Ptolemy, on hearing the melancholy news of his ſiſter's death determined to take the moſt ſevere vengeance on her murderers. Joining his forces to thoſe of the Aſiatics, he carried every thing before him. Having in the firſt place put an end to the life of Laodice, he made himſelf maſter of all Syria and Cilicia; then paſſing the Euphrates, he ſubdued all the country as far as Babylon and the Tigris; and had not the progreſs of his arms been interrupted by a ſedition which obliged him to return to Egypt, it is more than probable that he would have ſubdued the whole Syrian empire. As ſoon as he was returned, Seleucus attempted to revenge himſelf; but his fleet being deſtroyed by a violent ſtorm, and his land army defeated by Ptolemy, he concluded a truce for ten years. During all this time the Parthian prince had eſtabliſhed himſelf ſo firmly on the throne, that it was in vain to think of diſpoſſeſſing him. However, as ſoon as his other affairs would permit, Seleucus undertook an expedition againſt Arſaces the Parthian monarch; by whom he was utterly defeated, taken priſoner, and carried into Parthia, where he died four years after. He was ſucceeded by his eldeſt ſon Seleucus Ceraunus, a weak prince, who was poiſoned by a conſpiracy of two of his officers, when he had reigned one year; after which his brother Antiochus, ſurnamed the *Great*, aſcended the throne in 225 B. C.

16 Great part of his dominions conquered by Ptolemy Euergetes.

17 Seleucus defeated and taken priſoner by the Parthians.

In the very beginning of his reign, two of his generals, Alexander and Molo, rebelled againſt him. The former had been appointed governor of Perſia, and the latter of Media, but they, deſpiſing the king's youth, refuſed to obey. The occaſion of this revolt is ſaid to have been their dread of the cruelty of Hermias the king's prime miniſter; and as they hoped to draw into their ſchemes Achæus governor of the provinces of Aſia Minor, they doubted not of ſucceſs. In this, however, they failed; but this did not diſcourage them from proceeding in their rebellion. Epigenes, the commander of the troops about the king's perſon, adviſed him to march without delay againſt the rebels; but as Hermias reproached him with treachery and a deſign to betray the king into the hands of his enemies, Antiochus ſent two of his generals into the eaſt, while he himſelf undertook an expedition againſt Ptolemy Philadelphus, with a view of recovering Cœleſyria. In this attempt, however, he was diſappointed; and the generals whom he had ſent into the eaſt were totally defeated and their troops cut off: upon which he determined to lay aſide for the preſent his Syrian enterpriſe, and march in perſon againſt the rebels. This was again oppoſed by Hermias; but as he found it impoſſible to alter the king's mind, the treacherous miniſter found means to get Epigenes the author of this project executed, under pretence of holding a correſpondence with Molo one of the rebel chiefs. Antiochus in the mean time purſued his

18 Antiochus the Great.

19 Undertakes an unſucceſsful expedition againſt Egypt.

Syria.

his march againſt the rebels, whom he defeated in a pitched battle; upon which their chiefs laid violent hands on themſelves. On his return he received the ſubmiſſion of the Atropatii, a barbarous people in Media; and put to death his prime miniſter Hermias, whom he found hatching treacherous deſigns againſt him. During his lifetime, however, the traitor, by accuſing Achæus of treaſon, had obliged him to revolt in his own defence; ſo that the king had ſtill two important wars on his hands, viz. that with Ptolemy king of Egypt, and the other againſt Achæus. After ſome deliberation, he reſolved to march firſt againſt the king of Egypt; and was at firſt very ſucceſsful, reducing many cities in Cœleſyria and Paleſtine, and defeating the Egyptians in a pitched battle: but in the year 217 B. C. being worſted in the battle of Raphia, he was obliged to abandon all his conqueſts; of which Ptolemy immediately took poſſeſſion, and Antiochus was obliged to cede them to him, that he might be at leiſure to purſue the war againſt Achæus.

20 Suppreſſes one rebellion, but is embarraſſed by another.

21 Is defeated by the Egyptians, but ſuppreſſes the rebellion.

Antiochus having made vaſt preparations for his expedition, ſoon reduced Achæus to ſuch diſtreſs, that he was obliged to ſhut himſelf up in the city of Sardis, which he defended for ſome time with great bravery; till at laſt, being betrayed by two Cretans, he was delivered up to the king, and by his order put to death. Antiochus then undertook an expedition againſt the Parthians, whom he obliged to conclude a peace on very advantageous terms. He then turned his arms againſt the king of Bactria, whom he alſo compelled to agree to his terms; one of which was, that he ſhould give him up all his elephants. For the confirmation of the treaty, the king of Bactria ſent his ſon to Antiochus; who being taken with his majeſtic mien and agreeable converſation, gave him one of his daughters in marriage. He then croſſed Mount Caucaſus, and entered India: where having renewed his alliance with the king of that country, he received alſo of his elephants, which increaſed his ſtock to 150. From India he marched into Arachoſia, Drangiana, and Carmania, eſtabliſhing order and diſcipline in all thoſe countries: then paſſing through Perſia, Babylonia, and Meſopotamia, he returned to Antioch, after an abſence of ſeven years.

22 His ſucceſſes in the eaſt.

23 Enters into a league with Philip of Macedon againſt the king of Egypt.

In the year 204 B. C. Antiochus entered into a league with Philip of Macedon, on purpoſe to deprive Ptolemy Epiphanes, the infant king of Egypt, of all his dominions. The Egyptians, however, put the young king under the tuition of the Romans; who immediately required the confederate princes to deſiſt from any enterpriſe againſt the king of Egypt, under the penalty of incurring the diſpleaſure of the republic. After delivering this meſſage, M. Emilius Lepidus, one of the ambaſſadors, repaired to Egypt, where he took upon himſelf the office of regent and guardian to the young king. Having regulated affairs there in the beſt manner he could, he returned to Rome, after having appointed one Ariſtomenes, an Acarnanian, to be chief miniſter to the king. Ariſtomenes being a man of prudence and fidelity, acquitted himſelf very well in his new ſtation. Having taken care to recruit his army as well as he could, he ſent one Scopas, a man of great authority among the Ætolians, into that country, to raiſe auxiliaries. Scopas ſoon raiſed an army of 6000 Ætolians, at that time reputed the beſt ſoldiers in the world; and having joined the Egyptian army, reduced all Judea, put a garriſon into the caſtle at Jeruſalem, and, on the approach of winter, returned to Alexandria loaded with booty. Theſe exploits, however, were performed when Antiochus was abſent in Aſia Minor; and no ſooner was he returned, than the face of affairs was changed. Scopas was defeated in a pitched battle, where one half of his men were deſtroyed. He himſelf eſcaped to Sidon, where he ſhut himſelf up with 10,000 of his ſoldiers; but Antiochus having inveſted the place, Scopas was reduced to the neceſſity of ſurrendering at diſcretion. The king purſued his conqueſts; recovered all Paleſtine and Cœleſyria; after which he invaded Aſia Minor, in hopes of reducing it alſo, and reſtoring the Syrian empire to the ſame extent it had in the time of Seleucus Nicator. The free cities in Aſia Minor immediately had recourſe to the Romans, who ſent an embaſſy to Antiochus on the occaſion; but as both parties put on thoſe haughty and imperious airs to which they thought the greatneſs of their power gave them a right, no ſatisfaction was given, but every thing tended to an open rupture. While matters were in this ſituation, Hannibal the Great being obliged to leave his own country, fled to Antiochus: from whom he met with a gracious reception. As Hannibal had, while a child, ſworn perpetual enmity againſt the Romans, he uſed all his eloquence to perſuade Antiochus to make war with them; and as the many victories which he had gained over them left no room to doubt of his capacity, Antiochus doubted nothing of being able, by his aſſiſtance, to conquer that haughty people. Several embaſſies paſſed between the two nations; but chiefly with a deſign, on the part of Antiochus, to gain time. Hannibal endeavoured to draw his countrymen into the confederacy againſt Rome, but without effect. Antiochus having ſtrengthened himſelf by ſeveral alliances, at laſt reſolved to begin the war in earneſt. To conſult on the meaſures proper to be taken, he called a council of war; but excluded from it the only man whoſe advice he ought to have followed; namely, Hannibal the Carthaginian. The reaſon of this was, that he had become jealous of him from the too great intimacy, as he thought, which he had kept with the Roman ambaſſadors. However, in this council it was agreed that the war ſhould be immediately commenced. The king himſelf was prevailed upon by the Ætolians to paſs over into Greece, and at the ſame time entirely to reject the advice which Hannibal had formerly given, of ſending him with an army into Italy. Here he was made generaliſſimo of all the Greek forces; but made none of thoſe efforts that had formerly obtained him the title of Great. Indeed it now plainly appeared, not only that he was incapable of carrying on war againſt ſuch enemies as the Romans, but even of accepting proper advice when it was given him. In another council, into which Hannibal was admitted, that commander adviſed the king, before he undertook any thing elſe, to uſe his utmoſt endeavours to gain over Philip of Macedon; which, he ſaid, was a ſtep ſo important, that if it could be gained, they might, without much ado, become maſters of all Greece. But if Philip could not be prevailed on to make war on the Romans, he was of opinion that the king ſhould ſend his ſon Seleucus into Macedon at the head of an army, and thus prevent Philip from giving the Romans any aſſiſtance. But he ſtill maintained, that the only way to defeat the Romans was to ſend an army into Italy. This advice was again rejected; and the king imprudently became the aggreſſor, by falling on a body of 500 Romans before war had been declared. He alſo make king Philip his enemy, by entertaining the regent of Athamania, who was a pretender to the crown of Macedon. To complete all, he himſelf fell in love, though above 50 years of age, with a beautiful young woman of Chalcis, whom he married; and became ſo great a ſlave to this paſſion, that he entirely neglected his affairs; the army gave themſelves up entirely to diſſipation and debauchery, and every trace of military diſcipline vaniſhed.

24 Deſtroys the Egyptian army.

25 His conqueſts checked by the Romans.

26 Hannibal flees to him for protection.

27 Antiochus neglects the advice of Hannibal.

28 His ſhameful behaviour.

In the year 191 B. C. Antiochus was raiſed from his lethargy by a declaration of war againſt him at Rome, and ſet out for Ætolia. His army at this time amounted to no more than 10,000 foot and 500 horſe. He had been made

Syria.

to believe that he would receive a vaſt reinforcement in Ætolia: but when he came to make the experiment, he ſoon found his miſtake; all the troops he could raiſe there amounted to no more than 4000 men. With this force, ſo exceedingly inadequate to the purpoſe, he was obliged to oppoſe the Roman army, who were advancing in conjunction with the Macedonians, and had already made ſurpriſing progreſs. Antiochus ſeized the Straits of Thermopylæ; but was driven from them by the Romans, the king himſelf being the firſt that fled. Almoſt his whole army was deſtroyed in the battle or in the purſuit, and Antiochus returned with diſgrace into Aſia.

29 Is defeated by the Romans at Thermopylæ.

Soon after his return, Antiochus equipped a fleet of 200 ſail; on which he immediately embarked for the Thracian Cherſoneſus, now Crim Tartary, where he fortified the cities of Lyſimachia, Seſtus, and Abydos, with others in that neighbourhood, to prevent the Romans from croſſing the Helleſpont. In the mean time Polyxenidas the Syrian admiral ſent intelligence to the king that the Roman fleet had appeared off Delos; upon which he deſired him to ſeek them out and engage them at all events. He did ſo, and was defeated with the loſs of 40 ſhips taken or ſunk in the engagement. This was ſoon after revenged by the deſtruction of the Rhodian fleet by the artifice of Polyxenidas; but in the end the king's affairs went everywhere to wreck. Having laid ſiege to the city of Pergamus, he was obliged to raiſe it with loſs; the Phœnician fleet commanded by Hannibal was defeated by the Rhodians; and ſoon after the Syrian fleet under Polyxenidas was utterly defeated by the Romans. Antiochus was ſo much diſheartened by theſe repeated defeats, that he appeared like one infatuated. Inſtead of fortifying more ſtrongly thoſe cities which lay on the frontiers of his kingdom, he entirely deſerted them: and thus Lyſimachia and Abydos, the two keys to Aſia, fell into the hands of the Romans without the leaſt reſiſtance.

30 His fleet defeated by that of the Romans.

31 Meets with two other defeats, and becomes like one infatuated.

The arrival of the Romans in Aſia ſtruck Antiochus with ſuch terror, that he inſtantly ſued for peace. The terms he offered were indeed very advantageous, but by no means agreeable to the expectations of the Romans. They therefore gave him this final anſwer: 1. That ſince he had drawn upon himſelf the war, he ſhould defray the whole expence of it; 2. That he ſhould reſtore liberty in general to all the Greek cities in Aſia; and, 3. That to prevent future hoſtilities, he ſhould relinquiſh all Aſia on this ſide Mount Taurus. Theſe terms, however, ſtill appeared to him ſo intolerable, that he reſolved to continue the war; and determined alſo to take the moſt imprudent method of carrying it on, namely, by hazarding all on the event of a general engagement. The king encamped near Magneſia, and ſtrongly fortified his camp. The Romans inſulted him in his trenches, and propoſed to attack his fortifications if he continued to decline an engagement. At laſt the king, thinking it would be ſhameful for him longer to refuſe an engagement, being at the head of an army far more numerous than that of the enemy, in a friend's country, and in the midſt of his allies, reſolved at all events to accept the challenge, and accordingly prepared for a deciſive battle.

32 Sues for peace, but is refuſed.

The Roman army conſiſted of four legions, partly Romans and partly Latins, each legion at this time containing 5500 men, and of 7000 auxiliaries ſent by the kings of Pergamus and Macedon; but of theſe 2000 were ordered to guard the camp during the action. The Romans were poſted in the centre, and the Latins in the two wings, the left of which extended to the river. On the ſide of the right wing, to cover and ſupport it, the conſul poſted the auxiliary troops of Eumenes, a ſmall body of horſe, and ſome Trallians and Cretans lightly armed. Sixteen elephants which the Romans had were placed behind the army by way of corps-de-reſerve, the conſul not thinking it proper to oppoſe them to thoſe of the enemy, which were far more numerous, being in all 52, and beſides excelled the Roman elephants in ſtrength, height, and courage, the former being brought from India and the latter from Africa. As for the Syrian army, all the nations of the eaſt ſeemed to be aſſembled to ſupport the cauſe of Antiochus. But the main ſtrength of it conſiſted in 16,000 foot, armed after the Macedonian manner, who compoſed the phalanx. This body faced every way, was armed with long pikes, and taught to fight in cloſe order, as the ſoldiers of Alexander the Great had formerly been. Antiochus did not draw up his phalanx as uſual, but divided it into 10 companies ſeparated from each other, placing, in the ſpaces between each of the companies, an elephant loaded with a tower full of armed men. On the right of the phalanx was drawn up in a line part of the cavalry, viz. 1500 Aſiatic Gauls, 3000 horſe armed cap-a-pee, and 1000 more, the flower of the Median cavalry. At ſome diſtance from theſe followed the cavalry of the king's houſehold richly clothed, and wearing bucklers plated over with ſilver. In the ſame line 1200 Scythians on horſeback, armed with bows and arrows, made a great figure, being all choſen men, and of an extraordinary ſize. The light-armed troops, to the number of 3000, partly Trallians and partly Cretans, with 10,000 Myſian archers and 4000 men more, partly Cyrtœans armed with ſlings, partly Perſians armed with bows, and partly Arabians mounted on dromedaries, cloſed the right wing, which was led on by the king in perſon, ſurrounded by a body of Syrians and Lydians well mounted, but not heavily armed. The left wing was commanded by Seleucus and Antipater; the former the king's ſon, and the latter his nephew, and diſpoſed thus: Cloſe to the phalanx were poſted 1500 Galatians and 2000 Cappadocians, which king Ariarathes had ſent to the aſſiſtance of his father-in-law. Next to theſe were placed 2700 auxiliaries ſent from different countries; theſe were followed by 3000 cuiraſſiers well mounted; and, laſtly, in the flank of this wing marched 2000 horſe lightly armed. At ſome diſtance were placed ſeveral ſmall bodies of light-armed troops both foot and horſe; among which were 2500 Galatian horſe, ſome Tarentines, Cretans, Carians, Cilicians, &c. The phalanx, which was in the centre, was commanded by three officers of diſtinction, viz. Minio, Zeuxis, and Philip. A vaſt number of chariots, armed with hooks and ſcythes, were drawn up before the firſt line, as were likewiſe a great many elephants carrying towers with ſeveral floors, all filled with ſlingers and archers; beſides many camels, animals then unknown to the Roman troops, mounted by Arabians armed with ſwords ſix feet long, that the riders might from their backs reach the enemy. The Romans had never ſeen a more numerous army, nor one more finely adorned; nevertheleſs they never ſhowed ſo great a contempt for an army as for this which they were now going to attack.

33 Battle of Magneſia.

On the day of the battle the weather proved very favourable to the Romans; for a thick fog riſing in the morning, the day was almoſt turned into night, ſo that the Syrian commanders could not have all the corps under their command in view, on account of their great extent, nor ſend them proper orders in time; whereas the fog was not thick enough to prevent the Roman generals from ſeeing their ſeveral bodies at the greateſt diſtance, as they took up but little ground. Beſides, the damp which was occaſioned by the fog ſlackened the ſtrings of the enemy's bows, ſo that the Aſiatics who uſed them could ſhoot their darts and arrows but faintly. The whole dependence of Antiochus in the firſt attack was on his armed chariots, which were to cut their way into the Roman army. For this purpoſe they had

Syria. had long halberts faſtened to their poles, and ſharp hooks to their axle-trees; the former were about the height of a man's head, and the latter almoſt ſwept the ground, and cut off the legs of all who ſtood in their way. But Eumenes undertook to render them uſeleſs, and even fatal, to the enemy. This brave prince, putting himſelf at the head of the bowmen and ſlingers, ordered them to charge, not in a body, but divided in platoons, and to aim only at the horſes in the chariots. Accordingly, as ſoon as the chariots moved, Eumenes advanced at the head of his men, who pouring on them from every quarter darts, ſtones, and javelins, and at the ſame time ſhouting as loud as they could, ſo frightened the horſes that they could no longer be kept in order, but ſcouring up and down, and turning againſt their own troops, fell on the Arabians who ſupported them, which occaſioned a great confuſion in that quarter. Thoſe in the Syrian army who were at a diſtance, hearing the noiſe and outcries, and not knowing the cauſe of them, were ſtruck with no ſmall terror. After this advantage, the Roman cavalry advanced, and fell on thoſe whom the chariots had put in diſorder. The Syrians being already intimidated, after a faint reſiſtance gave way; and the Romans made a great ſlaughter of their men and horſes, both being borne down with the weight of their heavy armour. Eumenes charged the left-wing, in which Seleucus commanded, with ſuch vigour, that he put it to flight; and the fugitives flying to the phalanx for protection, put that body likewiſe in diſorder: which Domitius obſerving, advanced againſt it at the head of his legionaries, but could not break it till he ordered his men to attack the elephants; which, as before obſerved, were placed in the ſpaces between the companies. The Romans had learned, in their wars with Pyrrhus and Hannibal, not to fear thoſe monſters which were once ſo terrible to them. They attacked them, therefore, with great reſolution; and driving them againſt the phalanx, put that body into diſorder, by means of thoſe very animals which had been placed there for its defence.

34 Gallant behaviour of Eumenes.

35 The Syrians defeated.

But in the mean time advice was brought that the left wing of the Romans was in great danger. Antiochus, who had obſerved that the flanks of the left wing were quite open and uncovered, the four ſquadrons which covered it having joined the reſt of the cavalry to fall upon the enemy's left wing, had charged it at the head of all his auxiliaries, not only in front but in flank. The Roman infantry, ſeeing themſelves in imminent danger of being ſurrounded and hemmed in on all ſides, fled in great diſorder to their camp, which was guarded by 2000 men under the command of a legionary tribune called *Æmilius*. This man ſeeing the Romans flying towards him, marched out at the head of all his troops to meet them; and after having bitterly reproached them for their cowardice and ignominious flight, ordered his men to draw their ſwords, and cut in pieces ſuch as ſhould advance one ſtep farther, or refuſe to face about againſt the enemy. This order, given ſo ſeaſonably, and put in execution without mercy againſt ſome, had the deſired effect. Thoſe who were flying firſt halted; and then, being both reinforced and encouraged by Æmilius, returned under his conduct to wipe off the diſhonour of their flight. At the ſame time Attalus the brother of Eumenes, having left the right wing on his receiving advice that the left was in danger, arrived very ſeaſonably with 200 horſe. Antiochus obſerving that the troops which had fled were returning to the battle, and that the enemy's right wing was ready to fall upon him, turned his horſe about and fled. This ſerved in a manner as a ſignal for the reſt of the troops, for the whole Syrian army immediately turned their backs. Eumenes alone purſued them at the head of the cavalry, and made a moſt dreadful havock of the fugitives. The Romans walking over heaps of dead bodies, eſpecially where the phalanx ſtood, marched up to the Syrian camp, attacked, and plundered it. The riches they found in it are not to be deſcribed: but the taking of it coſt the Romans a new battle, which proved more fatal to the Syrians than that in the field; for the Romans having, in ſpite of a moſt deſperate reſiſtance, forced the intrenchments, gave no quarter, but put all to the ſword without diſtinction. There fell this day in the battle, in the purſuit, and in the plunder of the camp, 50,000 foot and 4000 horſe; 1500 were taken priſoners, and 15 elephants. In the conſular army there were but 300 foot killed and 25 horſe. Eumenes had only 15 of his men killed; ſo that this victory, as we are told by the ancients, ſeemed a prodigy to all nations both of the eaſt and weſt.

Syria. 36 And then camp taken.

Antiochus retired to Sardis with as many of his forces that had eſcaped the ſlaughter as he could draw together. From Sardis he ſoon marched to rejoin his ſon Seleucus, who had fled to Apamea. As for the conſul, he took advantage of the king's defeat and flight, making himſelf maſter of all the neighbouring countries. Deputies haſtened to him from all parts; the cities of Thyatira, Magneſia, Trallis, Magneſia in Caria, all Lydia, and Epheſus itſelf, though highly favoured by Antiochus, declared for the Romans. Polyxenidas, upon the news of the king's defeat, left the port of Epheſus, and ſailed to Patara, where he landed with a very ſmall guard, and returned by land into Syria. The conſul took the road to Sardis, which opened its gates to him. As he ſtopped there, his brother Africanus, as ſoon as his health allowed him, came and joined him in that city, and congratulated him on the glory he had ſo lately acquired.

Antiochus finding his affairs in a bad ſituation both by ſea and land, and not daring to appear before the conſular army in the field, ſent Antipater his brother's ſon, and Zeuxis, who had been governor of Lydia and Phrygia, to ſue for a peace. They were ordered to treat chiefly with the elder brother, of whoſe clemency and good nature Antiochus entertained a high opinion. Accordingly, on their arrival at Sardis, where the conſul then was with his brother, they addreſſed the latter, and were by him preſented to the conſul. Their ſpeech was very ſubmiſſive, and ſuch as became a vanquiſhed people.

