, ash-colour: tail about four inches long; taper, and almost bare of hair; beneath is quite naked. The animal which Mr Pennant called the *new baboon*, in the first edition, seems by the taperness of the tail, and general form, to be of this kind.

15. The hoggish baboon, or simia papio porcaria, has a short tail, and coloured buttocks; the head is like that of a hog, with a naked snout; the body is of an olive brown colour; the nails are sharp and compressed. Inhabits Africa, and is about three feet and a half high when

Simia. when ſtanding erect. This, in all probability, is the ſame animal with the hog-faced ape, adopted from Pennant.

III. Monkeys, Cercopitheci, have long tails, which are not prehenſile; the under parts of their cheeks are furniſhed with pouches, in which they can keep their victuals; the partition between the noſtrils is thin, and the apertures are, like thoſe of man, placed in the under part of the noſe; the buttocks are naked, and provided with calloſities. Theſe animals, which are never found native in America, are the cercopitheci, and κῆβοι, of the ancients.

Plate CCCCLXIX. Fig. 15. 16. The Tartarin, dog-faced baboon of Pennant, and cercopithecus hamadryas of Gmelin, with a long, thick, and ſtrong noſe, covered with a ſmooth red ſkin; ears pointed, and hid in the hair; head great, and flat; hair on the head, and fore-part of the body as far as the waiſt, very long and ſhaggy; grey and olive-brinded; the ſides of the head very full, the hair on the limbs and hind part of the body very ſhort; limbs ſtrong and thick; hands and feet duſky; the nails on the fore-feet flat; thoſe on the hind like a dog's; buttocks very bare, and covered with a ſkin of a bloody colour; tail ſcarce the length of the body, and carried generally erect. They inhabit the hotteſt parts of Africa and Aſia; where they keep in vaſt troops, and are very fierce and dangerous. They rob gardens. They will run up trees when paſſengers go by, ſhake the boughs at them with great fury, and chatter very loud. They are exceſſively impudent, indecent, laſcivious; moſt deteſtable animals in their manners as well as appearance. They range the woods in hundreds; which obliges the owners of the coffee-plantations to be continually on their guard againſt their depredations. One of them was ſhown in London ſome years ago: it came from Mokha, in the province of Yeman, in Arabia Felix in the Perſian gulph; and was above five feet high. It was very fierce and untameable; ſo ſtrong as eaſily to maſter its keeper, a ſtout young man. Its inclinations to women appeared in the moſt violent manner. A footman, who brought a girl to ſee it, in order to teaze the animal, kiſſed and hugged her: the beaſt, enraged at being ſo tantalized, caught hold of a quart pewter-pot, which he threw with ſuch force and ſo ſure an aim, that, had not the man's hat and wig ſoftened the blow, his ſkull muſt have been fractured: but he fortunately eſcaped with a common broken head.

Fig. 16. 17. The white-bearded black wanderu, the ſimia ſilenus of Linnæus, the ouanderou of Buffon, and lion-tailed baboon of Pennant, the cercopithecus ſilenus albibarbatus of Gmelin, has a dog-like face, is naked, and of a duſky colour; a very large and full white or hoary beard; large canine teeth; body covered with black hair; belly of a light colour; tail terminated with a tuft of hair like that of a lion. Its bulk that of a middling ſized dog. It inhabits the Eaſt Indies and the hotter parts of Africa.

18. The purple-faced monkey, or cercopithecus ſilenus purpuratus, with a great triangular white beard, ſhort and pointed at the bottom, and on each ſide of the ears, extended a winged faſhion far beyond them; face and hands purple, body black. Inhabit Ceylon. They are very harmleſs; live in the woods, and feed on leaves and buds of trees; and when taken ſoon become tame.

19. Malbrouk, or cercopithecus faunus, has a long tail, and is bearded: the tail is buſhy at the extremity. It is a native of Bengal. This ſpecies has cheek-pouches, and calloſities on the buttocks; the tail is nearly as long as the body and head; and it is a miſtake of Cluſius that it terminates in a tuft; the face is of a cinereous grey colour, with a large muzzle, and large eyes, which have fleſh-coloured eyelids, and a grey band croſs the forehead in the place of eye-brows; the ears are large, thin, and fleſh-coloured; the upper parts of the body are of a uniform yellowiſh brown colour, and the lower of a yellowiſh grey: It walks on all fours and about a foot and a half from the muzzle to the extremity of the tail. The females menſtruate.

20. Macaque, or cercopithecus cynomologus, the hare-lipped monkey of Pennant, has no beard; the noſtrils are thick and divided; the tail is long and arched, and the buttocks are naked. He has cheek-pouches and calloſities on the buttocks. His tail is from 18 to 20 inches long. His head is large, his muzzle very thick, and his face naked, livid, and wrinkled. His ears are covered with hair. His body is ſhort and ſquat, and his limbs thick and ſhort. The hair on the ſuperior parts of his body is of a greeniſh aſh-colour, and of a yellowiſh grey on the breaſt and belly. He has a ſmall creſt of hair on the top of the head. He walks on four and ſometimes on two feet. The length of his body, comprehending that of the head, is about 18 or 20 inches. Fig. 17.

21. The dog-headed monkey, or cercopithecus cynocephalus, has no beard, and is of a yellow colour; the muzzle is long; the tail long and ſtraight, and the buttocks naked. It is a native of Africa. Fig. 18.

22. The ſpotted monkey, or cercopithecus Diana, with a long white beard: colour of the upper parts of the body reddiſh, as if they had been ſinged, marked with white ſpecks; the belly and chin whitiſh; tail very long; is a ſpecies of a middle ſize. It inhabits Guinea and Congo, according to Marcgrave; the Congeſe call it *exquima*. M. de Buffon denies it to be of that country; but from the circumſtance of the curl in its tail, in Marcgrave's figure, and the deſcription of ſome voyagers, he ſuppoſes it to be a native of South America. Linnæus deſcribes his S. Diana ſomewhat differently: he ſays it is of the ſize of a large cat; black, ſpotted with white; hind part of the back ferruginous; face black; from the top of the noſe is a white line paſſing over each eye to the ears, in an arched form; beard pointed, black above, white beneath, placed on a fattiſh excreſcence; breaſt and throat white; from the rump, croſs the thighs, a white line; tail long, ſtraight, and black; ears and feet of the ſame colour; canine teeth, large.

23. The green monkey, or cercopithecus ſabœus, has a black and flattiſh face: the ſide of it bounded by long white hairs, falling backwards, and almoſt covering the ears, which are black, and like the human: head, limbs, and whole upper part of the body and tail covered with ſoft hair, of a yellowiſh green colour at their ends, cinereous at their roots: under ſide of the body and tail, and inner ſide of the limbs, of a ſilvery colour: tail very long and ſlender. Size of a ſmall cat. Inhabit different parts of Africa: keep in great flocks, and live in the woods: are ſcarce diſcernible when among the leaves, except by their breaking the boughs with their Fig. 19.

Simia

gambols: in which they are very agile and silent: even when shot at, do not make the least noise: but will unite in company, knit their brows, and gnash their teeth, as if they meant to attack the enemy: are very common in the Cape de Verd islands.

24. The mustache, or cercopithecus cephus, has a beard on the cheeks; the crown of the head is yellowish: the feet are black, and the tip of the tail is of an ash colour. Its tail is much longer than the body and head, being 19 or 20 inches in length. The female menstruates.

Fig. 20. 25. The mangabey, cercopithecus æthiops, or white-eyed monkey, has a long, black, naked, and dog-like face: the upper eye-lids of a pure white: ears black, and like the human: no canine teeth: hairs on the sides of the face beneath the cheeks, longer than the rest: tail long: colour of the whole body tawny and black: flat nails on the thumbs and fore-fingers; blunt claws on the others: hands and feet black—Shown in London some years ago: place uncertain: that described by M. de Buffon came from Madagascar; was very good-natured; went on all-fours.

Fig. 21. 26. The egret, or cercopithecus aygula, has a long face, and an upright sharp-pointed tuft of hair on the top of the head. The hair on the forehead is black: the tuft, and the upper part of the body light-grey; the belly white: the eye-brows are large; the beard very small. Size of a small cat. They inhabit Java. They fawn on men, on their own species, and embrace each other. They play with dogs, if they have none of their own species with them. If they see a monkey of another kind, they greet him with a thousand grimaces. When a number of them sleep, they put their heads together. They make a continual noise during night.

27. The rillow, cercopithecus sinicus, or Chinese bonnet, has a long smooth nose, of a whitish colour; hair on the crown of the head long, lying flat, and parted like that of a man; colour, a pale cinereous brown. Inhabit Ceylon. They keep in great troops; and rob gardens of their fruit, and fields of their corn; to prevent which, the natives are obliged to watch the whole day: yet these animals are so bold, that, when driven from one end of the field, they will immediately enter at the other, and carrry off with them as much as their mouth and arms can hold. Bosman, speaking of the thefts of the monkeys of Guinea, says, that they will take in each paw one or two stalks of millet, as many under their arms, and two or three in their mouth; and thus laden, hop away on their hind-leges; but, if pursued, they fling away all, except what is in their mouths, that it may not impede their flight. They are very nice in the choice of the millet; examine every stalk: and if they do not like it, fling it away: so that this delicacy does more harm to the fields than their thievery.

Ker's Translation of Gmelin's Linnæus. 28. The tawny monkey, or cercopithecus fulvus, has long tusks in the lower jaw: the visage is long and flesh coloured, with flesh coloured ears, and a flattish nose. Inhabits India. This is a very ill natured animal, about the size of a cat; it was lately in the possession of Mr Brook, an animal merchant and exhibitor in London: The upper parts of the body are covered with a pale tawny coloured fur, which is ash coloured at the roots; the hinder part of the back is orange coloured, the legs ash coloured, the belly white, and the tail shorter than the body.

29. King monkey, full-bottom monkey, or cercopithecus regalis, has no thumb on the hands; the head, cheeks, throat, and shoulders, are covered with long, flowing, coarse hairs. Inhabits the forests of Sierra Leona in Guinea, where it is called *bey*, or, *king monkey*. It is above three feet high when erect: The head is small, with a short, black, naked face; and the head, cheeks, throat, neck, and shoulders, are covered with long, coarse, flowing hairs, of a dirty yellowish colour, mixed with black, and resembling a full-bottomed wig; the body, arms, and legs, are covered with short hairs of a fine glossy black colour; the hands are naked, and have no thumbs; the feet have five very long slender toes, which are armed with narrow pointed claws; the tail is very long, and is covered with snow-white hairs, having a tuft at the end; the body and limbs are very slender: Its skin is held in high estimation by the negroes for making pouches and gun cases. Fig. 22.

IV. Sapajous, Sapaji, have prehensile tails, and no cheek-pouches. These animals have long tails, which, at the extremity, is generally deprived of hair on the under side, and covered with a smooth skin; this part they can fold, extend, curl up, and unfold at pleasure; by which they are enabled to hang upon branches, or to lay hold of any thing which is beyond the reach of their hands, using the extremity of the tail like a finger or hand; the partition between the nostrils is very thick, and apertures are situated on the sides of the nose; the buttocks are clothed with hair, and have no callosities; the females of this subgenus do not menstruate; and this race of animals is only to be found in America: This subdivision of the genus is made with great propriety by Dr Gmelin, in imitation of the Count de Buffon.

30. The guariba, sapajus Beelzebub, or the preacher monkey, has black shining eyes; short round ears; and a round beard under the chin and throat. The hairs on the body are of a shining black, long, yet lie so close on each other that the animal appears quite smooth: the feet and end of the tail are brown; the tail very long, and always twisted at the end. Size of a fox. Inhabit the woods of Brazil and Guiana in vast numbers, and make a most dreadful howling. Sometimes one mounts on a higher branch, the rest seat themselves beneath: the first begins as if it was to harangue, and sets up so loud and sharp a howl as may be heard a vast way, and a person at a distance would think that a hundred joined in the cry: after a certain space, he gives a signal with his hand, when the whole assembly joins in chorus; but on another signal is silent, and the orator finishes his address (B). Their clamour is the most disagreeable and tremendous that can be conceived; owing to a hollow and hard bone placed in the throat, which Plate CCCCLXI. fig. 23.

(B) A singular account, yet related yet Marcgrave and several other writers. Marcgrave is a writer of the first authority, and a most able naturalist, long resident in the Brasils, speaks from his own knowledge.

Simia. which the English call the *throttle-bone*. These monkeys are very fierce, untameable, and bite dreadfully. There is a variety of a ferruginous or reddish bay colour, which the Indians call the *king of the monkeys*: it is large, and as noisy as the former. The natives eat this species, as well as several other sorts of monkeys, but are particularly fond of this. Europeans will also eat it, especially in those parts of America where food is scarce: when it is scalded in order to get off the hair, it looks very white; and has a resemblance shocking to humanity, that of a child of two or three years old when crying (c).

31. The quato, sapajus paniscus, or four-fingered monkey, has a long flat face, of a swarthy flesh colour: the eyes are sunk in the head; ears like the human; limbs of a great length, and uncommonly slender: the hair is black, long, and rough. There are only four fingers on the hands, being quite destitute of a thumb; five toes on the feet. The tail is long; and naked below, near the end. The body is slender; about a foot and an half long; the tail near two feet, and so prehensile as to serve every purpose of a hand. They inhabit the neighbourhood of Carthagena, Guiana, Brasil, and Peru; associate in vast herds; and are scarce ever seen on the ground. Dampier describes their gambols in a lively manner: "There was (says he) a great company dancing from tree to tree over my head, chattering, and making a terrible noise and a great many grim faces and antic gestures; some broke down dry sticks and flung them at me, others scattered their urine and dung about my ears: at last one bigger than the rest came to a small limb just over my head, and leaping directly at me, made me leap back; but the monkey caught hold of the bough with the tip of its tail, and there continued swinging to and fro, making mouths at me. The females with their young ones are much troubled to leap after the males; for they have commonly two, one she carries under her arm, the other sits on her back, and claps its two fore-paws about her neck: are very sullen when taken; and very hard to be got when shot, for they will cling with their tail or feet to a bough as long as any life remains. When I have shot at one, and broke a leg or arm, I have pitied the poor creature to see it look and handle the broken limb, and turn it from side to side."—They are the most active of monkeys, and quite enliven the forests of America. In order to pass from top to top of lofty trees, whose branches are too distant for a leap, they will form a chain, by hanging down, linked to each other by their tails, and swinging in that manner till the lowest catches hold of a bough of the next tree, and draws up the rest; and sometimes they pass rivers by the same expedient. They are sometimes brought to Europe; but are very tender, and seldom live long in our climate.

Fig. 24. 32. The sai, sapajus, capucinus, or weeper, with a round and flat face, of a reddish brown colour, very deformed: the hair on the head and upper part of the body black, tinged with brown; beneath and on the limbs tinged with red: tail black, and much longer than the head and body: the young excessively deformed; their hair very long, and thinly dispersed.—In the British museum are specimens of old and young. M de Buffon has a variety with a white throat. Inhabits Surinam and Brasil: appear as if it was always weeping; of a melancholy disposition; but very full of imitating what it sees done. These probably are the monkeys Dampier saw in the Bay of All Saints, which he says are very ugly, and smell strongly of musk. They keep in large companies; and make a great chattering, especially in stormy weather, reside much on a species of tree which bears a podded fruit, which they feed on.

33. Sapajus fatuellas, or horned sapajou, has two tufts of hair on the head, resembling little horns: Is beardless. Inhabits South America. The face, sides, belly, and fore-parts of the thighs are brown; the top of the head, middle of the back, tail, legs, and posterior parts of the thighs, are black; the nails are long and rather blunt; the tail is prehensile and twisted spirally. Perhaps of the same species with the simia apella or capuchin (*Gm.*). This, in all probability, is one of the factitious species, purposely deformed, by exhibitors of wild beasts, to impose on the public. Fig. 25.

34. Saimiri, sapajus sciureus, or orange monkey, has no beard; the hinder part of the head is prominent; and the nails on the four toes of the hind paws are narrower and pointed. It inhabits South America, and is the most beautiful of all the sapajous; its movements are graceful; its size small; its colour a brilliant yellow; its visage round, with large vivacious eyes, surrounded by flesh coloured rings; it has hardly any forehead; the nose is elevated at the base, and flattened at the point: the mouth is small, the face flat and naked, and the ears are garnished with hair, and a little pointed; the tail is only half prehensile: It stands with ease on two feet, but commonly walks on all four.

V. Sagoins, Sagoini. These have long tails, which are proportionally longer than those of the sapajous, straight, flaccid, entirely covered hith hair, and not prehensile; that is, incapable of laying hold of any object: the cheeks have no pouches; and the buttocks, which are covered with hair, have no callosities: the partition between the nostrils is very thick, and the apertures are placed on the sides of the nose. The females do not menstruate. This race of animals is only found in America. Ker's Translation of Gmelin's Linnæus.

35. The saki, sagoinus pithecia, or fox-tailed monkey, with a swarthy face, covered with short white down: forehead and sides of the face with whitish, and pretty long hair: body with long dusky brown hairs; white or yellowish at their tips: hair on the tail very long and bushy; sometimes black, sometimes reddish: belly and lower part of the limbs a reddish white: length from nose to tail near a foot and a half: tail longer, and like that of a fox: hands and feet black, with claws instead of nails. Inhabits Guiana.

36. The sanglin, sagoinus iacchus, or striated mon- Fig. 26.

 key,

(c) *Ulloa's Voy.* I. 113. *Des Marchais*, III. 311. says, they are excellent eating, and that a *soupe aux singes* will be found as good as any other, as soon as you have conquered the aversion to *bouilli* of their heads, which look very like those of little children.

key, with a very round head: about the ears two very long full tufts of white hair standing out on each side: irides reddish: face a swarthy flesh colour: ears like the human: head black: body ash coloured, reddish, and dusky; the last forms striated bars cross the body: tail full of hair, annulated with ash colour and black: body seven inches long; tail near eleven: hands and feet covered with short hairs: fingers like those of a squirrel: nails or rather claws, sharp. Inhabits Brasil: feed on vegetables; will also eat fish: makes a weak noise: very restless: often brought over to Europe.

Fig. 27. 37. Pinche, sagoinus œdipus, or red-tailed monkey, is beardless; has a flowing head of hair, which hangs down on each side; a red tail and sharp claws. It has neither cheek-pouches nor callosities on the buttocks. His tail is not prehensile, and is more than twice the length of the head and body. The partition of the nostrils is thick, and the apertures are placed at a side. The face, throat, and ears are black; on the head are long white hairs. The muzzle is broad, and the face round. The hair on the body is pretty long; of a yellowish brown or reddish colour till near the tail, where it becomes orange; on the breast, belly, hands, and feet, it is white, and shorter than on the body. The tail, from the origin to one-half of its length, is a vivid red, then brownish red, and towards the point it is black. He is about nine inches in length, and walks on four feet. The females are not subject to the menstrual evacuation.

Fig. 28. 38. The marikina, sagoinus rosalius, or silky monkey, is beardless; has a very hairy head: the circumference of the face and the feet are red; and the claws are sharp and narrow. It inhabits South America. A brisk animal, less impatient of cold than the rest of this race: the body is of a yellowish white colour; the nails on the thumbs and great toes are rounded; the ears are naked, but are hidden beneath the fur: It has a round head, and a brown face, which is surrounded with a kind of mane of a bright red colour; the hair on the body and tail is long, silky, and of a pale but vivid yellow colour, almost white, with a considerable tuft at the extremity of the tail. It walks on four feet, and is eight or nine inches in length, from the muzzle to the rump; and the tail is above 13 inches long. This species has the same manners and vivacity with the other sagoins, but is more robust in constitution, as an individual lived five or six years in Paris, being kept in a warm room during winter.

39. The mico, sagoinus argenteus, or fair monkey, with a small round head: face and ears of the most lively vermilion colour: body covered with most beautiful long hairs of a bright and silvery whiteness, of matchless elegance; tail of a shining dark chesnut: head and body eight inches long; tail 12. Inhabits the banks of the Amazons; discovered by M. de Condamine.

Fig. 29. 40. The tamarin, sagoinus Midas, or great-eared monkey, with a round head, swarthy, flesh coloured, naked face: upper lip a little divided: ears very large, erect, naked and almost square: hair on the forehead upright and long; on the body soft, but shaggy: the head, whole body, and upper part of the limbs black, except the lower part of the back, which is tinged with yellow: hands and feet covered with orange-coloured hairs, very fine and smooth: nails long and crooked: tail black, and twice the length of the body: teeth very white. It is of the size of a squirrel. It inhabits the hotter parts of South America, and the isle of Gorgona, south of Panama, in the south sea. There are, says Dampier, a great many little black monkeys; at low-water they come to the sea-side to take muscles and periwinkles, which they dig out of the shells with their claws.

Besides these which we have described, there are a great many species which we have omitted. Those who wish to be better acquainted with the simiæ, may consult Buffon, Pennant, and Gmelin's edition of the Zoology of Linnæus by Mr Ker.

SIMILE, or Similitude, in rhetoric, a comparison of two things, which though different in other respects, yet agree in some one. The difference between a simile and comparison is said to consist in this, that the simile properly belongs to whatever we call the quality of a thing, and the comparison to the quantity. See Comparison; and Oratory, n° 118.

SIMILOR, a name given to an alloy of red copper and zinc, made in the best proportions, to imitate silver and gold.

SIMON Maccabeus, a celebrated leader and high-priest of the Jews, who, after rendering the most important services to his country, was at last treacherously slain by his son-in-law. See *the History of the Jews*, n° 15.

Simon Magus, or the Sorcerer, was a native of Gitton, a village of Samaria. According to the usual practice of the Asiatics of that age, he visited Egypt, and there probably became acquainted with the sublime mysteries taught in the Alexandrian school, and learned those theurgic or magical operations by means of which it was believed that men might be dilivered from the power of evil demons. Upon his return into his own country, the author of the Clementine Recognitions relates, that he imposed upon his countrymen by high pretensions to supernatural powers. And St Luke attests, that this artful fanatic, using sorcery, had bewitched the people of Samaria, giving out that he was *some great one*; and that he obtained such general attention and reverence in Samaria, that the people all gave heed to him from the least to the greatest, saying, "This man is the Great power of God."

Enfield's History of Philosophy, vol. ii p. 161.

By the preaching of Philip the Deacon, he was with other Samaritans converted to the Christian faith, and admitted into the infant church by the ordinance of baptism. His conversion, however, seems not to have been real; for, upon seeing the miraculous effects of the laying on of the apostle's hands, he offered them money, saying, "Give me also this power, that on whomsoever I lay hands he may receive the Holy Ghost." He probably thought Peter and John magicians like himself, but better skilled in the art of deceiving the multitude.

Being sharply reproved for this impiety, he seems by his answer to have been made sensible of his sin; but his repentance, if sincere, was of short duration. Returning to his former practices of imposture, he travelled through various provinces of the empire, opposing the progress of the Gospel; and arriving at Rome, he led astray vast numbers of people by his pretended miracles. How long he lived in that metropolis of the world, or in what manner he died, we have no accounts that

that can be fully depended on. The Christian writers tell us, that being raised in the air by two demons, he was deprived of their support by the prayers of St Peter and St Paul, and falling, broke his legs. By some he is thought to have been the person mentioned by Suetonius, who, undertaking to fly in the presence of Nero, fell to the ground with such violence, that his blood spurted up to the gallery where the emperor was sitting.

The sum of this impostor's doctrine, divested of allegory, was, that from the Divine Being, as a fountain of light, flow various orders of æons, or eternal natures, subsisting within the plentitude of the divine essence; that beyond these, in the order of emanation, are different classes of intelligences, among the lowest of which are human souls; that matter is the most remote production of the emanative power, which, on account of its infinite distance from the Fountain of Light, possesses sluggish and malignant qualities, which oppose the divine operations, and are the cause of evil; that it is the great design of philosophy to deliver the soul from its imprisonment in matter, and restore it to that divine light from which it was derived; and that for this purpose God had sent him one of the first æons among men. To his wife Helena he also ascribed a similar kind of divine nature, pretending that a female æon inhabited the body of this woman, to whom he gave the name of Εννοια, *Wisdom;* whence some Christian fathers have said, that he called her the *Holy Spirit*. He also taught the transmigration of souls, and denied the resurrection of the body.

Simon (Richard), was born at Dieppe the 15th May 1638. He began his studies among the priests of the Oratory in that city, but quitted their society in a short time. From Dieppe he went to Paris, where he made great progress in the study of the oriental languages. Some time afterwards he joined the society of the Oratory again, and became a priest of it in 1660. In 1670 he published some pieces of a smaller kind. In 1678 his Critical History of the Old Testament appeared, but was immediately suppressed by the intrigues of Messieurs du Port Royal. It was reprinted the year after, and its excellence soon drew the attention of foreigners; an edition of it was accordingly published at Amsterdam in Latin, and at London in English.

He died at Dieppe in 1712, at the age of 74.

He certainly possessed a vast deal of learning: his criticism is exact, but not always moderate; and there reigns in his writings a spirit of novelty and singularity which raised him a great many adversaries. The most celebrated of these were Le Clerc, Vossius, Jurieu, Du Pin, and Bossuet. Simon wrote an answer to most of the books that were published against him, and displays a pride and obstinacy in his controversial writings which do him little honour.

He was the author of a great many books. The following are the principal: 1. The Ceremonies of the Jews, translated from the Italian of Leo of Modena, with a supplement concerning the sects of the Karraites and Samaritans. 2. *L'Histoire Critique du Vieux Testament*, "The Critical History of the Old Testament." This is a very important work, and deserves the attention of every clergyman. He sometimes, however deviates from the road of integrity, to serve the cause of the church of Rome, particularly in his endeavours to prove the uncertainty of the Hebrew language. These passages have been very justly exposed and confuted by Dr Campbell, in his ingenious Preliminary Dissertations to his new Translation of the Gospels. 3. Critical History of the Text of the New Testament. 4. Critical History of the Versions of the New Testament. 5. Critical History of the principal commentators on the New Testament. 6. Inspiration of the Sacred Books. 7. A Translation of the New Testament. This book was censured by Cardinal Noailles and Bossuet. 8. The History of the rise and progress of Ecclesiastical Revenues, which is commended by Voltaire, as is his Critical History of The Old Testament. It resulted from a quarrel with a community of Benedictines. 9. A new select Library, which points out the good books in various kinds of literature, and the use to be made of them. 10. Critical History of the Belief and Customs of the Nations on the Levant. 11. Critical Letters, &c.

SIMONICAL, is applied to any person guilty of simony. See Simony.

SIMONIDES, the name of several poets celebrated in antiquity; but by the Marbles it appears that the eldest and most illustrious of them was born in the 55th Olympiad, 538 years B. C. and that he died in his 90th year; which nearly agrees with the chronology of Eusebius. He was a native of Ceos, one of the Cyclades, in the neighbourhood of Attica, and the preceptor of Pindar. Both Plato and Cicero give him the character not only of a good poet and musician, but speak of him as a person of great virtue and wisdom. Such longevity gave him an opportunity of knowing a great number of the first characters in antiquity with whom he was in some measure connected. It appears in Fabricius, from ancient authority, that Simonides was cotemporary and in friendship with Pittacus of Mitylene, Hipparchus tyrant of Athens, Pausanias king of Sparta, Hiero tyrant of Syracuse, with Themistocles, and with Alevades king of Thessaly. He is mentioned by Herodotus; and Xenophon, in his Dialogue upon Tyranny, makes him one of the interlocutors with Hiero king of Syracuse. Cicero alleges, what has often been quoted in proof of the modesty and wisdom of Simonides, that when Hiero asked him for a definition of God, the poet required a whole day to meditate on so important a question: at the end of which, upon the prince putting the same question to him a second time, he asked two days respite; and in this manner always doubled the delay each time he was required to answer it; till at length, to avoid offending his patron by more disappointments, he frankly confessed that he found the question so difficult, that the more he meditated upon it, the less was his hope of being able to solve it.

In his old age, perhaps from seeing the respect which money procured to such as had lost the charms of youth and the power of attaching mankind by other means, he became somewhat mercenary and avaricious. He was frequently employed by the victors at the games to write panegyrics and odes in their praise, before his pupil Pindar had exercised his talents in their behalf; but Simonides would never gratify their vanity in this particular, till he had first tied them down to a stipulated sum for his trouble; and upon being upbraided for his meanness, he said, that he had two coffers, in one of which he had for many years put his pecuniary rewards; the other was for honours, verbal thanks, and promises; that the first was pretty well filled, but the last remained always empty. And he made no scruple to confess, in his old age, that of all the enjoyments of life, the love of money, was the only one of which time had not deprived him.

He was frequently reproached for this vice; however, he always defended himself with good humour. Upon being asked by Hiero's queen, Whether it was most desirable to be learned or rich? he answered, that it was far better to be rich; for the learned were always dependent on the rich, and waiting at their doors; whereas, he never saw rich men at the doors of the learned. When he was accused of being so sordid as to sell part of the provisions with which his table was furnished by Hiero, he said he had done it in order "to display to the world the magnificence of that prince and his own frugality." To others he said, that his reason for accumulating wealth was, that "he would rather leave money to his enemies after death, than be troublesome to his friends while living."

He obtained the prize in poetry at the public games when he was fourscore years of age. According to Suidas, he added four letters to the Greek alphabet; and Pliny assigns to him the eighth string of the lyre; but these claims are disputed by the learned.

His poetry was so tender and plaintive, that he acquired the cognomen of *Melicertes* "sweet as honey;" and the tearful eye of his muse was proverbial. Dionysius places him among those polished writers who excel in a smooth volubility, and flow on like plenteous and perennial rivers, in a course of even and uninterrupted harmony.

It is to Dionysius that we are indebted for the preservation of the following fragment of this poet. Danae being by her merciless father inclosed in a chest, and thrown into the sea with her child, when night comes on, and a storm arises which threatens to overset the chest, she, weeping and embracing the young Perseus, cries out:

Sweet child! what anguish does thy mother know,
Ere cruel grief has taught thy tears to flow!
Amidst the roaring wind's tremendous sound,
Which threats destruction as it howls around;
In balmy sleep thou liest, as at the breast,
Without one bitter thought to break thy rest.——
The glim'ring moon in pity hides her light,
And shrinks with horror at the ghastly sight.
Didst thou but know, sweet innocent! our woes,
Not opiate's pow'r thy eyelids now could close.
Sleep on, sweet babe! ye waves in silence roll;
And lull, O lull, to rest my tortur'd soul!

There is a second great poet of the name of Simonides recorded on the Marbles, supposed to have been his grandson, and who gained, in 478 B. C. the prize in the games at Athens.

SIMONY, is the corrupt presentation of any one to an ecclesiastical benefice for money, gift, or reward. It is so called from the resemblance it is said to bear to the sin of Simon Magus, though the purchasing of holy orders seems to approach nearer to his offence. It was by the canon law a very grievous crime: and is so much the more odious, because, as Sir Edward Coke observes, it is ever accompanied with perjury; for the presentee is sworn to have committed no simony. However, it was not an offence punishable in a criminal way at the common law: it being thought sufficient to leave the clerk to ecclesiastical censures. But as these did not affect the simoniacal patron, nor were efficacious enough to repel the notorious practice of the thing, divers acts of parliament have been made to restrain it by means of civil forfeitures; which the modern prevailing usage, with regard to spiritual preferments, calls aloud to be put in execution. The statute 31 Eliz. c. 6. enacts, that if any patron for money or any other corrupt consideration or promise, directly or indirectly given, shall present, admit, institute, induct, install, or collate any person to an ecclesiastical benefice or dignity, both the giver and taker shall forfeit two years value of the benefice or dignity; one moiety to the king, and the other to any one who will sue for the same. If persons also corruptly resign or exchange their benefices, both the giver and taker shall in like manner forfeit double the value of the money or other corrupt consideration. And persons who shall corruptly ordain or license any minister, or procure him to be ordained or licensed (which is the true idea of simony), shall incur a like forfeiture of forty pounds; and the minister himself of ten pounds, besides an incapacity to hold any ecclesiastical preferment for seven years afterwards. Corrupt elections and resignations in colleges, hospitals, and other eleemosynary corporations, are also punished, by the same statute, with forfeiture of the double value, vacating the place or office, and a devolution of the right of election, for that turn, to the crown.

SIMOOM, a hot wind which blows occasionally in the deserts of Africa, and probably in other widely extended countries parched in the same manner by a vertical sun. Its effects on the human body are dreadful. If inhaled in any quantity, it produces instant suffocation, or at least leaves the unhappy sufferer oppressed with asthma and lowness of spirits. The approach of this awful scourge of God is indicated by a redness in the air, well understood by those who are accustomed to journey through the desert; and the only refuge which they have from it, is to fall down with their faces close to the ground, and to continue as long as possible without drawing in their breath.

Mr Bruce, who, in his journey through the desert, suffered from the simoom, gives of it the following graphical description: "At eleven o'clock, while we contemplated with great pleasure the rugged top of Chiggre, to which we were fast approaching, and where we were to solace ourselves with plenty of good water, Idris our guide cried out, with a loud voice, fall upon your faces, for here is the simoom. I saw from the south-east a haze come, in colour like the purple part of the rainbow, but not so compressed or thick. It did not occupy twenty yards in breadth, and was about twelve feet high from the ground. It was a kind of blush upon the air, and it moved very rapidly; for I scarce could turn to fall upon the ground with my head to the northward, when I felt the heat of its current plainly upon my face. We all lay flat on the ground as if dead, till Idris told us it was blown over. The meteor or purple haze which I saw was indeed passed, but the light air that still blew was of heat to threaten

Bruce's Travels, vol. iv. p. 559.

threaten suffocation. For my part, I found distinctly in my breast that I had imbibed a part of it, nor was I free of an asthmatic sensation till I had been some months in Italy, at the baths of Poretta, near two years afterwards." Though the severity of this blast seems to have passed over them almost instantaneously, it continued to blow so as to exhaust them till twenty minutes before five in the afternoon, lasting through all its stages very near six hours, and leaving them in a state of the utmost despondency.

SIMPLE, something not mixed or compounded; in which sense it stands opposed to *compound*.

Simple, in the materia medica, a general name for all herbs or plants, as having each its particular virtue, whereby it becomes a simple remedy.

SIMPLICITY in writing. If we examine the writers whose compositions have stood the test of ages, and obtained that highest honour, "the concurrent approbation of distant times and nations," we shall find that the character of simplicity is the unvarying circumstance which alone hath been able to gain this universal homage from mankind. Among the Greeks, whose writers in general are of the simple kind, the divinest poet, the most commanding orator, the finest historian, and deepest philosopher, are, above the rest, conspicuously eminent in this great quality. The Roman writers rise towards perfection according to that measure of simplicity which they mingle in their works; indeed they are all inferior to the Greek models. But who will deny that Lucretius, Horace, Virgil, Livy, Terence, Tully, are at once the simplest and best of Roman writers? unless we add the noble annalist who appeared in after-times; who, notwithstanding the polical turn of his genius, which sometimes interferes, is admirable in this great quality, and by it far superior to his contemporaries. It is this one circumstance that hath raised the venerable Dante, the father of modern poetry, above the succeeding poets of his country, who could never long maintain the local and temporary honours bestowed upon them; but have fallen under that just neglect which time will ever decree to those who desert a just simplicity for the florid colourings of style, contrasted phrases, affected conceits, the mere trappings of composition and Gothic minutiæ. It is this hath given to Boileau the most lasting wreath in France, and to Shakespeare and Milton in England; especially to the former, whose writings contain specimens of perhaps the purest and simplest English that is anywhere to be found, except in the Bible or Book of Common Prayer. As it appears from these instances, that simplicity is the only universal characteristic of just writing, so the superior eminence of the sacred Scriptures in this quality hath been generally acknowledged. One of the greatest critics in antiquity, himself conspicuous in the sublime and simple manner, hath borne this testimony to the writings of Moses and St Paul; and by parity of reason we must conclude, that had he been conversant with the other sacred writers, his taste and candour would have allowed them the same encomium.

It hath been often observed even by writers of no mean rank, that the "Scriptures suffer in their credit by the disadvantage of a literal version, while other ancient writings enjoy the advantage of a free and embellished translation." But in reality these gentlemen's concern is ill-placed and groundless: for the truth is, "that most other writings are impaired by a literal translation; whereas giving only a due regard to the idiom of different languages, the sacred writings, when literally translated, are then in their full perfection."

Now this is an internal proof, that in all other writings there is a mixture of local, relative, exterior ornament, which is often lost in the transfusion from one language to another. But the internal beauties, which depend not on the particular construction of tongues, no change of tongue can destroy. Hence the Bible preserves its native beauty and strength alike in every language, by the sole energy of unadorned phrase, natural images, weight of sentiment, and great simplicity.

It is in this respect like a rich vein of gold, which, under the severest trials of heat, cold, and moisture, retains its original weight and splendour, without either loss or alloy; while baser metals are corrupted by earth, air, water, fire, and assimilated to the various elements through which they pass.

This circumstance, then, may be justly regarded as sufficient to vindicate the composition of the sacred Scriptures, as it is at once their chief excellence and greatest security. It is their excellence, as it renders them intelligible and useful to all; it is their security, as it prevents their being disguised by the false and capricious ornaments of vain or weak translators. We may safely appeal to experience and fact for the confirmation of these remarks on the superior simplicity, utility, and excellence, of the style of the Holy Scripture. Is there any book in the world so perfectly adapted to all capacities? that contains such sublime and exalted precepts, conveyed in such an artless and intelligible strain, that can be read with such pleasure and advantage by the lettered sage and the unlettered peasant?

SIMPLOCE. See Oratory, n° 72.

SIMPSON (Thomas), professor of mathematics at the royal academy at Woolwich, fellow of the Royal Society, and member of the Royal Academy at Stockholm, was born at Market Bosworth in Leicestershire in 1710. His father, a stuff-weaver, taught him only to read English, and brought him up to his own business; but meeting with a scientifical pedlar, who likewise practised fortune-telling, young Simpson by his assistance and advice left off weaving, and professed astrology. As he improved in knowledge, however, he grew disgusted with his pretended art; and renouncing it, was driven to such difficulties for the subsistence of his family, that he came up to London, where he worked as a weaver, and taught mathematics at his spare hours. As his scholars increased, his abilities became better known, and he published his Treatise on Fluxions, by subscription, in 1737: in 1740, he published his Treatise on the Nature and Laws of Chance; and Essays in Speculative and Mixed Mathematics. After these appeared his Doctrine of Annuities and Reversions; Mathematical Dissertations; Treatise on Algebra; Elements of Geometry; Trigonometry, Plane and Spherical; Select Exercises; and his Doctrine and Application of Fluxions, which he professes to be rather a new work, than a second edition of his former publication on fluxions. In 1743, he obtained the mathematical professorship at Woolwich academy; and soon after was chosen a member of the Royal Society, when the president and council, in consideration of his moderate circumstances, were pleased to excuse his admission-

Simpson, Simson.

fees, and his giving bonds for the settled future payments. At the academy he exerted all his abilities in instructing the pupils who were the immediate objects of his duty, as well as others whom the superior officers of the ordnance permitted to be boarded and lodged in his house. In his manner of teaching he had a peculiar and happy address, a certain dignity and perspicuity, tempered with such a degree of mildness, as engaged the attention, esteem, and friendship, of his scholars. He therefore acquired great applause from his superiors in the discharge of his duty. His application and close confinement, however, injured his health. Exercise and a proper regimen were prescribed to him, but to little purpose: for his spirits sunk gradually, till he became incapable of performing his duty, or even of reading the letters of his friends. The effects of this decay of nature were greatly increased by vexation of mind, owing to the haughty and insulting behaviour of his superior the first professor of mathematics. This person, greatly his inferior in mathematical accomplishments, did what he could to make his situation uneasy, and even to depreciate him in the public opinion: but it was a vain endeavour, and only served to depress himself. At length his physicians advised his native air for his recovery, and he set out in February 1761; but was so fatigued by his journey, that upon his arrival at Bosworth, he betook himself to his chamber, and grew continually worse till the day of his death, which happened on the 14th of May, in the 51st year of his age.

SIMSON (Dr Robert), professor of mathematics in the university of Glasgow, was born in the year 1687 of a respectable family, which had held a small estate in the county of Lanerk for some generations. He was, we think, the second son of the family. A younger brother was professor of medicine in the university of St Andrew's, and is known by some works of reputation, particularly a dissertation on the Nervous System, occasioned by the Dissection of a Brain completely Ossified.

Dr Simson was educated in the university of Glasgow under the eye of some of his relations who were professors. Eager after knowledge, he made great progress in all his studies; and, as his mind did not, at the very first openings of science, strike into that path which afterwards so strongly attracted him, and in which he proceeded so far almost without a companion, he acquired in every walk of science a stock of information, which, though it had never been much augmented afterwards, would have done credit to a professional man in any of his studies. He became, at a very early period, an adept in the philosophy and theology of the schools, was able to supply the place of a sick relation in the class of oriental languages, was noted for historical knowledge, and one of the most knowing botanists of his time.

It was during his theological studies, as preparatory for his entering into orders, that mathematics took hold of his fancy. He used to tell in his convival moments how he amused himself when preparing his exercises for the divinity hall. When tired with vague speculation, in which he did not meet with certainty to reward his labours, he turned up a book of oriental philology, in which he found something which he could discover to be true or to be false, without going out of the line of study which was to be of ultimate use to him. Sometimes even this could not relieve his fatigue. He then had recourse to mathematics, which never failed to satisfy and refresh him. For a long while he restricted himself to a very moderate use of the cordial, fearing that he would soon exhaust the small stock which so limited and abstract a science could yield; till at last he found, that the more he learned, a wider field opened to his view, and scenes that were inexhaustible. Becoming acquainted with subjects far beyond the elements of the science, and with numbers of names celebrated during that period of ardent research all over Europe, he found it to be a manly and important study, by which he was as likely to acquire reputation as by any other. About this time, too, a prospect began to open of making mathematics his profession for life. He then gave himself up to it without reserve.

Simson.

His original incitement to this study as a treat, as something to please and refresh his mind in the midst of severer tasks, gave a particular turn to his mathematical studies, from which he never could afterwards deviate. Perspicuity and elegance are more attainable, and more discernible, in pure geometry, than in any other parts of the science of measure. To this therefore he chiefly devoted himself. For the same reason he preferred the ancient method of studying pure geometry, and even felt a dislike to the Cartesian method of substituting symbols for operations of the mind, and still more was he disgusted with the substitution of symbols for the very objects of discussion, for lines, surfaces, solids, and their affections. He was rather disposed in the solution of an algebraic problem, where quantity alone was considered, to substitute figure and its affections for the algebraic symbols, and to convert the algebraic formula into an analogous geometrical theorem. And he came at last to consider algebraic analysis as little better than a kind of mechanical knack, in which we proceed without ideas of any kind, and obtain a result without meaning, and without being conscious of any process of reasoning, and therefore without any conviction of its truth. And there is no denying, that if genuine unsophisticated taste alone is to be consulted, Dr Simson was in the right: for though it must also be acknowledged, that the reasoning in algebra is as strict as in the purest geometry of Euclid or Apollonius, the *expert* analyst has little perception of it as he goes on, and his final equation is not felt by himself as the result of ratiocination, any more than if he had obtained it by Pascal's arithmetical mill. This does not in the least diminish our admiration of the algebraic analysis; for its almost boundless grasp, its rapid and certain procedure, and the delicate metaphysics and great address which may be displayed in conducting it. Such, however, was the ground of the strong bias of Dr Simson's mind to the analysis of the ancient geometers. It increased as he went forward; and his veneration (we may call it his *love* or *affection)* for the ancient geometry was carried to a degree of idolatry. His chief labours were exerted in efforts to restore the works of the ancient geometers; and he has nowhere bestowed much pains in advancing the modern discoveries in mathematics. The noble inventions, for example, of fluxions and of logarithms, by which our progress in mathematical knowledge, and in the useful application of this knowledge, is so much promoted, attracted the notice of Dr Simson; but he has contented himself with demonmonstrating their truth on the genuine principles of the ancient geometry. Yet was he very thoroughly acquainted with all the modern discoveries; and there are to be seen among his papers discussions and investigations in the Cartesian method, which show him thoroughly acquainted with all the principles, and even expert in the *tours de main*, of the most refined symbolical analysis (A).

About the age of 25 Dr Simson was chosen regius professor of mathematics in the university of Glasgow. He went to London immediately after his appointment, and there formed an acquaintance with the most eminent men of that bright era of British science. Among these he always mentioned Captain Halley (the celebrated Dr Edmund Halley) with particular respect; saying, that he had the most acute penetration, and the most just taste in that science, of any man he had ever known. And, indeed, Dr Halley has strongly exemplified both of these in his divination of the work of *Apollonius de Sectione Spatii*, and the 8th book of his *Conics*, and in some of the most beautiful theorems in Sir Isaac Newton's *Principia*. Dr Simson also admired the wide and masterly steps which Newton was accustomed to take in his investigations, and his manner of substituting geometrical figures for the quantities which are observed in the phenomena of nature. It was from Dr Simson that the writer of this article had the remark which has been oftener than once repeated in the course of this Work, "That the 39th proposition of the first book of the *Principia* was the most important porposition that had ever been exhibited to the physico-mathematical philosopher;" and he used always to illustrate to his more advanced scholars the superiority of the geometrical over the algebraic analysis, by comparing the solution given by Newton of the inverse problem of centripetal forces, in the 42d proposition of that book, with the one given by John Bernoulli in the Memoirs of the Academy of Sciences at Paris for 1713. We have heard him say, that to his own knowledge Newton frequently investigated his propositions in the symbolical way, and that it was owing chiefly to Dr Halley that they did not finally appear in that dress. But if Dr Simson was well informed, we think it a great argument in favour of the symbolic analysis, when this most successful *practical artist* (for so we must call Newton when engaged in a task of discovery) found it conducive either to dispatch or perhaps to his very progress.

Returning to his academical chair, Dr Simson discharged the duties of a professor for more than 50 years with great honour to the university and to himself.

It is almost needless to say, that in his prelections he followed strictly the Euclidian method in elementary geometry. He made use of Theodosius as an introduction to spherical trigonometry. In the higher geometry he prelected from his own Conics; and he gave a small specimen of the *linear problems* of the ancients, by explaining the properties, sometimes of the conchoid, sometimes of the cissoid, with their application to the solution of such problems. In the more advanced class he was accustomed to give Napier's mode of conceiving logarithms, *i. e.* quantities as generated by motion; and Mr Cotes's view of them, as the sums of ratiunculæ; and to demonstrate Newton's lemmas concerning the limits of ratios; and then to give the elements of the fluxionary calculus; and to finish his course with a select set of propositions in optics, gnomonics, and central forces. His method of teaching was simple and perspicuous, his elocution clear, and his manner easy and impressive. He had the respect, and still more the affection, of his scholars.

With respect to his studies, we have already informed the reader that they got an early bias to pure geometry, and to the elegant but scrupulous methods of the ancients.

We have heard Dr Simson say, that it was in a great measure owing to Dr Halley that he so early directed his efforts to the restoration of the ancient geometers. He had recommended this to him, as the most certain way for him, then a very young man, both to acquire reputation, and to improve his own knowledge and taste, and he presented him with a copy of Pappus's Mathematical Collections, enriched with some of his own notes. The perspicuity of the ancient geometrical analysis, and a certain elegance in the nature of the solutions which it affords, especially by means of the local theorems, soon took firm hold of his fancy, and made him, with the sanguine expectation of a young man, direct his very first efforts to the recovery of this *in toto*; and the restoration of Euclid's Porisms was the first task which he set himself. The accomplished geometer knows what a desperate task this was, from the scanty and mutilated account which we have of this work in a single passage of Pappus. It was an ambition which nothing but success could justify in so young an adventurer. He succeeded; and so early as 1718 seemed to have been in complete possession of this method of investigation, which was considered by the eminent geometers of antiquity as their surest guide through the labyrinths of the higher geometry. Dr Simson gave a specimen of his discovery in 1723 in the Philosophical Transactions. And after this time he ceased not from his endeavours to recover that choice collection of Porisms which Euclid had collected, as of the most general use in the solution of difficult questions. What some of these must have been was pointed out to Dr Simson by the very nature of the general proposition of Pappus, which he has restored. Others were pointed out by the lemmas which Pappus has given as helps to the young mathematician towards their demonstration. And, being thus in possession of a considerable number, their mutual relations pointed out a sort of system, of which these made a part, and of which the blanks now remained to be filled up.

Dr Simson, having thus gained his favourite point, had

(A) In 1752 the writer of this article being then his scholar, requested him to examine an account which he gave him of what he thought a new curve (a conchoid having a circle for its base). Dr Simson returned it next day with a regular list of its leading proporties, and the investigation of such as he thought his scholar would not so easily trace. In this hasty scrawl the lines related to the circle were familiarly considered as arithmetical fractions of the radius considered as unity. This was before Euler published his Arithmetic of the Sines and Tangents, now in universal use.

Simson.

had leisure to turn his attention to the other works of the ancient geometers, and the porisms of Euclid now had only an occasional share. The *loci plani* of Apollonius was another task which he very early engaged in, and completed about the year 1738. But, after it was printed, he imagined that he had not given the *ipsissimæ propositiones* of Apollonius, and in the precise spirit and order of that author. The impression lay by him for some years; and it was with great reluctance that he yielded to the intreaties of his mathematical friends, and published the work, in 1746, with some emendations, where he thought he had deviated farthest from his author. He quickly repented of this scanty concession, and recalled what he could of the small number of copies which he had given to the booksellers, and the impression again lay by him for years. He afterwards re-corrected the work, and still with some reluctance allowed it to come abroad as the Restitution of Apollonius. The public, however, had not been so fastidious as Dr Simpson, and the work had acquired great celebrity, and he was now considered as one of the first and the most elegant geometers of the age: for, in the mean time, he had published his Conic Sections, a work of uncommon merit, whether we consider it as equivalent to a complete restitution of the celebrated work of Apollonius Pergæus, or as an excellent system of this important part of mathematics. It is marked with the same features as the *loci plani*, the most anxious solicitude to exhibit the very text of Apollonius, even in the propositions belonging to the books which had been completely lost. These could be recovered in no other way but by a thorough knowledge of the precise plan proposed by the author, and by taking it for granted that the author had accurately accomplished this plan. In this manner did Viviani proceed in the first attempt which was made to restore the conics of Apollonius; and he has given us a detail of the process of his conjectures, by which we may form an opinion of its justness, and of the probability how far he has attained the desired object. Dr Simson's view in his performance was something different, deviating a little in this one case from his general track. He was not altogether pleased with the work of Viviani, even as augmented by the eighth book added by Halley, and his wish was to restore the ancient original. But, in the mean time, an academical text book for conic sections was much wanted. He was much dissatisfied with those in common use; and he was not insensible of the advantage resulting from the consideration of these sections, independent of the cone first introduced by Dr Wallis. He therefore composed this excellent treatise as an elementary book, not to supersede, but to prepare for the study of Apollonius; and accordingly accommodates it to this purpose, and gives several important propositions in their proper places, *expressly as restitutions of Apollonius*, whom he keeps constantly in view through the whole work.

Much about this time Dr Simson seriously began to prepare a perfect edition of Euclid's Elements. The intimate acquaintance which he had by this time acquired with all the original works of the ancient geometers, and their ancient commentators and critics, encouraged him to hope that he could restore to his original lustre this leader in mathematical science; and the errors which had crept into this celebrated work, and which still remained in it, appeared of magnitude sufficient to merit the most careful efforts for their removal. The DATA also, which were in like manner the introduction to the whole art of geometrical investigation, seemed to call more loudly for his amending hand. For it appears that the Saracens, who have preserved to us the writings of the ancients, have contented themselves with admiring these celebrated works, and have availed themselves of the knowledge which they contain; but they have shown no inclination to add to the stock, or to promote the sciences which they had received. They could not do any thing without the synthetical books of the geometers; but, not meaning to go beyond the discoveries which they had made, they neglected all the books which related to the analytic art alone, and the greatest part of them (about 25 out of 30) have irrecoverably perished. The data of Euclid have fortunately been preserved, but the book was neglected, and the only ancient copies, which are but three or four, are miserably erroneous and mutilated. Fortunately, it is no very arduous matter to reinstate this work in its original perfection. The plan is precise, both in its extent and its method. It had been restored, therefore, with success by more than one author. But Dr Simson's comprehensive view of the whole analytical system pointed out to him many occasions for amendment. He therefore made its institution a joint task with that of the elements. All the lovers of true geometry will acknowledge their obligations to him for the edition of the Elements and data which he published about 1758. The text is corrected with the most judicious and scrupulous care, and the notes are inestimable, both for their information, and for the tendency which they must have to form the mind of the student to a true judgment and taste in mathematical subjects. The more accomplished reader will perhaps be sometimes disposed to smile at the axiom which seems to pervade the notes, "that a work of Euclid must be supposed without error or defect." If this was not the case, Euclid has been obliged to his editor in more instances than one. Nor should his greatest admirers think it impossible that in the progress of human improvement, a geometrical truth should occur to one of these latter days, which escaped the notice of even the Lincean Euclid. Such merit, however, Dr Simson nowhere claims, but lays every blame of error, omission, or obscurity, to the charge of Proclus, Theon, and other editors and commentators of the renowned Grecian.

There is another work of Apollonius on which Dr Simson has bestowed great pains, and has restored, as we imagine, *omnibus numeris perfectum*, viz. the SECTIO DETERMINATA; one of those performances which are of indispensable use in the application of the ancient analysis. This also seems to have been an early task, though we do not know the date of his labours on it. It did not appear till after his death, being then published along with the great work, the Porisms of Euclid, at the expence of the late Earl Stanhope, a nobleman intimately conversant with the ancient geometry, and zealous for its reception among the mathematicians of the present age. He had kept up a constant correspondence with Dr Simson on mathematical subjects; and at his death in 1768, engaged Mr Clow professor of logic in the university of Glasgow, to whose care the Doctor had left all his valuable papers, to make a

Simson.

selection of such as would serve to support and increase his well earned reputation as THE RESTORER OF ANCIENT GEOMETRY.

We have been thus particular in our account of Dr Simson's labours in these works, because his manner of execution, while it does honour to his inventive powers, and shows his just taste in mathematical composition, also confirms our former assertion, that he carried his respect for the ancient geometers to a degree of superstitious idolatry, and that his fancy, unchecked, viewed them as incapable of error or imperfection. This is distinctly to be seen in the emendations which he has given of the texts, particularly in his editions of Euclid. Not only every imperfection of the reading is ascribed to the ignorance of copyists, and every indistinctness in the conception, inconclusiveness in the reasoning, and defect in the method, is ascribed to the ignorance or mistake of the commentators; but it is all along assumed that the work was perfect in its kind; and that by exhibiting a perfect work, we restore the genuine original. This is surely gratuitous; and it is very possible that it has, in some instances, made Dr Simson fail of his anxious purpose, and give us even a better than the original. It has undoubtedly made him fail in what *should have been* his great purpose, viz. to give the world a connected system of the ancient geometrical analysis; such as would, in the first place, exhibit it in its most engaging form, elegant, perspicuous, and comprehensive; and, in the next place, such as should engage the mathematicians of the present age to adopt it as the most certain and successful conductor in those laborious and difficult researches in which the demands of modern science continually engage them. And this might have been expected, in the province of speculative geometry at least, from a person of such extensive knowledge of the properties of figure, and who had so eminently succeeded in the many trials which he had made of its powers. We might have expected that he would at least have exhibited in one systematic point of view, what the ancients had done in several detached branches of the science, and how far they had proceeded in the solution of the several successive classes of problems; and we might have hoped, that he would have instructed us in what manner we should apply that method to the solution of problems of a more elevated kind, daily presented to us in the questions of physico-mathematical science. By this he would have acquired distinguished honour, and science would have received the most valuable improvement. But Dr Simson has done little of all this; and we cannot say that great helps have been derived from his labours by the eminent mathematicians of this age, who are successfully occupied in advancing our knowledge of nature, or in improving the arts of life. He has indeed contributed greatly to the entertainment of the speculative mathematician, who is more delighted with the conscious exercise of his own reasoning powers, than with the final result of his researches. Yet we are not even certain that Dr Simson has done this to the extent he wished and hoped. He has not engaged the liking of mathematicians to this analysis, by presenting it in the most agreeable form. His own extreme anxiety to tread in the very footsteps of the original authors, has, in a thousand instances, precluded him from using his own extensive knowledge, that he might not employ principles which were not of a class inferior to that of the question in hand. Thus, of necessity, did the method appear trammelled. We are deterred from employing a process which appears to restrain us in the application of the knowledge which we have already acquired; and, disgusted with the tedious, and perhaps indirect path, by which we must arrive at an object which we see clearly over the hedge, and which we could reach by a few steps, of the security of which we are otherwise perfectly assured. These prepossessions are indeed founded on mistake; but the mistake is such, that all fall into it, till experience has enlarged their views. This circumstance alone has hitherto prevented mathematicians from acquiring that knowledge of the ancient analysis which would enable them to proceed in their researches with certainty, dispatch, and delight. It is therefore deeply to be regretted, that this eminent genius has occupied, in this superstitious palæology, a long and busy life, which might have been employed in original works of infinite advantage to the world, and honour to himself.

Our readers will, it is hoped, consider these observations as of general scientific importance, and as intimately connected with the history of mathematics; and therefore as not improperly introduced in the biographical account of one of the most eminent writers on this science. Dr Simson claimed our notice as a mathematician; and his affectionate admiration of the ancient analysis is the prominent feature of his literary character. By this he is known all over Europe; and his name is never mentioned by any foreign author without some very honourable allusion to his distinguished geometrical elegance and skill. Dr James Moor, professor of Greek in the university of Glasgow, no less eminent for his knowledge in ancient geometry than for his professional talents, put the following apposite inscription below a portrait of Dr Simson:

GEOMETRIAM, SUB TYRANNO BARBARO SÆVA
SERVITUTE DIU SQUALENTEM, IN LIBERTATEM
ET DECUS ANTIQUUM VINDICAVIT
UNUS.

Yet it must not be understood that Dr Simson's predilection for the geometrical analysis of the ancients did so far mislead him as to make him neglect the symbolical analysis of the present times; on the contrary, he was completely master of it, as has been already observed, and frequently employed it. In his academical lectures to the students of his upper classes, he used to point out its proper province (which he by no means limited by a scanty boundary), and in what cases it might be applied with safety and advantage even to questions of pure geometry. He once honoured the writer of this article with the sight of a very short dissertation on this subject (perhaps the one referred to in the preface to his Conic Sections). In this piece he was perhaps more liberal than the most zealous partisans of the symbolical analysis could desire, admitting as a sufficient equation of the Conic Sections $L=\frac{p^2c}{x^2}$, where L is the *latus rectum* x is the distance of any point of the curve from the focus, p is the perpendicular drawn from the focus to the tangent in the given point, and c is the chord of the equicurve circle drawn through the focus. Unfortunately this dissertation was not found among his pa-

 pers.

pers. He spoke in high terms of the Analytical Works of Mr Cotes, and of the two Bernoullis. He was consulted by Mr M'Laurin during the progress of his inestimable Treatise of Fluxions, and contributed not a little to the reputation of that work. The spirit of that most ingenious algebraic demonstration of the fluxions of a rectangle, and the very process of the argument, is the same with Dr Simson's in his dissertation on the limits of quantities. It was therefore from a thorough acquaintance with the subject, and by a just taste, that he was induced to prefer his favourite analysis, or, to speak more properly, to exhort mathematicians to employ it in its own sphere, and not to become ignorant of geometry, while they successfully employed the symbolical analysis in cases which did not require it, and which suffered by its admission. It must be acknowledged, however, that in his later years, the disgust which he felt at the artificial and slovenly employment on subjects of pure geometry, sometimes hindered him from even looking at the most refined and ingenious improvements of the algebraic analysis which occur in the writings of Euler, D'Alembert, and other eminent masters. But, when properly informed of them, he never failed to give them their due praise; and we remember him speaking, in terms of great satisfaction, of an improvement of the infinitesimal calculus, by D'Alembert and De la Grange, in their researches concerning the propagation of sound, and the vibrations of musical cords.

And that Dr Simpson not only was master of this calculus and the symbolical calculus in general, but held them in proper esteem, appears from two valuable dissertations to be found in his posthumous works; the one on logarithms, and the other on the limits of ratios. The last, in particular, shows how completely he was satisfied with respect to the solid foundation of the method of fluxions; and it contains an elegant and strict demonstration of all the applications which have been made of the method by its illustrious author to the objects of pure geometry.

We hoped to have given a much more complete and instructive account of this eminent geometer and his works, by the aid of a person fully acquainted with both, and able to appreciate their value; but an accident has deprived us of this assistance, when it was too late to procure an equivalent: and we must request our readers to accept of this very imperfect account, since we cannot do justice to Dr Simson's merit, unless almost equally conversant in all the geometry of the ancient Greeks.

The life of a literary man rarely teems with anecdote; and a mathematician, devoted to his studies, is perhaps more abstracted than any other person from the ordinary occurrences of life, and even the ordinary topics of conversation. Dr Simson was of this class; and having never married, lived entirely a college life. Having no occasion for the commodious house to which his place in the university entitled him, he contented himself with chambers, good indeed, and spacious enough for his sober accommodation, and for receiving his choice collection of mathematical writers, but without any decoration or commodious furniture. His official servant sufficed for valet, footman, and chambermaid. As this retirement was entirely devoted to study, he entertained no company in his chambers, but in a neighbouring house, where his apartment was sacred to him and his guests.

Having in early life devoted himself to the restoration of the works of the ancient geometers, he studied them with unremitting attention; and, retiring from the promiscuous intercourse of the world, he contented himself with a small society of intimate friends, with whom he could lay aside every restraint of ceremony or reserve, and indulge in all the innocent frivolities of life. Every Friday evening was spent in a party at whist, in which he excelled, and took delight in instructing others, till increasing years made him less patient with the dulness of a scholar. The card-party was followed by an hour or two dedicated solely to playful conversation. In like manner, every Saturday he had a less select party to dinner at a house about a mile from town. The Doctor's long life gave him occasion to see the *dramatis personæ* of this little theatre several times completely changed, while he continued to give it a personal identity: so that, without any design or wish of his own, it became, as it were, his own house and his own family, and went by his name. In this state did the present writer first see it, with Dr Simson as its father and head, respected and beloved by every branch; for, as it was for relaxation, and not for the enjoyment of his acknowledged superiority, that he continued this habit of his early youth; and as his notions "of a fine talk" did not consist in the pleasure of having "tossed and gored a good many to day," his companions were as much at their ease as he wished to be himself; and it was no small part of their entertainment (and of his too), to smile at those innocent deviations from common forms, and those mistakes with respect to life and manners, which an almost total retirement from the world, and incessant occupation in an abstract science, caused this venerable president frequently to exhibit. These are remembered with a more affecting regret, that they are now "with the days that are past," than the most pithy apophthegms, ushered in with an emphatical, "Why, Sir!" or "No, Sir!" which precludes all reply. Dr Simson never exerted his presidial authority, unless it were to check some infringement of good breeding, or any thing that appeared unfriendly to religion or purity of manners; for these he had the highest reverence. We have twice heard him sing (he had a fine voice and most accurate ear) some lines of a Latin hymn to the divine geometer, and each time the rapturous tear stood in his eye.

But we ask the reader's pardon for this digression; it is not however useless, since it paints the man as much as any recital of his studies; and to his acquaintances we are certain that it will be an acceptable memorandum. To them it was often matter of regret, that a person of such eminent talents, which would have made him shine equally in any line of life, should have allowed himself to be so completely devoted to a study which abstracted him from the ordinary pursuits of men, unfitted him for the active enjoyment of life, and kept him out of those walks which they frequented, and where they would have rejoiced to meet him.

Dr Simson was of an advantageous stature, with a fine countenance; and even in his old age had a graceful carriage and manner, and always, except when in mourning, dressed in white cloth. He was of a cheerful disposition; and though he did not make the first advances

Sin, Sinai. advances to acquaintance, had the most affable manner, and strangers were at perfect ease in his company. He enjoyed a long course of uninterrupted health; but towards the close of life suffered from an acute disease, and was obliged to employ an assistant in his professional labours for a few years preceding his death, which happened in 1768, at the age of 81. He left to the university his valuable library, which is now arranged apart from the rest of the books, and the public use of it is limited by particular rules. It is considered as the most choice collection of mathematical books and manuscripts in the kingdom, and many of them are rendered doubly valuable by Dr Simson's notes.

SIN, a breach or transgression of some divine law or command.

SINAI, or SINA, a famous mountain of Arabia Petræa, upon which God gave the law to Moses. It stands in a kind of peninsula, formed by the two arms of the Red Sea, one of which stretches out towards the north, and is called the *Gulph of Kolsum*; the other extends towards the east, and is called the *Gulph of Elan*, or the *Elanitish Sea*. At this day the Arabians call Mount Sinai by the name of *Tor*, that is, the "mountain," by way of excellence; or *Gibel* or *Jibel Mousa*, "the mountain of Moses." It is 260 miles from Cairo, and generally it requires a journey of ten days to travel thither. The wilderness of Sinai, where the Israelites continued incamped for almost a year and, where Moses erected the tabernacle of the covenant, is considerably elevated above the rest of the country; and the ascent to it is by a very craggy way, the greatest part of which is cut out of the rock; then one comes to a large space of ground, which is a plain surrounded on all sides by rocks and eminences, whose length is nearly 12 miles. Towards the extremity of this plain, on the north side, two high mountains show themselves, the highest of which is called *Sinai* and the other *Horeb*. The tops of Horeb and Sinai have a very steep ascent, and do not stand upon much ground, in comparison to their extraordinary height: that of Sinai is at least one-third part higher than the other, and its ascent is more upright and difficult.

Niebuhr's Travels, vol. i. p. 192. Two German miles and a half up the mountain stands the covent of St Catharine. The body of this monastery is a building 120 feet in length and almost as many in breadth. Before it stands another small building, in which is the only gate of the convent, which remains always shut, except when the bishop is here. At other times, whatever is introduced within the convent, whether men or provisions, is drawn up by the roof in a basket, and with a cord and a pulley. The whole building is of hewn stone; which, in such a desert, must have cost prodigious expence and pains. Near this chapel issues a fountain of very good fresh water; it is looked upon as miraculous by some who cannot conceive how water can flow from the brow of so high and barren a mountain. Five or six paces from it they show a stone, the height of which is four or five feet, and breadth about three which, they say, is the very stone whence Moses caused the water to gush out. Its colour is of a spotted grey, and it is as it were set in a kind of earth, where no other rock appears. This stone has 12 holes or channels, which are about a foot wide, whence it is thought the water came forth for the Israelites to drink.

Much has been said of the writings to be seen at Sinai and in the plain about it; and such were the hopes of discoveries respecting the wanderings of the Israelites from these writings, that Dr Clayton bishop of Clogher offered L. 500 Sterling to defray the expences of journey to any man of letters who would undertake to copy them. No man, we believe, undertook this task: and the accurate Danish traveller Niebuhr found no writings there but the names of persons who had visited the place from curiosity, and of Egyptains who had chosen to be buried in that region. Sinapis.

SINAPIS, MUSTARD, in botany: A genus of plants belonging to the class of *tetradynamia*, and to the order of *siliquosa*; and in the natural system ranged under the 39th order, *Siliquosa*. The calyx consists of four expanding strap-shaped deciduous leaves: the ungues or bases of the petals are straight; two glandules between the shorter stamina and pistillum, also between the longer and the calyx. There are 17 species; the arvensis, orientalis, brassicata, alba, nigra, pyrenaica, pubescens, chinensis, juncea, erucoides, allioni, hispanica, millefolia, incana, lævigata, cernua, and japonica. Three of these are natives of Britain; the alba, nigra, and arvensis.

1. The alba, or white mustard, which is generally cultivated as a salad herb for winter and spring use. This rises with a branched hairy stalk two feet high; the leaves are deeply jagged on their edges and rough. The flowers are disposed in loose spikes at the end of the branches, standing upon horizontal footstalks; they have four yellow petals in form of a cross, which are succeeded by hairy pods, that end with long, compressed, oblique beaks; the pods generally contain four white seeds.

2. The nigra, or common mustard, which is frequently found growing naturally in many parts of Britain, but is also cultivated in fields for the seed, of which the sauce called *mustard* is made. This rises with a branching stalk four or five feet high; the lower leaves are large, rough, and very like those of turnip; the upper leaves are smaller and less jagged. The flowers are small, yellow, and grow in spiked clusters at the end of the branches; they have four petals placed in form of a cross, and are succeeded by smooth four-cornered pods.

3. The arvensis, grows naturally on arable land in many parts of Britain. The seed of this is commonly sold under the title of *Durham mustard-seed*. Of this there are two varieties, if not distinct species; the one with cut, the other with entire leaves. The stalks rise two feet high; the leaves are rough; in the one they are jagged like turnip-leaves; in the other they are long and entire. The flowers are yellow; the pods are turgid, angular, and have long beaks.

Mustard, by its acrimony and pungency, stimulates the solids, and attenuates viscid juices; and hense stands deservedly recommended for exciting appetite, assisting digestion, promoting the fluid secretions, and for the other purposes of the acrid plants called *antiscorbutic*. It imparts its taste and smell in perfection to aqueous liquors, and by distillation with water yields an essential oil of great acrimony. To rectified spirit its seeds give out very little either of their smell or taste. Subjected to the press, they yield a considerable quantity of mild insipid oil, which is as free from acrimony as that of almonds. They are applied as an external stimulant to benumbed or paralytic limbs; to parts affected with fixed rheumatic pains; and to the soles of the feet, in the low stage of acute diseases, for raising the pulse: in this intention, a mixture of equal parts of the powdered seeds and crumb of bread, with the addition sometimes of a little bruised garlic, are made into a cataplasm with a sufficient quantity of vinegar.

SINAPISM, in pharmacy, an external medicine, in form of a cataplasm, composed chiefly of mustard-seed pulverized, and other ingredients mentioned in the preceding article.

SINCERITY, honesty of intention, freedom from hypocrisy. See MORAL PHILOSOPHY, n° 157.

SINCIPUT, in anatomy, the forepart of the head, reaching from the forehead to the coronal suture.

SINDY, a province of Hindostan Proper, bounded on the west by Macran, a province of Persia; on the north by the territories of the king of Candahar; on the north-east by those of the Seiks; on the east by a sandy desert; and on the south-east by Cutch. It extends along the course of the river Sinde or Indus from its mouth to Behker or Bhakor, on the frontiers of Moultan. Reckoned that way, it is 300 miles long; and its breadth, in its widest part, is about 160. In many particulars of soil and climate, and in the general appearance of the surface, Sindy resembles Egypt; the lower part of it being composed of rich vegetable mould, and extended into a wide dell; while the upper part of it is a narrow slip of country, confined on one side by a ridge of mountains, and on the other by a sandy desert, the river Indus, equal at least to the Nile, winding through the midst of this level valley, and annually overflowing it. During great part of the south-west monsoon, or at least in the months of July, August, and part of September, which is the rainy season in most other parts of India, the atmosphere is here generally clouded; but no rain falls except very near the sea. Indeed, very few showers fall during the whole year; owing to which, and the neighbourhood of the sandy deserts, which bound it on the east and on the north-west, the heats are so violent, and the winds from those quarters so pernicious, that the houses are contrived so as to be occasionally ventilated by means of apertures on the tops of them, resembling the funnels of small chimneys. When the hot winds prevail, the windows are closely shut; and the lowest part of the current of air, which is always the hottest, being thus excluded, a cooler, because more elevated, part descends into the house through the funnels. By this contrivance also vast clouds of dust are excluded; the entrance of which would alone be sufficient to render the houses uninhabitable. The roofs are composed of thick layers of earth instead of terraces. Few countries are more unwholesome to European constitutions, particularly the lower part of the Delta. The prince of this province is a Mahometan, tributary to the king of Candahar. He resides at Hydrabad, although Tatta is the capital. The Hindoos, who were the original inhabitants of Sindy, are by their Mahometan governors treated with great rigour, and denied the public exercise of their religion; and this severity drives vast numbers of them into other countries. The inland parts of Sindy produce saltpetre, sal-ammoniac, borax, bezoar, lapis lazuli, and raw silk. They have also manufactories of cotton and silk or various kinds; and they make fine cabinets, inlaid with ivory, and finely lackered. They also export great quantities of butter, clarified and wrapt up in duppas, made of the hides of cattle. The ladies wear hoops of ivory on both their arms and legs, which when they die are burnt with them. They have large black cattle, excellent mutton, and small hardy horses. Their wild game are deer, hairs, antelopes, and foxes, which they hunt with dogs, leopards, and a small fierce creature called a shiahgush.

SINE or *Right Sine of an Arch*, in trigonometry, is a right line drawn from one end of that arch, perpendicular to the radius drawn to the other end of the arch; being always equal to half the cord of twice the arch. See TRIGONOMETRY and GEOMETRY.

SINECURE, a nominal office, which has a revenue without any employment.

SINEW, a tendon, that which unites the muscles to the bones.

SINGING, the action of making divers inflections of the voice, agreeable to the ear, and correspondent to the notes of a song or piece of melody. See MELODY.

The first thing to be done in learning to sing, is to raise a scale of notes by tones and semitones to an octave, and descend by the same notes; and then to rise and fall by greater intervals, as a third, fourth, fifth, &c. and to do all this by notes of different pitch. Then these notes are represented by lines and spaces, to which the syllables *fa, sol, la, mi*, are applied, and the pupil taught to name each line and space thereby; whence this practice is called *sol-faing*, the nature, reason, effects, &c. whereof, see under the article SOLFAING.

SINGING of Birds. It is worthy of observation, that the female of no species of birds ever sings: with birds it is the reverse of what occurs in human kind. Among the feathered tribe, all the cares of life fall to the lot of the tender sex; theirs is the fatigue of incubation; and the principal share in nursing the helpless brood: to alleviate these fatigues, and to support her under them, nature hath given to the male the song, with all the little blandishments and soothing arts; these he fondly exerts (even after courtship) on some spray contiguous to the nest, during the time his mate is performing her parental duties. But that she should be silent is also another wise provision of nature, for her song would discover her nest; as would a gaudiness of plumage, which, for the same reason, seems to have been denied her.

On the song of birds several curious experiments and observations have been made by the Hon. Daines Barrington. See *Phil. Trans.* vol. lxiii.

SINGULAR NUMBER, in grammar, that number of nouns and verbs which stands opposed to plural. See GRAMMAR, n° 14.

SINISTER, something on or towards the left hand. Hence some derive the word *sinister, à sinendo*; because the gods, by such auguries, permit us to proceed in our designs.

SINISTER, is ordinarily used among us for unlucky; though, in the sacred rites of divination, the Romans used it in an opposite sense. Thus *avis sinistra*, or a bird on the left hand, was esteemed a happy omen: whence, in the law of the 12 tables, *Ave sinistra populi magister esto*.

Sinister, in heraldry. The sinister side of an escutcheon is the left-hand side: the sinister chief, the left angle of the chief; the sinister base, the left-hand part of the base.

Sinister Aspect, among astrologers, is an appearance of two planets happening according to the succession of the signs; as Saturn in Aries, and Mars in the same degree of Gemini.

SINISTRI, a sect of ancient heretics, thus called because they held the left hand in abhorrence, and made it a point of religion not to receive any thing therewith.

SINKING fund, a provision made by parliament, consisting of the surplusage of other funds, intended to be appropriated to the payment of the national debt; on the credit of which very large sums have been borrowed for public uses. See *National Debt* and Revenue.

SINOPICA terra, in natural history, the name of a red earth of the ochre kind, called also *rubrica sinopica*, and by some authors *sinopis*. It is a very close, compact, and weighty earth, of a fine glowing purple colour. It is of a pure texture, but not very hard, and of an even but dusty surface. It adheres firmly to the tongue, is perfectly fine and smooth to the touch, does not crumble easily between the fingers, and stains the hands. It melts very slowly in the mouth, is perfectly pure and fine, of an austere astringent taste, and ferments violently with aquafortis. It was dug in Cappadocia, and carried for sale to a city in the neighbourhood called *Sinope*, whence it had its name. It is now found in plenty in New Jersey, (in North America), and is called by the people there *bloodstone*. Its fine texture and body, with its high florid colour, must make it very valuable to painters; and from its astringency it will probably be a powerful medicine.

SINOPLE, in heraldry, denotes vert, or green colour in armories.—Sinople is used to signify love, youth, beauty, rejoicing, and liberty; whence it is that letters of grace, ambition, legitimation, &c. are always sealed with green wax.

SINUOSITY, a series of bends and turns in arches or other irregular figures, sometimes jutting out and sometimes falling in.

SINUS, in anatomy, denotes a cavity in certain bones and other parts, the entrance whereof is very narrow, and the bottom wider and more spacious.

Sinus, in surgery, a little cavity or sacculus, frequently formed by a wound or ulcer, wherein pus is collected.

SIPHON. See Hydrostatics, n° 25.

SIPHONANTHUS, in botany; a genus of plants belonging to the class of *tetrandia* and order of *monogynia*. The corolla is monopetalous, funnel-shaped; the tube is very narrow, and much longer than the calyx. There are four berries, each containing one seed. There is only one species, the *indica*.

SIPONTUM, Sepuntum, or *Sipus* (anc. geog.), a town of Apulia, so denominated (according to Strabo) from the great quantity of *sepiæ* or cuttlefish that are thrown upon the coast. Diomed is supposed by the same author to have been the founder of this place; which appears from Livy to have become a colony of Roman citizens. In the early ages of Christian hierarchy, a bishop was fixed in this church; but, under the Lombards, his see was united to that of Beneventum. Being again separated, Sipontum became an archiepiscopal diocese in 1094, about which time it was so ill treated by the Barbarians, that it never recovered its splendour, but sunk into such misery, that in 1260 it was a mere desert, from the want of inhabitants, the decay of commerce, and the insalubrity of the air. Manfred having taken these circumstances into consideration, began in 1261 to build a new city on the sea-shore, to which he removed the few remaining Sipontines. (See the article Manfredonia). Sipontum was situated at the distance of a mile from the shore. Excepting a part of its Gothic cathedral, scarce one stone of the ancient city now remains upon another.

SIPUNCULUS, in natural history, a genus of the *intestina* class of worms in the Linnæan system. Its characters are these: the body is round and elongated; the mouth attenuated and cylindrical; and the lateral aperture of the body rugged. There are two species; one found under stones in the European, and the other in the Indian ocean.

SIR, the title of a knight or baronet, which, for distinction's sake, as it is now given indiscriminately to all men, is always prefixed to the knight's Christian name, either in speaking or writing to them.

SIRCAR, any office under the government in Hindostan. It is sometimes used for the state or government itself. Likewise a province, or any number of Pergunnahs placed under one head in the government books, for conveniency in keeping accounts. In common usage in Bengal, the under banyans of European gentlemen are called *sircars*.

SIRE, a title of honour formerly given to the king of France as a mark of sovereignty.

Sire, was likewise anciently used in the same sense with *sieur* and *seigneur*, and applied to barons, gentlemen, and citizens.

SIRENS, in fabulous history, certain celebrated songstresses who were ranked among the demigods of antiquity. Hyginus places their birth among the consequences of the rape of Proserpine. Others make them daughters of the river Acheloüs and one of the muses*. The number of the Sirens was three; and their names were *Parthenope*, *Lygea*, and *Leucosia*. Some make them half women and half fish; others, half women and half birds. There are antique representations of them still subsisting under both these forms. Pausanias tells us, that the Sirens, by the persuasion of Juno, challenged the Muses to a trial of skill in singing; and these having vanquished them, plucked the golden feathers from the wings of the Sirens, and formed them into crowns, with which they adorned their own heads. The Argonauts are said to have been diverted from the enchantment of their songs by the superior strains of Orpheus: Ulysses, however, had great difficulty in securing himself from seduction. See *Odyss.* lib. xii.

* Ovid. Met. lib. iv.

Pope, in his notes to the twelfth book of the Odyssey, observes, the critics have greatly laboured to explain what was the foundation of this fiction of the Sirens. We are told by some, that the Sirens were queens of certain small islands named *Sirenusæ*, that lie near Capræa in Italy, and chiefly inhabited the promontory of Minerva, upon the top of which that goddess had a temple, as some affirm, built by Ulysses. Here there was a renowned academy, in the reign of the Sirens, famous for eloquence and the liberal sciences, which gave occasion to the invention of this fable of the sweetness of the voice and attracting songs of the Sirens. But why then are they fabled to be destroyers, and painted in such dreadful colours? We are told, that at last the students abused their knowledge, to the colouring of wrong, the corruption of manners, and the subversion of government: that is, in the language of poetry, they were feigned to be transformed into monsters, and with their music to have enticed passengers to their ruin, who there consumed their patrimonies, and poisoned their virtues with riot and effeminacy. The place is now called *Massa*. Some writers tell us of a certain bay, contracted within winding straits and broken cliffs, which, by the singing of the winds and beating of the waters, returns a delightful harmony, that allures the passenger to approach, who is immediately thrown against the rocks, and swallowed up by the violent eddies. Thus Horace, moralising, calls idleness a *Siren*.

——*Vitanda est improba Siren*
Desida.——

But the fable may be applied to all pleasures in general, which, if too eagerly pursued, betray the incautious into ruin; while wise men, like Ulysses, making use of their reason, stop their ears against their insinuations.

The learned Mr Bryant says, that the Sirens were Cuthite and Canaanitish priests, who had founded temples in Sicily, which were rendered infamous on account of the women who officiated. They were much addicted to cruel rites, so that the shores upon which they resided are described as covered with the bones of men destroyed by their artifice. *Virgil. Æneid.* lib. v. 864.

All ancient authors agree in telling us, that Sirens inhabited the coast of Sicily. The name, according to Bochart, who derives it from the Phœnician language, implies a songstress. Hence it is probable, says Dr Burney, that in ancient times there may have been excellent singers, but of corrupt morals, on the coast of Sicily, who, by seducing voyagers, gave rise to this fable. And if this conjecture be well founded, he observes, the Muses are not the only pagan divinities who preserved their influence over mankind in modern times; for every age has its Sirens, and every Siren her votaries; when beauty and talents, both powerful in themselves are united, they become still more attractive.

Siren, in zoology, a genus of animals belonging to the class of *amphibia* and the order of *meantes*. It is a biped, naked, and furnished with a tail; the feet are brachiated with claws. This animal was discovered by Dr Garden in Carolina; it is found in swampy and muddy places, by the sides of pools, under the trunks of old trees that hang over the water. The natives call it by the name of *mud-inguana*. Linnæus first apprehended, that it was the larva of a kind of lizard; but as its fingers are furnished with claws, and it makes a croaking noise, he concluded from these properties, as well as from the situation of the anus, that it could not be the larva of the lizard, and therefore formed of it a new genus under the name of *siren*. He was also obliged to establish for this uncommon animal a new order called *meantes* or *gliders*: the animals of which are amphibious, breathing by means of gills and lungs, and furnished with arms and claws.

Phil. Transf. vol. lvi. p. 189.

SIREX, in zoology, a genus of animals belonging to the class of *insects*, and to the order of *hymenopteræ*. The mouth has two strong jaws; there are two truncated palpi or feelers, filiform antennæ, an exserted, stiff, serrated sting, a sessile, mucronated abdomen, and lanceolated wings. There are seven species.

SIRIUM, in botany; a genus of plants belonging to the class of *tetrandia* and order of *monogynia*. The calyx is quadrifid; there is no corolla; the nectarium is quadriphyllous and crowning the throat of the calyx; the germen is below the corolla; the stigma is trifid, and the berry trilocular. There is only one species, the myrtifolium.

SIRIUS, in astronomy, a bright star in the constellation Canis. See Astronomy, n° 403, &c.

SIRLET (Flavius), an eminent Roman engraver on precious stones: his Lacoon, and representations in miniature of antique statues at Rome, are very valuable and scarce. He died in 1737.

SIROCCO, a periodical wind which generally blows in Italy and Dalmatia every year about Easter. It blows from the south-east by south: it is attended with heat, but not rain; its ordinary period is twenty days, and it usually ceases at sunset. When the sirocco does not blow in this manner, the summer is almost free from westerly winds, whirlwinds, and storms. This wind is prejudicial to plants, drying and burning up the buds; though it hurts not men any otherwise than by causing an extraordinary weakness and lassitude; inconveniences that are fully compensated by a plentiful fishing and a good crop of corn on the mountains. In the summer time, when the westerly wind ceases for a day, it is a sign that the sirocco will blow the day following, which usually begins with a sort of whirlwind.

Fortis's Travels in Dalmatia, p. 277.

SISKIN. See Fringilla.

SISON, bastard-stone parsley, in botany: A genus of plants belonging to the class of *pentandria*, and to the order of *digynia*; and in the natural system arranged under the 45th order, *umbellatæ*. The fruit is egg-shaped and streaked; the involucra are subtetraphyllous. There are seven species; the amomum, inundatum, segetum, verticillatum, salsum, canadense, and ammi. The four first are natives of Great Britain. 1. The *amomum*, common bastard parsley, or field stonewort, is a biennial plant about three feet high, growing wild in many places of Britain. Its seeds are small, striated, of an oval figure and brown colour. Their taste is warm and aromatic. Their whole flavour is extracted by spirit of wine, which elevates very little of it in distillation; and hence the spirituous extract has the flavour in great perfection, while the watery extract has very little. A tincture drawn with pure spirit is of a green colour. The seeds have been esteemed aperient, diuretic, and carminative; but are little regarded in the present practice. 2. The *inundatum*, least water-parsnep. The stem is about eight or ten inches high, branched, and

Sistrum, Sisymbrium.

and creeping: the leaves, below the water, are capillary; above it are pinnated: the umbels are bifid. It grows in ditches and ponds. 3. *Segetum*, corn parsley, or honeywort. The stems are numerous, slender, striated, branched, and leaning; the leaves are pinnated; the pinnæ are oval, pointed, and serrated, six or eight pair, and one at the end; the umbels small and drooping; the flowers minute and white. It grows in corn-fields and hedges. 4. *Verticillatum* verticillate sison, has small leaves in whirls, and capillary; the stem is two feet, with few leaves; the common umbel is composed of 8 or 10 rays, the partial of 18 or 20; both involucra are composed of five or six acute foliola; the flowers are all hermaphrodite, and the petals white.

SISTRUM, or CISTRUM, a kind of ancient musical instrument used by the priests of Isis and Osiris. It is described by Spon as of an oval form, in manner of a racket, with three sticks traversing it breadthwise; which playing freely by the agitation of the whole instrument, yielded a kind of sound which to them seemed melodious. Mr Malcolm takes the sistrum to be no better than a kind of a rattle. Oiselus observes, that the sistrum is found represented on several medals, and on talismans.

SISYMBRIUM, WATER-CRESSES, in botany: A genus of plants belonging to the class of *tetradynamia*, and to the order of *siliquosa*; and in the natural system ranged under the 39th order, *Siliquosæ*. The siliqua, or pod, opens with valves somewhat straight. The calyx and corolla are expanded. There are 29 species, of which eight are natives of Britain; the nasturtium, or common water-cress; sylvestre, water-rocket; amphibium, water-radish; terrestre, annual water-radish; monense: sophia, flixweed; irio, broad-leaved hedge-mustard.

1. The nasturtium grows on the brinks of rivulets and water ditches. The leaves have from 6 to 8 pair of smooth succulent and sessile pinnæ; the flowers are small and white, and grow in short spikes or tufts. The leaves of water-cresses have a moderately pungent taste, emit a quick penetrating smell, like that of mustard seed, but much weaker. Their pungent matter is taken up both by watery and spirituous menstrua, and accompanies the aqueous juice, which issues copiously upon expression. It is very volatile, so as to arise in great part in distillation with rectified spirt, as well as with water, and almost totally to exhale in drying the leaves, or inspissating by the gentlest heat to the consistence of an extract, either the expressed juice, or the watery or spirituous tinctures. Both the inspissated juice, and the watery extract discover to the taste a saline impregnation, and in keeping throw up crystalline efflorescences to the surface. On distilling considerable quantities of the herb with water, a small proportion of a subtile volatile very pungent oil is obtained.

Lewis's Meteria Medica.

Water-cresses obtain a place in the Materia Medica for their antiscorbutic qualities, which have been long very generally acknowledged by physicians. They are also supposed to purify the blood and humours, and to open visceral obstructions. They are nearly allied to scurvy-grass, but are more mild and pleasant, and for this reason are frequently eaten as salad. In the pharmacopœias the juice of this plant is directed with that of scurvy-grass and Seville oranges: and Dr Cullen has remarked, that the addition of acids renders the juices of the plantæ siliquosæ more certainly effectual, by determining them more powerfully to an acescent fermentation.

Woodville's Medical Botany, p. 135.

2. Silvestre, or water-rocket. The stem is weak, branched, and above a foot high. The leaves are pinnated; the pinnæ lance-shaped, and serrated; the flowers small, and yellow; and grow frequently in shallow water.

Berkenhout's Synopsis of Natural History.

3. Amphibium, or water-radish. The stem is firm, erect, and two or three feet high; the leaves are pinnatifid, and serrated; the flowers are yellow, and in spikes; the pods are somewhat oval, and short. It grows in water.

4. Terrestre, or land-rocket. The leaves are pinnatifid; the pods are filled with seed; the root is annual, and white; the stem is angular, red-green, and smooth.

5. Murale, or wall-rocket. The stems are rough, and about eight inches high; the leaves grow on foot-stalks, lance-shaped, smooth, sinuated, and serrated; the flowers are yellow; the pods a little compressed, and slightly carinated. It grows on sandy ground in the North, Anglesea, &c.

6. Monense, or yellow rocket. The stem is smooth, and about 6 or 8 inches high; the leaves are pinnatifid; the pinnæ remote, generally 7 pair; the flower is yellow; the petals entire; the calyx is closed. It grows in the Isle of Man.

7. Irio, broad-leaved rocket, or hedge mustard; the stem is smooth, and about two feet high; the leaves are broad, naked, pinnated, and halberd shaped at the end; the flowers are yellow, and the pods erect. It grows on waste ground.

8. Sophia, flixweed. The stem is firm, branched, and two or three feet high; the leaves are multifid; the segments are narrow; the flowers are yellow; the petals much less than the calyx; the pods are long, stiff, curved, without style, and erect; the seeds are minute, and yellow. It grows on walls, waste ground, &c.

SISYPHUS, in fabulous history, one of the descendents, of Eolus, married Merope, one of the pleiades, who bore him Glaucus. He resided at Epyra in Peloponnesus, and was a very crafty man. Others say, that he was a Trojan secretary, who was punished for discovering secrets of state; and others again, that he was a notorious robber, killed by Theseus. However, all the poets agree that he was punished in Tartarus for his crimes, by rolling a great stone to the top of a hill, which constantly recoiled, and, rolling down incessantly, renewed his labour.

SISYRINCHIUM, in botany: A genus of plants belonging to the class of *gynandria*, and order of *triandria*; and in the natural system ranged under the 6th order, *Ensatæ*. The spatha is diphyllous; there are 6 plane petals. The capsule is trilocular and inferior.—There are two species, the bermudiana and palmifolium.

SITE, denotes the situation of an house, &c. and sometimes the ground-plot or spot of earth it stands on.

SITTA NUTHACH, in ornithology: A genus belonging to the class of *aves*, and order of *picæ*. It is thus characterized by Dr Latham. The bill is for the most part straight; on the lower mandible there is a small angle; nostrils small, covered with bristles reflected over them; tongue short, horny at the end, and jagged; toes placed three forward and one backward;

Latham's Ornithology, vol ii. p. 647, &c.

Sisymbrium ‖ Sitta.

the middle toe joined closely at the base to both the outmost; back toe as large as the middle one.—there are 11 species: the europæa, canadensis, carolinensis, jamaicensis, pusilla, major, nævia, surinamensis, cafra, longirostra, and chloris. The europæa, or nuthatch, is in length near five inches three-quarters, in breadth nine inches; the bill is strong and straight, about three-quarters of an inch long; the upper mandible black, the lower white: the irides are hazel; the crown of the head, back, and coverts of the wings, of a fine bluish grey; a black stroke passes over the eye from the mouth: the cheeks and chin are white; the breast and belly of a dull orange-colour; the quill-feathers dusky; the wings underneath are marked with two spots, one white at the root of the exterior quills, the other black at the joint of the bastard-wing; the tail consists of twelve feathers; the two middle are grey, the two exterior feathers tipt with grey; then succeeds a transverse white spot; beneath that the rest is black: the legs are of a pale yellow; the back toe very strong, and the claws large. The female is like the male, but less in size, and weighs commonly 5 or at most 6 drams. The eggs are six or seven in number, of a dirty white, dotted with rufous; these are deposited in some hole of a tree, frequently one which has been deserted by a woodpecker, on the rotten wood mixed with a little moss, &c. If the entrance be too large, the bird nicely stops up part of it with clay, leaving only a small hole for itself to pass in and out by. While the hen is sitting, if any one puts a bit of stick into the hole, she hisses like a snake, and is so attached to her eggs, that she will sooner suffer any one to pluck off her feathers than fly away. During the time of incubation, the male supplies her with sustenance, with all the tenderness of an affectionate mate.

The bird runs up and down the bodies of trees, like the woodpecker tribe; and feeds not only on insects, but nuts, of which it lays up a considerable provision in the hollows of trees. It is a pretty sight, says Mr Willoughby, to see her fetch a nut out of her hoard, place it fast in a chink, and then, standing above it with its head downwards, striking it with all its force, break the shell, and catch up the kernel. It is supposed not to sleep perched on a twig like other birds; for when confined in a cage, it prefers sleeping in a hole or corner. When at rest it keeps the head down. In autumn it begins to make a chattering noise, being silent for the greatest part of the year." Dr Plott tells us, that this bird, by putting its bill into a crack in the bough of a tree, can make such a violent sound as if it was rending asunder, so that the noise may be heard at least twelve score yards.

SITOPHYLAX, Σιτοφυλαξ, formed from σιτος "corn," and φυλαξ, "keeper," in antiquity, an Athenian magistrate, who had the superintendence of the corn, and was to take care that nobody bought more than was necessary for the provision of his family. By the Attic laws, particular persons were prohibited from buying more than fifty measures of wheat a man; and that such persons might not purchase more, the sitophylax was appointed to see the laws properly executed. It was a capital crime to prevaricate in it. There where 15 of these *sitophylaces*, ten for the city, and five for the Piræus.

SIVA, a name given by the Hindoos to the Supreme Being, when considered as the avenger or destroyer. Sir William Jones has shown that in several respects the character of Jupiter and Siva are the same. As Jupiter overthrew the Titans and giants, so did Siva overthrow the Daityas, or children of Diti, who frequently rebelled against Heaven; and as during the contest the god of Olympus was furnished with lightening and thunderbolts by an eagle, so Brahma, who is sometimes represented riding on the Garuda, or eagle, presented the god of destruction with fiery shafts. Siva also corresponds with the Stygian Jove, or Pluto; for, if we can rely on a Persian translation of the Bhágavat, the sovereign of Pátála, or the infernal regions, is the king of serpents, named *Seshanaga*, who is exhibited in painting and sculpture, with a diadem and sceptre, in the same manner as Pluto. There is yet another attribute of Siva, or Mahádéva, by which he is visibly distinguished in the drawings and temples of Bengal. To destroy, according to the Vedantis of India, the Sufis of Persia, and many philosophers of our European schools, is only to generate and reproduce in another form. Hence the god of destruction is holden in this country to preside over generation, as a symbol of which he rides on a white bull. Can we doubt that the loves and feats of Jupiter Genitor (not forgetting the white bull of Europa), and his extraordinary title of Lapis, for which no satisfactory reason is commonly given, have a connection with the Indian philosophy and mythology?

Asiatic Researches.

SIUM WATER PARSNEP, in botany: A genus of plants belonging to the class of *pentandria*, and order of *digynia*, and in the natural system ranging under the 45th order, *Umbellatæ*. The fruit is a little ovated, and streaked. The involucrum is polyphyllous, and the petals are heart-shaped. There are 12 species; the latifolium, angustifolium, nodiflorum, sisarum, ninsi rigidius, japonicum, falcarica, græcum, siculum, repens, and decumbens. The three first are natives of Britain. 1. The *latifolium*, or great water-parsnep, which grows spontaneously in many places both of England and Scotland on the sides of lakes, ponds, and rivulets. The stalk is erect and furrowed, a yard high or more. The leaves are pinnated with three or four pair of large elliptic pinnæ, with an odd one at the end, all serrated on the edges. The stalk and branches are terminated with erect umbels, which is the chief characteristic of the species. Cattle are said to have run mad by feeding upon this plant. 2. The *angustifolium*, or narrow-leaved water-parsnep, has pinnated leaves; the axillary umbels are pedunculated, and the general involucrum is pinnatifid. It grows in ditches and rivulets, but is not common. 3. The *nodiflorum*, reclining water-parsnep, has pinnated leaves, but the axillary umbels are sessile. It grows on the sides of rivulets.

The *sium sisarum*, or skirret, is a native of China, but has been for a long time cultivated in Europe, and particularly in Germany. The root is a bunch of fleshy fibres, each of which is about as thick as a finger, but very uneven, covered with a whitish rough bark, and has a hard core or pith running thro' the centre. From the crown of this bunch come several winged leaves, consisting of two or three pair of oblong dentated lobes each, and terminated by an odd one. The stalk rises to about two feet, is set with leaves at the joints, and breaks into branches towards the top, each terminating with an umbel of small white flowers, which are succeeded by striated seeds like those of parsley. Skirrets come nearest to parsneps of any of the esculent roots, both for flavour and nutritive qualities. They are rather sweeter than the parsnep, and therefore to some few palates are not altogether so agreeable.

Mr Margraaf extracted from ½ lb. of skirret root 1½ ounces of pure sugar.

SIX-Clerks, officers in chancery of great account, next in degree below the twelve masters, whose business is to inrol commissions, pardons, patents, warrants, &c. which pass the great seal, and to transact and file all proceedings by bill, answer, &c. They were anciently *clerici*, and forfeited their places, if they married; but when the constitution of the court began to alter, a law was made to permit them to marry. Stat. 14. and 15. Hen. VIII. cap. 8. They are also solicitors for parties in suits depending in the court of chancery. Under them are 6 deputies and 60 clerks, who, with the under clerks, do the business of the office.

SIX Nations. See Niagara.

SIXTH, in music, one of the simple original concords, or harmonical intervals. See Interval.

SIXTUS V. (Pope), was born the 13th December 1521, in La Marca, a village in the seigniory of Montalto. His father, Francis Peretti, was a gardener, and his mother a servant maid. He was their eldest child, and was called Felix. At the age of nine he was hired out to an inhabitant of the village to keep sheep; but disobliging his master, he was soon after degraded to be keeper of the hogs. He was engaged in this employment when Father Michael Angelo Selleri, a Franciscan friar, asked the road to Ascoli, where he was going to preach. Young Felix conducted him thither, and struck the father so much with his conversation and eagerness for knowledge, that he recommended him to the fraternity to which he had come. Accordingly he was received among them, invested with the habit of a lay brother, and placed under the sacristan, to assist in sweeping the church, lighting the candles, and other offices of that nature; for which he was to be taught the responses, and the rudiments of grammar. His progress in learning was so surprising, that at the age of 14 he was thought qualified to begin his noviciate, and was admitted the year following to make his profession.

He pursued his studies with such unwearied assiduity, that he was soon reckoned equal to the best disputants. He was ordained priest in 1545, when he assumed the name of Father Montalto; soon after he took his doctor's degree, and was appointed professor of theology at Sienna. It was then that he so effectually recommended himself to Cardinal di Carpi, and his secretary Bossius, that they ever remained his steady friends. Meanwhile the severity and obstinacy of his temper incessantly engaged him in disputes with his monastic brethren. His reputation for eloquence, which was now spread over Italy, about this time gained him some new friends. Among these were the Colonna family, and Father Ghisilieri, by whose recommendation he was appointed inquisitor-general at Venice; but he exercised that office with so much severity, that he was obliged to flee precipitately from that city. Upon this he went to Rome, where he was made procurator-general of his order, and soon after accompanied Cardinal Buon Compagnon into Spain, as a chaplain and consultor to the inquisition. There he was treated with great respect, and liberal offers were made him to induce him to continue in Spain, which, however, he could not be prevailed on to accept.

In the mean time, news were brought to Madrid that Pius IV. was dead, and that Father Ghisilieri, who had been made Cardinal Alexandrino by Paul IV. had succeeded him under the name of Pius V. These tidings filled Montalto with joy, and not without reason, for he was immediately invested by the pontiff with new dignities. He was made general of his order, bishop of St Agatha, was soon after raised to the dignity of cardinal, and received a pension. About this time he was employed by the Pope to draw up the bill of excommunication against Queen Elizabeth.

He began now to cast his eyes upon the papacy; and, in order to obtain it, formed and executed a plan of hypocrisy with unparalleled constancy and success. He became humble, patient, and affable. He changed his dress, his air, his words, and his actions, so completely, that his most intimate friends declared him a new man. Never was there such an absolute victory gained over the passions; never was a fictitious character so long maintained, nor the foibles of human nature so artfully concealed. He courted the ambassadors of every foreign power, but attached himself to the interests of none; nor did he accept a single favour that would have laid him under any peculiar obligation. He had formerly treated his relations with the greatest tenderness, but he now changed his behaviour altogether. When his brother Anthony came to visit him, he lodged him in an inn, and sent him home next day, charging him to inform his family that he was now dead to his relations and the world.

When Pius V. died in 1572, he entered the conclave with the other cardinals, but seemed altogether indifferent about the election, and never left his apartment except to his devotion. When solicited to join any party, he declined it, declaring that he was of no consequence, and that he would leave the choice of a Pope entirely to persons of greater knowledge and experience. When Cardinal Buon Compagnon, who assumed the name of Gregory XIII. was elected, Montalto assured him that he never wished for any thing so much in his life, and that he would always remember his goodness, and the favours he had conferred on him in Spain. But the new Pope treated him with the greatest contempt, and deprived him of his pension. The cardinals also, deceived by his artifices, paid him no greater respect, and used to call him, by way of ridicule, the Roman beast; the ass of La Marca.

He now assumed all the infirmities of old age; his head hung down upon his shoulders; he tottered as he walked, and supported himself on a staff. His voice became feeble, and was often interrupted by a cough so exceedingly severe, that it seemed every moment to threaten his dissolution. He interfered in no public transactions, but spent his whole time in acts of devotion and benevolence. Mean time he constantly employed the ablest spies, who brought him intelligence of every particular.

When Gregory XIII. died in 1585, he entered the conclave with the greatest reluctance, and immediately shut himself up in his chamber, and was no more thought of than if he had not existed. When he went

Sixtus. to mass, for which purpose alone he left his apartment, he appeared perfectly indifferent about the event of the election. He joined no party, yet flattered all.

He knew early that there would be great divisions in the conclave, and he was aware that when the leaders of the different parties were disappointed in their own views, they all frequently agreed in the election of some old and infirm cardinal, the length of whose life would merely enable them to prepare themselves sufficiently for the next vacancy. These views directed his conduct, nor was he mistaken in his hopes of success.

Three cardinals, the leaders of opposite factions, being unable to procure the election which each of them wished, unanimously agreed to make choice of Montalto. When they came to acquaint him wiith their intention, he fell into such a violent fit of coughing that every person thought he would expire on the spot. He told them that his reign would last but a few days; that, besides a continual difficulty of breathing, he wanted strength to support such a weight, and that his small experience rendered him very unfit for so important a charge. He conjured them all three not to abandon him, but to take the whole weight of affairs upon their own shoulders; and declared that he would never accept the mitre upon any other terms: "If you are resolved," added he, "to make me Pope, it will only be placing yourselves on the throne. For my part, I shall be satisfied with the bare title. Let the world call me Pope, and I make you heartily welcome to the power and authority". The cardinals swallowed the bait, and exerted themselves so effectually that Montalto was elected. He now pulled off the mask which he had worn for 14 years. No sooner was his election secured, than he started from his seat, flung down his staff in the middle of the hall, and appeared almost a foot taller than he had done for several years.

When he was asked, according to custom, if he would accept of the Papacy, he replied, "It is trifling to ask whether I will accept what I have already accepted.—However, to satisfy any scruple that may arise, I tell you that I accept it with great pleasure, and would accept another if I could get it; for I find myself able, by the Divine assistance, to manage two papacies." His former complaisance and humility disappeared, together with his infirmities, and he now treated all around him with reserve and haughtiness. The first care of Sixtus V. the name which Montalto assumed, was to correct the abuses, and put a stop to the enormities, which were daily committed in every part of the ecclesiastical state. The lenity of Gregory's government had introduced a general licentiousness of manners, which burst forth with great violence, after that Pontiff's death. It had been usual with former Popes to release delinquents on the day of their coronation, who were therefore accustomed to surrender themselves voluntary prisoners immediately after the election of the Pope. At present, however they were fatally disappointed.—When the governor of Rome and the Keeper of St Angelo waited on his Holiness, to know his intention in this particular, he replied, "What have you to do with pardons, and releasing of prisoners? Is it not sufficient that our predecessor has suffered the judges to remain unemployed these 13 years? Shall we also stain our pontificate with the same neglect of justice? We have too long seen, with inexpressible concern, the prodigious degree of wickedness that reigns in the state to think of granting pardons. Let the prisoners be brought to a speedy trial, and punished as they deserve, to show the world that Divine Providence has called us to the chair of St Peter, to reward the good, and chastise the wicked; that we bear not the sword in vain, but are the ministers of God, and a revenger to execute wrath on them that do evil."

He appointed commissioners to inspect the conduct of the judges, displaced those who were inclined to lenity, and put others of severe dispositions in their room. He offered rewards to any person who could convict them of corruption or partiality. He ordered the syndics of all the towns and signiories to make out a complete list of the disorderly persons within their districts, and threatened the strapado for the smallest omission. In consequence of this edict, the syndic of Albino was scourged in the market-place, because he had left his nephew, an incorrigible libertine, out of his list.

He made very severe laws against robbers and assassins. Adulterers, when discovered, suffered death; and they who willingly submitted to the prostitution of their wives, a custom then common in Rome, received the same punishment. He was particularly careful of the purity of the female sex, and never forgave those who attempted to debauch them.

His execution of justice was as prompt as his edicts were rigorous. A Swiss happening to give a Spanish gentleman a blow with his halberd, was struck by him so rudely with a pilgrim's staff that he expired on the spot. Sixtus informed the governor of Rome that he was to dine early, and that justice must be executed on the criminal before he sat down to table. The Spanish ambassador and four cardinals intreated him not to disgrace the gentleman by suffering him to die on a gibbet, but to order him to be beheaded. "He shall be hanged (replied Sixtus), but I will alleviate his disgrace by doing him the honour to assist personally at his death." He ordered a gibbet to be erected before his own windows, where he continued sitting during the whole execution. He then called to his servants to bring in dinner, declaring that the act of justice which he had just seen had increased his appetite. When he rose from table, he exclaimed, "God be praised for the good appetite with which I have dined!"

When Sixtus ascended the throne, the whole ecclesiastical state was infested with bands of robbers, who, from their numbers and outrages, were exceedingly formidable; by his prudent and vigorous conduct, however, he in a short time extirpated the whole of these banditti.

Nor was the vigour of his conduct less conspicuous in his transactions with foreign nations. Before he had been pope two months he quarrelled with Philip II. of Spain, Henry III. of France, and Henry king of Navarre. His intrigues indeed in some measure influenced all the councils of Europe.

After his accession to the pontificate he sent for his family to Rome, with express orders that they should appear in a decent and modest manner. Accordingly, his sister Camilla came thither, accompanied by her daughter and two grandchildren. Some cardinals, in order to pay court to the pope, went out to meet her, and introduced her in a very magnificent dress. Sixtus pretended not to know her, and asked two or three times

times who she was: Upon this one of the cardinals said, "It is your sister, holy father." "I have but one sister (replied Sixtus with a frown), and she is a poor woman at Le Grotte; if you have introduced her in this disguise, I declare I do not know her; yet I think I would know her again, if I saw her in the clothes she used to wear."

Her conductors at last found it necessary to carry her to an inn, and strip her of her finery. When Camilla was introduced a second time, Sixtus embraced her tenderly, and said, "Now we know indeed that it is our sister: nobody shall make a princess of you but ourselves." He stipulated with his sister, that she should neither ask any favour in matters of government, nor intercede for criminals, nor interfere in the administration of justice; declaring that every request of that kind would meet with a certain refusal. These terms being agreed to, and punctually observed, he made the most ample provision not only for Camilla but for his whole relations.

This great man was also an encourager of learning. He caused an Italian translation of the Bible to be published, which raised a good deal of discontent among the Catholics. When some cardinals reproached him for his conduct in this respect, he replied, "It was published for the benefit of you cardinals who cannot read Latin."

Sixtus died in 1590, after having reigned little more than five years. His death was ascribed to poison, said to have been administered by the Spaniards; but the story seems rather improbable.

It was to the indulgence of a disposition naturally formed for severity, that all the defects of this wonderful man are to be ascribed. Clemency was a stranger to his bosom; his punishments were often too cruel, and seemed sometimes to border on revenge. Pasquin was dressed one morning in a very nasty shirt, and being asked by Martorio why he wore such dirty linen? replied, that he could get no other, for the pope had made his washerwoman a princess, alluding to Camilla, who had formerly been a laundress. The pope ordered strict search to be made for the author of this lampoon, and offered him his life and a thousand pistoles if he would discover himself. The author was simple enough to make his appearance and claim the reward. "It is true (said the pope) we made such a promise, and we shall keep it; your life shall be spared, and you shall receive the money presently: but we have reserved to ourselves the power of cutting off your hands and boring your tongue through, to prevent your being so witty for the future." It is needless to add, that the sentence was immediately executed. This, however, is the only instance of his resenting the many severe satires that were published against him.

But though the conduct of Sixtus seldom excites love, it generally commands our esteem, and sometimes our admiration. He strenuously defended the cause of the poor, the widow, and the orphan: he never refused audience to the injured, however wretched or forlorn their appearance was. He never forgave those magistrates who were capable of partiality or corruption; nor suffered crimes to pass unpunished, whether committed by the rich or the poor. He was frugul, temperate, sober, and never neglected to regard the smallest favour which had been conferred on him before his exaltation.

When he mounted the throne, the treasury was not only exhausted, but in debt: at his death it containded five millions of gold.

Rome was indebted to him for several of her greatest embellishments, particularly the Vatican library: it was by him, too, that trade was first introduced into the Ecclesiastical State.

SIYA-GHUSH, the caracal of Buffon, an animal of the cat kind. See FELIS, n° xviii.

SIZAR, or SIZER, in Latin *Sizator*, an appellation by which the lowest order of students in the universities of Cambridge and Dublin are distinguished, is derived from the word *size*, which in Cambridge, and probably in Dublin likewise, has a peculiar meaning. To *size*, in the language of the university, is to get any sort of victuals from the kitchens, which the students may want in their own rooms, or in addition to their commons in the hall, and for which they pay the cooks or butchers at the end of each quarter. A size of any thing is the smallest quantity of that thing which can be thus bought: two sizes, or a part of beef, being nearly equal to what a young person will eat of that dish to his dinner; and a size of ale or beer being equal to half an English pint.

The sizars are divided into two classes, viz. subsizatores or sizars, and sizatores or proper sizars. The former of these are supplied with commons from the table of the fellows and fellow-commoners; and in former times, when these were more scanty than they are now, they were obliged to supply the deficiency by sizing, as is sometimes the case still. The proper sizars had formerly no commons at all, and were therefore obliged to size the whole. In St John's college they have now some commons allowed them for dinner, from a benefaction, but they are still obliged to size their suppers: in the other colleges they are allowed a part of the fellow-commons, but must size the rest; and from being thus obliged to size the whole or part of their victuals, the whole order derived the name of *sizars*.

In Oxford, the order similar to that of sizar is denominated *servitor*, a name evidently derived from the menial duties which they perform. In both universities these orders were formerly distinguished by round caps and gowns of different materials from those of the pensioners or commoners, the order immediately above them. But about 30 years ago the round cap was entirely abolished in both seminaries. There is still, however, in Oxford, we believe, a distinction in the gowns, and there is also a trifling difference in some of the small colleges in Cambridge; but in the large colleges the dress of the pensioners and sizars is entirely the same.

In Oxford, the servitors are still obliged to wait at table on the fellows; and gentlemen-commoners; but much to the credit of the university of Cambridge, this most degrading and disgraceful custom was entirely abolished about 10 or 12 years ago, and of course the sizars of Cambridge are now on a much more respectable footing than the servitors of Oxford.

The sizars are not upon the foundation, and therefore while they continue sizars are not capable of being elected fellows; but they may at any time, if they choose,

choose, become pensioners; and they generally sit for scholarships immediately before they take their first degree. If successful, they are then on the foundation, and are entitled to become candidates for fellowships when they have got that degree. In the mean time, while they continue sizars, besides free commons they enjoy many benefactions, which have been made at different times, under the name of *sizar's prætor, exhibitions*, &c. and the rate of tuition, the rent of rooms, and other things of that sort within their respective colleges, is less than to the other orders. But tho' their education is thus obtained at a less expence, they are not now considered as a menial order; for sizars, pensioner-scholars, and even sometimes fellow-commoners, mix together with the utmost cordiality. It is worthy of remark, that at every period this order has supplied the university with its most distinguished officers; and that many of the most illustrious members of the church, many of the most distinguished men in the other liberal professions, have, when under-graduates, been sizars, when that order was on a less respectable footing than it is now.

SIZE, the name of an instrument used for finding the bigness of fine round pearls. It consists of thin pieces or leaves, about two inches long, and half an inch broad, fastened together at one end by a rivet. In each of these are round holes drilled of different diameters. Those in the first leaf serve for measuring pearls from half a grain to seven grains; those of the second, for pearls from eight grains or two carats to five carats, &c.; and those of the third, for pearls from six carats and a half to eight carats and a half.

Size, is also a sort of paint, varnish, or glue, used by painters, &c.

The shreds and parings of leather, parchment, or vellum, being boiled in water and strained, make size. This substance is much used in many trades.—The manner of using size is to melt some of it over a gentle fire; and scraping as much whiting into it as will just colour it, let them be well incorporated together; after which you may whiten frames, &c. with it. After it dries, melt the size again, and put more whiting, and whiten the frames, &c. seven or eight times, letting it dry between each time: but before it is quite dry, between each washing with size, you must smoothe and wet it over with a clean brush-pencil in fair water.

To make gold-size. Take gum-animi and asphaltum, of each one ounce; minium, litharge of gold, and amber, of each half an ounce: reduce all into a very fine powder, and add to them four ounces of linseed oil, and eight ounces of drying oil: digest them over a gentle fire that does not flame, so that the mixture may only simmer, but not boil; lest it should run over and set the house on fire, stir it constantly with a stick till all the ingredients are dissolved and incorporated, and do not leave off stirring till it becomes thick and ropy; after being sufficiently boiled, let it stand till it is almost cold, and then strain it through a coarse linen cloth, and keep it for use.—To prepare it for working, put what quantity you please in a horse-muscle shell, adding as much oil of turpentine as will dissolve it; and making it as thin as the bottom of your seed-lac varnish, hold it over a candle, and then strain it through a linen-rag into another shell; add to these as much vermillion as will make it of a darkish red: if it is too thick for drawing, you may thin it with some oil of turpentine. The chief use of this size is for laying on metals.

The best gold-size for burnishing is made as follows: Take fine bole, what quantity you please; grind it finely on a piece of marble, then scrape into it a little beef-suet; grind all well together; after which mix in a small proportion of parchment-size with a double proportion of water, and it is done.

To make silver-size. Take tobacco-pipe clay in fine powder, into which scrape some black-lead and a little Genoa soap, and grind them all together with parchment size as already directed.

SKATING, an exercise on ice, both graceful and healthy. Although the ancients were remarkable for their dexterity in most of the athletic sports, yet skating seems to have been unknown to them. It may therefore be considered as a modern invention; and probably it derived its origin in Holland, where it was practised, not only as a graceful and elegant amusement, but as an expeditious mode of travelling when the lakes and canals were frozen up during winter. In Holland long journeys are made upon skates with ease and expedition; but in general less attention is there paid to graceful and elegant movement, than to the expedition and celerity of what is called *journey skating*. It is only in those countries where it is considered as an amusement, that its graceful attitudes and movements can be studied; and there is no exercise whatever better calculated to set off the human figure to advantage. The acquirement of most exercises may be attained at an advanced period of life; but to become an expert skater, it is necessary to begin the practice of the art at a very early age. It is difficult to reduce the art of skating to a system. It is principally by the imitation of a good skater that a young practitioner can form his own practice. The English, though often remarkable for feats of agility upon skates, are very deficient in gracefulness; which is partly owing to the construction of the skates. They are too much curved in the surface which embraces the ice, consequently they involuntarily bring the users of them round on the outside upon a quick and small circle; whereas the skater, by using skates of a different construction, less curved, has the command of his stroke, and can enlarge or diminish the circle according to his own wish and desire. The metropolis of Scotland has produced as many instances of elegant skaters as perhaps any other country whatever; and the institution of a Skating Club about 40 years ago, has contributed not a little to the improvement of this elegant amusement. We are indebted for this article to a gentleman of that Club, who has made the practice and improvement of skating his particular study; and as the nature of our work will not permit the insertion of a full treatise on skating, we shall present our readers with a few instructions.

Those who wish to be proficients should begin at an early period of life; and should first endeavour to throw off the fear which always attends the commencement of an apparently hazardous amusement. They will soon acquire a facility of moving on the inside: when they have done this, they must endeavour to acquire the movement on the outside of the skates; which is nothing more than throwing themselves upon the outer edge of the skate, and making the balance of their body tend towards that side,

side, which will necessarily enable them to form a semicircle. In this, much assistance may be derived from placing a bag of lead-shot in the pocket next to the foot employed in making the outside stroke, which will produce an artificial poise of the body, which afterwards will become natural by practice. At the commencement of the outside stroke, the knee of the employed limb should be a little bended, and gradually brought to a rectilineal position when the stroke is completed. When the practitioner becomes expert in forming the semicircle with both feet, he is then to join them together, and proceed progressively and alternately with both feet, which will carry him forward with a graceful movement. Care should be taken to use very little muscular exertion, for the impelling motion should proceed from the mechanical impulse of the body thrown into such a position as to regulate the stroke. At taking the outside stroke, the body ought to be thrown forward easily, the unimployed limb kept in a direct line with the body, and the face and eyes directly looking forward: the unemployed foot ought to be stretched towards the ice, with the toes in a direct line with the leg. In the time of making the curve, the body must be gradually, and almost imperceptibly, raised, and the unemployed limb brought in the same manner forward; so that, at finishing the curve, the body will bend a small degree backward, and the unemployed foot will be about two inches before the other, ready to embrace the ice and form a correspondent curve. The muscular movement of the whole body must correspond with the movement of the skate, and should be regulated so as to be almost imperceptible to the spectators. Particular attention should be paid in carrying round the head and eyes with a regular and imperceptible motion; for nothing so much diminishes the grace and elegance of skating as sudden jerks and exertions, which are too frequently used by the generality of skaters. The management of the arms likewise deserves attention. There is no mode of disposing of them more gracefully in skating outside, than folding the hands into each other, or using a muff.

There are various feats of activity and manœuvres used upon skates; but they are so various that we cannot pretend to detail them. Moving on the outside is the primary object for a skater to attain; and when he becomes an adept in that, he will easily acquire a facility in executing other branches of the art. There are few exercises but will afford him hints of elegant and graceful attitudes. For example, nothing can be more beautiful than the attitude of drawing the bow and arrow whilst the skater is making a large circle on the outside: the manual exercise and military salutes have likewise a pretty effect when used by an expert skater.

SKELETON, in anatomy, the dried bones of any animal joined together by wires, or by the natural ligament dried, in such a manner as to show their position when the creature was alive.

We have in the Philosophical Transactions, an account of a human skeleton, all the bones of which were so united, as to make but one articulation from the back to the os sacrum, and downwards a little way. On sawing some of them, where they were unnaturally joined, they were found not to cohere throughout their whole substance, but only about a sixth of an inch deep all round. The figure of the trunk was crooked, the spinæ making the convex, and the inside of the vertebræ the concave part of the segment. The whole had been found in a charnel-house, and was of the size of a full grown person.

SKIDS, or Skeeds, in sea-language, are long compassing pieces of timber, notched below so as to fit closely upon the wales, extending from the main-wale to the top of the side, and retained in this position by bolts or spike-nails. They are intended for preserving the planks of the side, when any heavy body is hoisted or lowered.

SKIE (Isle of). See Sky.

SKIFF, a small boat resembling a yawl, usually employed for passing rivers.

SKIMMER, black. See Shearbill.

SKIMMIA, in botany: A genus of the *monogynia* order, belonging to the *tetrandria* class of plants; and in the natural method ranking under the 40th order, *Personatæ*. The calyx is quadripartite; the corolla consists of four concave petals; and the berry contains four seeds. There is only one species, viz. the *Japonica*.

SKIN, in anatomy, the general covering of the body of any animal. See Anatomy, n° 74.

Skin, in commerce, is particularly used for the membrane stripped off the animal to be prepared by the tanner, skinner, parchment maker, &c. and converted into leather, &c. See Tanning.

SKINNER (Stephen), an English antiquarian, born in 1622. He travelled, and studied in several foreign universities during the civil wars; and in 1654, returned and settled at Lincoln, where he practised physic with success until the year 1667, when he died of a malignant fever. His works were collected in folio in 1671, by Mr Henshaw, under the title of *Etymologicon Linguæ Anglicanæ*, &c.

SKIPPER, or Saury, a species of Esox, which see.

SKIRMISH, in war, a slight engagement between small parties, without any regular order; and is therefore easily distinguished from a *battle*, which is a general engagement between two armies continued for some time.

SKULL, in anatomy, the bony case in which the brain is inclosed. See Anatomy, n° 11. &c.

Skull-Cap. See Scutellaria.

SKY, the blue expanse of air or atmosphere. For the reason of its blue colour and concave figure see Optics.

Sky, one of the greatest of the Western Islands of Scotland, so called from *Skianach*, which in the Erse dialect signifies *winged*, because the two promontories of Valerness and Troternish, by which it is bounded on the north-west and north-east, are supposed to resemble wings. The island lies between the shire of Ross and the western part of Lewis. According to the computation of Mr Pennant, Dr Johnson, and Dr Campbell, it is 60 miles in length, and nearly the same in width where broadest; according to others it is 50 miles in length, and in some places 30 broad. The island of Sky is divided between two proprietors; the southern part belongs to the laird of Macleod, said to be lineally descended from Leod son to the black prince of Man: the northern district, or barony of Troternish, is the property of Lord Macdonald, whose ancestor was Do-

nald,

nald, king, or lord of the Isles, and chief of the numerous clan of Macdonalds, who are counted the most warlike of all the Highlanders. Sky is part of the shire of Inverness, and formerly belonged to the diocese of the Isles: on the south it is parted from the main land by a channel three leagues in breadth; tho' at the ferry of Glenelly, it is so narrow that a man may be heard calling for the boat from one side to the other. Sky is well provided with a variety of excellent bays and harbours.

The face of the country is roughened with mountains, some of which are so high as to be covered with snow on the top at midsummer; in general, their sides are cloathed with heath and grass, which afford good pasturage for sheep and black cattle. Between the mountains there are some fertile valleys, and the greater part of the land towards the sea-coast is plain and arable. The island is well watered with a great number of rivers, above 30 of which afford salmon: and some of them produce black muscles in which pearls are bred, particularly the rivers Kilmartin and Ord; Martin was assured by the proprietor of the former, that a pearl hath been found in it valued at 20 l. Sterling. Here is also a considerable number of fresh-water lakes well stored with trout and eels. The largest of these lakes takes its denomination from St Columba, to whom is dedicated a chapel that stands upon a small isle in the middle of the lake. Sky likewise affords several cataracts, that roar down the rocks with great impetuosity. That the island has been formerly covered with woods, appears from the large trunks of fir and other trees daily dug out of the bogs and peat-marshes in every part of this country.

Statistical Account of Scotland, vol. xvi. p. 140.

From the height of the hills, and proximity of the sea, the air seldom continues long of the same temperature; sometimes it is dry, oftener moist, and in the latter end of winter and beginning of spring cold and piercing; at an average, three days in twelve throughout the year scarcely free from rain, far less from clouds. These, attracted by the hills, sometimes break in useful and refreshing showers; at other times suddenly bursting, pour down their contents with tremendous noise, in impetuous torrents that deluge the plains below, and render the smallest rivulet impassable; which, together with the stormy winds so common in this country in the months of August and September, frequently blast the hopes, and disappoint the expectations, of the husbandman. Snow has been often known to lie on the ground from three to seven weeks; and on the highest hills, even in the middle of June, some spots of it are to be seen. To this various temperature of the air, and uncertainty of weather, the fevers and agues, headachs, rheumatisms, colds, and dysenteries, which are the prevailing distempers, may be ascribed. That it is far, however, from being unwholesome, is sufficiently evinced by experience; for the inhabitants are, in general, as strong and healthy, and arrive at as advanced an age, as those who live in milder climates, and under a serener sky. The gout is scarcely known in this island.

The soil is generally black, though it likewise affords clay of different colours; such as white, red, and blue, and in some places fuller's earth. It is, however, much less adapted for agriculture than for pasture, and seldom, unless in very good years, supplies itself with a sufficiency of provisions. Yet, though the soil is not very fertile or rich, it might with proper management be made to produce more plentiful crops. But the generality of the farmers are so prejudiced in favour of old customs, and indeed so little inclined to industry, that they will not easily be prevailed on to change them for better; especially if the alteration or amendment proposed be attended with expence. Therefore, with respect to improvements in agriculture, they are still much in the same state as they were 20 or 30 years ago. Ploughs, on a new and improved model, that in comparison to the advantages derived from them might be had at a moderate expence, have lately been introduced into several districts around, where their good effects are manifest, in improving the crops and diminishing the labour of man and beast; but the laird of Raasay and one other gentleman are the only persons in Portree that have used them. The *cascroim*, a crooked kind of spade, is almost the only instrument for labouring the ground used among the ordinary class of tenants. The average crops of corn are 8000 bolls.

When Mr Knox visited this island in 1786, the number of inhabitants amounted to 15.000: but some gentlemen who resided there affirmed there were 16,000. It is divided into eight parishes, in each of which there is a school, besides three charity-schools in different places.

The minerals found here are lead and iron ore, which, however, have never been wrought to any advantage. Near the village of Sartle, the natives find black and white marcasites, and variegated pebbles. The Applesglen, in the neighbourhood of Loch-fallart, produces beautiful agates of different sizes and colours: stones of a purple hue are, after great rains, found in the rivulets; crystal, of different colours and forms, abounds in several parts of the island, as well as black and white marble, free-stone, lime-stone, and talc: small red and white coral is found on the southern and western coasts in great abundance. The fuel consists chiefly of peat and turf, which are impregnated with iron ore and saltpetre; and coal has been discovered in several districts.

The wild birds of all sorts most common in the country are, solan geese, gulls, cormorants, cranes, wild geese, and wild ducks; eagles, crows, ravens, rooks, cuckoos, rails, woodcocks, moor-fowl, partridges, plover, wild pigeons, and blackbirds, owls, hawks, snipes, and a variety of small birds. In mild seasons, the cuckoo and rail appear in the latter end of April; the former disappears always before the end of June; the latter sometimes not till September. The woodcock comes in October, and frequently remains till March. The tame sorts of fowl are geese, ducks, turkeys, cocks, pullets, and tame pigeons.

The black cattle are here exposed to all the rigours of the severe winter, without any other provender than the tops of the heath and the alga marina; so that they appear like mere skeletons in the spring; though, as the grass grows up, they soon become plump and juicy, the beef being sweet, tender, and finely interlarded.—The amphibious animals are seals and otters. Among the reptiles they reckon vipers, asps, weasels, frogs, toads, and three different kinds of serpents; the first spotted black and white, and very poisonous; the second yellow,

low, with brown ſpots; and the third of a brown colour, the ſmalleſt and leaſt poiſonous.

Whales and cairbans, or ſun-fiſh, come in ſometimes to the ſounds after their prey, but are rarely purſued with any ſucceſs. The fiſhes commonly caught on the coaſt are herrings, ling, cod, ſcate, haddock, mackerel, lythe, ſye, and dog fiſh. The average price of ling at home is L. 13, 13 s. *per* ton; when ſold, one by one, if freſh, the price is from 3 d. to 5 d.; if cured, from 5 d. to 7d. The barrel of herrings ſeldom ſells under 19 s. which is owing to the great difficulty of procuring ſalt, even ſometimes at any price; and the ſame cauſe prevents many from taking more than are ſufficient for their own uſe.

The kyle of Scalpe teems with oyſters, in ſuch a manner, that after ſome ſpring-tides, 20 horſe-loads of them are left upon the ſands. Near the village of Bernſtill, the beach yields muſcles ſufficient to maintain 60 perſons *per* day; this providential ſupply helps to ſupport many poor families in times of ſcarcity.

The people are ſtrong, robuſt, healthy, and prolific. They generally profeſs the Proteſtant religion; are honeſt, brave, innocent, and hoſpitable. They ſpeak the language, wear the habit, and obſerve the cuſtoms that are common to all the Hebrides. The meconium in new-born infants is purged away with freſh butter: the children are bathed every morning and evening in water, and grow up ſo ſtrong, that a child of 10 months is able to walk alone: they never wear ſhoes or ſtockings before the age of eight or ten, and night-caps are hardly known; they keep their feet always wet; they lie on beds of ſtraw or heath, which laſt is an excellent reſtorative: they are quick of apprehenſion, ingenious, and very much addicted to muſic and poetry. They eat heartily of fiſh; but ſeldom regale themſelves with fleſh-meat: their ordinary food conſiſts of butter, cheeſe, milk, potatoes, colewort, brochan, and a diſh called *oon*, which indeed is no other than the froth of boiled milk or whey raiſed with a ſtick like that uſed in making chocolate.

A ſort of coarſe woollen cloth called *cloa*, or *caddoes*, the manufacture of their wives, made into ſhort jackets and trouſers, is the common dreſs of the men. The philibeg is rarely worn, except in ſummer and on Sundays; on which days, and ſome other occaſions, thoſe in better circumſtances appear in tartans, a bonnet, and ſhort hoſe, and ſome in a hat, ſhort coat, waiſtcoat, and breeches, of Scotch or Engliſh manufacture. The women are in general very cleanly, and ſo exceſſively fond of dreſs, that many maid-ſervants are often known to lay out their whole wages that way.

There are two fairs held annually at Portree, to which almoſt every part of Sky ſends cattle. The firſt is held in the end of May, and the ſecond in the end of July. The fair commonly continues from Wedneſday till the Saturday following. The commodities which are ſold in theſe are horſes, cows, ſheep, goats, hides, butter, cheeſe, fiſh, and wool. The cattle ſold in theſe fairs ſwim over to the main land through a mile or half a mile of ſea. Thouſands of theſe are yearly exported, at from L. 2 to L. 3 each. Many of them are driven to England, where they are fatted for the market, and counted delicious eating.

In Sky appear many ruins of Daniſh forts, watch-towers, beacons, temples, and ſepulchral monuments. All the forts are known by the term *Dun;* ſuch as Dun-Skudborg, Dun-Derig, Dun-Skerineſs, Dun-David, &c.

Sky-Colour. To give this colour to glaſs, ſet in the furnace a pot of pure metal of fritt from rochetta or barilla, but the rochetta fritt does beſt; as ſoon as the metal is well purified, take for a pot of twenty pounds of metal ſix ounces of braſs calcined by itſelf; put it by degrees at two or three times into the metal, ſtirring and mixing it well every time, and diligently ſkimming the metal with a ladle: at the end of two hours the whole will be well mixed, and a proof may be taken; if the colour be found right, let the whole ſtand 24 hours longer in the furnace, and it will then be fit to work, and will prove of a moſt beautiful ſky colour.

SLAB, an outſide ſappy plank or board ſawed off from the ſides of a timber-tree. The word is alſo uſed for a flat piece of marble.

Slab-Line, in ſea-language, a ſmall cord paſſing up behind a ſhip's main-ſail or fore-ſail, and being reeved through a block attached to the lower part of the yard, is thence tranſmitted in two branches to the foot of the ſail, to which it is faſtened. It is uſed to truſs up the ſail as occaſion requires, and more particularly for the convenience of the pilot or ſteerſman, that they may look forward beneath it as the ſhip advances.

SLACK-WATER, in ſea-language, denotes the interval between the flux and reflux of the tide, or between the laſt of the ebb and the firſt of the flood, during which the current is interrupted, and the water apparently remains in a ſtate of reſt.

SLACKEN, in metallurgy, a term uſed by the miners to expreſs a ſpongy and ſemivitrified ſubſtance, which they uſed to mix with the ores of metals, to prevent their fuſion. It is the ſcoria or ſcum ſeparated from the ſurface of the former fuſions of metals. To this they frequently add limeſtone, and ſometimes a kind of coarſe iron-ore, in the running of the poorer gold ores.

SLATE *(Stegania)*, a ſtone of a compact texture and laminated ſtructure, ſplitting into fine plates.

Dr Hill diſtinguiſhes four ſpecies of ſtegania. 1. The whitiſh ſteganium, being a ſoft, friable, ſlaty ſtone, of a tolerably fine and cloſe texture, conſiderably heavy, perfectly dull and deſtitute of brightneſs, variegated with a pale brown or browniſh yellow. This ſpecies is common in many counties of England, lying near the ſurface of the ground. It is generally very full of perpendicular as well as horizontal cavities, many of which are filled up with a ſpar a little purer and more cryſtalline than the reſt; and is commonly uſed for covering houſes. 2. The red ſteganium is a very fine and elegant ſlate, of a ſmooth ſurface, firm and compact texture, conſiderably heavy, and of a very beautiful pale purple, glittering all over with ſmall gloſſy ſpangles: it is compoſed of a multitude of very thin plates or flakes, laid cloſely and evenly over one another, and cohering pretty firmly: this is very common in the northern parts of England, and is much valued as a ſtrong and beautiful covering for houſes. 3. The common blue ſteganium is very well known as an uſeful and valuable ſtone, of a fine ſmooth texture and gloſſy ſurface, moderately heavy, and of a pale greyiſh blue; compoſed of a multitude of even plates, laid close upon one another, and easily splitting at the commissures of them: this is also very common in the north parts of England, and is used in most places for the covering of houses. There are other species of this slate, viz. the brownish blue friable steganium, usually called *Coal slate*; the greyish black friable steganium, commonly called *shiver*; and the greyish blue sparkling steganium. 5. The friable, aluminous, black steganium, being the Irish slate of the shops: this is composed of a multitude of thin flakes, laid very evenly and regularly over one another, and splits very regularly at the commissures of them. It is common in many parts of Ireland, and is found in some places in England always lying near the surface in very thick strata. In medicine it is used in hemorrhagies of all kinds with success, and is taken often as a good medicine in fevers.

The island of Eusdale, one of the Hebrides on the west coast of Scotland, is entirely composed of slate. The stratum it 36 feet thick. About two millions and a half, at the rate of twenty shillings per thousand, are sold annually to England, Canada, the West Indies, and Norway.

SLAVE. See SLAVERY.

1 Slavery defined.

SLAVERY is a word, of which, though generally understood, it is not easy to give a proper definition. An excellent moral writer has defined it to be "an obligation to labour for the benefit of the master, without the contract or consent of the servant." But may not he be properly called a slave who has given up his freedom to discharge a debt which he could not otherwise pay, or who has thrown it away at a game of hazard? In many nations, debts have been legally discharged in this manner; and in some savage tribes, such is the universal ardour for gaming, that it is no uncommon thing for a man, after having lost at play all his other property, to stake, on a single throw of dice, himself, his wife, and his children (A). That persons who have thus lost their liberty are slaves, will hardly be denied; and surely the infatuated gamester is a slave by his own contract. The debtor, too, if he was aware of the law, and contracted debts larger than he could reasonably expect to be able to pay, may justly be considered as having come under an obligation to labour for the benefit of a master *with his own consent*; for every man is answerable for all the known consequences of his voluntary actions.

This definition of slavery seems to be defective as well as inaccurate. A man may be under an obligation to labour through life for the benefit of a master, and yet that master have no right to dispose of him by sale, or in any other way to make him the property of a third person; but the word *slave*, as used among us, always denotes a person who may be bought and sold like a beast in the market (B). In its original sense, indeed, it was of the same import with *noble, illustrious*; but vast numbers of the people among whom it had that signification being, in the decline of the Roman empire sold by their countrymen to the Venetians, and by them dispersed over all Europe, the word *slave* came to denote a person in the lowest state of servitude, who was considered as the absolute property of his master. See PHILOLOGY, n° 220.

2 Inequalities of rank inevitable.

As nothing can be more evident than that all men have, by the law of nature, an equal right to life, liberty, and the produce of their own labour (see RIGHT, n° 5.), it is not easy to conceive what can have first led one part of them to imagine that they had a right to enslave another. Inequalities of rank are indeed inevitable in civil society; and from them results that servitude which is founded in contract, and is of temporary duration. (See MORAL PHILOSOPHY, n° 141.) He who has much property has many things to attend to, and must be disposed to hire persons to assist and serve him; while those who have little or no property must be equally willing to be hired for that purpose. And if the master be kind, and the servant faithful, they will both be happier in this connection than they could have been out of it. But from a state of servitude, where the slave is at the absolute disposal of his master in all things, and may be transferred without his own consent from one proprietor to another, like an ox or an ass, happiness must be for ever banished. How then came a traffic so unnatural and unjust as that of slaves to be originally introduced into the world?

The common answer to this question is, that it took its rise among savages, who, in their frequent wars with each other, either massacred their captives in cold blood, or condemned them to perpetual slavery. In support of this opinion we have heard it observed, that the Latin word *servus*, which signifies not a *hired* servant, but a *slave*, is derived from *servare*, "to preserve;" and that such men were called *servi*, because they were captives, whose lives were preserved on the condition of their becoming the property of the victor.