Hereupon a council was ſummoned, and after long debates the ambaſſadors were called in; and Scipio Africanus being deſired by the conſul to acquaint the deputies with the reſolutions of the aſſembly, is ſaid to have expreſſed himſelf in the following terms: "We are ſenſible that the victory which we have lately gained is owing to the gods, and therefore ſhall treat the vanquiſhed with moderation, demanding little more of them now than we did at our firſt entering into Aſia. Antiochus ſhall obtain a peace upon the following terms: That he give up his pretenſions to Europe, confine his dominions to Aſia beyond Mount Taurus; and that he pay 15,000 Euboec talents for the expences of the war; 500 down, 2500 when the ſenate and people ſhall confirm the articles, and 1000 more every year for 12 years together. We alſo inſiſt upon his ſatisfying king Eumenes, and his paying him the 400 talents he owes him, and what remains due for the corn which his father ſent to the king of Syria. It is likewiſe the pleaſure of the council that you deliver up to us Hannibal the Carthaginian, Thoas the Ætolian, Mneſilochus the Acarnanian, and Philo and Eubulus two Chalcidians; for theſe have been the authors of our diviſions, the incendiaries who kindled the preſent war. Laſtly, the king of Syria, for a further proof of his ſincerity, ſhall give us 20 ſuch hoſtages as we ſhall chooſe, of whom Antiochus his youngeſt ſon ſhall be one."

37 Antiochus obtains peace on very hard terms.

Syria.

The ambaſſadors of Antiochus had been ordered to refuſe no terms; and therefore theſe were accepted, and the whole affair concluded. So that the Syrian ambaſſadors now prepared to ſet out for Rome, to get the conditions of peace propoſed by Scipio ratified there. In the mean time, the conſul dividing his army into three bodies, put it into winter-quarters; one part continued at Magneſia, another was ſent to Trallis, and the third to Epheſus, where the Scipios took up their quarters. There they received a new embaſſy from Antiochus, with the hoſtages he had promiſed, the Roman priſoners and deſerters, and the ſtrangers which the conſul had demanded, except Hannibal, who after the king's defeat had fled out of his dominions; and Thoas the Ætolian, who, as ſoon as he heard that a treaty was on foot between Antiochus and the Romans, had returned to Ætolia, where a war was likely to break out between that republic and Rome. L. Aurelius Cotta was ſent with the ambaſſadors to Rome, to acquaint the ſenate with the particulars of the treaty. When they appeared before the conſcript fathers, they ſpoke with great ſubmiſſion, and only deſired them to ratify the articles which the Scipios had offered to their maſter. The ſenate, after examining them ordered that a treaty of peace ſhould be concluded with Antiochus, and the articles of it engraved on braſs, and fixed up in the Capitol. They only added one clauſe, which was, That the Syrians ſhould change every year all their hoſtages, except the ſon of king Antiochus, who ſhould continue at Rome as long as the republic thought fit. The peace being thus ratified, and all Aſia on this ſide Mount Taurus delivered into the hands of the Romans, the Greek cities were by them reſtored to their liberty, the provinces of Caria and Lydia given to the Rhodians, and all the reſt that had belonged to Antiochus beſtowed upon Eumenes.

38 His death.

Antiochus did not long ſurvive his misfortune at Magneſia. Some tell us, that being greatly puzzled how to raiſe the ſum he had engaged to pay to the Romans, he ſeized on the riches which had for many ages been depoſited in a temple of Jupiter Belus in the province of Elymais; upon which the populace roſe in arms, and ſlew him and all his attendants. Others inform us, that he was killed at an entertainment by one of his gueſts.

Antiochus the Great died in 187, and with him the glory of the Syrian empire. The Romans now gave laws to the kings of Syria, inſomuch, that when Antiochus Epiphanes the grandſon of Antiochus the Great heſitated at obeying the commands of the ſenate, one of the ambaſſadors drew a circle round him with a rod on the floor, and told him that he ſhould not go out of that ſpot before he had told him what he was to do. The moſt remarkable tranſactions of this prince are his wars with the Jews, and perſecutions of them; of which a full account is given under the article Jews. After a variety of uſurpers and tyrants, the kingdom of Syria fell under Tigranes king of Armenia in the year 83 B. C.; and upon his overthrow by the Romans, it became a province of the dominions of the republic. From them it was taken by the Saracens in the reign of the caliph Omar, and is now a province of Turkey in Aſia.

39 Syria becomes a Roman province.

40 Climate, ſoil, &c. of the country.

Syria is in ſome meaſure only a chain of mountains, varying in their levels, ſituation, and appearances. The part of the country, however, next the ſea is in general low, and beſides this there are ſeveral extenſive valleys. The climate on the ſea-coaſt and in theſe valleys is very hot, but in the higher parts of the country it bears a good deal of reſemblance to that of France. Syria is exceedingly fertile, and the variety of its productions is very great. Beſides wheat, rye, barley, beans, and the cotton plant, which is cultivated everywhere, Paleſtine abounds in ſeſamum, from which oil is procured, and doura as good as that of Egypt. Maize thrives in the light ſoil of Balbec, and even rice is cultivated with ſucceſs on the borders of the marſhy country of Havula. They have lately begun to plant ſugar-canes in the gardens of Saide and of Bairout, and they find them equal to thoſe of the Delta. Indigo grows without cultivating on the banks of the Jordan, in the country of Biſan, and only requires care to make it of an excellent quality. The hill-ſides of Latakia produce tobacco. Gaza produces dates like Mecca, and pomegranates like Algiers; Tripoli affords oranges equal to thoſe of Malta; Bairout figs like thoſe of Marſeilles, and bananas not inferior to thoſe of St Domingo; Aleppo enjoys the excluſive advantage of producing piſtachios; and Damaſcus juſtly boaſts of poſſeſſing all the fruits known in our provinces. Its ſtony ſoil ſuits equally the apples of Normandy, the plums of Touraine, and the peaches of Paris. Twenty ſorts of apricots are reckoned there, the ſtone of one of which contains a kernel highly valued through all Turkey. The cochineal plant, which grows on all that coaſt, contains perhaps that precious inſect in as high perfection as it is found in Mexico and St Domingo.

Syriac ‖ Syſtem.

Volney's Travels, vol. i.

The inhabitants may be divided into three principal claſſes: the deſcendants of the Greeks of the Lower Empire; the Arabs, their conquerors; and the Turks, the preſent ruling power: and theſe again, the firſt into three, the ſecond into four, claſſes; beſides three wandering tribes of Turkomen, Curds, and Bedouin Arabs. The ancient inhabitants before the Greeks under Alexander are entirely loſt. The inhabitants are in general of a middling ſtature, and the eyes of the women almoſt everywhere beautiful, and their ſhape correct and well proportioned. The general language is Arabic. Syriac is a dead language.

SYRINGA, the Lilac, in botany: A genus of plants belonging to the claſs of *diandria*, and order of *monogynia*; and in the natural ſyſtem ranging under the 44th order, *Sepiariæ*. The corolla is quadrifid, and the capſule is bilocular. There are three ſpecies, the vulgaris, perſica, and ſuſpenſa. The two firſt are natives of Perſia, and the laſt of Japan.—The *vulgaris*, which is diſtinguiſhed by ovate heart-ſhaped leaves, was cultivated in Britain about the year 1597 by Mr John Gerard.—The *perſica*, which has lanceolate leaves, was cultivated in 1658; but how long both ſpecies might have been introduced into Britain before theſe dates, it is perhaps impoſſible to aſcertain.

SYRINGE, a well-known inſtrument, ſerving to imbibe or ſuck in a quantity of fluid, and to ſquirt or expel the ſame with violence. The word is formed from the Greek συριγξ, or the Latin *ſyrinx* "a pipe,"—A ſyringe is only a ſingle pump, and the water aſcends in it on the ſame principle as in the common ſucking-pump. See Hydrostatics, n° 25, *et ſeq.*

SYRUP, in pharmacy, a ſaturated ſolution of ſugar, made in vegetable decoctions or infuſions. See Pharmacy, ch. xxiii.

SYSTEM, in general, denotes an aſſemblage or chain of principles or concluſions, or the whole of any doctrine, the ſeveral parts whereof are bound together, and follow or depend on each other; in which ſenſe we ſay a *ſyſtem of philoſophy*, a *ſyſtem of divinity*, &c. The word is formed from the Greek συστημα "compoſition, compages."

System, in the animal economy, the *vaſcular*, the *nervous*, and the *cellular*. See Anatomy.

System, in muſic, an aſſemblage of the rules for harmony, deduced from ſome common principle by which they are reunited; by which their connection one with another is formed; from whence, as from their genuine ſource, they natively flow; and to which, if we would account for them, we muſt have recourſe. See the articles Chromatic, Diatonic,

System || Systyle.

TONIC, ENHARMONIC, HARMONY, INTERVAL, and MUSIC.

SYSTEM, in botany. See BOTANY, page 430.

SYSTEM, in aſtronomy. See ASTRONOMY.

SYSTOLE, in anatomy, the contraction of the heart, whereby the blood is drawn off its ventricles into the arteries; the oppoſite ſtate to which is called the *diaſtole*, or *dilatation of the heart*. See ANATOMY, n° 124.

SYSTYLE, in architecture, that manner of placing columns where the ſpace between the two ſhafts conſiſts of two diameters or four modules. Syzygy.

SYZYGY, SYZYGIA, in aſtronomy, a term equally uſed for the conjunction and oppoſition of a planet with the ſun. The word is formed from the Greek συζυγια, which properly ſignifies *conjunctio*. On the phenomena and circumſtances of the ſyzygies a great part of the lunar theory depends. See ASTRONOMY.

T.

T. Tabanus.

T or t, the 19th letter and 16th conſonant of our alphabet; the ſound whereof is formed by a ſtrong expulſion of the breath through the mouth, upon a ſudden drawing back of the tongue from the fore part of the palate, with the lips at the ſame time open. The proper ſound of *t* is expreſſed in moſt words beginning or ending with that letter; as in *take, tell, hot, put*. *Ti* before a vowel has the ſound of *ſi*, or rather of *ſhi*, as in *creation*, except when *ſ* precedes, as in *queſtion*; and in derivatives from words ending in *ty*, as, *mighty, mightier*. *Th* has two ſounds; the one ſoft, as *thou, father*; the other hard, as *thing, think*. The ſound is ſoft in theſe words, *then, thence*, and *there*, with their derivatives and compounds; and in the words *that, this, thus, thy, they, though*; and in all words in which *th* comes between two vowels, as, *whether, rather*; and between *r* and a vowel, as *burthen*.

In abbreviations, amongſt the Roman writers, T. ſtands for *Titus, Titius*, &c.; Tab. for *Tabularius*; Tab. P. H. C. *Tabularius Provinciæ Hiſpaniæ Citerioris*; Tar. *Tarquinius*; Ti. *Tiberius*; Ti. F. *Tiberii filius*; Ti. L. *Tiberii libertus*; Ti. N. *Tiberii Nepos*; T. J. A. V. P. V. D. *tempore judicem arbitrumve poſtulat ut det*; T. M. P. *terminum poſuit*; T. M. D. D. *terminum dedicavit*; Tr. *trans, tribunus*; Tr. M. or Mil. *tribunus militum*; TR. PL. DES. *tribunus plebis deſignatus*; TR. AER. *tribunus ærarii*; TRV. CAP. *triumviri capitales*; T. P. or TRIB. POT. *tribunicia poteſtate*; Tul. H. *Tullus Hoſtilius*.

Amongſt the ancients, T, as a numeral, ſtood for *one hundred and ſixty*; and with a daſh at top, thus, $\overline{T}$, it ſignified *one hundred and ſixty thouſand*. In muſic, T ſtands for *tutti*, "all, or altogether."

TABANUS, the BREEZE-FLY: a genus of inſects belonging to the order of *diptera*. The mouth is extended in a fleſhy proboſcis, terminated by two lips. The roſtrum is furniſhed with two pointed palpi placed on each ſide of the proboſcis, and parallel to it. Gmelin has enumerated 38 ſpecies; of which three only are found in Great Britain, the bovinus, pluviatilis, and cœcutiens.

1. The *bovinus*, or great horſe fly, has a grey head; the eyes almoſt of a black brown, occupying the greateſt part of it. The thorax is of a grey colour; the abdomen is yellowiſh, with a triangular white ſpot on the middle of every ring, which conſtitutes a longitudinal band of ſpots, the point of which is directed towards the thorax. The thighs are blackiſh, and the legs yellow. The wings are ſomewhat duſky, with brown veins of a deeper dye. This inſect is the terror of horned cattle, horſes, &c. Its mouth is armed with two ſharp hooks which penetrate their hide; while with its proboſcis, which is ſhaped like a ſting, it ſucks their blood, of which it is very greedy. The puncture of the tabanus is keen and painful. The inſect is very common in damp woods and meadows, eſpecially during the great heats, when it is moſt troubleſome. The horned cattle are ſometimes ſo moleſted by their ſtings, that they go mad, run down precipices, tear themſelves on the ſtumps of trees, ſtones, &c. Tabarca, Tabaſheer.

2. The *pluviatilis* is of an aſhen grey colour; its eyes are green, with brown ſtreaks. The thorax is brown, marked with about ſeven longitudinal grey lines; the wings, which are brown and aſh-coloured, are dotted over with ſmall white ſpots, and have a black ſpot on the margin; the legs are ſurrounded with brown and white rings alternately. This ſpecies is very common in meadows, and is about four lines in length.

3. The *cœcutiens* has a brown head; eyes green and brown, with black ſpots; the thorax brown with black ſpots; the abdomen above, yellow with triangular brown ſpots; yellow legs, and white wings with black and brown ſpots. The length is four lines and a half.

TABARCA, a little iſland lying oppoſite to a ſmall town of that name, which divides the maritime coaſts of Tunis and Algiers, in Africa, two miles from the land, in poſſeſſion of the noble family of the Lamellini of Genoa, who have here a governor and a garriſon of 200 men to protect the coral fiſhery. N. L. 36. 56. E. Long. 9. 16.

TABASHEER, a Perſian word, ſignifying a hard ſubſtance found in the cavities of the bamboo or Indian reed, and highly valued as a medicine in the Eaſt Indies. Though ſome account was given of the tabaſheer by the Arabian phyſicians, no accurate knowledge of it was obtained till Dr Ruſſel favoured the public with his obſervations on it.

According to this gentleman's information, the tabaſheer is produced from the female bamboo, which is diſtinguiſhed from the male by the largeneſs of its cavity. It is eaſy to diſcover, without opening them, what bamboos contain it, as they make a rattling noiſe when ſhaken. Dr Ruſſel having examined a bamboo brought from Vellore, conſiſting of ſix joints, found no appearance of tabaſheer in two of them: all the reſt contained ſome, but of various quality and quantity; the whole amounting to about 27 grains. The beſt was of a bluiſh white reſembling ſmall fragments of ſhells, harder alſo than the reſt, but which might be eaſily crumbled between the fingers into a gritty powder; and when applied to the tongue and palate, had a ſlight ſaline and teſtaceous taſte; the weight not exceeding four grains. The colour of the reſt was cineritious, rough on the ſurface, and more friable; having ſome particles of a larger ſize intermixed, but light, ſpongy, and ſomewhat reſembling pumice ſtones; which appearance our author ſuppoſes, led the Arabians to think that fire was concerned in the production. The two middle joints were of a pure white colour within, and lined with a thin film. In theſe the tabaſheer was principally found. The other joints, particularly the two upper ones, were diſcoloured within; and in ſome parts of the cavity was found a blackiſh ſubſtance in grains or in powder, adhering to the ſides, the film being there obliterated.

Tabaſheer ‖ Tabernacle.

In two or three of the joints a ſmall round hole was found at top and bottom, which ſeemed to have been perforated by ſome inſect.

Garzius informs us, that it is not found in all bamboos, nor in all the branches indiſcriminately, but only in thoſe growing about Biſnagur, Batecala, and one part of the Malabar coaſt. Dr Ruſſel was informed by a letter from a medical gentleman attending the embaſſy to the Nizam, that though Tabaſheer bears a high price at Hydrabad, it is never brought thither from Biſnagur; and that ſome of what is ſold in the markets comes from the paſs of Atcour in Canoul; and ſome from Emnabad, at the diſtance of about 80 miles to the north weſt; but that the moſt part comes from Maſulipatam. That ſold in the markets is of two kinds; one at the rate of a rupee *per* dram, but the other only half that price; the latter, however, is ſuppoſed to be factitious, and made up moſtly of burnt teeth and bones. Dr Ruſſel himſelf alſo, is perſuaded that the Tabaſheer met with in commerce is greatly adulterated. The above-mentioned gentleman likewiſe informed the doctor that tabaſheer was produced in great quantities at Sylhat, where it is ſold by the pound, from one rupee to one and an half; forming a conſiderable article of trade from Bengal to Perſia and Arabia. There is, however, a third kind, much ſuperior to either of the two above deſcribed; differing not only in its ſuperior whiteneſs, but likewiſe in being much leſs mixed with heterogeneous particles; being likewiſe much harder, heavier, and ſcarcely in any degree friable by the finger.

From the experiments of Dr Ruſſel, it appears that the tabaſheer is the juice of the bamboo thickened and hardened to a certain degree. Its chemical qualities, as far as we have heard, have not yet been minutely examined. The following obſervations on its medical effects were taken from a Perſian work, intitled the "Tofut ul Monein of Mahommed Monein Hoſeiny," by Mr Williams, a ſurgeon in the ſervice of the Eaſt India company. The tabaſheer puts a ſtop to bilious vomitings and to the bloody flux. It is alſo of ſervice in caſes of palpitation of the heart, in faintings, and for ſtrengthening thoſe members of the body that are weakened by heat. It is uſeful alſo for the piles, and for acute or burning fevers, and for puſtules in the mouth (thruſh); and, given with oxymel, is of ſervice againſt reſtleſſneſs, melancholy, and hypochondriacal affections. The habitual internal uſe of it is prejudicial to the virile powers. It is alſo ſaid to be prejudicial to the lungs. Its correctives are the gum of the pine and honey. The doſe of it is to the weight of two d'herems, or ſeven maſhás.

TABBY, in commerce, a kind of rich ſilk which has undergone the operation of tabbying.

TABBYING, the paſſing a ſilk or ſtuff under a calendar, the rolls of which are made of iron or copper variouſly engraven, which bearing unequally on the ſtuff renders the ſurface thereof unequal, ſo as to reflect the rays of light differently, making the repreſentation of waves thereon.

TABELLIO, in the Roman law, an officer or ſcrivener, much the ſame with our notaries-public, who are often called *tabelliones*.

TABERNACLE, among the Hebrews, a kind of building, in the form of a tent, ſet up, by expreſs command of God, for the performance of religious worſhip, ſacrifices, &c. during the journeying of the Iſraelites in the wilderneſs; and, after their ſettlement in the land of Canaan, made uſe of for the ſame purpoſe till the building of the temple of Jeruſalem. It was divided into two parts; the one covered, and properly called the *tabernacle*; and the other open, called the *court*. The curtains which covered the tabernacle were made of linen, of ſeveral colours, embroidered. There were ten curtains, twenty eight cubits long and four in breadth. Five curtains faſtened together made up two coverings, which covered up all the tabernacle. Over theſe there were two other coverings; the one of goat's hair, the other of ſheep's ſkins. The holy of holies was parted from the reſt of the tabernacle by a curtain made faſt to four pillars, ſtanding ten cubits from the end. The length of the whole tabernacle was 32 cubits, that is, about 50 feet; and the breadth 12 cubits, or 19 feet. The court was a ſpot of ground 100 cubits long, and 50 in breadth, encloſed by 20 columns, each 20 cubits high and 10 in breadth, covered with ſilver, and ſtanding on copper baſes, five cubits diſtant from one another; between which there were curtains drawn, and faſtened with hooks. At the eaſt end was an entrance, 20 cubits wide, covered with a curtain hanging looſe. Taberna. ‖ Table.

Feaſt of TABERNACLES, a ſolemn feſtival of the Hebrews, obſerved after harveſt, on the 15th day of the month Tiſri, inſtituted to commemorate the goodneſs of God, who protected the Iſraelites in the wilderneſs, and made them dwell in booths, when they came out of Egypt. On the firſt day of the feaſt, they began to erect booths of the boughs of trees, and in theſe they were obliged to continue ſeven days. The booths were placed in the open air, and were not to be covered with cloths, nor made too cloſe by the thickneſs of the boughs; but ſo looſe that the ſun and the ſtars might be ſeen, and the rain deſcend through them. For further particulars of the celebration of this feſtival, ſee LEVIT. ch. xxiii.

TABERNÆ (anc. geog.) See *Tres Tabernæ*.

TABERNÆMONTANA, in botany: A genus of plants belonging to the claſs of *pentandria*, and order of *monogynia*; and in the natural ſyſtem arranged under the 30th order, *Contortæ*. There are two horizontal follioles, and the ſeeds are immerſed in pulp. There are eight ſpecies, all of foreign growth.

TABLE, a moveable piece of furniture, uſually made of wood or ſtone, and ſupported on pillars or the like, for the commodious reception of things placed thereon.

TABLE is alſo uſed for the fare or entertainment ſerved up.

TABLE, in mathematics, ſyſtems of numbers calculated to be ready at hand for the expediting aſtronomical, geometrical, and other operations.

Table-Book. See WRITING.

Table-Mountain, a mountain of Africa, being the moſt weſterly cape or promontory in that part of the world, and near the Cape of Good Hope. The bay which is formed thereby is called the *Table-bay*.

Laws of the Twelve TABLES, were the firſt ſet of laws of the Romans; thus called either becauſe the Romans then wrote with a ſtyle on thin wooden tablets covered with wax; or rather, becauſe they were engraved on tables or plates of copper, to be expoſed in the moſt noted part of the public forum. After the expulſion of the kings, as the Romans were then without any fixed or certain ſyſtem of law, at leaſt had none ample enough to take in the various caſes that might fall between particular perſons, it was reſolved to adopt the beſt and wiſeſt laws of the Greeks. One Hermodorus was firſt appointed to tranſlate them, and the decemviri afterwards compiled and reduced them into ten tables. After a world of care and application, they were at length enacted and confirmed by the ſenate and an aſſembly of the people, in the year of Rome 303. The following year they found ſomething wanting therein, which they ſupplied from the laws of the former kings of Rome, and from certain cuſtoms which long uſe had authoriſed: all theſe being engraven on two other tables, made the law of the twelve tables, ſo famous in the Roman juriſprudence, the ſource and foundation of the civil or Roman law.

Taboo || Tacamahaca.

Tables of the Law, in Jewiſh antiquity, two tables on which were written the decalogue, or ten commandments, given by God to Moſes on mount Sinai.