3 Origin of slavery.

That slavery had its origin from war, we think extremely probable (C), nor are we inclined to controvert this etymology of the word *servus*; but the traffic in men prevailed almost universally long before the Latin lan-

(A) Aleam (quod mirere) sobrii inter seria exercent, tanta lucrandi perdendive temeritate, ut cum omnia defecerunt, extremo ac novissimo jactu de libertate et corpore contendant. Victus voluntariam servitutem adit; quamvis junior, quamvis robustior, alligari se ac venire patitur.—*Tacitus de Mor. Germ.*

The savages of North America are equally addicted to gaming with the ancient Germans, and the negroes on the Slave Coast of Guinea perhaps still more.

(B) The Roman orator's definition of *slavery*, Parad. V. is as accurate as any that we have seen. "Servitus est obedientia fracti animi et abjecti et arbitrio carentis suo;" whether the unhappy person fell into that state with or without his own contract or consent.

(C) In the article SOCIETY, the reader will find another account of the origin of slavery, which we think likewise probable, though we have not transferred it to this place; as it would, in our opinion, be wrong to give to one writer what we know to belong to another. It may be proper, however, to observe here, that between the two articles there is no contradiction, as barbarous wars were certainly *one* source of slavery.

language or Roman name was heard of; and there is no good evidences that it began among savages. The word עבד, in the Old Testament, which in our version is rendered *servant*, signifies literally a *slave*, either born in the family or bought with money, in contradistinction to שכיר, which denotes a hired servant: and as Noah makes use of the word עבד in the curse which he denounces upon Ham and Canaan immediately after the deluge, it would appear that slavery had its origin before that event. If so, there can be little doubt but that it began among those violent persons whom our translators have called *giants* *, though the original word נפלים literally signifies *assaulters of others*. Those wretches seem first to have seized upon women, whom they forcibly compelled to minister to their pleasures; and from this kind of violence the progress was natural to that by which they enslaved their weaker brethren among the men, obliging them to labour for their benefit, without allowing them fee or reward.

4 Prior to the deluge.

* Gen. vi.

5 Nimrod enslaved his captives.

After the deluge the first dealer in slaves seems to have been Nimrod. "He began," we are told, "to be a mighty one in the earth, and was a mighty hunter before the Lord." He could not, however, be the first hunter of wild beasts; for that species of hunting must have been practised from the beginning; nor is it probable that his dexterity in the chase, which was then the universal employment, could have been so far superior to that of all his contemporaries, as to entitle him to the appellation of the "mighty hunter before the Lord." Hence most commentators have concluded, that he was a hunter of men; an opinion which they think receives some countenance from the import of his name, the word *Nimrod* signifying a rebel. Whatever be in this, there can be little doubt but that he became a mighty one by violence; for being the sixth son of his father, and apparently much younger than the other five, it is not likely that his inheritance exceeded theirs either in extent or in population. He enlarged it, however, by conquest; for it appears from Scripture, that he invaded the territories of Ashur the son of Shem, who had settled in Shinar; and obliging him to remove into Assyria, he seized upon Babylon, and made it the capital of the first kingdom in the world. As he had great projects in view, it seems to be in a high degree probable that he made bond servants of the captives whom he took in his wars, and employed them in building or repairing the metropolis of his kingdom; and hence we think is to be dated the origin of postdeluvian slavery.

6 Slavery in the days of Abraham.

That it began thus early can hardly be questioned; for we know that it prevailed universally in the age of Abraham, who was born within seventy years after the death of Nimrod. That patriarch had three hundred and eighteen servants or slaves, born in his own house, and trained to arms, with whom he pursued and conquered the four kings who had taken captive his brother's son †. And it appears from the conversation which took place between him and the king of Sodom after the battle, that both believed the conqueror had a right to consider his prisoners as part of his spoil. "Give me (says the king) the *persons*, and take the *goods* to thyself." It is indeed evident from numberless passages of Scripture, that the domestics whom our translators call *servants* were in those days universally considered as the most valuable part of their master's property, and classed with his flocks and herds. Thus, when the sacred historian describes the wealth of Abraham, he says, that "he had sheep and oxen, and he-asses, and men-servants, and maid-servants, and she-asses, and camels." And when Abimelech wished to make some reparation to the patriarch for the unintended injury that he had done him, "he took sheep and oxen, and men-servants, and women-servants, and gave them unto Abraham, and restored to him Sarah his wife." The riches and power of Isaac and Jacob are estimated in the very same manner. Of the former it is said, that "the man waxed great, and went forward and grew, until he became very great; for he had possession of flocks, and possession of herds, and great store of servants, ועבדה of slaves; and the Philistines envied him." The latter, we are told, "increased exceedingly, and had much cattle, and maid-servants, and men-servants, and camels, and asses‡."

† Gen. xiv.

‡ Gen. xii. 16. xx. 14. xxiv. 35. xxvi. 13, 14. xxx. 43.

That the practice of buying and selling servants thus early begun among the patriarchs descended to their posterity, is known to every attentive reader of the Bible. It was expressly authorised by the Jewish law, in which are many directions how such servants were to be treated. They were to be bought only of the heathen; for if an Israelite grew poor and sold himself either to discharge a debt, or to procure the means of subsistence, he was to be treated not as a slave עבד, but as a hired servant שכיר, and restored to freedom at the year of Jubilee. "Both thy bond-men and thy bond-maids (says Moses) shall be of the heathen that are round about you: of them shall ye buy bond-men and bond-maids. And ye shall take them as an inheritance for your children after you, to inherit them for a possession; they shall be your bond-men for ever ||." Unlimited as the power thus given to the Hebrews over their bond-servants of heathen extraction appears to have been, they were strictly prohibited from acquiring such property by any other means than fair purchase: "he that *stealeth* a man and selleth him," said their great lawgiver, "shall surely be put to death §."

7 Authorised by the Mosaic law.

|| Lev. xxv. 39, 40, 44. 46.

§ Lev. xxi. 16.

8 Spread over the whole world.

Whilst slavery, in a mild form, was permitted among the people of God, a much worse kind of it prevailed among the heathen nations of antiquity. With other abominable customs, the traffic in men quickly spread from Chaldea into Egypt, Arabia, and over all the east, and by degrees found its way into every known region under heaven (D).

Of this hateful commerce we shall not attempt to trace the progress thro' every age and country, but shall content

(D) If credit be due to a late account of China, the people of that vast empire have never made merchandise of men or women. The exception however, is so singular, that we should be glad to see it better authenticated; for it is apparent from works of the most undoubted credit, that over all the other eastern countries with which we are acquainted slavery has prevailed from time immemorial, and that some of the Indian nations make long journeys into Africa for the sole purpose of buying slaves.

Slavery. tent ourselves with taking a transient view of it among the Greeks and Romans, and a few other nations, in whose customs and manners our readers must be interested.

9 Slavery among the Greeks and

One can hardly read a book of the Iliad or Odyssey, without perceiving that, in the age of Homer, all prisoners of war were liable to be treated as slaves, and compelled, without regard to their rank, sex, or years, to labour for their masters in offices of the vilest drudgery. So universally was this cruel treatment of captives admitted to be the right of the victor, that the poet introduces Hector, in the very act of taking a tender and perhaps last farewell of his wife, when it was surely his business to afford her every consolation in his power, telling her, as a thing of course which could not be concealed, that, on the conquest of Troy, she would be compelled

To bear the victor's hard commands, or bring
The weight of water from Hyperia's spring (E).

Pope.

At that early period, the Phœnicians, and probably the Greeks themselves, had such an established commerce in slaves, that, not satisfied with reducing to bondage their prisoners of war, they scrupled not to kidnap in cold blood persons who had never kindled their resentment, in order to supply their foreign markets. In the 14th book of the Odyssey, Ulysses represents himself as having narrowly escaped a snare of this kind laid for him by a false Phœnician, who had doomed the hero to Libyan slavery; and as the whole narrative, in which this circumstance is told, is an artful fiction, intended to have the appearance of truth to an Ithacan peasant, the practice of kidnapping slaves could not then have appeared incredible to any inhabitant of that island.

Such were the manners of the Greeks in the heroic age; nor were they much improved in this respect at periods of greater refinement. Philip of Macedon having conquered the Thebans, not only sold his captives, but even took money for premitting the dead to be buried *; and Alexander, who had more generosity than Philip, afterwards razed the city of Thebes, and sold the inhabitants, men, women, and children, for slaves†. This cruel treatment of a brave people may indeed be supposed to have proceeded, in the first instance, from the avarice of the conqueror; and in the second, from the momentary resentment of a man who was savage and generous by turns, and who had no command of his passions. We shall not positively assign it to other causes; but from the manner in which the Spartans behaved to their slaves, there is little reason to imagine that had they received from the Thebans the same provocation with Alexander, they would have treated their captives with greater lenity. "At Sparta (says a humane and elegant writer) slaves were treated with a degree of rigour that is hardly conceivable; although to them, as their husbandmen and artificers, their proud and idle masters were indebted for all the necessaries of life. The Lacedemonian youth, trained up in the practice of deceiving and butchering those poor men, were from time to time let loose upon them in order to show their proficiency in stratagem and massacre. And once, without any provocation, and merely for their own amusement, we are told that they murdered three thousand in one night, not only with the connivance of law, but by its avowed permission. Such, in promoting the happiness of one part of society, and the virtue of another, are the effects of slavery."

* Justin. lib. iii. cap. 4.

† Justin et Arrian.

Beattie's Moral Science, vol. ii.

It has been said, that in Athens and Rome slaves were better treated than in Sparta: but in the former city their treatment cannot have been good, nor their lives comfortable, where the Athenians relished that tragedy of Euripides in which Hecuba, the wife of Priam, is introduced as lamenting that she was chained like a dog at Agamemnon's gate! Of the estimation in which slaves were held in Rome, we may form a tolerable notion from the well known fact, that one of those unhappy beings was often chained at the gate of a great man's house, to give admittance to the guests invited to a feast*. In the early periods of the commonwealth it was customary, in certain sacred shews exhibited on solemn occasions, to drag through the circus a slave, who had been scourged to death holding in his hand a fork in the form of a gibbet†. But we need not multiply proofs of the cruelty of the Romans to their slaves. If the inhuman combats of the gladiators (see GLADIATORS) admit of any apology on account of the martial spirit with which they were thought to inspire the spectators, the conduct of Vedius Pollio must have proceeded from the most wanton and brutal cruelty. This man, who flourished not in the earliest periods of the republic, when the Romans were little better than a savage banditti, but in the polished age of Augustus, frequently threw such slaves as gave him the slightest offence into his fish-ponds to fatten his lampreys; and yet he was suffered to die in peace! The emperor, indeed, upon coming to the knowledge of his cruelty, ordered his lampreys to be destroyed, and his ponds to be filled up; but we do not recollect that any other punishment was inflicted on the savage master. Till the reign of the same emperor the depositions of slaves were never admitted in the courts of judicature; and then they were received only when persons were accused of treasonable practices.

10 Romans.

* Kames's Sketches.

† Cicero de Div. lib. i. cap. 26.

11 Origin of Roman slavery.

The origin of slavery in Rome was the same as in every other country. Prisoners of war were of course reduced to that state, as if they had been criminals. The dictator Camillus, one of the most accomplished generals of the republic, sold his Hetrurian captives to pay the Roman ladies for the jewels which they had presented to Apollo. Fabius, whose cautious conduct saved his country when Hannibal was victorious in Italy, having subdued Tarentum, reduced 30,000 of the citizens to slavery, and sold them to the highest bidder. Coriolanus, when driven from Rome, and fighting for the Volsci, scrupled not to make slaves of his own countrymen; and Julius Cæsar, among whose faults wanton cruelty

(E) In those early times drawing water was the office of the meanest slaves. This appears from Joshua's curse upon the Gibeonites who had deceived him —"Now therefore ye are cursed, and there shall none of you be freed from being bond-men, and hewers of wood, and drawers of water, for the house of my God." To this state of bondage Homer makes Hector say, that Andromache would *necessarily* be brought upon the destruction of Troy; κρατερη δ' επικεισετ' αναγκη —*Il. lib.* vi.

Slavery. cruelty has never been reckoned, sold at one time fifty-three thousand captives for slaves. Nor did the slaves in Rome consist only of foreigners taken in war. By one of the laws of the twelve tables, creditors were empowered to seize their insolvent debtors, and keep them in their houses till, by their services or labour, they had discharged the sum they owed: and in the beginning of the commonwealth they were authorised to sell such debtors, and even to put them to death (F). The children of slaves were the property not of the commonwealth, or of their own parents, but of their masters; and thus was slavery perpetuated in the families of such unhappy men as fell into that state, whether through the chance of war or the cruelty of a sordid creditor (G). The consequence was, that the number of slaves belonging to the rich Patricians was almost incredible. Caius Cæcilius Isidorus, who died about seven years before the Christian era, left to his heirs 4116 slaves; and if any one of those wretched creatures made an unsuccessful attempt to regain his liberty, or was even suspected of such a design, he was marked on the forehead with a red hot iron (H). In Sicily, during the most flourishing periods of the commonwealth, it seems to have been customary for masters to mark their slaves in this manner; at least we know that such was the practice of Damophilus, who, not satisfied with this security, shut up his slaves every night in close prisons, and led them out like beasts in the morning to their daily labour in the field. Hence arose the servile war in Sicily.

12 Its duration.

Though many laws were enacted by Augustus and other patriotic emperors to diminish the power of creditors over their insolvent debtors; though the influence of the mild spirit of Christianity tended much to meliorate the condition of slaves, even under Pagan masters, and though the emperor Adrian made it capital to kill a slave without a just reason; yet this infamous commerce prevailed universally in the empire for many ages after the conversion of Constantine to the religion of Christ. It was not indeed completely abolished even in the reign of Justinian; and in many countries which had once been provinces of the empire it continued long after the empire itself had fallen to pieces.

13 Slavery among the ancient Germans.

It has already been observed, that among the ancient Germans it was not uncommon for an ardent gamester to lose his personal liberty by a throw of the dice. This was indeed a strong proof of savage manners; but the general condition of slaves among those savages seems to have been much better than among the polished Greeks and Romans. In Germany the slaves were generally attached to the soil, and only employed in tending cattle, and carrying on the business of agriculture; for the menial offices of every great man's house were performed by his wife and children. Such slaves were seldom beaten, or chained, or imprisoned. Sometimes indeed they were killed by their masters in a fit of sudden passion; but none were considered as materials of commerce, except those who had originally been freemen, and lost their freedom by play. These, indeed, the successful gamester was very ready to sell, both because he felt them an useless burden, and because their presence continually put him in mind of that state to which a throw of the dice might one day reduce himself.

Such is the account which Tacitus gives ‡ of slavery among the ancient Germans. The Anglo-Saxons, however, after they were settled in Britain seem not to have carried on that traffic so honourably. By a statute of Alfred the Great †; the purchase of a *man*, a *horse*, or an *ox*, without a voucher to warrant the sale, was strictly forbidden. That law was, doubtless, enacted to prevent the *stealing* of *men* and cattle; but it shows us

‡ De Mor. Germ. 24–25.

† Wilkins's Collection of Laws from Ethelbert to Henry III.

(F) After a certain number of citations, the law granted to the debtor thirty days of grace to raise the sum for which he was accountable. The words of the law are: "Æris confessi, rebusque jure judicatis, triginti dies justi sunto. Post dein manum endojacito.—Vincito aut nervo, aut compedibus." "When the debt is confessed, and the trial passed, let there be thirty days of forbearance: afterwards lay hands on him; bind him either with a cord or fetters." After the thirty days were expired, if the debtor had not discharged the debt, he was led to the prætor, who delivered him over to the mercy of his creditors; these bound him and kept him in chains for the space of sixty days. Afterwards, for three market-days successively, the debtor was brought to the tribunal of the prætor; then a public crier proclaimed in the forum the debt for which the prisoner was detained. It often happened, that rich persons redeemed the prisoner by paying his debts; but if nobody appeared in behalf of the debtor after the third market-day, the creditor had a right to inflict the punishments appointed by the law. "Tertiis nundinis capite pœnas dato aut trans Tiberim peregre venumduito;" that is, "Let him on the third market-day be punished with death, or sold beyond the Tiber as a slave." If there were several creditors, they were allowed, in consequence of this severe law, to divide the body of the prisoner into several parts, and share it among them in proportion to the sum which they demanded.

(G) This is evident from the story of Appius and Virginia. See Rome, n° 113.

(H) How capriciously and unjustly this infamous mark was impressed, we learn from the story of Restio. This man being proscribed, and a reward offered for his head by the triumvirs Octavianus, Antony, and Lepidus, concealed himself from the fury of the tyrants in the best way that he could. A slave whom he had marked with the hot iron having found out the place of his retreat, conducted him to a cave, and there supported him for some time with what he earned by his daily labour. At length a company of soldiers coming that way, and approaching the cave, the faithful slave, alarmed at the danger his master was in, followed them close, and falling upon a poor peasant, killed him in their presence, and cut off his head, crying out, "I am now revenged on my master for the marks with which he has branded me." The soldiers, seeing the infamous marks on his forehead, and not doubting but he had killed Restio, snatched the head out of his hand, and returned with it in all haste to the triumvirs. They were no sooner gone, than the slave conveyed his master to the sea-side, where they had the good luck to find one of Sextius Pompeius's vessels, which transported them safe into Sicily.

Slavery.

14 In England and

us that ſo late as the ninth or tenth century a man, when fairly purchaſed, was, in England, as much the property of the buyer as the horſe on which he rode, or the ox which dragged his plough. In the ſame country, now ſo nobly tenacious of freedom and the rights of man, a ſpecies of ſlavery ſimilar to that which prevailed among the ancient Germans ſubſiſted even to the end of the ſixteenth century. This appears from a commiſſion iſſued by Queen Elizabeth in 1574, for inquiring into the lands and goods of all her *bond-men* and *bond-women* in the counties of Cornwall, Devon, Somerſet, and Glouceſter, in order to compound with them for their manumiſſion, that they might enjoy their lands and goods as freemen ‖. In Scotland there certainly exiſted an order of ſlaves or bond-men, who tilled the ground, were attached to the ſoil, and with it were transferable from one proprietor to another, at a period ſo late as the thirteenth century; but when or how thoſe villains, as they were called, obtained their freedom, ſeems to be unknown to every lawyer and antiquary of the preſent day. Coalliers and ſalters were, in the ſame country, ſlaves till little more than 20 years ago, that they were manumitted by an act of the Britiſh legiſlature, and reſtored to the rights of freemen and citizens. Before that period the ſons of coalliers could follow no buſineſs, but that of their fathers; nor were they at liberty to ſeek employment in any other mines that thoſe to which they were attached by birth, without the conſent of the lord of the manor, who, if he had no uſe for their ſervices himſelf, transferred them by a written deed to ſome neighbouring proprietor.

15 Scotland.

16 Slavery among the Carthaginians,

That the ſavage nations of Africa were at any period of hiſtory exempted from this opprobrium of our nature which ſpread over all the reſt of the world, the enlightened reader will not ſuppoſe. It is indeed in that vaſt country that ſlavery has in every age appeared in its uglieſt form. We have already obſerved, that about the era of the Trojan war, a commerce in ſlaves was carried on between Phœnicia and Lybia: and the Carthaginians, who were a colony of Phœnicians, and revered the cuſtoms, manners, and religion of their parent ſtate, undoubtedly continued the Tyrian traffic in human fleſh with the interior tribes of Africa. Of this we might reſt aſſured, although we had no other evidence of the fact than what reſults from the practice of human ſacrifices ſo prevalent in the republic of Carthage. The genuine inſtincts of nature are often ſubdued by dire ſuperſtition, but they cannot be wholly eradicated; and the rich Carthaginian, when a human victim was demanded from him to the gods, would be ready to ſupply the place of his own child by the ſon of a poor ſtranger, perfidiouſly purchaſed at whatever price. That this was, indeed, a very common practice among them, we learn from the teſtimony of various hiſtorians *, who aſſure us, that when Agathocles the tyrant of Syracuſe had overthrown their generals Hanno and Bomilcar, and threatened Carthage itſelf with a ſiege, the people attributed their misfortunes to the juſt anger of Saturn for having been worſhipped, for ſome years, by the ſacrifices of children meanly born and ſecretly *bought* inſtead of thoſe of noble extraction. Theſe ſubſtitutions of one offering for another were conſidered as a profane deviation from the religion of their forefathers; and therefore to expiate the guilt of ſo horrid an impiety, a ſacrifice of two hundred children of the firſt rank was on that occaſion made to the bloody god. As the Carthaginians were a commercial people, we cannot ſuppoſe that they purchaſed ſlaves only for ſacrifices. They undoubtedly condemned many of their priſoners of war to the ſtate of ſervitude, and either ſold them to foreigners, or diſtributed them among their ſenators and the leaders of their armies. Hanno who endeavoured to uſurp the ſupreme power in Carthage whilſt that republic was engaged in war with Timoleon in Sicily ‡, armed twenty thouſand of his ſlaves in order to carry his nefarious purpoſe into execution; and Hannibal, after his deciſive victory at Cannæ, ſold to the Greeks many of his priſoners whom the Roman ſenate refuſed to redeem ¶. That illuſtrious commander was indeed more humane, as well as more politic, than the generality of his countrymen. Before his days it was cuſtomary with the Carthaginians either to maſſacre their captives in cold blood, that they might never again bear arms againſt them, or to offer them in ſacrifice as a grateful acknowledgment to the gods by whoſe aſſiſtance they believed that they were vanquiſhed; but this was not always done even by their moſt ſuperſtitious or moſt unprincipled leaders. Among other rich ſpoils which Agathocles, after his victory already mentioned, found in the camp of Hanno and Bomilcar, were twenty thouſand pair of fetters and manacles, which thoſe generals had provided for ſuch of the Sicilian priſoners as they intended to preſerve alive and reduce to a ſtate of ſlavery.

‡ Juſtin. lib. xxi. cap. 6. and Univerſal Hiſtory.
¶ Tit. Liv. Appian and Zonaras

16 And Numidians.

With the ancient ſtate of the other African nations we are but very little acquainted. The Numidians, Mauritanians, Getulians, and Garamantes, are indeed mentioned by the Roman hiſtorians, who give us ample details of the battles which they fought in attempting to preſerve their national independence; but we have no particular account of their different manners and cuſtoms in that age when Rome was diſputing with Carthage the ſovereignty of the world. All the African ſtates of which we know any thing, were in alliance with one or other of thoſe rival republics; and as the people of thoſe ſtates appear to have been leſs enlightened than either the Romans or the Carthaginians, we cannot ſuppoſe that they had purer morals, or a greater regard for the ſacred rights of man, than the powerful nations by whom they were either protected or oppreſſed. They would, indeed, inſenſibly adopt their cuſtoms; and the ready market which Marius found for the priſoners taken in the town Capſa, although Salluſt acknowledges ‡ that the ſale was contrary to the laws of war, ſhows that ſlavery was then no ſtrange thing to the Numidians. It ſeems indeed to have prevailed through all Africa from the very firſt peopling of that unexplored country; and we doubt if in any age of the world the unhappy negro was abſolutely ſecure of his perſonal freedom, or even of not being ſold to a foreign trader.

‡ Bell. Jug. cap. 91.

18 Slave-trade with the coaſt of Guinea begun not by the Portugueſe,

It is the common opinion that the practice of making ſlaves of the negroes is of a very modern date; that it owes its origin to the incurſions of the Portugueſe on the weſtern coaſt of Africa; and that but for the cunning or cruelty of Europeans, it would not now exiſt, and would never have exiſted. But all this is a complication of miſtakes. A learned writer has lately proved, with a force of evidence which admits of no reply *, that from the Coaſt of Guinea a great trade in ſlaves

* Whitaker's Review of Gibbon's Roman Hiſtory.

Slavery.

19 But by the Arabs at an early period.

was carried on by the Arabs some hundreds of years before the Portuguese embarked in that traffic, or had even seen a woolly-headed negro. Even the wandering Arabs of the desert, who never had any friendly correspondence with the Christians of Europe, have from time immemorial been served by negro slaves. "The Arab must be poor indeed (says M. Saugnier) not to have at least one negro slave. His sole occupation is the care of the herd. They are never employed in war, but they have it in their power to marry. Their wives, who are captive negresses, do all the domestic work, and are roughly treated by the Arabian women, and by the Arabs themselves. Their children are slaves like them, and put to all kinds of drudgery." Surely no man whose judgement is not completely warped by prejudice, will pretend that those roving tribes of savages, so remarkable for their independent spirit and attachment to ancient customs, learned to enslave the negroes from the Europeans. In all probability they have, without interruption, continued the practice of slavery from the days of their great ancestor Ishmael; and it seems evident, that *none of the European nations had even seen a woolly-headed negro till the year* 1100, when the crusaders fell in with a small party of them near the town of Hebron in Judea, and were so struck with the novelty of their appearance, that the army burst into a general fit of laughter ||. Long before the crusades, however, we know with certainty that the natives of Guinea had been exposed to sale in foreign countries. In 651 the Mahometan Arabs of Egypt so harassed the king of Nubia or Ethiopia, who was a Christian, that he agreed to send them annually, by way of tribute, a *vast number of Nubian or Ethiopian slaves* into Egypt. Such a tribute as this at that time, we are told, was more agreeable to the khalif than any other, as the Arabs then made *no small account of those slaves* ‡.

Saugnier's and Brisson's Voyages.

|| Malmsbury, fol. p. 83.

‡ Modern Universal History, vol. i. 525.

The very proposal of such a tribute, and the estimation in which black slaves were held in Egypt, shows that a commerce in bond-servants could not then be a new branch of trade either to the Arabs or the Ethiopians; but the vast number which the Ethiopian monarch was now compelled to furnish every year, induced him to feed this great drain upon his subjects from the natives of the neighbouring countries. "He ranged accordingly into all that vast *blank of geography*, upon the map of the world, the spreading bosom of the African continent; and even pushed through it to its farthest extremities in the west. He thus brought the blacks of Guinea, for the first time, into the service and families of the east; and the slaves which he paid in tribute to the Arabs, whether derived from the nearer neighbourhood of Ethiopia, fetched from the Mediterranean regions of Africa, or brought from the distant shores of the Atlantic, were all denominated *Ethiopians*, from the country by which they were conveyed into Egypt ‡. "At this time, therefore, according to Mr Whitaker, began that kind of traffic in human flesh

‡ Whitaker's Review.

"Which spoils unhappy Guinea of its sons."

There are not many authors from whom, in questions of antiquity, we differ with greater hesitation; but, as we meet with a female Ethiopian slave in the Eunuch of Terence, we cannot help suspecting that Guinea was occasionally "spoiled of its sons" at a much earlier period. At any rate, from the observations made by the European travellers who first penetrated into that continent, it appears undeniable that slavery must have prevailed from time immemorial among such of the tribes as had never carried on any commerce with foreign nations. When Battel first visited the Giagas*, those people had never before seen a white man; yet they welcomed him and the English, with whom he had come, to their country, invited them to bring their goods on shore, and without hesitation loaded the ship with slaves. The Giagas were indeed waging war with the kingdom of Benguela; and being cannibals, who prefer human flesh to all others, the slaves whom they had sold to the English were probably prisoners whom they would have killed and eaten if they had not found an opportunity of otherwise disposing of them to greater advantage. But as they had not been incited by the Europeans to eat their prisoners, there can be no reason to suppose that by the Europeans they had been first induced to sell them: for we have seen that this kind of commerce prevailed in Africa among people much more polished than the Giagas so early as in the reign of Jugurtha.

20 The negroes have enslaved one another from time immemorial.

* Modern Universal History, vol. xiii. chap. 47. sect. 2.

That it was not introduced among the negroes either by the Arabs or by the Portuguese, appears still more evident from the behaviour of the Dahomans at the conquest of Whidah, and from the manner in which the people of Angola at the earliest stage of their foreign trade procured a supply of slaves for the Portuguese market. The greater part of the slaves whom the Angolans exported from St Paulo de Loanda were brought from interior countries, some hundreds of leagues distant, where they could not have been regularly purchased had that commerce been till then unknown in those countries. The Dahomans, in the beginning of the year 1727, had never seen a white man: and when their victorious prince and his army, in their rout through Whidah, first met with some Europeans in the town of Sabi, they were so shocked at their complexion and their dress, that they were afraid to approach them, and could not be persuaded that they were men till they heard them speak, and were assured by the Whidanese that these were the merchants who purchased all the slaves that were sold in Guinea †. Slavery, therefore, if it prevailed among the Dahomans before that period, could not have been introduced among them by European or Arabian intrigues: but we are assured by Snelgrave, who was then in the army, that those people treated their captives with such horrid cruelty as was shocking to the natives of the sea-coast, and leaves no room for doubt but that slavery had been practised among them from the earliest ages. A great part of their prisoners were sacrificed to their gods or eaten by the soldiers; and when our author expressed to a colonel of the guard some surprise that a prince so enlightened as the sovereign of Dahomy should sacrifice so many men whom he might have sold to great advantage, he was gravely told, that it had been the custom of their nation, from time immemorial, to offer, after victory, a certain number of prisoners to the gods; and that they selected the old men for victims, because they were of less value at market, and more dangerous from their experience and cunning, than the young men. To those persons who fancy that the wars between the African princes are carried on for the sole purpose of supplying the European ships with slaves, it may be proper to remark, that one of the kings of Dahomy slaughtered at once not only all the captives taken

† Modern Universal History, vol. xiii. p. 346, &c.

ken in war, but also 127 prisoners of different kinds, that he might have a sufficiency of skulls to adorn the walls of his palace; though at the very time of that massacre he *knew* that there were six slave-ships in the road of Whidah from which he could have got for every prime slave a price little short of thirty pounds Sterling ‡.

‡ Dalzel's History of the kingdom of Dahomy.

These facts, and numberless others which the reader will find detailed in the 13th volume of the Modern Universal History, by writers who were at the greatest pains to procure authentic information; who were neither biassed by interest nor blinded by enthusiasm; and who appear to have held the infamous traffic in utter abhorrence—prove beyond the possibility of doubt, that slavery of the worst kind must have prevailed among all the negro nations before they were visited either by the Portuguese or by the Arabs (I). These two nations may indeed have been the first who dragged the unhappy negro from his native continent, and made his slavery doubly severe, by compelling him to labour, without his own consent, for masters whom he hardly considered as human beings.

On the beginning of this commerce, or the dreadful cruelty with which it has been carried on to the present day, it is impossible to reflect without horror: but there is some consolation, however small, in knowing that its original authors were not Europeans. The purchase of Guinea blacks for slaves by foreign nations commenced ages before the Portuguese had laid that country open to the intercourse of Europe. Even after they had made many incursions into it, the inhabitants were as regularly purchased for slaves by some of the adjoining states as
21
they are now by the maritime Europeans.

21 The route by which the Arabs carried on the slave-trade, Whitaker's Review, p. 185.

"The Arabs of Egypt having reduced all the north of Africa, and carrying with them their love of black servants, would be sure to open a ready communication for themselves to their country. They certainly had one so early as 1512, and before the Europeans had any for that purpose (K). They went from Barbary by a route that was so much practised, as to be denominated expressly 'the way of the camels.' Meeting together at the town of Cape Cantin, that of Valadie near it, the commercial caravan traversed the vast deserts, those of Sarra, which run like the tropic of Cancer over them in a long line across the country; to a place of great population called Hoden, the *Waden* or *Hoden* of our maps, and a little to the south-west of Cape Blanco. From Hoden they turned to the left, and pushed directly into the interior of the continent, to reach Tegazza, the *Tagazel* or *Tagaza* of our maps, and lying nearly east of Hoden. Here assuredly they did, as the caravan does certainly at this day; and added to the other wares upon their camels a quantity of salt from those mines of rock-salt, which are extraordinary enough to be noticed as rocks in our maps. This they carried, as they still carry it, to Tanbut, the *Tombut* of the maps, and a town in the heart of the African continent. And from this town they turned on the right for the sea coast again, and reached it in the great kingdom of Mele, the *Melli* of our maps, to the south of the Gambia, and just at the springing as it were of that grand arch of sea which curves so deeply into the body of the land, and constitutes the extensive gulph of Guinea. At Melli and at Tombut they received a measure of gold for a measure of salt. The caravan collects gold at Tombut to the present time; but at Melli they purchased gold, and also silver, in pieces as large as pebbles. And at Hoden they had *a great mart for slaves*; the blacks being brought thither from the countries adjoining, and bartered away to the traders. Such was the Slave Coast and the Gold Coast of former days. The staple commodity of Hoden is only transferred now to Whidah; and diverted from the Arabs of Barbary
to the Christians of Europe," by whom the negroes are 22
carried to the continent of America or to the Sugar Islands in the West Indies. In these countries they are all sold like beasts in a market; but they experience very different degrees of servitude from the different masters who hold them as property. Such of them as are reconciled to the appearance of white men, or have been born in the European colonies, feel themselves as happy under a humane master as they could be in their native continent (L); and we believe that few of them in such circumstances have expressed a desire to return."

22 Which is now transferred to the Europeans.

In the French West India islands, before the late revolution

(I) The same thing appears from the voyages of M. Saugnier, who had an opportunity of conversing with many tribes of negroes, and who always speaks of slavery as an established practice among them; adding, that such as are sold for crimes are put to death by their own countrymen if they fly from their master. It appears likewise in a still more striking light from Dalzel's History of Dahomy, where we are told that all the Dahomans, from the lowest to the highest, acknowledge the right of the sovereign to dispose of their persons and properties at pleasure; and where we learn, that the sovereign himself assured Mr Abson the English governor at Whidah, that all his ancestors had from time immemorial put to death every prisoner of war whom they could not sell as a slave.

(K) In the year 1442, Anthony Gonsalez, a Portuguese adventurer, restored to their native country some Moorish prisoners whom he had two years before forcibly carried off from the coast of Africa. He landed them at *Rio del Oro*, and received from the Moors in exchange ten blacks, and a quantity of gold dust. This transaction proves, that a commerce in black servants was then regularly carried on by the Moors and not by the Portuguese. So early as the year 1502, the Spaniards began to employ a few negroes in the mines of Hispaniola; but in the year following, Ovando, the governor of that island, forbade the further importation of them, alleging that they taught the Indians all manner of wickedness, and rendered them less tractable than formerly: and it was not till the year 1517 that the supply of negroes to the Spanish American plantations became an established and regular branch of commerce. *Edward's History of the West Indies*, Book IV. Chap. ii.

(L) "I have observed many of my slaves go on board the vessel with joy, on my assurance that they would be well treated and happy on the plantation where I was going to send them. When the Banbarans find that they are trusted by the whites, they never think of making their escape, choosing to be the slaves of *Europeans* rather than

Slavery.

volution in the mother country, which has produced in all its dependencies anarchy and massacre, the condition of the negro-slaves was better than that of the bondmen among the ancient Germans. "Those of them who cultivated the plantations were attached to the soil, and could not be drawn off to pay debts, or be sold separately from the estate on which they lived. This gave them a lasting property in their huts and little spots of ground, which they might safely cultivate without dread of being turned out of possession, or transferred contrary to their interest and feelings from one proprietor to another. They were under the protection of law as soon as they arrived in the colony. Proper missionaries were appointed for the purpose of training them up to a certain degree of religious knowledge, and ample funds were allotted for the maintainance of those ecclesiastics On ill treatment received from his master, or on being deprived of his allowance of food and raiment, the slave was directed to apply to the king's attorney, who was obliged to prosecute the master forthwith. That officer was also bound to prosecute, if by any other means he heard of the abuse; the law adding as the reason, *This we will to be observed, to check the abuse of power in the master*‡."

23 Condition of slaves in the French West Indies under the old government.

‡ Ramsay's Essays on the Treatment and Conversion of Slaves, sect. v.

We wish it were in our power to say, that in the British West India colonies slaves are equally protected by law as they were in the French islands under the old government, and that the same care is taken of their moral and religious improvement. This, however, we are afraid, cannot be said with truth. In the island of Jamaica, before the passing of the *consolidated slave act*, not many years ago, a white man, whether proprietor or not, who had killed a negro, or by an act of severity been the cause of his death, was, for the first offence, entitled to benefit of clergy, and not liable to capital punishment till a repetition of the crime. By the present law, it is enacted, "That if any person, whether owner or superintendant of slaves, shall be convicted of having, by any act of passion or cruelty, occasioned the death of any negro, it shall be capital for the *first* offence: and for the greater security of the property, and as a check on those who may have the punishment of slaves in their power, it is particularly required, that every surgeon or doctor belonging to each estate shall swear to the cause of the death of each negro, to the best of his knowledge and belief; and if any negro dies, and is interred by the owner or overseer, without the doctor's having seen or been sent for to such negro, in this case, the owner or overseer causing the negro to be so interred is liable to a prosecution for such conduct."

24 In the British islands.

M'Neil's Observations on the Treatment of Negroes in the Island of Jamaica.

This law must doubtless be productive of good effects; but being a colonial act, it cannot have the vigour of the *Code Noir*; nor do we know of any attorney in the island who is *obliged* to defend the rights of the negroes, or prosecute the master whose cruelty has by any means come to his knowledge. The justices and vestry of each parish are indeed constituted *a council of protection*, for the express purpose of making full enquiry into the barbarities exercised on slaves, and bringing the authors to punishment at the public expence; and by a new slave-act of Grenada, the justices are required annually to nominate three freeholders to be *guardians of the slaves*, who are to take an oath to see the law duly executed‡. These are benevolent regulations; but we doubt if protection can be so promptly afforded by a council of guardians as by an individual attorney who has no other employment. In some of the other British islands, we have been confidently told that the unfortunate sons of Africa have no protection whatever against the tyranny of a sordid owner, or the caprice of a boyish overseer (M): though it is added, that the humanity of many masters more than supplies the want of laws in every respect but that of improvement, and that the attachment of others has in them a like effect. In some cases good sense, a regard for their reputation, and a well-informed conviction of their interest, induce men to treat their slaves with discretion and humanity. The slaves of many a planter possess advantages beyond what the labourer even of Britain enjoys†;" yet these advantages all depend upon the good will of his master; and in no part of the British colonies are the slaves attached to the soil. This single circumstance, together with the total neglect of their moral and religious culture, makes their situation much less eligible than was that of the French slaves under the old government; and affords a striking proof of what the humane author whom we have just quoted well observes, that "those men and nations whom liberty hath exalted, and who therefore ought to regard it tenderly in others, are constantly for restraining its blessings within their own little circle, and delight more in augmenting the train of their dependants than in adding to the rank of fellow-citizens, or in diffusing the benefits of freedom among their neighbours."

‡ Edwards's History of the West Indies, book iv. chap. 5.

† Ramsay's Essay, p. 66. and 91.

Having given this ample detail of the rise and progress of slavery in the world, and shown that it has prevailed in every age, and under all religions, we shall now proceed to enquire whether a practice so general be in any instance lawful; and if it be, how it must be modified, in order to be rendered consistent with the rights of man and the immutable laws of virtue.

25 The lawfulness of slavery inquired into.

That in a state of nature one man has a right to seize upon another, and to compel him by force to labour for his subsistence, is a position which we believe has never been seriously maintained But independent communities stand to each other in the very same relation that individuals do in a state of nature; and therefore if in such a state the man of greater bodily strength or mental sagacity would have no right to convert his weaker neighbour into personal property, neither can the

than of a *black man* who would treat them with the greatest cruelty. *Voyages to the Coast of Africa by Messrs Saugnier and Brisson*, p. 332. 335. English Translation.

(M) In Barbadoes there is said to be a law for the protection of slaves, which is the most insolent trifling with justice and humanity that the writer of this article has ever seen. It is enacted, forsooth, "That if any man shall, of *wantonness*, or only of *bloody mindedness*, or *cruel intention*, *wilfully kill* a negro or other slave, if his own, he shall pay into the public treasury *fifteen pounds Sterling!* See *Dickson's Letters on Slavery*, p. 4.

the more powerful and enlightened nation have a right to carry off by force, or entice by fraud, the ſubjects of a weaker and more barbarous community for the purpoſe of reducing them to a ſtate of ſervitude. This is a truth ſo obvious as to admit neither of proof nor of denial.

In thus ſtating the caſe between two independent nations, we have in our eye that traffic in ſlaves which is carried on between the civilized Europeans and the barbarous Africans: and the utmoſt length which we think an apologiſt for that trade can go is to contend, that we may lawfully purchaſe ſlaves in thoſe countries where from time immemorial they have been a common branch of commerce. But the European right to purchaſe cannot be better than the African right to ſell; and we have never yet been informed what gives one African a right to ſell another. Such a right cannot be natural, for the reaſon which we have elſewhere aſſigned (ſee RIGHT): neither can it be adventitious; for adventitious rights are immediately derived from the municipal law, which is the public will of the ſtate. But the ſtate has no authority to deprive an innocent man of his perſonal freedom, or of the produce of his own labour; for it is only to ſecure theſe, by protecting the weak from the violence of the ſtrong, that ſtates are formed, and individuals united under civil government.

26
The common apology for it inſufficient.

It may perhaps be ſaid, that by patiently ſubmitting to governments which authoriſe the traffic in human fleſh, men virtually give up their perſonal liberty, and veſt their governors with a right to ſell them as ſlaves: but no man can veſt another with a right which he poſſeſſes not himſelf; and we ſhall not heſitate to affirm, that in a ſtate of nature, where all have equal rights, no individual can ſubmit himſelf to the abſolute diſpoſal of another without being guilty of the greateſt crime. The reaſon is obvious. From the relation in which men ſtand to one another as fellow-creatures, and to God as their common Creator, there are duties, incumbent upon each peculiar to himſelf; in the performance of which he can be guided only by his own reaſon, which was given him for that very purpoſe. But he who renounces his perſonal freedom, and ſubmits unconditionally to the caprice of a maſter, impiouſly attempts to ſet himſelf free from the obligation of that law which is interwoven with his very being, and chooſes a director of his conduct different from that which God has aſſigned him. A man therefore cannot put himſelf in a ſtate of unconditional ſervitude; and what he cannot do for himſelf, he ſurely cannot authorize others to do for him either by a tacit or by an open conſent.

27
No man has a right to give himſelf up to the abſolute diſpoſal of another.

Theſe conſiderations have often made us regret that writers, for whoſe talents and integrity we have the higheſt reſpect, ſhould, without accurately defining what they mean by ſlavery, have peremptorily affirmed, that, conſiſtently with the law of nature men may be reduced to that ſtate as a puniſhment for crimes, or to diſcharge debts which they cannot otherwiſe pay. That a criminal, who has forefeited his life to the laws of his country, may have his puniſhment commuted for hard labour, till death in the courſe of nature ſhall put a period to his terreſtrial exiſtence, is a truth which we apprehend cannot be controverted; but to make ſuch a commutation of puniſhments conſiſtent with the laws of nature and of nature's God, it appears to us that the kind and degree of labour muſt be preciſely aſcertained, and the conduct of the criminal not left to the capricious direction of any individual.

28
What kind of ſlavery may be employed as a puniſhment.

Puniſhments can be juſtly inflicted only for one or other of two ends, or for both. They may be calculated either to reform the criminal or to be a warning to the innocent; and thoſe which moſt effectually anſwer both theſe purpoſes are ſurely to be perferred to ſuch as anſwer but one of them. For this reaſon we conſider hard labour as a much fitter puniſhment for moſt crimes than death: but to intitle it to preference, the kind and degree of the labour muſt be aſcertained by the law; for if theſe circumſtances be omitted, and the offender delivered over as a ſlave to the abſolute diſpoſal and caprice of a private maſter, the labour to which he is condemned, inſtead of operating to his reformation, may be converted into the means of tempting him to the commiſſion of new crimes. A young woman, in the ſtate of ſervitude, would hardly be able to maintain her virtue againſt the ſolicitations of a maſter who ſhould promiſe her liberty or a remiſſion of toil upon her yielding to his deſires; and the felon, who had long been accuſtomed to a life of vagrancy and idleneſs, would not ſtrenuouſly object to the perpetration of any wickedneſs to obtain his freedom, or even a diminution of his daily taſk. Indeed ſuch temptations might be thrown in his way, as human nature could not reſiſt but by means of much better principles than felons can be ſuppoſed to poſſeſs. He might be ſcourged into compliance; or his labour might be ſo increaſed as to make him for a little reſpite eagerly embrace the moſt nefarious propoſal which his maſter could make: for being abſolute property, there is no earthly tribunal to which he could appeal for juſtice; and felons do not commonly ſupport themſelves under trials by pious meditation on a future ſtate.

By reaſoning in this way, we are far from meaning to inſinuate that ſlave-holders in general torture their ſlaves into the commiſſion of crimes. God forbid! Many of them we know to be religious, humane, and benevolent: but they are not infallible; and ſome of them may be inſtigated, ſome of them undoubtedly have been inſtigated, by avarice and other worſe principles, to compel creatures, who are ſo abſolutely their dependents, to execute deeds of darkneſs too hazardous for themſelves. But the morality or immorality of any action, and the moral fitneſs of any ſtate, are to be judged of by their natural tendency, if the one were univerſally practiſed and the other univerſally prevalent (ſee MORAL PHILOSOPHY, nº 156.): and as the natural tendency of abſolute domeſtic ſlavery among ſuch creatures as men is to throw the moſt powerful temptations to vice in the way both of maſter and ſlave, it muſt be in every inſtance, even when employed as a puniſhment, inconſiſtent with the fundamental principles of moral virtue.

29
Children not the property of their parents.

Some writers indeed have maintained, and the civil law ſeems to ſuppoſe, that children are the property of their parents, and may by them be ſold as ſlaves in caſes of urgent neceſſity: but if we duly conſider how property is acquired (ſee PROPERTY), and attend to the natural conſequences of ſlavery, we ſhall ſoon be convinced that this opinion is very ill founded. The rights of parents reſult from their duties; and it is certainly the duty of that man who has been the inſtrument of bringing into the world an intellectual and moral being,

to

Slavery.

to do every thing in his power to render the existence of that being happy both in the present life and in that which is to come. If this duty be conscientiously discharged, the parent has a manifest right to the gratitude, love, and reasonable obedience, of his child; but he cannot, in consequence of any duty performed, claim a right to transfer that child as property to the uncontrolled disposal of any private master; for this plain reason, that the man who is considered as the private property of another, cannot reasonably be supposed to enjoy happiness in this world, and is under many temptations to do what must necessarily render him miserable in the next. See Moral Philosophy, n° 138.

If criminals cannot be lawfully reduced to a state of absolute private slavery, much less surely can it be lawful to reduce insolvent debtors and prisoners of war to that state. Many a virtuous man, who has contracted debts with the fairest prospect of paying them, has been suddenly rendered insolvent by fire, by shipwreck, or by the bankruptcy of others with whom he was necessarily engaged in the course of his trade. Such a man can be considered in no respect as criminal. He has been indeed unfortunate; but it would be grossly unjust, as well as shockingly cruel, to add to his misfortune by reducing him to a state to which we have just seen that the vilest felon cannot be reduced without a violation of

30 Fraudulent bankrupts may be compelled to labour for the benefit of their creditors.

the laws of morality. Fraudulent bankrupts indeed, of whom we daily see many, might with great propriety and the strictest justice be compelled to extenuate their debts by labouring for the benefit of those whom they have injured; and criminals of other descriptions might be made to work for the benefit of the public: but in both cases the task to be performed should be ascertained by the law, and the persons of the labourers be protected by the state. If such can be called slaves, their slavery is undoubtedly consistent with every principle of virtue and religion; for they suffer nothing but the due reward of their deeds. Prisoners of war, however, can upon no honest principle be reduced even to this state of mitigated bondage; for they are so far from incurring guilt by fighting for their country, that even to their enemies their courage and conduct in such a cause must appear worthy of reward. A victorious general has certainly a right to prevent the prisoners taken in battle from again drawing their swords against him during the continuance of the war; but there are many ways by which this may be done effectually without chaining the unfortunate captives to the oar, or selling them like cattle to private purchasers, by whom they may be treated with capricious cruelty, and driven to the perpetration of the greatest crimes.

31 Two objections to our conclusions.

To these conclusions, and the reasoning on which they are built, we are aware it may be objected, that if private slavery were in every instance unlawful and inconsistent with the fundamental principles of morality, it would not have prevailed among the ancient patriarchs, and far less have been authorised by the Jewish law.

32 The former answered.

In reply to this objection, it may be observed, that Abraham, Isaac, and Jacob, though excellent men, were not characters absolutely perfect; that as their practice does nor authorise polygamy or incest among us, it will not authorise the reducing of our fellow-creatures to a state of hopeless servitude; and that from the circumstances of the age in which they lived, many things were permitted to them, and were indeed harmless, which are forbidden to us, and would now be pernicious. The character of Abraham appears to have been much more perfect than that of his son or grandson; and was certainly equal, if not superior, to that of any other mere man of whom we read either in profane or even in sacred history. We are to remember, however, that he was born amidst idolaters, and was probably an idolater himself till enlightend by the inspiration of Jehovah, and called from his kindred and from his father's house. Before his conversion, he must have had much cattle and many slaves, which constituted the riches of that early period; and his case would indeed have been peculiarly hard, had he been commanded to divest himself of his servants, and to depart into a strange country very thinly inhabited, without people to protect his flocks and herds from beasts of prey. Nor would his loss have contributed in any degree to the benefit of his slaves, who, as the ranks of men were then adjusted, could not long have preserved their liberty. Had they not been forcibly reduced to their former state by their idolatrous countrymen, which in all probability they would have been, they must have soon submitted to it, or perished by hunger. Let it be remembered, too, that the bond-servants of Abraham, though constituting the most valuable part of his property, were not considered as a species of inferior beings, but were treated rather as children than as slaves. This is evident from his speaking of the steward of his house as his heir, when complaining to God of the want of seed. Indeed the manner in which this circumstance is mentioned, shows that it was then the general practice to consider domestic slaves as members of the family; for the patriarch does not say, "I will leave my substance to this Eliezer of Damascus;" but his words are, "Behold to me thou hast given no seed; and, lo! one born in my house is *my heir* ‡." From this mode of expression we are strongly inclined to think that captives taken in war were in that age of simplicity incorporated into the family or tribe of the conqueror, as they are said to be at present among the North American Indians, to supply the place of those who had fallen in battle. If so, slavery was then a very mild thing, unattended with the evils which are now in its train, and must often have been highly beneficial to the captive.

‡ Gen. xv. 3.

33 Answer to the other.

The other part of the objection appears at first sight more formidable; but perhaps a little attention to the design of the Mosaic economy may enable us to remove it even more completely than this. We need not inform our theological readers that one great purpose for which the posterity of Abraham were separated from the heathen nations around them, was to preserve the knowledge of the true God in a world run headlong into idolatry. As idolatry appears to have had something in its forms of worship extremely captivating to rude minds, and as the minds of the Israelites at the era of their departure from Egypt were exceedingly rude, every method was taken to keep their separation from their idolatrous neighbours as complete as possible. With this view they were commanded to sacrifice the animals which their Egyptian masters had worshipped as gods, and were taught to consider hogs and such other creatures as the heathen offered in sacrifice, when celebrating their mystical and magic rites, as too unclean to be eaten or even to be touched. Of this di-

Slavery. ſtinction between clean and unclean beaſts, God himſelf aſſigns the reaſon: "I am the Lord your God (ſays he,) who have ſeparated you from other people; ye ſhall therefore put difference between clean and unclean beaſts, and between unclean fowls and clean ‡." For the ſame reaſon they were prohibited from intermarrying with the heathen, or having any tranſaction whatever with them as neighbours; and the ſeven idolatrous nations of Canaan they were ſtrictly commanded to exterminate. "When the Lord thy God (ſays Moſes) ſhall deliver them before thee, thou ſhalt ſmite them, and utterly deſtroy them: thou ſhalt make no covenant with them, nor ſhow mercy unto them: neither ſhalt thou make marriages with them: thy daughter thou ſhalt not give unto his ſon, nor his daughter ſhalt thou take to thy ſon; for they will turn away thy ſon from following me, that they may ſerve other gods†."

‡ Lev. xx. 24, 25, 26.

† Deut. vii. 2, 3, 4.

Under theſe laws, it is plain that no intercourſe whatever could have place between an Iſraelite and a man of any other nation, unleſs the latter was reduced to ſuch a ſtate as that he could neither tempt the former nor practiſe himſelf the rites of his idolatrous worſhip. But the Iſrealites were not ſeparated from the reſt of the world for their own ſakes only: They were intended to be the repoſitories of the lively oracles of God, and gradually to ſpread the light or divine truth thro' other nations, till the fulneſs of time ſhould come, when in Chriſt all things were to be gathered together in one. To anſwer this end, it was neceſſary that there ſhould be ſome intercourſe between them and their Gentile neighbours; but we have ſeen that ſuch an intercourſe could only be that which ſubſiſts between maſters and their ſlaves.

Should this apology for the ſlavery which was authoriſed by the Jewiſh law be deemed fanciful, we beg leave to ſubmit to the conſideration of our readers the following account of that matter, to which the ſame objection will hardly be made. It was morally impoſſible that between nations differing ſo widely in religion, cuſtoms, and manners, as the Jews and Gentiles, peace ſhould for ever reign without interruption; but when wars broke out, battles would be fought, and priſoners would be taken. How were theſe priſoners to be diſpoſed of? Cartels for exchange were not then known: it was the duty of the Iſraelites to prevent their captives from taking up arms a ſecond time againſt them; they could not eſtabliſh them among themſelves either as artificers or as huſbandmen; for their law enjoined them to have no communication with the heathen. There was therefore no other alternative but either to maſſacre them in cold blood, or to reduce them to the condition of ſlaves. It would appear, however, that thoſe ſlaves were raiſed to the rank of citizens, or at leaſt that their burdens were much lightened, as ſoon as they were convinced of the truth of the Moſaic revelation, and received into covenant with God by the rite of circumciſion. They were then admitted to the celebration of the paſſover; concerning which one law was decreed to the ſtranger, and to him that was home-born. Indeed, when we conſider who was the legiſlator of the Jews; when we reflect upon the number of laws enacted to mitigate ſlavery among them, and call to mind the means by which the due execution of all their laws was enforced, (See THEOLOGY), we cannot help being of opinion that the heathen, who was reduced to ſlavery in Judea, might be happier, if he pleaſed, than when living as a freeman in his own country. But whether this be ſo or not, is a matter with which we have no concern. On account of the hardneſs of their hearts, and the peculiarity of their circumſtances, many things, of which ſlavery may have been one, were permitted to the Jews, which, if practiſed by Chriſtians, would render them highly guilty. Slave-trade.

After treating thus largely of ſlavery in general, we need not occupy much of the reader's time with the

SLAVE-TRADE carried on at preſent by the merchants of Europe with the natives of Africa. It is well known that the Potuguese were the firſt Europeans who embarked in this trade, and that their example was ſoon followed by the Dutch and the Engliſh. Of the riſe and progreſs of the Engliſh commerce in ſlaves, the reader will find a ſufficient account in other articles of this work§. That commerce, though long cheriſhed by the government as a ſource of national and colonial wealth, was from its commencement conſidered by the thinking part of the nation as a traffic inconſiſtent with the rights of man, and ſuſpected to be carried on by acts of violence. Theſe ſuſpicions have been gradually ſpread through the people at large, and confirmed, in many inſtances, by evidence incontrovertible. Laws have in conſequence been enacted to make the negroes more comfortable on what is called the middle paſſage, and to protect them againſt the wanton cruelty of their maſters in the Weſt Indies: but the humanity of the nation was rouſed; and not many years ago a number of gentlemen, of the moſt reſpectable characters, finding that no adequate protection can be afforded to perſons in a ſtate of hopeleſs ſervitude, formed themſelves into a ſociety at London, for the purpoſe of procuring a total abolition of the ſlave-trade. That the motives which influence the leading men of this ſociety are of the pureſt kind, cannot, we, think, be queſtioned; for their object is to deliver thoſe who had none to help them, and from whom they can expect no other reward for their labours of love than the bleſſings of them who are ready to periſh. To a cauſe ſo truly Chriſtian, who would not pray for ſucceſs? or who but muſt feel the moſt pungent regret, if that ſucceſs has been rendered doubtful, or even been delayed, by the imprudence of ſome of the agents employed by the ſociety? This we apprehend to have been really the caſe. Language calculated only to exaſperate the planters cannot ſerve the negroes; and the legiſlature of Great Britain will never ſuffer itſelf to be forced into any meaſure by the menaces of individuals. Slave-trade.

§ See Company, vol. v. p. 225. and Guinea.

35 Petitions for the abolition of it.

In the year 1793, petitions were preſented to parliament for the abolition of this inhuman traffic, which gave a pleaſing picture of the philanthropy of the nation; but, unfortunately for the cauſe of freedom, it was diſcovered that many of the names ſubjoined to thoſe petitions had been collected by means not the moſt honourable. This diſcovery, perhaps, would never have been made, had not the inſulting epithets indiſcriminately heaped upon the ſlave-holders provoked thoſe men to watch with circumſpection over the conduct of their opponents. The conſequence was, that ſuſpicions of unfair dealing on the part of the petitioners were excited

Slave-trade.

cited in the breasts of many who, though they ardently wished well to the cause, chose not to add their names to those of school-boys under age, and of peasants who knew not what they were subscribing. Let the rights of the Africans be maintained with ardour and firmness; but never let their advocates suppose that the cause of humanity requires the support of artifice. Absolute slavery, in which the actions of one man are regulated by the caprice of another, is a state demonstrably inconsistent with the obvious plan of the moral government of the world. It degrades the mental faculties of the slave, and throws, both in his way and in his master's, temptations to vice almost insurmountable. Let these truths be set in a proper light by those who have doubtless seen them exemplified; and they will surely have their full effect on the minds of a generous, and, we trust, not yet an impious people (N). The trade will be gradually abolished; pains will be taken to cultivate the minds of the West Indian negroes; and the era may be at no great distance when slavery shall cease through all the British dominions.

36 Objection to the abolition.

But what benefit, it will be asked, would the negroes of Africa reap from an abolition of the slave trade? Should any thing so wildly incredible happen, as that all the nations of Christendom, in one common paroxysm of philanthropy, should abandon this commerce in servants, which has been prosecuted in all ages, and under all religions; they would only abandon it to those who were originally possessed of it, who still penetrate into the country, and who even push up to Gago at the very head of the slave coast; and leave the wool-headed natives of it to Mahometan masters, in preference to Christian. Under such masters they were in Judea at the time of the crusades. Under such, as we learn from Messrs Saugnier, Brisson, and others they still are in the deserts of Africa, as well as in the islands of Johanna ‡ and Madagascar: and it is universally known that they enslave one another as a punishment for the most whimsical crimes. Among them, indeed, slavery seems to be reduced to a system, and to descend, as it has done in more polished nations, from father to son; for both Saugnier and Wadstrom § speak of particular families of negroes who are exempted from that degrading state by the laws of the country.

‡ Asiatic Researches, vol. ii.

§ Essay on Colonization.

All this we admit to be true. Most certainly the negroes would not be exempted from the miseries of servitude, though Europe and the West Indies were swallowed up in the ocean. The *customs* of the country, as the king of Dahomy assured Mr Abson §, will be made as long as black men shall continue to possess their own territories, in their present state of depravity and ignorance; and these customs appear to involve slavery of the cruelest kind. But if slavery be in itself unlawful, is it a sufficient excuse for our continuing the traffic that it is carried on by the rude negroes and the savage Arabs? Are people, whom we sometimes affect to consider as an inferior order of beings, to furnish examples of conduct to those who boast of their advancements in science, in literature, and in refinement? Or will the benevolent Lord of all things pardon us for oppressing our helpless brethren, merely because they are cruelly oppressed by others? It is indeed true that the natives of Guinea cannot be made really free but by introducing among them the blessings of religion and the arts of civil life; but surely they would have fewer temptations than at present to kidnap one another, or to commence uprovoked wars for the purpose of making captives, were the nations of Europe to abandon the commerce in slaves (O). That commerce, we grant, would be continued by the Arabs, and perhaps by others of the eastern nations; but the same number of people could not be carried off by them alone that is now carried off both by them and by the Europeans.

§ Dalzel's History.

37 Of no Strength.

Were it indeed possible to put the slave-trade under proper regulations, so as to prevent all kidnapping and unjust wars among the Africans, to supply the markets; and were it likewise to ensure to the negroes in the West Indies mild treatment and religious instruction; we are far from being sure that while the natives of Guinea continue so rude, and their neighbours the Arabs so selfishly savage, it would be proper to abandon at once to hordes of barbarians the whole of this commerce in bond servants. "The trade, which in its present form is a reproach to Britain, might be made to take a new shape, and become ultimately a blessing to thousands of wretches who, left in their native country, would have dragged out a life of miserable ignorance, unknowing the hand that framed them, unconscious of the reason of which they were made capable, and heedless of the happiness laid up for them in store §."

§ Ramsay's Essay, p. 292, &c.

Slavery is, indeed, in every form an evil; but it seems to be one of those many evils which, having long prevailed in the world, can be advantageously removed only by degrees, and as the moral cultivation of the slaves may

(N) We have not insisted upon the impolicy of the slave-trade, or endeavoured to prove that its abolition would be *advantageous* to the sugar-planters; for the planters surely understand their own interest better than those can do, who, having never been in the West Indies, are obliged to content themselves with what information they can glean on the subject from a number of violent and contradictory publications. To countenance slavery under any form is undoubtedly immoral. This we know; and therefore upon this ground only have we opposed the slave-trade, which cannot be continued without preferring interest to virtue.

(O) In a speech which Mr Dalzel says the king of Dahomy made to Mr Abson, when he was informed of what had passed in England on the subject of the slave-trade, are these remarkable words: "In the name of my ancestors and myself, I aver that no Dahoman ever embarked in war merely for the sake of procuring wherewithal to purchase your commodities." With all due respect for his sable majesty, we must take the liberty to question the truth of this solemn averment. That the slave-trade was not the *sole* cause of the Dahoman wars every man will admit, who does not fancy that those people have neither passions nor appetites, but for the commodities of Europe: but the bare affirmation of this bloody despot, who boasted of having killed many thousands at the *customs*, will not convince those who have read either Wadstrom's Essay on Colonization, or the evidence respecting the slave-trade given at the bar of the House of Commons, "that no Dahoman *ever* embarked in war merely to procure slaves to barter for European commodities.

Slave-trade || Sleep-walker.

may enable them to support the rank and discharge the duties of freemen. This is doubtless the reason why it was not expressly prohibited by the divine Author of our religion, but suffered to vanish gradually before the mild influence of his Heavenly doctrines. It has vanished before these doctrines in most countries of Europe; and we trust that the time is at hand when our traffic in human flesh with the inhabitants of Africa shall cease; and that the period is not very distant when the slaves in the West Indies shall be so much improved in moral and religious knowledge, as that they may be safely trusted with their own freedom. To set them free in their present state of ignorance and depravity, is one of the wildest proposals that the ardour of innovation has ever made. Such freedom would be equally ruinous to themselves and to their masters; and we may say of it what Cicero said of some unseasonable indulgences proposed to be granted to the slaves in Sicily; *Quæ cum accidunt, nemo est, quin intelligat ruere illam rempublicam; hæc ubi veniunt, nemo est, qui ullam spem salutis reliquam esse arbitretur.*

38 The abolition should be gradual.

39 Danger of a sudden manumission of slaves.

SLAUGHTER. See MAN-SLAUGHTER, HOMICIDE, MURDER, &c.

SLEDGE, a kind of carriage without wheels, for the conveyance of very weighty things, as huge stones, bells, &c. The sledge for carrying criminals, condemned for high treason, to execution, is called HURDLE. The Dutch have a kind of sledge on which they can carry a vessel of any burden by land. It consists of a plank of the length of the keel of a moderate ship, raised a little behind, and hollow in the middle; so that the sides go a little aslope, and are furnished with holes to receive pins, &c. The rest is quite even.

SLEDGE is a large smith's hammer, to be used with both hands; of this there are two sorts, the up-hand sledge, which is used by under workmen, when the work is not of the largest sort; it is used with both the hands before, and they seldom raise it higher than their head. But the other, which is called the about-sledge, and which is used for battering or drawing out the largest work, is held by the handle with both hands, and swung round over their heads, at their arm's end, to strike as hard a blow as they can.

SLEEP, that state of the body in which, though the vital functions continue, the senses are not affected by the ordinary impressions of external objects. See DREAMS; and PHYSIOLOGY, n° 287.

SLEEP-Walker, one who walks in his sleep. Many instances might be related of persons who were addicted to this practice; but it will be sufficient to select one remarkable instance from a report made to the Physical Society of Lausanne, by a committee of gentlemen appointed to examine a young man who was accustomed to walk in his sleep.

"The disposition to sleep-walking seems, in the opinion of this committee, to depend on a particular affection of the nerves, which both seizes and quits the patient during sleep. Under the influence of this affection, the imagination represents to him the objects that struck him while awake, with as much force as if they really affected his senses; but does not make him perceive any of those that are actually presented to his senses, except in so far as they are connected with the dreams which engross him at the time. If, during this state, the imagination has no determined purpose, he receives the impression of objects as if he were awake; only, however, when the imagination is excited to bend its attention towards them. The perception obtained in this state are very accurate, and, when once received. the imagination renews them occasionally with as much force as if they were again acquired by means of the senses. Lastly, these academicians suppose, that the impressions received during this state of the senses disappear entirely when the person awakes, and do not return till the return of the same disposition in the nervous system.

Sleep-walker.

"Their remarks were made on the Sieur Devaud, a lad thirteen years and a half old, who lives in the town of Vevey, and who is subject to that singular affection or disease called *Somnambulism* or sleep-walking. This lad possesses a strong and robust constitution, but his nervous system appears to be organised with peculiar delicacy, and to discover marks of the greatest sensibility and irritability. His senses of smell, taste, and touch, are exquisite; he is subject to fits of immoderate and involuntary laughter, and he sometimes likewise weeps without any apparent cause.

"This young man does not walk in his sleep every night; several weeks sometimes pass without any appearance of a fit. He is subject to the disease generally two nights successively, one fit lasting for several hours. The longest are from three to four hours, and they commonly begin about three or four o'clock in the morning.

"The fit may be prolonged, by gently passing the finger or a feather over his upper lip, and this slight irritation likewise accelerates it. Having once fallen asleep upon a staircase, his upper lip was thus irritated with a feather, when he immediately ran down the steps with great precipitation, and resumed all his accustomed activity. This experiment was repeated several times.

"The young Devaud thinks he has observed, that, on the evenings previous to a fit, he is sensible of a certain heaviness in his head, but especially of a great weight in his eyelids.

"His sleep is at all times unquiet, but particularly when the fits are about to seize him. During his sleep, motions are observable in every part of his body, with starting and palpitations; he utters broken words, sometimes sits up in his bed, and afterwards lies down again. He then begins to pronounce words more distinctly, he rises abruptly, and acts as he is instigated by the dream that then possesses him. He is sometimes in sleep subject to continued and involuntary motions.

"The departure of the fit is always preceded by two or three minutes of calm sleep, during which he snores. He then awakes rubbing his eyes like a person who has slept quietly.

"It is dangerous to awaken him during the fit, especially if it is done suddenly; for then he sometimes falls into convulsions. Having risen one night with the intention of going to eat grapes, he left the house, passed through the town, and went to a vineyard where he expected good cheer. He was followed by several persons, who kept at some distance from him, one of whom fired a pistol, the noise of which instantly awakened him, and he fell down without sense. He was carried home and brought to himself, when he recollected very well the having been awakened in the vineyard; but nothing more, except the fright at being found there alone, which had made him swoon.

"After the fits he generally feels a degree of lassitude:

Sleep-walker.

tude: sometimes, though rarely, of indisposition. At the end of one of those fits, of which the gentlemen of the committee were witnesses, he was affected with vomitings; but he is always soon restored.

"When he is awaked, he never for the most part recollects any of the actions he has been doing during the fit.

"The subject of his dreams is circumscribed in a small circle of objects, that relate to the few ideas with which at his age his mind is furnished; such as his lessons, the church, the bells, and especially tales of ghosts. It is sufficient to strike his imagination the evening before a fit with some tale, to direct his somnambulism towards the object of it. There was read to him while in this situation the story of a robber; he imagined the very next moment that he saw robbers in the room. However, as he is much disposed to dream that he is surrounded with them, it cannot be affirmed that this was an effect of the reading. It is observed, that when his supper has been more plentiful than usual, his dreams are more dismal.

"In their report, the gentlemen of the committee dwell much on the state of this young man's senses, on the impression made upon them by strange objects, and on the use they are of to him.

"A bit of strong smelling wood produced in him a degree of restlessness; the fingers had the same effect, whether from their smell or their transpiration. He knew wine in which there was wormwood by the smell, and said that it was not wine for his table. Metals make no impression on him.

"Having been presented with a little common wine while he was in a state of apathy, and all his motions were performed with languor, he drank of it willingly; but the irritation which it occasioned produced a deal of vivacity in all his words, motions, and actions, and caused him to make involuntary grimaces.

"Once he was observed dressing himself in perfect darkness. His clothes were on a large table, mixed with those of some other persons; he immediately perceived this, and complained of it much; at last a small light was brought, and then he dressed himself with sufficient precision. If he is teased or gently pinched, he is always sensible of it, except he is at the time strongly engrossed with some other thing, and wishes to strike the offender; however, he never attacks the person who has done the ill, but an ideal being whom his imagination presents to him, and whom he pursues thro' the chamber without running against the furniture, nor can the persons whom he meets in his way divert him from his pursuit.

"While his imagination was employed on various subjects, he heard a clock strike, which repeated at every stroke the note of the cuckoo. There are cuckoos here, said he; and, upon being desired, he imitated the song of that bird, immediately.

"When he wishes to see an object, he makes an effort to lift his eyelids; but they are so little under his command, that he can hardly raise them a line or two, while he draws up his eyebrows; the iris at that time appears fixed, and his eye dim. When any thing is presented to him, and he is told of it, he always half opens his eyes with a degree of difficulty, and then shuts them after he has taken what was offered to him.

"The report infers from these facts, and from many others relative to the different senses, that their functions are not suspended as to what the sleep-walker wishes to see, that is, as to all those perceptions which accord with the objects about which his imagination is occupied; that he may also be disposed to receive those impressions, when his imagination has no other object at the time; that in order to see, he is obliged to open his eyes as much as he can, but when the impression is once made, it remains; that objects may strike his sight without striking his imagination, if it is not interested in them; and that he is sometimes informed of the presence of objects without either seeing or touching them.

"Having engaged him to write a theme, say the committee, we saw him light a candle, take pen, ink, and paper, from the drawer of his table, and begin to write, while his master dictated. As he was writing, we put a thick paper before his eyes, notwithstanding which he continued to write and to form his letters very distinctly; showing signs, however, that something was incommoding him, which apparently proceeded from the obstruction which the paper, being held too near his nose, gave to his respiration.

"Upon another occasion, the young somnambulist arose at five o'clock in the morning, and took the necessary materals for writing, with his copy-book. He meant to have begun at the top of a page; but finding it already written on, he came to the blank part of the leaf, and wrote some time from the following words, *Fiunt ignari pigritia-ils deviennent ignorans par la paresse;* and, what is remarkable, after several lines he preceived he had forgot the *s* in the word *ignorans*, and had put erroneously a double *r* in *paresse;* he then gave over writing, to add the *s* he had forgot, and to erase the superfluous *r*.

"Another time he had made, of his own accord, a piece of writing, in order, as he said, to please his master. It consisted of three kinds of writing, text, half text, and small writ; each of them performed with the proper pen. He drew, in the corner of the same paper, the figure of a hat; he then asked for a penknife to take out a blot of ink which he had made between two letters, and he erased it without injuring them. Lastly, he made some arithmetical calculations with great accuracy.

"In order to explain some of the facts observed by the academicians which we have here mentioned, they establish two general observations, which result from what they have said with respect to the senses and the dreams of this sleep-walker.

"1. That he is obliged to open his eyes, in order to recognise objects which he wishes to see; but the impression once made, although rapidly, is vivid enough to supersede the necessity of his opening them again, to view the same objects anew; that is, the same objects are afterwards presented to his imagination with as much force and precision as if he actually saw them.

"2. That his imagination, thus warmed, represents to him objects, and such as he figures to himself, with as much vivacity as if he really saw them; and, lastly, that all his senses, being subordinate to his imagination, seem concentrated in the object with which it is occupied, and have at that time no perception of any thing but what relates to that object.

"These two causes united seem to them sufficient

for

Sleep-walker.

for explaining one of the most singular facts that occurred to their observation, to wit, how the young Devaud can write, although he has his eyes shut, and an obstacle before them. His paper is imprinted on his imagination, and every letter which he means to write is also painted there, at the place in which it ought to stand on the paper, and without being confounded with the other letters; now it is clear that his hand, which is obedient to the will of his imagination, will trace them on the real paper, in the same order in which they are represented on that which is pictured in his head. It is thus that he is able to write several letters, several sentences, and entire pieces of writing; and what seems to confirm the idea, that the young Devaud writes according to the paper painted on his imagination is, that a certain sleep-walker, who is described in the French *Encyclopédie* (article *Somnambulism*), having written something on a paper, another piece of paper of the same size was substituted in its stead, which he took for his own, and made upon this blank paper the corrections he meant to have made on the other which had been taken away, precisely in the places where they would have been.

"It appears from the recital of another fact, that Devaud, intending to write at the top of the first leaf of a white-paper book, *Vevey, le*— stopped a moment as if to recollect the day of the month, left a blank space and then proceeded to *December* 1787: after which he asked for an almanac: a little book, such as is given to children for a new year's gift, was offered to him; he took it, opened it, brought it near his eyes, then threw it down on the table. An almanac which he knew was then presented to him; this was in German, and of a form similar to the almanac of Vevey: he took it, and then said, 'What is this they have given me; here, there is your German almanac.' At last they gave him the almanac of Berne; he took this likewise, and went to examine it at the bottom of an alcove that was perfectly dark. He was heard turning over the leaves, and saying 24, then a moment afterwards 34. Returning to his place, with the almanac open at the month of December, he laid it on the table and wrote in the space which he had left blank the 24th. This scene happened on the 23d; but as he imagined it to be the 24th, he did not mistake. The following is the explication given of this fact by the authors of the report.

"The dates 23d, 24th, and 25th, of the month of December, had long occupied the mind of the young Devaud. The 23d and 25th were holidays, which he expected with the impatience natural to persons of his age, for the arrival of those moments when their little daily labours are to be suspended. The 25th especially was the object of his hopes; there was to be an illumination in the church, which had been described to him in a manner that quite transported him. The 24th was a day of labour, which came very disagreeably between the two happy days. It may easily be conceived, how an imagination so irritable as that of the young Devaud would be struck with those pleasing epochs. Accordingly, from the beginning of the month he had been perpetually turning over the almanac of Vevey. He calculated the days and the hours that were to elapse before the arrival of his wished-for holidays; he showed to his friends and acquaintance the dates of those days which he expected with so much impatience; every time he took up the almanac, it was only to consult the month of December. We now see why that date presented itself to his mind. He was performing a task, because he imagined the day to be the Monday which had so long engrossed him. It is not surprising, that it should have occurred to his imagination, and that on opening the almanac in the dark he might have thought he saw this date which he was seeking, and that his imagination might have represented it to him in as lively a manner as if he had actually seen it. Neither is it surprising that he should have opened the almanac at the month of December; the custom of perusing this month must have made him find it in the dark by a mere mechanical operation. Man never seems to be a machine so much as in the state of somnambulism; it is then that habit comes to supply those of the senses that cannot be serviceable, and that it makes the person act with as much precision as if all his senses were in the utmost activity. These circumstances destroy the idea of there being any thing miraculous in the behaviour of young Devaud with respect to the date and the month that he was in quest of; and the reader, who has entered into our explanations, will not be surprised at his knowing the German almanac; the touch alone was sufficient to point it out to him; and the proof of this is the shortness of the time that it remained in his hands.

"An experiment was made by changing the place of the ink-standish during the time that Devaud was writing. He had a light beside him, and had certified himself of the place where his ink-holder was standing by means of sight. From that time he continued to take ink with precision, without being obliged to open his eyes again: but the ink-standish being removed, he returned as usual to the place where he thought it was: It must be observed, that the motion of his hand was rapid till it reached the height of the standish, and then he moved it slowly, till the pen gently touched the table as he was seeking for the ink: he then perceived that a trick had been put on him, and complained of it; he went in search of his ink-standish and put it in its place. This experiment was several times repeated, and always attended with the same circumstances. Does not what we have here stated prove, that the standish, the paper, the table, &c. are painted on his imagination in as lively a manner as if he really saw them, as he sought the real standish in the place where his imagination told him it ought to have been? Does it not prove that the same lively imagination is the cause of the most singular actions of this sleep-walker? And lastly, does it not prove, that a mere glance of his eye is sufficient to make his impressions as lively as durable?

"The committee, upon the whole, recommend to such as wish to repeat the same experiments, 1. To make their observations on different sleep-walkers. 2. To examine often whether they can read books that are unknown to them in perfect darkness. 3. To observe whether they can tell the hours on a watch in the dark. 4. To remove when they write the ink-standish from its place, to see whether they will return to the same place in order to take ink. 5. And, lastly, to take notice whether they walk with the same confidence in a dark and

and unknown place, as in one with which they are acquainted.

"They likewise recommend to such as would confirm or invalidate the above observations, to make all their experiments in the dark; because it has been hitherto supposed that the eyes of sleep-walkers are of no use to them."

SLEEPERS, in natural history, a name given to those animals which sleep all winter; such as bears, marmots, dormice, bats, hedgehogs, swallows, &c. These do not feed in winter, have no sensible evacuations, breathe little or none at all, and most of the viscera cease from their functions. Some of these creatures seem to be dead, and others return to a state like that of the fœtus before birth: in this state they continue, till by new heat the fluids are attenuated, the animal is restored to life, and the functions begin where they left off.

SLEEPERS, in a ship, timbers lying before and aft in the bottom of the ship, as the rungheads do: the lowermost of them is bolted to the rungheads and the uppermost to the futtocks and rungs.

SLEIDAN (John), an excellent German historian, born of obscure parents, in 1506, at Sleidan, a small town on the confines of the duchy of Juliers. After studying some time in his own country, together with his townsman the learned John Sturmius, he went to France, and in 1535 entered into the service of the cardinal and archbishop John du Bellay. He retired to Strasburg in 1542, where he acquired the esteem and friendship of the most considerable persons, particularly of James Sturmius; by whose advice and assistance he was enabled to write the history of his own time. He was employed in some public negociations; but the death of his wife, in 1555, plunged him into so deep a melancholy, that he lost his memory entirely, and died the year following. In 1555 came out, in folio, *De statu Religionis et Reipublicæ sub Carolo Quinto*, &c. in 25 books; from the year 1517, when Luther began to preach, to the year of its publication; which history was presently translated into most of the languages of Europe. Besides this great work, he wrote, *De quatuor summis Imperiis, libri tres*; with some other historical and political pieces.

SLEIGHT *of* HAND. See LEGERDEMAIN.

SLEUT-HOUNDE, the ancient Scots name of the blood-hound. The word is from the Saxon *slot*, "the impression that a deer leaves of its foot in the mire," and *hound* "a dog"; so they derive their name from following the track. See the article *Blood-Hound*.

SLESWICK, an ancient and considerable town of Denmark, and capital of a duchy of the same name in the province of Gottorp, with a bishop's see, secularized in 1586. Close to it is the old palace of Gottorp, formerly the ducal residence, but at present inhabited by the stadtholder or governor. This town was once much more considerable than it is at present, having suffered greatly by the wars of Germany. It is seated on the gulph of Sley, where there is a good harbour, 60 miles north-west of Lubeck, and 125 south-west of Copenhagen. E. Long. 10. 0. N. Lat. 54. 40.

SLESWICK, the duchy of, or *South Jutland*, is about 100 miles in length and 60 in breadth. It is bounded on the north by North Jutland, on the east by the Baltic Sea, on the south by Holstein, and on the west by the ocean. It contains 14 cities, 17 towns, 13 castles, 278 parishes, 1480 villages, 162 farms, 116 water-mills. and 106 gentlemen's seats. It is a pleasant, fertile, populous country, and a sovereign duchy. Formerly the king of Denmark had half of it, and the other belonged to the house of Holstein-Gottorp; but the former having conquered this duchy, had the possession of it confirmed to him by the treaty of the north in 1720. In 1731, a prince of Bareith-Culmbach was made governor of this duchy, who resides at Gottorp.

SLICH, in metallurgy, the ore of any metal, particularly of gold, when it has been pounded, and prepared for farther working.

The manner of preparing the slich at Chremnitz in Hungary is this; they lay a foundation of wood three yards deep, upon this they place the ore, and over this there are 24 beams, armed at their bottoms with iron; these, by a continual motion, beat and grind the ore, till it is reduced to powder: during this operation, the ore is covered with water. There are four wheels used to move these beams, each wheel moving six; and the water, as it runs off, carrying some of the metalline particles with it, is received into several basons, one placed behind another; and finally, after having passed through them all, and deposited some sediment in each, it is let off into a very large pit, almost half an acre in extent; in which it is suffered to stand so long, as to deposit all its sediment, of whatever kind, and after this it is let out. This work is carried on day and night, and the ore taken away and replaced by more as often as occasion requires. That ore which lies next the beams, by which it was pounded, is always the cleanest or richest.

When the slich is washed as much as they can, a hundred weight of it usually contains about an ounce, or perhaps but half an ounce of metal, which is not all gold; for there is always a mixture of gold and silver, but the gold is in the largest quantity, and usually is two-thirds of the mixture: they then put the slich into a furnace with some limestone, and slacken, or the scoria of former meltings, and run them together. The first melting produces a substance called *lech*; this lech they burn with charcoal, to make it lighter, to open its body, and render it porous, after which it is called *rost*; to this rost they add sand in such quantity as they find necessary, and then melt it over again.

At Chremnitz they have many other ways of reducing gold out of its ore, but particularly one, in which they employ no lead during the whole operation; whereas, in general, lead is always necessary, after the before mentioned processes. See GOLD.

SLIDING RULE, a mathematical instrument, serving to work questions in gauging, measuring, &c. without the use of compasses; merely by the sliding of the parts of the instrument one by another, the lines and divisions whereof give the answers by inspection.

This instrument is variously contrived, and applied by various authors, particularly Everard, Coggeshall, Gunter, Hunt, and Partridge; but the most common and useful are those of Everard and Coggeshall.

SLIGO, a county, in the province of Connaught, Ireland, 25 miles in length, and as much in breadth; bounded on the east by that of Leitrim, on the west by the county of Mayo, on the north and north-west by the western ocean, and on the south and south-west by Roscommon and Mayo. It contains 5970 houses, 41 parishes, 6 baronies, 1 borough, and sends 4 members to Parliament, two for the county, and two for the borough of the same name, which is the only market-town in the county, and is seated on a bay of the same name, 30 miles west of Killalla, and 110 north-east of Dublin. W. Long. 8. 26. N. Lat. 54. 13.

SLING, an instrument serving for casting stones with great violence. The inhabitants of the Balearic islands were famous in antiquity for the dexterous management of the sling: it is said they used three kinds of slings, some longer, others shorter, which they used according as their enemies were either nearer or more remote. It is added, that the first served them for a head-band, the second for a girdle, and that the third they constantly carried in their hand.

SLINGING is used variously at sea; but chiefly for hoisting up casks or other heavy things with slings, *i. e.* contrivances of ropes spliced into themselves at either end, with one eye big enough to receive the cask or whatever is to be slung. There are other slings, which are made longer, and with a small eye at each end; one of which is put over the breech of a piece of ordnance, and the other eye comes over the end of an iron crow, which is put into the mouth of the piece, to weigh and hoise the gun as they please. There are also slings by which the yards are bound fast to the cross-tree aloft, and to the head of the mast, with a strong rope or chain, that if the tie should happen to break, or to be shot to pieces in fight, the yard, nevertheless, may not fall upon the hatches.

Slinging a Man overboard, in order to stop a leak in a ship, is done thus: the man is trussed up about the middle in a piece of canvas, and a rope to keep him from sinking, with his arms at liberty, a mallet in one hand, and a plug, wrapped in oakum and well tarred in a tarpawling clout, in the other, which he is to beat with all dispatch into the hole or leak.

SLOANE (Sir Hans), baronet, eminently distinguished as a physician and a naturalist, was of Scotch extraction, his father Alexander Sloane being at the head of that colony of Scots which King James I. settled in the north of Ireland, where our author was born, at Killieagh, on the 16th of April 1660. At a very early period, he displayed a strong inclination for natural history; and this propensity being encouraged by a suitable education, he employed those hours which young people generally lose by pursuing low and trifling amusements, in the study of nature, and contemplating her works. When about sixteen, he was attacked by a spitting of blood which threatened to be attended with considerable danger, and which interrupted the regular course of his application for three years; he had, however, already learned enough of physic to know that a malady of this kind was not to be removed suddenly, and he prudently abstained from wine and other liquors that were likely to increase it.

By strictly observing this severe regimen, which in some measure he continued ever after, he was enabled to prolong his life beyond the ordinary bounds; being an example of the truth of his own favourite maxim, that sobriety, temperance, and moderation, are the best and most powerful preservatives that nature has granted to mankind.

As soon as he recovered from this infirmity, he resolved to perfect himself in the different branches of physic, which was the profession he had made choice of; and with this view he repaired to London, where he hoped to receive that assistance which he could not find in his own country.

On his arrival in the metropolis, he entered himself as a pupil to the great Stafforth, an excellent chemist, bred under the illustrious Stahl; and by his instructions he gained a perfect knowledge of the composition and preparation of the different kinds of medicines then in use. At the same time, he studied botany at the celebrated garden at Chelsea, assiduously attended the public lectures of anatomy and physic, and in short neglected nothing that he thought likely to prove serviceable to him in his future practice. His principal merit, however, was his knowledge of natural history; and it was this part of his character with introduced him early to the acquaintance of Mr Boyle and Mr Ray, two of the most eminent naturalists of that age. His intimacy with these distinguished characters continued as long as they lived; and as he was careful to communicate to them every object of curiosity that attracted his attention, the observations which he occasionally made often excited their admiration and obtained their applause.

After studying four years at London with unremitting severity, Mr Sloane determined to visit foreign countries for farther improvement. In this view he set out for France in the company of two other students, and having crossed to Dieppe, proceeded to Paris. In the way thither they were elegantly entertained by the famous M. Lemery the elder; and in return Mr Sloane presented that eminent chemist with a specimen of four different kinds of phosphorus, of which, upon the credit of other writers, M. Lemery had treated in his book of chemistry, though he had never seen any of them.

At Paris Mr Sloane lived as he had done in London. He attended the hospitals, heard the lectures of Tournefort, De Verney, and other eminent masters; visited all the literati, who received him with particular marks of esteem, and employed himself wholly in study.

From Paris Mr Sloane went to Montpelier; and, being furnished with letters of recommendation from M. Tournefort to M. Chirac, then chancellor of that university, he found easy access, through his means, to all the learned men of the province, particularly to M. Magnol, whom he always accompanied in his botanical excursions in the environs of that city, where he beheld with pleasure and admiration the spontaneous productions of nature, and learned under his instructions, to class them in a proper manner.

Having here found an ample field for contemplation, which was entirely suited to his taste, he took leave of his two companions, whom a curiosity of a different kind led into Italy.

After spending a whole year in collecting plants, he travelled through Languedoc with the same design; and passing through Thoulouse and Bourdeaux, returned to Paris, where he made a short stay. About the end of the year 1684 he set out for England, with an intention of settling there as a physician. On his arrival in London, he made it his first business to visit his two illustrious friends Mr Ray and Mr Boyle, in order

to

Sloane.

to communicate to them the discoveries he had made in his travels. The latter he found at home, but the former had retired to Essex; to which place Mr Sloane transmitted a great variety of plants and seeds, which Mr Ray has discribed in his History of Plants, and for which he makes a proper acknowledgment.

About the year 1706 our author became acquainted with the celebrated Sydenham; who soon contracted so warm an affection for him that he took him into his house, and recommended him in the strongest manner to his patients. He had not been long in London before he was proposed by Dr Martin Lister as a candidate to be admitted a member of the Royal Society, on the 26th of November 1684; and being approved he was elected on the 21st of January following.

In 1685 he communicated some curiosities to the Society; and in July the same year he was a candidate for the office of their assistant secretary, but without success, as he was obliged to give way to the superior interest of his competitor Dr Halley. On the 12th of April 1687, he was chosen a fellow of the college of physicians in London; and the same year his friend and fellow traveller Dr Tancred Robinson, having mentioned to the Society the plant called the *star of the earth*, as a remedy newly discovered for the bite of a mad dog, Dr Sloane acquainted them that this virtue of the plant was to be found in a book called *De Grey's Farriery*; and that he knew a man who had cured with it twenty couple of dogs. This observation he made on the 13th of July, and on the 12th of September following he embarked at Portsmouth for Jamaica with the duke of Albemarle, who had been appointed governor of that island. The doctor attended his grace in quality of physician, and arrived at Jamaica on the 19th of December following.

Here a new field was opened for fresh discoveries in natural productions; but the world would have been deprived of the fruits of them, had not our author, by incredible application, converted, as we may say, his minutes into hours. The duke of Albemarle died soon after he landed, and the duchess determined to return to England whenever an answer should be received to the letter she had sent to court on that melancholy occasion. As Dr Sloane could not think of leaving her grace in her distress, whilst the rest of her retinue were preparing for their departure he improved it in making collections of natural curiosities; so that though his whole stay at Jamaica was not above fifteen months, he brought together such a prodigious number of plants, that on his return to England Mr Ray was astonished that one man could procure in one island, and in so short a space, so vast a variety.

On his arrival in London he applied himself to the practice of his profession; and soon became so eminent, that he was chosen physician to Christ's Hospital on the 17th of October 1694: and this office he held till the year 1730, when, on account of his great age and infirmities, he found it necessary to resign. It is somewhat singular, and redounds much to the Doctor's honour, that though he received the emoluments of his office punctually, because he would not lay down a precedent which might hurt his successors, yet he constantly applied the money to the relief of those who were the greatest objects of compassion in the hospital, that it might never be said he enriched himself by giving health to the poor. He had been elected secretary to the Royal Society on the 30th of November 1693; and upon this occasion he revived the publication of the Philosophical Transactions, which had been omitted for some time. He continued to be the editor of this work till the year 1712; and the volumes which appeared during that period are monuments of his industry and ingenuity, many of the pieces contained in them being written by himself.

In the mean time he published *Catalogus Plantarum quæ in Insula Jamaica sponte proveniunt*, &c. *Seu Prodromi Historiæ Naturalis pars prima*, which he dedicated to the Royal Society and College of Physicians. About the same time he formed the plan of a dispensary, where the poor might be furnished at prime cost with such medicines as their several maladies might require; which he afterwards carried into execution, with the assistance of the president and other members of the college of physicians.

Our author's thirst for natural knowledge seems to have been born with him, so that his cabinet of curiosities may be said to have commenced with his being. He was continually enriching and enlarging it; and the fame which, in the course of a few years, it had acquired, brought every thing that was curious in art or nature to be first offered to him for purchase. These acquisitions, however, increased it but very slowly in comparison of the augmentation it received in 1701 by the death of William Courten, Esq; a gentleman who had employed all his time, and the greater part of his fortune, in collecting rarities, and who bequeathed the whole to Dr Sloane, on condition of his paying certain debts and legacies with which he had charged it. These terms our author accepted, and he executed the will of the donor with the most scrupulous exactness; on which account some people have said, that he purchased Mr Courten's curiosities at a dear rate.

In 1707 the first volume of Dr Sloane's Natural History of Jamaica appeared in folio, though the publication of the second was delayed till 1725. By this very useful as well as magnificent work the materia medica was enriched with a great number of excellent drugs not before known. In 1708 the Doctor was elected a foreign member of the Royal Academy of Sciences at Paris, in the room of Mr Tschirnaus; an honour so much the greater, as we were then at war with France, and the queen's express consent was necessary before he could accept it. In proportion as his credit rose among the learned, his practice increased among the people of rank: Queen Anne herself frequently consulted him, and in her last illness was blooded by him.

On the advancement of George I. to the throne, that prince, on the 3d of April 1716, created the Doctor a baronet, an hereditary title of honour to which no English physician had before attained; and at the same time made him physician general to the army, in which station he continued till 1727, when he was appointed physician in ordinary to George II. He attended the royal family till his death; and was particularly favoured by Queen Caroline, who placed the greatest confidence in his prescriptions. In the mean time he had been unanimously chosen one of the elects of the college of physicians June 1, 1716, and he was elected president of the same body on September 30, 1719, an office which he held for sixteen years. During

ring that period he not only gave the highest proofs of his zeal and assiduity in the discharge of his duty, but in 1721 made a present to that society of L. 100; and so far remitted a very considerable debt, which the corporation owed him, as to accept it in such small sums as were least inconvenient to the state of their affairs. Sir Hans was no less liberal to other learned bodies. He had no sooner purchased the manor of Chelsea, than he gave the company of apothecaries the entire freehold of their botanical garden there, upon condition only that they should present yearly to the Royal Society fifty new plants, till the number should amount to 2000 (A). He gave besides several other considerable donations for the improvement of this garden; the situation of which, on the banks of the Thames, and in the neighbourhood of the capital, was such as to render it useful in two respects: First, by producing the most rare medicinal plants; and, secondly, by serving as an excellent school for young botanists; an advantage which he himself had derived from it in the early part of his life.

The death of Sir Isaac Newton, which happened in 1727, made way for the advancement of Sir Hans to the presidency of the Royal Society. He had been vice-president, and frequently sat in the chair for that great man; and by his long connection with this learned body he had contracted so strong an affection for it, that he made them a present of an hundred guineas, caused a curious bust of King Charles II. its founder, to be erected in the great hall where it met, and, as is said was very instrumental in procuring Sir Godfrey Copley's benefaction of a medal of the value of five guineas, to be annually given as an honorary mark of distinction to the person who communicates the best experiments to the Society.

On his being raised to the chair, Sir Hans laid aside all thoughts of further promotion, and applied himself wholly to the faithful discharge of the duties of the offices which he enjoyed. In this laudable occupation he employed his time from 1727 to 1740, when, at the age of fourscore, he formed a resolution of quitting the service of the public, and of living for himself. With this view he resigned the presidency of the Royal Society much against the inclination of that respectable body, who chose Martin Folkes, Esq; to succeed him, and in a public assembly thanked him for the great and eminent services he had rendered them. In the month of January 1741, he began to remove his library, and his cabinet of rarities, from his house in Bloomsbury to that at Chelsea; and on the 12th of March following, having settled all his affairs, he retired thither himself, to enjoy in peaceful tranquillity the remains of a well-spent life. He did not, however, bury himself in that solitude which excludes men from society. He received at Chelsea, as he had done in London, the visits of people of distinction, of all learned foreigners, and of the royal family, who sometimes did him the honour to wait on him; but, what was still more to his praise, he never refused admittance or advice to rich or poor who came to consult him concerning their health. Not contented with this contracted method of doing good, he now, during his retreat, presented to the public such useful remedies as success had warranted, during the course of a long continued practice. Among these is the efficacious receipt for distempers in the eyes, and his remedy for the bite of a mad dog.

During the whole course of his life, Sir Hans had lived with so much temperance, as had preserved him from feeling the infirmities of old age; but in his 90th year he began to complain of pains, and to be sensible of an universal decay. He was often heard to say, that the approach of death brought no terrors along with it; that he had long expected the stroke; and that he was prepared to receive it whenever the great Author of his being should think fit. After a short illness of three days, he died on the 11th of January 1752, and was interred on the 18th at Chelsea, in the same vault with his lady, the solemnity being attended with the greatest concourse of people, of all ranks and conditions, that had ever been seen before on the like occasion.

Sir Hans being extremely solicitous lest his cabinet of curiosities, which he had taken so much pains to collect, should be again dissipated at his death, and being at the same time unwilling that so large a portion of his fortune should be lost to his children, he bequeathed it to the public, on condition that L. 20,000 should be made good by parliament to his family. This sum, though large in appearance, was scarcely more than the intrinsic value of the gold and silver medals, the ores and precious stones that were found in it; for in his last will we declares, that the first cost of the whole amounted at least to L. 50,000. Besides his library, consisting of more than 50,000 volumes, 347 of which were illustrated with cuts finely engraven and coloured from nature, there were 3560 manuscripts, and an infinite number of rare and curious works of every kind. The parliament accepted the legacy, and fulfilled the conditions.

SLOANEA, in botany: A genus of plants belonging to the class of *polyandria*, and order of *monogynia;* and in the natural system ranging under the 50th order, *Amentaceæ*. The corolla is pentapetalous; the calyx pentaphyllous and deciduous; ; the stigma is perforated;

(A) This garden was first established by the company in 1673; and having after that period been stocked by them with a great variety of plants, for the improvement of Botany, Sir Hans, in order to encourage so serviceable an undertaking, granted to the company the inheritance of it, being part of his estate and manor of Chelsea, on condition that it should be for ever preserved as a physic garden. As a proof of its being so maintained, he obliged the company, in consideration of the said grant, to present yearly to the Royal Society, in one of their weekly meetings, fifty specimens of plants that had grown in the garden the preceding year, and which were all to be specifically distinct from each other, until the number of two thousand should be completed. This number was completed in the year 1761. In 1733 the company erected a marble statue of Sir Hans, executed by Rysbrac, which is placed upon a pedestal in the centre of the garden, with a Latin inscription, expressing his donation, and the design and advantages of it.

perforated; the berry is corticose, echinated, polyspermous, and gaping. Their are two species, the *dentata* and *emarginata*.

SLOE. See Prunus.

SLOOP, a small vessel furnished with one mast, the mainsail of which is attached to a gaff above, or to the mast on its foremost edge, and to a long boom below, by which it is occasionally shifted to either quarter. See Ship.

Sloop of War, a name given to the smallest vessels of war except cutters. They are either rigged as ships or snows.

SLOT, in the sportsman's language, a term used to express the mark of the foot of a stag or other animal proper for the chace in the clay or earth, by which they are able to guess when the animal passed, and which way he went. The slot, or treading of the stag, is very nicely studied on this occasion; if the slot be large, deep printed in the ground, and with an open cleft, and, added to these marks, there is a large space between mark and mark, it is certain that the stag is an old one. If there be observed the slots of treadings of two, the one long and the other round, and both of one size, the long slot is always that of the larger animal. There is also another way of knowing the old ones from the young ones by the treading; which is, that the hinder feet of the old ones never reach to their fore feet, whereas those of the young ones do.

SLOTH, in zoology. See Bradypus.

SLOUGH, a deep muddy place. The cast skin of a snake, the damp of a coal pit, and the scar of a wound are also called by the same appellation. The slough of a wild boar is the bed, soil, or mire, wherein he wallows, or in which he lies in the day-time.

SLUCZK, a large and populous town in Poland, in Lithuania, and capital of a duchy of the same name; famous for three battles gained here by Constantine duke of Ostrog over the Tartars, in the reign of Sigismund I. It is seated on the river Sluczk, 72 miles south-east of Minski, and 70 south of Novogrodeck. E. Long. 27. 44. N. Lat. 53. 2.

SLUG, in zoology. See Limax.

SLUICE, a frame of timber, stone, or other matter, serving to retain and raise the water of a river, &c. and on occasion to let it pass.

Such is the sluice of a mill, which stops and collects the water of a rivulet, &c. to let it fall at length in the greater plenty upon the mill-wheel: such also are those used as vents or drains to discharge water off land. And such are the sluices of Flanders, &c. which serve to prevent the waters of the sea from overflowing the lower lands.

Sometimes there is a kind of canal inclosed between two gates or sluices, in artificial navigations, to save the water, and render the passage of boats equally easy and safe, upwards and downwards; as in the sluices of Briare in France, which are a kind of massive walls built parallel to each other, at the distance of 20 or 24 feet, closed with strong gates at each end, between which is a kind of canal or chamber considerably longer than broad; wherein a vessel being inclosed, the water is let out at the first gate, by which the vessel is raised 15 or 16 feet, and passed out of this canal into another much higher. By such means a boat is conveyed out of the Loire into the Seine, though the ground between them rise above 150 feet higher than either of those rivers ‡.

‡ See Canal.

Sluices are made different ways, according to the use for which they are intended; when they serve for navigation, they are shut with two gates, presenting an angle towards the stream: when they are made near the sea, two pair of gates are made, the one to keep the water out and the other in, as occasion requires; in this case, the gates towards the sea present an angle that way, and the others the contrary way; and the space inclosed by those gates is called the *chamber*. When sluices are made in the ditches of a fortress, to keep up the water in some parts, instead of gates, shutters are made so as to slide up and down in grooves; and when they are made to raise an inundation, they are then shut by means of square timbers let down in cullises, so as to lie close and firm.

The word *sluice* is formed of the French *escluse*, which Menage derives from the Latin *exclusa*, found in the Salic law in the same sense. But this is to be restrained to the sluices of mills, &c. for as those serving to raise vessels, they were wholly unknown to the ancients.

SLUR, in music, a mark like the arch of a circle, drawn from one note to another, comprehending two or more notes in the same or different degrees. If the notes are in different degrees, it signifies that they are all to be sung to one syllable; for wind instruments, that they are to be made in one continued breath; and for stringed instruments that are struck with a bow, as a violin, &c. that they are made with one stroke. If the notes are in the same degree, it signifies that it is all one note, to be made as long as the whole notes so connected; and this happens most frequently betwixt the last note of one line and the first of the next; which is particularly called *syncopation*.

SLUYS, a town in Dutch Flanders, opposite the island of Cadsand, with a good harbour, 10 miles north of Bruges. E. Long. 3. 25. N. Lat. 51. 19.

SMACK, a small vessel, commonly rigged as a sloop or hoy, used in the coasting or fishing trade, or as a tender in the king's service.

SMALAND, or East Gothland, a province of Sweden, which makes part of Gothland; and is bounded on the north by Ostrogothia or East Gothland, on the east by the Baltic Sea, on the south by Schonen and Bleckingia, and on the west by Westrogothia or West Gothland. It is about 112 miles in length, and 62 in breadth. Calmar is the capital-town.

SMALKALD, a town of Germany, in Franconia, and in the county of Henneberg: famous for the confederacy entered into by the German Protestants against the emperor, commonly called the *league of Smalkald*. The design of it was to defend their religion and liberties. It is seated on the river Werra, 25 miles south west of Erford, and 50 north-west of Bamberg. E. Long. 10. 53. N. Lat. 50. 49. It is subject to the prince of Hesse-Cassel.

SMALLAGE, in botany. See Apium.

SMALT, a kind of glass of a dark blue colour, which when levigated appears of a most beautiful colour; and if it could be made sufficiently fine, would be an excellent succedaneum for ultramarine, as not only resisting all kinds of weather, but even the most violent fires. It is prepared by melting one part of calcined cobalt with two of flint powder, and one of pot-ash.

At the bottoms of the crucibles in which the ſmalt is manufactured we generally find a regulus of a whitiſh colour inclining to red, and extremely brittle. This is melted afreſh, and when cold ſeparates into two parts; that at the bottom is the cobaltic regulus, which is employed to make more of the ſmalt; the other is biſmuth.

SMARAGDUS, in natural hiſtory. See EMERALD.

SMEATON (John,) an eminent civil engineer, was born the 28th of May 1724. O. S. at Auſthorpe, near Leeds, in a houſe built by his grandfather, and where his family have reſided ever ſince.

The ſtrength of his underſtanding and the originality of his genius appeared at an early age; his playthings were not the playthings of children, but the tools which men employ; and he appeared to have greater entertainment in ſeeing the men in the neighbourhood work, and aſking them queſtions, than in any thing elſe. One day he was ſeen (to the diſtreſs of his family) on the top of his father's barn, fixing up ſomething like a windmill; another time, he attended ſome men fixing a pump at a neighbouring village, and obſerving them cut off a piece of bored pipe, he was ſo lucky as to procure it, and he actually made with it a working pump that raiſed water. Theſe anecdotes refer to circumſtances that happened while he was in petticoats, and moſt likely before he attained his ſixth year.

About his 14th and 15th year, he had made for himſelf an engine for turning, and made ſeveral preſents to his friends of boxes in ivory or wood very neatly turned. He forged his iron and ſteel, and melted his metal; he had tools of every ſort for working in wood, ivory, and metals. He had made a lathe, by which he had cut a perpetual ſcrew in braſs, a thing little known at that day, which was the invention of Mr Henry Hindley of York; with whom Mr Smeaton ſoon became acquainted, and they ſpent many a night at Mr Hindley's houſe till day-light, converſing on thoſe ſubjects.

Thus had Mr Smeaton, by the ſtrength of his genius and indefatigable induſtry, acquired, at the age of 18, an extenſive ſet of tools, and the art of working in moſt of the mechanical trades, without the aſſiſtance of any maſter. A part of every day was generally occupied in forming ſome ingenious piece of mechaniſm.

Mr Smeaton's father was an attorney, and deſirous of bringing him up to the ſame profeſſion, Mr Smeaton therefore came up to London in 1742, and attended the courts in Weſtminiſter hall; but finding (as his common expreſſion was) that the law did not ſuit the bent of his genius, he wrote a ſtrong memorial to his father on that ſubject; whoſe good ſenſe from that moment left Mr Smeaton to purſue the bent of his genius in his own way.

In 1751 he began a courſe of experiments to try a machine of his invention to meaſure a ſhip's way at ſea, and alſo made two voyages in company with Dr Knight to try it, and a compaſs of his own invention and making, which was made magnetical by Dr Knight's artificial magnets: the ſecond voyage was made in the Fortune ſloop of war, commanded at that time by Captain Alexander Campbell.

In 1753 he was elected member of the Royal Society; the number of papers publiſhed in their Tranſactions will ſhow the univerſality of his genius and knowledge. In 1759 he was honoured by an unanimous vote with their gold medal for his paper intitled "An Experimental Inquiry concerning the Natural Powers of Water and Wind to turn Mills, and other Machines depending on a Circular Motion."

This paper, he ſays, was the reſult of experiments made on working models in the years 1752 and 1753, but not communicated to the Society till 1759; before which time he had an opportunity of putting the effect of theſe experiments into real practice, in a variety of caſes, and for various purpoſes, ſo as to aſſure the Society he had found them to anſwer.

In December 1755, the Eddyſtone lighthouſe was burnt down: Mr Weſton, the chief proprietor, and the others, being deſirous of rebuilding it in the moſt ſubſtantial manner, inquired of the earl of Macclesfield (then preſident of the Royal Society) whom he thought the moſt proper to rebuild it; his Lordſhip recommended Mr Smeaton.

Mr Smeaton undertook the work, and completed it in the ſummer of 1759. Of this Mr Smeaton gives an ample deſcription in the volume he publiſhed in 1791: that edition has been ſold ſome time ago, and a ſecond is now in the preſs, under the reviſal of his much eſteemed friend Mr Aubert, F. R. S. and governor of the London aſſurance corporation.

Though Mr Smeaton completed the building of the Eddyſtone lighthouſe in 1759 (a work that does him ſo much credit), yet it appears he did not ſoon get into full buſineſs as a civil engineer; for in 1764, while in Yorkſhire, he offered himſelf a candidate for one of the receivers of the Derwentwater eſtate; and on the 31ſt of December in that year, he was appointed at a full board of Greenwich hoſpital, in a manner highly flattering to himſelf; when two other perſons ſtrongly recommended and powerfully ſupported were candidates for the employment. In this appointment he was very happy, by the aſſiſtance and abilities of his partner Mr Walton one of the receivers, who taking upon himſelf the management and accounts, left Mr Smeaton leiſure and opportunity to exert his abilities on public works, as well as to make many improvements in the mills and in the eſtates of Greenwich hoſpital. By the year 1775 he had ſo much buſineſs as a civil engineer, that he wiſhed to reſign this appointment; and would have done it then, had not his friends the late Mr Stuart the hoſpital ſurveyor, and Mr Ibbetſon their ſecretary, prevailed upon him to continue in the office about two years longer.

Mr Smeaton having now got into full buſineſs as a civil engineer, performed many works of general utility. He made the river Calder navigable; a work that required great ſkill and judgment, owing to the very impetuous floods in that river: He planned and attended the execution of the great canal in Scotland for conveying the trade of the country either to the Atlantic or German ocean; and having brought it to the place originally intended, he declined a handſome yearly ſalary in order that he might attend to the multiplicity of his other buſineſs.

On the opening of the great arch at London bridge, the excavation around and under the ſterlings was ſo conſiderable, that the bridge was thought to be in great

great danger of falling. He was then in Yorkshire, and was sent for by express, and arrived with the utmost dispatch: "I think (says Mr Holmes, the author of his life) it was on a Saturday morning, when the apprehension of the bridge was so general that few would pass over or under it. He applied himself immediately to examine it, and to sound about the sterlings as minutely as he could; and the committee being called together, adopted his advice, which was to repurchase the stones that had been taken from the middle pier, then laying in Moorfields, and to throw them into the river to guard the sterlings." Nothing shows the apprehensions concerning the falling of the bridge more than the alacrity with which this advice was pursued; the stones were repurchased that day, horses, carts, and barges, were got ready, and they began the work on Sunday morning. Thus Mr Smeaton, in all human probability, saved London-bridge from falling, and secured it till more effectual methods could be taken.

The vast variety of mills which Mr Smeaton constructed, so greatly to the satisfaction and advantage of the owners will show the great use which he made of his experiments in 1752 and 1753; for he never trusted to theory in any case where he could have an opportunity to investigate it by experiment. He built a steam engine at Austhorpe, and made experiments thereon, purposely to ascertain the power of Newcomen's steam-engine, which he improved and brought to a far greater degree of perfection, both in its construction and powers, than it was before.

Mr Smeaton during many years of his life was a frequent attendant on parliament, his opinion being continually called for; and here his strength of judgment and perspicuity of expression had its full display: it was his constant custom, when applied to, to plan or support any measure, to make himself fully acquainted with it, to see its merits before he would engage in it: by this caution, added to the clearness of his description and the integrity of his heart, he seldom failed to obtain for the bill which he supported an act of parliament. No one was heard with more attention, nor had any one ever more confidence placed in his testimony. In the courts of law he had several compliments paid him from the bench by Lord Mansfield and others, for the new light which he threw on difficult subjects.

About the year 1785 Mr Smeaton's health began to decline; and he then took the resolution to endeavour to avoid all the business he could, so that he might have leisure to publish an account of his inventions and works, which was certainly the first wish of his heart; for he has often been heard to say, that "he thought he could not render so much service to his country as by doing that." He got only his account of the Edystone lighthouse completed, and some preparations to his intended Treatise on Mills; for he could nor resist the solicitations of his friends in various works: and Mr Aubert, whom he greatly loved and respected, being chosen chairman of Ramsgate harbour, prevailed upon him to accept the place of engineer to that harbour; and to their joint efforts the public is chiefly indebted for the improvements that have been made there within these few years, which fully appears in a report that Mr Smeaton gave in to the board of trustees in 1791, which they immediately published.

Mr Smeaton being at Austhorpe, walking in his garden on the 16th of September 1792, was struck with the palsy, and died the 28th of October. "In his illness (says Mr Holmes) I had several letters from him, signed with his name, but written and signed by another's pen; the diction of them showed the strength of his mind had not left him. In one written the 26th of September, after minutely describing his health and feelings, he says, "in consequence of the foregoing, I conclude myself nine-tenths dead; and the greatest favour the Almighty can do me (as I think), will be to complete the other part; but as it is likely to be a lingering illness, it is only in His power to say when that is likely to happen."

Mr Smeaton had a warmth of expression that might appear to those who did not know him well to border on harshness; but those more intimately acquainted with him, knew it arose from the intense application of his mind, which was always in the pursuit of truth, or engaged in investigating difficult subjects. He would sometimes break out hastily, when any thing was said that did not tally with his ideas; and he would not give up any thing he argued for, till his mind was convinced by sound reasoning.

In all the social duties of life he was exemplary; he was a most affectionate husband, a good father, a warm, zealous, and sincere friend, always ready to assist those he respected, and often before it was pointed out to him in what way he could serve them. He was a lover and encourager of merit wherever he found it; and many men are in a great measure indebted to his assistance and advice for their present situation. As a companion, he was always entertainign and instructive; and none could spend any time in his company without improvement.

SMELL, ODOUR, with regard to the organ, is an impression made on the nose by little particles continually exhaling from odorous bodies: With regard to the object, it is the figure and disposition of odorous effluvia, which, sticking on the organ, excite the sense of smelling: And with regard to the soul, it is the perception of the impression of the object on the organ, or the affection in the soul resulting therefrom. See ANATOMY, n° 140; and METAPHYSICS.

SMELLING, the act whereby we perceive smells, or whereby we become sensible of odorous bodies, by means of certain effluvia thereof; which, striking on the olfactory organ, briskly enough to have their impulse propagated to the brain, excite a sensation in the soul. The principal organs of smelling are the nostrils and the olfactory nerves; the minute ramifications of which latter are distributed throughout the whole concave of the former. For their descriptions, see ANATOMY.

Smelling is performed by drawing into the nostrils the odorous effluvia floating in the air in inspiration, which strike with such force against the fibrillæ of the olfactory nerves, which the figure of the nose, and the situation of the little bones, render opposite thereto, as to shake them, and give them a vibratory motion; which action, being communicated hence to the common-sensory, occasions an idea of a sweet, or fetid, or sour, or an aromatic, or a putrefied object, &c. The matter in animals, vegetables, fossils, &c. which chiefly affects the sense of smelling, Boerhaave observes, is that subtile substance, inherent in their oily parts, called

called *spirit*: because, when this is taken away fom the most fragrant bodies, what remains has scarce any smell at all; but this, poured on the most inodorous bodies, gives them a fragrancy.

Willis observes, that brutes have generally the sense of smelling in much greater perfection than man: by this alone they distinguish the qualities of bodies, which could not otherwise be known; hunt out their food at a great distance, as hounds and birds of prey; or hid among other substances, as ducks, &c. Man, having other means of judging of his food, &c. did not need so much sagacity in his nose; yet have we instances of a great deal even in man. In the *Histoire des Antilles*, we are assured there are negroes who, by the smell alone, can distinguish between the footsteps of a Frenchman and a negro. It is found, that the laminæ, wherewith the upper part of the nostrils is fenced, and which serve to receive the divarications of the olfactory nerves, are always longer, and folded up together in greater numbers, as the animal has this sense more acute: the various windings and turnings of these laminæ detaining the odoriferous particles.

The sense of smelling may be diminished or destroyed by disease; as by the moisture, dryness, inflammation, or suppuration of the olfactory membrane, the compression of the nerves which supply it, or some fault in the brain itself at their origin. A defect, or too great a degree of solidity of the small spongy bones of the upper jaw, the caverns of the forehead, &c. may likewise impair this sense; and it may be also injured by a collection of fetid matter in these caverns, which is continually exhaling from them, and also by immoderate use of snuff. When the nose abounds with moisture, after gentle evacuations, such things as tend to take off irritation and coagulate the thin sharp serum may be applied; as the oil of anise mixed with fine flour, camphor dissolved in oil of almonds, &c. the vapours of amber, frankincense, gum-mastic, and benjamin, may likewise be received into the nose and mouth. For moistening the mucus when it is too dry, some recommend snuff made of the leaves of marjoram, mixed with oil of amber, marjoram, and aniseed; or a sternutatory of calcined white vitriol, twelve grains of which may be mixed with two ounces of marjoram water and filtrated. The steam of vinegar upon hot iron, and received up the nostrils, is also of use for softening the mucus, removing obstructions, &c. If there be an ulcer in the nose, it ought to be dressed with some emollient ointment, to which, if the pain be very great, a little laudanum may be added. If it be a venereal ulcer, 12 grains of corrosive sublimate may be dissolved in a pint and a half of brandy, a table spoonful of which may be taken twice a day. The ulcer ought likewise to be washed with it, and the fumes of cinnabar may be received up the nostrils.

If there be reason to suspect that the nerves which supply the organs of smelling are inert, or want stimulating, volatile salts, or strong snuffs, and other things which occasion sneezing, may be applied to the nose; the forehead may likewise be anointed with balsam of Peru, to which may be added a little oil of amber.

SMELT, in ichthyology. See Salmo.

SMELTING, in metallurgy, the fusion or melting of the ores of metals, in order to separate the metalline part from the earthy, stony, and other parts. See Metallurgy. Part III.

SMEW, in ornithology. See Mergus.

SMILAX, rough bindweed, in botany: A genus of plants belonging to the class of *diœcia* and order of *hexandria*; and in the natural system ranging under the 11th order, *Sarmentaceæ*. The male calyx is hexaphyllous, and there is no corolla; the female calyx is also hexaphyllous, without any corolla: there are three styles, a trilocular berry, and two seeds. There are 18 species; the aspera, excelsa, zoilanica, sarsaparilla, china, rotundifolia, laurifolia, tamnoides, caduca, bona nox, herbacea, tetragona, lanceolata, and pseudo-china. Of these, the smilax sarsaparilla, which affords the sarsaparilla root, is the most valuable. This is well described in the London Medical Journal by Dr Wright, who, during a long residence in Jamaica, made botany his peculiar study.

"This species (says he) has stems of the thickness of a man's finger: they are jointed, triangular, and beset with crooked spines. The leaves are alternate, smooth and shining on the upper side; on the other side are three nerves or costæ, with sundry small crooked spines. The flower is yellow, mixed with red. The fruit is a black-berry, containing several brown seeds.

"Sarsaparilla delights in low moist grounds and near the banks of rivers. The roots run superficially under the surface of the ground. The gatherers have only to loosen the soil a little, and to draw out the long fibres with a wooden hook. In this manner they proceed till the whole root is got out. It is then cleared of the mud, dried, and made into bundles.

"The sensible qualities of sarsaparilla are mucilaginous and farinaceous, with a slight degree of acrimony. The latter, however, is so slight as not to be perceived by many; and I am apt to believe that its medicinal powers may fairly be ascribed to its demulcent and farinaceous qualities.

"Since the publication of Sir William Fordyce's paper on Sarsaparilla in the Medical Observations and Inquiries, Vol. I. sarsaparilla has been in more general use than formerly. The planters in Jamaica supply their estates with great quantities of it; and its exhibition has been attended with very happy consequences in the yaws and in venereal affections; as nodes, tophi, and exostosis; pains of the bones, and carious or cancerous ulcers.

"Sir William Fordyce seems to think sarsaparilla a specific in all stages of lues; but from an attentive and careful observation of its effects in some thousands of cases, I must declare I could place no dependence on sarsaparilla alone. But if mercury had formerly been tried, or was used along with sarsaparilla, a cure was soon effected. Where the patients had been reduced by pain, disorder, and mercury, I prescribed a decoction of sarsaparilla, and a table-spoonful of the powder of the same, twice a day, with the greatest success, in the most deplorable cases of lues, ill cured yaws, and carious or ill-disposed sores or cancers.

The china, or oriental species of china root, has roundish prickly stalks and red berries, and is a native of China and Japan. The pseudo-china, or occidental species, has rounder smooth stalks and black berries, grows wild in Jamacia and Virginia, and bears the colds of our own climate.

These roots have scarce any smell or particular taste: when fresh, they are said to be somewhat acrid, but as brought to us they discover, even when long chewed, no other than a slight unctuosity in the mouth. Boiled in water, they impart a reddish colour, and a kind of vapid softness: the decoction when inspissated yields an unctuous, farinaceous, almost insipid mass, amounting to upwards of half the weight of the root. They give a gold yellow tincture to rectified spirit, but make no sensible alteration in its taste; on drawing off the spirit from the filtered liquor, there remains an orange-coloured extract, nearly as insipid as that obtained by water, but scarcely in half its quantity.

Lewis's Materia Medica.

China root is generally supposed to promote perspiration and urine, and by its soft unctuous quality to blunt acrimonious humours. It was first introduced into Europe about the year 1535, with the character of a specific against venereal disorders: the patient was kept warm, a weak decoction of china root was used for common drink, and a stronger decoction taken twice a day in bed to promote a sweat. Such a regimen is doubtless a good auxiliary to mercurial alteratives: but whatever may be its effects in the warmer climates, it is found in this to be itself greatly insufficient. At present the china root is very rarely made use of, having for some time given place to sarsaparilla, which is supposed to be more effectual. Prosper Alpinus informs us, that this root is in great esteem among the Egyptian women for procuring fatness and plumpness.

SMITH (Sir Thomas), was born at Walden in Essex in 1512. At 14 he was sent to Queen's college Cambridge, where he distinguished himself so much that he was made Henry VIII.'s scholar together with John Cheke. He was chosen a fellow of his college in 1531, and appointed two years after to read the public Greek lecture. The common mode of reading Greek at that time was very faulty; the same sound being given to the letters and dipthongs ι, η, υ, ει, οι, υι. Mr Smith and Mr Cheke had been for some time sensible that this pronunciation was wrong: and after a good deal of consultation and research, they agreed to introduce that mode of reading which prevails at present. Mr Smith was lecturing on *Aristotle de Republica* in Greek. At first he dropped a word or two at intervals in the new pronunication, and sometimes he would stop as if he had committed a mistake and correct himself. No notice was taken of this for two or three days; but as he repeated more frequently, his audience began to wonder at the unusual sounds, and at last some of his friends mentioned to him what they had remarked. He owned that something was in agitation, but that it was not yet sufficiently digested to be made public. They entreated him earnestly to discover his project: he did so; and in a short time great numbers resorted to him for information. The new pronunication was adopted with enthusiasm, and soon became universal at Cambridge. It was afterwards opposed, by bishop Gardiner the chancellor; but its superiority to the old mode was so visible, that in a few years it spread over all England.

In 1539 he travelled into foreign countries, and studied for some time in the universities of France and Italy. On his rerurn he was made regius professor of civil law at Cambridge. About this time he published a treatise on the mode of pronouncing English. He was useful likewise in promoting the reformation. Having gone into the family of the duke of Somerset, the protector during the minority of Edward VI. he was employed by that nobleman in public affairs; and in 1548 was made secretary of state, and received the honour of knighthood. While that nobleman continued in office, he was sent ambassador, first to Brussels and afterwards to France.

Upon Mary's accession he lost all his places, but was fortunate enough to preserve the friendship of Gardiner and Bonner. He was exempted from persecution, and was allowed, probably by their influence, a pension of L. 100. During Elizabeth's reign he was employed in public affairs, and was sent three times by that princess as her ambassador to France. He died in 1577. His abilities were excellent, and his attainments uncommonly great: He was a philosopher, a physician, a chemist, mathematician, linguist, historian and architect. He wrote, 1. A treatise called the *English Commonwealth*. 2. A letter *De Recta et Emendata, Linguæ Græcæ Pronunciatione*. 3. *De Moribus Turcarum*. 4. *De Druidum Moribus*

Smith (Edmund), a distinguished English poet, the only son of Mr Neale an eminent merchant, by a daughter of baron Lechmere, was born in 1668. By his father's death he was left young to the care of Mr Smith, who had married his father's sister, and who treated him with so much tenderness, that at the death of his generous guardian he assumed his name. His writings are not many, and those are scattered about in miscellanies and collections: his celebrated tragedy of Phædra and Hippolitus was acted in 1707; and being introduced at a time when the Italian opera so much engrossed the polite world, gave Mr Addison, who wrote the prologue, an opportunity to rally the vitiated taste of the public. However, notwithstanding the esteem it has always been held in, it is perhaps rather to be considered as a fine poem than as a good play. This tragedy, with a Poem to the memory of Mr John Philips, three or four Odes, with a Latin oration spoken at Oxford *in laudem Thomæ Bodleii*, were published as his works by his friend Mr Oldisworth. Mr Smith died in 1710, sunk into indolence and intemperance by poverty and disappointments; the hard fate of many a man of genius.

Smith (John), an excellent mezzotinter, flourished about 1700; but neither the time of his birth nor death are accurately known. He united softness with strength, and finished with freedom. He served his time with one Tillet a painter in Moorfields; and as soon as he became his own master, learned from Becket the secret of mezzotinto, and being farther instructed by Van der Vaart, was taken to work in Sir Godfrey Kneller's house; and as he was to be the publisher of that master's works, doubtless received considerable hints from him, which he amply repaid. "To posterity perhaps his prints (says Mr Walpole) will carry an idea of something burlesque; perukes of an enormous length flowing over suits of armour, compose wonderful habits. It is equally strange that fashion could introduce the one, and establish the practice of representing the other, when it was out of fashion. Smith excelled in exhibiting both, as he found them in the portraits of Kneller,

Walpole's Catalogue of Engravers.

Smith.

lar, who was less happy in what he substituted to armour. In the Kit-cat club he has poured full bottoms chiefly over night-gowns. If those streams of hair were *incommode* in a battle, I know nothing (he adds) they were adapted to that can be done in a night-gown. Smith composed two large volumes, with proofs of his own plates, for which he asked L. 50. His finest works are duke Schomberg on horseback; that duke's son and successor Maynhard; the earls of Pembroke, Dorset, and Albemarle; three plates with two figures in each, of young persons or children, in which he shone; William Cowper; Gibbons and his wife; Queen Anne; the duke of Gloucester, a whole length, with a flower-pot; a very curious one of Queen Mary, in a high head, fan, and gloves; the earl of Godolphin; the duchess of Ormond, a whole length, with a black; Sir George Rooke, &c. There is a print by him of James II. with an anchor, but no inscription; which not being finished when the king went away, is so scarce that it is sometimes sold for above a guinea. Smith also performed many historic pieces; as the loves of the gods, from Titian, at Blenheim, in ten plates; Venus standing in a shell, from a picture by Correggio, and many more, of which perhaps the most delicate is the holy family with angels, after Carlo Maratti."

Philosophical Transactions of the Royal Society of Edinburgh, vol. iii.

Smith (Dr Adam), the celebrated author of the Inquiry into the Nature and Causes of the Wealth of Nations, was the only son of Adam Smith comptroller of the customs at Kirkaldy, and of Margaret Douglas daughter of Mr Douglas of Strathenry. He was born at Kirkadly on the 5th June 1723, a few months after the death of his father. His constitution during his infancy was infirm and sickly, and required all the care of his surviving parent. When only three years old he was carried by his mother to Strathenry on a visit to his uncle Mr Douglas; and happening one day to be amusing himself alone at the door of the house, he was stolen by a party of those vagrants who in Scotlaud are called *tinkers*. Luckily he was missed immediately, and the vagrants pursued and overtaken in Leslie wood; and thus Dr Smith was preserved to extend the bounds of science, and reform the commercial policy of Europe.

He received the rudiments of his education in the school of Kirkaldy under David Miller, a teacher of considerable eminence, and whose name deserves to be recorded on account of the great number of eminent men which that seminary produced while under his direction. Dr Smith, even while at school, attracted notice by his passionate attachment to books, and by the extraordinary powers of his memory; while his friendly and generous disposition gained and secured the affection of his schoolfellows. Even then he was remarkable for those habits which remained with him through life, of speaking to himself when alone and of absence in company. He was sent in 1737 to the university of Glasgow, where he remained till 1740, when he went to Baliol college Oxford, as an exhibitioner on Snell's foundation. His favourite pursuits while at the university were mathematics and natural philosophy. After his removal to England he frequently employed himself in translating, particularly from the French, with a view to the improvement of his own style: a practice which he often recommended to all who wished to cultivate the art of composition. It was probably then also that he applied himself with the greatest care to the study of languages, of which, both ancient and modern, his knowledge was uncommonly extensive and accurate.

After seven years residence at Oxford he returned to Kirkaldy, and lived two years with his mother without any fixed plan for his future life. He had been designed for the church of England; but disliking the ecclesiastical profession, he resolved to abandon it altogether, and to limit his ambition to the prospect of obtaining some of those preferments to which literary attainments lead in Scotland. In 1748 he fixed his residence in Edinburgh, and for three years read a course of lectures on rhetoric and belles lettres under the patronage of Lord Kames. In 1751 he was elected professor of logic in the university of Glasgow, and the year following was removed to the professorship of moral philosophy, vacant by the death of Mr Thomas Craigie the immediate successor of Dr Hutcheson. In this situation he remained 13 years, a period he used frequently to look back to as the most useful part of his life. His lectures on moral philosophy were divided into four parts: The first contained natural theology; in which he considered the proofs of the being and attributes of God, and those truths on which religion is founded: the second comprehended ethics, strictly so called, and consisted chiefly of those doctrines which he afterwards published in his theory of moral sentiments: in the third part he treated more at length of that part of morality called *justice*; and which, being susceptible of precise and accurate rules, is for that reason capable of a full and accurate explanation: in the last part of his lectures he examined those political regulations which are founded, not upon the principle of justice, but of expediency; and which are calculated to increase the riches, the power, and the prosperity of a state. Under this view he considered the political institutions relating to commerce, to finances, to ecclesiastical and military governments: this contained the substance of his *Wealth of Nations*. In delivering his lectures he trusted almost entirely to extemporary elocution: his manner was plain and unaffected, and he never failed to interest his hearers. His reputation soon rose very high, and many students resorted to the university merely upon his acccount.

When his acquaintance with Mr Hume first commenced is uncertain, but it had ripened into friendship before the year 1752.

In 1759 he published his Theory of Moral Sentiments; a work which deservedly extended his reputation: for, though several of its conclusions be ill-founded, it must be allowed by all to be a singular effort of invention, ingenuity, and subtility. Besides, it contains a great mixture of important truth; and, tho' the author has sometimes been misled, he has had the merit of directing the attention of philosophers to a view of human nature, which had formerly in a great measure escaped their notice. It abounds everywhere with the purest and most elevated maxims concerning the practical conduct of life; and when the subject of his work leads him to address the imagination and the heart, the variety and felicity of his illustrations, the richness and fluency of his eloquence, and the skill with which

which he wins the attention and commands the paſſions of his reader, leave him among the Britiſh moraliſts without a rival.

Towards the end of 1763 Dr Smith received an invitation from Mr Charles Townſend to accompany the Duke of Buccleugh on his travels; and the liberal terms in which this propoſal was made induced him to reſign his office at Glaſgow. He joined the Duke of Buccleugh at London early in the year 1764, and ſet out with him for the continent in the month of March following. After a ſtay of about ten days at Paris, they proceeded to Thoulouſe, where they fixed their reſidence for about 18 months; thence they went by a pretty extenſive route through the ſouth of France to Geneva, where they paſſed two months. About Chriſtmas 1765 they returned to Paris, and remained there till October following. The ſociety in which Dr Smith paſſed theſe ten months may be conceived in conſequence of the recommendation of Mr Hume. Turgot, Queſnai, Necker, D'Alembert, Helvetius, Marmontel, Madame Riccoboni, were among the number of his acquaintances; and ſome of them he continued ever after to reckon among the number of his friends. In October 1766 the duke of Buccleugh returned to England.

Dr Smith ſpent the next ten years of his life with his mother at Kirkaldy, occupied habitually in intenſe ſtudy, but unbending his mind at times in the company of ſome of his old ſchoolfellows, who ſtill continued to reſide near the place of their birth. In 1776 he publiſhed his *Inquiry into the Nature and Cauſes of the Wealth of Nations*; a book ſo univerſally known, that any panegyric on it would be uſeleſs. The variety, importance, and (may we not add) novelty, of the information which it contains; the ſkill and comprehenſiveneſs of mind diſplayed in the arrangement; the admirable illuſtrations with which it abounds; together with a plainneſs and perſpicuity which makes it intelligible to all—render it unqueſtionably the moſt perfect work which has yet appeared on the general principles of any branch of legiſlation.

He ſpent the next two years of his life in London, where he enjoyed the ſociety of ſome of the moſt eminent men of the age: but he removed to Edinburgh in 1778, in conſequence of having been appointed, at the requeſt of the duke of Buccleugh, one of the commiſſioners of the cuſtoms in Scotland. Here he ſpent the laſt twelve years of his life in an affluence which was more than equal to all his wants. But his ſtudies ſeemed entirely ſuſpended till the infirmities of old age reminded him, when it was too late, of what he yet owed to the public and to his own fame. The principal materials of the works which he had announced had long ago been collected, and little probably was wanting but a few years of health and retirement to complete them. The death of his mother, who had accompained him to Edinburgh in 1784, together with that of his couſin Miſs Douglas in 1788, contributed to fruſtrate theſe projects. They had been the objects of his affection for more than 60 years, and in their Society he had enjoyed from his infancy all that he ever knew of the endearments of a family. He was now alone and helpleſs; and though he bore his loſs with equanimity, and regained apparently his former cheerfulneſs, yet his health and ſtrength gradually declined till the period of his death, which happened in July 1790. Some days before his death he ordered all his papers to be burnt except a few eſſays, which have ſince been publiſhed.

Of the originality and comprehenſiveneſs of his views; the extent, the variety, and the correctneſs of his information; the inexhauſtible fertility of his invention—he has left behind him laſting monuments. To his private worth, the moſt certain of all teſtimonies may be found in that confidence, reſpect, and attachment, which followed him through all the various relations of life. He was habitually abſent in converſation, and was apt when he ſpoke to deliver his ideas in the form of a lecture. He was rarely known to ſtart a new topic himſelf, or to appear unprepared upon thoſe topics that were introduced by others. In his external form and appearance there was nothing uncommon. When perfectly at eaſe, and when warmed with converſation, his geſtures were animated and not ungraceful; and in the ſociety of thoſe he loved, his features were often brightened by a ſmile of inexpreſſible benignity. In the company of ſtrangers, his tendency to abſence, and perhaps ſtill more his conſciouſneſs of that tendency, rendered his manners ſomewhat embarraſſed; an effect which was probably not a little heightened by thoſe ſpeculative ideas of propriety which his recluſe habits tended at once to perfect in his conception, and to diminiſh his power of realizing.

SMITHIA, in botany: A genus of the *decandria* order belonging to the *diadelphia* claſs of plants; and in the natural method ranking under the 32d order, *Papilionaceæ*. The calyx is monophyllous and bilabiated; the corolla winged; the legumen incloſed in the calyx, with three or four joints, and contain as many ſeeds, which are ſmooth, compreſſed, and kidney-ſhaped. There is only one ſpecies, viz. the *thonina*.

SMITZ (Gaſpar), who, from painting a great number of Magdalens, was called *Magdalen Smith*, was a Dutch painter, who came to England ſoon after the Reſtoration. For theſe portraits ſat a woman that he kept, and called his wife. A lady, whom he had taught to draw, took him with her to Ireland, where he painted ſmall portraits in oil, had great buſineſs, and high prices. His flowers and fruit were ſo much admired, that one bunch of grapes ſold there for L. 40. In his Magdalens he generally introduced a thiſtle on the fore ground. He had ſeveral ſcholars, particularly Maubert, and one Gawdy of Exeter. Yet, notwithſtanding his ſucceſs, he died poor in Ireland in 1707.

SMITHERY, a ſmith's ſhop; alſo the art of a ſmith, by which iron is wrought into any ſhape by means of fire, hammering, filing, &c.

SMITING-LINE, in a ſhip, is a ſmall rope faſtened to the mizen-yard-arm, below at the deck, and is always furled-up with the mizen-ſail, even to the upper end of the yard, and thence it comes down to the poop. Its uſe is to looſe the mizen-ſail without ſtriking down the yard, which is eaſily done, becauſe the mizen-ſail is furled up only with rope-yarns; and therefore when this rope is pulled hard, it breaks all the rope-yarns, and ſo the ſail falls down of itſelf. The ſailor's phraſe is, *ſmite the mizen* (whence this rope takes its name), that is, hale by this rope that the ſail may fall down.

SMOKE, a denſe elaſtic vapour, ariſing from burning bodies. As this vapour is extremely diſagreeable to the ſenſes, and often prejudicial to the health, mankind have fallen upon several contrivances to enjoy the benefit of fire, without being annoyed by smoke. The most universal of those contrivances is a tube leading from the chamber in which the fire is kindled to the top of the building, through which the smoke ascends, and is dispersed into the atmosphere. These tubes are called *chimneys*; which, when constructed in a proper manner, carry off the smoke entirely; but, when improperly constructed, they carry off the smoke imperfectly, to the great annoyance of the inhabitants. As our masons at present seem to have a very imperfect knowledge of the manner in which chimneys ought to be built, we can hardly perform a more acceptable service to the public than to point out the manner in which they ought to be constructed, so as to carry off the smoke entirely; as well as to explain the causes from which the defects so often complained of generally proceed, and the method of removing them.

Transactions of the American Philosophical Society.

Those who would be acquainted with this subject should begin by considering on what principle smoke ascends in any chimney. At first many are apt to think that smoke is in its nature, and of itself, specifically lighter than air, and rises in it for the same reason that cork rises in water. These see no cause why smoke should not rise in the chimney though the room be ever so close. Others think there is a power in chimneys to *draw* up the smoke, and that there are different forms of chimneys which afford more or less of this power. These amuse themselves with searching for the best form. The equal dimensions of a funnel in its whole length is not thought artificial enough, and it is made, for fancied reasons, sometimes tapering and narrowing from below upwards, and sometimes the contrary, &c. &c. A simple experiment or two may serve to give more correct ideas. Having lighted a pipe of tobacco, plunge the stem to the bottom of a decanter half filled with cold water; then putting a rag over the bowl, blow through it, and make the smoke descend in the stem of the pipe, from the end of which it will rise in bubbles through the water; and being thus cooled, will not afterwards rise to go out through the neck of the decanter, but remain spreading itself and resting on the surface of the water. This shows that smoke is really heavier than air, and that it is carried upwards only when attached to or acted upon by air that is heated, and thereby rarefied and rendered specifically lighter than the air in its neighbourhood.

Smoke being rarely seen but in company with heated air, and its upward motion being visible, though that of the rarefied air that drives it is not so, has naturally given rise to the error. It is now well known that air is a fluid which has weight as well as others, though about 800 times lighter than water; that heat makes the particles of air recede from each other, and take up more space, so that the same weight of air heated will have more bulk than equal weights of cold air which may surround it, and in that case must rise, being forced upwards by such colder and heavier air, which presses to get under it and take its place. That air is so rarefied or expanded by heat, may be proved to their comprehension by a lank blown bladder, which laid before a fire, will soon swell, grow tight, and burst.

Plate CCCCLXXI. fig. 1.