TABOO, a word uſed by the South Sea iſlanders, nearly of the ſame import as prohibited or interdicted. It applies equally to perſons and things, and is alſo expreſſive of any thing ſacred, devoted, or eminent.

TABOR, a mountain of Galilee, about 12 miles from the city of Tiberias. It riſes in the form of a ſugar-loaf, in the midſt of an extenſive plain, to the height of 30 ſtadia, according to Joſephus. The aſcent is ſo eaſy, that one may aſcend on horſeback. On the top there is a plain two miles in circumference.

The ſituation of Mount Tabor is moſt delightful. Riſing amidſt the plains of Galilee, it exhibits to the enchanted eye a charming variety of proſpects. On one ſide there are lakes, rivers, and a part of the Mediterranean; and on the other a chain of little hills, with ſmall valleys, ſhaded by natural groves, and enriched by the hands of the huſbandmen with a great number of uſeful productions. Here you behold an immenſity of plains interſperſed with hamlets, fortreſſes, and heaps of ruins; and there the eye delights to wander over the fields of Jezrael or Mageddon, named by the Arabs *Ebn Aamer*, which ſignifies "the field of the ſons of Aamer." A little farther you diſtinguiſh the mountains of Hermon, Gilboa, Samaria, and Arabia the Stony. In ſhort, you experience all thoſe ſenſations which are produced by a mixture and rapid ſucceſſion of rural, gay, gloomy, and majeſtic objects.

Mariti's Travels, vol. ii.

It was upon this enchanting mount that the apoſtle Peter ſaid to Chriſt, "It is good for us to be here: and let us make three tabernacles; one for thee, and one for Moſes, and one for Elias."

Flavian Joſephus, governor of Galilee, cauſed the ſummit of this mountain, for the ſpace of two miles and a half, to be ſurrounded with walls. The inhabitants of Tabor long braved the power of the Roman armies; but being deprived of water in conſequence of the great heats, they were forced to ſurrender at diſcretion to Placidus, the general of Veſpaſian.

Several churches were built upon this mountain by St Helen, who founded here alſo ſome monaſteries. Of the two moſt remarkable, one was dedicated to Moſes, and inhabited by Cenobites of the order of St Benedict, who followed the Latin rites: the other was dedicated to the prophet Elias by monks of the order of St Baſil, attached to the Greek rites. The kings of Hungary erected here alſo a pretty ſpacious convent for ſome monks belonging to that nation, of the order of St Paul the firſt hermit. Tabor was alſo the ſeat of a biſhop, dependant on the patriarchate of Jeruſalem.

When Godfrey of Bouillon ſeized on this mountain, he repaired the ancient churches, which were beginning to fall into ruins. Under Baldwin I. in 1113, the Saracen troops retook Tabor; and their ſanguinary fury gained as many victories as there were prieſts and Cenobites. This mountain again fell into the hands of the Chriſtians; but the Catholic ſtandard was not long diſplayed on it. Saladin pulled it down the year following, and deſtroyed all the churches. The Chriſtians retook it once more in 1253; and their zeal made them rebuild all the ſacred places. At this time Rome being accuſtomed to give away empires, Pope Alexander IV. granted Tabor to the Templars, who fortified it again. At length, in the courſe of the year 1290, the ſultan of Egypt deſtroyed and laid waſte the buildings of this mountain, which could never be repaired afterwards; ſo that at preſent it is uninhabited.

TACAMAHACA, in pharmacy, a ſolid reſin, improperly called a *gum* in the ſhops. It exudes from a ſpecies of poplar; and is in repute for mitigating pain and aches, and is alſo reckoned a vulnerary.

Tacca. Tacitus.

TACCA, in botany: A genus of plants belonging to the claſs of *dodecandria*, and order of *trigynia*. The flower is above. The corolla has ſix petals, and is vaulted. The calyx is hexaphyllous; the fruit a dry, angular, three-celled berry. There is only one ſpecies known, the pinnatifida.

TACITUS (Caius Cornelius), a celebrated Roman hiſtorian, and one of the greateſt men of his time, appears to have been born about the year of Rome 809 or 810, and applied himſelf early to the labours of the bar, in which he gained very conſiderable reputation. Having married the daughter of Agricola, the road to public honours was laid open to him in the reign of Veſpaſian; but during the ſanguinary and capricious tyranny of Domitian, he, as well as his friend Pliny, appears to have retired from the theatre of public affairs. The reign of Nerva reſtored theſe luminaries of Roman literature to the metropolis, and we find Tacitus engaged, in the year 850, to pronounce the funeral oration of the venerable Virginius Rufus, the colleague of the emperor in the conſulſhip, and afterwards ſucceeding him as conſul for the remainder of the year.

Murphy's Tranſlation of Tacitus.

The time of his death is not mentioned by any ancient author, but it is probable that he died in the reign of Trajan.

His works which ſtill remain are, 1. Five books of his Hiſtory. 2. His Annals. 3. A Treatiſe on the different Nations which in his time inhabited Germany: and, 4. The Life of Agricola his father-in-law. There is alſo attributed to him a Treatiſe on Eloquence, which others have aſcribed to Quintilian. The Treatiſe on the Manners of the Germans was publiſhed in 851.—In the year 853, Pliny and Tacitus were appointed by the ſenate to plead the cauſe of the oppreſſed Africans againſt Marius Priſcus, a corrupt proconſul, who was convicted before the fathers; and the patriot orators were honoured with a declaration that they had executed their truſt to the entire ſatisfaction of the houſe. The exact time when Tacitus publiſhed his hiſtory is uncertain, but it was in ſome period of Trajan's reign, who died ſuddenly, A. U. C. 870, A. D. 117.—The hiſtory compriſes a period of 27 years, from the acceſſion of Galba, 822, to the death Domitian, 849. The hiſtory being finiſhed, he did not think he had completed the tableature of ſlavery; he went back to the time of Tiberius: and the ſecond work, which, however, comes firſt in the order of chronology, includes a period of 54 years, from the acceſſion of Tiberius, 767, to the death of Nero, 821: this work is his "Annals."

It is remarkable, that princes and politicians have always held the works of Tacitus in the higheſt eſteem; which look as if they either found their account in reading them, or where pleaſed to find courts, and the people who live in them, ſo exactly deſcribed after the life as they are in his writings. Part of what is extant was found in Germany by a receiver of Pope Leo X. and publiſhed by Beroaldus at Rome in 1515. Leo was ſo much charmed with Tacitus, that he gave the receiver a reward of 500 crowns; and promiſed not only indulgences, but money alſo and honour, to any one who ſhould find the other part; which it is ſaid was afterwards brought to him. Pope Paul III. as Muretus relates, wore out his Tacitus by much reading it; and Coſmo de Medicis, who was the firſt great duke of Tuſcany, and formed for governing, accounted the reading of him his greateſt pleaſure. Muretus adds, that ſeveral princes, and privy-counſellors to princes, read him with great application, and regarded him as a ſort of oracle in politics. A certain author relates, that Queen Chriſtina of Sweden,

Biographical Dictionary.

Tacitus. Sweden, though extremely fond of the Greek tongue, which she made "the diversion of her leisure hours, was not restrained by that from her serious studies; so she called among others Tacitus's History, some pages of which she read constantly every day." Lastly, the late Lord Bolingbroke, an authority surely of no mean rank, calls him, "a favourite author," and gives him manifestly the preference to all the Greek and Roman historians.

Baillet Vie de Des Cartes, tom. ii.

Study of History, letter v.

No author has obtained a more splendid reputation than Tacitus. He has been accounted, and with good reason, the most cultivated genius of antiquity; and we must not seek for his parallel in modern times. It is impossible not to admire and recommend his intimate knowledge of the human heart, the spirit of liberty which he breathes, and the force and vivacity with which he perpetually expresses himself. The reader of taste is struck by the greatness of his thoughts and the dignity of his narration; the philosopher by the comprehensive powers of his mind; and the politician by the sagacity with which he unfolds the springs of the most secret transactions. Civil liberty and the rights of mankind never met with a bolder or a more able asserter: servitude, debasement, and tyranny, appear not in the writings of any other author in juster or more odious colours. He has been censured as obscure; and indeed nothing can be more certain than that he did not write for the common mass of men. But to those who are judges of his compositions, it is no matter of regret that his manner is his own, and peculiar. Never were description and sentiment so wonderfully and so beautifully blended; and never were the actions and characters of men delineated with so much strength and precision. He has all the merits of other historians, without their defects. He possesses the distinctness of Xenophon without his uniformity; he is more eloquent than Livy, and is free from his superstition; and he has more knowledge and judgment than Polybius, without his affectation of reasoning on every occasion.

One of the best editions of the works of Tacitus was published at Paris by Brotier, in 4 vols. 4to. There have been four translations of his works into English; the first by Greenway and Sir Henry Saville, in the reign of Elizabeth; the second by Dryden and others; the third by Gordon, which is remarkable for affectation of style, though some think it bears a striking resemblance to the original: and the fourth and best by Murphy, in 1793, in 4 vols 4to.

Tack ‖ Tactics.

TACK, a rope used to confine the foremost lower corners of the courses and stay-sails in a fixed position, when the wind crosses the ship's course obliquely. The same name is also given to the rope employed to pull out the lower corner of a studding-sail or driver to the extremity of its boom.

The main-sail and fore-sail of a ship are furnished with a tack on each side, which is formed of a thick rope tapering to the end, and having a knot wrought upon the largest end, by which it is firmly retained in the clue of the sail. By this means one tack is always fastened to windward, at the same time that the sheet extends the sail to the leeward.

Tack, is also applied, by analogy, to that part of any sail to which the tack is usually fastened.

A ship is said to be on the starboard or larboard tack, when she is close-hauled, with the wind upon the starboard or larboard side; and in this sense the distance which she sails in that position is considered as the length of the tack; although this is more frequently called *board*. See that article.

To Tack, to change the course from one board to another, or turn the ship about from the starboard to the larboard tack, in a contrary wind. Thus a ship being close-hauled on the larboard tack, and turning her prow suddenly to windward, receives the impression of the wind on her head-sails, by which she falls off upon the line of the starboard-tack. Tacking is also used in a more enlarged sense, to imply that manœuvre in navigation by which a ship makes an oblique progression to the windward, in a zig-zag direction. This, however, is more usually called *beating*, or *turning to windward*. See Navigation, Sailing, and *Naval Tactics*.

Falconer's Marine Dictionary.

Tack, in Scots law. See Law, n° clxvii.

TACKLE, among seamen, denotes all the ropes or cordage of a ship used in managing the sails, &c.

TACKSMAN. See Tenure.

TACTICS, in the art of war, is the method of disposing forces to the best advantage in order of battle, and of performing the several military motions and evolutions. See War.

Naval TACTICS;

Or, The Military Operations of Fleets.

1 Definition. Naval tactics is the art of ranging fleets in such order or disposition, as may be judged most convenient, either for attacking, defending, or retreating, to the greatest advantage; and to regulate their several movements accordingly. It is not a science established on principles absolutely invariable, but founded on such reasons as the alteration and improvement of arms must necessarily occasion in a course of time and experience; from which also will naturally result a difference in the construction of ships, in the manner of working them, and, in fine, in the total disposition and regulation of fleets and squadrons. We shall cursorily run through this succession and change of arms, &c. to the present improvement of our lines of battle, in order to make us the more sensible of the reasons which have induced the moderns to prefer so advantageous a choice as they now follow in the arrangement of their ships.

2 History. The ancient galleys were so constructed as to carry several banks of oars, very differently disposed from those in our modern galleys, which, however, vary the least of any others from their ancient model. Advanced by the force of their oars, the galleys ran violently aboard of each other, and by the mutual encounter of their beaks and prows, and sometimes of their sterns, endeavoured to dash in pieces, or sink their enemies.

The prow, for this purpose, was commonly armed with a brazen point or trident, nearly as low as the surface of the sea, in order to pierce the enemy's ships under the water. Some of the galleys were furnished with large turrets, and other accessions of building, either for attack or defence. The soldiers also annoyed their enemies with darts and slings, and, on their nearer approach, with swords and javelins; and in order that their missive weapons might be directed with greater force and certainty, the ships were equipped with several platforms, or elevations above the level of the deck. The sides of the ship were fortified with a thick fence of hides, which served to repel the darts of their adversaries, and to cover their own soldiers, who thereby annoyed the enemy with greater security.

As the invention of gunpowder has rendered useless many of the machines employed in the naval wars of the ancients, the great distance of time has also consigned many of them to oblivion: some few are, nevertheless, recorded in ancient authors,

History. authors, of which we ſhall endeavour to preſent a ſhort deſcription. And firſt,

The Δελφιν was a large and maſſy piece of lead or iron, caſt in the form of a dolphin. This machine being ſuſpended by blocks at their maſt-heads or yard-arms, ready for a proper occaſion, was let down violently from thence into the adverſe ſhips; and either penetrated through their bottom, and opened a paſſage for the entering waters, or by its weight immediately ſunk the veſſel.

The Δρεπανον was an engine of iron crooked like a ſickle, and fixed on the top of a long pole. It was employed to cut aſunder the ſlings of the ſail-yards, and, thereby letting the ſails fall down, to diſable the veſſel from eſcaping, and incommode her greatly during the action. Similar to this was another inſtrument, armed at the head with a broad two-edged blade of iron, wherewith they uſually cut away the ropes that faſtened the rudder to the veſſel.

Δορατα ναυμαχα, a ſort of ſpears or maces of an extraordinary length, ſometimes exceeding 20 cubits, as appears by the 15th Iliad of Homer, by whom they are alſo called μακρα.

Κριαι were certain machines uſed to throw large ſtones into the enemy's ſhips.

Vegetius mentions another engine which was ſuſpended to the main-maſt, and reſembled a battering-ram; for it conſiſted of a long beam and an head of iron, and was with great violence puſhed againſt the ſides of the enemy's galleys.

They had alſo a grappling-iron, which was uſually thrown into the adverſe ſhip by means of an engine: this inſtrument facilitated the entrance of the ſoldiers appointed to board, which was done by means of wooden bridges, that were generally kept ready for this purpoſe in the fore-part of the veſſel. See the article CORVUS.

The arms uſed by the ancients rendered the diſpoſition of their fleets very different, according to the time, place, and circumſtances of the engagement. They generally conſidered it an advantage to be to windward, and to have the ſun ſhining directly on the front of their enemy. The order of battle chiefly depended on their power of managing the ſhips, or of drawing them readily into form; and on the ſchemes which their officers had concerted. The fleet being compoſed of rowing veſſels, they lowered their ſails previous to the action; they preſented their prows to the enemy, and advanced againſt each other by the force of their oars. Before they joined battle, the admirals went from ſhip to ſhip, and exhorted their ſoldiers to behave gallantly. All things being in readineſs, the ſignal was diſplayed by hanging out of the admiral's galley a gilded ſhield, or a red garment or banner. During the elevation of this, the action continued; and by its depreſſion, or inclination towards the right or left, the reſt of the ſhips were directed how to attack or retreat from their enemies. To this was added the ſound of trumpets; which began in the admiral's galley, and continued round the whole fleet. The fight was alſo begun by the admiral's galley, by grappling, boarding, and endeavouring to overſet, ſink, or deſtroy the adverſary, as we have above deſcribed. Sometimes, for want of grappling irons, they fixed their oars in ſuch a manner as to hinder the enemy from retreating. If they could not manage their oars as dexterouſly as their antagoniſt, or fall alongſide ſo as to board him, they penetrated his veſſel with the brazen prow. The veſſels approached each other as well as their circumſtances would permit, and the ſoldiers were obliged to fight hand to hand till the battle was decided: nor indeed could they fight otherwiſe with any certainty, ſince the ſhorteſt diſtance rendered their ſlings and arrows, and almoſt all their offenſive weapons, ineffectual, if not uſeleſs. The ſquadrons were ſometimes ranged in two or three right lines, parallel to each other; being ſeldom drawn up in one line, unleſs when formed into an half-moon. This order indeed appears to be the moſt convenient for rowing veſſels, that engage by advancing with their prows towards the enemy. At the battle of Ecnomus, between the Romans and the Carthaginians, the fleet of the former was ranged into a triangle, or a ſort of wedge in front, and towards the middle of its depth of two right parallel lines. That of the latter was formed into a rectangle, or two ſides of a ſquare, of which one branch extended behind, and as the opening of the other profecuted the attack, was ready to fall upon the flank of ſuch of the Roman galleys as ſhould attempt to break their line. Ancient hiſtory has preſerved many of theſe orders, of which ſome have been followed in later times. Thus in a battle A. D. 1340, the Engliſh fleet was formed in two lines, the firſt of which contained the larger ſhips, the ſecond conſiſted of all the ſmaller veſſels, uſed as a reſerve to ſupport the former whenever neceſſary. In 1545, the French fleet under the command of the Mareſchal d'Annebault, in a engagement with the Engliſh in the Channel, was arranged in the form of a creſcent. The whole of it was divided into three bodies, the centre being compoſed of 36 ſhips, and each of the wings of 30. He had alſo many galleys; but theſe fell not into the line, being deſigned to attack the enemy occaſionally. This laſt diſpoſition was continued down to the reigns of James I. and Louis XIII.

History.

Meanwhile, the invention of gunpowder in 1330 gradually introduced the uſe of fire-arms into naval war, without finally ſuperſeding the ancient method of engagement. The Spaniards were armed with cannon in a ſea-fight againſt the Engliſh and the people of Poitou abreaſt of Rochelle in 1372; and this battle is the firſt wherein mention is made of artillery in our navies. Many years elapſed before the marine armaments were ſufficiently provided with fire-arms. So great a revolution in the manner of fighting, and which neceſſarily introduced a total change in the conſtruction of ſhips, could not be ſuddenly effected. In ſhort, the ſquadrons of men of war are no longer formed of rowing veſſels, or compoſed of galleys and ſhips of the line; but entirely of the latter, which engage under ſail, and diſcharge the whole force of their artillery from their ſides. Accordingly, they are now diſpoſed in no other form than that of a right line parallel to the enemy; every ſhip keeping cloſe-hauled upon a wind on the ſame tack. Indeed the difference between the force and manner of fighting of ſhips and galleys, rendered their ſervice in the ſame line incompatible. When we conſider therefore the change introduced, both in the conſtruction and working of the ſhips, occaſioned by the uſe of cannon, it neceſſarily follows, that ſquadrons of men of war muſt appear in the order that is now generally adopted.

The machines which owe their riſe to the invention of gunpowder have now totally ſupplanted the others; ſo that there is ſcarce any but the ſword remaining, of all the weapons uſed by the ancients. Our naval battles are therefore almoſt always decided by fire-arms, of which there are ſeveral kinds, known by the general name of *artillery*. In a ſhip of war, fire-arms are diſtinguiſhed into cannon mounted on carriages, ſwivel-cannon, grenadoes, and muſquetry. See CANNON, &c. Beſides theſe machines, there are ſeveral others uſed in merchant ſhips and privateers, as cohorns, carabines, fire-arrows, organs, ſtink pots, &c.

The writers on naval tactics have been but few, indeed, conſidering the importance of the ſubject; and the only countries that have produced writers on this ſubject, ſo far as we know, are France and Britain, particularly the firſt. One would be led to imagine that Britain, from its inſular ſituation, having bred ſo great a number of excellent ſeamen,

and

History. and having so often been engaged in naval contests, would naturally have produced a number of writers on this, as well as on subjects of much less consequence to it as a nation. The reader will, however, no doubt be surprised to hear, that we have only one scientific treatise on naval tactics, intitled *An Essay on Naval Tactics, &c.* by John Clerk, Esq; of Elden, near Edinburgh; and all the other treatises published in Britain on this subject being either translations from the French, or remarks upon the French authors (A). Some of the principal French treatises on naval tactics are the following: 1. *L'Art des Armées Navales, ou Traité des Evolutions Navales*, par Paul L'Hoste, 1 vol. folio, printed at Lyons 1727. This book was translated and published by Christopher O'Bryen, Esq; in 4to, in 1762. 2. *Tactique Navale, ou Traité des Evolutions et des Signaux*, par M. le Viscompte de Morogues, 4to, Paris 1763. 3. *Le Manœuvrier*, par M. Bourdé de Villehuet. 4. *L'Art de Guerre en Mer, ou Tactique Navale, &c.* par M. le Viscompte de Grenier. Translations of the two last have appeared in English in 4to in 1788, under the name of the *Chevalier de Saufeuil*; and a translation of parts of the three last is in the 2d vol. of the Elements and Practice of Rigging and Seamanship, published at London in 1794. Other books on evolutions and tactics are, *Théorie de la Manœuvre des Vaisseaux*, Paris, 1689. *Pitot's Theory of Working Ships applied to Practice* &c. translated by Stone, 1743. *De la Manœuvre des Vaisseaux, ou Traité de Mechanique et de Dynamique, &c.* par M. Bouguer. *The British Mars*, &c. by William Flexney, 1763. *A Sea Manual*, by Sir Alexander Schomberg, 1789. *A View of the Naval Force of Great Britain*, &c. by an Officer of Rank, 1791, &c. History.

We shall occasionally consult all these works; and as some of them treat largely of the tactics in present use, while in others new systems are proposed, our article will naturally be divided into two parts, keeping the present practice and proposed innovations totally distinct from each other.

PART I. THE PRESENT SYSTEM OF NAVAL TACTICS.

CHAP. I. *Of the Orders of Sailing.*

3 Division of a fleet into three squadrons, the van, centre, and rear.

A FLEET of ships of war is usually divided into three divisions or squadrons, called the *centre*, *van*, and *rear*; and each squadron has a commanding officer. The commander in chief, or admiral of the fleet, is in the centre column; the vice-admiral has the command of the van; and the rear admiral, that of the rear. The ships of each squadron are distinguished by the position of their colours. The ships of the first or centre squadron carry their pendants at the main-top-gallant mast head. The ships of the second division carry their pendants at the fore top-gallant mast head, and those of the third division at the mizen-top mast head. Each squadron ought, if possible, to consist of the same number of ships; and also to be of the same force, so that each may be equally able to attack or repulse the enemy; and when in a line, the several parts will be equally strong. When the fleet is very numerous, each squadron is sometimes subdivided in a similar manner into three divisions of centre, van, and rear.

When the fleet is formed in the line or order of battle, each admiral takes his post in the centre of his squadron, the commander in chief being in the middle of the line. If the enemy be not in sight, the store-ships, fire-ships, sloops, &c. are to be to the windward of the fleet, because they can be more easily supported, and can more readily obey the signals that may be made to them. There are frigates to the windward of the van and rear of the convoy, for the purpose of looking out for the enemy, and keeping those vessels in their proper stations. But if the enemy is in sight, then all those ships which are not to be in the line of battle are to be on the other side of the line with respect to the enemy. If the fleet is sailing in three columns, the first or centre squadron is in the middle between the second and third squadrons; one of which, according to circumstances, forms the starboard and the other the larboard column: and each admiral leads his respective division. If the fleet is destined for a certain place at a considerable distance, it is generally formed into squadrons; but if cruising in expectation of meeting the enemy, the admiral naturally keeps his ships in such sailing positions as may be most advantageous to form for action as quickly as possible. These various positions or arrangements are called *orders*; and that they may be better understood, it is necessary to premise the following definitions:

4 The starboard.

The starboard line of bearing, is that line upon which the ships of a fleet, being ranged, bear from each other upon a close-hauled line, whatever course they may be steering; and so that, upon hauling their wind or tacking together as may be necessary, the ships will be in a line close-hauled upon the starboard tack.