Another experiment may be to take a glass tube about an inch in diameter, 12 inches long, open at both ends, and fixed upright on legs so that it need not be handled, for the hands might warm it. At the end of a quill fasten five or six inches of the finest light filament of silk, so that it may be held either above the upper end of the tube or under the lower end, your warm hand being at a distance by the length of the quill. If there were any motion of air through the tube, it would manifest itself by its effect on the silk; but if the tube and the air in it are of the same temperature with the surrounding air, there will be no such motion, whatever may be the form of the tube, whether crooked or straight, narrow below and widening upwards, or the contrary, the air in it will be quiescent. Warm the tube, and you will find as long as it continues warm, a constant current of air entering below and passing up through it till discharged at the top; because the warmth of the tube being communicated to the air it contains, rarefies that air, and makes it lighter than the air without; which therefore presses in below, forces it upwards, follows and takes its place, and is rarefied in its turn. And, without warming the tube, if you hold under it a knob of hot iron, the air thereby heated will rise and fill the tube, going out at its top; and this motion in the tube will continue as long as the knob remains hot, because the air entering the tube below, is heated and rarefied by passing near and over that knob.

That this motion is produced merely by the difference of specific gravity between the fluid within and that without the tube, and not by any fancied form of the tube itself, may appear by plunging it into water contained in a glass jar a foot deep, through which such motion might be seen. The water within and without the tube being of the same specific gravity, balance each other, and both remain at rest. But take out the tube, stop its bottom with a finger, and fill it with olive oil, which is lighter than water; then stopping the top, place it as before, its lower end under water, its top a very little above. As long as you keep the bottom stopped the fluids remain at rest; but the moment it is unstopt, the heavier enters below, forces up the lighter, and takes its place: and the motion then ceases, merely because the new fluid cannot be successively made lighter, as air may be by a warm tube.

In fact, no form of the funnel of a chimney has any share in its operation or effect respecting smoke except its height. The longer the funnel, if erect, the greater its force when filled with heated and rarefied air to draw in below and drive up the smoke, if one may, in compliance with custom, use the expression *draw*, when in fact it is the superior weight of the surrounding atmosphere that presses to enter the funnel below, and so drives up before it the smoke and warm air it meets with in its passage.

What is it then which makes a smoky chimney, that is, a chimney which, instead of conveying up all the smoke, discharges a part of it into the room, offending the eyes and damaging the furniture.

The causes of this effect may be reduced to *nine*, differing from each other, and therefore requiring different remedies.

1. *Smoky chimneys in a new house are such frequently from mere want of air.* The workmanship of the rooms being all good, and just out of the workman's hands, the joints of the boards of the flooring, and of the pannels of wainscotting, are all true and tight; the more so as the

Smoke.

the walls, perhaps not yet thoroughly dry, preserve a dampneſs in the air of the room which keeps the wood work ſwelled and cloſe. The doors and the ſaſhes too, being worked with truth, ſhut with exactneſs, ſo that the room is as tight as a ſnuff-box, no paſſage being left open for air to enter except the key-hole, and even that is ſometimes covered by a little dropping ſhutter. Now if ſmoke cannot riſe but as connected with rarefied air, and a column of ſuch air, ſuppoſe it filling the funnel, cannot riſe unleſs other air be admitted to ſupply its place; and if therefore no current of air enter the opening of the chimney—there is nothing to prevent the ſmoke from coming out into the room. If the motion upwards of the air in a chimney that is freely ſupplied be obſerved by the riſing of the ſmoke or a feather in it, and it be conſidered that in the time ſuch feather takes in riſing from the fire to the top of the chimney, a column of air equal to the content of the funnel muſt be diſcharged, and an equal quantity ſupplied from the room below, it will appear abſolutely impoſſible that this operation ſhould go on if the tight room is kept ſhut; for were there any force capable of drawing conſtantly ſo much air our of it, it muſt ſoon be exhauſted like the receiver of an air-pump, and no animal could live in it. Thoſe therefore who ſtop every crevice in a room to prevent the admiſſion of freſh air, and yet would have their chimney carry up the ſmoke, require inconſiſtencies, and expect impoſſibilities. Yet under this ſituation it is not uncommon to ſee the owner of a new houſe in deſpair, and ready to ſell it for much leſs than it coſt; conceiving it uninhabitable becauſe not a chimney in any one of its rooms will carry off the ſmoke unleſs a door or window be left open. Much expence has alſo been made to alter and amend new chimneys which had really no fault: in one houſe particularly which Dr Franklin knew that belonged to a nobleman in Weſtminſter, that expence amounted to no leſs than L. 300, after his houſe had been, as he thought, finiſhed and all charges paid. And after all, ſeveral of the alterations were ineffectual, for want of underſtanding the true pinciples.

Remedies. When you find on trial that opening the door or a window enables the chimney to carry up all the ſmoke, you may be ſure that want of air from without was the cauſe of its ſmoking. "I ſay from *without* (adds Dr Franklin), to guard you againſt a common miſtake of thoſe who may tell you the room is large, contains abundance of air ſufficient to ſupply any chimney, and therefore it cannot be that the chimney wants air. Theſe reaſoners are ignorant that the largeneſs of a room, if tight, is in this caſe of ſmall importance, ſince it cannot part with a chimney full of its air without occaſioning ſo much vacuum; which it requires a great force to effect, and could not be borne if effected."

It appearing plainly then, that ſome of the outward air muſt be admitted, the queſtion will be, how much is abſolutely neceſſary? for you would avoid admitting more, as being contrary to one of your intentions in having a fire, viz. that of warming your room. To diſcover this quantity, ſhut the door gradually while a middling fire is burning, till you find that before it is quite ſhut the ſmoke begins to come out into the room; then open it a little till you preceive the ſmoke comes out no longer. There hold the door, and obſerve the width of the open crevice between the edge of the door and the rabbet it ſhould ſhut into. Suppoſe the diſtance to be half an inch, and the door eight feet high; you find thence that your room requires an entrance for air equal in area to 96 half inches, or 48 ſquare inches, or a paſſage of 6 inches by 8. This, however, is a large ſuppoſition; there being few chimneys that, having a moderate opening and a tolerable height of funnel, will not be ſatisfied with ſuch a crevice of a quarter of an inch: Dr Franklin found a ſquare of 6 by 6, or 36 ſquare inches, to be a pretty good medium that will ſerve for moſt chimneys. High funnels with ſmall ~~and low openings~~ may indeed be ſupplied through a leſs ſpace; becauſe, for reaſons that will appear hereafter, the force of levity, if one may ſo ſpeak, being greater in ſuch funnels, the cool air enters the room with greater velocity, and conſequently more enters in the ſame time. This, however, has its limits; for experience ſhows, that no increaſed velocity ſo occaſioned has made the admiſſion of air, through the key-hole equal in quantity to that through an open door, though through the door the current moves ſlowly, and through the key-hole with great rapidity.

It remains then to be conſidered, how and where this neceſſary quantity of air from without is to be admitted ſo as to be leaſt inconvenient: for if at the door, left ſo much open, the air thence proceeds directly to the chimney; and in its way comes cold to your back and heels as you ſit before your fire. If you keep the door ſhut, and raiſe a little the ſaſh of your window, you feel the ſame inconvenience. Various have been the contrivances to avoid this; ſuch as bringing in freſh air through pipes in the jams of the chimney, which pointing upwards ſhould blow the ſmoke up the funnel; opening paſſages into the funnel above, to let in air for the ſame purpoſe. But theſe produce an effect contrary to that intended: for as it is the conſtant current of air paſſing from the room through the opening of the chimney into the funnel which prevents the ſmoke from coming out into the room, if you ſupply the funnel by other means or in other ways with the air which it wants, and eſpecially if that air be cold, you diminiſh the force of that current, and the ſmoke in its efforts to enter the room finds leſs reſiſtance.

The wanted air muſt then indiſpenſably be admitted into the room, to ſupply what goes off through the opening of the chimney. M. Gauger, a very ingenious and intelligent French writer on the ſubject, propoſes with judgment to admit it above the opening of the chimney; and to prevent inconvenience from its coldneſs, he directs that it may be ſo made, that it ſhall paſs in its entrance through winding cavities made behind the iron back and ſides of the fire-place, and under the iron hearth-plate; in which cavities it will be warmed, and even heated, ſo as to contribute much, inſtead of cooling, to the warming of the room. This invention is excellent in itſelf, and may be uſed with advantage in building new houſes; becauſe the chimneys may then be ſo diſpoſed as to admit conveniently the cold air to enter ſuch paſſages: but in houſes built without ſuch views, the chimneys are often ſo ſituated as not to afford that convenience without great and expenſive alterations. Eaſy and cheap methods, though not quite ſo perfect in themſelves, are of more general utility; and ſuch are the following.

Smoke.

In all rooms where there is a fire, the body of air warmed and rarefied before the chimney is continually changing place, and making room for other air that is to be warmed in its turn. Part of it enters and goes up the chimney, and the rest rises and takes place near the ceiling. If the room be lofty, that warm air remains above our heads as long as it continues warm, and we are little benefited by it, because it does not descend till it is cooler. Few can imagine the difference of climate between the upper and lower parts of such a room, who have not tried it by the thermometer, or by going up a ladder till their heads are near the ceiling. It is then among this warm air that the wanted quantity of outward air is best admitted, with which being mixed, its coldness is abated, and its inconvenience diminished so as to become scarce observable. This may be easily done by drawing down about an inch the upper sash of a window; or, if not movable, by cutting such a crevice through its frame; in both which cases it will be well to place a thin shelf of the length to conceal the opening, and sloping upwards, to direct the entering air horizontally along and under the ceiling. In some houses the air may be admitted by such a crevice made in the wainscot, cornice, or plastering, near the ceiling and over the opening of the chimney. This, if practicable, is to be chosen, because the entering cold air will there meet with the warmest rising air from before the fire, and be soonest tempered by the mixture. The same kind of shelf should also be placed here. Another way, and not a very difficult one, is to take out an upper pane of glass in one of your sashes, set it in a tin frame, giving it two springing angular sides, and then replacing it, with hinges below on which it may be turned to open more or less above. It will then have the appearance of an internal sky-light. By drawing this pane in, more or less, you may admit what air you find necessary. Its position will naturally throw that air up and along the ceiling. This is what is called in France a *Was ist das?* As this is a German question, the invention is probably of that nation, and takes its name from the frequent asking of that question when it first appeared. In England some have of late years cut a round hole about five inches diameter in a pane of the sash and placed against it a circular plate of tin hung on an axis, and cut into vanes; which, being separately bent a little oblique, are acted upon by the entering air, so as to force the plate continually round like the vanes of a windmill. This admits the outward air, and by the continual whirling of the vanes, does in some degree disperse it. The noise only is a little inconvenient.

Fig. 2.

2. A second cause of the smoking of chimneys is, *their openings in the room being too large*; that is, too wide, too high, or both. Architects in general have no other ideas of proportion in the opening of a chimney than what relate to symmetry and beauty respecting the dimensions of the room; while its true proportion respecting its function and utility depends on quite other principles; and they might as properly proportion the step in a staircase to the height of the story, instead of the natural elevation of men's legs in mounting. The proportion then to be regarded, is what relates to the height of the funnel. For as the funnels in the different stories of a house are necessarily of different heights or lengths, that from the lowest floor being the highest or longest, and those of the other floors shorter and shorter, till we come to those in the garrets, which are of course the shortest; and the force of draft being, as already said, in proportion to the height of funnel filled with rarefied air, and a current of air from the room into the chimney, sufficient to fill the opening, being necessary to oppose and prevent the smoke from coming out into the room, it follows, that the openings of the longest funnels may be larger, and that those of the shorter funnels should be smaller. For if there be a large opening to a chimney that does not draw strongly, the funnel may happen to be furnished with the air which it demands by a partial current entering on one side of the opening, and leaving the other side free of any opposing current, may permit the smoke to issue there into the room. Much too of the force of draft in a funnel depends on the degree of rarefaction in the air it contains, and that depends on the nearness to the fire of its passage in entering the funnel. If it can enter far from the fire on each side or far above the fire, in a wide or high opening, it receives little heat in passing by the fire, and the contents of the funnel are by those means less different in levity from the surrounding atmosphere, and its force in drawing consequently weaker. Hence if too large an opening be given to chimneys in upper rooms, those rooms will be smoky: On the other hand, if too small openings be given to chimneys in the lower rooms, the entering air operating too directly and violently on the fire, and afterwards strengthening the draft as it ascends the funnel, will consume the fuel too rapidly.

Smoke.

Remedy. As different circumstances frequently mix themselves in these matters, it is difficult to give precise dimensions for the openings of all chimneys. Our fathers made them generally much too large: we have lessened them; but they are often still of greater dimensions than they should be, the human eye not being easily reconciled to sudden and great changes. If you suspect that your chimney smokes from the too great dimension of its opening, contract it by placing moveable boards so as to lower and narrow it gradually till you find the smoke no longer issues into the room. The proportion so found will be that which is proper for that chimney, and you may employ the bricklayer or mason to reduce it accordingly. However, as in building new houses something must be sometimes hazarded, Dr Franklin proposes to make the openings in the lower rooms about 30 inches square and 18 deep, and those in the upper only 18 inches square and not quite so deep; the intermediate ones diminishing in proportion as the height of the funnel is diminished. In the larger openings, billets of two feet long, or half the common length of cordwood, may be burnt conveniently; and for the smaller, such wood may be sawed into thirds. Where coals are the fuel, the grates will be proportioned to the openings. The same depth is nearly necessary to all, the funnels being all made of a size proper to admit a chimney-sweeper. If in large and elegant rooms custom or fancy should require the appearance of a larger chimney, it may be formed of expensive marginal decorations, in marble, &c. But in time perhaps, that which is fittest in the nature of things may come to be thought handsomest.

3. Another cause of smoky chimneys is *too short a funnel.* This happens necessarily in some cases, as where a chimney

a chimney is required in a low building; for, if the funnel be raised high above the roof, in order to strengthen its draft, it is then in danger of being blown down, and crushing the roof in its fall.

Remedies. Contract the opening of the chimney, so as to oblige all the entering air to pass through or very near the fire; whereby it will be more heated and rarefied, the funnel itself be more warmed, and its contents have more of what may be called the force of levity, so as to rise strongly and maintain a good draft at the opening.

Or you may in some cases, to advantage, build additional stories over the low building, which will support a high funnel.

If the low building be used as a kitchen, and a contraction of the opening therefore inconvenient, a large one being necessary, at least when there are great dinners for the free management of so many cooking utensils; in such case the best expedient perhaps would be to build two more funnels joining to the first, and having three moderate openings, one to each funnel, instead of one large one. When there is occasion to use but one, the other two may be kept shut by sliding plates, hereafter to be described; and two or all of them may be used together when wanted. This will indeed be an expence, but not an useless one, since your cooks will work with more comfort, see better than in a smoky kitchen what they are about, your victuals will be cleaner dressed and not taste of smoke, as is often the case; and to render the effect more certain, a stack of three funnels may be safely built higher above the roof than a single funnel.

The case of too short a funnel is more general than would be imagined, and often found where one would not expect it. For it is not uncommon, in ill contrived buildings, instead of having a funnel for each room or fire-place, to bend and turn the funnel of an upper room so as to make it enter the side of another funnel that comes from below. By these means the upper room funnel is made short of course, since its length can only be reckoned from the place where it enters the lower room funnel; and that funnel is also shortened by all the distance between the entrance of the second funnel and the top of the stack: for all that part being readily supplied with air through the second funnel, adds no strength to the draft, especially as that air is cold when there is no fire in the second chimney. The only easy remedy here is, too keep the opening of that funnel shut in which there is no fire.

4. Another very common cause of the smoking of chimneys is, *their overpowering one another*. For instance, if there be two chimneys in one large room, and you make fires in both of them, the doors and windows close shut, you will find that the greater and stronger fire shall overpower the weaker, from the funnel of which it will draw air down to supply its own demand; which air descending in the weaker funnel, will drive down its smoke, and force it into the room. If, instead of being in one room, the two chimneys are in two different rooms, communicating by a door, the case is the same whenever that door is open. In a very tight house, a kitchen chimney on the lowest floor, when it had a great fire in it, has been known to overpower any other chimney in the house, and draw air and smoke into its room as often as the door communicating with the staircase was opened.

Remedy. Take care that every room have the means of supplying itself from without with the air which its chimney may require, so that no one of them may be obliged to borrow from another, nor under the necessity of lending. A variety of these means have been already described.

5. Another cause of smoking is, *when the tops of chimneys are commanded by higher buildings, or by a hill*, so that the wind blowing over such eminences falls like water over a dam, sometimes almost perpendicularly on the tops of the chimneys that lie in its way, and beats down the smoke contained in them.

To illustrate this, let A (fig. 3.) represent a small building at the side of a great rock B, and the wind coming in the direction CD; when the current of air comes to the point D, being hurried forward with great velocity, it goes a little forward, but soon descends downward, and gradually is reflected more and more inward, as represented by the dotted lines EE, &c. so that, descending downwards upon the top of the chimney A, the smoke is beat back again into the apartments.

It is evident that houses situated near high hills or thick woods will be in some measure exposed to the same inconvenience; but it is likewise plain, that if a house be situated upon the slope of a hill (as at F, fig. 3.), it will not be in any danger of smoke when the wind blows towards that side of the hill upon which it is situated; for the current of air coming over the house-top in the direction GH, is immediately changed by the slope of the hill to the direction HC, which powerfully draws the smoke upward from the top of the chimney. But it is also evident, that a house in this situation will be liable to smoke when the wind blows from the hill; for the current of air coming downward in the direction CH, will beat downward on the chimney F, and prevent the smoke from ascending with freedom. The effect will be much heightened if the doors and windows are chiefly in the lowermost side of the house.

Remedy. That commonly applied to this case is a turncap made of tin or plate iron, covering the chimney above and on three sides, open on one side, turning on a spindle; and which being guided or governed by a vane always presents its back to the current. This may be generally effectual, though not certain, as there may be cases in which it will not succeed. Raising your funnels if practicable, so as their tops may be higher, or at least equal, with the commanding eminence, is more to be depended on. But the turning cap, being easier and cheaper, should first be tried. "If obliged to build in such a situation, I would choose (says Dr Franklin) to place my doors on the side next the hill, and the backs of my chimneys on the farthest side; for then the column of air falling over the eminence, and of course pressing on that below, and forcing it to enter the doors or *was-ist-das*es on that side, would tend to balance the pressure down the chimneys, and leave the funnels more free in the exercise of their functions."

6. There is another case which is the reverse of that last mentioned. It is where the commanding eminence is

Smoke. Fig. 4.

is farther from the wind than the chimney commanded. To explain this a figure may be necessary. Suppose then a building whose side AB happens to be exposed to the wind, and forms a kind of dam against its progress. Suppose the wind blowing in the direction FE. The air obstructed by this dam or building AB will like water press and search for passages through it; but finding none, it is beat back with violence, and spreads itself on every side, as is represented by the curved lines *e, e, e, e, e, e*. It will therefore force itself down the small chimney C, in order to get through by some door or window open on the other side of the building. And if there be a fire in such chimney, its smoke is of course beat down, and fills the room.

Remedy. There is but one remedy, which is to raise such a funnel higher than the roof, supporting it if necessary by iron bars. For a turncap in this case has no effect, the dammed up air pressing down through it in whatever position the wind may have placed its opening.

Dr Franklin mentions a city in which many houses are rendered smoky by this operation. For their kitchens being built behind, and connected by a passage with the houses, and the tops of the kitchen-chimneys lower than the tops of the houses, the whole side of a street when the wind blows against its back forms such a dam as above described; and the wind so obstructed forces down those kitchen-chimneys (especially when they have but weak fires in them) to pass through the passage and house into the street. Kitchen-chimneys so formed and situated have another inconvenience. In summer, if you open your upper room windows for air, a light breeze blowing over your kitchen chimney towards the house, though not strong enough to force down its smoke as aforesaid, is sufficient to waft it into your windows, and fill the rooms with it; which, besides the disagreeablness, damages your furniture.

7. Chimneys, otherwise drawing well, are sometimes made to smoke by *the improper and inconvenient situation of a door.* When the door and chimney are on the same side of the room, if the door being in the corner is made to open against the wall, which is common, as being there, when open, more out of the way, it follows, that when the door is only opened in part, a current of air rushing in passes along the wall into and across the opening of the chimney, and flirts some of the smoke out into the room. This happens more certainly when the door, is shutting, for then the force of the current is augmented, and becomes very inconvenient to those who, warming themselves by the fire, happen to sit in its way.

The *remedies* are obvious and easy. Either put an intervening screen from the wall round great part of the fireplace; or, which is perhaps preferable, shift the hinges of your door, so as it may open the other way, and when open throw the air along the other wall.

8. A room that has no fire in its chimney is sometimes filled with *smoke which is received at the top of its funnel and descends into the room.* Funnels without fires have an effect according to their degree of coldness or warmth on the air that happens to be contained in them. The surrounding atmosphere is frequently changing its temperature; but stacks of funnels covered from winds and sun by the house that contains them, retain a more equal temperature. If, after a warm season, the outward air suddenly grows cold, the empty warm funnels begin to draw strongly upward; that is, they rarefy the air contained in them, which of course rises, cooler air enters below to supply its place, is rarefied in its turn, and rises; and this operation continues till the funnel grows cooler, or the outward air warmer, or both, when the motion ceases. On the other hand, if after a cold season the outward air suddenly grows warm and of course lighter, the air contained in the cool funnels being heavier descends into the room; and the warmer air which enters their tops being cooled in its turn, and made heavier, continues to descend; and this operation goes on till the funnels are warmed by the passing of warm air thro' them, or the air itself grows cooler. When the temperature of the air and of the funnels is nearly equal, the difference of warmth in the air between day and night is sufficient to produce these currents: the air will begin to ascend the funnels as the cool of the evening comes on, and this current will continue till perhaps nine or ten o'clock the next morning, when it begins to hesitate; and as the heat of the day approaches, it sets downwards, and continues so till towards evening, when it again hesitates for some time, and then goes upwards constantly during the night, as before mentioned. Now when smoke issuing from the tops of neighbouring funnels passes over the tops of funnels which are at the time drawing downwards, as they often are in the middle part of the day, such smoke is of necessity drawn into these funnels, and descends with the air into the chamber.

Smoke.

The remedy is to have a sliding plate that will shut perfectly the offending funnel. Dr Franklin has thus described it: "The opening of the chimney is contracted by brick-work faced with marble slabs to about two feet between the jams, and the breast brought down to within about three feet of the hearth. An iron frame is placed just under the breast, and extending quite to the back of the chimney, so that a plate of the same metal may slide horizontally, backwards and forwards in the grooves on each side of the frame. This plate is just so large as to fill the whole space, and shut the chimney entirely when thrust quite in, which is convenient when there is no fire. Draw it out, so as to leave between its further edge and the back a space of about two inches; this space is sufficient for the smoke to pass; and so large a part of the funnel being stopt by the rest of the plate, the passage of warm air out of the room, up the chimney, is obstructed and retarded; and by those means much cold air is prevented from coming in through crevices, to supply its place. The effect is made manifest three ways. 1. When the fire burns briskly in cold weather, the howling or whistling noise made by the wind, as it enters the room through the crevices, when the chimney is open as usual, ceases as soon as the plate is slid into its proper distance. 2. Opening the door of the room about half an inch, and holding your hand against the opening, near the top of the door, you feel the cold air coming in against your hand, but weakly, if the plate be in. Let another person suddenly draw it out, so as to let the air of the room go up the chimney, with its usual freedom where chimneys are open, and you immediately feel the cold air rushing in strongly. 3. If something be set against the door, just sufficient, when the plate is in, to keep the door nearly shut, by resisting the pressure of the air, Smoke. air that would force it open; then, when the plate is drawn out, the door will be forced open by the increased pressure of the outward cold air endeavouring to get in to supply the place of the warm air that now passes out of the room to go up the chimney. In our common open chimneys, half the fuel is wasted, and its effect lost; the air it has warmed being immediately drawn off."

9. Chimneys which generally draw well, do nevertheless sometimes give smoke into the rooms, *it being driven down by strong winds passing over the tops of their funnels*, though not descending from any commanding eminence. This case is most frequent where the funnel is short and the opening turned from the wind. It is the more grievous, when it happens to be a cold wind that produces the effect, because when you most want your fire you are sometimes obliged to extinguish it. To understand this, it may be considered that the rising light air, to obtain a free issue from the funnel, must push out of its way or oblige the air that is over it to rise. In a time of calm or of little wind this is done visibly; for we see the smoke that is brought up by that air rise in a column above the chimney: but when a violent current of air, that is, a strong wind, passes over the top of a chimney, its particles have received so much force, which keeps them in a horizontal direction and follow each other so rapidly, that the rising light air has not strength sufficient to oblige them to quit that direction and move upwards to permit its issue.

Remedies. In Venice, the custom is to open or widen the top of the flue rounding it in the true form of a funnel. In other places the contrary is practised; the tops of the flues being narrowed inwards, so as to form a slit for the issue of the smoke, long as the breadth of the funnel, and only four inches wide. This seems to have been contrived on a supposition that the entry of the wind would thereby be obstructed, and, perhaps it might have been imagined, that the whole force of the rising warm air being condensed, as it were, in the narrow opening, would thereby be strengthened, so as to overcome the resistance of the wind. This, however, did not always succeed; for when the wind was at north-east and blew fresh, the smoke was forced down by fits into the room where Dr Franklin commonly sat, so as to oblige him to shift the fire into another. The position of the slit of this funnel was indeed north-east and south-west. Perhaps if it had lain across the wind, the effect might have been different. But on this we can give no certainty. It seems a matter proper to be referred to experiment. Possibly a turncap might have been serviceable, but it was not tried.

With all the science, however, that a man shall suppose himself possessed of in this article, he may sometimes meet with cases that shall puzzle him. "I once lodged (says Dr Franklin) in a house at London, which in a little room had a single chimney and funnel. The opening was very small, yet it did not keep in the smoke, and all attempts to have a fire in this room were fruitless. I could not imagine the reason, till at length observing that the chamber over it, which had no fireplace in it, was always filled with smoke when a fire was kindled below, and that the smoke came through the cracks and crevices of the wainscot; I had the wainscot taken down, and discovered that the funnel which went up behind it had a crack many feet in length, and wide enough to admit my arm; a breach very dangerous with regard to fire, and occasioned probably by an apparent irregular settling of one side of the house. The air entering this breach freely, destroyed the drawing force of the funnel. The remedy would have been, filling up the breach, or rather rebuilding the funnel: but the landlord rather chose to stop up the chimney.

"Another puzzling case I met with at a friend's country house near London. His best room had a chimney in which he told me, he never could have a fire, for all the smoke came out into the room. I flattered myself I could easily find the cause and prescribe the cure. I had a fire made there, and found it as he said. I opened the door, and perceived it was not want of air. I made a temporary contraction of the opening of the chimney, and found that it was not its being too large that caused the smoke to issue. I went out and looked up at the top of the chimney: Its funnel was joined in the same stack with others; some of them shorter, that drew very well, and I saw nothing to prevent its doing the same. In fine, after every other examination I could think of, I was obliged to own the insufficiency of my skill. But my friend, who made no pretension to such kind of knowledge, afterwards discovered the cause himself. He got to the top of the funnel by a ladder, and looking down found it filled with twigs and straw cemented by earth and lined with feathers. It seems the house, after being built had stood empty some years before he occupied it; and he concluded that some large birds had taken the advantage of its retired situation to make their nest there. The rubbish, considerable in quantity, being removed, and the funnel cleared, the chimney drew well, and gave satisfaction."

Chimneys whose funnels go up in the north wall of a house, and are exposed to the north winds, are not so apt to draw well as those in a south wall; because when rendered cold by those winds, they draw downwards.

Chimneys inclosed in the body of a house are better than those whose funnels are exposed in cold walls.

Chimneys in stacks are apt to draw better than separate funnels, because the funnels that have constant fires in them warm the others in some degree that have none.

Smoke-Jack. *Smoke-Jack*. This ingenious machine is of German extraction; and Messinger, in his *Collection of Mechanical Performances*, says it is very ancient, being represented in a painting at Nurenbergh, which is known to be older than the year 1350.

Its construction is abundantly simple. An upright iron spindle GA (fig. 5.), placed in the narrow part of the kitchen chimney, turns round on two pivots H and I. The upper one H passes through an iron bar, which is built in across the chimney; and the lower pivot I is of tempered steel, and is conical or pointed, resting in a conical bell-metal socket fixed on another cross bar. On the upper end of the spindle is a circular fly G, consisting of 4, 6, 8, or more thin iron plates, set obliquely on the spindle like the sails on a windmill, as we shall describe more particularly by and by. Near the lower end of the spindle is a pinion A, which works in the teeth of a contrate or face wheel B, turning on a horizontal axis BC. One pivot of this axis turns in a cock fixed on the cross bar, which supports the lower end of the upright spindle HI, and the other pivot Plate CCCCLXXV.

turns in a cock fixed on the side wall of the chimney; so that this axle is parallel to the front of the chimney. On the remote end of this horizontal axle there is a small pulley C, having a deep angular groove. Over this pulley there passes a chain CDE, in the lower bight of which hangs the large pulley E of the spit. This end of the spit turns loosely between the branches of the fork of the rack or raxe F, but without resting on it. This is on the top of a moveable stand, which can be shifted nearer to, or farther from the fire. The other end turns in one of the notches of another rack. The number of teeth in the pinion A and wheel B, and the diameters of the pulleys C and E, are so proportioned that the fly G makes from 12 to 20 turns for one turn of the spit.

The manner of operation of this useful machine is easily understood. The air which contributes to the burning of the fuel, and passes through the midst of it, is greatly heated, and expanding prodigiously in bulk, becomes lighter than the neighbouring air, and is therefore pushed by it up the chimney. In like manner, all the air which comes near the fire is heated, expanded, becomes lighter, and is driven up the chimney. This is called the *draught* or *suction*, but would with greater propriety be termed the *drift* of the chimney. As the chimney gradually contracts in its dimensions, and as the same quantity of heated air passes through every section of it, it is plain that the rapidity of its ascent must be greatest in the narrowest place. There the fly G should be placed, because it will there be exposed to the strongest current. This air, striking the fly vanes obliquely, pushes them aside, and thus turns them round with a considerable force. If the joint of meat is exactly balanced on the spit, it is plain that the only resistance to the motion of the fly is what arises from the friction of the pivots of the upright spindle, the friction of the pinion and wheel, the friction of the pivots of the horizontal axis, the friction of the small end of the spit, and the friction of the chain in the two pulleys. The whole of this is but a mere trifle. But there is frequently a considerable superiority in the weight of the meat on different sides of the spit; there must therefore be a sufficient overplus of force in the impulse of the ascending air on the vanes of the fly, to overcome this want of equilibrium occasioned by the unskilfulness or negligence of the cook. There is, however, commonly enough of power when the machine is properly constructed. The utility of this machine will, we hope, procure us the indulgence of some of our readers, while we point out the circumstances on which its performance depends, and the maxims which should be followed in its construction.

The upward current of air is the moving power, and should be increased as much as possible, and applied in the most advantageous manner. Every thing will increase the current which improves the draught of the chimney, and secures it from smoking. A smoky chimney must always have a weak current. For this particular, therefore, we refer to what has been delivered in the article Pneumatics, n° 359; and in the article Smoke.

With respect to the manner of applying this force, it is evident that the best construction of a windmill sails will be nearly the best construction for the fly. According to the usual theory of the impulse of fluids, the greatest effective impulse (that is, in the direction of the fly's motion) will be produced if the plane of the vane be inclined to the axes in an angle of 54 degrees 46 minutes. But, since we have pronounced this theory to be so very defective, we had better take a determination founded on the experiments on the impulse of fluids made by the academy of Paris. These authorise us to say, that 49½ or 50 degrees will be the best angle to give the vane: but this must be understood only of that part of it which is close adjoining to the axis. The vane itself must be twisted, or *weathered* as the millwrights term it, and must be much more oblique at its outer extremity. The exact position cannot be determined with any precision; because this depends on the proportion of the velocity of the vane to that of the current of heated air. This is subject to no rule, being changed according to the load on the jack. We imagine that an obliquity of 65 degrees for the outer ends of the vanes will be a good position for the generality of cases. Messinger describes an ingenious contrivance for changing this angle at pleasure, in order to vary the velocity of the motion. Each vane is made to turn round a midrib, which stands out like a radius from the spindle, and the vane is moved by a stiff wire attached to one of the corners adjoining to the axle. These wires are attached to a ring which slides on the spindle like the spreader of an umbrella; and it is stopped on any part of the spindle by a pin thrust through a hole in the spindle and ring. We mention this briefly, it being easily understood by any mechanic, and but of little consequence, because the machine is not susceptible of much precision.

It is easy to see that an increase of the surface of the vanes will increase the power: therefore they should occupy the whole space of the circle, and not consist of four narrow arms like the sails of a windmill. It is better to make many narrow vanes than a few broad ones; as will appear plain to one well acquainted with the mode of impulse of fluids acting obliquely. We recommend 8 or 12 at least; and each vane should be so broad, that when the whole is held prependicular between the eye and the light, no light shall come through the fly, the vanes overlapping each other *a very small matter*. We also recommend the making them of stiff plate. Their weight contributes to the steady motion, and enables the fly, which has acquired a considerable velocity during a favourable position of things, to retain a momentum sufficient to pull round the spit while the heavy side of the meat is rising from its lowest position. In such a situation a light fly soon loses its momentum, and the jack staggers under its load.

It is plain from what has been said, that the fly should occupy the whole of that section of the vent where it is placed. The vent must therefore be brought to a round form in that place, that none of the current may pass uselessly by it.

It is an important question where the fly should be placed. If in a wide part of the vent, it will have a great surface, and act by a long lever; but the current in that place is slow, and its impulse weak. This is a fit subject of calculation. Suppose that we have it in our choice to place it either as it is drawn in the figure, or farther up at *g*, where its diameter must be one half of what it is at G. Since the same quantity of heated air passes through both sections, and the section *g* has only one-

fourth

Smoke-Jack.

fourth of the area of the section G, it is plain that the air must be moving four times faster, and that its impulse is 16 times greater. But the surface on which it is acting is the fourth part of that of the fly G; the actual impulse therefore is only four times greater, supposing both flies to be moving with the same relative velocity in respect of the current; that is, the rim of each moving with the same portion of the velocity of the current. This will be the case when the small fly turns eight times as often in a minute as the large fly: for the air is moving four times as quick at *g*, and the diameter of *g* is one-half of that of G. Therefore, when the small fly is turning eight times as quick as the great one, there is a quadruple impulse acting at half the distance from the axis. The momentum or energy therefore of the current is double. Therefore, supposing the pinion, wheel, and pulleys of both jacks to be the same, the jack with the small fly, placed in the narrow part of the vent, will be 16 times more powerful.

By this example, more easily understood than a general process, it appears that it is of particular importance to place the fly in an elevated part of the vent, where the area may be much contracted. In order still farther to increase the power of the machine, it would be very proper to lengthen the spindle still more, and to put another fly on it at a considerable distance above the first, and a third above this, &c.

As the velocity of the current changes by every change of the fire, the motion of this jack must be very unsteady. To render it as adjustable as may be to the particular purpose of the cook, the pulley E has several grooves of different diameters, and the spit turns more or less slowly, by the same motion of the fly, according as it hangs in the chain by a larger or smaller pulley or groove.

Such is the construction of the smoke-jack in its most simple form. Some are more artificial and complicated, having, in place of the pulleys and connecting chain, a spindle coming down from the horizontal axis BC. On the upper end of this spindle is a horizontal contrate wheel, driven by a pinion in place of the pulley C. On the lower end is a pinion, driving a contrate wheel in place of the pulley E. This construction is represented in fig. 6. Others are constructed more simply, in the manner represented in fig. 7. But our first construction has great advantage in point of simplicity, and allows a more easy adjustment of the spit, which may be brought nearer to the fire or removed farther from it without any trouble; whereas, in the others, with a train of wheels and pinions, this cannot be done without several changes of pins and screws. The only imperfection of the pulley is, that by long use the grooves become slippery, and an ill balanced joint is apt to hold back the spit, while the chain slides in the grooves. This may be completely prevented by making the grooves flat instead of angular (which greatly diminishes the friction), and furnishing them with short studs or pins which take into every third or fourth link of the chain. If the chain be made of the simplest form, with flat links, and each link be made of an exact length (making them all on a mould), the motion will be as easy as with any wheelwork, and without the least chance of slipping.

It is always of importance to avoid this slipping of the chain by balancing the loaded spit. For this purpose it will be extremely convenient to have what is called a *balance skewer*. Let a part of the spit, immediately adjoining to the pulley, be made round, and let an arm be made to turn on it stiffly, so that it may be made fast in any position by a screw. Let a leaden ball be made to slide along this arm, with a screw to fasten it at any distance from the spit. When the meat is spitted, lay it on the racks, and the heaviest side will immediately place itself undermost. Now turn round the balance-skewer, so that it may point straight upwards, and make it fast in that position by the screw. Put the leaden ball on it, and slide it inwards or outwards till it exactly balances the heavy side, which will appear by the spit's remaining in any position in which it is put.

The greatest difficulty is to keep the machine in repair. The most consequential part of it, the first mover, the fly, and the pinion and wheel, by which its motion is transmitted to the rest of the machine, are situated in a place of difficult access, and where they are exposed to violent heat and to the smoke and soot. The whole weight of the fly, resting on the lower pivot I, must exert a great pressure there, and occasion great friction, even when this pinion is reduced to the smallest size that is compatible with the necessary strength. The pivot must be of hardened steel, tapered, like an obtuse cone, and must turn in a conical socket, also of hardened steel or of bell-metal: and this seat of pressure and friction must be continually supplied with oil, which it consumes very quickly. It is not sufficient that it be from time to time smeared with an oiled feather; there must be an iron cup formed round the socket, and kept filled with oil. It is surprising how quickly it disappears: it soon becomes clammy by evaporation, and by the soot which gathers about it. The continued rubbing of the pivot and socket wears them both very fast; and this is increased by hard powders, such as sandy dust, that are hurried up by the rapid current every time that the cook stirs the fire. These, getting between the rubbing parts, cause them to grind and wear each other prodigiously. It is a great improvement to invert these rubbing parts. Let the lower end of the spindle be of a considerable thickness, and have a conical hollow nicely drilled in its extremity. Let a blunt pointed conical pin rise up in the middle of the oil-cup, on which the conical hollow of the spindle may rest. Here will be the same steady support, and the same friction as in the other way; but no grinding dust can now lodge between the pivot and its socket: and if this upright pin be screwed up through the bottom of the cup, it may be screwed farther up in proportion as it wears; and thus the upper pivot *g* will never desert its hole, a thing which soon happens in the common way. We can say from experience, that a jack constructed in this way will not require the fifth part of the repairs of one done in the other way.

It is of importance that the whole be so put together as to be easily taken down, in order to sweep the vent, or to be repaired, &c. For this purpose, let the cross bar which carries the lower end of the upright spindle be placed a little on one side of the perpendicular line from the upper pivot hole. Let the cock which carries the oil-cup and the pivot of the horizontal axis BC be ſcrewed to one ſide of this croſs bar, ſo that the centre of the cup may be exactly under the upper pivot hole. By this conſtruction we have only to unſcrew this cock, and then both axles come out of their places at once, and may be replaced without any trouble. We have ſketched in fig. 8. the manner in which this may be done, where M repreſents a ſection of the lower croſs bar. BCDE is the cock, fixed to the bar by the pins which go through both, with finger nuts *a* and *b* on the oppoſite ſide. F *i* is the hard ſteel pin with the conical top *i*, on which the lower end I of the upright ſpindle AG reſts, in the manner recommended as the beſt and the moſt durable. The pivot of the horizontal axis turns in a hole at E the top of the cock.

After all, we muſt acknowledge that the ſmoke jack is inferior to the common jack that is moved by a weight. It is more expenſive at firſt, and requires more frequent repairs; its motion is not ſo much under command; it occaſions ſoot to be thrown about the fire, to the great annoyance of the cook; and it is a great encumbrance when we would clean the vent.

Smoke-Farthings. The pentecoſtals or cuſtomary oblations offered by the diſperſed inhabitants within a dioceſe when they made their proceſſion to the mother or cathedral church, came by degrees into a ſtanding annual rent called *ſmoke farthings*.

Smoke-Silver. Lands were holden in ſome places by the payment of the ſum of 6 d. yearly to the ſheriff, called *ſmoke-Silver* (Par. 4. Edw. VI.) Smoke-ſilver and ſmoke-penny are to be paid to the miniſters of divers pariſhes as a *modus* in lieu of tithe-wood: and in ſome manors formerly belonging to religious houſes, there is ſtill paid, as appendant to the ſaid manors, the ancient Peter-pence by the name of *ſmoke-money (Twiſd. Hiſt. Vindicat.* 77.)—The biſhop of London *anno* 1444 iſſued out his commiſſion, *Ad levandum le* ſmoke-farthings, &c.

SMOLENSKO, a large and ſtrong city of Ruſſia and capital of a palatinate of the ſame name, with a caſtle ſeated on a mountain, and a biſhop's ſee. It is ſtrong by its ſituation, being in the middle of a wood, and ſurrounded by almoſt inacceſſible mountains. It has been taken and retaken ſeveral times by the Poles and Ruſſians; but theſe laſt have had poſſeſſion of it ever ſince the year 1687. It is ſeated on the river Nieper, near the frontiers of Lithuania, 188 miles ſouth weſt of Moſcow. E. Long. 31. 22. N. Lat. 54. 50.

Smolensko, a duchy and palatinate of Ruſſia, bounded on the north by Biela, on the eaſt by the duchy of Moſcow, on the ſouth by that of Severia and the palatinate Meiſlaw, and on the weſt by the ſame palatinate and by that of Witepſk. It is full of foreſts and mountains: and the capital is of the ſame name.

SMOLLET (Dr Tobias), an author whoſe writings will tranſmit his name with honour to poſterity, was born in the year 1740 at a ſmall village within two miles of Cameron, on the banks of the river Leven. He appears to have received a claſſical education, and was bred to the practice of phyſic and ſurgery; and in the early part of his life ſerved as a ſurgeon's mate in the navy.

The incidents that befel him during his continuance in this capacity ſerved as a foundation for Roderic Random, one of the moſt entertaining novels in the Engliſh tongue. He was preſent at the ſiege of Carthagena; and in the before-mentioned novel he has given a faithful, though not very pleaſing, account of the management of that ill-conducted expedition, which he cenſures in the warmeſt terms, and from circumſtances which fell under his own particular obſervation.

His connection with the ſea ſeems not to have been of long continuance; and it is probable that he wrote ſeveral pieces before he became known to the public by his capital productions. The firſt piece we know of with certainty is a Satire in two parts, printed firſt in the years 1746 and 1747, and reprinted in a Collection of his Plays and Poems in 1777. About this period, or ſome time before, he wrote for Mr Rich an opera intitled Alceſte, which has never been performed nor printed.

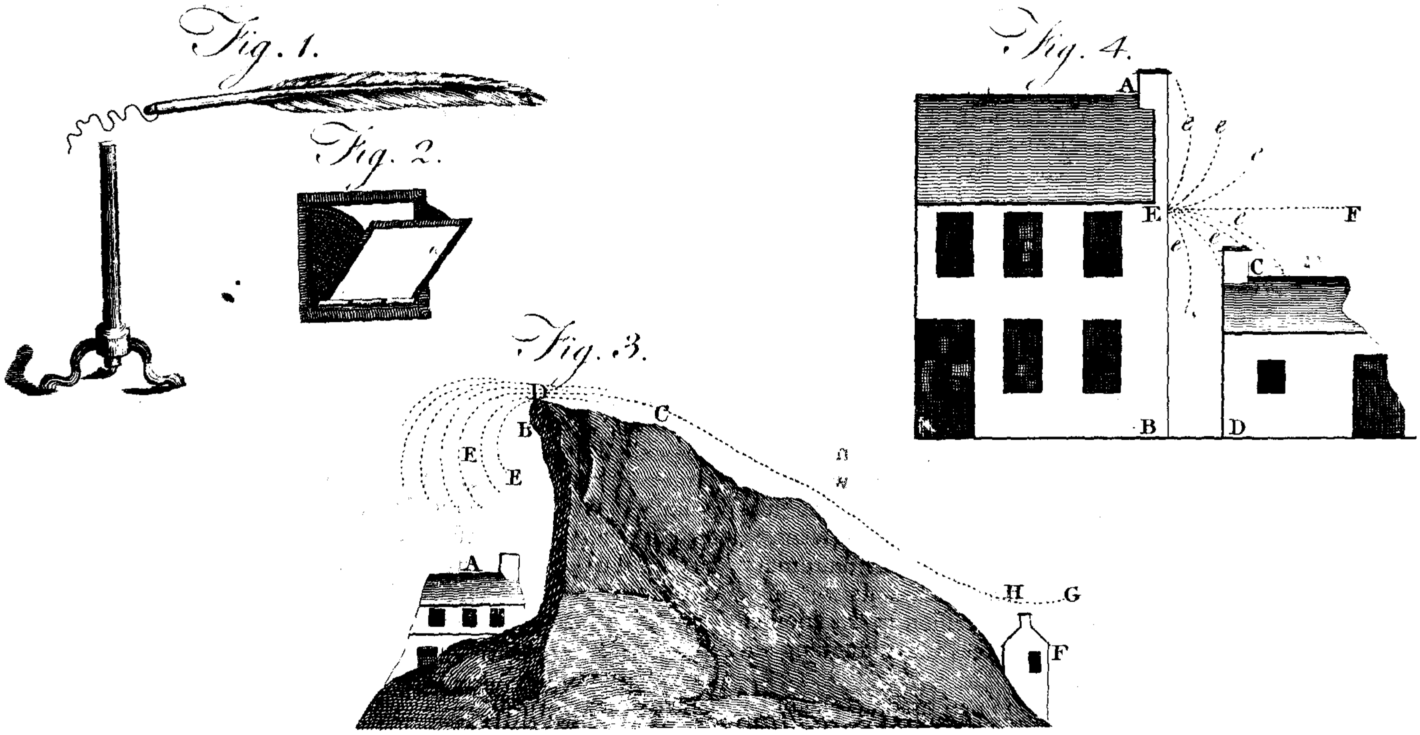
At the age of 18 he wrote a tragedy intitled The Regicide, founded on the ſtory of the aſſaſſination of James I. of Scotland. In the preface to this piece, publiſhed by ſubſcription in the year 1749, he bitterly exclaimed againſt falſe patrons, and the duplicity of theatrical managers. The warmth and impetuoſity of his temper hurried him, on this occaſion, into unjuſt reflections againſt the late George Lord Lyttleton and Mr Garrick: the character of the former he characteriſed in the novel of Peregrine Pickle, and he added a burleſque of the monody written by that nobleman on the death of his lady. Againſt Mr Garrick he made illiberal ill-founded criticiſms; and in his novel of Roderic Random gave a very unfair repreſentation of his treatment of him reſpecting this tragedy. Of this conduct he afterwards repented, and acknowledged his errors; though in the ſubſequent editions of the novel the paſſages which were the haſty effuſions of diſappointment are not omitted.

However, in giving a ſketch of the liberal arts in his hiſtory of England, he afterwards remarked, "the exhibitions of the ſtage were improved to the moſt exquiſite entertainment by the talents and management of Garrick, who greatly ſurpaſſed all his predeceſſors of this and perhaps every other nation, in his genius for acting, in the ſweetneſs and variety of his tones, the irreſiſtible magic of his eye, the fire and vivacity of his action, the eloquence of attitude, aud the whole pathos of expreſſion.

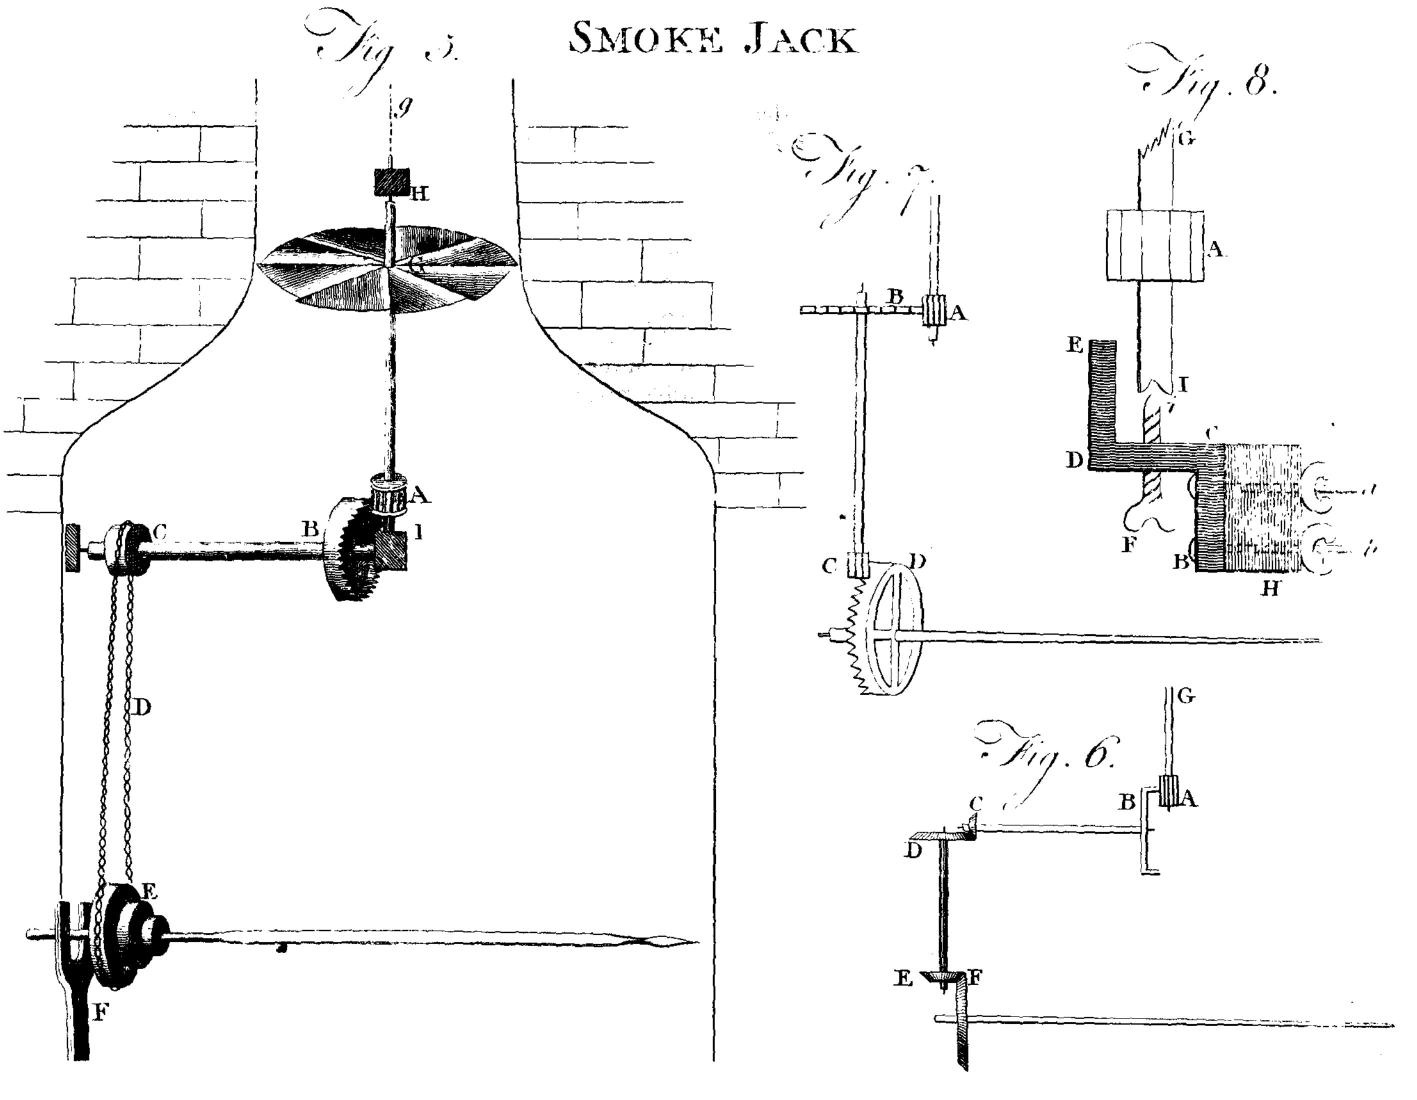
"Candidates for literary fame appeared even in the higher ſphere of life, embelliſhed by the nervous ſenſe and extenſive erudition of a Corke; by the delicate taſte, the poliſhed muſe, and the tender feelings, of a Lyttleton."

Not ſatisfied with this public declaration, he wrote an apology, to Mr Garrick in ſtill ſtronger terms. With theſe ample conceſſions, Mr Garrick was completely ſatisfied; ſo that in 1757, when Dr Smollet's comedy of the Repriſals, an afterpeice of two acts, was performed at Drury Lane theatre, the latter acknowledged himſelf highly obliged for the friendly care of Mr Garrick, exerted in preparing it for the ſtage; and ſtill more for his acting the part of Luſignan in Zara for his benefit, on the ſixth inſtead of the ninth night, to which he was only intitled by the cuſtom of the theatre.

The Adventures of Roderic Random, publiſhed in 1748, 2 vols 12mo, a book which ſtill continues to have a moſt extenſive



SMOKE JACK



Thackara sc.

Smollet.

extensive sale, first established the Doctor's reputation. All the first volume and the beginning of the second appears to consist of real incident and character, tho' certainly a good deal heightened and disguised. The Judge his grandfather, Crab and Potion the two apothecaries, and 'Squire Gawky, were characters well known in that part of the kingdom where the scene was laid. Captains Oakhum and Whiffle, Doctors Mackshane and Morgan, were also said to be real personages: but their names we have either never learned or have now forgotten. A bookbinder and barber long eagerly contended for being shadowed under the name of *Strap*. The Doctor seems to have enjoyed a peculiar felicity in describing sea characters, particularly the officers and sailors of the navy. His Trunnion, Hatchway, and Pipes, are highly finished originals; but what exceeds them all, and perhaps equals any character that has yet been painted by the happiest genius of ancient or modern times, is his Lieutenant Bowling. This is indeed nature itself; original, *unique*, and *sui generis*.

By the publication of this work the Doctor had acquired so great a reputation, that henceforth a certain degree of success was insured to every thing known or suspected to proceed from his hand. In the course of a few years, the Adventures of Peregrine Pickle appeared; a work of great ingenuity and contrivance in the composition, and in which an uncommon degree of erudition is displayed, particularly in the description of the entertainment given by the Republican Doctor, after the manner of the ancients. Under this personage the late Dr Akenside, author of The Pleasures of Imagination, is supposed to be typified; and it would be difficult to determine whether profound learning or genuine humour predominate most in this episode. Another episode of the Adventures of a Lady of Quality, likewise inserted in this work, contributed greatly to its success, and is indeed admirably executed; the materials, it is said, the lady herself (the celebrated lady *Vane*) furnished.

These were not the only original compositions of this stamp with which the Doctor has favoured the public. Ferdinand Count Fathom, and Sir Launcelot Greaves, are still in the list of what may be called *reading novels*, and have gone through several editions; but there is no injustice in placing them in a rank far below the former. No doubt invention, character, composition, and contrivance, are to be found in both; but then situations are described which are hardly possible, and characters are painted which, if not altogether unexampled, are at least incompatible with modern manners; and which ought not to be, as the scenes are laid in modern times.

The last work which we believe the Doctor published was of much the same species, but cast into a different form—The Expedition of Humphrey Clinker. It consists of a series of letters, written by different persons to their respective correspondents. He has here carefully avoided the faults which may be justly charged to his two former productions. Here are no extravagant characters nor unnatural situations. On the contrary, an admirable knowledge of life and manners is displayed; and most useful lessons are given applicable to interesting but to very common situations.

We know not whether the remark has been made, but there is certainly a very obvious similitude between the characters of the three heroes of the Doctor's chief productions. Roderic Random, Peregrine Pickle, and Matthew Bramble, are all brothers of the same family. The same satirical, cynical, disposition, the same generosity and benevolence, are the distinguishing and characteristical features of all three; but they are far from being servile copies or imitations of each other. They differ as much as the Ajax, Diomed, and Achilles of Homer. This was undoubtedly a great effort of genius; and the Doctor seems to have described his own character at the different stages and situations of his life.

Smollet.

Before he took a house at Chelsea, he attempted to settle as practitioner of physic at Bath; and with that view wrote a treatise on the waters; but was unsuccessful, chiefly because he could not render himself agreeable to the women, whose favour is certainly of great consequence to all candidates for eminence, whether in medicine or divinity. This, however, was a little extraordinary; for those who remember Dr Smollet at that time, cannot but acknowledge that he was as graceful and handsome a man as any of the age he lived in; besides, there was a certain dignity in his air and manner which could not but inspire respect wherever he appeared. Perhaps he was too soon discouraged; in all probability, had he persevered, a man of his great learning, profound sagacity, and intense application, besides being endued with every other external as well as internal accomplishment, must have at last succeeded, and, had he attained to common old age, been at the head of his profession.

Abandoning physic altogether as a profession, he fixed his residence at Chelsea, and turned his thoughts entirely to writing. Yet, as an author, he was not near so successful as his happy genius and acknowledged merit certainly deserved. He never acquired a patron among the great, who by his favour or beneficence relieved him from the necessity of writing for a subsistence. The truth is, Dr Smollet possessed a loftiness and elevation of sentiment and character which appears to have disqualified him from paying court to those who were capable of conferring favours. It would be wrong to call this disposition pride or haughtiness; for to his equals and inferiors he ever was polite, friendly, and generous. Booksellers may therefore be said to have been his only patrons; and from them he had constant employment in translating, compiling, and reviewing. He translated Gil Blas and Don Quixote, both so happily, that all the former translations of these excellent productions of genius have been almost superseded by his. His name likewise appears to a translation of Voltaire's Prose Works: but little of it was done by his own hand; he only revised it, and added a few notes. He was concerned in a great variety of compilations. His History of England was the principal work of that kind. It had a most extensive sale; and the Doctor is said to have received L. 2000 for writing it and the continuation.

In 1755 he set on foot the Critical Review, and continued the principal manager of it till he went abroad for the first time in the year 1763. He was perhaps too acrimonious sometimes in the conduct of that work; and at the same time displayed too much sensibility

when

when any of the unfortunate authors attempted to retaliate whose works he had perhaps justly censured.

Among other controversies in which his engagements in this publication involved him, the most material in its consequences was that occasioned by his remarks on a pamphlet published by Admiral Knowles. That gentleman, in defence of his conduct on the expedition to Rochford, published a vindication of himself; which falling under the Doctor's examination, produced some very severe strictures both on the performance and on the character of the writer. The admiral immediately commenced a prosecution against the printer; declaring at the same time that he desired only to be informed who the writer was, that if he proved to be a gentleman he might obtain the satisfaction of one from him. In this affair the Doctor behaved both with prudence and with spirit. Desirous of compromising the dispute with the admiral in an amicable manner, he applied to his friend Mr Wilkes to interpose his good offices with his opponent. The admiral, however, was inflexible; and just as sentence was going to be pronounced against the printer, the Doctor came into court, avowed himself the author of the Strictures, and declared himself ready to give Mr Knowles any satisfaction he chose. The admiral immediately commenced a fresh action against the Doctor, who was found guilty, fined L. 100, and condemned to three months imprisonment in the King's Bench. It is there he is said to have written The Adventures of Sir Launcelot Greaves, in which he has described some remarkable characters, then his fellow-prisoners.

When Lord Bute was called to the chief administration of affairs, he was prevailed upon to write in defence of that nobleman's measures; which he did in a weekly paper called the *Briton*. This gave rise to the famous North Briton; wherein, according to the opinion of the public, he was rather baffled. The truth is, the Doctor did not seem to possess the talents necessary for political altercation. He wanted temper and coolness; and his friends accused his patron of having denied him the necessary information, and even neglected the fulfilling of some of his other engagements with him. Be that as it will, the Doctor is said not to have forgotten him in his subsequent performances.

Besides the Briton, Dr Smollet is supposed to have written other pieces in support of the cause he espoused. The Adventures of an Atom, in two volumes, are known to be his production.

His constitution being at last greatly impaired by a sedentary life and assiduous application to study, he went abroad for his health in June 1763, and continued in France and Italy two years. He wrote an account of his travels in a series of letters to some friends, which were afterwards published in two volumes octavo, 1766. During all that time he appears to have laboured under a constant fit of chagrin. A very slight perusal of these letters will sufficiently evince that this observation is founded in fact, and is indeed a melancholy instance of the influence of bodily distemper over the best disposition.

His relation of his travels is actually cynical; for which Stern in his Sentimental Journey, has animadverted on him under the character of Smelfungus. The Doctor lived to return to his native country: but his health continuing to decline, and meeting with fresh mortifications and disappointments, he went back to Italy, where he died in October 21, 1771. He was employed, during the last years of his life, in abridging the Modern Universal History, great part of which he had originally written himself, particularly the histories of France, Italy, and Germany.

He certainly met with many mortifications and disappointments; which, in a letter to Mr Garrick, he thus feelingly expresses: "I am old enough to have seen and observed, that we are all playthings of Fortune; and that it depends upon something as insignificant and precarious as the tossing up of a halfpenny, whether a man rises to affluence and honours, or continues to his dying day struggling with the difficulties and disgraces of life."

It would be needless to expatiate on the character of a man so well known as Dr Smollet, who has, besides, given so many strictures of his own character and manner of living in his writings, particularly in Humphrey Clinker; where he appears under the appellation of *Mr Serle*, and has an interview with Mr Bramble; and his manner of living is described in another letter, where young Melford is supposed to dine with him at his house in Chelsea. No doubt he made money by his connections with the booksellers; and had he been a rigid economist, or endued with the gift of retention (an expression of his own), he might have lived and died very independent. However, to do justice to his memory, his difficulties, whatever they were, proceeded not from extravagance or want of economy. He was hospitable, but not ostentatiously so; and his table was plentiful, but not extravagant. No doubt he had his failings; but still it would be difficult to name a man who was so respectable for the qualities of his head, or more amiable for the virtues of his heart.

Since his death a monument has been erected to his memory near Leghorn, on which is inscribed an epitaph written in Latin by his friend Dr Armstrong, author of The Art of Preserving Health, and many other excellent pieces. An inscription written in Latin was likewise inscribed on a pillar erected to his memory on the banks of the Leven, by one of his relations.

To these memoirs we are extremely sorry to add, that so late as 1785 the widow of Dr Smollet was residing in indigent circumstances at Leghorn. On this account the tragedy of Venice Preserved was acted for her benefit at Edinburgh on the 5th of March, and an excellent prologue spoken on that occasion.

The pieces inserted in the posthumous collection of Dr Smollet's plays and poems are, The Regicide, a tragedy; The Reprisal, a comedy; Advice and Reproof, two satires; The Tears of Scotland; Verses on a Young Lady; a Love Elegy, in imitation of Tibullus; two Songs; a Burlesque Ode; Odes to Mirth, to Sleep, to Leven Water, to Blue-ey'd Ann, and to Independence.

SMUGGLERS, persons who import or export prohibited goods without paying the duties appointed by the law.

The duties of customs, it is said, were originally instituted in order to enable the government to afford protection to trade against pirates: they have since been continued as a branch of the public revenue. As duties

Smugglers. imposed upon the importation of goods necessarily raises their price above what they might otherwise had been sold for, a temptation is presented to import the commodity clandestinely and to evade the duty. Many persons, prompted by the hopes of gain, and considering the violation of a positive law of this nature as in no respect criminal (an idea in which they have been encouraged by a great part of the community, who make no scruple to purchase smuggled goods), have engaged in this illicit trade. It was impossible that government could permit this practice, which is highly injurious to the fair trader, as the smuggler is enabled to undersell him, while at the same time he impairs the national revenue, and thus wholly destroys the end for which these duties were appointed. Such penalties are therefore inflicted as it was thought would prevent smuggling.

Burn's Law Dictionary, vol. ii.

Many laws have been made with this view. If any goods be shipped or landed without warrant and presence of an officer, the vessel shall be forfeited, and the wharfinger shall forfeit L. 100, and the master or mariner of any ship inward bound shall forfeit the value of the goods: and any carman, porter, or other assisting, shall be committed to gaol, till he find surety of the good behaviour, or until he shall be discharged by the court of exchequer (13 & 14 C. II. c. 11.) If goods be relanded after drawback, the vessel and goods shall be forfeited; and every person concerned therein shall forfeit double the valne of the drawback (8 An. c. 13.) Goods taken in at sea shall be forfeited, and also the vessel into which they are taken; and every person concerned therein shall forfeit treble value (9 G. II. c. 35.) A vessel hovering near the coast shall be forfeited, if under 50 tons burden; and the goods shall also be forfeited, or the value thereof (5. G. III. c. 43.) Persons receiving or buying run goods shall forfeit L. 20 (8 G. c. 18.) A concealer of run goods shall forfeit treble value (8 G. c. 18.) Offering run goods to sale, the same shall be forfeited, and the person to whom they are offered may seize them; and the person offering them to sale shall forfeit treble value (11 G. c. 30.) A porter or other person carrying run goods shall forfeit treble value (9 G. II. c. 35.) Persons armed or disguised carrying run goods shall be guilty of felony, and transported for seven years (8 G. c. 18. 9 G. II. c. 35.)

But the last statute, 19 G. II. c. 34. is for this purpose *instar omnium*; for it makes all forcible acts of smuggling, carried on in defiance of the laws, or even in disguise to evade them, felony without benefit of clergy: enacting, that if three or more persons shall assemble, with fire-arms or other offensive weapons, to assist in the illegal exportation or importation of goods, or in rescuing the same after seizure, or in rescuing offenders in custody for such offences; or shall pass with such goods in disguise; or shall wound, shoot at, or assault, any officers of the revenue when in the execution of their duty; such persons shall be felons, without the benefit of clergy.

When we consider the nature, and still more the history of mankind, we must allow that the enacting of severe penal laws is not the way to prevent crimes. It were indeed much to be wished that there were no such thing as a political crime; for the generality of men, but especially the lower orders, not discerning the propriety or utility of such laws, consider them as oppressive and tyrannical, and never hesitate to violate them when they can do it with impunity. Instead therefore of punishing smugglers, it would be much better to remove the temptation. But the high duties which have been imposed upon the importation of many different sorts of foreign goods, in order to discourage their consumption in Great Britain, have in many cases served only to encourage smuggling; and in all cases have reduced the revenue of the customs below what more moderate duties would have afforded. The saying of Dr Swift, that in the arithmetic of the customs two and two, instead of making four, make sometimes only one, holds perfectly true with regard to such heavy duties, which never could have been imposed, had not the mercantile system taught us, in many cases, to employ taxation as an instrument, not of revenue, but of monopoly.

Smugglers | Smyrna.

Smith's Wealth of Nations, vol. iii.

The bounties which are sometimes given upon the exportation of home produce and manufactures, and the drawbacks which are paid upon the re-exportation of the greater part of foreign goods, have given occasion to many frauds, and to a species of smuggling more destructive of the public revenue than any other. In order to obtain the bounty or drawback, the goods, it is well known, are sometimes shipped and sent to sea, but soon afterwards clandestinely relanded in some other part of the country.

Heavy duties being imposed upon almost all goods imported, our merchant importers smuggle as much, and make entry of as little as they can. Our merchant exporters, on the contrary, make entry of more than they export; sometimes out of vanity, and to pass for great dealers in goods which pay no duty; and sometimes to gain a bounty or a drawback. Our exports, in consequence of these different frauds, appear upon the customhouse books greatly to overbalance our imports; to the unspeakable comfort of those politicians who measure the national prosperity by what they call the balance of trade.

SMUT, in husbandry, a disease in corn, when the grains, instead of being filled with flour, are full of a stinking black powder. See Wheat.

SMYRNA, or Ismir, at present the largest and richest city of Asia Minor, is situated in north latitude 38° 28', and in E. Long. 27° 25' from Greenwich, and about 183 miles west by south of Constantinople. The town extends along the shore about half a mile on a gentle declivity. The houses of the English, French, and Dutch consuls are handsome structures; these, with most of those occupied by the Christian merchants, are washed on one side by the sea, forming a street named *Frank-street*, from its being solely inhabited by European Christians. In the year 1763 the whole of this quarter was consumed by fire: the loss sustained by this calamity in merchandise was estimated at a million and a half of Turkish dollars, or near L. 200,000 Sterling. The port is one of the finest of the Levant, it being able to contain the largest fleet; and indeed there are seldom in it fewer than 100 ships of different nations.

A castle stands at its entrance, and commands all the shipping which sail in or out. There is likewise an old ruinous castle, near a mile in circumference, which stands in the upper part of the city, and, according to tradi-

Payne's Geography.

tion,

tion, was built by the empress Helena: and near it is an ancient structure, said to be the remains of a palace where the Greek council was held when Smyrna was the metropolis of Asia Minor. They also show the ruins of an amphitheatre, where it is said St Polycarp, the first bishop, fought with lions.

This city is about four miles in circumference, and nearly of a triangular form; but the side next the mountain is much longer than the other sides. The houses are low, and mostly built with clay-walls on account of the earthquakes to which the country is subject; but the caravanseras and some other of the public buildings have an air of magnificence. The streets are wide, and almost a continued bazar, in which a great part of the merchandize of Europe and Asia is exposed to sale, with plenty of provisions; though these are not so cheap as in many other parts of Turkey, on account of the populousness of the place, and the great resort of foreigners. It is said to contain 15,000 Turks, 10,000 Greeks, 1800 Jews, 200 Armenians, and 200 Franks. The Turks have 19 mosques; two churches belonging to the Greeks; one to the Armenians; and the Jews have eight synagogues. The Romanists have three convents. There is also one of the fathers Della Terra Santa. Here resides an archbishop of the Greek church; a Latin bishop who has a salary from Rome, with the title of bishop of Smyrna *in partibus infidelium*; and the English and Dutch factories have each their chaplain.

The walks about the town are extremely pleasant, particularly on the west side of Frank street, where there are several little groves of orange and lemon trees, which being always clothed with leaves, blossoms, and fruit, regale several of the senses at the same time. The vines which cover the little hills about Smyrna afford both a delightful prospect and plenty of grapes, of which good wine is made. These hills are agreeably intersperesed with fertile plains, little forests of olives and other fruit-trees, and many pleasure-houses, to which the Franks usually retire during the summer. In the neighbourhood of Smyrna is great plenty of game and wild-fowl, and particularly deer and wild-hogs. The sea also abounds with a variety of good fish. The European Christians are here allowed all imaginable liberties, and usually clothe themselves after the European manner.

The chief commerce of this city consists in raw silk, silk-stuffs, grograms, and cotton yarn.

However, the unhealthfulness of the situation, and more especially the frequent earthquakes, from which, it is said, they are scarcely ever free for two years together, and which have been felt 40 days successively, are an abatement of the pleasure that might otherwise be enjoyed here. A very dreadful one happened in June 1688, which overthrew a great number of the houses; and the rock opening where the castle stood, swallowed it up, and no less than 5000 persons perished on this occasion.

In the year 1758, so desolating a plague raged here, that scarcely a sufficient number of the inhabitants survived to gather in the fruits of the earth. In the year 1772, three-fourth parts of the city were consumed by fire; and six years after it was visited by the most dreadful earthquakes, which continued from the 25th of June to the 5th of July; by which successive calamities the city has been so much reduced, that its former consequence is never likely to be restored.

The ladies here wear the oriental dress, consisting of large trowsers or breeches, which reach to the ancle; long vests of rich silk or velvet, lined in winter with costly furs; and round their waist an embroidered zone with clasps of silver or gold. Their hair is plaited, and descends down the back often in great profusion. The girls have sometimes above twenty thick tresses, besides two or three encircling the head as a coronet, and set off with flowers and plumes of feathers, pearls, or other jewels. They commonly stain it of a chesnut colour, which is the most desired. Their apparel and carriage are alike antique. It is remarkable that the trowsers are mentioned in a fragment of Sappho as part of the female dress.

SMYRNIUM, Alexanders: A genus of plants belonging to the class of *pentandria*, and to the order of *digynia*; and in the natural system ranging under the 45th order, *Umbellatæ*. The fruit is oblong and striated; the petals have a sharp point, and are keel-shaped. There are five species: 1. The *perfoliatum*, or perfoliate alexanders, which is a native of Candia and Italy; 2. The *Ægyptiacum*; 3. The *aureum*, or golden alexanders, which is a native of North America; 4. The *integerrimum*; 5. The *olusatrum*, common alexanders, a native of Britain; the leaves of which are cauline, ternate petiolated, and serrated. It grows on the sea-coast at Dunglas on the borders of Berwickshire North Britain. Since the introduction of celery into the garden, the alexanders is almost forgotten. It was formerly cultivated for salading, and the young shoots or stalks blanched were eaten either raw or stewed. The leaves too were boiled in broths and soups. It is a warm comfortable plant to a cold weak stomach, and was in much esteem among the monks, as may be inferred by its still being found in great plenty by old abbey walls.

SNAFFLE, in the manege, is a very slender bit-mouth without any branches, much used in England; the true bridles being reserved for war.

SNAIL, in zoology. See Helix and Limax.

SNAKE, in zoology. See Anguis and Serpens.

Method of Preserving Snakes. When the snake is killed, it must first be washed clean, and freed from all filth and nastiness; then it is to be put into a glass of a proper size, the tail first, and afterwards the rest of the body, winding it in spiral ascending circles, and disposing the back which is always the most beautiful, outwardly. A thread connected with a small glass bead, is, by the help of a needle, to be passed through the upper jaw from within outwardly, and then through the cork of the bottle, where it must be fastened; by this means the head will be drawn into a natural posture, and the mouth kept open by the bead, whereby the teeth, &c. will be discovered: the glass is then to be filled with rum, and the cork sealed down to prevent its exhalation. A label, containing the name and properties of the snake, is then to be affixed to the wax over the cork; and in this manner the snake will make a beautiful appearance, and may be preserved a great number of years; nor will the spirits impair or change the lustre of its colours.

Snake-Stones.

Snake-Stones, *Ammonitæ*, in natural hiſtory, the name of a large genus of foſſil ſhells, very few if any of which are yet known in their recent ſtate, or living either on our own or any other ſhores; ſo that it ſeems wonderful whence ſo vaſt a number and variety of them ſhould be brought into ſubterranean regions. They ſeem indeed diſperſed in great plenty throughout the world, but nowhere are found in greater numbers, beauty, and variety, than in Great Britain.

Mr Harenberg found prodigious numbers of them on the banks of a river in Germany. He traced this river through its ſeveral windings for many miles, and among a great variety of belemnitæ, cornua ammonis, and cochlitæ, of various kinds; he found alſo great quantities of wood of recent petrifaction, which ſtill preſerved plain marks of the axe by which it had been cut from the trees then growing on the ſhore. The water of this river he found in dry ſeaſons, when its natural ſprings were not diluted with rains, to be conſiderably heavier than common water; and many experiments ſhowed him that it contained ferruginous, as well as ſtony particles, in great quantity, whence the petrifactions in it appeared the leſs wonderful, though many of them of recent date.

Of the cornua ammonis, or ſerpent-ſtones, he there obſerved more than 30 different ſpecies. They lie immerſed in a bluiſh foſſil ſtone, of a ſoft texture and fatty appearance, in prodigious numbers, and of a great variety of ſizes, from the larger known ſorts down to ſuch as could not be ſeen without very accurate inſpection or the aſſiſtance of a microſcope. Such as lie in the ſofteſt of theſe ſtones are ſoft like their matrix, and eaſily crumble to pieces; others are harder. In a piece of this ſtone, of the bigneſs of a finger, it is common to find 30 or more of theſe foſſils; and often they are ſeen only in form of white ſpecks, ſo minute that their figure cannot be diſtinguiſhed till examined by the microſcope.

They all conſiſt of ſeveral volutæ, which are different in number in the different ſpecies, and their ſtriæ alſo are extremely various; ſome very deep with very high ridges between them, others very ſlight; ſome ſtraight, others crooked; others undulated, and ſome terminating in dots, tubercles, or cavities, towards the back, and others having tubercles in two or three places. They are all compoſed of a great number of chambers or cells, in the manner of the *nautilus Græcorum*, each having a communication with the others, by means of a pipe or ſiphunculus. There is a ſmall white ſhell fiſh of Barbadoes, which ſeems truly a recent animal of this genus; and in the Eaſt Indies there is another alſo, ſmall and greyiſh; but the large and beautifully marked ones are found only foſſil.

They are compoſed of various foſſil bodies, often of quarry ſtone, ſometimes of the matter of the common pyrites, and of a great variety of other ſubſtances; and though they appear uſually mere ſtones, yet in ſome the pearly part of the original ſhell is preſerved in all its beauty. Sometimes alſo, while the outer ſubſtance is of the matter of the pyrites, or other coarſe, ſtony, or mineral matter, the inner cavity is filled with a pure white ſpar of the common plated texture. This gives a great beauty to the ſpecimen. The cornua ammonis, or ſnake-ſtones, are found in many parts of England, particularly in Yorkſhire, where they are very plentiful in the alum rocks of ſeveral ſizes.

Snake-Root || Sneezing.

Snake-Root, in botany. See Polygala.

Snake-Weed, in botany. See Polygonum.

SNAPEDRAGON, in botany. See Antirrhinum.

SNEEZING, a convulſive motion of the muſcles of the breaſt, whereby the air is expelled from the noſe with much vehemence and noiſe. It is cauſed by the irritation of the upper membrane of the noſe, occaſioned by acrid ſubſtances floating in the air, or by medicines called *ſternutatory*.

This irritation is performed either externally, by ſtrong ſmells, as marjoram, roſes, &c. or by duſt floating in the air, and taken in by inſpiration; or by ſharp pungent medicines as creſſes and other ſternutatories, which vellicate the membrane of the noſe; or internally, by the acrimony of the lympha or mucus, which naturally moiſtens that membrane. The matters caſt forth in ſneezing come primarily from the noſe and throat; the pituitary membrane continually exuding a mucus thither; and, ſecondarily, from the breaſt, the trachea, and the bronchia of the lungs.

The practice of ſaluting the perſon who ſneezed exiſted in Africa, among nations unknown to the Greeks and Romans. The accounts we have of Monomotapa inform us*, that when the prince ſneezes, all his ſubjects in the captial are advertiſed of it, that they may offer up prayers for his ſafety. The author of the conqueſt of Peru aſſures us, that the cacique of Guachoia having ſneezed in preſence of the Spaniards, the Indians of his train fell proſtrate before him, ſtretched forth their hands, and diſplayed to him the accuſtomed marks of reſpect, while they invoked the ſun to enlighten him, to defend him, and to be his conſtant guard.

* Strada, Prol. Acad.

Every body knows that the Romans ſaluted each other on theſe occaſions: and Pliny relates†, that Tiberius exacted theſe ſigns of homage when drawn in his chariot. Superſtition, whoſe influence can debaſe every thing, had degraded this cuſtom for ſeveral ages, by attaching favourable or unfavourable omens to ſneezing according to the hour of the day or night, according to the ſigns of the zodiac, according as a work was more or leſs advanced, or according as one had ſneezed to the right or to the left‡. If a man ſneezed at riſing from table or from his bed, it was neceſſary for him to ſit or lie down again. You are ſtruck with aſtoniſhment, ſaid Timotheus to the Athenians, who wiſhed to return into the harbour with their fleet §, becauſe he had ſneezed; you are ſtruck with aſtoniſhment, becauſe among 10,000 there is one man whoſe brain is moiſt.

† Plin. Hiſt. Nat. lib. ii. cap. 2.

‡ Spond. Homeri Comment.

§ Frontin. lib. i. cap. 11.

Ploydore Virgil pretends, that in the time of Gregory the great, there reigned in Italy an epidemic diſtemper, which carried off by ſneezing all thoſe who were ſeized by it; and that this pontiff ordered prayers to be made againſt it, accompained by certain ſigns of the croſs. But beſides that, there are very few caſes in which ſneezing can be conſidered as dangerous, and that it is frequently a favourable ſymptom ||: it is evident, that we ought not to date from the ſixth century the origin of a cuſtom which loſes itſelf in the obſcurity of antiquity. Avicenna and Cardan ſay, it is a ſort of convulſion, which gives occaſion to dread an epilepſy, and that this diſeaſe is endeavoured to be warded off by prayers. Clement of Alexandria conſiders it as a mark of intemperance and effeminacy, which ought to be proſcribed. And he inveighs bitterly againſt thoſe who

|| Hippocrates Hubleri Phyſ.

Sneezing.

who endeavour to procure sneezing by external aid. Montaigne, on the contrary, explains this fact in a tone rather cynical. It is singular enough, that so many ridiculous, contradictory, and superstitious opinions, have not abolished those customary civilities which are still preserved equally among high and low; and which only the Anabaptists and Quakers have rejected, because they have renounced salutations in every case.

Among the Greeks sneezing was almost always a good omen. It excited marks of tenderness, of respect, and attachment. The genius of Socrates informed him by sneezing, when it was necessary to perform any action*. The young Parthenis, hurried on by her passion, resolved to write to Sarpedon an avowal of her love †; she sneezes in the most tender and impassioned part of her letter: This is sufficient for her; this incident supplies the place of an answer, and persuades her that Sarpedon is her lover. Penelope, harassed by the vexatious courtship of her suitors, begins to curse them all, and to pour forth vows for the return of Ulysses ‡. Her son Telemachus interrupts her by a loud sneeze. She instantly exults with joy, and regards this sign as an assurance of the approaching return of her husband. Xenophon was haranguing his troops; a soldier sneezed in the moment when he was exhorting them to embrace a dangerous but necessary resolution. The whole army, moved by this presage, determine to pursue the project of their general; and Xenophon orders sacrifices to Jupiter the preserver §.

* Plutarch de gen. Socrate.

† Aristenæt

‡ Homeri Odyss. lib. xvii.

§ Xenoph. Anab.

This religious reverence for sneezing, so ancient and so universal even in the times of Homer, always excited the curiosity of the Greek philosophers and of the rabbins. These last have spread a tradition, that, after the creation of the world, God made a general law to this purport, that every living man should sneeze but once in his life, and that at the same instant he should render up his soul into the hand of his Creator ||, without any preceding indisposition. Jacob obtained an exemption from the common law, and the favour of being informed of his last hour: He sneezed and did not die; and this sign of death was changed into a sign of life. Notice of this was sent to all the princes of the earth; and they ordained, that in future sneezing should be accompained with forms of blessing, and vows for the persons who sneezed.

|| Acad des Inscrip. vol. iv.

Aristotle remounts likewise to the sources of natural religion. He observes, that the brain is the origin of the nerves, of our sentiments, our sensations, the seat of the soul, the image of the Divinity ¶; that upon all these accounts, the substance of the brain has ever been held in honour; that the first men swore by their head; that they durst not touch nor eat the brains of any animal; that it was even a sacred word which they dared not to pronounce. Filled with these ideas, it is not wonderful that they extended their reverence even to sneezing. Such is the opinion of the most ancient and sagacious philosophers of Greece.

¶ Aristot. in Prob.

According to mythology, the first sign of life Prometheus's artificial man gave was by sternutation. This supposed creator is said to have stolen a portion of the solar rays; and filling with them a phial, which he had made on purpose, sealed it up hermetically. He instantly flies back to his favourite automaton, and opening the phial holds it close to the statue; the rays still retaining all their activity, insinuate themselves through the pores, and set the factitious man a sneezing. Prometheus, transported with the success of his machine, offers up a fervent prayer, with wishes for the preservation of so singular a being. His automaton observed him, remembering his ejaculations, was very careful, on the like occasions, to offer these wishes in behalf of his descendants, who perpetuated it from father to son in all their colonies.

Sniggling || Snoring.

SNIGGLING, a method of fishing for eels, chiefly used in the day-time, when they are found to hide themselves near wears, mills, or flood-gates. It is performed thus: Take a strong line and hook, baited with a garden-worm, and observing the holes where the eels lie hid, thrust your bait into them by the help of a stick; and if there be any, you shall be sure to have a bite; and may, if your tackling hold, get the largest eels.

SNIPE, in ornithology. See SCOLOPAX and SHOOTING.

SNORING, in medicine, otherwise called *stertor*, is a sound like that of the cerchnon, but greater and more manifest.

Many confound those affections, and make them to differ only in place and magnitude, calling by the name of *stertor* that sound or noise which is heard or supposed to be made in the passage between the palate and the nostrils as in those who sleep; that boiling or bubbling noise, which in respiration proceeds from the larynx, or head, or orifice of the aspera arteria, they call *cerchon*; but if the sound comes from the aspera arteria itself, they will have it called *cerchnos*, that is, as some understand it, a rattling, or as others a stridulous or wheezing roughness of the aspera arteria. In dying persons this affection is called by the Greeks ῥεγχος, *rhenchos*, which is a snoring or rattling kind of noise, proceeding as it were from a conflict between the breath and the humours in the aspera arteria.

This and such like affections are owing to a weakness of nature, as when the lungs are full of pus or humours: to which purpose we read in the Prognostics of Hippocrates, "it is a bad sign when there is no expectoration, and no discharge from the lungs, but a noise as from an ebullition is heard in the aspera arteria from a plenitude of humour." Expectoration is suppressed either by the viscidity of the humour, which requires to be discharged, and which adhering to the aspera arteria, and being there agitated by the breath, excites that bubbling noise or stertor; or by an obstruction of the bronchia; or, lastly, by a compression of the aspera arteria and throat, whence the passage is straitened, in which the humours being agitated, excite such a kind of noise as before described. Hence Galen calls those who are strait-breasted *stertorous*. That author assigns but two causes of this symptom, which are either the straitness of the passage of respiration or redundance of humours, or both together; but it is necessary to add a third, to wit, the weakness of the faculty, which is the cause of the rhenchos in dying persons, where nature is too weak to make discharges.

From what has been said we conclude, that this symptom, or this sort of fervour or ebullition in the throat, is not always mortal, but only when nature is oppressed with the redundance of humour, in such a manner, that the lungs cannot discharge themselves by spitting; or the passage appointed for the breath (being the aspera arteria) is very much obstructed, upon which

account

Snow.

account many dying perſons labour under a ſtertor with their mouth gaping.

SNOW, a well-known meteor, formed by the freezing of the vapours in the atmoſphere. It differs from hail and hoar-froſt, in being as it were cryſtallized, which they are not. This appears on examining a flake of ſnow by a magnifying glaſs; when the whole of it will appear to be compoſed of fine ſhining ſpicula diverging like rays from a centre. As the flakes fall down through the atmoſphere, they are continually joined by more of theſe radiated ſpicula, and thus increaſe in bulk like the drops of rain or hailſtones. Dr Grew, in a diſcourſe of the nature of ſnow, obſerves, that many parts thereof are of a regular figure, for the moſt part ſtars of ſix points, and are as perfect and tranſparent ice as any we ſee on a pond, &c. Upon each of theſe points are other collateral points, ſet at the ſame angles as the main points themſelves: among which there are divers other irregular, which are chiefly broken points, and fragments of the regular ones. Others alſo, by various winds, ſeem to have been thawed and frozen again into irregular cluſters; ſo that it ſeems as if the whole body of ſnow were an infinite maſs of icicles irregularly figured. That is, a cloud of vapours being gathered into drops, the ſaid drops forthwith deſcend; upon which deſcent, meeting with a freezing air as they paſs through a colder region, each drop is immediately frozen into an icicle, ſhooting itſelf forth into ſeveral points; but theſe ſtill continuing their deſcent, and meting with ſome intermitting gales of warmer air, or in their continual waftage to and fro touching upon each other, ſome of them are a little thawed, blunted, and again frozen into cluſters, or entangled ſo as to fall down in what we call *flakes*.

The lightneſs of ſnow, although it is firm ice, is owing to the exceſs of its ſurface, in compariſon to the matter contained under it; as gold itſelf may be extended in ſurface till it will ride upon the leaſt breath of air.

The whiteneſs of ſnow is owing to the ſmall particles into which it is divided; for ice, when pounded, will become equally white. An artificial ſnow has been made by the following experiment. A tall phial of aquafortis being placed by the fire till it is warm, and filings of pure ſilver, a few at a time, being put into it; after a briſk ebullition, the ſilver will diſſolve ſlowly. The phial being then placed in a cold window, as it cools the ſilver particles will ſhoot into cryſtals, ſeveral of which running together will form a flake of ſnow, which will deſcend to the bottom of the phial. While they are deſcending, they repreſent perfectly a ſhower of ſilver ſnow, and the flakes will lie upon one another at the bottom like real ſnow upon the ground.

According to Signior Beccaria, clouds of ſnow differ in nothing from clouds of rain, but in the circumſtance of cold that freezes them. Both the regular diffuſion of the ſnow, and the regularity of the ſtructure of its parts (particularly ſome figures of ſnow or hail which fall about Turin, and which he calls *roſette*), ſhow that clouds of ſnow are acted upon by ſome uniform cauſe like electricity; and he endeavours to ſhow how electricity is capable of forming theſe figures. He was confirmed in his conjectures by obſerving, that his apparatus for obſerving the electricity of the atmoſphere never failed to be electrified by ſnow as well as rain. Profeſſor Winthrop ſometimes found his apparatus electrified by ſnow when driven about by the wind, though it had not been affected by it when the ſnow itſelf was falling. A more intenſe electricity, according to Beccaria, unites the particles of hail more cloſely than the more moderate electricity does thoſe of ſnow, in the ſame manner as we ſee that the drops of rain which fall from thunder-clouds are larger than thoſe which fall from others, though the former deſcend through a leſs ſpace.

But we are not to conſider ſnow merely as a curious and beautiful phenomenon. The Great Diſpenſer of univerſal bounty has ſo ordered it, that it is eminently ſubſervient, as well as all the works of creation, to his benevolent deſigns. Were we to judge from appearances only, we might imagine, that ſo far from being uſeful to the earth, the cold humidity of ſnow would be detrimental to vegetation. But the experience of all ages aſſerts the contrary. Snow, particularly in thoſe northern regions where the ground is covered with it for ſeveral months, fructifies the earth, by guarding the corn or other vegetables from the intenſer cold of the air, and eſpecially from the cold piercing winds. It has been a vulgar opinion, very generally received, that ſnow fertilizes the lands on which it falls more than rain, in conſequence of the nitrous ſalts which it is ſuppoſed to acquire by freezing. But it appears from the experiments of Margraaf (A) in the year 1751, that the chemical difference between rain and ſnow-water is exceedingly ſmall; that the latter is ſomewhat leſs nitrous, and contains a ſomewhat leſs proportion of earth than the former; but neither of them contain either earth or any kind of ſalt in any quantity which can be ſenſibly efficacious in promoting vegetation. Allowing, therefore, that nitre is a fertilizer of lands, which many are upon good grounds diſpoſed utterly to deny, yet ſo very ſmall is the quantity of it contained in ſnow, that it cannot be ſuppoſed to promote the vegetation of plants upon which the ſnow has fallen. The peculiar agency of ſnow, as a fertilizer in preference to rain, may admit of a very rational explanation, without recurring to nitrous ſalts ſuppoſed to be contained in it. It may be rationally aſcribed to its furniſhing a covering to the roots of vegetables, by which they are guarded from the influence of the atmoſpherical cold, and the internal heat of the earth is prevented from eſcaping.

The internal parts of the earth, by ſome principle which

(A) Margraaf collected of the pureſt ſnow he could find as much as when melted afforded 100 meaſures of water, each meaſure containing 36 ounces. By diſtilling this quantity he obtained 60 grains, not of *nitre* but of *calcareous earth*, with ſome grains of the acid of ſea-ſalt, impregnated with a nitrous vapour. The ſame quantity of rain-water collected in the winter months with equal attention, when diſtilled yielded 100 grains of calcareous earth with ſome grains of the acid of nitre and ſea-ſalt. The chemical difference therefore between rain and ſnow is very ſmall.

which we do not underſtand, is heated uniformly to the 48th degree of Fahrenheit's thermometer. This degree of heat is greater than that in which the watery juices of vegetables freeze, and it is propagated from the inward parts of the earth to the ſurface, on which the vegetables grow. The atmoſphere being variably heated by the action of the ſun in different climates, and in the ſame climate at different ſeaſons, communicates to the ſurface of the earth and to ſome diſtance below it the degree of heat or cold which prevails in itſelf. Different vegetables are able to preſerve life under different degrees of cold, but all of them periſh when the cold which reaches their roots is extreme. Providence has therefore, in the coldeſt climates, provided a covering of ſnow for the roots of vegetables, by which they are protected from the influence of the atmoſpherical cold. The ſnow keeps in the internal heat of the earth, which ſurrounds the roots of vegetables, and defends them from the cold of the atmoſphere.

Snow or ice water is always deprived of its fixed air, which eſcapes during the proceſs of congelation. Accordingly, as ſome of the inhabitants of the Alps who uſe it for their conſtant drink have enormous wens upon their throats, it has been aſcribed to this circumſtance. If this were the cauſe of theſe wens, it would be eaſy to remove it by expoſing the ſnow-water to the air for ſome time. But ſeveral eminent phyſicians have rejected the notion that ſnow-water is the cauſe of theſe wens; for in Greenland, where ſnow-water is commonly uſed, the inhabitants are not affected with ſuch ſwellings: on the other hand, they are common in Sumatra where ſnow is never ſeen.

Snow, in ſea-affairs, is generally the largeſt of all two-maſted veſſels employed by Europeans, and the moſt convenient for navigation.

The ſails and rigging on the main-maſt and fore-maſt of a ſnow are exactly ſimilar to thoſe on the ſame maſts in a ſhip; only that there is a ſmall maſt behind the main-maſt of the former, which carries a ſail nearly reſembling the mizen of a ſhip. The foot of this maſt is fixed on a block of wood on the quarter-deck abaſt the main-maſt; and the head of it is attached to the after-top of the main-top. The ſail which is called the *try-ſail* is extended from its maſt towards the ſtern of the veſſel.

When the ſloops of war are rigged as ſnows, they are furniſhed with a horſe, which anſwers the purpoſe of the tryſail-maſt, the fore-part of the ſail being attached by rings to the ſaid horſe, in different places of its height.

Snow-Grotto, an excavation made by the waters on the ſide of Mount Etna, by making their way under the layers of lava, and by carrying away the bed of pozzolana below them. It occurred to the proprietor, that this place was very ſuitable for a magazine of ſnow: for in Sicily, at Naples, and particularly at Malta, they are obliged for want of ice to make uſe of ſnow for cooling their wine, ſherbet, and other liquors, and for making ſweetmeats.

This grotto was hired or bought by the knights of Malta, who having neither ice nor ſnow on the burning rock which they inhabit, have hired ſeveral caverns on Etna, into which people whom they employ collect and preſerve quantities of ſnow to be ſent to Malta when needed. This grotto has therefore been repaired within at the expence of that order; flights of ſteps are cut into it, as well as two openings from above, by which they throw in the ſnow, and through which the grotto is enlightened. Above the grotto they have alſo levelled a piece of ground of conſiderable extent: this they have incloſed with thick and lofty walls, ſo that when the winds, which at this elevation blow with great violence, carry the ſnow from the higher parts of the mountain, and depoſite it in this incloſure, it is retained and amaſſed by the walls. The people then remove it into the grotto through the two openings; and it is there laid up, and preſerved in ſuch a manner as to reſiſt the force of the ſummer heats; as the layers of lava with which the grotto is arched above prevent them from making any impreſſion.

When the ſeaſon for exporting the ſnow comes on, it is put into large bags, into which it is preſſed as cloſely as poſſible; it is then carried by men out of the grotto, and laid upon mules, which convey it to the ſhore, where ſmall veſſels are waiting to carry it away.

But before thoſe lumps of ſnow are put into bags, they are wrapped in freſh leaves; ſo that while they are conveyed from the grotto to the ſhore, the leaves may prevent the rays of the ſun from making any impreſſion upon them.

The Sicilians carry on a conſiderable trade in ſnow, which affords employment to ſome thouſands of mules, horſes, and men. They have magazines of it on the ſummits of their loftieſt mountains, from which they diſtribute it through all their cities, towns, and houſes; for every perſon in the iſland makes uſe of ſnow. They conſider the practice of cooling their liquors as abſolutely neceſſary for the preſervation of health; and in a climate the heat of which is conſtantly relaxing the fibres, cooling liquors, by communicating a proper tone to the fibres of the ſtomach, muſt greatly ſtrengthen them for the performance of their functions.

In this climate a ſcarcity of ſnow is no leſs dreaded than a ſcarcity of corn, wine, or oil. We are informed by a gentleman who was at Syracuſe in the year 1777, when there was a ſcarcity of ſnow, the people of the town learned that a ſmall veſſel loaded with that article was paſſing the coaſt: without a moment's deliberation they ran in a body to the ſhore and demanded her cargo; which when the crew refuſed to deliver up, the Syracuſans attacked and took, though with the loſs of ſeveral men.

Snow-Drop, in botany. See Chionanthus.

SNOWDON-hill, the name of a mountain in Caernarvonſhire in Wales, generally thought to be the higheſt in Britain; though ſome have been of opinion that its height is equalled, or even exceeded, by mountains in the Highlands of Scotland. The mountain is ſurrounded by many others, called in the Welſh language *Crib Coch*, *Crib y Diſtill*, *Lliwedd yr Arran*, &c.

According to Mr Pennant*, this mountainous tract yields ſcarcely any corn. Its produce is cattle and ſheep; which, during ſummer, keep very high in the mountains, followed by their owners with their families, who reſide during that ſeaſon in *havodtys*, or "ſummer dairy-houſes," as the farmers in the Swiſs Alps do in their *ſennes*. Theſe houſes conſiſt of a long low room, with a hole at one end to let out the ſmoke from the fire which is made beneath. Their furniture is very ſimple; ſtones are ſubſtituted for ſtools, and their beds are of

* Journey to Snowdon.

hay,

Snowdon-Hill.

hay, ranged along the sides. They manufacture their own clothes, and dye them with the *lichen omphaloides* and *lichen parietinus*, mosses collected from the rocks. During summer the men pass their time in tending their herds or in making hay, &c. and the women in milking or in making butter and cheese. For their own use they milk both ewes and goats, and make cheese of the milk. Their diet consists of milk, cheese, and butter: and their ordinary drink is whey; though they have, by way of reserve, a few bottles of very strong beer, which they use as a cordial when sick. They are people of good understanding, wary, and circumspect; tall, thin, and of strong constitutions. In the winter-time they descend into the *hen-dref*, or "old dwelling," where they pass their time in inactivity.

The view from the highest peak of Snowdon is very extensive. From it Mr Pennant saw the county of Chester, the high hills of Yorkshire, part of the north of England, Scotland, and Ireland; a plain view of the Isle of Man; and that of Anglesea appeared like a map extended under his feet, with every rivulet visible. Our author took much pains to have this view to advantage; sat up at a farm on the west till about 12, and walked up the whole way. The night was remarkably fine and starry; towards morning the stars faded away, leaving an interval of darkness, which, however, was soon dispelled by the dawn of day. The body of the sun appeared most distinct, with the roundness of the moon, before it appeared too brilliant to be looked at. The sea, which bounded the western part of the prospect, appeared gilt with the sun-beams, first in slender streaks, and at length glowed with redness. The prospect was disclosed like the gradual drawing up of a curtain in a theatre; till at last the heat became sufficiently strong to raise mists from the various lakes, which in a slight degree obscured the prospect. The shadow of the mountain extended many miles, and showed its bicapitated form; the Wyddfa making one head, and Crib y Distill the other. At this time he counted between 20 and 30 lakes either in Caernarvon or in Merionethshire. In making another visit, the sky was obscured very soon after he got up. A vast mist involved the whole circuit of the mountain, and the prospect down was horrible. It gave an idea of numbers of abysses, concealed by a thick smoke furiously circulating around them. Very often a gust of wind made an opening in the clouds, which gave a fine and distinct vista of lake and valley. Sometimes they opened in one place, at others in many at once; exhibiting a most strange and perplexing sight of water, fields, rocks, and chasms. They then closed again, and every thing was involved in darkness; in a few minutes they would separate again, and repeat the abovementioned scene with infinite variety. From this prospect our traveller descended with great reluctance; but before he had reached the place where his horses were left, he was overtaken by a thunder storm. The rolling of the thunder-claps, being reiterated by the mountains, was inexpressibly awful; and after he had mounted, he was in great danger of being swept away by the torrents which poured down in consequence of a very heavy rain.

It is very rare (Mr Pennant observes) that the traveller gets a proper day to ascend this hill: it indeed often appears clear; but by the evident attraction of the clouds by this lofty mountain, it becomes suddenly and unexpectedly enveloped in mist, when the clouds have just before appeared very high and very remote. At times he observed them lower to half their height; and notwithstanding they have been dispersed to the right and left, yet they have met from both sides, and united to involve the summit in one great obscurity.

The height of Snowdon was measured, in 1682, by Mr Caswell, with instruments made by Flamstead: according to his mensuration, the height is 3720 feet; but more modern computations make it only 3568, reckoning from the quay at Caernarvon to the highest peak. The stone that composes this mountain is excessively hard. Large coarse crystals, and frequently cubic pyrites, are found in the fissures. An immense quantity of water rushes down the sides of Snowdon and the neighbouring mountains, insomuch that Mr Pennant supposes, if collected into one stream, they would exceed the waters of the Thames.

SNUFF, a powder chiefly made of tobacco, the use of which is too well known to need any description here.

Tobacco is usually the basis of snuff; other matters being only added to give it a more agreeable scent, &c. The kinds of snuff, and their several names, are infinite, and new ones are daily invented; so that it would be difficult, not to say impossible, to give a detail of them. We shall only say, that there are three principal sorts: the first granulated; the second an impalpable powder; and the third the bran, or coarse part remaining after sifting the second sort.

"Every professed, inveterate, and incurable snuff-taker (says Lord Stanhope), at a moderate computation, takes one pinch in ten minutes. Every pinch, with the agreeable ceremony of blowing and wiping the nose and other incidental circumstances, consumes a minute and a half. One minute and a half out of every ten, allowing 16 hours to a snuff-taking day, amounts to two hours and 24 minutes out of every natural day or one day out of every ten. One day out of every 10 amounts to 36 days and a half in a year. Hence if we suppose the practice to be persisted in 40 years, two entire years of the snuff-taker's life will be dedicated to tickling his nose, and two more to blowing it. The expence of snuff, snuff-boxes, and handkerchiefs, will be the subject of a second essay; in which it will appear, that this luxury encroaches as much on the income of the snuff-taker as it does on his time; and that by a proper application of the time and money thus lost to the public, a fund might be constituted for the discharge of the national debt." See Nicotiana.

Snyders.

SNYDERS (Francis), a Flemish painter, born at Antwerp in 1579, and bred under his countryman Henry Van Balen. His genius first displayed itself in painting fruit; he afterwards attempted animals, huntings, &c. in which he exceeded all his predecessors. He also painted kitchens, &c. and gave dignity to subjects that seemed incapable of it. He was made painter to Ferdinand and Isabella, archduke, and duchess, and became attached to the house of the cardinal infant of Spain. The king of Spain and the elector Palatine adorned their palaces with huntings by this artist. Rubens, Jordaens, and Snyders used to co-operate in the enriching of each other's pictures according to their

several

several talents; and thus they became more valuable than if finished by either of them singly. Snyders died in 1657.

SOAL-FISH, in ichthyology. See PLEURONECTES.

SOAP, a composition of caustic, fixed alkaline salt, and oil, sometimes hard and dry, sometimes soft and liquid; much used in washing, whitening linens, and by dyers and fullers.—Soap may be made by several methods, which, however, all depend upon the same principle. The soap which is used in medicine is made without heat. See CHEMISTRY, n° 1026.

In manufactures where large quantities of it are prepared, soap is made with heat. A lixivium of quicklime and soda is made, but is less concentrated than that above referred to, and only so much that it can sustain a fresh egg. A part of this lixivium is to be even diluted and mixed with an equal weight of oil of olives. The mixture is to put on a gentle fire, and agitated, that the union may be accelerated. When the mixture begins to unite well, the rest of the lixivium is to be added to it; and the whole is to be digested with a very gentle heat, till the soap be completely made. A trial is to be made of it, to examine whether the just proportion of oil and alkali has been observed. Good soap of this kind ought to be firm, and very white when cold; not subject to become moist by exposure to air, and entirely miscible with pure water, to which it communicates a milky appearance, but without any drops of oil floating on the surface. When the soap has not these qualities the combination has not been well made, or the quantity of salt or of oil is too great, which faults must be corrected.

In soft or liquid soaps, green or black soaps, cheaper oils are employed, as oil of nuts, of hemp, of fish, &c. These soaps, excepting in consistence, are not essentially different from white soap.

Fixed alkalis are much disposed to unite with oils that are not volatile, both vegetable and animal, since this union can be made even without heat. The compound resulting from this union partakes at the same time of the properties of oil and of alkali; but these properties are modified and tempered by each other, according to the general rule of combinations. Alkali formed into soap has not nearly the same acrimony as when it is pure; it is even deprived of almost all its causticity, and its other saline alkaline properties are almost entirely abolished. The same oil contained in soap is less combustible than when pure, from its union with the alkali, which is an uninflammable body. It is miscible, or even soluble, in water, to a certain degree, by means of the alkali. Soap is entirely soluble in spirit of wine; and still better in aquavitæ sharpened by a little alkaline salt, according to an observation of Mr Geoffroy.

The manufacture of soap in London first began in the year 1524; before which time this city was served with white soap from foreign countries, and with grey soap speckled with white from Bristol, which was sold for a penny a pound; and also with black soap, which sold for a half-penny the pound.

The principal soaps of British manufacture are the soft, the hard, and the ball soap. The soft soap is either white or green. The process of making each of these shall now be described.

Green soft soap. The chief ingredients used in making this are lees drawn from pot-ash and lime, boiled up with tallow and oil. First, the ley of a proper degree of strength (which must be estimated by the weight of the liquor), and tallow, are put into the copper together, and as soon as they boil up, the oil is added; the fire is then damped or stopped up, while the ingredients remain in the copper to unite; when they are united, the copper is again made to boil, being fed or filled with lees as it boils, till there be a sufficient quantity put into it; then it is boiled off and put into casks. When this soap is first made it appears uniform; but in about a week's time the tallow separates from the oil into those white grains which we see in common soap. Soap thus made would appear yellow, but by a mixture of indigo added at the end of the boiling, it is rendered green, that being the colour which results from the mixture of yellow and blue.

White soap. Of this one sort is made after the same manner as green soft soap, oil alone excepted, which is not used in white. The other sort of white soft soap is made from the lees of ashes of lime boiled up two different times with tallow. First, a quantity of lees and tallow are put into the copper together, and kept boiling, being fed with lees as they boil, until the whole is boiled sufficiently; then the lees are separated or discharged from the tallowish part, which part is removed into a tub, and the lees are thrown away; this is called the *first half-boil*: then the copper is filled again with fresh tallow and lees, and the first half-boil is put out of the tub into the copper a second time, where it is kept boiling with fresh lees and tallow till the soap is produced. It is then put out of the copper into the same sort of casks as are used for green soft soap. The common soft soap used about London, generally of a greenish hue, with some white lumps, is prepared chiefly with tallow: a blackish sort, more common in some other places, is said to be made with whale oil.

Hard soap is made with lees from ashes and tallow, and is most commonly boiled twice: the first, called the *half-boil*, hath the same operation as the first half-boil of soft white soap. Then the copper is charged with fresh lees again, and the first half boil put into it, where it is kept boiling, and fed with lees as it boils, till it grains or is boiled enough; then the ley is discharged from it, and the soap put into a frame to cool and harden. Common salt is made use of for the purpose of graining the soap; for when the oil or tallow has been united with the ley, after a little boiling, a quantity of salt is thrown into the mass, which dissolving readily in water, but not in the oil or tallow, draws out the water in a considerable degree, so that the oil or tallow united with the salt of the ley swims on the top. When the ley is of a proper strength, less salt is necessary to raise the curd than when it is too weak. It must be observed, that there is no certain time for bringing off a boiling of any of these sorts of soap: it frequently takes up part of two days.

Ball soap, commonly used in the north, is made with lees from ashes and tallow. The lees are put into the copper, and boiled till the watery part is quite gone, and there remains nothing in the copper but a sort of saline matter (the very strength or essence of the ley); to this the tallow is put, and the copper is kept boiling and stirring for above half an hour, in which time the

Soap.

the ſoap is made; and then it is put out of the copper into tubs or baſkets with ſheets in them, and immediately (whilſt ſoft) made into balls. It requires near 24 hours in this proceſs to boil away the watery part of the ley.

When oil unites with alkali in the formation of ſoap, it is little altered in the connection of its principles; for it may be ſeparated from the alkali by decompoſing ſoap with any acid, and may be obtained nearly in its original ſtate.

Concerning the decompoſition of ſoap by means of acids, we muſt obſerve, firſt, that all acids, even the weakeſt vegetable acids, may occaſion this decompoſition, becauſe every one of them has a greater affinity than oil with fixed alkali. Secondly, theſe acids, even when united with any baſis, excepting fixed alkali, are capable of occaſioning the ſame decompoſition; whence all ammonical ſalts, all ſalts with baſis of earth, and all thoſe with metallic baſes, are capable of decompoſing ſoap, in the ſame manner as diſengaged acids are; with this difference, that the oil ſeparated from the fixed alkali, by the acid of theſe ſalts, may unite more or leſs intimately with the ſubſtance which was the baſis of the neutral ſalt employed for the decompoſition.

Soap may alſo be decompoſed by diſtillation, as Lemery has done. When firſt expoſed to fire, it yields a phlegm called by him a *ſpirit*: which nevertheleſs is neither acid nor alkaline, but ſome water which enters into the compoſition of ſoap. It becomes more and more coloured and empyreumatic as the fire is increaſed, which ſhows that it contains the moſt ſubtle part of the oil. It ſeems even to raiſe along with it, by help of the oil and action of the fire, a ſmall part of the alkali of the ſoap: for, as the ſame chemiſt obſerves, it occaſions a precipitate in a ſolution of corroſive ſublimate. After this phlegm the oil riſes altered, preciſely as if it had been diſtilled from quicklime, that is, empyreumatic, ſoluble in ſpirit of wine, at firſt ſufficiently ſubtle and afterwards thicker. An alkaline reſiduous coal remains in the retort, conſiſting chiefly of the mineral alkali contained in the ſoap, and which may be diſengaged from the coal by calcination in an open fire, and obtained in its pure ſtate.

Alkaline ſoaps are very uſeful in many arts and trades, and alſo in chemiſtry and medicine. Their principal utility conſiſts in a deterſive quality that they receive from their alkali, which, although it is in ſome meaſure faturated with oil, is yet capable of acting upon oily matters, and of rendering them ſaponaceous and miſcible with water. Hence ſoap is very uſeful to cleanſe any ſubſtances from all fat matters with which they happen to be ſoiled. Soap is therefore daily uſed for the waſhing and whitening of linen, for the cleaſing of woollen-cloths from oil, and for whitening ſilk and freeing it from the reſinous varniſh with which it is naturally covered. Pure alkaline lixiviums being capable of diſſolving oils more effectually than ſoap, might be employed for the ſame purpoſes; but when this activity is not mitigated by oil, as it is in ſoap, they are capable of altering, and even of deſtroying entirely by their cauſticity, moſt ſubſtances, eſpecially animal matters, as ſilk, wool, and others: whereas ſoap cleanſes from oil almoſt as effectually as pure alkali, without danger of altering or deſtroying; which renders it very uſeful.

Soap was imperfectly known to the ancients. It is mentioned by Pliny as made of fat and aſhes, and as an invention of the Gauls. Aretæus and others inform us, that the Greeks obtained their knowledge of its medical uſe from the Romans. Its virtues, according to Bergius, are detergent, reſolvent, and aperient, and its uſe recommended in jaundice, gout, calculous complaints, and in obſtructions of the viſcera. The efficacy of ſoap in the firſt of theſe diſeaſes was experienced by Sylvius, and ſince recommended very generally by various authors who have written on this compliant; and it has alſo been thought of uſe in ſupplying the place of bile in the primæ viæ. The utility of this medicine in icterical caſes was inferred chiefly from its ſuppoſed power of diſſolving biliary concretions; but this medicine has loſt much of its reputation in jaundice, ſince it is now known that gall-ſtones have been found in many after death who had been daily taking ſoap for ſeveral months and even years. Of its good effects in urinary calculous affections, we have the teſtimony of ſeveral, eſpecially when diſſolved in lime-water, by which its efficacy is conſiderably increaſed; for it thus becomes a powerful ſolvent of mucus, which an ingenious modern author ſuppoſes to be the chief agent in the formation of calculi: it is, however, only in the incipient ſtate of the diſeaſe that theſe remedies promiſe effectual benefit; though they generally abate the more violent ſymptoms where they cannot remove the cauſe. With Boerhaave ſoap was a general medicine: for as he attributed moſt complaints to viſcidity of the fluids, he, and moſt of the Boerhaavian ſchool, preſcribed it in conjunction with different reſinous and other ſubſtances, in gout, rhumatiſm, and various viſceral complaints. Soap is alſo externally employed as a reſolvent, and gives name to ſeveral officinal preparations.

Soap. Woodville's Medical Botany, p. 390.

From the properties of ſoap we may know that it muſt be a very effectual and convenient anti-acid. It abſorbs acids as powerfully as pure alkalis and abſorbent earths, without having the cauſticity of the former, and without oppreſſing the ſtomach by its weight like the latter.

Laſtly, we may perceive that ſoap muſt be one of the beſt of all antidotes to ſtop quickly, and with the leaſt inconvenience, the bad effects of acid corroſive poiſons, as aquafortis, corroſive ſublimate, &c.

British Statutes.

"Soap imported is ſubject by 10 Ann. cap. 19. to a duty of 2d. a pound (over and above former duties); and by 12 Ann. ſtat. 2. cap. 9. to the farther ſum of 1d. a pound. And by the ſame acts, the duty on ſoap made in the kingdom is $1\frac{1}{2}$d. a pound. By 17 G. III. cap. 52. no perſon within the limits of the head office of exciſe in London ſhall be permitted to make any ſoap unleſs he occupy a tenement of 10 l. a year, be aſſeſſed, and pay the pariſh rates; or elſewhere, unleſs he be aſſeſſed, and pay to church and poor. Places of making are to be entered on pain of 50 l. and covers and locks to be provided under a forfeiture of 100 l.; the furnace-door of every utenſil uſed in the manufacture of ſoap ſhall be locked by the exciſe officer, as ſoon as the fire is damped or drawn out, and faſtenings provided, under the penalty of 50 l.; and opening or damaging ſuch faſtening incurs a penalty of 100 l. Officers are required to enter and ſurvey at all times, by day or night, and the penalty of obſtructing is 20 l. and they may unlock and examine every copper, &c. between the hours of five in the morning and ele-

Soap || Socage.

ven in the evening, and the penalty of obstructing is 100 l. Every maker of soap before he begins any making, if within the bills of mortality, shall give 12 hours, if elsewhere 24 hours, notice in writing to the officer, of the time when he intends to begin, on pain of 50 l. No maker shall remove any soap unsurveyed on pain of 20 l. without giving proper notice of his intention. And if any maker shall conceal any soap or materials, he shall forfeit the same, and also 500 l. Every barrel of soap shall contain 256 lb. avoirdupois, half barrel 128 lb. firkin 64 lb. half-firkin 32 lb. besides the weight or tare of each cask: and all soap, excepting hard cake soap and ball soap, shall be put into such casks and no other, on pain of forefeiture, and 5 l. The maker shall weekly enter in writing at the next office the soap made by him in each week, with the weight and quantity at each boiling, on pain of 50 l.; and within one week after entry clear off the duties, on pain of double duty. See, besides the statues, above cited, 5 Geo. III. cap. 43. 12 Geo. III. cap. 46. 11 Geo. cap. 30. 1. Geo. stat. 2. cap. 36."

Starkey's Soap. See CHEMISTRY, n° 1027.

Acid Soap. This is formed by the addition of concentrated acids to the expressed oils. Thus the oil is rendered partially soluble in water; but the union is not sufficiently complete to answer any valuable purpose.

Soap-Berry Tree. See SAPINDUS.

Soap-Earth. See STEATITES.

SOAPWORT. See SAPONÁRIA.

SOC (Sax.), signifies power or liberty to minister justice or execute laws: also the circuit or territory wherein such power is exercised. Whence our law-Latin word *socca* is used for a seigniory or lordship enfranchised by the king, with the liberty of holding or keeping a court of his *sockmen*: And this kind of liberty continues in divers parts of England to this day, and is known by the names of *soke* and *soken*.

SOCAGE, in its most general and extensive signification, seems to denote a tenure by any certain and determinate service. And in this sense it is by our ancient writers constantly put in opposition to chivalry or knight-service, where the render was precarious and uncertain. The service must therefore be certain, in order to denominate it socage; as to hold by fealty and 20 s. rent; or, by homage, fealty, and 20 s. rent; or, by homage and fealty without rent; or, by fealty and certain corporal service, as ploughing the lord's land for three days; or, by fealty only without any other service: for all these are tenures in socage.

Blackst. Comment. vol. ii.

Socage is of two sorts: *free*-socage, where the services are not only certain but honourable; and *villein*-socage, where the services, though certain, are of a baser nature (see VILLENAGE). Such as hold by the former tenure are called, in Glanvil and other subsequent authors, by the name of *liberi solemanni*, or tenants in free-socage. The word is derived from the Saxon appellation *soc*, which signifies liberty or privilege; and, being joined to an usual termination, is called *socage*, in Latin *socagium*; signifying thereby a free or privileged tenure.

It seems probable that the socage-tenures were the relics of Saxon liberty; retained by such persons as had neither forfeited them to the king, nor been obliged to exchange their tenure for the more honourable, as it was called, but at the same time more burthensome, tenure of knight-service. This is peculiarly remarkable in the tenure which prevails in Kent, called *gavelkind*, which is generally acknowledged to be a species of socage-tenure; the preservation whereof inviolate from the innovations of the Norman conqueror is a fact universally known. And those who thus preserved their liberties were said to hold in free and common socage.

Society.

As therefore the grand criterion and distinguishing mark of this species of tenure are the having its renders or services ascertained, it will include under it all other methods of holding free lands by certain and invariable rents and duties; and in particular, *Petit* SERJEANTY, *Tenure in* BURGAGE, and GAVELKIND. See these articles.

SOCIETY, a number of rational and moral beings, united for their common preservation and happiness. 1 Definition.

There are shoals of fishes, herds of quadrupeds, and flocks of birds. But till observation enable us to determine with greater certainty, how far the inferior animals are able to look through a series of means to the end which these are calculated to produce, how far their conduct may be influenced by the hope of reward and the fear of punishment, and whether they are at all capable of moral distinctions—we cannot with propriety apply to them the term *Society*. We call crows, and beavers, and several other species of animals, *gragarious*; but it is hardly good English to say that they are *social*. 2 How far brutes are capable of a social state.

It is only human society, then, that can become the subject of our present investigation. The phenomena which it presents are highly worthy of our notice. 3 Mankind the only social beings subject to our observation

Such are the advantages which each individual evidently derives from living in a social state; and so helpless does any human being appear in a solitary state, that we are naturally led to conclude, that if there ever was a period at which mankind were solitary beings, that period could not be of long duration; for their aversion to solitude and love of society would soon induce them to enter into social union. Such is the opinion which we are led to conceive, when we compare our own condition as members of civilized and enlightened society with that of the brutes around us, or with that of savages in the earlier and ruder periods of social life. When we hear of Indians wandering naked through the woods, destitute of arts, unskilled in agriculture, scarce capable or moral distinctions, void of all religious sentiments, or possessed with the most absurd notions concerning superior powers, and procuring means of subsistence in a manner equally precarious with that of the beasts of prey—we look down with pity on their condition, or turn from it with horror. When we view the order of cultivated society, and consider our institutions, arts, and manners—we rejoice over our superior wisdom and happiness. 4 A social and a savage state.

Man in a civilized state appears a being of a superior order to man in a savage state; yet some philosophers tell us, that it is only he who, having been educated in society, has been taught to depend upon others, that can be helpless or miserable when placed in a solitary state. They view the savage who exerts himself with intrepidity to supply his wants, or bears them with fortitude, as the greatest hero, and possessing the greatest happiness. And therefore if we agree with them, that the propensities of nature may have prompted men to enter

Society

enter into social union, though they may have hoped to enjoy superior security and happiness by engaging to protect and support each other, we must conclude that the Author of the universe has destined man to attain greater dignity and happiness in a savage and solitary than in a social state; and therefore that those dispositions and views which lead us to society are fallacious and inimical to our real interest.

Whatever be the supposed advantages of a solitary state, certain it is that mankind, at the earliest periods, were united in society. Various theories have been formed concerning the circumstances and principles which gave rise to this union: but we have elsewhere shown, that the greater part of them are founded in error; that they suppose the original state of man to have been that of savages; and that such a supposition is contradicted by the most authentic records of antiquity. For though the records of the earlier ages are generally obscure, fabulous, and imperfect; yet happily there is *one* free from the imperfections of the rest, and of undoubted authenticity, to which we may safely have recourse †. This record is the Pentateuch of Moses, which presents us with a genuine account of the origin of man and of society, perfectly consonant to what we have laid down in the article referred to (see SAVAGE). According to Moses, the first society was that of a husband and wife united in the bonds of marriage: the first government that of a father and husband, the master of his family. Men lived together under the patriarchal form of government while they employed themselves chiefly in tending flocks and herds. Children in such circumstances cannot soon rise to an equality with their parents, where a man's importance depends on his property, not on his abilities. When flocks and herds are the chief articles of property, the son can only obtain these from his father; in general therefore the son must be entirely dependent on the father for the means of subsistence. If the parent during his life bestow on his children any part of his property, he may do it on such conditions as shall make their dependence upon him continue till the period of his death. When the community are by this event deprived of their head, instead of continuing in a state of union, and selecting some one from among themselves whom they may invest with the authority of a parent, they separate into so many distinct tribes, each subjected to the authority of a different lord, the master of the family, and the proprietor of all the flocks and herds belonging to it. Such was the state of the first societies which the narrative of Moses exhibits to our attention.

† See Scripture, n° 7—15.

5
First state of society according to authentic history.

6
Theories of philosophers concerning the origin of society

Those philosophers who have made society, in its various stages between rudeness and refinement, the subject of their speculations, have generally considered mankind, in whatever region of the globe, and under whatever climate, as proceeding uniformly through certain regular gradations from one extreme to the other. They regard them, first, as gaining a precarious subsistence by gathering the spontaneous fruits of the earth, preying on the inhabitants of the waters, if placed on the sea shore, or along the banks of large rivers; or hunting wild beasts, if in a situation where these are to be found in abundance, without foresight or industry to provide for future wants when the present call of appetite is gratified. Next, they say, man rises to the shepherd state, and next to that of husbandmen, when they turn their attention from the management of flocks to the cultivation of the ground. Next, these husbandmen improve their powers, and better their condition, by becoming artizans and merchants; and the beginning of this period is the boundary between barbarity and civilization.

These are the stages through which they who have employed themselves on the natural history of society have generally conducted mankind in their progress from rudeness to refinement; but they seem to have overlooked the manner in which mankind where at first established on this earth; for the circumstances in which the parents of the human race were originally placed; for the degree of knowledge communicated to them; and for the instruction which they must have been capable of communicating to their posterity. They rather appear to consider the inhabitants of every different region of the globe as aborigines, springing at first from the ground, or dropped on the spot which they inhabit; no less ignorant than infants of the nature and relations of the objects around them, and of the purposes which they may accomplish by the exercise of their organs and faculties.

7
Are fanciful.

The absurdity of this theory has been fully demonstrated in another place: and if we agree to receive the Mosaic account of the original establishment of mankind, we shall be led to view the phenomena of social life in a light very different. We must first allow, that though many of the rudest tribes are found in the state of *hunters* or *fishers*; yet the hunting or fishing state cannot have been invariably the primary form of society. Notwithstanding the powers with which we are endowed, we are in a great measure the creatures of circumstances. Physical causes exert, though indirectly, a mighty influence in forming the character and directing the exertions of the human race. From the information of Moses we gather, that the first societies of men lived under the patriarchal form of government, and employed themselves in the cultivation of the ground and the management of flocks. And as we know that mankind, being subjected to the influence both of physical and moral causes, are no less liable to degeneracy than capable of improvement; we may easily conceive, that though descending all from the same original pair, and though enlightened with much traditionary knowledge relative to the arts of life, the order of society, moral distinctions, and religious obligations; yet as they were gradually, and by various accidents, dispersed over the earth, being removed to situations in which the arts with which they were acquainted could but little avail them, where industry was overpowered, or indolence encouraged by the severity or the profusion of nature, they might degenerate and fall into a condition almost as humble and precarious as that of the brutal tribes. Other moral causes might also concur to debase or elevate the human character in that early period. The particular character of the original settlers in any region, the manner in which they were connected with one another, and the arts which they were best qualified to exercise, with various other causes of a similar nature, would have considerable influence in determining the character of the society.

When laying aside the spirit of theory and system, we set ourselves, with due humility, to trace facts, and to listen to evidence, though our discoveries may be fewer

fewer than we ſhould otherwiſe fancy them; yet the knowledge which we thus acquire will be more uſeful and ſolid, and our ſpeculations more conſiſtent with the ſpirit of true philoſophy. Here, though we learn from the information of the ſacred writings, that the firſt family of mankind was not cruelly expoſed in this world, as children whom the inhumanity of their parents induces them to deſert; yet we are not, in conſequence of admitting this fact, laid under any neceſſity of denying or explaining away any of the other phenomena which occur to our obſervation when tracing the natural hiſtory of ſociety. Tradition may be corrupted; arts and ſciences may be loſt; the ſublimeſt religious doctrines may be debaſed into abſurdity.

If then we are deſirous of ſurveying ſociety in its rudeſt form, we muſt look, not to the earlieſt period of its exiſtence, but to thoſe diſtricts of the globe where external circumſtances concur to drive them in a ſtate of ſtupidity and wretchedneſs. Thus in many places of the happy clime of Aſia, which a variety of ancient records concur with the ſacred writings in repreſenting as the firſt peopled quarter of the globe, we cannot trace the form of ſociety backwards beyond the ſhepherd ſtate. In that ſtate indeed the bonds which connect ſociety extend not to a wide range of individuals, and men remain for a long period in diſtinct families; but yet that ſtate is highly favourable to knowledge, to happineſs, and to virtue. Again, the torrid and the frozen regions of the earth, though probably peopled at a later period, and by tribes ſprung from the ſame ſtock with the ſhepherds of Aſia, have yet exhibited mankind in a much lower ſtate. It is in the parched deſerts of Africa and the wilds of America that human beings have been found in a condition approaching the neareſt to that of the brutes.

Yet in ſome particular inſtances realized.

We may therefore with ſome propriety deſert the order of time, and take a view of the different ſtages through which philoſophers have conſidered mankind as advancing, beginning with that of rudeneſs, though we have ſhown that it cannot have been the firſt in the progreſs.

9
Rudeſt ſtate or firſt ſtage of ſociety.

Where the human ſpecies are found in the loweſt and rudeſt ſtate, their rational and moral powers are very faintly diſplayed; but their external ſenſes are acute, and their bodily organs active and vigorous. Hunting and fiſhing are then their chief employments on which they depend for ſupport. During that portion of their time which is not ſpent in theſe purſuits, they are ſunk in liſtleſs indolence. Deſtitute of foreſight, they are rouſed to active exertion only by the preſſure of immediate neceſſity or the urgent calls of appetite. Accuſtomed to endure the ſeverity of the elements, and but ſcantily provided with the means of ſubſiſtence, they acquire habits of reſignation and fortitude, which are beheld with aſtoniſhment by thoſe who enjoy the plenty and indulgence of cultivated life. But in this ſtate of want and depreſſion, when the powers and poſſeſſions of every individual are ſcarce ſufficient for his own ſupport, when even the calls of appetite are repreſſed becauſe they cannot always be gratified, and the more refined paſſions, which either originate from ſuch as are merely animal, or are intimately connected with them, have not yet been felt—in this ſtate all the milder affections are unknown; or if the breaſt is at all ſenſible to their impulſe, it is extremely feeble. Huſband and wife, parent and child, brother and brother, are united by the weakeſt ties. Want and miſfortune are not pitied. Why indeed ſhould they, where they cannot be relieved? It is impoſſible to determine how far beings in this condition can be capable of moral diſtinctions. One thing certain is, that in no ſtate are the human race entirely incapable of theſe. If we liſten, however, to the relations of reſpectable travellers, we muſt admit that human beings have ſometimes been found in that abject ſtate where no proper ideas of ſubordination, government, or diſtinction of ranks, could be formed. No diſtinct notions of Deity can be here entertained. Beings in ſo humble a condition cannot look through the order of the univerſe and the harmony of nature to that Eternal Wiſdom and Goodneſs which contrived, and that Almighty Power which brought into exiſtence, the ſyſtem of things. Of arts they muſt be almoſt totally deſtitute. They may uſe ſome inſtruments for fiſhing or the chace; but theſe muſt be extremely rude and ſimple. If they be acquainted with any means to ſhelter them from the inclemency of the elements, both their houſes and clothing will be aukward and inconvenient.

10
Second ſtage in the progreſs of ſociety.

But human beings have not been often found in ſo rude a ſtate as this. Even thoſe tribes which we denominate ſavage, are for the moſt part farther removed from mere animal life. They generally appear united under ſome ſpecies of government, exerciſing the powers of reaſon, capable of morality, though that morality be not always very refined; diſplaying ſome degree of ſocial virtues, and acting under the influence of religious ſentiments. Thoſe who may be conſidered as but one degree higher in the ſcale than the ſtupid and wretched beings, whoſe condition we have ſurveyed, are to be found ſtill in the hunting and fiſhing ſtate; but they are farther advanced towards ſocial life, and are become more ſenſible to the impulſe of ſocial affection. By unavoidable intercourſe in their employments, a few individual hunters or fiſhers contract a certain degree of fondneſs for each other's company, and are led to take ſome part in each other's joys and ſorrows; and when the ſocial affections thus generated (ſee Passion) begin to exert themſelves, all the other powers of the mind are at the ſame time called forth, and the circumſtances of the little ſociety are immediately improved. We behold its members in a more comfortable condition, and find reaſon to view the human character with more complacency and reſpect. Huts are now built, more commodious clothes are faſhioned, inſtruments for the annoyance of wild beaſts and even of enemies are contrived; in ſhort, arts, and ſcience, and ſocial order, and religious ſentiments, and ceremonies, now make their appearance in the riſing ſociety, and ſerve to characterize it by the particular form which diſtinguiſhes each of them. But though ſocial order is no longer unknown nor unobſerved, yet the form of government is ſtill extremely ſimple, and its ties are but looſe and feeble. It will perhaps bear ſome reſemblance to the patriarchal; only all its members are on a more equal footing, and at the ſame time leſs cloſely connected than in the ſhepherd ſtate, to which that form of government ſeems almoſt peculiar. The old men are treated with veneration; but the young are not entirely ſubject to them. They may liſten reſpectfully to their advice; but they do not ſubmit to their arbitrary commands.

commands. Where mankind are in the state of hunters and fishers, where the means of subsistence are precariously acquired, and prudent foresight does not prompt to accumulate much provision for the future, no individual can acquire comparative wealth. As soon as the son is grown up, he ceases to be dependent on his father, as well as on the society in general. Difference of experience therefore constitutes the only distinction between the young and the old; and if the old have experience, the young have strength and activity. Here, then, neither age nor property can give rise to any striking distinction of ranks. All who have attained to manhood, and are not disabled by unusual deficiency of strength or agility, or by the infirmities of old age, are on an equal footing; or if any one possess a pre eminence over the rest, he owes it to superior address or fortitude. The whole tribe deliberate; the old give their advice; each individual of the assembly receives or rejects it at his pleasure (for the whole body think not of exercising any compulsatory power over the will of individuals); and the warrior who is most distinguished for strength, address, and valour, leads out the youth of the tribe to the chace or against the enemy. War, which in the former stage did not prevail, as they who were strangers to social sentiments were, at the same time, scarce capable of being enemies, now first begins to depopulate the thinly inhabited regions where those hunters and fishers pursue their prey. They are scattered, possibly in scanty and separate tribes, over an immense tract of country; but they know no medium between the affection which brethren of the same tribe bear to each other and the hatred of enemies. Though thinly scattered over the earth, yet the hunting parties of different tribes will sometimes meet as they range the forests; and when they meet, they will naturally view each other with a jealous eye; for the success of the one party in the chace may cause the other to be unsuccessful; and while the one snatches the prey, the other must return home to all the pangs of famine. Inveterate hostility will therefore long prevail among neighbouring tribes in the hunting state.

If we find them not incapable of social order, we may naturally expect that their conduct will be influenced by some sentiments of religion. They have at this period ideas of superior beings. They also practise certain ceremonies to recommend them to those beings; but both their sentiments and ceremonies are superstitious and absurd.

We have elsewhere shown (see POLYTHEISM) how savage tribes have probably degenerated from the pure worship of the one true God to the adoration of a multitude of imaginary divinities in heaven, earth, and hell. We have traced this idolatrous worship from that of the heavenly bodies, through all the gradations of dæmon-worship, hero-worship, and statue-worship, to that wonderful instance of absurd superstition which induced the inhabitants of some countries to fall prostrate in adoration before the vilest reptiles. But though we are convinced that the heavenly bodies have by all idolaters been considered as their first and greatest gods, we pretend not that the progress through the other stages of polytheism has been everywhere in the very same order. It is indeed impossible to exhibit under one general view an account of arts, manners, and religious sentiments, which may apply to some certain period in the history of every nation. The characters and circumstances of nations are scarce less various and anomalous than those of individuals. Among many of the American tribes among the ancient inhabitants of the forests of Germany, whose manners have been so accurately delineated by the masterly pen of Tacitus, and in some of the islands scattered over the southern ocean, religion, arts, and government, have been found in that state which we have described as characterizing the second stage of social life. But neither can we pretend that all those simple and rude societies have been described by historians and travellers as agreeing precisely in their arts, manners, and religious sentiments; or that the difference of circumstances always enables us to account in a satisfactory manner for the distinction of their characters. There is a variety of facts in the history of the early periods of society, which no ingenuity, no industry however painful, can reduce under general heads. Here, as well as when we attempt to philosophize on the phenomena of the material world, we find reason to confess that our powers are weak, and our observation confined within a narrow sphere.

11
Third stage in the progress of society, in which ideas of property and inequality of ranks appear.

But we may now carry our views a little forward, and survey human life as approaching somewhat nearer to a civilized and enlightened state. As property is acquired, inequality and subordination of ranks necessarily follow: and when men are no longer equal, the many are soon subjected to the will of the few. But what gives rise to these new phenomena is, that after having often suffered from the precariousness of the hunting and fishing state, men begin to extend their cares beyond the present moment, and to think of providing some supply for future wants. When they are enabled to provide such a supply, either by pursuing the chace with new eagerness and perseverance, by gathering the spontaneous fruits of the earth, or by breeding tame animals—these acquisitions are at first the property of the whole society, and distributed from a common store to each individual according to his wants: But as various reasons will soon concur to convince the community, that by this mode of distribution, industry and activity are treated with injustice, while negligence and indolence receive more than their due, each individual will in a short time become his own steward, and a community of goods will be abolished. As soon as distinct ideas of property are formed, it must be unequally distributed; and as soon as property is unequally distributed there arises an inequality in ranks. Here we have the origin of the depression of the female sex in rude ages, of the tyrannical authority exercised by parents over their children, and perhaps of slavery. The women cannot display the same perseverance, or activity, or address, as the men in pursuing the chace. They are therefore left at home; and from that moment are no longer equals, but slaves and dependants, who must subsist by the bounty of the males, and must therefore submit with implicit obedience to all their capricious commands. Even before the era of property, the female sex were viewed as inferiors; but till that period they were not reduced to a state of abject slavery.

In this period of society new notions are formed of the relative duties. Men now become citizens, masters, and servants; husbands, parents, &c. It is impossible to enumerate all the various modes of government which take place among the tribes who have advanced to this ſtage; but one thing certain is, that the authority of the few over the many is now firſt eſtabliſhed, and that the riſe of property firſt introduces inequality of ranks. In one place, we ſhall perhaps find the community ſubjected during this period to the will of a ſingle perſon; in another, power may be lodged in the hands of a number of chiefs; and in a third, every individual may have a voice in creating public officers, and in enacting laws for the ſupport of public order. But as no code of laws is formed during this period, juſtice is not very impartially adminiſtered, nor are the rights of individuals very faithfully guarded. Many actions, which will afterwards be conſidered as heinouſly immoral, are now conſidered as praiſe-worthy or indifferent. This is the age of hero-worſhip, and of houſehold and tutelary gods; for it is in this ſtage of ſociety that the invention of arts, which gave riſe to that worſhip, contributes moſt conſpicuouſly to the public good. War, too, which we conſider as beginning firſt to ravage the earth during the former period, and which is another cauſe of the deification of dead men, will ſtill prevail in this age, and be carried on with no leſs ferocity than before, though in a more ſyſtematic form.