5 And larboard lines of bearing.

The larboard line of bearing, is that line from which the ships of the fleet, by hauling their wind, or tacking together, may be formed in a line close-hauled on the larboard tack.

6 The line abreast.

A fleet of ships is said to be in the *line a-breast* when the ships keels are parallel to each other, and their mainmasts in the same straight line.

7 Bow and quarter line.

The bow and quarter line, is when the ships are ranged in a straight line cutting their keels obliquely in the same angle. Hence at any intermediate ship, the ships towards one extremity of the line will be on the bow, and those towards the other extremity will be on the quarter, of that ship.

8 Ships steering chequerwise.

If several ships stand on the same line and steer the same course, but different from that line, they are said to be in *echiquier*, or *chequerwise*.

9 Manœuvre in succession.

Manœuvre in succession, is when a fleet, ranged in one of the orders of sailing, and standing on the same line, the same manœuvre is successively performed by each ship as she arrives at the wake of the van ship of the whole fleet, if in one line; or of the van ship of her particular division when divided into squadrons. So that a fleet tacks or veers, bears away or comes to the wind in succession, when all the ships of every line execute, one after another, the same manœuvre on the same point of the wake of the leading ship.

10 Five orders of sailing.

The number of orders of sailing is commonly assumed to be five; and denominated the *first*, *second*, *third*, *fourth*, and *fifth* orders of sailing; besides an order of *battle*, an order of *retreat*, &c.

(A) The reason why Britain falls short of the French in this respect, is, that in various sea-ports in France there are academies established for the express purpose of educating those intended for the navy in the various branches of naval science; whereas, in Britain, there is only one academy established at the expence of government, namely, The Marine Academy at Portsmouth; and, excepting navigation, scarcely any other branch of naval science is taught in that seminary. It also requires great interest to be admitted. We are, indeed, well aware that there are boys educated for the sea-service in Christ's Hospital, London, and at Greenwich school, &c. The education there is not, however, adapted for officers in the navy, being only writing, arithmetic, a little mathematics necessary to understand navigation, and navigation.

Orders of Sailing. Plate ccccxciii.

In the first order of sailing, the fleet is ranged on one of the lines of bearing, and each ship steering the same course. Thus, in fig. 1. let the wind be north, and the fleet ranged on the starboard line of bearing, and let the ships steer any course, as south-west. In this case, the fleet is ready to form the line on the starboard tack by hauling the wind. Again, let the fleet be ranged on the larboard line of bearing, and steering the same course as before, as in fig. 2.; then the fleet is in a position ready to form the line on the larboard tack, by tacking.

11 First order of sailing.

In a numerous fleet this method of sailing is defective; as the fleet will be too much extended, and therefore the communication between the van and the rear rendered more difficult than when in a more connected order. It is of use, however, when the enemy is in sight, as then the fleet may be readily formed in order of battle; and in that case only, or in passing through a strait, will it be necessary to range the fleet in this order.

12 Second order of sailing.

In the second order of sailing the fleet is ranged on a line perpendicular to the direction of the wind, and steering any proper course. This order, which is represented in fig. 3. has the same defects as the former; and has also this disadvantage attending it, that the fleet cannot safely tack in succession from this order, as each ship at the time of tacking is in danger of falling on board the ship next astern; and therefore, if the line is close, the ship astern must bear up considerably, in order to avoid being on board the ship ahead, which at that time is in stays.

13 Third order of sailing.

The third order of sailing is that in which the whole fleet is close-hauled, ranged upon the two lines or lines of bearing, and therefore containing an angle of twelve points; the admiral's ship being at the angular point, and the whole fleet steering the same course. Thus, in fig. 4. the wind being supposed north, and the fleet close-hauled on the starboard tack: Then A being the admiral's ship, one part of the fleet bears from him west-north-west, and the other part east-north-east.

This order of sailing is no doubt preferable to either of the former, as the ships are more collected, and can more distinctly perceive and obey the signals; but if the fleet is numerous, it will be too much extended.

14 Fourth order of sailing.

In the fourth order of sailing, the fleet is divided into six or more columns, as may be judged necessary: by which means the fleet is much more connected than in any of the former orders. The commanders, ranged upon the two lines of bearing, have their squadrons astern of them upon two lines parallel to the direction of the wind; the first ships of each column being, with respect to the commander of their squadron, the one on his starboard and the other on his larboard quarter. The distance between the columns should, however, be such, that the fleet may readily reduce itself to the third order of sailing, and from that to the order of battle. This order is adapted for fleets or convoys crossing the ocean, and is represented in fig. 5. But as it requires much time to reduce a fleet from this order to that of battle, it is therefore defective when in presence of an enemy.

15 Fifth order of sailing.

The fifth and last order of sailing is that in which the fleet is divided into three columns close-hauled, and therefore parallel to each other; and also the respective ships abreast of each other. The van commonly forms the weather column; the centre division, the middle column; and the rear division, the lee column. Circumstances may however require the van to be the lee column, and the rear the weather column. If the fleet is very numerous, each division may be divided into two columns; and each admiral is to place himself at a little distance before, and in the direction of the middle of his division. Fig. 6. and 7. represent this order of sailing.

Orders of Sailing.

16 Method of finding the distance between the columns.

The distance between any ship and that adjacent to it in the same column, and also the interval between the columns, are regulated by the commander in chief according to circumstances. The interval or perpendicular distance between the columns is commonly taken; such as, that the angle contained between the line of the columns and an imaginary line joining one of the extreme ships of that column, and the ship at the other extremity of the adjacent column, may be about two points. The measure of this angle must however depend in part upon the length of the column; and when it is determined upon, the distance between the columns may be found by multiplying the length of one of the columns by the tangent of the above angle to the radius unity: whence, if that angle be taken equal to two points, the length of a column multiplied by the decimal .414 will give the distance between the columns. Thus let a column contain six ships; let the distance between each be 100 fathoms; and the length of each ship from the extremity of the bowsprit to the stern 46 fathoms; then the whole length of the column will be 776 fathoms. Now the above angle being taken equal to two points, the distance between the columns is equal to $776 \times .414 = 321\frac{1}{4}$ fathoms.

17 Order of battle.

The order of battle is formed by drawing up the ships of the fleet in a line nearly close-hauled, and under an easy sail; each ship being at a certain assigned distance from that next ahead, as a half or a whole cable's length. The fire-ships, with frigates ahead and astern, form a line parallel to the former, and to the windward of it if the enemy is to the leeward; but to the leeward if the enemy is to the windward. Without this line another is formed, parallel thereto, of the store ships, &c. with frigates ahead and astern. Fig. 8. represents the order of battle, the fleet being on the starboard tack.

18 Order of retreat.

In retreating from a superior force, it is necessary to draw up the fleet in such an order that it may, with the greatest advantage, oppose or annoy the fast sailing vessels of the enemy: for this purpose, the order of retreat commonly taken is that which is the inverse of the third order of sailing. As the fleet generally runs before the wind, the ships of the line are therefore ranged on the low lines of bearing; hence these lines contain an angle equal to 135 degrees. The admiral is at the angular point, and the frigates, transports, &c. are included within the wings to leeward. In place of running before the wind, the fleet may take any other proper direction; but still the angle contained by the wings is to be 135°. This order of retreat is represented in fig. 9.

19 Order of convoy.

The order of convoy is that in which the ships are all in the wake of one another, steering on the same point of the compass, and forming a right line. If the fleet is numerous, it may be divided into three columns, which are to be ranged parallel to each other, that of the admiral occupying the middle, and all steering the same course.

Having defined the different orders of sailing, we shall now proceed to show the method of getting a fleet under way, and of bringing it to an anchor.

20 To get a fleet under way.

In order to get a fleet under way, the lee column is to get under way first, and bring to all at the same time, just as they find themselves after casting. The centre column is then to perform the same manœuvre, and cast likewise as soon as the other column is brought to; and both columns will remain in that position till the weather column, which is still apeak, having weighed, shall be also under way. The three columns may often be got under way all at once: but to execute this the fleet must all act together, and with equal ardour; for the weather ships must not, at any rate, be under way before the lee ones. If it be necessary to get immediately in order of battle, the weather columns are at once to bear away two points together, that they may take their posts in the line of battle ahead of the lee column.

Orders of Sailing.

If the fleet be moored in a line, head to wind, the rear ſhip may get under way firſt, and haul immediately by the wind; the others in ſucceſſion, from the rear to the van, can eaſily take their ſtation in her wake, ſo that the rear ſhip will now become the leader. Or, the fleet may all get under way at the ſame time; but the van ſhip is to bring to, while the reſt, caſting the other way, would ſtand on by the wind on the ſame tack on which they have caſt, and come to tack ſucceſſively in her wake, to form the order of battle.

21 To bring a fleet to an anchor.

To bring a fleet to an anchor, it ought, if conſiderable, to anchor in three parallel lines, on one of the lines of bearing, and at the proper diſtance which the length of the columns require; the diſtance between the adjacent ſhips in the ſame column being about a cable's length. The van and rear of the columns are to correſpond with each other exactly in the direction of the wind, that they may with eaſe get under way, and form the order of battle with facility, ſo as to be able to diſpute the weather-gage with the enemy if he ſhould come in ſight. As this evolution is to be performed in moderate weather, the fleet being in three columns, they are all at the ſame time to bring their ſhip's head to the wind under their topſails, and let go their anchors together, clewing up their topſails with all poſſible diſpatch; putting the foot of the ſails in the tops, and looſening the ſheets before hauling them down; then veering away an equal quantity of cable to preſerve the aſſigned diſtance. When it blows ſo freſh as to require the topſails being reefed, two cables length may be kept between the ſhips, and even three if it be likely to blow hard.

If the fleet do not exceed 20 ſhips, they may anchor on one of the lines of bearing; or parallel to the coaſt, in places where trade-winds are common, provided they blow in the direction of the land; for, in all caſes, they muſt be in a condition to get under way at the firſt ſight of the enemy, whoſe approach is never to be waited for at anchor; becauſe, if it be dangerous for a ſingle ſhip, it muſt be ſtill more ſo for a fleet, the movements of which are interrupted by the difficulty there is in getting with celerity under way ſhips which are moored, and which, in that caſe, are not able mutually to ſupport one another, as is abſolutely requiſite in a fleet.

CHAP. II. *The Manner of Forming the ſeveral Orders of Sailing.*

22 To form the firſt order of ſailing.

THE firſt order of ſailing is formed as follows: As the fleet is ſuppoſed to be in no particular order, that ſhip which is to lead on the propoſed line of bearing on which the fleet is to ſail, runs to the leeward of the whole or greater part of the fleet, and then hauls her wind, carrying an eaſy ſail: each ſhip then endeavours to get into her proper ſtation, by chaſing the ſhip which is to be next ahead of her; and when in the wake of the leader, muſt take care to preſerve the aſſigned diſtance from the ſhip immediately ahead, by increaſing or diminiſhing the quantity of ſail: and if any of the fleet ſhould happen to be ſo far removed from her ſecond ahead as not to be able to chaſe her without getting out of her way towards the line, in that caſe ſhe muſt take her ſtation diſcretionally in a line with the leaders, and leave a proper interval. The fleet will now be formed in the line of battle; from which the firſt order of ſailing is formed by each ſhip bearing away at the ſame inſtant, and ſteering each the ſame propoſed courſe.

23 To form the ſecond order of ſailing.

To form the ſecond order of ſailing, the leader runs to the leeward of the whole, or of ſo many of the fleet as that each ſhip may eaſily fetch his wake, and then ſteers a courſe eight points from the wind, carrying an eaſy ſail. Each ſhip now gets into her proper ſtation, by chaſing that which is to be ahead of her; and when the whole fleet is formed in a line, which will be perpendicular to the direction of the wind, each ſhip bears away at the ſame inſtant, and the whole ſteer the ſame intended courſe. Manner of Forming the ſeveral Orders of Sailing.

24 To form the third order of ſailing.

In the third order of ſailing the admiral is in the middle of his fleet. Now, the fleet being formed in a line, on one of the lines of bearing, as above directed, and the ſhips ſteering in the wakes of each other, or ten points from the wind, the leading or leewardmoſt ſhip firſt hauls her wind; the ſecond ſhip, as ſoon as ſhe is in the wake of the leader, hauls her wind alſo; and in like manner each ſhip until the admirals ſucceſſively haul their wind as ſoon as they have reached the wake of the leading ſhip; and at the ſame inſtant that the admiral's ſhip hauls her wind, the other, or ſternmoſt half of the fleet, do the ſame. The fleet will then be in the third order of ſailing, as repreſented in fig. 4. From this order of ſailing the fleet can be expeditiouſly formed into the line of battle on either tack.

25 To form the fourth order of ſailing.

As the fleet, in the fourth order of ſailing, is divided into ſix columns, and the three commanders ranged on the two lines of bearing, the commander in chief being at the angular point; in order, therefore, to form this order, the admirals range themſelves on the two lines of bearing, at a proper diſtance from each other, and ſteer the proper courſe; the ſhips of the ſeveral columns come each into its reſpective place, forming themſelves into lines in the direction of the wind, and parallel to each other, as in fig. 5.

26 To form the fifth order of ſailing.

In order to form the fifth order of ſailing, the three leading ſhips of the diviſions are to take their poſts abreaſt, and to leeward of each other, keeping their wind under an eaſy ſail. Then the ſhips of each ſquadron making ſail, will range themſelves in their reſpective ſtations, aſtern of their leaders, and keeping the ſame courſe; each ſhip preſerving the appointed diſtance from that next ahead; and the commanders of each diviſion, and each ſecond, third, &c. ſhip, are to keep themſelves mutually abreaſt of each other.

27 To form the order of battle.

To form the order of battle, it has already been obſerved, in the firſt order of ſailing, that the ſhip which is to lead runs to the leeward of the whole, and then hauls her wind upon the tack directed, carrying an eaſy ſail. Each ſhip then makes ſail according to her diſtance, and chaſes the ſhip which is to be immediately ahead of her in the line, and hauls in her wake in the line on which the van ſhip is moving.

28 To form the order of retreat.

The admiral, or ſhip appointed to make the angular point, runs to the leeward of the fleet, and brings to; then each ſhip runs to its reſpective ſtation in one of the lines of bearing, and brings to; one half of the fleet being on one of the lines of bearing, aſtern and in the wake of the admiral, and the other half on the other line of bearing, on the ſtarboard or larboard bow of the admiral. When this is accompliſhed, the whole fleet bears away before the wind: the two wings will now bear from the admiral two points before his beam, and ready to form the line of battle upon either tack; the ſhips on the admiral's ſtarboard bow being in the line of bearing for the larboard tack, and thoſe on his larboard bow in the line of bearing for the ſtarboard tack.

CHAP. III. *To Change from the ſeveral Orders of Sailing to the Line of Battle.*

29 To form the line of battle from the firſt order of ſailing.

To form the line from the firſt order of ſailing: If the ſhips be running large on the tack anſwering to the line of bearing on which they are ſailing and the line to be formed on the ſame tack, all the ſhips haul the wind at the ſame time, or at leaſt each ſhip hauls her wind immediately after the next to windward: but if the fleet be on the other tack with

To change from the Orders of Sailing to the Line of Battle.

with reſpect to the line of bearing, all the ſhips haul their wind and tack together, or all veer together according to circumſtances. If the line of battle is to be formed on the other line of bearing, the leewardmoſt ſhip either veers or tacks, and hauls her wind: the reſt of the fleet veer or tack at the ſame time, and ſteer with the wind four points free; and each ſhip ſucceſſively, as ſoon as ſhe gets into the wake of the leader, hauls her wind. Hence the line of battle will be formed from the firſt order of ſailing. See figs. 10. and 11.

Plate cccxciv.

30 From the ſecond order of ſailing.

To form the line from the ſecond order of ſailing, the fleet running large or before the wind: All the ſhips of the fleet haul up together on the tack directed, preſenting their heads on the line upon which they are ranged, or eight points from the wind. The leading ſhip then hauls her wind, and is followed in ſucceſſion by the reſt. That the ſhips may not be too near each other, they make ſail as they haul their wind, or their ſeconds aſtern ſhorten ſail to open the order. See fig. 12.

31 From the third order of ſailing.

To change from the third order of ſailing to the line of battle: The ſhips being ſuppoſed going large, that wing which is in the line of bearing for the tack on which the line is to be formed, and the ſhip at the angular point, haul their wind at the ſame time; the ſhips of the other wing haul up together eight points from the wind; then each ſhip moves in this direction until ſhe reaches the wake of the other wing, where ſhe hauls cloſe up. See fig. 13.

32 From the fifth order of ſailing.

To form the line of battle on the ſame tack from the fifth order of ſailing: Let the weather column form the van, and the lee column the rear. The centre brings to, or only keeps ſteerage-way; the weather column bears away two points, and hauls its wind as ſoon as it is ahead of the centre; the lee-column tacks together, and runs under a preſs of ſail, to gain the wake of the centre, when it retacks together and completes the line (ſee fig. 14.) This evolution may alſo be performed as follows: The weather-column brings to; the centre and lee columns tack together, and go away two points free: when the centre-column has gained the wake of the van, it retacks together, and brings to; and when the lee-column has gained the rear line, it retacks together, and then all ſtand on: otherwiſe the lee-column brings to; the centre goes under an eaſy ſail two points free, to get ahead of the rear-ſquadron; while the van carries a preſs of ſail, alſo two points free, to get ahead of the centre diviſions.

Hitherto the weather column has uniformly been ſuppoſed to form the van, and the lee-column the rear-diviſion: the line may, however, be formed by interchanging theſe columns in a variety of different ways, ſome of which are as follow.

33 The centre and weather columns interchanging.

1. Let the weather and centre columns interchange: In this caſe the centre-column ſtands on, the weather-column bears away eight points, and as ſoon as it reaches the wake of the centre-column, which now forms the van, hauls up together: the lee-column tacks together, and goes under a preſs of ſail ſcarcely two points free, ſo as juſt to gain the rear of the line, and then retacks together, as in fig. 15. This evolution may alſo be performed by the lee-column bringing to; the centre ſquadron then bears away together one point, and as ſoon as it has gained the head of the line, hauls its wind; and the weather column bears away together three points, under an eaſy ſail; and when it has got into the wake of the van, hauls up together, forming the centre diviſion.

34 The centre and lee-columns interchanging.

2. Let the centre and lee-columns interchange: The lee-column ſtands on cloſe-hauled, under an eaſy ſail; the weather column bears away two points under a preſs of ſail, until it reaches the head of the line, and then hauls up: the centre column bears away eight points; and when in the wake of the lee-column, which is now the centre diviſion, hauls its wind. See fig. 16.

To change from the Orders of Sailing to the Line of Battle.

3. The weather and lee-columns interchanging: For this purpoſe, the lee-column ſtands on cloſe-hauled under a preſs of ſail; the centre-column bears away two points under an eaſy ſail, and hauls up as ſoon as it has come into the wake of the new van ſquadron; and the weather-column bears away eight points until it gains the wake of the centre-column, and then hauls up, as in fig. 17.

35 The weather and lee columns interchanging.

4. The centre forming the van, and the weather-column the rear-diviſion: The lee-column brings to, the centre-column bears away together two points, and forms the line ahead of the new centre ſquadron; the weather-column veers away together ſeven points on the other tack, and forms the rear ſquadron. See fig. 18.

36 The centre forming the van and the weather the rear.

Plate cccxcv.

5. The lee-column to form the van, and the centre the rear diviſion: In order to this, the lee-column ſtands on under a preſs of ſail, the weather-column bears away together three points under an eaſy ſail, and the centre column bears away eight points; and each, when it has gained the wake of the new van, hauls its wind. See fig. 19.

37 The lee-column forming the van and the centre the rear diviſion.

To form the line of battle on the other tack from the fifth order of ſailing. The weather-column firſt tacks in ſucceſſion; the centre and lee columns ſtand on, the firſt under an eaſy ſail, and the ſecond under ſtill leſs ſail, according to the length of the columns; and the leaders tack when they gain the wake of the new-formed van, and each ſhip tacks in ſucceſſion as it reaches the wake of the abovementioned van (ſee fig. 20.) Very great care muſt be taken by the centre and lee-columns, leſt they draw too near the ſternmoſt ſhips of the van, and alſo each other.

38 To form the line on the other tack, the weather-column forming the van, &c.

To perform this evolution, the centre and weather columns interchanging: The weather column brings to, the centre column ſtands on until the leader judges he will be fully able to clear the weather-column, and then the centre-column tacks in ſucceſſion: when the laſt ſhip of this new-formed van has paſſed the weather-column, that column ſtands on, and each ſhip tacks in ſucceſſion as ſoon as it reaches the wake of the van. The lee-column ſtands on, and tacks in ſucceſſion as the ſhips attain the wake of the van, and at the ſame time carrying a moderate ſail, that there may be a ſufficient interval left for the weather-column to form the centre diviſion. See fig. 21.

39 The centre and weather columns interchanging.

To form the line from the fifth order of ſailing on the other tack, the centre and lee-columns interchanging. The centre-column brings to; the weather-column tacks in ſucceſſion under very little ſail, and the lee-column ſtands on under a preſs of ſail: when the leader of the lee-column has gained the wake of the line, he tacks, and is followed in ſucceſſion by his diviſion. The centre-column is to fill and ſtand on, when the firſt ſhip of that column, and the laſt ſhip of the lee-column, bear from each other in a line perpendicular to the direction of the wind. See fig. 22.

40 The centre and lee-columns interchanging.

To form the line on the other tack from the fifth order of ſailing, the weather and lee-columns interchanging: The weather and centre-columns bring to; the lee-column ſtands on under a preſs of ſail, until it can paſs ahead of the weather-column, and then tacks in ſucceſſion; the centre-column fills where its leading ſhip and the laſt ſhip of the lee-column bear from each other, in a line perpendicular to the direction of the wind, and tacks in ſucceſſion when it has gained the wake of the new van. In like manner, the weather-column fills when its leading ſhip and the laſt of the centre bear in a line perpendicular to the wind, and each ſhip tacks in ſucceſſion when it has gained the wake of the centre. See fig. 23.

41 The weather and lee columns interchanging.

42 The weather-column paſſing to the rear.

To form the line on the other tack, the centre forming the

To change from the Line of Battle to the Orders of Sailing.

the van, and the weather the rear diviſion: The weather-column brings to, the other columns make ſail and ſtand on, till they can paſs on the other tack ahead of the weather-column, when they tack in ſucceſſion. When both columns have paſſed the weather column, it fills, tacks in ſucceſſion, and forms the rear. See fig. 24.

43 The lee-column paſſing to the van.

To form the line on the other tack from the fifth order of ſailing, the lee-column forming the van: The weather and centre columns bring to; the lee-column carries a preſs of ſail, and tacks in ſucceſſion when it can paſs a-head of the weather-column; and when the laſt ſhip of this new van has paſſed to the windward of the former weather-column, the van ſquadron ſhortens ſail, to give time for the other columns to form: the weather and centre columns fill at the ſame time, to gain the wake of the van, when they tack in ſucceſſion. See fig. 25.

44 To form the line from the order of retreat.

To form the line from the order of retreat: The leader of the wing, which is to form the head of the line, hauls the wind, and that wing follows in ſucceſſion; the other wing goes four points free together, on the ſame tack, and thus runs parallel to the wing which firſt began the evolution; and they haul up together when they arrive in the wake of the line. See fig. 26.

CHAP. IV. *To change from the Line of Battle to the different Orders of Sailing.*

45 To change from the line of battle to the firſt order of ſailing.

To change from the line of battle to the firſt order of ſailing on the ſame tack: All the ſhips bear away together the number of points directed by the admiral, obſerving to keep themſelves in the line of bearing for the tack they are in. The ſternmoſt ſhip bears away firſt, and the reſt ſucceſſively as quickly as poſſible, to prevent being too near each other.

To change to the firſt order of ſailing in bearing for the line on the other tack: The leader bears away four points to leeward, and is followed in ſucceſſion by the reſt. When the ſternmoſt ſhip has bore away, the whole haul up, and they will be in bearing for the line on the other tack. See fig. 27.

46 To change to the ſecond order of ſailing.

To change from the line of battle to the ſecond order of ſailing: The whole fleet bears away together ten points; and ſo proportions the ſailing from the van to the rear of the line, that when the headmoſt ſhip, which firſt preſſes ſail, ſhall come abreaſt of the ſecond ſhip, the ſecond ſhip adapts her ſail to keep in this bearing; and ſo on in ſucceſſion, each obſerving to keep the ſhip that immediately preceded her in the evolution in a line with herſelf, perpendicular to the direction of the wind; and the whole fleet will now be running before the wind (ſee fig. 28.) But if it is intended that the fleet ſhall ſteer any other given courſe than that before the wind, the whole fleet may then alter together to the propoſed courſe.

47 To change to the third order of ſailing.

To change to the third order of ſailing from the line of battle: The whole fleet bears away together ten points; the headmoſt half of the fleet, including the centre ſhip, carry an equal degree of ſail, in order to preſerve their line of bearing; each ſhip of the remainder of the fleet carries leſs ſail in ſucceſſion, ſuch as will form and preſerve on the other line of bearing with reſpect to that upon which they were ranged before the evolution; and by this means the fleet will be formed in the third order of ſailing. See fig. 29.

Plate ccccxcvi.

48 To change to the fifth order of ſailing on the ſame tack.

To change from the line of battle to the fifth order of ſailing on the ſame tack: In the treatiſe of *Naval Tactics*, publiſhed in the ſecond volume of *The Elements of Rigging and Seamanſhip*, there are various rules for performing this evolution, according as the different ſquadrons in the line of battle are intended to form the weather, the centre, and the lee columns, in the order of ſailing. We ſhall give two of them as examples.

To change from the Line of Battle to the Orders of Sailing.

1. When it is intended to change from the line of battle to this order of ſailing, ſo as that the van ſhall form the weather, and the rear the lee column, and the fleet at the ſame time keep as much to windward as poſſible; the van and centre tack together, and run cloſe-hauled in bow and quarter-line; the rear moves on its former courſe under an eaſy ſail. When each ſhip of the centre is abreaſt of its correſpondent ſhip in the rear, the centre retacks: the van ſtands on until the centre and rear come up, and then retacks, and all the columns regulate their diſtances. See fig. 30.

49 The van forming the weather and the rear the lee column.

2. When it is intended that the van ſhall form the lee, and the rear the weather column; the van bears away together under an eaſy ſail, and goes at right angles with the line ahead: the centre at the ſame time goes away two points free, and each ſhip ſteers for that ſhip of the van reſpectively which is to be abreaſt of her when in column. The leader of the van muſt determine the diſtance, by not hauling up with his diviſion until his ſhip and the ſternmoſt ſhip of the centre-column, which is drawn up with him, are in a line at right angles with the wind: They then both ſtand on under an eaſy ſail, while the rear crowding ſail paſſes to the windward of both. See fig. 31.

50 The van forming the lee and the rear the weather column.

To change from the line of battle to the fifth order of ſailing on the other tack: This evolution may be performed in as many ways as the former, according to the intended poſitions of the different columns; but in ſuch a Work as ours, it may be ſufficient to obſerve, that,

51 To change to the fifth order of ſailing from the line of battle on the other tack.

1. When the van is meant to form the weather, and the rear the lee column: The van tacks in ſucceſſion; the leader of the centre tacks when the leader of the van is paſſing him exactly to windward, and his diviſion follows him; the rear manœuvres in the ſame manner with reſpect to the centre. See fig. 32.

52 The van forming the weather and the rear the lee column.

2. When the rear is to form the weather, and the van the lee column: The van tacks in ſucceſſion; and when about, either brings to, or ſhortens ſail, to allow the other columns time to form. The centre and rear then carry ſail, and tack in ſucceſſion. The centre tacks when its leader has the centre of the lee-column in a line at right angles with the wind, or when its centre paſſes aſtern of the lee-column. When the centre is about, it regulates its rate of ſailing by the lee-column, either by bringing to or making equal ſail; and thus both wait for the rear to paſs to windward. The rear tacks when its leader has the firſt ſhip of the lee-column in a line at right angles with the wind, or when its centre ſhip paſſes aſtern of the laſt ſhip of the centre-column. See fig. 33.

53 The rear forming the weather and the van the lee column.

54 To change to the order of retreat.

To change from the line of battle to the order of retreat: The leader bears away four points; and all the fleet following cloſe hauled, they will come to file off in ſucceſſion at the ſame point in the van ſhip's wake, till the centre ſhip arrives at the angle where the evolution began. Then the order of retreat will be formed, and any courſe whatever may be ſteered, ſince the two wings will be equal and in order on the ſtarboard and larboard lines of bearing, forming conſequently between them an angle of 135 degrees. Fig. 34. repreſents the order of retreat formed from the line of battle, the whole fleet going four points free.

CHAP. V. *To Manœuvre the Line of Battle.*

THE method of forming the line of battle, when the ſhips are in no previous order, has already been explained. In this place it is intended to point out ſome of the various evolutions

Manœuvre the Line of Battle.

evolutions that are, or may be, performed by a fleet which is already formed in line of battle.

55 To form the line on the other tack by tacking in ſucceſſion.

The fleet being in line of battle, to form the line on the other tack, by tacking in ſucceſſion: The headmoſt ſhip of the fleet tacks firſt, having previouſly made more ſail, or the ſecond having ſhortened ſail, in order to increaſe the interval between them; for it often happens that one or two cables length are run over before the ſhip ahead has been able to fill her ſails on the other tack. When the firſt ſhip is about, either the ſecond makes more ſail, or the third ſhortens ſail; and then the ſecond tacks as ſoon as ſhe has gained the wake of the leader, the helm being put down at the inſtant ſhe opens the weather quarter of the firſt ſhip, which is already on the other tack. In like manner the third, fourth, &c. ſhips tack each at the inſtant it has gained the wake of the leader; and thoſe ſhips already about muſt preſerve their aſſigned diſtances, by ſhortening ſail, if neceſſary, until the whole fleet is on the other tack. If a ſhip miſſes ſtays, ſhe is immediately to fill again on the ſame tack, and make ſail with all poſſible expedition, taking care to keep as cloſe as poſſible to the wind, and not to fall off to leeward. By this means ſhe will get ahead and to windward of thoſe which follow her; and they will perform ſucceſſively their evolutions in the wake of the ſhips which are already on the other tack, only ſtanding on a little farther than they would have done if the ſhip ahead had not miſſed ſtays. The ſhip that miſſed ſtays will return ſooner to her ſtation, by making all poſſible ſail to windward of the line. See fig. 35.

56 Without tacking in ſucceſſion.

To form the line on the other tack without tacking in ſucceſſion: The whole fleet veers together: the rear ſhip hauls her wind on the other tack, and ſtands on, while all the others go two points free on the other tack, and haul up as they ſucceſſively gain the wake of the leading ſhip. Thus the rear of the line on the one tack becomes the van on the other tack. See fig. 36.

57 To veer in ſucceſſion.

The line to veer in ſucceſſion: The van ſhip of the line veers round, and ſteers four points free on the other tack; and when ſhe is clear of the rear ſhip of the line, ſhe hauls her wind; the reſt follow, and haul up in ſucceſſion. See fig. 37.

58 To tack and retack.

The line to tack and retack together: In tacking together, the ſternmoſt ſhip of the line puts in ſtays; then her ſecond ahead puts her helm down; and ſo on through the whole line, to prevent the ſhip ahead from falling on board the ſhips aſtern. The fleet will then be in bow and quarter line; from which, if tacking together, no ſhip muſt put in ſtays till the ſhip on her weather quarter is in the act of tacking.

59 To bear away together.

The line bear away together, preſerving their bearing for the line: The rear begins this evolution, the ſternmoſt ſhip bearing away the number of points propoſed; and ſo on as quickly as poſſible, to prevent falling on board of each other.

60 To turn to windward.

To turn to windward in line of battle: When the fleet has ſea-room, the moſt advantageous method of gaining to windward is, that all the ſhips of the fleet may go about together; as by this means the whole fleet will gain as much to windward as in the caſe of a ſingle ſhip. The fleet will be in line of battle on the one board, and in bow and quarter line on the other. This is alſo the moſt proper method to get to windward on a coaſt when the wind is parallel to the land: but if the fleet is turning to windward in a ſtrait or between two ſhores, the fleet ſhould tack in ſucceſſion; for if all the ſhips tacked together, the van would be ſoon in with the land on one ſide, and ſoon after the fleet had retacked the rear would be in with the land on the other ſide: hence this would occaſion a number of ſhort boards. In paſſing through a ſtrait, other circumſtances are alſo to be attended to, as tides, &c.

Manœuvre a Fleet in the Fifth Order of Sailing.

61 To interchange the van and centre ſquadrons.

To interchange the van and centre ſquadrons: The van bears away a little, and brings to; the centre paſſes on to windward, edging a little, to get ahead of the former van on the ſame line; the rear, coming on under an eaſy ſail, edges away likewiſe, to obtain the wake of the new centre ſquadron. See fig. 38.

62 Van and rear ſquadrons.

To interchange the van and rear ſquadrons: The van and centre ſquadrons bear away a little, and then bring to, the van obſerving to bear away a little more to the leeward than the centre. The rear ſtands on to gain the head of the line; and when abreaſt of the former van, the centre fills, and both ſtanding on, form ahead of the new rear, by edging down until they are in a line with it. See fig. 39.

63 Centre and rear ſquadrons.

To interchange the centre and rear ſquadrons: The van ſtands on under an eaſy ſail, while the centre bears away a little and brings to, and the rear at the ſame time carries a preſs of ſail to paſs the centre to windward and get into the wake of the van. The van and centre then edge away to gain the line with the new rear ſquadron, which then fills. See fig. 40.

64 The van to paſs to the rear.

The van to paſs and form the rear: The van ſquadron edges away a little and brings to; the other two ſquadrons, crowding ſail, ſtand on till they get ahead of the new rear, and then edge away a little to form in the line; after which the rear fills.

65 The rear to paſs to the van.

The rear to paſs and form the van: The van and centre bear away a little and bring to; the rear makes ſail, paſſes ahead of both, and then edges away to form on the ſame line. Theſe two manœuvres are ſo ſimple as not to ſtand in need of illuſtration by figures.

CHAP. VI. *To Manœuvre a Fleet formed in the Fifth Order of Sailing.*

66 To manœuvre the fifth order of ſailing.

THIS order of ſailing is very advantageous for a numerous fleet, as it keeps the ſhips cloſer together, and therefore more connected with each other than either of the three firſt orders. The method of forming this order is ſhown in Chap. II.: and the method of manœuvring in it, which with very little alteration is alſo applicable to the fourth order, is to be the ſubject of this chapter.

67 To tack in ſucceſſion.

To tack the columns in ſucceſſion: The ſhips of the lee-column having more diſtance to run before they can recover their poſition, muſt go about firſt in ſucceſſion. When the centre leader finds himſelf abreaſt of the leader to leeward of him, or at right angles with the cloſe-hauled line on the other tack, upon which the lee leader is now moving, he tacks, and is followed in ſucceſſion by his diviſion. The weather-column paying the ſame regard to the centre-column, manœuvres in the ſame manner (ſee fig. 41.) In this evolution the weather-column ſtill continues to windward; and ſhould the columns have cloſed too much, or be too far aſunder, either of which may happen from the inequality in the rate of ſailing of the different ſhips, the order may be recovered either by the lee or windward column bearing away, ſo as to make an angle equal to that propoſed, as two points, between any column, and a line joining the leader of that column and the ſternmoſt ſhip of the next column.

If this evolution is to be performed in the night, the weather-column muſt tack firſt. In order to prevent the riſk of one column paſſing through the van of the other columns, the next column muſt not tack till its leader is ſenſible that many ſhips of the column immediately to windward are about. When about, the leaders make little ſail, while their followers make ſucceſſively a little more, in order to form their reſpective columns. The columns which are

com-

Manœuvre a Fleet in the Fifth Order of Sailing.

pletely about ſhould either bring to and wait for the next, or ſhould juſt keep ſteerage way; thus the former weather-column ſhould wait for the centre, and both ſhould then wait for the former lee-column. In this evolution the weather and lee-columns will be interchanged. As ſome riſk may attend the execution of this at night, it is moſt adviſable to tack the columns together, and ſail in bow and quarter line; becauſe ſhould it become neceſſary to retack, or ſhould the wind change before the completion of this evolution, much confuſion might enſue. By tacking together this will be avoided.

68 To tack together.

To tack the columns together: the ſternmoſt ſhips of the three columns put in ſtays together; and when they are obſerved to be ſo, their ſeconds ahead immediately put their helm down, and ſo on through the whole fleet. Each column will then be in bow and quarter line. See fig. 42.

69 To veer in ſucceſſion.

To veer the columns in ſucceſſion: The leader of the lee-column veers round, and ſteers four points free upon the other tack, followed by the ſhips of that diviſion; and of which, when he is clear of the ſternmoſt ſhips, he hauls up. The centre and weather columns perform ſucceſſively the ſame evolution, obſerving to continue ſtanding on till they ſucceſſively bring the point at which the lee-column began to veer to bear in a right line to leeward of them. They likewiſe ſucceſſively ſpring their luffs when the point at which the lee-column hauled its wind bears right to leeward (fig. 43.) Each column having the ſame diſtance to run, if the evolution be well executed, the leaders of the windward columns will find themſelves, when they ſpring their luffs, exactly abreaſt of the leader of the lee-column, and ſo will all the other ſhips. But the making or ſhortening ſail will at all events rectify the inequality of ſailing.

70 To turn to windward.

To turn to windward in the fifth order of ſailing: Let the ſhips of the fleet be ſo arranged, that the leaders, and alſo the correſponding ſhips of the columns, may be in the direction of the wind; as by this means the fleet will gain more to windward, and at the ſame time be leſs liable to diſorder. Now the van ſhips of the columns tack at the ſame inſtant, and are followed in ſucceſſion each by the remaining ſhips of the diviſion, when they reach the wake of their leaders, or the ſame point when they went about; hence there will always be three ſhips in ſtays at the ſame time until the whole fleet has got on the other tack. The fleet then ſtands on any aſſigned diſtance, and then retacks in the ſame manner as before. See fig. 44.

Plate CCCCXCVII.

71 To interchange the weather and centre columns.

To interchange the weather and centre columns: The weather and lee-columns lie to, or only keep ſteerage way. The centre column tacks together; and forming a bow and quarter line, goes cloſe-hauled to gain the wake of the weather-column; it then retacks together, and ſtands on, while the weather-column bears away to its new ſtation in the centre, and the lee-column fills. See fig. 45.

72 The weather and lee-columns.

To interchange the weather and lee-columns: The centre column brings to; the lee-column ſtands on under a preſs of ſail; and when its ſternmoſt ſhip can paſs to windward of the van of the centre column, which will be when the centre ſhip of the lee-column is in a line perpendicular to the direction of the wind with the van of the centre column, the lee column then tacks together, and ſtands on cloſe-hauled till it comes in a line with the centre column, when it goes large two points to get into the ſtation which the weather-column left; and then veers together, hauling the wind for the other tack. At the beginning of the evolution, the weather column bears away together under little ſail, and goes large ſix points on the other tack, ſo as to get into the wake of the centre column; it then hauls to the former tack, going two points large, till it ranges abreaſt of the centre column, when it brings to, and waits for the new weather column. See fig. 46.

Manœuvre a Fleet in the Fifth Order of Sailing.

To interchange the centre and lee-columns: The centre and weather columns bring to, or keep ſteerage way, as is moſt convenient; the lee-column tacks together, and preſſes ſail to gain the wake of the centre column; which, when they have effected, they retack together and ſtand on; the centre-column then edges away under an eaſy ſail, ſteering, if it lay to, eight points from the wind, and if it kept ſteerage way only two points, until it comes into the ſtation of the lee column, where it hauls to the wind; while the weather-column fills and ſtands on: and the order is reeſtabliſhed by ſhortening or making ſail, according to circumſtances.

73 The centre and lee-columns.

74 The weather column to paſs to leeward.

The weather-column to paſs to leeward: The weather-column ſtands on under very little ſail, while the centre and lee-columns tack together, and carry a preſs of ſail till they reach the wake of the weather-column, when they retack, and crowd ſail till they come up with the weather-column; and when they have gained the wake of the weather-column, it bears away two points, to gain its ſtation to leeward, and then hauls to the wind or brings to till the new weather and centre columns come up. See fig. 47.

75 The lee-column to paſs to windward.

The lee-column to paſs to windward: The weather and centre columns bring to, while the lee column carries ſail and tacks in ſucceſſion as ſoon as the leading ſhip can weather the headmoſt ſhip of the weather-column; and when arrived upon the line on which the weather-column is formed, it retacks in ſucceſſion, forms on the ſame line, and either brings to or ſtands on under very little ſail. If it brings to, the other two columns bear away together two points, to put themſelves abreaſt of the column now to windward; but if the new weather-column ſtood on under an eaſy ſail, they may bear away only one point to gain their proper ſtations. See fig. 48.

76 Method of keeping a ſhip in its proper ſtation by means of the naval ſquare.

As it is of the utmoſt importance that each ſhip be in her reſpective ſtation, both to preſerve order, and that the various evolutions may be more readily performed, the officer of the watch will therefore be ever anxious to preſerve the ſtation of his ſhip. This he may do by his quadrant; but the more ready method for this purpoſe is by means of the NAVAL SQUARE, which is conſtructed as follows:

77 Its conſtruction.

Upon ſome convenient place at the middle of the quarter-deck, deſcribe the ſquare ABCD (fig. 49.), of which the ſides AD and BC are parallel to the keel; through the centre line G draw the line EF parallel to AD or BC, and draw the diagonals AC and BD; biſect the angles EGD, EGC by the ſtraight lines GH, GI, and the naval ſquare will be conſtructed. Now ſince the angles FGD, FGC are equal to four points, being each half a right angle; therefore the angles EGD, EGC are each equal to 12 points, and conſequently the angles EGH, EGI are each equal to ſix points. Hence, if a ſhip is running cloſe-hauled on the ſtarboard tack, in the direction FE, the direction of the wind will be IG, and her cloſe-hauled courſe on the other tack will be GC: But if ſhe be running in the ſame direction FE upon the larboard tack, her cloſe-hauled courſe on the ſtarboard tack will be in the direction GD.

78 And application.

In order now to apply the naval ſquare to the keeping of ſhips in their reſpective ſtations, let the fleet be formed in the fifth order of ſailing cloſe-hauled, the correſponding ſhips of the columns coinciding with the direction of the wind, in order to turn to windward with greater facility. The correſponding ſhips in the column muſt be kept in the direction of GH, or GI, according to the direction of the wind and the tack they are upon, while all the ſhips of the

To reſtore the Order of Battle upon Shifts of the Wind.

the ſame column muſt be in the direction of EF. See fig. 50.

Again, let the fleet be in three columns in one of the lines of bearing, the ſhip being cloſe-hauled on the other tack. The ſhips of each column will be in the direction of one of the diagonals, while the correſponding ſhips of the other columns will be in the direction of the other diagonal (fig. 51.) It will alſo be the ſame if the columns are in one line of bearing, and going four points large on the ſame tack. The application of the naval ſquare in other caſes will be obvious.

CHAP. VII. *To reſtore or reform the Order of Battle upon Shifts of the Wind.*

79 To reſtore the order of battle upon ſhifts of the wind on the ſame tack, the wind coming forward leſs than ſix points.

1. LET it be intended to reſtore the order of battle on the ſame tack, the wind coming forward, and ſhifting ahead leſs than ſix points. In this caſe, the whole fleet is to bring to except the leader; who, in order that the ſame diſtances between the ſhips may be preſerved when the line is reformed, ſteers a courſe *a b* (fig. 52.) ſuch as to be at right angles to the middle point between the former and preſent direction of the wind: hence the courſe he muſt ſteer will be known by adding half the number of points the wind has ſhifted to eight points, and applying this ſum to the former cloſe-hauled courſe. As ſoon as the leader has arrived at the new cloſe-hauled line with reſpect to the ſecond ſhip ahead, that ſhip immediately fills, and bears away the ſame number of points as the leader; and when both theſe have reached the cloſe hauled line with reſpect to the third ſhip, ſhe alſo fills, and bears away. In like manner the remaining part of the fleet bear away in ſucceſſion; and when they have got into the cloſe-hauled line *b c* with the ſternmoſt ſhip, they all haul their wind at the ſame inſtant, and the ſternmoſt ſhip fills and ſtands on cloſe-hauled.

A very expeditious method of performing this evolution is as follows: The whole fleet having fallen off as ſoon as the wind ſhifted the ſame number of points which it changed, the leader bears away eight points from the middle point between the former and preſent directions of the wind; or, if the wind has ſhifted near ſix points, in this caſe the leader muſt bear away eight points from the new direction of the wind; but then the fleet will be cloſer than before, and the leader hauls his wind as ſoon as the ſternmoſt ſhip bears on the cloſe-hauled line from him: The ſecond ſhip bears away when ſhe has reached the wake of the leader, and alſo hauls her wind when ſhe has again gained his wake. In like manner the third, fourth, &c. ſhips bear away, and alſo haul their wind in ſucceſſion, until the ſternmoſt and the whole line is formed again. See fig. 53.