The prevalence of war, and the means by which ſubſiſtence is procured, cannot but have conſiderable influence on the character and ſentiments of ſocieties and individuals. The hunter and the warrior are characters in many reſpects different from the ſhepherd and the huſbandman. Such, in point of government, arts, and manners, religious and moral ſentiments, were ſeveral of the German tribes deſcribed by Tacitus; and the Britons whoſe character has been ſketched by the pen of Cæſar: ſuch, too, were the Romans in the early period of their hiſtory; ſuch too the inhabitants of Aſia Minor about the time of the ſiege of Troy, as well as the Greeks whom Homer celebrates as the deſtroyers of the Trojan ſtate: the northern tribes alſo, who poured thro' Aſia, Africa, and Europe, and overthrew the Roman empire, appear to have been of a nearly ſimilar character. It ſeems to be a general opinion among thoſe who have directed their attention to the hiſtory of ſociety, that, in the ſcale aſcending from the loweſt condition of human beings to the moſt civilized and enlightened ſtate of ſociety, the ſhepherd ſtate is the next in order above the hunting; and that as mankind improve in knowledge and in moral ſentiments, and as the foreſts are gradually depopulated of their inhabitants, inſtead of deſtroying the inferior animals, men become their guardians and protectors. But we cannot unreſervedly ſubſcribe to this opinion: we believe, that in the ſhepherd ſtate ſocieties have been ſometimes found ſuperior to the moſt poliſhed tribes of hunters; but upon viewing the annals of mankind in early ages, we obſerve that there is often no inconſiderable reſemblance even between hunters and ſhepherds in point of the improvement of the rational faculties and the moral ſenſe; and we are therefore led to think, that theſe two ſtates are ſometimes parallel; for inſtance, ſeveral of the American tribes, who ſtill procure their ſubſiſtence by hunting, appear to be nearly in the ſtate which we have deſcribed as the third ſtage in the progreſs of ſociety; and the ancient ſhepherds of Aſia do not appear to have been much more cultivated and refined. We even believe that men have ſometimes turned their attention from hunting to agriculture without paſſing through any intermediate ſtate. Let us remember, that much depends upon local circumſtances, and ſomewhat undoubtedly on original inſpiration and traditionary inſtruction. In this period of ſociety the ſtate of the arts well deſerves our attention. We ſhall find, that the ſhepherds and the hunters are in that reſpect on a pretty equal footing. Whether we examine the records of ancient hiſtory, or view the iſlands ſcattered through the South Sea, or range the wilds of America, or ſurvey the ſnowy waſtes of Lapland and the frozen coaſt of Greenland—ſtill we find the uſeful arts in this period, though known and cultivated, in a very rude ſtate; and the fine arts, or ſuch as are cultivated merely to pleaſe the fancy or to gratify caprice, diſplaying an odd and fantaſtic, not a true or natural, taſte; yet this is the period in which eloquence ſhines with the trueſt luſtre: all is metaphor or glowing ſentiment. Languages are not yet copious; and therefore ſpeech is figurative, expreſſive, and forcible. The tones and geſtures of nature, not being yet laid aſide, as they generally are, from regard to decorum, in more poliſhed ages, give a degree of force and expreſſion to the harangues of the ruſtic or ſavage orator, which the moſt laborious ſtudy of the rules of rhetoric and elocution could not enable even a more poliſhed orator to diſplay.

12
Fourth ſtage; in which agriculture flouriſhes, the arts are ſubdivided, commerce and regular government are introduced.

But let us advance a little farther, and contemplate our ſpecies in a new light, where they will appear with greater dignity and amiableneſs of character. Let us view them as huſbandmen, artizans, and legiſlators. Whatever circumſtances might turn the attention of any people from hunting to agriculture, or cauſe the herdſman to yoke his oxen for the cultivation of the ground, certain it is that this change in the occupation would produce an happy change on the character and circumſtances of men; it would oblige them to exert a more regular and perſevering induſtry. The hunter is like one of thoſe birds that are deſcribed as paſſing the winter in a torpid ſtate. The ſhepherd's life is extremely indolent. Neither of theſe is very favourable to refinement. But different is the condition of the huſbandman. His labours ſucceed each other in regular rotation through the year. Each ſeaſon with him has its proper employments; he therefore muſt exert active perſevering induſtry; and in this ſtate we often find the virtues of rude and poliſhed ages united. This is the period where barbariſm ends and civilization begins. Nations have exiſted for ages in the hunting or the ſhepherd ſtate, fixed as by a kind of ſtagnation, without advancing farther. But ſcarce any inſtances occur in the hiſtory of mankind of thoſe who once reached the ſtate of huſbandmen, remaining long in that condition without riſing to a more civilized and poliſhed ſtate. Where a people turn their attention in any conſiderable degree to the objects of agriculture, a diſtinction of occupations naturally ariſes among them. The huſbandman is ſo cloſely employed thro' the ſeveral ſeaſons of the year in the labours of the field, that he has no longer leiſure to exerciſe all the rude arts known among his countrymen. He has not time to faſhion the inſtruments of huſbandry, to prepare his clothes, to build his houſe, to manufacture houſehold utenſils, or to tend thoſe tame animals which he continues to rear. Thoſe different departments therefore now begin to employ different perſons; each of whom

dedicates

Society. dedicates his whole time and attention to his own occupation. The manufacture of cloth is for a considerable time managed exclusively by the women; but smiths and joiners arise from among the men. Metals begin now to be considered as valuable materials. The intercourse of mankind is now placed on a new footing. Before, every individual practised all the arts that were known, as far as was necessary for supplying himself with the conveniences of life. Now he confines himself to one or to a few of them; and, in order to obtain a necessary supply of the productions of those arts which he does not cultivate himself, he gives in exchange a part of the productions of his own labours. Here we have the origin of commerce.

After continuing perhaps for some time in this state, as arts and distinctions multiply in society, the exchange of one commodity for another is found troublesome and inconvenient. It is ingeniously contrived to adopt a medium of commerce, which being estimated not by its intrinsic value, but by a certain nominal value which it receives from the agreement of the society among whom it is used, serves to render the exchange of property, which is so necessary for the purposes of social life, easy and expeditious. Wherever metals have been known, they appear to have been adopted as the medium of commerce almost as soon as such a medium began to be used: and this is one important purpose for which they serve; but they have still more important uses. Almost all the necessary arts depend on them. Where the metals are known, agriculture practised, and the necessary arts distributed among different orders of artisans—civilization and refinement, if not obstructed by some accidental circumstances, advance with a rapid progress. With regard to the first applying of the precious metals as the medium of commerce, we may observe, that this was probably not accomplished by means of a formal contract. They might be first used as ornaments; and the love of ornament, which prevails among rude as much as among civilized nations, would render every one willing to receive them in exchange for such articles as he could spare. Such might be the change produced on society with regard to the necessary arts by the origin of agriculture. As soon as ornament and amusement are thought of the fine arts begin to be cultivated. In their origin therefore they are not long posterior to the necessary and useful arts. They appear long before men reach the comfortable and respectable condition of husbandmen; but so rude is their character at their first origin, that our *Dilettanti* would probably view their productions of that period with unspeakable contempt and disgust. But in the period of society which we now consider, they have aspired to an higher character; yet poetry is now perhaps less generally cultivated than during the shepherd state. Agriculture, considered by itself, is not directly favourable either to refinement of manners or to the fine arts. The conversation of shepherds is generally supposed to be far more elegant than that of husbandmen; but though the direct and immediate effects of this condition of life be not favourable to the fine arts, yet directly it has a strong tendency to promote their improvement. Its immediate influence is extremely favourable to the necessary and useful arts; and these are no less favourable to the fine arts.

One of the noblest changes which the introduction of the arts by agriculture produces on the form and circumstances of society, is the introduction of regular government and laws. In tracing the history of ancient nations, we scarce ever find laws introduced at an earlier period. Minos, Solon, and Lycurgus, do not appear to have formed codes of wisdom and justice for regulating the manners of their countrymen, till after the Cretans, the Athenians, and even the Lacedemonians, had made some progress in agriculture and the useful arts.

Religion, under all its various forms, has in every stage of society a mighty influence on the sentiments and conduct of men (see Religion); and the arts cultivated in society have on the other hand some influence on the system of religious belief. One happy effect which will result from the invention of arts, though perhaps not immediately, will be, to render the character of the deities more benevolent and amiable, and the rites of their worship more mild and humane.

The female sex in this period generally find the yoke of their slavery somewhat lightened. Men now become easier in their circumstances; the social affections assume stronger influence over the mind; plenty, and security, and ease, at once communicate both delicacy and keenness to the sensual desires. All these circumstances concur to make men relax in some degree that tyrannic sway by which they before depressed the softer sex. The foundation of that empire, where beauty triumphs over both wisdom and strength, now begins to be laid. Such are the effects which history warrants us to attribute to agriculture and the arts; and such the outlines of the character of that which we reckon the fourth stage in the progress of society from rudeness to refinement.

13 Fifth stage in the progress of society; in which literature, arts, and sciences, are much cultivated, and religion assumes a mild and engaging aspect.

Let us advance one step farther. We have not yet surveyed mankind in their most polished and cultivated state. Society is rude at the period when the arts first begin to show themselves, in comparison of that state to which it is raised by the industrious cultivation of them. The neighbouring commonwealths of Athens and Lacedemon afford us a happy opportunity of comparing this with the former stage in the progress of society. The chief effect produced by the institutions of Lycurgus seems to have been, to fix the manners of his countrymen for a considerable period in that state to which they he had attained in his days. Spartan virtue has been admired and extolled in the language of enthusiasm; but in the same manner has the character and the condition of the savage inhabitants of the wilds of America, been preferred by some philosophers, to the virtues and the enjoyments of social life in the most polished and enlightened state. The Spartans in the days of Lycurgus had begun to cultivate the ground, and were not unacquainted with the useful arts. They must soon have advanced farther had not Lycurgus arisen, and by effecting the establishment of a code of laws, the tendency of which appears to have been in many particulars directly opposite to the designs of nature, retarded their progress towards complete civilization and refinement. The history of the Lacedemonians, therefore, while the laws of Lycurgus continued in force, exhibits the manners and character of a people in that which we have denominated the fourth stage in the progress of society. But if we turn our eyes to their neigh-

neighbours the Athenians, we behold in their history the natural progress of opinions, arts, and manners. The useful arts are first cultivated with such steady industry, as to raise the community to opulence, and to furnish them with articles for commerce with foreign nations. The useful arts cannot be raised to this height of improvement without leading man to the pursuit of science. Commerce with foreign nations, skill in the useful arts, and a taste for science, mutually aid each other, and conspire to promote the improvement of the fine arts. Hence magnificent buildings, noble statues, paintings expressive of life, action, and passion; and poems in which imagination adds new grace and sublimity to nature, and gives the appearances of social life more irresistible power over the affections of the heart. Hence are moral distinctions more carefully studied, and the rights of every individual and every order in society better understood and more accurately defined. Moral science is generally the first scientific pursuit which strongly attracts the attention of men. Lawgivers appear before geometricians and astronomers. Some particular circumstances may cause these sciences to be cultivated at a very early period. In Egypt the overflowing of the Nile caused geometry to be early cultivated. Causes no less favourable to the study of astronomy, concurred to recommend that science to the attention of the Chaldeans long before they had attained the height of refinement. But, in general, we find, that the laws of morality are understood, and the principles of morals inquired into, before men make any considerable progress in physical science, or even prosecute it with any degree of keenness. Accordingly, when we view the state of literature in this period (for it is now become an object of so much importance as to force itself on our attention), we perceive that poetry, history, and morals, are the branches chiefly cultivated. Arts are generally casual inventions, and long practised before rules and principles on which they are founded assume the form of science. But morality, if considered as an art, is that art which men have soonest and most constantly occasion to practise. Besides, we are so constituted by the wisdom of nature, that human actions, and the events which befal human beings, have more powerful influence than any other object to engage and fix our attention. Hence we are enabled to explain why morality, and those branches of literature more immediately connected with it, are almost always cultivated in preference to physical science. Though poetry, history, and morals, be pursued with no small eagerness and success in that period of society which we now consider, we need not therefore be greatly surprised that natural philosophy is neither very generally nor very successfully cultivated. Were we to consider each particular in that happy change which is now produced on the circumstances of mankind, we should be led into a too minute and perhaps unimportant detail. This is the period when human virtue and human abilities shine with most splendour. Rudeness, ferocity, and barbarism, are now banished. Luxury has made her appearance; but as yet she is the friend and the benefactress of society. Commerce has stimulated and rewarded industry, but has not yet contracted the heart and debased the character. Wealth is not yet become the sole object of pursuit. The charms of social intercourse are known and relished; but domestic duties are not yet deserted for public amusements. The female sex acquire new influence, and contribute much to refine and polish the manners of their lords. Religion now assumes a milder and more pleasing form; splendid rites, magnificent temples, pompous sacrifices, and gay festivals, give even superstition an influence favourable to the happiness of mankind. The gloomy notions and barbarous rites of former periods fall into disuse. The system of theology produced in former ages still remains: but only the mild and amiable qualities of the deities are celebrated; and none but the gay, humane, and laughing divinities, are worshipped. Philosophy also teaches men to discard such parts of their religion as are unfriendly to good morals, and have any tendency to call forth or cherish unsocial sentiments in the heart. War (for in this period of society enough of causes will arise to arm one nation against another)—war, however, no longer retains its former ferocity; nations no longer strive to extirpate one another; to procure redress for real or imaginary injuries; to humble, not to destroy, is now its object. Prisoners are no longer murdered in cold blood, subjected to horrid and excruciating tortures, or condemned to hopeless slavery. They are ransomed or exchanged; they return to their country, and again fight under its banners. In this period the arts of government are likewise better understood, and practised so as to contribute most to the interests of society. Whether monarchy, or democracy, or aristocracy, be the established form, the rights of individuals and of society are in general respected. The interests of society are so well understood, that the few, in order to preserve their influence over the many, find it necessary to act rather as the faithful servants than the imperious lords of the public. Though the liberties of a nation in this state be not accurately defined by law, nor their property guaranteed to them by any legal institutions, yet their governors dare not violate their liberties, nor deprive them wantonly of their properties. This is truly the golden age of society: every trace of barbarism is entirely effaced; and vicious luxury has not yet begun to sap the virtue and the happiness of the community. Men live not in listless indolence; but the industry in which they are engaged is not of such a nature as to overpower their strength or exhaust their spirits. The social affections have now the strongest influence on men's sentiments and conduct.

14 Degeneracy and decline of society.

But human affairs are scarce ever stationary. The circumstances of mankind are almost always changing, either growing better or worse. Their manners are ever in the same fluctuating state. They either advance towards perfection or degenerate. Scarce have they attained that happy period in which we have just contemplated them, when they begin to decline till they perhaps fall back into a state nearly as low as that from which we suppose them to have emerged. Instances of this unhappy degeneracy occur more than once in the history of mankind; and we may finish this short sketch of the history of society by mentioning in what manner this degeneracy takes place. Perhaps, strictly speaking, every thing but the simple necessaries of life may be denominated luxury: for a long time, however, the welfare of society is best promoted, while its members aspire after something more than the mere necessaries of life. As long as these superfluities are to be obtained only by active and honest exertion; as long as they only engage the leisure hours without becoming the chief objects of pursuit—the employment which they give to the faculties is favourable both to the virtue and the happiness of the human race.

The period arrives, however, when luxury is no longer serviceable to the interests of nations; when she is no longer a graceful, elegant, active form, but a languid, overgrown, and bloated carcase. It is the love of luxury, which contributed so much to the civilization of society, that now brings on its decline. Arts are cultivated and improved, and commerce extended, till enormous opulence be acquired: the effect of opulence is to awake the fancy, to conceive ideas of new and capricious wants, and to inflame the breast with new desires. Here we have the origin of that selfishness which, operating in conjunction with caprice and the violence of unbridled passions, contributes so much to the corruption of virtuous manners. Selfishness, caprice, indolence, effeminacy, all join to loosen the bonds of society, to bring on the degeneracy both of the useful and the fine arts, to banish at once the mild and the austere virtues, to destroy civil order and subordination, and to introduce in their room anarchy or despotism.

Scarce could we have found an example of the beautiful form of society which we last attempted to describe. Never, at least, has any nation continued long to enjoy such happy circumstances, or to display so amiable and respectable a character. But when we speak of the declining state of society, we have no difficulty in finding instances to which we may refer. History tells of the Assyrians, the Egyptians, and the Persians all of them once flourishing nations, but brought low by luxury and an unhappy corruption of manners. The Greeks, the Romans, and the Arabians, owed their fall to t e same causes; and we know not if a similar fate does not now threaten many of those nations who have long made a distinguished figure in the system of Europe. The Portuguese, the Venetians, and the Spaniards, have already fallen; and what is the present state of our neighbours the French? They have long been a people destitute of religion, corrupted in morals, unsteady in conduct, and slaves to pleasure and public amusements. Among them luxury had arrived at its highest pitch; and the consequence has been, that after capriciously shaking off the yoke of depotism, they have established, or rather set up (for established it cannot be), a motely kind of government, which, in the course of a few years, has exhibited scenes of tyranny and oppression, to which we doubt if the annals of the world can furnish any parallel. Yet this is the people whose manners the other nations of Europe were ambitious to imitate. May those nations take warning in time, and avoid the rocks upon which they have split.

15 Concluding remarks.

Thus have we viewed the several stages in which society appears in its progress from rudeness to refinement and decay. The intelligent reader will perceive, that the various and anomalous phenomena which occur in the natural history of society, cannot easily be solved; because the necessary information cannot be obtained. Others have been well accounted for by the researches of curious philosophical inquirers. Local circumstances, the influence of climate, the intercourse of nations in different states of civilization, have been taken notice of, as causes serving to accelerate or retard the progress of arts and manners. But our proper business here was merely to mark the gradations between barbarism and refinement: and as the painter who is to exhibit a series of portraits representing the human form in infancy, puerility, youth, and manhood, will not think of delineating all that variety of figures and faces which each of those periods of life affords, and will find himself unable to represent in any single figure all diversities of form and features; so we have not once thought of describing particularly under this article, all the various national characters reducible to any one of those divisions under which we have viewed the progress of society, nor have found it possible to comprehend under one consistent view, all the particulars which may be gathered from the remains of antiquity, from the relations of later travellers, and the general records of history concerning the progressive character of mankind in various regions, and under the influence of various accidents and circumstances. This indeed would have even been improper, as all that information appears under other articles in this Work.

SOCIETIES, associations voluntarily formed by a number of individuals for promoting knowledge, industry, or virtue. They may therefore be divided into three classes; societies for promoting science and literature, societies for encouraging and promoting arts and manufactures, and societies for diffusing religion and morality and relieving distress. Societies belonging to the first class extend their attention to all the sciences and literature in general, or devote it to one particular science. The same observation may be applied to those which are instituted for improving arts and manufactures. Those of the third class are established, either with a view to prevent crimes, as the Philanthropic Society; for the diffusion of the Christian religion among unenlightened nations, as the Society for the Propagation of the Gospel in Foreign Parts; or for introducing arts and civilization, along with a knowledge of the Christian religion, as the Sierra Leona company.

The honour of planning and instituting societies for those valuable purposes is due to modern times. A literary association is said to have been formed in the reign of Charlemagne (see ACADEMY); but the plan seems to have been rude and defective. Several others were instituted in Italy in the 16th century; but from the accounts which we have seen of them, they seem to have been far inferior to those which are most flourishing at pesent. The most enlarged idea of literary societies seems to have orginated with the great Lord Bacon, the father of modern philosophy, who recommended to the reigning prince to institute societies of learned men, who should give to the world from time to time a regular account of their researches and discoveries. It was the idea of this great philosopher, that the learned world should be united, as it were, into one immense republic; which, though consisting of many detached states, should hold a strict union and preserve a mutual intelligence with each other, in every thing that regards the common interest. The want of this union and intelligence he laments as one of the chief obstacles to the advancement of science; and, justly considering the institution of public societies, in the different countries of Europe, under the auspices of the sovereign, to be the best remedy for that defect, he has given, in his fanciful work, the New Atalantis, the delineation of a philosophical

Societies.

society on the most extended plan, for the inprovement of all arts and sciences; a work which, though written in the language, and tinctured with the colouring of romance, is full of the noblest philosophic views. The plan of Lord Bacon, which met with little attention from the age in which he lived, was destined to produce its effect in a period not very distant. The scheme of a philosophical college by Cowley is acknowledged to have had a powerful influence in procuring the establishment of the Royal Society of London by charter from Charles II. §; and Cowley's plan is manifestly copied in almost all its parts from that in the New Atlantis. The institution of the Royal Society of London was soon followed by the establishment of the Royal Academy of Sciences at Paris; and these two have served as models to the philosophical academies of highest reputation in the other kingdoms of Europe.

§ Sprat's History of the Royal Society, 2d edit. p. 59.

The experience of ages has shown, that improvements of a public nature are best carried on by societies of liberal and ingenious men, uniting their labours without regard to nation, sect, or party, in one grand pursuit alike interesting to all, whereby mutual prejudices are worn off, and a humane philosophical spirit is cherished. Men united together, and frequently meeting for the purpose of advancing the sciences, the arts, agriculture, manufactures, and commerce, may oftentimes suggest such hints to one another as may be improved to important ends: and such societies, by being the repositories of the observations and discoveries of the learned and ingenious, may from time to time furnish the world with useful publications which might otherwise be lost: for men of ingenuity and modesty may not choose to risk their reputation, by sending abroad upatronized what a learned society might judge richly worthy the public eye; or perhaps their circumstances being straitened, they may not be able to defray the expence of publication. Societies instituted for promoting knowledge may also be of eminent service, by exciting a spirit of emulation, and by enkindling those sparks of genius which otherwise might for ever have been concealed; and if, when possessed of funds sufficient for the purpose, they reward the exertions of the industrious and enterprising with pecuniary premiums or honorary medals, many important experiments and useful discoveries will be made, from which the public may reap the highest advantages.

Eminent instances of the beneficial effects of such institutions we have in the Royal academy of Sciences at Paris, the Royal Society, and the Society instituted for the Encouragement of Arts, Manufactures, and Commerce, in London, and many others of a similar kind. Hereby a spirit of discovery and improvement has been excited among the ingenious in almost every nation; knowledge of various kinds, and greatly useful to mankind, has taken place of the dry and uninteresting speculations of schoolmen; and bold and erroneous hypothesis has been obliged to give way to demonstrative experiment. In short, since the establishment of these societies, solid learning and philosophy have more increased than they had done for many centuries before.

As to those societies established for promoting industry, religion, and morality, and relieving distress, the design is laudable and excellent, and presents a beautiful picture of the philanthropy of modern times. We are happy to find, from the minutes of some of these societies, that their beneficial effects are already conspicuous.

Religious and Humane Societies.

We will now give some account of the most eminent societies; arranging them under the three classes into which we have divided them: I. *Religious and Humane Societies.* II. *Societies for Promoting Science and Literature.* III. *Societies for Encouraging Arts, Manufactures, &c.*

I. Religious and Humane Societies.

1. *Society for the Propagation of the Gospel in Foreign Parts* was instituted by King William III. in 1701, in order to secure a maintenance for an orthodox clergy, and to make other provisions for propagating the Gospel in the plantations, colonies, and factories beyond the seas. To that end he incorporated the archbishops, several of the bishops, and others of the nobility, gentry, and clergy, to the number of 90, into one body, which, by the name of *The Society for the Propagation of the Gospel in Foreign Parts*, was to plead and be impleaded; to have perpetual succession, with privilege to purchase L. 2000 a-year inheritance, and estates for lives or years, with other goods and chattels to any value. By its charter the society is authorised to use a common seal; and to meet annually on the third Friday in February for the purpose of choosing a president, vice president, and officers of the year ensuing; and on the third Friday in every month, or oftener if there should be occasion, to transact business, and to depute persons to take subscriptions, and collect money contributed for the purposes aforesaid; and of all moneys received and laid out, it is obliged to give account yearly to the lord-chancellor or keeper, the lord chief-justice of the King's-bench, the lord-chief-justice of the common-pleas, or to any two of these magistrates. Of this society there is a standing committee at St Paul's chapter-house, to prepare matters for the monthly meeting, which is held at St Martin's library.

Before the incorporation of the society for the propagation of the Gospel in foreign parts, there had been formed, for the promoting of Christian knowledge both at home and in the colonies, a voluntary association of persons of rank and respectability, who in March 1699 began to hold stated meetings in London for that purpose, regulating themselves by the laws of the land and the canons of the church; and when the new society was formed, they had already transmitted to America and the West Indies L. 800 worth of Bibles, Books of Common Prayer, and treatises of practical religion, besides securing a tolerable maintenance to several clergymen on this continent. This association still subsists under the denomination of *The Society for Promoting Christian Knowledge* and has been productive of much good in the cities of London and Westminster; but upon the formation of the new society into which all its original members were incorporated by name, the care which the voluntary association had taken of the colonies devolved of course upon the incorporated society; of which incorporation we believe the object has been sometimes mistaken, and the labours of its missionaries grossly misrepresented. It has by many been supposed that the society was incorporated for the *sole* purpose of converting the savage Americans; and it has been much blamed for sending missionaries into provinces where, in the despicable cant of the complainers, a *Gospel-ministry* was already established. But an impartial view of the

rise

rise and progress of the American provinces, now become independant states, will show the folly and injustice of those complaints.

The English colonies in North America were in the last century formed and first peopled by religious men; who, made uneasy at home by their intolerant brethren, left the *old world* to enjoy in peace that first and chief prerogative of man, *the free worship of God, according to his own conscience*. At one time PURITANS were driven across the Atlantic by the episcopal church; at another, CHURCHMEN were forced away by the presbyterians just as the revolutions of state threw the civil power into the hands of the one or the other party; and not a few members of the CHURCH OF ROME were chased to the wilds of America by the united exertions of both. It has been often observed, that people persecuted for their religion become for the most part enthusiastically attached to it; and the conduct of those colonists was in perfect harmony with this observation. Their zeal, inflamed by their violent removal to the other hemisphere, kept religion alive and active among themselves; but their poverty disabled them from supplying fuel to the flame, by making provision for a ministry to instruct their offspring. The consequence was, that the new Christian commonwealth, without the kindly assistance of its mother-country, would have been, in the words of the Roman historian, *Res unius ætatis*. Against this danger a timely aid was to be provided by the society; which, as it consisted not of fanatical members, would not intrust the important business of the mission to fanatical preachers, who, though always ready for such spiritual enterprises, are never qualified to carry them on with success.

It was therefore thought fit to assign a decent maintenance for clergymen of the church of England, who might preach the gospel to their brethren in America: and though those missionaries in general carefully avoided the conduct of those of Rome, whose principal aim is to reduce all churches under submission to the papal tyranny; yet so lately as 1765, did some of the colonies, in which the puritanic spirit of the last century characterised the church established by law, raise a hideous outcry against the society for sending a mission into their quarters, though only for the service of the dispersed members of the Episcopal church residing among them, and for the conversion of those men whom their rigid fanaticism had prejudiced against Christianity itself.

Indeed the commodity called FREETHINKING, as Bishop Warburton expresses it, was at an early period imported by the opulent and fashionable colonists. The celebrated Berkeley, who had resided some years in Rhode Island, and at his return was called upon to preach the anniversary sermon before the society, informs us, that the island where he lived was inhabited by an English colony, consisting chiefly of sectaries of many different denominations; that several of the better sort of the inhabitants of towns were accustomed to assemble themselves regularly on the Lord's day for the performance of divine worship; but that most of those who were dispersed through the colony rivalled some well bred people of other countries, in a thorough indifference for all that is sacred, being equally careless of outward worship and of inward principles. He adds, that the missionaries had done, and were continuing to do, good service in bringing those planters to a serious sense of religion. "I speak it knowingly (says he), that the ministers of the Gospel, in those provinces which go by the name of New England, sent and supported at the expence of the society, have, by their sobriety of manners, discreet behaviour, and a competent degree of useful knowledge, shown themselves worthy of the choice of those who sent them." We have the honour to be acquainted with some of the missionaries sent at a later period, and have reason to believe that, down to the era of the American revolution, they had the same virtues, and were doing the same good services, which procured to their predecessors this honourable testimony from one of the greatest and the best of men. Surely such a mission deserved not to be evil spoken of by sectarists of any denomination who believe in Christ; especially as the very charter of incorporation assigns as a reason for missionaries being sent to the colonies, "that by reason of their poverty those colonies were destitute and unprovided of a MAINTENANCE for ministers and the public worship of God."

‡ See his Sermon, Vol. II. of his Works, 4to.

The society, however, was incorporated for other purposes than this. It was obliged by its charter to attempt the conversion of the native Americans and the negro slaves; and we have reason to believe, that, as soon as the spiritual wants of the colonists were decently supplied, it was not inattentive to these glorious objects. Its success indeed in either pursuit has not been so great as could be wished; but it would be rash and unfair to attribute this failure to the president, vice-president, or other officers of the corporation at home. An erroneous notion, that the being baptized is inconsistent with a state of slavery, rendered the selfish colonists for a long time averse from the conversion of their negroes, and made them throw every obstacle in the way of all who made the attempt; while the difficulties of the Indian mission are such as hardly any clergyman educated in a Protestant country can be supposed able to surmount.

He who hopes successfully to preach the Gospel among a tribe of savage wanderers, must have an ardent zeal and unwearied diligence; appetites subdued to all the distresses of want; and a mind superior to all the terrors of mortality. These qualities and habits may be acquired in the church of Rome by him who from infancy has been trained up in the severities of some of the monastic orders, and afterwards sent to the college *de propaganda fide* to be instructed in the languages, and inured to the manners and customs of the barbarous nations whose conversion he is destined to attempt. But in the reformed churches of Britain there are no monastic orders, nor any college *de propaganda fide*; and yet without the regular preparation, which is to be looked for in such institutions alone, it is not in nature, whatever grace may effect, for any man cheerfully, and at the same time soberly, to undergo all the accumulated distresses ever ready to overtake a faithful missionary among savage idolaters. A fanatic zealot will indeed undertake it, though he is totally unqualified for every sober and important work; and a man of ruined fortunes may be pressed into the service, though the impotency of his mind has shown him unable to bear either poverty or riches. The failure of the society therefore in its attempts to convert the American Indians may be attributed, we think, in the first instance,

ſtance, to the want of a college *de propaganda* for training up young men for the American miſſion.

Perhaps another cauſe of this failure may be found in the conduct of the miſſionaries, who, it is to be preſumed, have not always employed in a proper manner even the ſcanty qualifications which they actually poſſeſſed. The Goſpel plain and ſimple as it is, and fitted in its nature for what it was ordained to effect, cannot be apprehended but by an intellect ſomewhat raiſed above that of a ſavage. Such of the miſſionaries therefore as began their work with *preaching to ſavage and brutal men*, certainly ſet out at the wrong end; for to make the Goſpel underſtood, and much more to propagate and eſtabliſh it, thoſe ſavages ſhould have been firſt taught the neceſſary arts of civil life, which, while they improve every bodily accommodation, tend at the ſame time to enlarge and enlighten the underſtanding. For want of this previous culture, we doubt not, it hath happened that ſuch of the ſavages as have been baptiſed into the faith have ſo ſeldom perſevered themſelves, or been able in any degree to propagate among their tribes the Chriſtianity which they had been taught, and that ſucceſſive miſſions have always found it neceſſary to begin anew the work of converſion.

To one or other of theſe cauſes, or to both, may juſtly be attributed the little progreſs which reformed Chriſtianity has made among the Indians of North America; and not to any want of zeal, attention, or liberality, in the directors of the ſociety at home. During the dependence of the United States on the mother-country, great part of the ſociety's funds was properly expended in keeping alive a juſt ſenſe of religion among the Chriſtian coloniſts from Europe, who had ſurely the firſt claims upon this beſt of charities; but now that America has ſeparated herſelf from Great Britain, and ſhown that ſhe is able to maintain her independence, and to make ample proviſion for a regular clergy of her own, the members of the corporation muſt feel themſelves at liberty to beſtow greater attention, and to expend more money than they could formerly do, on the converſion of ſuch Indians as have any intercourſe with the ſettlements which Britain ſtill poſſeſſes. To a body ſo reſpectable, we preſume not to offer advice; but we cannot help thinking, with Biſhop Berkeley, that the moſt ſucceſsful miſſionaries would be children of Indians, educated in a conſiderable number together from the age of ten or twelve in a college *de propaganda fide*, where they ſhould be in no danger of loſing their mother-tongue while they were acquiring a competent knowledge of religion, morality, hiſtory, practical mathematics, and agriculture. "If there were a yearly ſupply (ſays he) of a dozen ſuch miſſionaries ſent abroad into their reſpective countries, after they had received the degree of maſter of arts, and been admitted into holy orders, it is hardly to be doubted but that in a little time the world would ſee good and great effects of their miſſion."

Proposal for the better ſupplying of Churches in our Foreign Plantations, &c.

2. *Society in Scotland for propagating Chriſtian Knowledge*, was inſtituted in the beginning of the preſent century. At that period the condition of the Scotch Highlanders was truly deplorable. Shut up in deſolate iſlands by tempeſtuous ſeas, or diſperſed over a wide extent of country, interſected by high mountains, rapid rivers, and arms of the ſea, without bridges or highways, by which any communication could be kept open either with remote or neighbouring diſtricts, they lived in ſmall detached companies in hamlets or ſolitary huts. Being thus ſecluded from intercourſe with the more civilized part of the iſland, they could not enjoy the advantages of trade and manufactures. As their ſoil was barren and their climate ſevere, in agriculture no progreſs was to be expected: and as they were acquainted with no language but Gaelic, in which no books were then written, to poſſeſs knowledge was impoſſible. Their pariſhes being of great extent, often 30 or 40 miles long and of a proportionable breadth, and ſometimes conſiſting of ſeveral iſlands ſeparated by ſeas, which are often impaſſable, a conſiderable number of the inhabitants was entirely deprived of religious inſtruction or fell a prey to Popiſh emiſſaries. A ſingle ſchool in ſuch extenſive pariſhes could be of little benefit; yet many pariſhes were entirely deſtitute even of this reſource: and where ſchools were eſtabliſhed, the want of books prevented them from producing the uſeful effects otherwiſe to have been expected from them (A). To all this we muſt add, that they lived in a ſtate of the greateſt oppreſſion: For though the Highlands formed a part of the Britiſh empire, the bleſſings of the Britiſh conſtitution had not reached them. The feudal ſyſtem reigned in its utmoſt rigour; the chieftains exerciſing the moſt deſpotic ſway over the inferior Highlanders, whom at their pleaſure they deprived of their lives or property (B).

Thus the Highlanders were ignorant, oppreſſed, and uncivilized; ſlaves rather than ſubjects; and either entirely deſtitute of the advantages of the Chriſtian religion, or unqualified to improve them. Hitherto they had been unhappy and uſeleſs to themſelves and dangerous to the ſtate; for they were ready at the call of their chieftains to iſſue from their mountains, and to turn their arms againſt their lawful king and his loyal ſubjects. This character, however, aroſe from their ſituation. It was therefore impoſſible for benevolent minds to contemplate this unhappy ſituation of their countrymen without feeling a deſire to raiſe them to the dignity of rational beings, and to render them uſeful as citizens.

Accordingly, in the year 1701, ſome private gentlemen of the city of Edinburgh, who had formed themſelves into a ſociety for the reformation of manners, directed their attention to the Highlands of Scotland, and endeavoured to deviſe ſome plan for alleviating the diſtreſſes of the inhabitants. The remedy which promiſed to be moſt efficacious was, to eſtabliſh charity ſchools in different places. But as the exigency was great, it was no eaſy matter to raiſe a ſufficient fund for this

(A) Even ſo late as the year 1758, no fewer than 175 pariſhes, within the bounds of 39 preſbyteries, had no parochial ſchool. We are ſorry to add, that even in the preſent enlightened and benevolent age the complaint is not entirely removed.

(B) The feudal ſyſtem was at length aboliſhed in the year 1748 by the juriſdiction act.

Religious and Humane Societies.

this purpose. They began therefore with what voluntary subscriptions they could procure, hoping afterwards to increase their capital by vacant stipends and public contributions. A memorial with this view was presented to the General Assembly in 1704, which received their approbation; and they accordingly passed an act, recommending a general contribution. In 1706 the General Assembly appointed some of their number to inquire more carefully into the state of the Highlands, and the year following appointed a select committee to confer with the gentlemen who had suggested the plan. The result of these conferences was the publication of proposals "for propagating Christian knowledge in the Highlands and islands of Scotland, and in foreign parts of the world." Copies of these proposals, with subscription papers, were distributed through the kingdom; and the contributions having soon amounted to L. 1000, her majesty Queen Anne encouraged this infant society by her royal proclamation, and at the same time issued letters patent under the great seal of Scotland for erecting certain of the subscribers into a corporation; the first nomination of whom was lodged with the lords of council and session.

This corporation held its first meeting on Thursday 3d November 1709. It was attended by several of the nobility, fourteen of the lords of session, many gentlemen of rank, together with most of the ministers of the city of Edinburgh and neighbourhood. A president, secretary, and treasurer, with a committee of fifteen directors, were appointed for the dispatch of business. At their second meeting in January 1710, a scheme of management was formed and approved; in which it was proposed, 1. To erect and maintain schools in such places of Scotland, particularly in the Highlands and Islands, as should be found to need them most; in which schools all persons whatsoever should be taught by fit and well qualified schoolmasters, appointed by the society, to read the Holy Scriptures and other pious books; as also to write, and to understand the common rules of arithmetic, with such other things as should be thought suitable to their circumstances. 2. That the schoolmasters should be particularly careful to instruct their scholars in the principles of the Christian reformed religion; and for that end should be obliged to catechise them at least twice a week, and to pray publicly with them twice a-day. 3. That not only such as were unable to pay should be taught gratis, but that those whose circumstances required it, should have such farther encouragement as the society should think fit in a consistency with their patent. 4. To name some prudent persons, ministers and others, to be overseers of those schools, who should take care that the schoolmasters do their duty, and that the instructions to be given from time to time by the society or their committee be punctually observed; which overseers should make their report to the society quarterly or half-yearly at farthest. 5. To give suitable encouragement to such ministers or catechists as should be willing to contribute their assistance towards the farther instruction of the scholars remote from church, by not only catechising, but preaching to them; which ministers or catechists should take the same care of the other inhabitants as of the scholars. 6. To extend their endeavours for the advancement of the Christian religion to heathen nations; and for that end to give encouragement to ministers to preach the Gospel among them.

Having thus formed a plan, they immediately proceeded to establish schools in the most useful and economical manner; and as the capital continued to accumulate, the interest was faithfully applied, and the utility of the institution was more extensively diffused.

Until the year 1738 the attention of the society had been wholly directed to the establishment of schools; but their capital being then considerably augmented, they began to extend their views of utility much farther. The grand object of all public associations ought certainly to be the promoting of religion and morality. It must, however, be evident to every man of reflection, that these can neither be propagated nor preserved among a people without agriculture, unaccustomed to commerce and manufactures, and consequently without labour or exertion. Languor and debility of mind must always be the companions of idleness. While the Highlanders roved about with arms in their hands, the latent vigour of their minds must often have been called forth into action; but when their arms were taken away, and themselves confined to a domestic life, where there was nothing to rouse their minds, they must have sunk into indolence and inactivity. All attempts therefore to instruct them in religion and morality, without introducing among them some of the necessary arts of life, would probably have been unavailing. The society accordingly resolved to adopt what appeared to them the most effectual methods of introducing industry among the Highlanders. But as their patent did not extend far enough, they applied to his majesty George II. for an enlargment of their powers; and accordingly obtained a second patent, by which they are empowered, "besides fulfilling the purposes of their original patent, to cause such of the children as they shall think fit to be bred to husbandry and housewifery, to trades and manufactures, or in such manual occupations as the society shall think proper."

The objects of this second patent the society have not failed to pursue; and though many obstacles and discouragements to their efforts occurred among a rude and barbarous people, yet their perseverance, and the obvious utility of their plans, at length so far overcame the reluctance of the inhabitants, that no less than 94 schools of industry in various parts of the Highlands and islands are now upon their establishment, at which are educated 2360 scholars.

The society, while anxiously endeavouring to diffuse a spirit of industry through the Highlands, were still equally solicitous to promote the knowledge of the Christian religion. As the English language had been the only channel by which knowledge was conveyed to them (a language which, being not used in conversation, was in all respects foreign to them), it was judged requisite that they should have the Scriptures in their vernacular tongue. The society therefore first appointed a translation of the New Testament to be made into Gaelic: A translation was accordingly undertaken by the Rev. Mr Stewart minister of Killin in Perthshire, and printed in 1767, which is said to be executed with much fidelity. Of this work many thousand copies have been distributed in the Highlands. The greater part of the Old Testament has also been translated by by the Rev. Dr Smith of Campbelton and others, but chiefly by the Rev. Dr Stewart of Luſs, by the appointment and at the expence of the ſociety: and as ſoon as the remaining part can be got ready, the whole will be ſold at ſo low a price as the poor may without difficulty afford. This plan the ſociety have judiciouſly choſen, in order to prevent diſcontent and murmuring; effects which the diffuſion of the Scriptures ought never to produce; but which could not poſſibly have been prevented, had the diſtribution been gratuitous, and of courſe partial.

For ſome years paſt the funds of the ſociety have rapidly accumulated, from the very liberal donations of ſeveral individuals.

Lady Glenorchy	L. 5,000
By a perſon unknown	10,000
Lord Van Vryhouven of Holland	20,000
Miſs Gray of Teaſſes	3,500

In conſequence of theſe great additions to their ſtock, inſinuations have been thrown out that the ſociety have become ſo wealthy as to be at a loſs for proper objects on which to beſtow their increaſed revenue. If ſuch an opinion be *ſeriouſly* entertained by any one, we muſt beg him to remember, that the ſociety have erected and endued no leſs than 323 ſchools for religion, the firſt principles of literature and induſtry, at the annual expence of L. 3214, 10s. Sterling; and that at theſe ſeminaries are educated from 14,000 to 15,000 children; who, but for the means of inſtruction thus obtained, would in all probability be bred up in ignorance and idleneſs: That they employ 12 miſſionary miniſters and catechiſts in remote parts of the Highlands and iſlands, or among the ignorant Highlanders ſettled in the great towns of Scotland, at the annual expence of L. 296: That they beſtow a burſary or penſion of L. 15 *per annum* on each of ſix ſtudents of divinity having the Gaelic language: That they employ two miſſionary miniſters and one ſchoolmaſter among the Oneida and Stockbridge Indians of North America (being the deſtination of certain legacies bequeathed to them for that purpoſe), at the annual expence of L. 140. Such is their fixed ſcheme of annual expenditure, amounting in all to L. 3740, 10s. Sterling—a ſum it will be acknowledged of very conſiderable magnitude. The whole of their incidental expences ariſing from the Gaelic tranſlation of the Scripture of the Old Teſtament; from annuities which they have to pay, in conſequence of ſums left them as reſiduary legatees; from land and houſe-taxes; from enabling candidates for the office of ſchoolmaſter to come to Edinburgh for examination; from furniſhing books to poor ſcholars in their various ſchools; and from removing ſchoolmaſters from one ſtation to another, is generally about L. 875, which added to the former ſum makes the whole annual expence amount to L. 4615, 10s.

If it be inquired at what expence, in the *management* of it, this extenſive and complicated charity is annually conducted, we are authoriſed to ſay, that the treaſurer, bookholder, and clerk, are allowed each L. 25 *per annum*, the ſame ſalaries which were annexed to theſe offices from the commencement of the ſociety. The beadle or officer is allowed L. 12 *per annum*. No ſalary whatever is enjoyed by any of the other officers of the ſociety. The ſecretary, comptroller, accountant, and librarian, although ſubjected, ſome of them eſpecially, to no ſmall expence of time and labour, have no pecuniary recompence or emolument. Theirs are labours of love, for which they ſeek and expect no other reward than the conſciouſneſs of endeavouring to promote the beſt intereſt of mankind. The whole amount of the expence of managing the buſineſs of the ſociety, including the above ſalaries, and coals, candle, ſtationary ware, poſtages, and other incidents, exceeds not at an average L. 115 *per annum*. From this ſtatement it appears, that hitherto at leaſt the directors have been at no loſs for important objects within the proper ſphere of their inſtitution on which to beſtow their increaſed funds. They have, it is true, the diſpoſal of very conſiderable ſums for promoting the objects of the inſtitution; but they are ſo far from accumulating wealth, that every year their expenditure, notwithſtanding the late increaſe of their capital, exceeds rather than falls ſhort of their income. They have depended upon a kind Providence and a generous public to refund theſe anticipations of their revenue, and hitherto they have never been diſappointed.

Thus has the Society for Propagating Chriſtian Knowledge proceeded for almoſt a century. It was founded by the pious exertions of a few private individuals, whoſe names are unknown to the world; and its funds, by faithful and judicious management, as well as by generous contributions, have now become of ſuch magnitude, as to excite the hope that they will be productive of the moſt valuable effects. The benefits ariſing from public ſocieties, it is well known, depend entirely upon the management of their directors. If ſo, the advantages which have accrued from this ſociety intitle it to the praiſe and gratitude of the nation. While eager to increaſe the number of ſchools, the ſociety have not been inattentive to their proſperity. In the year 1771 Mr. Lewis Drummond, a gentleman in whom they placed great confidence, was commiſſioned by them to viſit their ſchools, and to make an exact report of their ſtate and circumſtances. Again, in the year 1790, a commiſſion was granted to the Rev. Dr Kemp, one of the miniſters of Edinburgh and ſecretary to the ſociety, to viſit all the ſchools on their eſtabliſhment. This laborious and gratuitous taſk he accompliſhed in the courſe of four ſummers with much ability and care, and highly to the ſatiſfaction of the ſociety. At his return he communicated a variety of important information reſpecting the ſtate of the Highlands and iſlands, and the means neceſſary for their improvement in religion, literature, and induſtry; an abſtract of which was publiſhed by the ſociety in appendixes to the anniverſary ſermons preached before them in the years 1789, 90, 91, and 92 (c). The

(c) It is well known, that the number of Roman Catholics in the Highlands is conſiderable; but it muſt give much pleaſure to the Proteſtant reader to be informed, that the ancient malignant ſpirit of Popery has in that diſtrict given place to mildneſs and liberality. This is chiefly owing to the gentleman who ſuperintends the prieſts in that quarter, whoſe mind is enlightened by ſcience and learning. So far from being hoſtile to the views

Religious and Humane Societies

The following table will exhibit at a glance the funds, establishment, and expenditure, of the society, from a few years after its commencement to the present time. Where the number of scholars is not mentioned, the defect may be supplied by taking an average from those years where a computation has been made. Where the capital is not mentioned, it may easily be made out by considering the salaries as the interest.

Hitherto we have taken no notice of the corresponding board which was established at London so early as the year 1729, to receive subscriptions and lay out sums. That board indeed remained long inactive; but in 1773 its members began to co-operate more cordially with their brethren in Scotland. Since that period an annual sermon has been preached in recommendation of the charity; and the preacher is now selected without any regard to the religious denomination to which he belongs; sometimes from the church of England, sometimes from the church of Scotland, and sometimes from sectaries of different persuasions. The meetings of the correspondent board have been attended by many of the nobility and gentry, who have made great exertions to promote the views of the society. From its present flourishing state therefore, from the indefatigable exertion and laudable zeal of the managers, and from the countenance and support which they have received from persons of the first rank and respectability in the nation, the benevolent mind may look forward with much confidence and satisfaction to a period not very distant, when its beneficial effects shall be felt not only in the Highlands, but shall be communicated to the rest of the nation. We have been thus particular in our account of the Society for Propagating Christian Knowledge, because we have had access to the most authentic sources of information, and because we know it to be an institution calculated to enlighten and improve a considerable part of the British nation.

3. *Society of the Sons of the Clergy*, was incorporated by King Charles II. in 1678, by the name of *The Governors of the Charity for Relief of the Poor Widows and Children of Clergymen*. This society is under the direction and management of a president and vice-president, three treasurers, and a court of assistants composed of forty members. Several hundreds of widows and children of the clergy have annually received considerable relief from this useful charity.

4. *Society for the Sons of the Clergy of the Established Church of Scotland*, was instituted at Edinburgh in February 1790, and was constituted a body corporate by his majesty's royal charter in 1792. The society, after several meetings, are of opinion, that the period in which the families of clergymen feel most urgently the need both of friends and of pecuniary aid, is that which commences with the introduction of the sons either to an university or to business, and terminates with their establishment in their respective professions; that many of the ministers of this church, living at great distances from the seats either of universities or of business, possess incomes which, in the present state of the country, are inadequate to the purposes of procuring for their sons either the literary or professional education which might enable them to come forward with credit and success in the world; that the sons of clergymen, from domestic tuition and example, have in general very advantageous means of receiving in their early years the impressions of virtue and honour, together with the rudiments of liberal knowledge; and that of course the public interest may be promoted, by enabling this class of young men to obtain their share in the respectable situations of life. The views of the society have been limited to the sons only of clergymen; as they are of opinion, that within the limits which they have fixed, the field of beneficence will be still very extensive, and the claims for aid as many and as great as their funds can be supposed able to answer, at least for many years to come. If the society shall ever be in a situation to undertake more than the aids which will be necessary in bringing forward the sons of the clergy, it may then be considered in what manner the daughters also may become sharers in its bounty.

5. *Royal Humane Society*, was instituted in London in 1774, for the recovery of persons drowned or otherwise suffocated. We have already given some account of societies instituted in other countries with the same views, and have also copied the directions of this society for the recovery of life, for which see the article Drowning. We have therefore only to state, that the plan of this society is so adverse to any private interested views, that it acquits its founders of all sordid motives. For the medical practitioners accept no pecuniary recompense for the time which they devote to a difficult and tedious process; for the anxiety which they feel while the event is doubtful; for the mortification which they too often undergo, when death, in spite of all their efforts, at last carries off his prey; nor for the insults to which they willingly expose themselves from vulgar incredulity. Their sole reward is in the holy joy of doing good. Of an institution thus free in its origin from the suspicion of ambitious views, and in its plan renouncing self-interest in every shape, philanthropy must be the only basis. The good intention therefore of the society is proved by its constitution; the

views of the society, he recommended to his clergy to promote them. They accordingly received the secretary with much politeness; exhorted the people to send their children to the Protestant schools to be instructed in literature, to be taught to read the Scriptures in their own language, and to be made acquainted with those great principles of religion in which all Christians are agreed. What a blessed reformation!

Religious and Humane Societies.

the wisdom and utility of the undertaking are proved by its success: not less than 3000 fellow-creatures having since its commencement been (1794) restored to the community by its timely and indefatigable exertions. For it is to be observed, that the benefit of this society is by no means confined to the two cases of drowning and suspension. Its timely succours have roused the lethargy of opium taken in immoderate and repeated doses; they have rescued the wretched victims of intoxication; rekindled the life extinguished by the sudden stroke of lightning; recovered the apoplectic; restored life to the infant that had lost it in the birth; they have proved efficacious in cases of accidental smothering and of suffocation by noxious damps; in instances in which the tenderness of the infant body or the debility of old age greatly lessen the previous probability of success; insomuch that no species of death seems to be placed beyond the reach of this society's assistance, where the mischief had gone no farther than an obstruction of the movements of the animal machine without any damage of the organs themselves. In consequence of every necessary assistance afforded by this society, similar institutions have been established at Algiers, Lisbon, Philadelphia, Boston, Jamaica, Dublin, Leith, Glasgow, Aberdeen,* Birmingham, Gloucester, Shropshire, Northamptonshire, Lancaster, Bristol, Whitehaven, Norwich, Exeter, Kent, and Newcastle. The society has published an 8vo volume with plates, consisting of cases, correspondence, and a variety of interesting matter relating to the object of this benevolent institution.

6. *The Philanthropic Society*, was instituted in September 1788. It aims at the prevention of crimes, by removing out of the way of evil counsel, and evil company, those children who are, in the present state of things, destined to ruin. It proposes to educate and instruct in some useful trade or occupation the children of convicts or other infant poor who are engaged in vagrant or criminal courses; thus to break the chain of those pernicious confederacies, deprive the wicked of successors, the gaols of inhabitants, justice of its victims, and by all these means add citizens to society. This institution is not only calculated to decrease vice and infamy, but to increase useful industry; so that those children who would otherwise succeed to their parents' hereditary crimes, and become the next race of beggars and thieves, will now be taught to supply by honest means their own wants and the wants of others.

To carry into effect these desirable purposes, it is the first business of the society to select from prisons, and from the haunts of vice, profligacy, and beggary, such objects as appear most likely to become obnoxious to the laws, or prejudicial to the community; and, in the execution of this duty, the assistance of the magistrates, the clergy, and all who are interested in the promotion of good morals and good government, is most earnestly requested. For the employment of the children, several houses are supported, at Cambridge Heath, near Hackney, in each of which a master-workman is placed for the purpose of teaching the children some useful trade. The trades already established are those of a printer, carpenter, shoemaker, and taylor. The girls are at present educated as menial servants.

In the year 1791 no less than 70 children were under the protection of this society, among whom were many who had been guilty of various felonies, burglaries, and other crimes. Yet, singular as it may appear, in less than two years those very children became no less remarkable for industry, activity, decency, and obedience, than they formerly were for the contrary vices. Such are the grounds on which the Philanthropic Society now claims the attention and solicits the patronage of the public. If we regard humanity and religion, this institution opens an asylum to the most forlorn and abject of the human race; it befriends the most friendless; it saves from the certain and fatal consequences of infamy and vicious courses orphans and deserted children. If we regard national prosperity and the public welfare, it is calculated to increase industry; and it directs that industry into the most useful and necessary channels. If we regard self-interest, its immediate object is to protect our persons from assault and murder, our property from depredation, and our peaceful habitations from the desperate fury of midnight incendiaries.

One guinea *per annum* constitutes a member of the society; and L. 10 at one payment a member for life. A life-subscription, or an annual payment of at least two guineas, is a necessary qualification for being elected into the committee.

Societies for Promoting Science and Literature.

II. Societies for Promoting Science and Literature.

1. *The Royal Society of London* is an academy or body of persons of eminent learning, instituted by Charles II. for the promoting of natural knowledge. The origin of this society is traced by Dr Sprat, its earliest historian, no farther back than to "some space after the end of the civil wars" in the last century. The scene of the first meetings of the learned men who laid the foundation of it, is by him fixed in the university of Oxford at the lodgings of Dr Wilkins warden of Wadham college. But Dr Birch, on the authority of Dr Wallis, one of its earliest and most considerable members, assigns it an earlier origin. According to him, certain worthy persons, residing in London about the year 1645, being "inquisitive into natural and the new and experimental philosophy, agreed to meet weekly on a certain day, to discourse upon such subjects, and were known by the title of *The Invisible* or *Philosophical College*." In the years 1648 and 1649, the company who formed these meetings were divided, part retiring to Oxford and part remaining in London; but they continued the same pursuits as when united, corresponding with each other, and giving a mutual account of their respective discoveries. About the year 1659 the greater part of the Oxford society returned to London, and again uniting with their fellow-labourers, met once, if not twice, a-week at Gresham college, during term time, till they were scattered by the public distractions of that year, and the place of their meeting made a quarter for soldiers. On the restoration 1660 their meetings were revived, and attended by a greater concourse of men eminent for their rank and learning. They were at last taken notice of by the king, who having himself a considerable taste for physical science, was pleased to grant them an ample charter, dated the 15th of July 1662, and afterwards a second dated 15th April 1663, by which they were erected into a corporation,

Societies for Promoting Science and Literature.

ration, consisting of a president, council, and fellows, for promoting natural knowledge; and to give their investigations, against which strange prejudices were entertained, every possible support, he sometimes honoured their meetings with his presence.

Their manner of electing fellows is by balloting. Their council are in number 21, including the president, vice president, treasurer, and two secretaries; 11 of which are continued for the next year, and 10 more added to them; all chosen on St Andrew's day. Each member at his admission subscribes an engagement that he will endeavour to promote the good of the society; from which he may be freed at any time, by signifying to the president that he desires to withdraw. The charges have been different at different times, and were at first irregularly paid; but they are now five guineas paid to the treasurer at admission; and 13 s. per quarter so long as the person continues a member: or, in lieu of the annual subscription, a composition of 25 guineas in one payment.

Their design is, to "make faithful records of all the works of nature or art which come within their reach; so that the present as well as future ages may be enabled to put a mark on errors which have been strengthened by long prescription; to restore truths that have been neglected; to push those already known to more various uses; to make the way more passable to what remains unrevealed," &c. To this purpose they have made a great number of experiments and observations on most of the works of nature; and also numbers of short histories of nature, arts, manufactures, useful engines, contrivances, &c. The services which they have rendered to the public are very great. They have improved naval, civil, and military architecture; advanced the security and perfection of navigation; improved agriculture; and put not only Great Britain but also Ireland, the plantations, &c. upon planting. They have registered experiments, histories, relations, observations, &c. and reduced them into one common stock; and have, from time to time, published those which they reckoned most useful, under the title of *Philosophical Transactions*, &c. and laid the rest up in public registers, to be nakedly transmitted to posterity, as a solid groundwork for future systems.

They have a library adapted to their institution; towards which Mr Henry Howard, afterwards duke of Norfolk contributed the Norfolcian library, and which is, at this time, greatly increased by a continual series of benefactions. The museum or repository of natural and artificial rarities, given them by Daniel Colwal, Esq; and since enriched by many others, is now removed to the British museum, and makes a part of that great repository. Their motto is *Nullius in verba;* and their place of assembling is Somerset-house in the Strand. Sir Godfrey Copley, baronet, left five guineas to be given annually to the person who should write the best paper in the year, under the head of experimental philosophy. This reward, which is now changed to a gold medal, is the highest honour the society can bestow. It is conferred on St Andrew's day.

2. *The Royal Society of Edinburgh*, was incorporated by royal charter on the 29th of March 1783, and has for its object the cultivation of every branch of science, erudition, and taste. Its rise and progress towards its present state was as follows: In the year 1718 a literary society was established in Edinburgh by the learned Ruddiman and others, which in 1731 was succeeded by a society instituted for the improvement of medical knowledge. In the year 1739 the celebrated Maclaurin conceived the idea of enlarging the plan of this society, by extending it to subjects of philosophy and literature. The institution was accordingly new modelled by a printed set of laws and regulations, the number of members was increased, and they were distinguished from that time by the title of *The Society for Improving Arts and Sciences*, or more generally by the title of *The Philosophical Society of Edinburgh*. Its meetings, however, were soon interrupted by the disorders of the country during the rebellion in 1745; and they were not renewed till the year 1752. Soon after this period the first volume of the Transactions of the Philosophical Society of Edinburgh was published under the title of *Essays and Observations, Physical and Literary*, and was followed by other volumes of acknowledged merit. About the end of the year 1782, in a meeting of the professors of the university of Edinburgh, many of whom were likewise members of the Philosophical Society, and warmly attached to its interests, a scheme was proposed by the Rev. Dr Robertson, principal of the university, for the establishment of a new society on a more extended plan, and after the model of some of the foreign academies. It appeared an expedient measure to solicit the royal patronage to an institution of this nature, which promised to be of national importance, and to request an establishment by charter from the crown. The plan was approved and adopted; and the Philosophical Society, joining its influence as a body in seconding the application from the university, his majesty, as we have already observed, was pleased to incorporate The Royal Society of Edinburgh by charter.

This society consists of ordinary and honorary members; and the honorary places are restricted to persons residing out of Great Britain and Ireland. The election of new members is appointed to be made at two stated general meetings, which are to be held on the fourth Monday of January and the fourth Monday of June. A candidate for the place of an ordinary member must signify by a letter, addressed to one of the members, his wish to be received into the society. He must then be publicly proposed at least a month before the day of election. If the proposal be seconded by two of the members present, his name is to be inserted in the list of candidates, and hung up in the ordinary place of meeting. The election is made by ballot, and is determined in favour of a candidate, if he shall have the votes of two thirds of those present, in a meeting consisting of at least 21 members. The general business of the society is managed by a president, two vice-presidents, with a council of 12, a general secretary, and a treasurer. These officers are chosen by ballot annually on the last Monday of November. All public deeds, whether of a civil or of a literary nature, are transacted by this board, and proceed in the name of the president or vice president.

As it was thought that the members would have a greater inducement to punctual attendance on the meetings of the society, if they had some general intimation of the nature of the subjects which were to be considered, and made the topics of conversation, it was therefore

Societies for Promoting Science and Literature.

fore resolved to divide the society into two classes, which should meet and deliberate separately. One of these classes is denominated the *Physical Class*, and has for its department the sciences of mathematics, natural philosophy, chemistry, medicine, natural history, and whatever relates to the improvement of arts and manufactures. The other is denominated the *Literary Class*, and has for its department literature, philology, history, antiquities, and speculative philosophy. Every member is desired at his admission to intimate which of those classes he wishes to be more particularly associated with; but he is at the same time intitled to attend the meetings of the other class, and to take part in all its proceedings. Each of the classes has four presidents and two secretaries, who officiate by turns. The meetings of the physical class are held on the first Mondays of January, February, March, April, July, August, November, and December; and the meetings of the Literary class are held on the third Mondays of January, February, March, April, June, July, November, and December, at 7 o'clock afternoon.

At these meetings the written essays and observations of the members of the society, or their correspondents, are read publicly, and become the subjects of conversation. The subjects of these essays and observations are announced at a previous meeting, in order to engage the attendance of those members who may be particularly interested in them. The author of each dissertation is likewise desired to furnish the society with an abstract of it, to be read at the next ensuing meeting, when the conversation is renewed with increased advantage, from the knowledge previously acquired of the subject. At the same meetings are exhibited such specimens of natural or artificial curiosities, such remains of antiquity, and such experiments, as are thought worthy of the attention of the society. All objects of natural history presented to the society, are ordered by the charter of the institution to be deposited, on receipt, in the museum of the university of Edinburgh; and all remains of antiquity, public records, or ancient manuscripts, in the library belonging to the faculty of advocates at Edinburgh.

The ordinary members, whose usual residence is in the city of Edinburgh or its immediate neighbourhood, are expected to attend regularly the monthly meetings; and are required to defray, by an annual contribution, the current expences of the institution. The members who reside at such a distance from Edinburgh, that they cannot enjoy the advantages arising from a regular attendance on the meetings of the society, are not subjected to any contribution for defraying its expences, but have a right to attend those meetings when occasionally in Edinburgh, and to take part in all their proceedings.

Three volumes of the Transactions of the society have been published, which bear ample testimony to the learning and acuteness of their various authors.

3. *Medical Society* of London, instituted in the year 1752, on the plan recommended by Lord Bacon (*De Augm. Scient.* lib. iv. cap. 2.), to revive the Hippocratic method of composing narratives of particular cases, in which the nature of the disease, the manner of treating it, and the consequences, are to be specified; to attempt the cure of those diseases which, in his opinion, have been too boldly pronounced incurable; and, lastly, to extend their inquiries after the powers of particular medicines in the cure of particular cases; the collections of this society have been already published, under the title of *Medical Observations and Inquiries*, in several volumes.

4. *The Medical Society* of Edinburgh was incorporated by royal charter in 1778; but there appears to have been in that city a voluntary association of the same name from the first establishment of a regular school of physic in the university. To the voluntary society the public is indebted for six volumes of curious and useful essays, collected principally by the late Dr Monro from June 1731 to June 1736; but in the year 1739 that society was united to another, as we have already observed in a former article. The ordinary members of the present medical society are elected by ballot, and three dissentient exclude a candidate; an ordinary member may also be elected an honorary member, who enjoys the privileges of the others, and receives a diploma, but is freed from the obligation of attendance, delivering papers in rotation, &c. to which the ordinary members are subject; but in this case the votes must be unanimous. The meetings of their society are held every Saturday evening in their own hall, during the winter season, when papers on medical subjects are delivered by the several members in rotation; and four of these are annually elected to fill the chair in rotation, with the title of annual presidents.

5. The *Royal Medical Society* of Paris was instituted in 1776. The members are divided into associates ordinary, limited to 30, honorary to 12, extraordinary to 60, and foreign to 60, and correspondents. This society has published several volumes of Memoirs in 4to.

6. *Asiatic Society*, an institution planned by the late illustrious Sir William Jones, and actually formed at Calcutta on the 15th of January 1784, for the purpose of tracing the history, antiquities, arts, sciences, and literature, of the immense continent of Asia. As it was resolved to follow as nearly as possible the plan of the Royal Society of London, of which the king is *patron*, the patronage of the Asiatic Society was offered to the governor-general and council, as the executive power in the territories of the company. By their acceptance of this offer, Mr Hastings, as governor-general, appeared among the patrons of the new society; "but he seemed in his private station as the first liberal promoter of useful knowledge in Bengal, and especially as the great encourager of Persian and Shanscrit literature, to deserve a particular mark of distinction:" he was requested, therefore to accept the honorary title of president. This was handsomely declined in a letter from Mr Hastings, in which he requested "to yield his pretensions to the gentleman whose genius planned the institution, and was most capable of conducting it to the attainment of the great and splendid purposes of its formation." On the receipt of this letter, Sir William Jones was nominated president of the society; and we cannot give the reader a view of the object of the institution in clearer language than that which he employed in his first discourse from the chair.

"It is your design, I conceive, (said the president) to take an ample space for your learned investigations, bounding them only by the geographical limits of Asia; so that, considering Hindostan as a centre, and turning your eyes in idea to the north, you have on your right

Societies or Promoting Science and Literature.

many important kingdoms in the eastern peninsula, the ancient and wonderful empire of China with all her Tartarian dependencies, and that of Japan, with the cluster of precious islands, in which many singular curiosities have too long been concealed: before you lies that prodigious chain of mountains, which formerly perhaps were a barrier against the violence of the sea, and beyond them the very interesting country of Tibet, and the vast regions of Tartary, from which, as from the Trojan horse of the poets, have issued so many consummate warriors, whose domain has extended at least from the banks of the Ilyssus to the mouths of the Ganges: on your left are the beautiful and celebrated provinces of Iran or Persia, the unmeasured and perhaps unmeasurable deserts of Arabia, and the once flourishing kingdom of Yemen, with the pleasant isles that the Arabs have subdued or colonized; and farther westward, the Asiatic dominions of the Turkish sultans, whose moon seems approaching rapidly to its wane. By this great circumference the field of your useful researches will be inclosed; but since Egypt had unquestionably an old connection with this country, if not with China, since the language and literature of the Abyssinians bear a manifest affinity to those of Asia, since the Arabian arms prevailed along the African coast of the Mediterranean, and even erected a powerful dynasty on the continent of Europe, you may not be displeased occasionally to follow the streams of Asiatic learning a little beyond its natural boundary; and, if it be necessary or convenient that a short name or epithet be given to our society, in order to distinguish it in the world, that of *Asiatic* appears both classical and proper, whether we consider the place or the object of the institution, and preferable to *Oriental*, which is in truth a word merely relative, and though commonly used in Europe, conveys no very distinct idea.

"If now it be asked, What are the intended objects of our inquiries within these spacious limits? we answer, Man and Nature; whatever is performed by the *one* or produced by the *other*. Human knowledge has been elegantly analysed according to the three great faculties of the mind, *memory*, *reason*, and *imagination*, which we constantly find employed in arranging and retaining, comparing and distinguishing, combining and diversifying, the ideas, which we receive through our senses, or acquire by reflection: hence the three main branches of learning are, *history*, *science*, and *art*; the first comprehends either an account of natural productions, or the genuine records of empires and states; the second embraces the whole circle of pure and mixed mathematics, together with ethics and law, as far as they depend on the reasoning faculty; and the third includes all the beauties of imagery and the charms of invention, displayed in modulated language, or represented by colour, figure, or sound.

"Agreeably to this analysis, you will investigate whatever is rare in the stupendous fabric of nature, will correct the geography of Asia by new observations and discoveries; will trace the annals and even traditions of those nations who from time to time have peopled or desolated it; and will bring to light their various forms of government, with their institutions civil and religious; you will examine their improvements and methods in arithmetic and geometry; in trigonometry, mensuration, mechanics, optics, astronomy, and general physics; their systems of morality, grammar, rhetoric, and dialectic; their skill in chirurgery and medicine; and their advancement, whatever it may be, in anatomy and chemistry. To this you will add researches into their agriculture, manufactures, trade; and whilst you inquire with pleasure into their music, architecture, painting, and poetry, will not neglect those inferior arts by which the comforts and even elegancies of social life are supplied or improved. You may observe, that I have omitted their languages, the diversity and difficulty of which are a sad obstacle to the progress of useful knowledge; but I have ever considered languages as the mere instruments of real learning, and think them improperly confounded with learning itself: the attainment of them is, however indispensably necessary; and if to the Persian, Armenian, Turkish, and Arabic, could be added not only the Shanscrit, the treasures of which we may now hope to see unlocked, but even the Chinese, Tartarian, Japanese, and the various insular dialects, an immense mine would then be open, in which we might labour with equal delight and advantage."

Of this society three volumes of the Transactions have been published, which are replete with information in a high degree curious and important; and we hope that the European world shall soon be favoured with another. The much to be lamented death of the accomplished president may indeed damp the spirit of investigation among the members; for to conquer difficulties so great as they must meet with, a portion seems to be necessary of that enthusiasm which accompanied all the pursuits of Sir William Jones; but his successor is a man of great worth and learning, and we trust will use his utmost endeavours to have the plan completed of which Sir William gave the outlines.

5. *The American Philosophical Society*, held at Philadelphia, was formed in January 1769 by the union of two societies which had formerly subsisted in that city. This society extends its attention to geography, mathematics, natural philosophy, and astronomy; medicine and anatomy; natural history and chemistry; trade and commerce; mechanics and architecture; husbandry and American improvements. Its officers are a patron, president, three vice-presidents, one treasurer, four secretaries, and three curators, who are anually chosen by ballot. The duty of the president, vice-presidents, treasurer, and secretaries, is the same as in other societies. The business of the curators is to take the charge of all specimens of natural productions, whether of the animal, vegetable, or fossil kingdom; all models of machines and instruments; and all other matters belonging to the society which shall be intrusted to them. The ordinary meetings are held on the first and third Fridays of every month from October to May inclusive. This society was incorporated by charter 15th March 1780; and has published three volumes of its Transactions, containing many ingenious papers on general literature and the sciences, as well as respecting those subjects peculiar to America. It is a delightful prospect to the philosopher to consider, that Asia, Europe, and America, though far separated and divided into a variety of political states, are all three combined to promote the cause of knowledge and truth.