80 Four points. If the wind ſhifts exactly four points ahead, the whole fleet is to veer round till the heads of all the ſhips are directed to the point exactly oppoſite to their former courſe; and the rear ſhip, which has now become the van, is to run four points large upon her new tack, and the reſt of the fleet to follow her in ſucceſſion; and when the laſt ſhip, which was the former leader, is got into the wake of the headmoſt in the line, the whole fleet is to veer together, and the order will be reformed on the former tack.

81 Right points. If the wind ſhifts eight points forward, the ſhips are to veer round altogether till their heads are on the point of the compaſs oppoſite to their former courſe; then the rear ſhip, having become the van, is to haul cloſe by the wind on the ſame board; all the other ſhips are to haul up in ſucceſſion, and range in the wake of the leading ſhip; and when the laſt ſhip is in her ſtation, the order will be reformed on the ſame tack. The Battle

82 Twelve points. If the wind changes 12 points exactly, the fleet muſt veer round together, and haul their wind in ſucceſſion on the firſt tack.

83 To reform the order of battle on the other tack, the wind coming forward leſs than ſix points. 2. The wind coming forward, and the order of battle to be reformed on the other tack.

If the wind ſhifts ahead leſs than ſix points, all the ſhips of the fleet are to veer round, till their heads come to the oppoſite point of the compaſs with reſpect to their former courſe; and then the rear ſhip, which is now become the van, is to haul cloſe by the wind on that tack, and the other ſhips follow her in ſucceſſion. From hence the fleet might paſs to the line of battle on the former tack by veering in ſucceſſion. If the wind comes ahead more than ſix points, but leſs than twelve, the fleet is to manœuvre in the ſame manner as before. If the wind comes ahead exactly twelve points, the tack is to be changed.

84 Between ſix and twelve points. 3. When the wind ſhifts aft, and the order of battle to be reformed on the ſame tack.

85 Twelve points. If the wind has ſhifted leſs than two points, the leader hauls his wind, the fleet ſtands on as before, and each ſhip hauls her wind in ſucceſſion as ſhe gains the wake of the leader. If it is intended to change the tack, the whole fleet tack together, and the ſternmoſt ſhip, which now becomes the leader, hauls up, and the reſt bear down and haul up in ſucceſſion.

86 The wind coming aft and the order of battle to be reformed on the ſame tack.

87 On the other tack. If the wind changes ſixteen points, all the ſhips brace about for the other tack immediately, by which means the fleet will be going four points large; then the ſhips tacking or veering inſtantly together, the order of battle will be reſtored or formed again on the ſame tack as they were before the wind changed.

88 The wind changing ſixteen points.

CHAP. VIII. *Of the Battle.*

89 Of the line of battle. IN a naval engagement, the preſent mode, as has already been obſerved, is to draw up the fleet in a ſtraight line upon one of the cloſe-hauled lines under an eaſy ſail. The frigates, fire-ſhips, tranſports, &c. are placed at proper diſtances on the other ſide, with reſpect to the enemy (B). The diſtance between two adjacent ſhips in the line is uſually about a cable's length; but the admiral increaſes or diminiſhes this interval according to circumſtances. The nearer, however, the ſhips are to each other, the ſtronger is the line, and the more difficult to be broken or forced by the enemy; but ſtill there muſt be a ſufficient interval left, ſo that if a ſhip receive conſiderable damage, ſhe may be cut out of the line without becoming foul or falling aboard of the ſhip next aſtern, which would be the means of putting the whole line in confuſion.

90 Its advantages being cloſe.

91 And compoſed of large ſhips though fewer in number. The ſtrength of a fleet depends alſo more on the largeneſs of the ſhips, and the weight of the metal, than in their number. The fewer the number of ſhips in a fleet, the more diſtinctly will the ſignals be perceived and anſwered by thoſe near the extremities of the line; the letter alſo will the order

(B) Several able officers have been of opinion, that when fleets are ranged in order of battle, inſtead of being cloſe-hauled, they ſhould have the wind two points free, or upon the beam. Some of the reaſons alleged in ſupport of this opinion are, that the ſhips can more eaſily keep their ſtations; and if any ſhip ſhould happen to fall to leeward, ſhe may eaſily regain her ſtation, which would be almoſt impoſſible were the fleet cloſe-hauled.

The Battle.

der of battle be kept, and the fleet more eaſily manœuvred. A large ſhip is not ſo ſoon diſabled as a ſmall one; and in the caſe of a three decker, although the upper deck ſhould happen to be confuſed with the wreck of broken maſts, yards, &c. and hence it being ſcarcely poſſible to work the guns on that deck, yet if the weather be not tempeſtuous, the guns on the other two decks may be worked. If boarding ſhould be deemed practicable, it is evident that the large ſhip, upon account of the height of her ſide, as well as for other reaſons, will have greatly the advantage over one of a leſs ſize. Large ſhips are alſo for the moſt part more able to encounter a ſtorm than ſmall ones; and in a gale of wind large ſhips have commonly the advantage in point of ſailing. Hence it is obvious, that a fleet compoſed of large ſhips may have greatly the advantage over a fleet conſiſting of leſs ſhips, though much more numerous.

As in a naval engagement the two fleets are drawn up cloſe-hauled, on two lines parallel to each other, one of theſe fleets is therefore to the windward of the other. The windward fleet has ſeveral advantages not poſſeſſed by the fleet to leeward, and the leeward fleet has alſo advantages over the weather fleet. The advantages and diſadvantages of each of theſe fleets are as follow:

92 Advantages of the fleet to windward.

The fleet to windward may approach the leeward fleet at pleaſure, and can therefore determine the time of commencement of the action. If the weather fleet is more numerous, it may ſend down a detachment of ſhips on the rear of the leeward fleet, and thereby put it into confuſion. If any of the ſhips of the fleet to leeward ſhould be diſabled, the fleet to windward may with great eaſe ſend down their fire-ſhips upon them, or ſend a detachment after any part that gives way. The weather fleet may board if the admiral thinks proper; and it is ſcarcely incommoded with the ſmoke, which is carried off by the wind to the fleet to leeward.

93 Diſadvantages of the fleet to windward.

The diſadvantages of the fleet to windward are, an inability to quit the fight when once engaged, without being obliged to paſs through the enemy's line, which is extremely dangerous; becauſe the ſhips being already very much injured before they are obliged to fly, they muſt expect to be ſtill more ſo; and as they have it no longer in their power to form the order of retreat, this manœuvre is abſolutely a deſperate one. If the fleet to windward tack altogether, in order to get off, the line to leeward may do the ſame, after having raked the weather ſhips in ſtays, and follow them on the other tack, with the advantage of having gained the wind of the centre and rear diviſions of the flying line. If it blows freſh, it is ſeldom that weather ſhips have their lower deck guns ſufficiently elevated; whence it reſults, that the ſhip being a little inclined on the lee ſide, the guns often run out again at their ports after being fired, which very much retards the ſervice of the artillery, ſince the guns are obliged to be bowſed in again every time for loading; and oftentimes they can make no uſe at all of their lower tier. Again, ſuch of the ſhips as are ſo diſabled as to be obliged to quit the line, cannot eaſily do it, becauſe in veering, for want of being able to tack, they fall between the two lines, where they are raked ahead, and by that means completely put in diſorder: but ſhould they be fortunate enough to be able to finiſh their evolution, it is ſtill very difficult for them, diſabled as they are, to get to windward of their line, and very often they fall foul of the next ſhips aſtern of them, which have it ſcarcely in their power to prevent the accident on account of the fire and ſmoke, eſpecially if the line is much contracted; and ſhould theſe perceive it, and try to avoid being run foul of by falling back on their next ſhip aſtern, and ſo on thus ſucceſſively, it might happen, that from one to the other a great part of the fleet being obliged to manœuvre, their fire would leſſen, and very often ceaſe, by their covering each other; when, if the enemy take the advantage of this critical moment, the diſorder increaſes, and all is loſt. But theſe inconveniencies may be partly prevented by having the diſabled ſhips quickly towed out of the line by the boats of the fleet, which for that purpoſe ſhould always be hoiſted out from each ſhip before the engagement begins. Otherwiſe, if the ſhips in the weather line, not being too cloſe, have the neceſſary ſpace to obſerve what paſſes ahead of them, and to manœuvre, they ought to range themſelves to leeward of the diſabled ſhip, in order to cover her, and approach nearer to the enemy; all the other ſhips bearing up alſo together to preſerve the line. The Battle.

94 Advantages of the fleet to leeward,

The ſhips in the line to leeward have the advantage of ſerving with facility and effect their lower deck guns in all weathers proper for fleets to come to action: they can quit the engagement at pleaſure: their diſabled ſhips can without difficulty quit their ſtations when neceſſity requires it: they can form the order of retreat with more readineſs, or continue the action as long as convenient: in ſhort, the lee line of battle, if ſuperior in number, can alſo double the enemy, by making ſome of the ſhips in the van or rear to tack, and put one of the extremities of the enemy's line between two fires; and if they are formed in time, they may cannonade the enemy while bearing down to the attack.

95 And its diſadvantages.

The diſadvantages of the fleet to leeward are, its being very much annoyed by the ſmoke, and a continued ſhower of fire from the wads falling on board, repelled by the wind, which if not attended to may be productive of dreadful conſequences. The ſhips of the line to leeward cannot attempt to board thoſe of the other whatever may be their inclination for it; they can hardly do more than accept the battle, without being able to determine either time or diſtance: it is even with great difficulty that they can avoid being boarded, or prevent their line from being broken, if the weather ſhips are bent upon doing it; and their fire-ſhips are very ſeldom of uſe.

96 No general rule for preferring the one before the other.

A general rule for the adoption of either the weather or lee gage cannot be laid down. Sometimes the one is preferable, and ſometimes the other; and very often the commander in chief has it not in his power to make an option.

Having proceeded ſo far with reſpect to the line of battle, it may not be improper to introduce in this place an account of a naval engagement, with the conduct to be obſerved previous to, and during the time of, its continuance.

97 The action not to begin before the ſignal is made for that purpoſe.

The engagement will not begin till the admiral makes the ſignal, unleſs an action is inſenſibly brought on by ſome unavoidable circumſtance in the line, or poſition of the van or rear of both fleets in forming or approaching each other. The admiral in ſuch caſe will make the proper ſignal for the van or rear, by the diſtinguiſhing flag of either of theſe diviſions, which will undoubtedly regulate the neceſſary manœuvres of the reſt of the fleet throughout the whole line.

98 Precautions to be obſerved during an engagement.

During the time of an engagement the greateſt ſilence is to be obſerved in each ſhip; no one muſt quit his poſt upon pain of death; and ſhould any one happen to refuſe obeying an officer, he ſhall be put to death on the ſpot; the ſame alſo ſhall be done to any one who ſhall hide himſelf, or feign to be wounded. The wounded muſt be carried or conducted to the ſurgeon by thoſe who have been appointed by the captain for that purpoſe. Should any one diſcover an advantage to be taken, he ſhall inform the officer who ſtands neareſt him. No kind of rigging whatever is to be touched without an order. Should any dangerous ſhot be received at the water line of the ſhip, ſuch of the caulkers, or carpenters, or any other perſon who perceives it, ſhall inform in private the captain with it, without ſaying a word of the ſame to any one elſe upon pain of death, unleſs

The Battle.

unleſs it be a ſuperior officer; the ſame precaution ſhall alſo be obſerved about any part of the ſhip catching fire.

99 The fleet to carry little ſail.

Whilſt the fleets are engaged, the admiral carries but little ſail: in this, however, he muſt conduct himſelf by the motions of the enemy, the ſhips always obſerving to keep cloſe in the line; and if any ſhip happen to get out of the line, the ſhip which immediately follows is to pay no regard to her, but endeavour to keep her ſtation in the line.

100 No captain to quit his poſt in the line,

A captain muſt not quit his poſt in the line upon any pretence whatever, unleſs his ſhip ſhould be ſo greatly damaged as to render her incapable of continuing the action. The little ſail a fleet is under at ſuch a time may in general give the ſhips, though damaged in their rigging, &c. time enough to repair their defects, without cauſing an unneceſſary interruption in the line, by withdrawing out of action when their ſervice might perhaps be of the utmoſt importance to the reſt of the fleet.

101 Nor make an attack without order from the admiral.

A captain, through too impetuous a deſire of diſtinguiſhing himſelf, ought never to break the order of the line, however inviting the advantage of an attack might then appear to him to ſecure ſucceſs: he muſt wait with patience the ſignal of the admiral or commanding officer of his diviſion, becauſe it is always more eſſential to preſerve and ſupport a cloſe line in action, as it conſtitutes the principal ſtrength of a fleet in general, than to attend to a particular attack between two ſhips which commonly decides but little with regard to the whole, however glorious in appearance, unleſs with a view at the ſame time of taking or deſtroying a flag-ſhip of the enemy's, and where ſucceſs alone, even then, can juſtify the attempt.

102 The admiral to be ſupported by his ſeconds,

The two immediate ſeconds to the admiral ought to direct part of their fire againſt the enemy's flag-ſhip, or any other that may attack their admiral; ſo that their chief attention ſhould be employed more in his defence than in that of their own proper ſhip, as they muſt ſacrifice every other conſideration to the honour of their flag.

The ſame attention muſt likewiſe be paid to any other ſhip that may find herſelf engaged with one of the enemy's flag-ſhips; the next to her ahead and aſtern ſhould ſerve in that reſpect as ſeconds, by dividing part of their fire againſt ſuch flag-officer, in order to make him ſtrike the ſooner.

If any flag-officer ſtand in need of being aſſiſted, he will of courſe make a ſignal for the corps de reſerve; or if there ſhould be none, he will ſignify the ſame to his diviſion; on which his two ſeconds, with thoſe neareſt him, will cloſe in to cover him, and continue the action. The frigates of his ſquadron will likewiſe be ready to give him the neceſſary aſſiſtance; and if he ſhould ſtill continue the attack, he will in a particular manner be ſupported by his whole diviſion.

103 And the ſhips mutually to protect each other.

Thoſe ſhips which happen to be moſt expoſed to danger will naturally make the ordinary ſignals upon the occaſion if they ſhould receive any hurt or damage, in order to be ſupported by ſuch of the line as are neareſt to them.

104 The body of reſerve

When a fleet is ſo far ſuperior in number as to be able to extend itſelf both ahead and aſtern conſiderably beyond the enemy's line, the admiral generally forms the exceſs into a body of reſerve, drawn up in a line on the other ſide of the fleet with reſpect to the enemy. If the body of reſerve

105 Formed in a line with the frigates.

is to windward, the ſhips compoſing it are to be drawn up in a line with the frigates neareſt abreaſt of the centre; but if to leeward, a little ahead of them; being careful at the ſame time to keep within reach of obſerving diſtinctly all the ſignals and motions of the fleet, and to be ready to replace ſuch of the ſhips as may happen to be diſmaſted or driven out of the line, where all intervals muſt be properly ſtrengthened, and carefully filled up again without loſs of time. The body of reſerve is uſually formed at the ſame time with the line, to prevent any irregularity that may happen on leaving any intervals or openings; yet the admiral may draw ſhips out of the line to form a body of reſerve, according to the time and circumſtances of his ſituation.

The Battle.

106 The oldeſt captain except the commander to relieve the firſt diſabled ſhip.

The eldeſt captain, after the ſenior officer who commands the body of reſerve, ought to relieve the firſt, or cloſe that part of the line which the diſabled ſhip has been obliged to quit; and ſo on ſucceſſively of the reſt.

107 The whole body of reſerve not to be detached unleſs in caſe of emergency.

The commanding officer of the body of reſerve will not be detached with the whole corps, unleſs on ſome preſſing occaſion, to fortify the line, where ſuch reinforcement is abſolutely neceſſary. If to defend one of the flag-officers of the three ſquadrons, he will be followed by the next ſenior officer of the reſerve who was not before detached, in order to place themſelves as ſeconds, the firſt ahead and the other aſtern of the flag they are to ſupport, without any diminution of the honour of his own proper ſeconds at the ſame time, as they are only called in through neceſſity on that emergency, being not engaged before, and conſequently better able to aſſiſt and ſupport the admiral; their duty being likewiſe to exert their utmoſt efforts in attacking, or, if poſſible, in boarding, the enemy's flag-ſhip, to force him to yield, except they are particularly ordered off to ſome other quarter or part of the line.

108 The admiral may order the whole body to reinforce either of the ſquadrons.

The admiral will ſometimes order the whole body of reſerve to reinforce one of the three ſquadrons of the fleet, as he may ſee occaſion; which, when he does, the body muſt make all the ſail it can, that each ſhip may place herſelf ſucceſſively, the firſt in the firſt interval, the ſecond in the ſecond interval, and ſo on throughout. If a part only of the body of reſerve is wanted, the proper ſignal will be made accordingly.

109 The body of reſerve to rejoin the line.

When the admiral has no further occaſion for the body of reſerve, he will make the proper ſignal for the ſhips compoſing it to reſume their reſpective poſts in the line, and theſe ſhips will repeat the ſignals.

110 In caſe a captain ſhould think boarding practicable.

If any captain in the fleet think he can board with ſucceſs one of the enemy's ſhips, he will ſignify the ſame to the admiral by hoiſting the boarding flag, together with his particular pendant to be more plainly diſtinguiſhed: the admiral in return will make the proper ſignal of approbation, or otherwiſe if he diſapproves of the attempt, by letting fly that ſhip's particular pendant that ſhe may obſerve the ſignal the better. Before the captain make the ſignal, he ought to conſider well the ill conſequences that might attend ſuch an enterpriſe if he ſhould fail of ſucceſs; for the breaking of the order or diſpoſition of the line, by quitting his poſt, may be of much greater diſadvantage to the whole, than any advantage ariſing from his victory, except that over a flag-ſhip.

111 The fire-ſhips to prepare when the ſignal is made to engage.

When the admiral makes the ſignal for his fleet to prepare for action, the fire-ſhips will at the ſame time get ready their grappling-irons, fire-engines, &c. for boarding, and will likewiſe diſpoſe all their combuſtibles into their proper channels of communication, &c. as ſoon as poſſible after the action begins: all which, when ready, they will take care to make known by ſignal to the particular diviſion or ſquadron they belong to, and they of courſe will repeat the ſame to the admirals.

112 To be out of the reach of the enemy's guns.

The fire-ſhips muſt be particularly careful in placing themſelves, out of the reach of the enemy's guns, which they may do abreaſt and under ſhelter of their own ſhips in the line, and not in the openings between the ſhips, unleſs to prevent any of the enemy's ſhips that ſhould attempt to force through their line, when they muſt in ſuch caſes uſe their utmoſt efforts to prevent them. They ought always

The Battle.

to be very attentive to the admiral's ſignals, as well as thoſe of the commanding officer of the particular ſquadron they belong to, that they may loſe no time when the ſignal is made for them to act, which they muſt quickly anſwer by a ſignal in return.

113 The fire-ſhip in her way to the enemy to be aſſiſted by the ſhip ahead of which ſhe paſſes.

Although no ſhip in the line ſhould be particularly appointed to lead down or protect the fire-ſhips, beſides the frigates already ordered for that particular purpoſe; yet the ſhip ahead of which the fire-ſhip paſſes in her way to the enemy, whatever diviſion ſhe may belong to, is to eſcort her, and muſt aſſiſt her with a boat well manned and armed, as well as any other ſuccour ſhe may ſtand in need of: The two next ſhips to her muſt likewiſe give her all neceſſary aſſiſtance. The captain of a fire-ſhip is to conſider, in ſhort, that he is anſwerable for the event, in proportion as he expects to be honourably rewarded if he ſucceed in ſo daring and hazardous an enterpriſe.

114 Particular deſcription of a naval engagement between two ſhips.

Since a general engagement of fleets or ſquadrons of men of war is nothing elſe than a variety of particular actions of ſingle ſhips with each other, in a line of battle, it may not be improper to begin by deſcribing the latter, and then proceed to repreſent the uſual manner of conducting the former.

115 Divided into preparation, action, and repair.

The whole economy of a naval engagement may be arranged under the following heads; namely, the *preparation*, the *action*, and the *repair* or *refitting* for the purpoſes of navigation.

116 The preparation.

The *preparation* is begun by iſſuing the orders to clear the ſhip for action, which is repeated by the boatſwain and his mates at all the hatchways or ſtaircaſes leading to the different batteries. As the management of the artillery, in a veſſel of war, requires a conſiderable number of men, it is evident that the officers and ſailors muſt be reſtrained to a narrow ſpace in their uſual habitations, in order to preſerve the internal regularity of the ſhip. Hence the hammocs, or hanging-beds, of the latter are crowded together as cloſe as poſſible between the decks, each of them being limited to the breadth of 14 inches. They are hung parallel to each other, in rows ſtretching from one ſide of the ſhip to the other, nearly throughout her whole length, ſo as to admit of no paſſage but by ſtooping under them. As the cannon therefore cannot be worked while the hammocs are ſuſpended in this ſituation, it becomes neceſſary to remove them as quickly as poſſible. By this circumſtance a double advantage is obtained: the batteries of cannon are immediately cleared of an encumbrance, and the hammocs are converted into a ſort of parapet, to prevent the execution of ſmall-ſhot on the quarter-deck, tops, and forecaſtle. At the ſummons of the boatſwain, *Up all hammocs!* every ſailor repairs to his own, and, having ſtowed his bedding properly, he cords it up firmly with a laſhing or line provided for that purpoſe. He then carries it to the quarter-deck, poop, or forecaſtle, or wherever it may be neceſſary. As each ſide of the quarter-deck and poop is furniſhed with a double net-work, ſupported by iron cranes fixed immediately above the gunnel or top of the ſhip's ſide, the hammocs thus corded are firmly ſtowed by the quarter-maſter between the two parts of the netting, ſo as to form an excellent barrier. The tops, waiſte, and forecaſtle, are then fenced in the ſame manner.

Whilſt theſe offices are performed below, the boatſwain and his mates are employed in ſecuring the ſailyards, to prevent them from tumbling down when the ſhip is cannonaded, as ſhe might thereby be diſabled, and rendered incapable of attack, retreat, or purſuit. The yards are now likewiſe ſecured by ſtrong chains or ropes, additional to thoſe by which they are uſually ſuſpended. The boatſwain alſo provides the neceſſary materials to repair the rigging, wherever it may be damaged by the ſhot of the enemy, and to ſupply whatever parts of it may be entirely deſtroyed. The carpenter and his mates, in the meanwhile, prepare ſhot-plugs and mauls, to cloſe up any dangerous breaches that may be made near the ſurface of the water; and provide the iron-work neceſſary to refit the chain-pumps, in caſe their machinery ſhould be wounded in the engagement. The gunner with his mates and quarter-gunners is buſied in examining the cannon of the different batteries, to ſee that their charges are thoroughly dry and fit for execution; to have every thing ready for furniſhing the great guns and ſmall arms with powder as ſoon as the action begins; and to keep a ſufficient number of cartridges continually filled, to ſupply the place of thoſe expended in battle. The maſter and his mates are attentive to have the ſails properly trimmed, according to the ſituation of the ſhip; and to reduce or multiply them, as occaſion requires, with all poſſible expedition. The lieutenants viſit the different decks, to ſee that they are effectually cleared of all encumbrance, ſo that nothing may retard the execution of the artillery; and to enjoin the other officers to diligence and alertneſs, in making the neceſſary diſpoſitions for the expected engagement, ſo that every thing may be in readineſs at a moment's warning. The Battle

When the hoſtile ſhips have approached each other to a competent nearneſs, the drums beat to arms: The boatſwain and his mates pipe, *All hands to quarters!* at every hatchway: All the perſons appointed to manage the great guns immediately repair to their reſpective ſtations: The crows, handſpikes, rammers, ſponges, powder-horns, matches, and train tackles, are placed in order by the ſide of every cannon: The hatches are immediately laid, to prevent any one from deſerting his poſt by eſcaping into the lower apartments: The marines are drawn up in rank and file on the quarter-deck, poop, and forecaſtle: The laſhings of the great guns are caſt looſe, and the tompions withdrawn: The whole artillery, above and below, is run out at the ports, and levelled to the point blank range, ready for firing.

117 The action, and

The neceſſary preparations being completed, and the officers and crew ready at their reſpective ſtations to obey the order, the commencement of the action is determined by the mutual diſtance and ſituation of the adverſe ſhips, or by the ſignal from the commander in chief of the fleet or ſquadron. The cannon being levelled in parallel rows projecting from the ſhip's ſide, the moſt natural order of battle is evidently to range the ſhips abreaſt of each other, eſpecially if the engagement is general. The moſt convenient diſtance is properly within the point blank range of a muſket, ſo that all the artillery may do effectual execution.

The combat uſually begins by a vigorous cannonade, accompanied with the whole efforts of the ſwivel-guns and the ſmall-arms. The method of firing in platoons, or volleys of cannon at once, appears inconvenient in the ſea-ſervice, and perhaps ſhould never be attempted unleſs in the battering of a fortification. The ſides and decks of the ſhip, although ſufficiently ſtrong for all the purpoſes of war, would be too much ſhaken by ſo violent an exploſion and recoil. The general rule obſerved on this occaſion throughout the ſhip, is to load, fire, and ſponge the guns with all poſſible expedition, yet without confuſion or precipitation. The captain of each gun is particularly enjoined to fire only when the piece is properly directed to its object, that the ſhot may not be fruitleſsly expended. The lieutenants, who command the different batteries, traverſe the deck to ſee that the battle is proſecuted with vivacity; and to exhort the men to their duty. The midſhipmen ſecond theſe injunctions, and give the neceſſary aſſiſtance, wherever it may be required, at the guns committed to their charge. The

gunner

The Battle.

gunner ſhould be particularly attentive that all the artillery is ſufficiently ſupplied with powder, and that the cartridges are carefully conveyed along the decks in covered boxes. The havock produced by a continuation of this mutual aſſault may be readily conjectured by the reader's imagination: battering, penetrating, and ſplintering the ſides and decks; ſhattering or diſmounting the cannon; mangling and deſtroying the rigging; cutting aſunder or carrying away the maſts and yards; piercing and tearing the ſails ſo as to render them uſeleſs; and wounding, diſabling, or killing the ſhip's company! The comparative vigour and reſolution of the aſſailants to effect theſe pernicious conſequences in each other, generally determine their ſucceſs or defeat: we ſay generally, becauſe the fate of the combat may ſometimes be decided by an unforeſeen incident, equally fortunate for the one and fatal to the other. The defeated ſhip having acknowledged the victory by ſtriking her colours, is immediately taken poſſeſſion of by the conqueror, who ſecures her officers and crew as priſoners in his own ſhip; and inveſts his principal officer with the command of the prize until a captain is appointed by the commander in chief.

118 Repair.

The engagement being concluded, they begin to repair: the cannon are ſecured by their breechings and tackles with all convenient expedition. Whatever ſails have been rendered unſerviceable and unbent; and the wounded maſts and yards ſtruck upon deck, and fiſhed or replaced by others. The ſtanding rigging is knotted, and the running-rigging ſpliced wherever neceſſary. Proper ſails are bent in the room of thoſe which have been diſplaced as uſeleſs. The carpenter and his mates are employed in repairing the breaches made in the ſhip's hull, by ſhot-plugs, pieces of plank, and ſheet-lead. The gunner and his aſſiſtants are buſied in repleniſhing the allotted number of charged cartridges, to ſupply the place of thoſe which have been expended, and in refitting whatever furniture of the cannon may have been damaged by the action.

Such is the uſual proceſs and conſequence of an engagement between two ſhips of war, which may be conſidered as an epitome of a general battle between fleets or ſquadrons. The latter, however, involves a greater variety of incidents, and neceſſarily requires more comprehenſive ſkill and judgement in the commanding officer. A ſhort account of which alſo we ſhall next proceed to lay before our readers.

119 Deſcription of an engagement between two fleets.

When the admiral or commander in chief of a naval armament has diſcovered an enemy's fleet, his principal concern is uſually to approach it, and endeavour to come to action as ſoon as poſſible. Every inferior conſideration muſt be ſacrificed to this important object, and every rule of action ſhould tend to haſten and prepare for ſo material an event. The ſtate of the wind, and the ſituation of his adverſary, will in ſome meaſure dictate the conduct neceſſary to be purſued with regard to the diſpoſition of his ſhips on this occaſion. To facilitate the execution of the admiral's orders, the whole fleet is ranged into three ſquadrons, each of which is claſſed into three diviſions, under the command of different officers. Before the action begins, the adverſe fleets are drawn up in two lines, as formerly deſcribed. As ſoon as the admiral diſplays the ſignal for the line of battle, the ſeveral diviſions ſeparate from the columns, in which they were diſpoſed in the uſual order of ſailing, and every ſhip crowds ſail to get into its ſtation in the wake of the next ahead; and a proper diſtance from each other is regularly obſerved from the van to the rear. The admiral, however, will occaſionally contract to extend his line, ſo as to conform to the length of that of his adverſary, whoſe neglect or inferior ſkill on this occaſion he will naturally convert to his own advantage, as well as to prevent his own line from being doubled; a circumſtance which might throw his van and rear into confuſion. The Battle.

When the adverſe fleets approach each other, the courſes are commonly hauled up in the brails, and the topgallant-ſails and ſtay-ſails furled. The movement of each ſhip is chiefly regulated by the main and fore-top ſails and the jib; the mizen top ſail being reſerved to haſten or retard the courſe of the ſhip; and, in fine by filling or backing, hoiſting or lowering it, to determine her velocity.

The ſignal for a general engagement is uſually diſplayed when the oppoſite fleets are ſufficiently within the range of point blank ſhot, ſo that they may level the artillery with certainty of execution, which is near enough for a line of battle. The action is begun and carried on throughout the fleet in the manner we have already deſcribed between ſingle ſhips. The various exigencies of the combat call forth the ſkill and reſources of the admiral to keep his line as complete as poſſible when it has been unequally attacked; by ordering ſhips from thoſe in reſerve to ſupply the place of others which have ſuffered greatly by the action; by directing his fire-ſhips at a convenient time to fall aboard the enemy; by detaching ſhips from one part of the line or wing which is ſtronger to another which is greatly preſſed by ſuperior force, and requires aſſiſtance. His vigilance is ever neceſſary to review the ſituation of the enemy from van to rear; every motion of whom he ſhould, if poſſible, anticipate and fruſtrate. He ſhould ſeize the favourable moments of occaſion, which are rapid in their progreſs, and never return. Far from being diſconcerted by any unforeſeen incident he ſhould endeavour, if poſſible, to make it ſubſervient to his deſign. His experience and reflection will naturally furniſh him with every method of intelligence to diſcover the ſtate of his different ſquadrons and diviſions. Signals of inquiry and anſwers, of requeſt and aſſent, of command and obedience, will be diſplayed and repeated on this occaſion. Tenders and boats will alſo continually be detached between the admiral and the commanders of the ſeveral ſquadrons or diviſions.

As the danger preſſes on him he ought to be fortified by reſolution and preſence of mind; becauſe the whole fleet is committed to his charge, and the conduct of his officers may in a great degree be influenced by his intrepidity, and perſeverance. In ſhort his renown or infamy may depend on the fate of the day.

CHAP. IX. *Manœuvres performed by adverſe Fleets when in ſight of each other.*

120 To diſpute the wind with the enemy.

To diſpute the weather-gage with the enemy.—When the enemy is to windward, and it is wiſhed to gain the weather-gage of him, the fleet to leeward ſhould avoid extending itſelf the length of the enemy's line, in order to oblige them to edge down upon theirs, if they intend to attack them; which will be a mean, if they ſtill perſiſt in doing ſo, of loſing the advantage of the wind.

It is impoſſible for a fleet to leeward to gain to windward ſo long as the enemy keep their wind, unleſs a change happens in their favour: therefore all that a fleet to leeward can do, muſt be to wait with patience for ſuch a change which they will undoubtedly avail themſelves of, as well as any miſtake or inadvertency the enemy may commit in the mean time. And as long as the fleet to leeward does not extend its line the length of the enemy's, it will be impoſſible for the latter to bring them to action without running the hazard, by bearing down, of loſing the advantage of the wind, which both fleets will be ſo deſirous of preſerving.

Manœuvres performed by adverſe Fleets when in ſight of each other.

Hence, that an admiral may benefit by the ſhifts of the wind that frequently happen, he muſt in a manner force them; which will not appear ſo extraordinary to officers of any experience, who know what winds reign moſt on the coaſt, or off the head-lands, where they may expect an enemy; and though an admiral may be ſometimes out in his conjecture, he alſo as often ſucceeds ſo happily as to gain the advantage of his enemy. The diſpoſition of projecting head-lands, and the ſetting of tides or currents, alſo contribute greatly towards gaining the wind of the enemy.

Again, the fleet to windward ought to keep that to leeward as much as poſſible always abreaſt of it; becauſe, by doing ſo, they will preſerve the advantage they have, unleſs the wind changes much againſt them. They ſhould force them likewiſe to keep their wind, unleſs they think it more prudent not to engage; but when that is the caſe, they ſhould keep entirely out of ſight.

The following obſervations, with reſpect to the ſhifting of the wind, are given by M. Bourdé de Villehuet: 1. If the weather fleet be in order of battle, and the wind draw ahead, the lee fleet, if they be ahead and in order of battle, ought to box off on the ſame tack as before, in order to tack in ſucceſſion in the wake of one another, to reſtore the order of battle; drawing at the ſame time a great deal to windward. This manœuvre may even be the means of weathering the enemy, if the wind ſhould ſhift much; for they have no other method to regain the order of battle, without loſing much ground: though they will always loſe a great deal with reſpect to the poſition of the enemy to leeward.

Elements of Rigging and Seamanſhip, vol. ii. p. 382.

2. If the lee fleet be aſtern, and the wind ſhifts aft while they are on the contrary tack with the enemy in order of ſailing on one line, the lee fleet ought to tack or veer altogether, and at the ſame inſtant; becauſe this ſhift of wind will be ahead for all the ſhips in reſpect to their tacks then on board, and aſtern in reſpect to the order of battle. When the van ſhip is full on the other tack, as well as all the reſt in their former order of battle, ſhe ſhall haul by the wind, while the reſt of the fleet run large on their firſt line of battle as many points as the wind has ſhifted aft, to get into her wake ſucceſſively, and reſtore the order of battle while approaching the enemy; by which they gain the wind of him, or elſe double him if the ſhift has been great; for the only means they have of reſtoring the line of battle is by the van ſhip hauling by the wind, and the reſt coming into her wake in ſucceſſion. If the ſhift of the wind was four points, the fleet to leeward would be obliged ſtill to perform the ſame manœuvre, that they might go about, after a certain time, ſucceſſively to windward of the enemy, who could only in the mean time have tacked all together, to bring their fleet ſuddenly in a line of battle on the other board.

If, when the wind ſhifts aft, the lee fleet is aſtern in order of battle, and the enemy be on the other tack in the order of ſailing, the leading ſhip muſt haul cloſe to the wind immediately, while the other veſſels will, in ſucceſſion, bear away as many points as the wind has ſhifted, in order to perform the ſame manœuvre and reſtore the line of battle. By obſerving this mode of manœuvring, you will approach the enemy, and gain as much to windward of him as poſſible, or get even the weather-gage of him entirely, if the wind has ſhifted conſiderably. The rear ſhip of the fleet to leeward may immediately keep cloſe to this new wind on the ſame board, while all the reſt of the fleet, after having tacked together and at the ſame time, will come and place themſelves cloſe by the wind in her wake, where they are again to tack ſucceſſively, in order to follow their rear ſhip, which is now become the leader, and which may break the enemy's line, or at leaſt gain the wind of him. But, to be able to go through this evolution, you muſt have nothing to fear from the enemy; for the fleet will be obliged to go about twice before the order of battle can be reſtored. The weather fleet ought to keep their wind as cloſe as poſſible, holding the enemy always exactly to leeward of them, by keeping on the ſame tack as he; and if the wind ſhifts a little, and becomes favourable to the enemy which is to leeward, the weather ſhips are then to keep exactly their wind, without caring for the preſervation of the line, unleſs the two fleets be very near one another.

Manœuvres performed by adverſe Fleets when in ſight of each other.

To force the enemy to action.

121 To force the enemy to action when he is to windward.

1. When the enemy has the weather-gage.—When two adverſe fleets are in ſight of each other, an engagement is almoſt unavoidable: For ſince it may be preſumed that the faſteſt ſailing ſhips of the one fleet will ſail faſter than the ſloweſt ſailing veſſels of the other fleet, hence the fleet that is in purſuit will gain upon the other. The lee fleet, which is wiſhing to bring on an engagement, muſt therefore keep always on the ſame tack with the weather fleet; and taking care to keep them ſo exactly abreaſt as to prevent the leaſt danger of loſing ſight of them, and hence be ready to take the advantage of the firſt favourable ſhift of wind to make the attack. Night is certainly the time when an alteration of the courſe may be beſt attempted. But the lee fleet is to have frigates on the look-out; which, by ſignals, will continually give notice of the manœuvre and courſe of the retreating fleet to windward; which, by theſe means, is always expoſed to be purſued without being able to get off unſeen, and muſt ſooner or later be compelled to come to action, unleſs they can get into ſome port, or a gale of wind ſhould come to reſcue them by diſperſing both fleets, and thus furniſh the means of retreating in a ſtorm.

Ibid. p. 384.

122 When he is to leeward.

2. When the enemy is to leeward.—If the lee fleet keep cloſe to the wind in the order of battle, the fleet to windward is to ſtand on in the ſame manner till it is abreaſt of the enemy, ſhip to ſhip, when they are all together, and at the ſame time, to bear away, and ſteer exactly ſo as to bring their reſpective opponents, in the adverſe line, on the ſame point of the compaſs with them; obſerving the principles of chaſing, which are to be obſerved by every chaſer to windward. Thus the fleets will be near enough to begin the action, in preſenting the bow of each ſhip to her opponent in the order of ſailing, which will be eaſily changed for the line of battle, by all the ſhips hauling cloſe to the wind together, in the moment which precedes the beginning of the action.

Ibid. and Manœuverer, p. 276.

If the fleet to leeward be inclined to engage, it might bring to, to prevent loſing time; as, by this manœuvre, leſs time will be requiſite for the weather fleet to join them: then they will fill as ſoon as the action begins, becauſe it is more favourable to a lee line to be advancing ahead; ſince, if a ſhip be diſabled in the weather line (which is obliged to follow with the topſails full), ſhe will infallibly drop, and run foul of the next veſſel aſtern of her, covered with fire and ſmoke, which may be productive of great diſorder.

As the lee fleet fills and ſtands on cloſe by the wind, it is neceſſary that the weather line ſhould be abreaſt and parallel to the other before they bear away to come within the requiſite diſtance for action, in order that the van ſhip of the weather fleet ſhould always keep to windward of the leading ſhip of the lee line, and be guarded againſt ſuch a ſhift of wind as might come ahead: which would not be the caſe if they were aſtern of the van ſhip in the lee fleet; which, as well as the reſt of the line, would be able then to double them to windward, by tacking in ſucceſſion.

Another reaſon for the weather line being right abreaſt of the enemy to leeward, and for every ſhip ſteering on the ſame point in approaching her opponent in the leeward line

of

Manœuvres performed by adverſe Fleets when in ſight of each other.

of battle, is, that the fleets may be placed exactly parallel to each other; for, as the weather line muſt not be aſtern, becauſe of the riſk of the wind coming more forward, neither muſt they be ahead of the line to leeward, in caſe the wind ſhould come aft; for then the lee fleet, keeping cloſe by the wind in the wake of their leading ſhip, might, by this ſhift, be as far to windward as the oppoſing fleet, or even get the weather gage of them. But if the weather fleet keep exactly abreaſt of the other, they will always be in a ſituation to preſerve their advantage without expoſing themſelves. It is, notwithſtanding, that thoſe ſhips keeping more away than the line to leeward will find themſelves, when come within gun-ſhot, in a very diſagreeable ſituation with reſpect to the enemy's ſhips, which will have it then in their power to rake them as they bear down. This may occaſion much diſorder among the ſhips of the weather line, which, for that moment, have it not in their power to fire their whole broadſide at the enemy, who has the advantage of beginning the action.

If the lee fleet bear away four points to move their order of battle on the other tack and avoid the action, filing off in ſucceſſion in the wake of the van ſhip, the weather line, by bearing away altogether eight points, cannot fail, as both fleets are ſuppoſed to ſail equally, to paſs through the middle of their line, and force them to fight with diſadvantage, if their extent be double the diſtance between the two fleets. If the extent of the fleet be leſs than the above limitation, then the weather fleet will divide the lee fleet more unequally; and if the diſtance between the fleets be conſiderable, the weather fleet will not be able to break through the line.

If the lee fleet bear away four points all together, being of equal extent with the fleet to windward, and their diſtance from each other equal to half the length of one of the lines; ſhould the weather fleet bear away at the ſame time eight points, they will approach very near the ſternmoſt of the retreating fleet; but they will not have it in their power to cut off any part of that fleet, even with an equality of ſailing: ſo that the only advantage gained by this manœuvre will be an ability of attacking the rear, and bringing it to action.

If the van ſhip and the reſt of the weather fleet had a ſufficient velocity to keep the centre ſhip of the lee line on the ſame point of bearing; in that caſe the leading ſhip may break through the enemy's line about the middle ſhip of the centre diviſion: for, ſuppoſing the fleets in order of battle, on the ſtarboard tack, ſteering eaſt, with the wind at ſouth-ſouth-eaſt, being at two leagues diſtance from each other, both the lines being four leagues in extent; then the lee line bearing away all together four points, will run north-eaſt, while the fleet to windward, bearing away all together eight points, will ſteer north; the van ſhip of which will keep the centre diviſion of the lee line on the point of bearing north-weſt. As ſhe is ſuppoſed to be able to continue in this poſition, it follows, that the van of the weather line muſt cloſe the centre of the flying line to leeward, after having run four leagues. The time and diſtance neceſſary to cut off a retreating fleet may always be known according to the laſt ſuppoſition. Should the lee fleet get upon the other tack and run large, ſtill preſerving the order of battle, they will be ſtill ſooner cloſed and forced to action by the weather fleet who have only to keep away from eight to nine points on the ſame tack, to run right before the wind.

The weather fleet can always force the lee one to action, whatever movements they make; for, if they run with the wind right aft in order of battle, they cannot, ſuppoſing an equality of ſailing, avoid being cloſed or broken nearly about the centre by the weather line, which has only to ſteer two points on each tack nearer the wind than the retreating fleet. So that the rear of the weather fleet having bore away no more than eight points, will be found at the end of a certain time to have approached extremely near the centre of the retreating fleet; and, in a ſhort time more, will be able to bring their rear to action. The weather fleet have yet another advantage; becauſe, as their ſhips have the wind on the quarter, they ſail with greater celerity than thoſe of the lee fleet, which run before the wind. The lee fleet being abſolutely determined to fly, has therefore no other expedient left to prolong time but to combat in the order of retreat right before the wind, or on the ſame courſe as the purſuing fleet; for other advantages are not to be relied on, if purſued by a victorious foe.

Manœuvres performed by adverſe Fleets when in ſight of each other.

If from all that has been ſaid, it reſults that it is not poſſible for a fleet of equal force to avoid an action, how then muſt it be with one much inferior? The more numerous has nothing to do but to form a detachment of ſuperior ſailors, which will gain upon the lee fleet and begin the action, while ſome others approach to finiſh it. Whence we may conclude, that when in preſence of too powerful an enemy, it will never be poſſible to avoid an action if he is determined to come to one.

To avoid coming to Action.

123 To avoid an action, the enemy being to windward,

1. When the enemy is to windward.—The lee fleet, which is wiſhing as much as poſſible to avoid an engagement, ought to form the order of retreat to fly from the enemy if they are in view of him, and run on the ſame tack as their chaſer. But if he is yet out of ſight and they have intelligence of his approach by their frigates which are looking out, they may run large from the hoſtile fleet, without confining themſelves to keep the wind exactly aft, unleſs they be in the order of retreat. There are, however, circumſtances when the lee fleet may run with the wind aft, without aſſuming the order of retreat; as, for example, when they wiſh to gain time, or are reſolved to engage the enemy, if they ſtill continue to purſue them. But except on ſuch extraordinary occaſions, a fleet ſhould not fly before the enemy without being in the order of retreat, as the rear is then in the beſt ſituation to extricate themſelves in caſe of accident.

124 The enemy being to leeward.

2. When the enemy is to leeward.—The weather fleet can ſcarcely ever be forced to engage; becauſe it can always continue on that tack which increaſes its diſtance from the enemy, by ſtanding on one tack, while the enemy continues upon the other. If the wind was to remain on the ſame point of the compaſs for any conſiderable ſpace of time, it would be very eaſy for the fleet to windward to keep in ſight of the enemy, without being under any apprehenſions of being forced to come to action; but the inconſtancy of the wind obliges the moſt experienced admiral to avoid meeting the enemy when he thinks it improper to engage him.

To double the Enemy, or to bring a Part of his Fleet between two Fires.

125 To double the enemy when he has the weather-gage.

1. When the enemy has the weather-gage.—The fleet which attempts to double an enemy ought always to be ſuperior to him in number of ſhips. The lee fleet ought to endeavour to range exactly abreaſt of, and parallel to, the weather fleet, ſo that the van or rear may extend beyond their line in order to over-reach them, by tacking in ſucceſſion to double to windward their van or rear, and bring them between two fires. Provided this manœuvre be properly executed, it will be impoſſible for the ſhips in the weather line, thus preſſed, to continue long in their ports; for there is no veſſel cloſely attacked by two others of equal force which can long reſiſt being overcome, ſince it is always in the power of one of them to get into ſuch a poſi-

Elements of Rigging and Seamanſhip, vol. ii. p. 386.

tion

Manœuvres performed by adverſe Fleets when in ſight of each other.

tion as to be able, without much danger on her ſide, to deſtroy the enemy in a very ſhort time. But whether the moſt advantageous evolution is to double the van or the rear, is neceſſary to be conſidered; for there is ſo conſiderable an advantage attending each of theſe evolutions, that either of them may in a very little time determine the fate of the battle.