6. *A Literary and Philosophical Society* of considerable reputation has been lately established at Manchester, under the direction of two presidents, four vice-presidents,

Societies for Promoting Science and Literature.

dents, and two secretaries. The number of members is limited to 50; besides whom there are several honorary members, all of whom are elected by ballot; and the officers are chosen annually in April. Four volumes of valuable essays have been already published by this society.

7. *Society for Promoting the Discovery of the Interior Parts of Africa.* This society or association for exploring the internal districts of Africa, of which so little is at present known, was formed in London by some opulent individuals in 1788; who, strongly impressed with a conviction of the practicability and utility of thus enlarging the fund of human knowledge, determined, if possible, to rescue the age from that stigma which attaches to its ignorance of so large and so near a portion of the globe. The founders of this society resolved to admit no man a member for a shorter period than three years, during which he must pay annually into the public fund five guineas. After three years, any member, upon giving a year's notice, may withdraw himself from the association. During the first 12 months each of the members was allowed to recommend for the approbation of the society such of his friends as he might think proper to be admitted into it; but since that period we believe all additional members have been elected by a ballot of the association at large. A committee was chosen by ballot to manage the funds of the society, to choose proper persons to be sent on the discovery of the interior parts of Africa, and to carry on the society's correspondence, with express injunctions to disclose no intelligence received from their agents but to the society at large. But a fuller account of the nature of this establishment, and the very happy efforts they have made, may be seen in the superb edition of their proceedings printed in 1790, 4to for their own use; or in the 8vo edition since made public. They soon found two gentlemen, Mr Lucas and Mr Ledyard, who were singularly well qualified for the important mission. The information they have acquired will be found in the above work; with a new map by Mr Rennel, exibiting the geographical knowledge collected by the African association. Mr Ledyard very unfortunately died during his researches at Cairo.

8. *The Society of Antiquaries of London*, was founded about the year 1572 by Archbishop Parker, a munificent patron of learned men. For the space of 20 years it assembled in the house of Sir Robert Cotton; in 1589 they resolved to apply to Queen Elizabeth for a charter and a public building where they might hold their meetings; but it is uncertain whether any such application was ever made. In the mean time, the reputation of the society gradually increased, and at length it excited the jealousy of James I. who was afraid lest it should presume to canvass the secret transactions of his government. He accordingly dissolved it. But in the beginning of the present century, the Antiquarian Society began to revive; and a number of gentlemen, eminent for their affection to this science, had weekly meetings, in which they examined the antiquities and history of Great Britain preceding the reign of James I. but without excluding any other remarkable antiquities that might be offered to them. From this time the society grew in importance; and in 1750 they unanimously resolved to petition the king for a charter of incorporation. This they obtained the year following, by the influence of the celebrated earl of Hardwicke, then lord-chancellor, and Martin Folkes, Esq; who was then their president. The king declared himself their founder and patron, and empowered them to have a body of statutes, and a common seal, and to hold in perpetuity lands, &c. to the yearly value of L. 1000.

The chief object of the inquiries and researches of the society are British antiquities and history; not, however, wholly excluding those of other countries. It must be acknowledged, that the study of antiquity offers to the curious and inquisitive a large field for research and amusement. The inquirer in this branch furnishes the historian with his best materials, while he distinguishes from truth the fictions of a bold invention, and ascertains the credibility of facts; and to the philosopher he presents a fruitful source of ingenious speculation, while he points out to him the way of thinking, and the manners of men, under all the varieties of aspect in which they have appeared.

An antiquarian ought to be a man of solid judgment, possessed of learning and science, that he may not be an enthusiastic admirer of every thing that is ancient merely because it is ancient; but be qualified to distinguish between those researches which are valuable and important and those which are trifling and useless. It is from the want of these qualifications that some men have contracted such a blind passion for every thing that is ancient, that they have exposed themselves to ridicule, and their study to contempt. But if a regard to utility were always to regulate the pursuits of the antiquarian, the shafts of satire would no longer be levelled at him; but he would be respected as the man who labours to restore or to preserve such ancient productions as are suited to illuminate religion, philosophy, and history, or to improve the arts of life.

We by no means intend to apply these observations to any particular society of antiquarians; but we throw them out, because we know that an assiduous study of antiquity is apt, like the ardent pursuit of money, to lose sight of its original object, and to degenerate into a passion which mistakes the mean for the end, and considers possession without a regard to utility as enjoyment.

An association similar to that of the Antiquarian Society of London was founded in *Edinburgh* in 1780, and received the royal charter in 1783.

Besides these literary societies here mentioned, there are a great number more in different parts of Europe, some of which are noticed under the article Academy. Those which are omitted are not omitted on account of any idea of their inferior importance; but either because we have had no access to authentic information, or because they resemble the societies already described so closely, that we could have given nothing but their names.

III. Societies for Encouraging and Promoting Arts, Manufactures, &c.

1. *London Society for the Encouragement of Arts, Manufactures, and Commerce*, was instituted in the year 1754 by Lord Folkstone, Lord Romney, Dr Stephen Hales, and a few private gentlemen; but the merit of this institution chiefly belonged to Mr William Shipley,

Societies for Encouraging and Promoting Arts, Manufactures, &c.

an ingenious mechanic; who, though deriving no advantages from learning, by unwearied personal attendance found means to engage a few persons of rank and fortune to meet at Peele's coffeehouse in Fleetstreet, and to adopt a plan for promoting arts and manufactures.

The office-bearers of this society are a president, 12 vice-presidents, a secretary, and register. Their proceedings are regulated by a body of rules and orders established by the whole society, and printed for the use of the members. All questions and debates are determined by the holding up of hands, or by ballot if required; and no matter can be confirmed without the assent of a majority at two meetings. They invite all the world to propose subjects for encouragement; and whatever is deemed deserving attention, is referred to the consideration of a committee, which, after due inquiry and deliberation, make their report to the whole society, where it is approved, rejected, or altered. A list is printed and published every year of the matters for which they propose to give premiums; which premiums are either sums of money, and those sometimes very considerable ones; or the society's medal in gold or silver, which they consider as the greatest honour they can bestow. All possible care is taken to prevent partiality in the distribution of their premiums, by desiring the claimants' names to be concealed, and by appointing committees (who when they find occasion call to their assistance the most skilful artists) for the strict examination of the real merit of all matters and things brought before them, in consequence of their premiums.

The chief objects of the attention of the Society for the Encouragement of Arts, Manufactures, and Commerce, in the application of their rewards, are ingenuity in the several branches of the polite and liberal arts, useful discoveries, and improvement in agriculture, manufactures, mechanics, and chemistry, or the laying open of any such to the public; and, in general, all such useful inventions, discoveries, or improvements (though not mentioned in the book of premiums), as may appear to have a tendency to the advantage of trade and commerce.

The following are some of the most important regulations of this society. It is required that the matters for which premiums are offered be delivered in without names, or any intimation to whom they belong; that each particular thing be marked in what manner each claimant thinks fit, such claimant sending with it a paper sealed up, having on the outside a corresponding mark, and on the inside the claimant's name and address; and all candidates are to take notice, that no claim for a premium will be attended to, unless the conditions of the advertisement are fully complied with. No papers shall be opened but such as shall gain premiums, unless where it appears to the society absolutely necessary for the determination of the claim: all the rest shall be returned unopened, with the matters to which they belong, if inquired after by the marks within two years; after which time, if not demanded, they shall be publicly burnt unopened at some meeting of the society. All the premiums of this society are designed for that part of Great Britain called England, the dominion of Wales, and the town of Berwick upon Tweed, unless expressly mentioned to the contrary. No person shall receive any premium, bounty, or encouragement, from the society for any matter for which he has obtained or proposes to obtain a patent. No member of this society shall be a canditate for or intitled to receive any premium, bounty, or reward whatsoever, except the honorary medal of the society.

The respectability of the members who compose it may be seen by perusing the list which generally accompanies their Transactions. In the last volume (vol. xii.) it occupies no less than 43 pages. Some idea may be formed of the wealth of this society, by observing that the list of their premiums fills 96 pages and amounts to 250 in number. These consist of gold medals worth from 30 to 50, and in a few instances to 100, guineas; and silver medals valued at 10 guineas.

This society is one of the most important in Great Britain. Much money has been expended by it, and many are the valuable effects of which it has been productive. Among these we reckon not only the discoveries which it has excited, but the institution of other societies on the same principles to which it has given birth; and we do not hesitate to conclude, that future ages will consider the founding of this society as one of the most remarkable epochs in the history of the arts. We contemplate with pleasure the beneficial effects which must result to this nation and to mankind by the diffusion of such institutions; and rejoice in the hope that the active minds of the people of Great Britain, instead of being employed as formerly in controversies about religion, which engender strife, or in discussions concerning the theory of politics, which lead to the adoption of schemes inconsistent with the nature and condition of man, will soon be more generally united into associations for promoting useful knowledge and solid improvement, and for alleviating the distresses of their fellow-creatures.

2. *Society instituted at Bath for the Encouragement of Agriculture, Arts, Manufactures, and Commerce.* It was founded in the year 1777 by several gentlemen who met at the city of Bath. This scheme met with a very favourable reception both from the wealthy and learned. The wealthy subscribed very liberally, and the learned communicated many important papers. On application to the London and provincial societies instituted for the like purposes, they very politely offered their assistance. Seven volumes of their transactions have already been published, containing very valuable experiments and observations, particularly respecting agriculture, which well deserve the attention of all farmers in the kingdom. We have consulted them with much satisfaction on several occasions, and have frequently referred to them in the course of this work; and therefore, with pleasure, embrace the present opportunity of repeating our obligations. We owe the same acknowledgments to the Society for the Improvement of Arts, &c. of London.

3. *Society for Working Mines*, an association lately formed on the continent of Europe. This institution arose from the accidental meeting of several mineralogists at Skleno near Schemnitz in Hungary, who were collected in order to examine a new method of amalgamation. Struck with the shackles imposed on mineralogy by monopolizers of new and useful processes, they thought no method so effectual to break them, as forming a society, whose common labours should be directed to fix mining on its surest principles; and whose memoirs,

Societies for Encouraging and Promoting Arts, Manufactures, &c.

spread over all Europe might offer to every adventurer the result of the researches, of which they are the object. By these means they supposed, that there would be a mass of information collected; the interests of individuals would be lost in the general interest; and the one would materially assist the other. Imposture and quackery would, by the same means, be banished from a science, which must be improved by philosophy and experience; and the society, they supposed, would find, in the confidence which they inspired, the reward and the encouragement of their labours. They design, that the memoirs which they publish shall be short and clear; truth must be their basis, and every idle discussion, every foreign digression, must be banished; politics and finance must be avoided, though the dissertations may seem to lead towards them; and they oblige themselves to oppose the affectation of brilliancy, and the ostentation of empty speculation, when compared with plain, simple, and useful facts.

The object of the society is physical geography; mineralogy founded on chemistry; the management of ore in the different operations which it undergoes; subterraneous geometry; the history of mining; founderies, and the processes for the extraction of metals from the ores, either by fusion or amalgamation, in every instance applied to practice. The end of this institution is to collect, in the most extensive sense, every thing that can assist the operations of the miner, and to communicate it to the different members, that they may employ it for the public good, in their respective countries. Each member must consider himself as bound to send to the society every thing which will contribute to the end of its institution; to point out, with precision, the several facts and observations; to communicate every experiment which occurs, even the unsuccessful ones, if the relation may seem to be advantageous to the public; to communicate to the society their examination of schemes, and their opinions on questions proposed by it; and to pay annually two ducats (about 18 s. 6 d.) to the direction every Easter. The society, on the other hand, is bound to publish every novelty that shall be communicated to it; to communicate to each member, at the member's expence, the memoirs, designs, models, productions, and every thing connected with the institution; to answer all the necessary demands made, relating in any respect to mining; and to give its opinion on every plan or project communicated through the medium of an honorary member.

The great centre of all intelligence is to be at Zellerfield in Hartz, Brunswick: but the society is not fixed to any one spot; for every particular state some practical mineralogist is nominated as director. Among these are the names of Baron Born, M. Pallas, M. Carpentier, M. Prebra, and M. Henkel. Their office is to propose the members; to take care that the views of the society are pursued in the different countries where they reside; to answer the requests of the members of their country who are qualified to make them; in case of the death of a director, to choose another; and the majority is to determine where the archives and the strong box is to be placed.

All the eminent mineralogists in Europe are members of this society. It is erected on so liberal and so extensive a plan, that we entertain the highest hopes of its success; and have only to add, that we wish much to see the study of several other sciences pursued in the same manner.

Societies for Encouraging and Promoting Arts, Manufactures, &c.

5. *The Society for the Improvement of Naval Architecture*, was founded in 1791. The object of it is to encourage every useful invention and discovery relating to naval architecture as far as shall be in their power, both by honorary and pecuniary rewards. They have in view particularly to improve the theories of floating bodies and of the resistance of fluids; to procure draughts and models of different vessels, together with calculations, of their capacity, centre of gravity, tonnage, &c.; to make observations and experiments themselves, and to point out such observations and experiments as appear best calculated to further their designs, and most deserving those premiums which the society can bestow. But though the improvement of naval architecture in all its branches be certainly the principal object of this institution, yet the society do not by any means intend to confine themselves merely to the form and structure of vessels. Every subordinate and collateral pursuit will claim a share of the attention of the society in proportion to its merits; and whatever may have any tendency to render navigation more safe, salutary, and even pleasant, will not be neglected.

This institution owes its existence to the patriotic disposition and extraordinary attention of Mr Sewel a private citizen of London, who (though engaged in a line of business totally opposite to all concerns of this kind) has been led, by mere accident, to take such ocular notice of, and make such observations on, the actual state of naval architecture in his country, as naturally occurred to a man of plain understanding, zealous for the honour and interest of his country, and willing to bestow a portion of that time for the public good, which men of a different description would rather have devoted to their own private advantage. His attention was the more seriously excited, by finding that it was the opinion of some private ship-builders, who, in a debate on the failure of one of our naval engagements, pronounced, that such "would ever be the case while that business (the construction of our ships of war) was not studied as a science, but carried on merely by precedent; that there had not been one improvement in our navy that did not originate with the French, who had naval schools and seminaries for the study of it; and that our ships were not a match for those of that nation either singly or in a fleet, &c. &c."

In a short time the society were enabled to offer very considerable premiums for particular improvements in the construction of our shipping, &c &c. and also to encourage our philosophers, mathematicians, and mechanics, to make satisfactory experiments, tending to ascertain the laws of resistance of water to solids of different forms, in all varieties of circumstance. On this head the reward is not less than L. 100 pounds or a gold medal. Other premiums of 50, 30, and 20 guineas, according to the importance or difficulty of the particular subject or point of investigation, are likewise offered, for different discoveries, inventions, or improvements. The terms of admission into the society are a subscription of two guineas annually, or twenty guineas for life.

5. *Society of Artists of Great Britain*, which consists of directors and fellows, was incorporated by charter in 1765, and empowered to purchase and hold lands, not exceeding

Societies for Encouraging and Promoting Arts, Manufactures, &c.

exceeding L. 1000 a year. The directors of this society, annually elected, are to consist of 24 persons, including the president, vice president, treasurer, and secretary; and it is required that they be either painters, sculptors, architects, or engravers by profession.

6. *British Society for Extending the Fisheries and Improving the Sea-Coasts of Great Britain*, was instituted in 1786. The end and design of this society will best appear from their charter, of which we present an abstract.

The preamble states, "the great want of improvement in fisheries, agriculture, and manufactures, in the Highlands and islands of North Britain; the prevalence of emigration from the want of employment in those parts; the prospect of a new nursery of seamen, by the establishment of fishing towns and villages in that quarter. The act therefore declares, that the persons therein named, and every other person or persons who shall thereafter become proprietors of the joint stock mentioned therein, shall be a distinct and separate body politic and corporate, by the name of *The British Society for Extending the Fisheries and Improving the Sea Coasts of this Kingdom*: That the said society may raise a capital joint stock not exceeding L. 150,000, to be applied to purchasing or otherwise acquiring lands and tenements in perpetuity, for the building thereon, and on no other land whatever, free towns, villages, and fishing stations: That the joint stock shall be divided into shares of L. 50 each: That no one person shall in his or her name possess more than ten shares, or L. 500: That the society shall not borrow any sum or sums of money whatsoever: That the sums to be advanced for this undertaking, and the profits arising therefrom, shall be divided proportionably to the sum subscribed; and that no person shall be liable for a larger sum than he or she shall have respectively subscribed: That one or two shares shall intitle to one vote and no more, in person or by proxy, at all meetings of proprietors; three of four shares to two votes; five, six, or seven shares, to three votes; eight or nine shares to four votes; and ten shares to five votes and no more: That more persons than one inclining to hold in their joint names one or more shares shall be intitled to vote, by one of such persons, according to the priority of their names, or by proxy: That bodies corporate shall vote by proxy under their seal: That all persons holding proxies shall be proprietors, and that no one person shall hold more than five votes by proxy: That the affairs of the society shall be managed by a governor, deputy governor, and 13 other directors, to be elected annually on the 25th of March, from among the proprietors of the society, holding at least one full share, by signed lists of their names to be transmitted by the proprietors to the secretary of the society: that five proprietors, not being governor, director, or other officer, shall be in like manner annually elected to audit the accounts of the society: That there shall be one general meeting of the proprietors annually on the 25th of March: That occasional general meetings shall be called on the request of nine or more proprietors: That the general meetings of the proprietors shall make all bye laws and constitutions for the government of the society, and for the good and orderly carrying on of the business of the same: That no transfer shall be made of the stock of the society for three years from the 10th of August 1786: That the cash of the society shall be lodged in the bank of England, bank of Scotland, or the royal bank of Scotland: That no director, proprietor, agent, or officer of the society, shall retain any sum or sums of money in his hands beyond the space of 30 days, on any account whatsoever: That all payments by the society shall be made by drafts on the said banks, under the hands of the governor or deputy-governor, countersigned by the secretary or his deputy, and two or more directors: And that the books in which the accounts of the society shall be kept shall be open to all the proprietors."

The institution of this public-spirited society was in a great measure owing to the exertions of the patriotic John Knox; who, in the course of 23 years, traversed and explored the Highlands of Scotland no less than 16 times, and expended several thousand pounds of his own fortune in pursuing his patriotic designs.

7. *British Wool Society*. See *British Wool Society*.

Society Isles, a cluster of isles, so named by Captain Cook in 1769. They are situated between the latitudes of 16. 10. and 16. 55. south, and between the longitudes of 150. 57. and 152 west. They are eight in number; namely, Otaheite, Huahine, Ulietea, Otaha, Bolabola, Maurua, Toobouai, and Tabooyamanoo or Saunders's Island. The soil, productions, people, their language, religion, customs, and manners, are so nearly the same as at Otaheite, that little need be added here on that subject. Nature has been equally bountiful in uncultivated plenty, and the inhabitants are as luxurious and as indolent. A plantain branch is the emblem of peace, and exchanging names the greatest token of friendship. Their dances are more elegant, their dramatic entertainments have something of plot and consistency, and they exhibit temporary occurrences as the objects of praise or satire; so that the origin of ancient comedy may be already discerned among them. The people of Huahine are in general stouter and fairer than those of Otaheite, and this island is remarkable for its populousness and fertility. Those of Ulietea, on the contrary, are smaller and blacker, and much less orderly. Captain Cook put on shore a Cape ewe at Bolabola, where a ram had been left by the Spaniards; and also an English boar and sow, with two goats, at Ulietea. If the valuable animals which have been transported thither from Europe should be suffered to multiply, no part of the world will equal these islands in variety and abundance of refreshments for future navigators.

SOCINIANS, in church-history, a sect of Christian heretics, so called from their founder Faustus Socinus (see Socinus). They maintain, "That Jesus Christ was a mere man, who had no existence before he was conceived by the Virgin Mary; that the Holy Ghost is no distinct person, but that the Father is truly and properly God. They own, that the name of God is given in the Holy Scriptures to Jesus Christ; but contend, that it is only a deputed title, which, however, invests him with an absolute sovereignty over all created beings, and renders him an object of worship to men and angels. They deny the doctrines of satisfaction and imputed righteousness; and say that Christ only preached the truth to mankind, set before them in himself an example of heroic virtue, and sealed his doctrines with his blood. Original sin and absolute predestination they esteem scholastic chimeras. They likewise maintain the sleep of the soul, which they say becomes insensible at death, and is raised again with the body at the resurrection, when the good shall be established in the possession of eternal felicity, while the wicked shall be consigned to a fire that will not torment them eternally, but for a certain duration proportioned to their demerits."

This sect has long been indignant at being styled *Socinians*. They disclaim every human leader; and professing to be guided solely by the word of God and the deductions of reason, they call themselves *Unitarians*, and affect to consider all other Christians, even their friends the Arians, as *Polytheists*. Modern Unitarianism, as taught by Dr Priestley, is, however, a very different thing from Socinianism, as we find it in the Racovian catechism and other standard works of the sect. This far-famed philosopher has discovered what escaped the sagacity of all the *fratres poloni*, that Jesus Christ was the son of Joseph as well as Mary; that the evangelists mistook the meaning of Isaiah's prophecy, that "a virgin should conceive and bear a son;" that the applying of this prophecy to the birth of our Saviour, led them to conclude that his conception was miraculous; and that we are not to wonder at this mistake, as the apostles were not always inspired, and were in general inconclusive reasoners. The modesty of the writer in claiming the merit of such discoveries will appear in its proper colours to all our readers: the truth of his doctrine shall be considered in another place. See Theology.

SOCINUS (Lælius,) the first author of the sect of the Socinians, was born at Sienna in Tuscany in 1525. Being designed by his father for the law, he began very early to search for the foundation of that science in the Word of God; and by that study discovered that the Romish religion taught many things contrary to revelation; when being desirous of penetrating farther into the true sense of the Scriptures, he studied Greek, Hebrew, and even Arabic. In 1547 he left Italy, to go and converse with the Protestants; and spent four years in travelling thro' France, England, the Netherlands, Germany, and Poland, and at length settled at Zurich. He by this means became acquainted with the most learned men of his time, who testified by their letters the esteem they had for him: but as he discovered to them his doubts, he was greatly suspected of heresy. He, however, conducted himself with such address, that he lived among the capital enemies of his opinions, without receiving the least injury. He met with some disciples, who heard his instructions with respect; these were Italians who left their native country on account of religion, and wandered about in Germany and Poland. He communicated likewise his sentiments to his relations by his writings, which he caused to be conveyed to them at Sienna. He died at Zurich in 1562. Those who were of sentiments opposite to his, and were personally acquainted with him, confess that his outward behaviour was blameless. He wrote a Paraphrase on the first chapter of St John; and other works are ascribed to him.

Socinus (Faustus), nephew of the preceding, and principal founder of the Socinian sect, was born at Sienna in 1539. The letters which his uncle Lælius wrote to his relations, and which infused into them many seeds of heresy, made an impression upon him; so that, knowing himself not innocent, he fled as well as the rest when the inquisition began to persecute that family. He was at Lyons when he heard of his uncle's death, and departed immediately to take possession of his writings. He returned to Tuscany; and made himself so agreeable to the grand duke, that the charms which he found in that court, and the honourable posts he filled there, hindered him for twelve years from remembering that he had been considered as the person who was to put the last hand to the system of samosatenian divinity, of which his uncle Lælius had made a rough draught. At last he went into Germany in 1574, and paid no regard to the grand duke's advices to return. He staid three years at Basil, and studied divinity there; and having adopted a set of principles very different from the system of Protestants, he resolved to maintain and propagate them; for which purpose he wrote a treatise *De Jesu Christo Servatore*. In 1579 Socinus retired into Poland, and desired to be admitted into the communion of the Unitarians; but as he differed from them in some points, on which he refused to be silent, he met with a repulse. However, he did not cease to write in defence of their churches against those who attacked them. At length his book against James Paleologus furnished his enemies with a pretence to exasperate the king of Poland against him but though the mere reading of it was sufficient to refute his accusers, Socinus thought proper to leave Cracow, after having resided there four years. He then lived under the protection of several Polish lords, and married a lady of a good family: but her death which happened in 1587, so deeply afflicted him as to injure his health; and to complete his sorrow, he was deprived of his patrimony by the death of Francis de Medicis great duke of Florence. The consolation he found in seeing his sentiments at last approved by several ministers, was greatly interrupted in 1598; for he met with a thousand insults at Cracow, and was with great difficulty saved from the hands of the rabble. His house was plundered, and he lost his goods; but this loss was not so uneasy to him as that of some manuscripts, which he extremely regretted. To deliver himself from such dangers, he retired to a village about nine miles distant from Cracow, where he spent the remainder of his days at the house of Abraham Blonski, a Polish gentlemen, and died there in 1604. All Faustus Socinus's works are contained in the two first volumes of the *Bibliotheca Fratrum Polonorum*.

SOCMANS, Sokemans, or *Socmen* (*Socmanni*), are such tenants as hold their lands and tenements by socage tenure. See Socage.

SOCOTORA, an island lying between Asia and Arabia Felix; about 50 miles in length, and 22 in breadth. It is particularly noted for its fine aloes, known by the name of *Socotrine Aloes*. The religion of the natives is a mixture of Mahometanism and Paganism; but they are civil to strangers who call there in their passage to the East Indies. It abounds in fruit and cattle; and they have a king of their own, who is dependent on Arabia.

SOCRATES, the greatest of the ancient philosophers, was born at Alopece, a village near Athens, in the fourth year of the 77th olympiad. His parents were of low rank; his father Sophroniscus being a statuary, and his mother Phænarcta a midwife. Sophroniscus

Socrates. niscus brought up his son, contrary to his inclination, in his own manual employment; in which Socrates, though his mind was continually aspiring after higher objects, was not unsuccessful; for whilst he was a young man, he is said to have formed statues of the habited graces, which were allowed a place in the citadel of Athens. Upon the death of his father he was left in such straitened circumstances as laid him under the necessity of exercising that art to procure the means of subsistence, though he devoted, at the same time, all the leisure which he could command to the study of philosophy. His distress, however, was soon relieved by Crito, a wealthy Athenian; who, remarking his strong propensity to study, and admiring his ingenuous disposition and distinguished abilities, generously took him under his patronage, and intrusted him with the instruction of his children. The opportunities which Socrates by this means enjoyed of attending the public lectures of the most eminent philosophers, so far increased his thirst after wisdom, that he determined to relinquish his occupation, and every prospect of emolument which that might afford, in order to devote himself entirely to his favourite pursuits. Under Anaxagoras and Archelaus he prosecuted the study of nature in the usual manner of the philosophers of the age, and became well acquainted with their doctrines. Prodicus the sophist was his preceptor in eloquence, Evenus in poetry, Theodorus in geometry, and Damo in music. Aspasia, a woman no less celebrated for her intellectual than her personal accomplishments, whose house was frequented by the most celebrated characters, had also some share in the education of Socrates. Under such preceptors it cannot reasonably be doubted but that he became master of every kind of learning which the age in which he lived could afford; and being blessed with very uncommon talents by nature, he appeared in Athens, under the respectable characters of a good citizen and a true philosopher. Being called upon by his country to take arms in the long and severe struggle between Athens and Sparta, he signalized himself at the siege of Potidæa, both by his valour and by the hardiness with which he endured fatigue. During the severity of a Thracian winter, whilst others were clad in furs, he wore only his usual clothing, and walked barefoot upon the ice. In an engagement in which he saw ALCIBIADES falling down wounded, he advanced to defend him, and saved both him and his arms: and though the prize of valour was on this occasion unquestionably due to Socrates, he generously gave his vote that it might be bestowed upon Alcibiades, to encourage his rising merit. He served in other campaigns with distinguished bravery, and had the happiness on one occasion to save the life of Xenophon, by bearing him, when covered with wounds, out of the reach of the enemy.

It was not till Socrates was upwards of 60 years of age that he undertook to serve his country in any civil office, when he was chosen to represent his own district, in the senate of five hundred. In this office, though he at first exposed himself to some degree of ridicule from the want of experience in the forms of business, he soon convinced his colleagues that he was superior to them all in wisdom and integrity. Whilst they, intimidated by the clamours of the populace, passed an unjust sentence of condemnation upon the commanders, who, after the engagement at the Arginusian islands, had been prevented by a storm from paying funeral honours to the dead, Socrates stood forth singly in their defence, and to the last refused to give his suffrage against them, declaring that no force should compel him to act contrary to justice and the laws. Under the subsequent tyranny he never ceased to condemn the oppressive and cruel proceedings of the thirty tyrants; and when his boldness provoked their resentment, so that his life was in hazard, fearing neither treachery nor violence, he still continued to support with undaunted firmness the rights of his fellow-citizens. Socrates.

Having given these proofs of public virtue both in a military and civil capacity, he wished to do still more for his country. Observing with regret how much the opinions of the Athenian youth were misled and their principles and taste corrupted by philosophers who spent all their time in refined speculations upon nature and the origin of things, and by sophists who taught in their schools the arts of false eloquence and deceitful reasoning; Socrates formed the wise and generous design of instituting a new and more useful method of instruction. He justly conceived the true end of philosophy to be not to make an ostentatious display of superior learning and ability in subtle disputations or ingenious conjectures, but to free mankind from the dominion of pernicious prejudices; to correct their vices; inspire them with the love of virtue; and thus conduct them in the path of wisdom to true felicity. He therefore assumed the character of a moral philosopher; and, looking upon the whole city of Athens as his school, and all who were disposed to lend him their attention as his pupils, he seized every occasion of communicating moral wisdom to his fellow citizens. He passed the greater part of his time in public; and the method of instruction of which he chiefly made use was, to propose a series of questions to the person with whom he conversed, in order to lead him to some unforeseen conclusion. He first gained the consent of his respondent to some obvious truths, and then obliged him to admit others from their relation or resemblance to those to which he had already assented. Without making use of any direct argument or persuasion, he chose to lead the person he meant to instruct, to deduce the truths of which he wished to convince him, as a necessary consequence from his own concessions. He commonly conducted these conferences with such address, as to conceal his design till the respondent had advanced too far to recede. On some occasions he made use of ironical language, that vain men might be caught in their own replies, and be obliged to confess their ignorance. He never assumed the air of a morose and rigid preceptor, but communicated useful instruction with all the ease and pleasantry of polite conversation. Though eminently furnished with every kind of learning, he preferred moral to speculative wisdom. Convinced that philosophy is valuable, not as it furnishes questions for the schools, but as it provides men with a law of life, he censured his predecessors for spending all their time in abstruse researches into nature, and taking no pains to render themselves useful to mankind. His favourite maxim was, Whatever is above us doth not concern us. He estimated the value of knowledge by its utility, and recommended the study of geometry, astronomy, and other sciences, only so far as they admit of a practical application to the purposes of human life. His great object

Socrates. object in all his conferences and discourses was, to lead men into an acquaintance with themselves; to convince them of their follies and vices; to inspire them with the love of virtue; and to furnish them with useful moral instructions. Cicero might therefore very justly say of Socrates, that he was the first who called down philosophy from heaven to earth, and introduced her into the public walks and domestic retirements of men, that she might instruct them concerning life and manners.

Through his whole life this good man discovered a mind superior to the attractions of wealth and power. Contrary to the general practice of the preceptors of his time, he instructed his pupils without receiving from them any gratuity. He frequently refused rich presents, which were offered him by Alcibiades and others, though importunately urged to accept them by this wife. The chief men of Athens were his stewards; they sent him in provisions, as they apprehended he wanted them; he took what his present wants required, and returned the rest. Observing the numerous articles of luxury which were exposed to sale in Athens, he exclaimed, "How many things are there which I do not want!" With Socrates, moderation supplied the place of wealth. In his clothing and food, he consulted only the demands of nature. He commonly appeared in a neat but plain cloak, with his feet uncovered. Though his table was only supplied with simple fare, he did not scruple to invite men of superior rank to partake of his meals; and when his wife, upon some such occasion, expressed her dissatisfaction on being no better provided, he desired her to give herself no concern; for if his guests were wise men, they would be contented with whatever they found at his table; if otherwise, they were unworthy of notice. Whilst others, says he, live to eat, wise men eat to live.

Though Socrates was exceedingly unfortunate in his domestic connection, he converted this infelicity into an occasion of exercising his virtues. Xantippe, concerning whose ill humour ancient writers relate many amusing tales, was certainly a woman of a high and unmanageable spirit. But Socrates, while he endeavoured to curb the violence of her temper, improved his own. When Alcibiades expressed his surprise that his friend could bear to live in the same house with so perverse and quarrelsome a companion, Socrates replied, that being daily inured to ill humour at home, he was the better prepared to encounter perverseness and injury abroad.

In the midst of domestic vexations and public disorders, Socrates retained such an unruffled serenity, that he was never seen either to leave his own house or to return home with a disturbed countenance. In acquiring this entire dominion over his passions and appetites, he had the greater merit, as it was not effected without a violent struggle against his natural propensities. Zopyrus, an eminent physiognomist, declared, that he discovered in the features of the philosopher evident traces of many vicious inclinations. The friends of Socrates who were present ridiculed the ignorance of this pretender to extraordinary sagacity. But Socrates himself ingenuously acknowledged his penetration, and confessed that he was in his natural disposition prone to vice, but that he had subdued his inclinations by the power of reason and philosophy.

Through the whole of his life Socrates gave himself up to the guidance of unbiassed reason, which is supposed by some to be all that he meant by the genius or *dæmon* from which he professed to receive instruction. But this opinion is inconsistent with the accounts given by his followers of that dæmon, and even with the language in which he spoke of it himself. Plato sometimes calls it his *guardian*, and Apuleius his *god;* and as Xenophon attests that it was the belief of his master that the gods occasionally communicate to men the knowledge of future events, it is by no means improbable that Socrates admitted, with the generality of his countrymen, the existence of those intermediate beings called *dæmons*, of one of which he might fancy himself the peculiar care.

It was one of the maxims of Socrates, "That a wise man will worship the gods according to the institutions of the state to which he belongs." Convinced of the weakness of the human understanding, and perceiving that the pride of philosophy had led his predecessors into futile speculations on the nature and origin of things, he judged it most consistent with true wisdom to speak with caution and reverence concerning the divine nature.

The wisdom and the virtues of this great man, whilst they procured him many followers, created him also many enemies. The Sophists§, whose knavery and ignorance he took every opportunity of exposing to public contempt, became inveterate in their enmity against so bold a reformer, and devised an expedient, by which they hoped to check the current of his popularity. They engaged Aristophanes, the first buffoon of the age, to write a comedy, in which Socrates should be the principal character. Arstophanes, pleased with so promising an occasion of displaying his low and malignant wit, endertook the task, and produced the comedy of *The Clouds*, still extant in his works. In this piece, Socrates is introduced hanging in a basket in the air, and thence pouring forth absurdity and prophaneness. But the philosopher, showing in a crouded theatre that he was wholly unmoved by this ribaldry, the satire failed of its effect; and when Aristophanes attempted the year following to renew the piece with alterations and additions, the representation was so much discouraged, that he was obliged to discontinue it.

§ See Sophist.

From this time Socrates continued for many years to pursue without interruption his laudable design of instructing and reforming his fellow-citizens. At length, however, when the inflexible integrity with which he had discharged the duty of a senator, and the firmness with which he had opposed every kind of political corruption and oppression, had greatly increased the number of his enemies, clandestine arts were employed to raise a general prejudice against him. The people were industriously reminded, that Critias, who had been one of the most cruel of the thirty tyrants, and Alcibiades, who had insulted religion, by defacing the public statues of Mercury, and performing a mock representation of the Eleusinian mysteries, had in their youth been disciples of Socrates; and the minds of the populace being thus prepared, a direct accusation was preferred against him before the supreme court of judicature. His accusers were Anytus a leather-dresser, who had long entertained a personal enmity against Socrates, for reprehending his avarice, in depriving his sons of the benefits of learning, that they might pursue the gains of trade;

Socrates. trade; Melitus, a young rhetorician who was capable of undertaking any thing for the sake of gain; and Lycon, who was glad of any opportunity of displaying his talents. The accusation, which was delivered to the senate under the name of Melitus, was this: "Melitus, son of Melitus, of the tribe of Pythos, accuseth Socrates, son of Sophroniscus, of the tribe of Alopece. Socrates violates the laws, in not acknowledging the gods which the state acknowledges, and by introducing new divinities. He also violates the laws by corrupting the youth. Be his punishment DEATH."

This charge was delivered upon oath to the senate; and Crito a friend of Socrates became surety for his appearance on the day of trial. Anytus soon afterwards sent a private message to Socrates, assuring him that if he would desist from censuring his conduct, he would withdraw his accusation. But Socrates refused to comply with so degrading a condition; and with his usual spirit replied, "Whilst I live I will never disguise the truth, nor speak otherwise than my duty requires." The interval between the accusation and the trial he spent in philosophical conversations with his friends, choosing to discourse upon any other subject rather than his own situation.

When the day of trial arrived, his accusers appeared in the senate, and attempted to support their charge in three distinct speeches, which strongly marked their respective characters. Plato, who was a young man, and a zealous follower of Socrates, then rose up to address the judges in defence of his master; but whilst he was attempting to apologise for his youth, he was abruptly commanded by the court to sit down. Socrates, however needed no advocate. Ascending the chair with all the serenity of conscious innocence, and with all the dignity of superior merit, he delivered, in a firm and manly tone, an unpremeditated defence of himself, which silenced his opponents, and ought to have convinced his judges. After tracing the progress of the conspiracy which had been raised against him to its true source, the jealousy and resentment of men whose ignorance he had exposed, and whose vices he had ridiculed, and reproved, he distinctly replied to the several charges brought against him by Melitus. To prove that he had not been guilty of impiety towards the gods of his country, he appealed to his frequent practice of attending the public religious festivals. The crime of introducing new divinities, with which he was charged, chiefly as it seems on the ground of the admonitions which he professed to have received from an invisible power, he disclaimed, by pleading that it was no new thing for men to consult the gods and receive instructions from them. To refute the charge of his having been a corrupter to youth, he urged the example which he had uniformly exhibited of justice, moderation, and temperance; the moral spirit and tendency of his discourses; and the effect which had actually been produced by his doctrine upon the manners of the young. Then, disdaining to solicit the mercy of his judges, he called upon them for that justice which their office and their oath obliged them to administer; and professing his faith and confidence in God, resigned himself to their pleasure.

The judges, whose prejudices would not suffer them to pay due attention to this apology, or to examine with impartiality the merits of the cause, immediately declared him guilty of the crimes of which he stood accused. Socrates, in this stage of the trial, had a right to enter his plea against the punishment which the accusers demanded, and instead of the sentence of death, to propose some pecuniary amercement. But he at first peremptorily refused to make any proposal of this kind, imagining that it might be construed into an acknowledgement of guilt; and asserted, that his conduct merited from the state reward rather than punishment. At length, however, he was prevailed upon by his friends to offer upon their credit a fine of thirty *minæ*. The judges, notwithstanding, still remained inexorable: they proceeded, without farther delay, to pronounce sentence upon him; and he was condemned to be put to death by the poison of hemlock.

The sentence being passed, he was sent to prison; which, says Seneca, he entered with the same resolution and firmness with which he had opposed the thirty tyrants; and took away all ignominy from the place, which could not be a prison while he was there. He lay in fetters 30 days; and was constantly visited by Crito, Plato, and other friends, with whom he passed the time in dispute after his usual manner. Anxious to save so valuable a life, they urged him to attempt his escape, or at least to permit them to convey him away; and Crito went so far, as to assure him that, by his interest with the jailor, it might be easily accomplished, and to offer him a retreat in Thessaly; but Socrates rejected the proposal, as a criminal violation of the laws; and asked them, whether there was any place out of Attica which death could not reach.

At length the day arrived when the officers to whose care he was committed delivered to Socrates early in the morning the final order for his execution, and immediately, according to the law, set him at liberty from his bonds. His friends, who came thus early to the prison that they might have an opportunity of conversing with their master through the day, found his wife sitting by him with a child in her arms. Socrates, that the tranquillity of his last moments might not be disturbed by her unavailing lamentations, requested that she might be conducted home. With the most frantic expressions of grief she left the prison. An interesting conversation then passed between Socrates and his friends, which chiefly turned upon the immortality of the soul. In the course of this conversation, he expressed his disapprobation of the practice of suicide, and assured his friends that his chief support in his present situation was an expectation, though not unmixed with doubts, of a happy existence after death, "It would be inexcusable in me (said he) to despise death, if I were not persuaded that it will conduct me into the presence of the gods, who are the most righteous governors, and into the society of just and good men: but I derive confidence from the hope that something of man remains after death, and that the condition of good men will then be much better than that of the bad." Crito afterwards asking him, in what manner he wished to be buried? Socrates replied, with a smile, "As you please, provided I do not escape out of your hands." Then, turning to the rest of his friends, he said, "Is it not strange, after all that I have said to convince you that I am going to the society of the happy, that Crito still thinks that this body, which will soon be a lifeless corpse, is Socrates? Let him dispose of my body as he pleases, but let him not at its interment mourn over it as if it were Socrates."

Towards the close of the day he retired into an adjoining apartment to bathe; his friends, in the mean time, expressing to one another their grief at the prospect of losing so excellent a father, and being left to pass the rest of their days in the solitary state of orphans. After a short interval, during which he gave some necessary instructions to his domestics, and took his last leave of his children, the attendant of the prison informed him, that the time for drinking the poison was come. The executioner, though accustomed to such scenes, shed tears as he presented the fatal cup. Socrates received it without change of countenance or the least appearance of perturbation: then offering up a prayer to the gods that they would grant him a prosperous passage into the invisible world, with perfect composure he swallowed the poisonous draught. His friends around him burst into tears. Socrates alone remained unmoved. He upbraided their pusillanimity and entreated them to exercise a manly constancy worthy of the friends of virtue. He continued walking till the chilling operation of the hemlock obliged him to lie down upon his bed. After remaining for a short time silent, he requested Crito (probably in order to refute a calumny which might prove injurious to his friends after his decease) not to neglect the offering of a cock which he had vowed to Esculapius. Then, covering himself with his cloak, he expired. Such was the fate of the virtuous Socrates! A story, says Cicero, which I never read without tears.

The friends and disciples of this illustrious teacher of wisdom were deeply afflicted by his death, and attended his funeral with every expression of grief. Apprehensive, however, for their own safety, they soon afterwards privately withdrew from the city, and took up their residence in distant places. Several of them visited the philosopher Euclid of Megara, by whom they were kindly received. No sooner was the unjust condemnation of Socrates known through Greece, than a general indignation was kindled in the minds of good men, who universally regretted that so distinguished an advocate for virtue should have fallen a sacrifice to jealousy and envy. The Athenians themselves, so remarkable for their caprice, who never knew the value of their great men till after their death, soon became sensible of the folly as well as criminality of putting to death the man who had been the chief ornament of their city and of the age, and turned their indignation against his accusers. Melitus was condemned to death; and Anytus, to escape a similar fate, went into voluntary exile. To give a farther proof of the sincerity of their regret, the Athenians for a while interrupted public business; decreed a general mourning; recalled the exiled friends of Socrates; and erected a statue to his memory in one of the most frequented parts of the city. His death happened in the first year of the 96th olympiad, and in the 70th year of his age.

Socrates left behind him nothing in writing; but his illustrious pupils Xenophon and Plato have in some measure supplied this defect. The Memoirs of Socrates, written by Xenophon, afford, however, a much more accurate idea of the opinions of Socrates, and of his manner of teaching, than the Dialogues of Plato, who everywhere mixes his own conceptions and diction with the ideas and language of his master. It is related, that when Socrates heard Plato recite his Lysis, he said, "How much does this young man make me say which I never conceived!"

His distinguishing character was that of a moral philosopher; and his doctrine concerning God and religion was rather practical than speculative. But he did not neglect to build the structure of religious faith upon the firm foundation of an appeal to natural appearances: He taught, that the Supreme Being, though invisible, is clearly seen in his works; which at once demonstrate his existence and his wise and benevolent providence. He admitted, besides the one Supreme Deity, the existence of beings who possess a middle station between God and man, to whose immediate agency he ascribed the ordinary phenomena of nature, and whom he supposed to be particularly concerned in the management of human affairs. Hence he declared it to be the duty of every one, in the performance of religious rites, to follow the customs of his country. At the same time, he taught, that the merit of all religious offerings depends upon the character of the worshipper, and that the gods take pleasure in the sacrifices of none but the truly pious.

Concerning the human soul, the opinion of Socrates, according to Xenophon, was, that it is allied to the Divine Being, not by a participation of essence, but by a similarity of nature; that man excels all other animals in the faculty of reason; and that the existence of good men will be continued after death in a state in which they will receive the reward of their virtue. Although it appears that on this latter topic he was not wholly free from uncertainty, the consolation which he professed to derive from this source in the immediate prospect of death, leaves little room to doubt that he entertained a real expectation of immortality: and there is reason to believe that he was the only philosopher of ancient Greece whose principles admitted of such an expectation (see Metaphysics, Part III. Chap. iv.) Of his moral system, which was in a high degree pure, and founded on the surest basis, the reader will find a short view in our article Moral Philosophy, n° 4.

Socrates was also the name of an ecclesiastical historian of the 5th century, born at Constantinople in the beginning of the reign of Theodosius: he professed the law and pleaded at the bar, whence he obtained the name of *Scholasticus*. He wrote an ecclesiastical history from the year 309, where Eusebius ended, down to 440; and wrote with great exactness and judgment. An edition of Eusebius and Socrates, in Greek and Latin, with notes by Reading, was published at London in 1720.

SODA, the name given by the French chemists to the mineral alkali, which is found native in many parts of the world: it is obtained also from common salt, and from the ashes of the *kali*, a species of salsoda. See Alkali, n° 7. and Chemistry-*Index*.

Soda is also a name for a heat in the stomach or heart-burn. See Medicine, n° 275.

SODOM, formerly a town of Palestine in Asia, famous in Scripture for the wickedness of its inhabitants, and their destruction by fire from heaven on account of that

that wickedneſs. The place where it ſtood is now covered by the waters or the Dead Sea, or the Lake Aſphaltites. See ASPHALTITES.

SODOMY, an unnatural crime, ſo called from the city of Sodom, which was deſtroyed by fire for the ſame. The Levitical law adjudged thoſe guilty of this execrable crime to death; and the civil law aſſigns the ſame puniſhment to it. The law of England makes it felony. There is no ſtatute in Scotland againſt Sodomy; the libel of the crime is therefore founded on the divine law, and practice makes its puniſhment to be burned alive.

SODOR, a name always conjoined with Man, in mentioning the biſhop of Man's dioceſe. Concerning the origin and application of this word, very different opinions have been formed by the learned. Buchanan (lib. i. cap. 34.) ſays, that before his time the name of *Sodor* was given to a town in the iſle of Man. In Gough's edition of Camden's *Britannia* (vol. iii. p. 701.) it is ſaid, that after the iſle of Man was annexed to the crown of England, this appellation was given to a ſmall iſland within muſket-ſhot of Man, in which the cathedral ſtands, called by the Norwegians the *Holm*, and by the inhabitants the *Peel*. In ſupport of this opinion a charter is quoted A. D. 1505, in which Thomas earl of Derby and lord of Man confirms to Huan Heſketh biſhop of Sodor all the lands, &c. anciently belonging to the biſhops of Man. "Eccleſiam cathedralem ſancti Germani in *Holm Sodor vel Pele* vocatam, eccleſiam ſancti Patricii ibidem, et locum præfatum in quo eccleſiæ præfatæ ſitæ ſunt." The truth of either, or perhaps of both, theſe accounts might be allowed; but neither of them are ſufficient to account for the conſtant conjunction of Sodor and Man, in charters, regiſters, and hiſtories. If Sodor was a ſmall town or iſland belonging to Man, it cannot be conceived why it is always mentioned before it, or rather why it ſhould be mentioned at all in ſpeaking of a biſhop's dioceſe. To ſpeak of the biſhopric of Sodor and Man in this caſe would be as improper as it would be to call the biſhopric of Durham the biſhopric of Holy Iſland and Durham, or the biſhopric of Darlington and Durham; the former being a ſmall iſland and the latter a town belonging to the county and dioceſe of Durham. Neither of theſe accounts, therefore, give a ſatisfactory account of the original conjunction of Sodor and Man.

The iſland of Iona was the place where the biſhop of the iſles reſided, the cathedral church of which, it is ſaid, was dedicated to our Saviour, in Greek *Soter*, hence *Sotorenſes*, which might be corrupted into *Sodorenſes*, a name frequently given by Daniſh writers to the weſtern iſles of Scotland. That we may be the more diſpoſed to accede to this Grecian etymology, the advocates for this opinion tell us, that the name *Icolumkill*, which is often applied to this iſland, is alſo of Greek extraction, being derived from *Columba*, "a pigeon;" a meaning that exactly correſponds to the Celtic word *Colum* and the Hebrew word *Iona*. We muſt confeſs, however, that we have very little faith in the conjectures of etymologiſts, and think that upon no occaſion they alone can eſtabliſh any fact, though when concurring with facts they certainly tend to confirm and explain them. It is only from hiſtorical facts that we can know to what Sodor was applied.

It appears from the hiſtory of the Orkneys, compiled by an old Iſlandic writer, tranſlated and enlarged by Torfæus, that the Æbudæ or Weſtern iſles of Scotland were divided into two cluſters, Nordureys and Sudereys. The Nordureys, which were ſeparated from the Sudereys by the point of Ardnamurchan, a promontory in Argyleſhire, conſiſted of Muck, Egg, Rum, Canna, Sky, Raſay, Barra, South Uiſt, North Uiſt, Benbecula, and Lewis, including Harris, with a great number of ſmall iſles. The Sudereys were, Man, Arran, Bute, Cumra, Avon, Gid, Ila, Colonſay, Jura, Scarba, Mull, Iona, Tiree, Coll, Ulva, and other ſmall iſlands. All theſe, when joined together, and ſubject to the ſame prince, made up the kingdom of Man and the iſles. In the Norwegian language *Suder* and *Norder*, ſignifying ſouthern and northern, and *ey* or *ay* an iſland. When the Æbudæ were under one monarch, the ſeat of empire was fixed in the Sudereys, and the Nordureys were governed by deputies; hence the former are much oftener mentioned in hiſtory than the latter; hence, too, the Sudereys often comprehend the Nordureys, as in our days Scotland is ſometimes comprehended under England. Sudereys, or Suder, when angliciſed, became Sodor; and all the weſtern iſles of Scotland being included in one dioceſe under the Norwegian princes, the biſhop appointed to ſuperintend them was called the biſhop of Man and the iſles, or the biſhop of Sodor and Man. Since Man was conquered by Edward III. it has been ſeparated from the other iſles, and its biſhops have exerciſed no juriſdiction over them. Should it now be aſked, why then is the biſhop of Man ſtill called the biſhop of Sodor and Man? we reply, that we have been able to diſcover no reaſon; but ſuppoſe the appellation to be continued in the ſame way, as the title king of France, has been kept up by the king of Great Britain, for ſeveral centuries after the Engliſh were entirely expelled from France.

SOFA, in the eaſt, a kind of alcove raiſed half a foot above the floor of a chamber or other apartment; and uſed as the place of ſtate, where viſitors of diſtinction are received. Among the Turks the whole floor of their ſtate-rooms is covered with a kind of tapeſtry, and on the window-ſide is raiſed a ſofa or ſopha, laid with a kind of matraſs, covered with a carpet much richer than the other. On this carpet the Turks are ſeated, both men and women, like the taylors in England, croſs legged, leaning againſt the wall, which is bolſtered with velvet, ſattin, or other ſtuff ſuitable to the ſeaſon. Here they eat their meals; only laying a ſkin over the carpet to ſerve as a table-cloth, and a round wooden board over all, covered with plates, &c.

SOFALA, or CEFALA, a kingdom of Africa, lying on the coaſt of Moſambique, near Zanguebar. It is bounded on the north by Monomotapa; on the eaſt by the Moſambique Sea; on the ſouth by the kingdom of Sabia; and on the weſt by that of Manica. It contains mines of gold and iron, and a great number of elephants. It is governed by a king, tributary to the Portugueſe, who built a fort at the principal town, which is of the ſame name, and of great importance for their trade to the Eaſt Indies. It is ſeated in a ſmall iſland, near the mouth of a river. E. Long. 35. 40. S. Lat. 20. 20.

SOFFITA, or SOFFIT, in architecture, any timber ceiling formed of croſs beams of flying cornices, the ſquare compartments or pannels of which are enriched with ſculpture, painting, or gilding; ſuch are thoſe in the palaces of Italy, and in the apartments of Luxembourg at Paris.

Soffita, or *Soffit*, is alſo uſed for the underſide or face of an architrave; and more particularly for that of the corona or larmier, which the ancients called *lacunar*, the French *plafond*, and we uſually the *drip*. It is enriched with compartments of roſes; and in the Doric order has 18 drops, diſpoſed in three ranks, ſix in each, placed to the right of the guttæ, at the bottom of the triglyphs.

SOFI, or Sophi. See Sophi.

SOFTENING, in painting, the mixing and diluting of colours with the bruſh or pencil.

SOHO, the name of a ſet of works, or manufactory of a variety of hard-wares, belonging to Mr Boulton, ſituated on the borders of Staffordſhire, within two miles of Birmingham; now ſo juſtly celebrated as to deſerve a ſhort hiſtorical detail.

About 30 years ago the premiſes conſiſted of a ſmall mill and a few obſcure dwellings. Mr. Boulton, in conjunction with Mr Fothergill, then his partner, at an expence of L. 9000, erected a handſome and extenſive edifice, with a view of manufacturing metallic toys. The firſt productions conſiſted of buttons, buckles, watch-chains, trinkets, and ſuch other articles as were peculiar to Birmingham. Novelty, taſte, and variety, were, however, always conſpicuous; and plated wares, known by the name of Sheffield plate, compriſing a great variety of uſeful and ornamental articles, became another permanent ſubject of manufacture.

To open channels for the conſumption of theſe commodities, all the northern part of Europe was explored by the mercantile partner Mr Fothergill. A wide and extenſive correſpondence was thus eſtabliſhed, the undertaking became well known, and the manufacturer, by becoming his own merchant, eventually enjoyed a double profit.

Impelled by an ardent attachment to the arts, and by the patriotic ambition of forming his favourite Soho into a fruitful ſeminary of artiſts, the proprietor extended his views; and men of taſte and talents were now ſought for, and liberally patroniſed. A ſucceſsful imitation of the French *or moulie* ornaments, conſiſting of vaſes, tripods, candelabra, &c. &c. extended the celebrity of the works. Services of plate and other works in ſilver, both maſſive and airy, were added, and an aſſay office was eſtabliſhed in Birmingham.

Mr Watt, the ingenious improver of the ſteam engine, is now in partnerſhip with Mr Boulton; and they carry on at Soho a manufactory of ſteam-engines, not leſs beneficial to the public than lucrative to themſelves. This valuable machine, the nature and excellences of which are deſcribed in another place (ſee *Steam-Engine*), Mr Boulton propoſed to apply to the operation of coining, and ſuitable apparatus was erected at a great expence, in the hope of being employed by government to make a new copper-coinage for the kingdom. Artiſts of merit were engaged, and ſpecimens of exquiſite delicacy were exhibited; but as no national coinage has taken place, the works are employed upon high finiſhed medals and private coins. To enumerate all the productions of this manufactory would be tedious (A).

In a national view, Mr Boulton's undertakings are highly valuable and important. By collecting around him artiſts of various deſcriptions, rival talents have been called forth, and by ſucceſſive competition have been multiplied to an extent highly beneficial to the public. The manual arts partook of the benefit, and became proportionably improved.

A barren heath has been covered with plenty and population; and Mr Boulton's works, which in their infancy were little known and attended to, now cover ſeveral acres, give employment to more than 600 perſons, and are ſaid to be the firſt of their kind in Europe.

SOIL, the mould covering the ſurface of the earth, in which vegetables grow. It ſerves as a ſupport for vegetables, and as a reſervoir for receiving and communicating their nouriſhment.

Soils are commonly double or triple compounds of the ſeveral reputed primitive earths, except the barytic (ſee Earths). The magneſian likewiſe ſparingly occurs. The more fertile ſoils afford alſo a ſmall proportion of coally ſubſtance ariſing from putrefaction, and ſome traces of marine acid and gypſum. The vulgar diviſion into clay, chalk, ſand, and gravel, is well underſtood. Loam denotes any ſoil moderately adheſive; and, according to the ingredient that predominates, it receives the epithets of clayey, chalky, ſandy, or gravelly. The intimate mixture of clay with the oxydes of iron is called *till*, and is of a hard conſiſtence and a dark reddiſh colour. Soils are found by analyſis to contain their earthy ingredients in very different proportions. According to M. Giobert, fertile mould in the vicinity of Turin, where the fall of rain amounts yearly to 40 inches, affords for each 100 parts, from 77 to 79 of ſilex, from 8 to 14 of argill, and from 5 to 12 of calx; beſides about one-half of carbonic matter, and nearly an equal weight of gas, partly carbonic and partly hydrocarbonic. The ſame experimenter repreſents the compoſition of barren ſoils in ſimilar ſituations to be from 42 to 88 *per cent.* of ſilex, from 20 to 30 of argill, and from 4 to 20 of calx. The celebrated Bergman found rich ſoils in the valleys of Sweden, where the annual quantity of rain is 24 inches, to contain, for each 100 parts, 56 of ſiliceous ſand, 14 of argill, and 30 of calx. In the climate of Paris, where the average fall of rain is 20 inches, fertile mixtures, according to M. Tillet, vary from 46 to 52 *per cent.* of ſilex, and from 11 to 17 of argill, with 37 of calx. Hence it appears that in dry countries rich earths are of a cloſer texture, and contain more of the calcareous ingredient, with leſs of the ſiliceous. Mr Arthur Young has diſcovered, that the value of fertile lands is nearly proportioned to the quantities of gas which equal weights of their ſoil afford by diſtillation. See Agriculture, n° 24. and 118.

SOISSONS, an ancient, large, and conſiderable city of France, in the department of Aiſne and late province of Soiſſonnois. It was the capital of a kingdom of the ſame name, under the firſt race of the French monarchs. It contains about 12,000 inhabitants, and is a biſhop's

(A) It was at this place, in the year 1772, that Mr Eginton invented his expeditious method of copying pictures in oil.

see. The environs are charming, but the streets are narrow, and the houses ill-built. The fine cathedral has one of the most considerable chapters in the kingdom; and the bishop, when the archbishop of Rheims was absent, had a right to crown the king. The castle, though ancient, is not that in which the kings of the first race resided. Soissons is seated in a very pleasant and fertile valley, on the river Aisne, 30 miles west by north of Rheims, and 60 north east of Paris. E. Long. 3. 24. N. Lat. 49. 23.

SOKE, or SOK. See SOCAGE.

SOKEMANS. See SOC and SOCAGE.

SOL, in music, the first note on the gamut, *ut, re, mi, fa, sol, la*. See GAMUT.

SOL, or *Sou*, a French coin made up of copper mixed with a little silver, and is worth upwards of an English halfpenny, or the 23d part of an English shilling. The sol when first struck was equal in value to 12 deniers Tournois, whence it was also called *douzain*, a name it still retains, tho' its ancient value be changed; the sol having been since augmented by three deniers, and struck with a puncheon of a flour-de-lis, to make it current for 15 deniers. Soon after the old sols were coined over again, and both old and new were indifferently made current for 15 deniers. In 1709, the value of the same sols was raised to 18 deniers. Towards the latter end of the reign of Louis XIV. the sol of 18 deniers was again lowered to 15; and by the late king it was reduced to the original value of 12. What it is at present posterity may perhaps discover.

The Dutch have also two kinds of sols: the one of silver, called *sols de gros*, and likewise *schelling*; the other of copper, called also the *stuyver*.

SOL, the *Sun*, in astronomy, astrology, &c. See ASTRONOMY, *passim*.

SOL, in chemistry, is gold; thus called from an opinion that this metal is in a particular manner under the influence of the sun.

SOL, in heraldry, denotes Or, the golden colour in the arms of sovereign princes.

SOLÆUS, or SOLEUS, in anatomy, one of the extensor muscles of the foot, rising from the upper and hinder parts of the tibia and fibula.

SOLAN-GOOSE, in ornithology. See PELICANUS.

SOLANDRA, in botany: A genus of plants belonging to the class of *monodelphia*, and to the order of *polyandria*; and in the natural system arranged under the 38th order, *Tricoccæ*. The calyx is simple; the capsule oblong, wreathed, and five celled; the seeds are many, disposed in cells in a double order. The valves after maturity are divaricated, even to the base, and winged inwards by the partition. The only species is the *Lobata*. This genus was first named *Solandra*, in honour of Dr Solander, by Murray in the 14th edition of the *Systema Vegetabilium*.

SOLANUM, in botany: A genus of the *monogynia* order, belonging to the *pentandria* class of plants; and in the natural method ranking under the 28th order, *Luridæ*. The calyx is inferior; the corolla is rotate, and generally monophyllous; the fruit a berry, bilocular, and containing many small and flat seeds. Of this genus there are 66 species, most of them natives of the East and West Indies. The most remarkable of which are the following.

1. The *Dulcamara*, a native of Britain and of Africa, is a slender climbing plant, rising to six or more feet in height. The leaves are generally oval, pointed, and of a deep green colour; the flowers hang in loose clusters, of a purple colour, and divided into five pointed segments. The calyx is purple, persistent, and divided into five. The five filaments are short, black, and inserted into the tube of the corolla. The antheræ yellow, erect, and united in a point as usual in this genus. The style is long, and terminates in an obtuse stigma. The berry, when ripe, is red, and contains many flat yellowish seeds. It grows in hedges well supplied with water, and flowers about the end of June. On chewing the roots, we first feel a bitter, then a sweet, taste: hence the name. The berries are said to be poisonous, and may easily be mistaken by children for currants. The *stipites* or younger branches are directed for use, and may be employed either fresh or dried: they should be gathered in the autumn. This plant is generally given in decoction or infusion. Razou directs the following: Take dried dulcamara twigs half a dram, and pour upon it 16 ounces of spring water, which must be boiled down to 8 ounces; then strain it. Three or four tea spoonfuls to be taken every four hours, diluted with milk to prevent its exciting a nausea. Several authors take notice, that the dulcamara partakes of the milder powers of the nightshade, joined to a resolvent and saponaceous quality; hence it promotes the secretions of urine, sweat, the menses, and lochia. It is recommended in a variety of disorders; but particularly in rheumatisms, obstructed menses, and lochia; also in some obstinate cutaneous diseases.

2 The *Nigrum*, common in many places in Britain about dunghills and waste places. It rises to about two feet in height. The stalk herbaceous, the leaves alternate, irregularly oval, indented, and clothed with soft hairs. The flowers are white; the berries black and shining. It appears to possess the deleterious qualities of the other nightshades in a very high degree, and even the smell of the plant is said to cause sleep. The berries are equally poisonous with the leaves; causing *cardialgia*, and *delirium*, and violent distortions of the limbs in children. Mr Getaker in 1757 recommended its internal use in old sores, in scrofulous and cancerous ulcers, cutaneous eruptions, and in dropsies. He says, that one grain infused in an ounce of water sometimes produced a considerable effect; that in the dose of two or three grains it seldom failed to evacuate the first passages, to increase very sensibly the discharges by the skin and kidneys, and sometimes to occasion headach, drowsiness, giddiness, and dimness of sight. Mr Broomfield declares, that in cases in which he tried this solanum, they were much aggravated by it; and that in one case in the dose of one grain it proved mortal to one of his patients; therefore he contends its use is prejudicial. This opinion seems tacitly to be confirmed, as it is now never given internally. In ancient times it was employed externally as a discutient and anodyne in some cutaneous affections, tumefactions of the glands, ulcers, and disorders of the eyes. The *solanum nigrum* & *rubrum*, a native of the West Indies, is called *guma* by the negroes. It is so far from having any deleterious quality, that it is daily served up at table as greens or spinnage. It has an agreeable bitter taste.

3. *Lycopersicum*, the love-apple, or tomato, cultivated in gardens in the warmer parts of Europe and in all tropical

pical countries. The ſtalk is herbaceous, the leaves pinnated, oval, pointed, and deeply divided. The flowers are on ſimple *racemi:* they are ſmall and yellow. The berry is of the ſize of a plum; they are ſmooth, ſhining, ſoft; and are either of a yellow or reddiſh colour. The tomato is in daily uſe; being either boiled in ſoups or broths, or ſerved up boiled as garniſhes to fleſh-meats.

4. *Melongena*, the egg-plant, or vegetable egg. This is alſo cultivated in gardens, particularly in Jamaica. It ſeldom riſes above a foot in height. The ſtalk is herbaceous and ſmooth; the leaves oval and downy; the flowers are large and blue; the fruit is as big, and very like, the egg of a gooſe. It is often uſed boiled as a vegetable along with animal food or butter, and ſuppoſed to be aphrodiſiac and to cure ſterility.

5. *Longum.* This plant is alſo herbaceous, but grows much ranker than the foregoing. The flowers are blue; and the fruit is ſix or eight inches long, and proportionally thick. It is boiled and eaten at table as the egg-plant.

6. *Tuberoſum*, the common potato. See POTATO.

SOLAR, ſomething belonging to the SUN.

SOLAR-*Spots*. See ASTRONOMY-*Index*.

SOLDAN. See SULTAN.

SOLDANELLA, in botany: A genus of plants belonging to the claſs of *pentandria*, and order of *monogynia;* and in the natural ſyſtem arranged under the 21ſt order, *Preciæ*. The corolla is campanulated; the border being very finely cut into a great many ſegments. The capſule is unilocular, and its apex polydentate.

SOLDER, SODDER, or *Soder*, a metallic or mineral compoſition uſed in ſoldering or joining together other metals.

Solders are made of gold, ſilver, copper, tin, biſmuth, and lead; uſually obſerving, that in the compoſition there be ſome of the metal that is to be ſoldered mixed with ſome higher and finer metals. Goldſmiths uſually make four kinds of ſolder, viz. ſolder of eight, where to ſeven parts of ſilver there is one of braſs or copper; ſolder of ſix, where only a ſixth part is copper; ſolder of four, and ſolder of three. It is the mixture of copper in the ſolder that makes raiſed plate come always cheaper than flat.

As mixtures of gold with a little copper are found to melt with leſs heat than pure gold itſelf, theſe mixtures ſerve as ſolders for gold: two pieces of fine gold are ſoldered by gold that has a ſmall admixture of copper; and gold alloyed with copper is ſoldered by ſuch as is alloyed with more copper: the workmen add a little ſilver as well as copper, and vary the proportions of the two to one another, ſo as to make the colour of the ſolder correſpond as nearly as may be to that of the piece. A mixture of gold and copper is alſo a ſolder for fine copper as well as for fine gold. Gold being particularly diſpoſed to unite with iron, proves an excellent ſolder for the finer kinds of iron and ſteel inſtruments.

The ſolder uſed by plumbers is made of two pounds of lead to one of block-tin. Its goodneſs is tried by melting it, and pouring the bigneſs of a crown piece on a table; for, if good, there will ariſe little bright ſhining ſtars therein. The ſolder for *copper* is made like that of the plumbers; only with copper and tin; and for very nice works, inſtead of tin, they ſometimes uſe a quantity of ſilver. Solder for *tin* is made of two-thirds of tin and one of lead, or of equal parts of each; but where the work is any thing delicate, as in organ pipes, where the juncture is ſcarce diſcernible, it is made of one part of biſmuth and three parts of pewter. The pewterers uſe a kind of ſolder made with two parts of tin and one of biſmuth; this compoſition melts with the leaſt heat of any of the ſolders.

Silver ſolder is that which is made of two parts of ſilver and one of braſs, and uſed in ſoldering thoſe metals. Spelter ſolder is made of one part of braſs and two of ſpelter or zinc, and is uſed by the braziers and copperſmiths for ſoldering braſs, copper, and iron. This ſolder is improved by adding to each ounce of it one pennyweight of ſilver; but as it does not melt without a conſiderable degree of heat, it cannot be uſed when it is inconvenient to heat the work red-hot; in which caſe copper and braſs are ſoldered with ſilver.

Though ſpelter ſolder be much cheaper than ſilver-ſolder, yet workmen in many caſes prefer the latter. And Mr Boyle informs us, that he has found it to run with ſo moderate a heat, as not much to endanger the melting of the delicate parts of the work to be ſoldered; and if well made, this ſilver ſolder will lie even upon the ordinary kind itſelf; and ſo fill up thoſe little cavities that may chance to be left in the firſt operation, which is not eaſily done without a ſolder more eaſily fuſible than the firſt made uſe of. As to iron, it is ſufficient that it be heated to a white heat, and the two extremities, in this ſtate, be hammered together; by which means they become incorporated one with the other.

SOLDERING, the joining and faſtening together of two pieces of the ſame metal, or of two different metals, by the fuſion and application of ſome metallic compoſition on the extremities of the metals to be joined.