As, in the preſent caſe, the enemy is ſuppoſed to be to windward, either their van or rear may be doubled; but the van may with the greateſt facility, becauſe, if they are engaged by the ſhips abreaſt of them, thoſe which are advanced ahead will be able, by making all ſail, to get on the perpendicular to the direction of the wind with the van of the enemy, and tack in ſucceſſion to gain the wind of them on the other board, thus keeping them to leeward; and when they are come ſufficiently to windward, they are again to go about, in order to keep the two headmoſt ſhips of the enemy's line continually under their fire. If there be two or three ſhips to tack in ſucceſſion and gain the wind of the enemy, they may edge down on the van of the weather line at pleaſure, keeping themſelves a little to windward of it; and as that van is already engaged by the other ſhips abreaſt on the other ſide, ſhe muſt neceſſarily be ſoon diſabled. If they bear away, they muſt drop upon the line with which they are engaged to leeward, while the ſhips to windward ſtill continue to cannonade them. If they attempt going about, in order to attack more cloſely the ſhips to windward, they will be raked, while in ſtays, by their opponents to leeward and to windward, who enfilading them with whole broadſides, which they cannot return, muſt abſolutely complete their diſorder. If they make ſail, in order to fruſtrate the deſign of the ſhips inclined to double, thoſe with which they are engaged abreaſt to leeward have only to perform the ſame manœuvre, and keep them under their fire; while the others, after having haraſſed them as much as poſſible, will do their beſt to perform the ſame manœuvre on the ſucceeding ſhips.

The captains deſtined to double the enemy ought to be men of known ability, as well as of approved courage. They ſhould not be ordered upon that ſervice but in weather fit for ſailing at the rate of three knots an hour at leaſt; and, for the greater promptitude and certainty of ſucceſs, none but the beſt going ſhips are to be employed.

If any of the ſhips in the van of the weather-line happen to be diſabled in their maſts or yards, as will moſt probably be the caſe after having been between two fires, they will drop aſtern and run foul of the next which follows, and theſe again of their ſubſequent comrades; at laſt, diſorder will become prevalent, by ſhips running foul of each other, or manœuvring to avoid the ſame accident: ſo that the order of battle will be broken; while, on the other hand, the line to leeward is preſerved with all the advantage poſſible. The ſhips which have gained the wind of the enemy will, by continuing their manœuvre, augment the confuſion; engaging, however, no more than they like; and if, by chance or miſfortune, they ſhould be crippled, it will not certainly be an eaſy matter for them to extricate themſelves. But as they may, on the other tack, drop aſtern to windward of the enemy's line, or veer again like him, they muſt extricate themſelves as well as they can, and always advantageouſly enough if, by doubling the van, they are able to throw it into diſorder.

If the rear of the lee fleet be extended beyond the ſternmoſt ſhip of the weather line, they will be obliged, if they want to double the rear of the enemy to windward, to make ſail and tack in ſucceſſion; in which manœuvre the headmoſt ſhip of thoſe deſtined for this ſervice is to go about firſt; then, continuing to keep up a briſk cannonade as they come to the wind, they will go and heave about again a little to windward of the rear of the enemy, in order to bring their ſtern ſhips between two fires: and ſhould they have the good fortune to oblige them to bear away, they muſt go on ſucceſſively from one ſhip to another, as long as they find they ſucceed in forcing them to give way. Should diſorder take place in the rear of the weather fleet, it will not be near ſo prejudicial to the enemy as if it had happened in the van; on the contrary, it may turn out to be of ſome advantage to them. But the veſſels combating to windward can eaſily withdraw from the fight, by backing aſtern when they find themſelves too hard preſſed.

Manœuvres performed by adverſe Fleets when in ſight of each other.

126 To double the enemy when he is to leeward.

2. When an enemy is to leeward.—The ſhips of the weather-line having extended their van beyond that of the lee-line, are to veer, in order to bring the headmoſt ſhips of the enemy's line between two fires. But, let them do as they will, there never can reſult ſo much advantage from this manœuvre as when doubling a fleet to windward, becauſe the diſabled ſhips can always veer with facility. True it is, they cannot fail becoming at the ſame time the prey of the enemy; for both thoſe which have doubled them, and thoſe with which they are engaged abreaſt in the weather-line, will always have it in their power jointly to preſs as cloſe as they think proper. Ibid. p. 388.

If the ſhips which have doubled the van of the lee fleet, with which they are engaged, be diſabled, they will be obliged, as they cannot make ſail, to paſs along the lee-line; and they cannot eſcape being totally deſtroyed if they do not bear away before the wind, to get out of gun-ſhot; during which manœuvre they cannot avoid being ſtill in a very diſagreeable ſituation.

Should the ſternmoſt ſhips of the weather fleet be diſabled in doubling the enemy's rear, they have only, if they want to extricate themſelves, to drop aſtern, and let the two fleets advance ahead; and after having refitted themſelves, they will reaſſume their ports.

To avoid being doubled.

127 To avoid being doubled, the enemy being to windward,

1. The enemy being to windward.—For this purpoſe, it has been propoſed to extend the line, by leaving a greater interval between the ſhips towards the centre than in the van or rear; but in this caſe the line runs the riſk of being divided, unleſs prevented by a corps de reſerve, conſiſting of a few ſhips of the line and fire-ſhips. It has alſo been propoſed as a general rule, that the flag-officers of the lee fleet ſhould oppoſe themſelves to thoſe of the enemy; by which means ſeveral of the enemy's ſhips will be rendered uſeleſs in the intervals. This method has, however, its inconveniencies; as ſometimes the van and rear of each diviſion may be expoſed to the fire of two ſhips at the ſame time: nor is the laſt diviſion out of danger of being doubled. In order to remedy theſe defects, the larger ſhips ought to be placed in the van and rear of each diviſion; and the whole fleet muſt regulate its ſailing in ſuch a manner that the rear of the enemy may not be aſtern of the rear of the laſt diviſion.

Other methods have been propoſed to avoid being doubled; as, that each ſquadron of the lee fleet ſhould attack its correſponding ſquadron in the weather fleet; each diviſion of the lee fleet, however, extending its line far enough to prevent the enemy from leaving any ſhips aſtern of it, but rather ahead. It has alſo been propoſed, that the lee fleet ſhould extend its line as long as the enemy's line. This method will be advantageous for the lee fleet, provided it is compoſed of ſhips of ſuperior force, though fewer in number, than the enemy. In other caſes, it is probably the worſt method that can be followed by the lee fleet, as it gives the enemy's fleet all the advantage it can deſire of exerting its whole force upon the inferior line.

128 The enemy being to leeward.

2. When the enemy is to leeward.—The weather fleet is to keep aſtern of the enemy, ſo that the van of the weather fleet may be oppoſed to and attack the enemy's centre; hence

Manœuvres performed by adverse Fleets when in ſight of each other.

hence the enemy's van will become uſeleſs for ſome time; and if it ſhould attempt to tack and double upon the weather fleet, much time will be loſt in performing that evolution; and it alſo runs the riſk of being ſeparated by the calm which generally happens in the courſe of a ſea-engagement in conſequence of the continual diſcharge of cannon. A conſiderable interval might alſo be left between the centre and van, provided the neceſſary precautions be taken to prevent the van from being cut off.

129 To force the enemy's line.

To force the enemy's line.

This is a manœuvre which the lee fleet may execute to gain the advantage of the wind. It is performed by the van ſhip, if within gun-ſhot, tacking when ſhe and the centre ſhip of the weather line are on a perpendicular to the direction of the wind; then all the lee fleet tack in ſucceſſion, and thus may paſs through the enemy's line, or perhaps a little more towards the enemy's van, and go about again in ſucceſſion to windward of him. But as he will not be long, without doubt, before he performs the ſame manœuvre, he will thus be able to regain the wind, if he be not forced to give way before his evolution is finiſhed. The enemy to windward may even cauſe his van ſhip to tack, as well as the reſt of the van ſquadron to follow in ſucceſſion, as ſoon as the leading ſhip of the lee fleet ſhall have paſſed through his line and be ready to go about; by which means he will bring them between two fires. This manœuvre, well executed, might perhaps give no little trouble to the ſhip attempting to force the line.

Ibid. p. 389.

This evolution may be performed with advantage, if, by ſome accident or fault in the manœuvring, the centre diviſion of the weather-line be ſeparated from their van or rear. For example, when the centre diviſion to windward is encumbered with diſabled ſhips, then the ſhips of the centre diviſion of the fleet to leeward, having all ſails ſet, are to tack in ſucceſſion, and force with promptitude through the weather fleet, leaving their own van diviſion to engage that of the enemy on the other tack.

130 To prevent the line being forced.

To prevent the line being forced.

When the ſhips of the fleet go about in ſucceſſion, in order to force the weather line, the whole line to windward is to tack together, and at the ſame time to get upon the ſame board as the lee fleet; then that fleet will neither be able to traverſe nor join them. To perform this evolution with advantage, it will be requiſite to permit ſome of the van ſhips of the lee fleet to paſs to windward; then the weather fleet muſt go all about rapidly, in order to put and keep them between two fires: thus may theſe ſhips be deſtroyed without their own fleet being able to give them any effectual aſſiſtance.

It is eaſy to perceive, from what has been ſaid, that there is little occaſion to fear being traverſed, as ſuch a manœuvre may turn out to be more prejudicial than advantageous to thoſe who perform it. Nevertheleſs, it may and ought to be put in practice when the weather fleet leave ſuch vacancies between their diviſions as to allow ſome ſhips of the lee fleet to be inactive. In this caſe, the ſhips which are without opponents abreaſt of them are made to tack, with all ſails ſet, in ſucceſſion, and paſs through theſe intervals in the weather line, in order to double the centre diviſion, or any other part of it, and bring it between two fires.

CHAP. X. *Of Chaſing.*

131 Chaſing in the caſe of ſingle ſhips.

1. IN the caſe of ſingle ſhips.—It is ſcarcely neceſſary to obſerve, that the ſhip which gives chaſe is uſually called the *chaſer*, and that which is purſued is called the *chaſe*. Unleſs the chaſer be the faſteſt ſailing veſſel of the two, it is generally ſuppoſed that ſhe will ſeldom or never come up with the chaſe: but we have heard experienced officers ſay, that a chaſing ſhip, ſailing equally faſt, in other circumſtances, will gain on her chaſe; becauſe ſhe has an object to ſteer by, whereas the chaſe cannot ſteer ſo nicely by the compaſs. In what follows, however, we ſhall ſuppoſe the chaſer to be the faſteſt ſailer.

Of Chaſing.

132 The chaſe being to windward.

When the chaſe is to windward, it is evident that as ſoon as ſhe perceives a ſtrange ſhip which ſhe takes for an enemy, ſhe will haul her wind, in order to prolong the chaſe, as otherwiſe her retreat would be ſoon cut off. The chaſer then ſtands on alſo nearly cloſe-hauled until he has the chaſe on his beam; he then tacks, and ſtands on cloſe hauled until the chaſe is again on his beam, and then retacks. In this manner he continues tacking every time he brings the chaſe perpendicular to his courſe on either board; and by manœuvring in this manner, it is very certain that the chaſer will, by the ſuperiority only of his ſailing, join the other in the ſhorteſt time. For ſince the chaſer tacks always as ſoon as the chaſe is perpendicular to his courſe, ſhe is then at the ſhorteſt diſtance poſſible on that board; and ſince the chaſer is ſuppoſed to be the faſteſt ſailer, theſe ſhorteſt diſtances will decreaſe every time the chaſer tacks. It is therefore of advantage to the chaſe to keep conſtantly on the ſame courſe, without loſing her time in going about; as tacking cannot be ſo favourable to her as to her adverſary, whoſe ſailing is ſuperior. If the chaſer ſhould ſo little underſtand his profeſſion as to ſtand on a long way, and tack in the wake of the chaſe, the beſt thing ſhe can do is to heave in ſtays, and paſs to windward of him on the other tack, unleſs ſhe would have a ſuperiority in going large; for if the chaſer perſiſts in tacking in the wake of the other ſhip, it is an unqueſtionable fact that the chaſe will be very much prolonged.

133 The chaſe being to leeward.

The chaſe being to leeward, the chaſer is to ſteer that courſe by which he thinks he will gain moſt upon her. If, after having run a ſhort time, the chaſe is found to draw more aft, the chaſer is then to bear away a little more; but if the chaſe draws ahead, the purſuer is to haul up a little, and by this means the courſe may be ſo regulated that the chaſe may always bear on the ſame point of the compaſs, and then the chaſer will get up with the chaſe in the ſhorteſt time poſſible; for were any other courſe ſteered than that which keeps the chaſe always on the ſame point, the chaſer would then be either too far ahead, or too far aſtern; and hence the chaſe would be prolonged.

The chaſe ought to run upon that courſe which will carry her directly from the chaſer; and, in general, to conſult which is her beſt trim with reſpect to the wind, that ſhe may move with the greateſt rapidity poſſible from the ſhip which purſues her; for ſome veſſels have more advantage in going large than others, ſome with the wind right aft, and others again are to be found that ſail beſt cloſe-hauled; ſo that attention ſhould be paid by the officer to the known qualities of his ſhip, in order to take the moſt advantageous direction capable to effect a retreat.

Another method has alſo been propoſed for chaſing a ſhip to leeward, that is, by conſtantly ſteering directly for the chaſe: In this caſe, the tract the purſuer deſcribes through the water is called the line or *curve of purſuit*. In order to illuſtrate this, let A (fig. 54.) repreſent the purſuer, and B the chaſe directly to leeward of it, and running with leſs velocity than the purſuer, in the direction BC, perpendicular to that of the wind. Now, to conſtruct this curve, let B *b* be the diſtance run by the chaſe in any ſhort interval of time; join A *b*, and make A 1 equal to the diſtance run by the purſuer in the ſame time. Again, make *b c*, *c d*, *d e*, *e f*, &c.

134 Curve of purſuit.

Of Chasing.

&c. each equal to B b; join 1c, and make 12 equal to A1; join 2d, and make 23 equal to A1; in like manner proceed until the two distances carried forward meet as at C, and a curve described through the points A, 1, 2, 3, &c. will represent nearly the curve of pursuit; and the less the interval A1 is taken, the more accurate will the curve be formed. In this particular case the length of the distance BC may be found as follows, provided the distance AB and the proportional velocities of the two ships be known.

Let the velocity of the chase be expressed by a fraction, that of the chaser being unity. Multiply the given distance AB by this fraction, and divide the product by the complement of the square of the same fraction, and the quotient will be the distance run by the chase E. Let AB, the distance of the chase directly to the leeward of the pursuer, be 12 miles, and the velocity of the chase three-fourths of that of the chaser; the distance to be run by the chase before she is overtaken is required?

Now $\frac{12 \times \frac{3}{4}}{1-\frac{3}{4}|^2} = \frac{9}{\frac{7}{16}} = 9 \times \frac{16}{7} = 20\frac{4}{7}$ miles; and since the velocity of the pursuer to that of the chase is as 4 to 3: hence the distance run by the chaser will be $= 20\frac{3}{7} \times \frac{4}{3} = 27\frac{3}{7}$ miles.

As the pursuer alters his course at every point, and since it is presumed his ship will sail better with the wind in one direction, with respect to her course, than in an another, her velocity will therefore be different at different points of the course. Thus suppose her to sail faster when the wind is upon the quarter, her velocity will constantly increase until she has attained a certain point, and then it will decrease: hence in real practice this curve will not be precisely the same as above, and of course the measure of BC will differ a little from the preceding determination. The investigation of the foregoing rule is in Simpson's Fluxions, p. 516.; and the application of the curve of pursuit in Sir George Pococke's engagement in the East Indies in the year 1758, is given in Clerk's Essay on Naval Tactics, p. 160. It must be confessed, however, that Mr Simpson's investigation, though a pretty specimen of mathematical investigation, proceeds on certain physical assumptions, which are by no means sanctioned by experience. See what has been said of these assumptions and principles in the articles *Resistance of Fluids*, and Seamanship.

Hitherto we have considered chasing in the case of single ships only; the same rules are also applicable to fleets: we shall, however, subjoin the following remarks with respect to chasing as practised by fleets.

Of Chasing.

135 Chasing as practised by fleets.

If the whole fleet is to give chase, the admiral will make the proper signal; and then each ship will instantly make all the sail possible. If the retreating fleet is not much inferior to the other, a few of the fastest sailing vessels only are to be detached from the victorious fleet, in order to pick up any straggglers or those ships which may have fallen astern; and the remaining part of the fleet will keep in the same line or order of sailing as the retreating fleet, so that they may, if possible, force them to action. But if the retreating fleet is much inferior, the admiral of the superior fleet will make the signal for a general chase; and then each ship will immediately crowd all the sail possible after the retreating fleet; or, if the chase be still less numerous, the admiral will detach one of the squadrons of his fleet, by hoisting the proper signal for that purpose, and he will follow with the remainder of the fleet. The squadron that chases, or the cruisers detached from the fleet, should be very careful not to engage too far in the chase for fear of being overpowered; but at the same time to endeavour to satisfy themselves as much as may be in their power with regard to the object of their chase. They must pay great attention to the admiral's signals at all times; and in order to prevent separation, they should collect themselves before night, especially if there be any appearance of thick or foggy weather coming on, and endeavour to join the fleet again. The ships are diligently to observe when the admiral makes the signal to give over chase; that each regarding the admiral's ship as a fixed point, is to work back or make sail into her station, to form the order or line again as expeditiously as the nature of the case and the distance will permit.

136 Precautions to be observed by the fleet which is pursued.

When a fleet is obliged to run from an enemy who is in sight, it is usual to draw up the ships in that form or order, called the *order of retreat*, which has been already described; and the admiral, when hard pursued, without any probability of escaping, ought, if practicable, to run his ships ashore, rather than suffer them to be taken afloat, and thereby transfer additional strength to the enemy. In short, nothing should be neglected that may contribute to the preservation of his fleet, or prevent any part of it from falling into the hands of the conqueror.

Part II. NEW SYSTEM of NAVAL TACTICS.

WE have now laid before our readers as comprehensive a view as the limits prescribed to such articles will permit of the various evolutions usually practised by fleets in naval war. Though we have transcribed liberally from the most approved writers on the subject, we doubt not but the scientific officer will perceive that we have compiled awkwardly and unskilfully: but we are not seamen ourselves; and the generosity of able officers will pardon the blunders into which mere literary landsman could hardly avoid falling. The young seaman, who has the noble ambition to excel in his profession, will consult the authors whom we have mentioned in our introduction, in whose works he will find our deficiencies amply supplied; but that the present article may be as complete as *we* can make it, a view must be given of the system of tactics proposed by the Viscount de Grenier and Mr Clerk; because, whether these systems shall ever be adopted or not, they are the offspring of ingenuity, and as such merit attention.

Chap. I. *View of De Grenier's Tactics.*

Of all the orders, that of battle is the most important in naval tactics; but the order of battle which was first formed in the last century by the Duke of York, and has been continued in use to the present day, the Viscount de Grenier thinks extremely defective. Various causes may conspire to render the task of breaking it not difficult. Its great extent must make it no easy matter for the admiral to judge what orders are proper to be issued to the ships stationed in its extremities; whilst his signals, however distinctly made, are liable to be mistaken by the commanders of those ships. The extremities of a long line are necessarily defenceless, especially if it be to leeward; because, after it is formed, the enemy may throw himself with a superior number on its van or rear, and put that squadron to flight before assistance can be sent to it from the other squadrons. These defects the Viscount de Grenier thinks may be remedied by never

137 Defects of the line of battle in the old tactics.

View of De Grenier's Tactics.

138 Remedied by the Viſcount de Grenier.

never preſenting to the enemy any part of a fleet without its being flanked; ſo that were the commander of the adverſe fleet to attack thoſe parts which hitherto have been reckoned weakeſt, he might find himſelf defeated when he looked for conqueſt. With this view he propoſes a new order of battle; in which the fleet, compoſed of three diviſions, inſtead of being drawn up in one line as uſual, ſhall be ranged on the three ſides of a regular lozenge, formed by the interſecting of the two cloſe-hauled lines. It is obvious that one of the diviſions of a fleet ranged in this manner will always be formed in the order of battle; whilſt the two others, reſting upon the firſt ſhip ahead and the laſt aſtern of that diviſion, will be formed on the cloſe-hauled line oppoſite, and will ſtand on chequerwiſe on the ſame tack with the ſhips which are in the line of battle, ſerving to cover the headmoſt and ſternmoſt of thoſe ſhips, and thereby prevent the enemy from penetrating the line or doubling the rear.

Our author thinks it a great miſtake, though very generally fallen into, that the weather gage is of any advantage to a fleet equal in force to its enemy and willing to engage.

139 Object of De Grenier's tactics.

To him the great art of war at ſea appears to conſiſt in drawing or keeping to *windward a part of the adverſe fleet*, and collecting all one's forces againſt that part; and it is chiefly to effect this purpoſe that he propoſes his new ſyſtem of tactics. The reader, who would underſtand his principles, muſt never loſe ſight of this evident truth, that each ſhip of a fleet neceſſarily occupies at all times the centre of an horizon; which the author divides into two unequal parts, calling the greater the *direct and graduated ſpace*, and the leſs the *indirect, croſſed, and ungraduated ſpace*. The reaſon of theſe appellations is, that on the greater ſegment of the horizontal circle there are twenty different points, which may be marked by degrees from one of the cloſe-hauled lines to the other, and to which a ſhip may ſail from the centre by ſo many direct courſes without tacking; whereas to the other twelve points, including that from which the wind blows, ſhe cannot arrive but by ſteering croſs courſes, which muſt neceſſarily delay her progreſs.

140 Principles of his ſyſtem.

Suppoſe now a fleet to leeward, ſo diſpoſed as that only a part of it can fight with another equally numerous, and ranged to windward in a ſingle line; and let the lee fleet be ranged on the three ſides of a lozenge *a b*, *c d*, *e f* (fig. 55.). The ſquadron *a b*, which is moſt to windward, being drawn up in line of battle, cannot be fought but by an equal number AB of the weather fleet AB, CD, F. All the reſt of that fleet therefore muſt remain inactive, unleſs the ſhips which are not engaged ſhould try to paſs to leeward of the fleet, *a b*, *c d*, *e f*. But ſhould the ſhips of the weather fleet, which are placed between B and F, bear away as they appear in the figure between C *i* and F *i*, it is evident that the ſhips between A and B, which are fighting to windward, cannot bear away with them. Suppoſe now that, after the ſhips between C *i* and F *i* have paſſed to leeward, the ſquadrons *c d*, *e f*, which are ranged according to the new ſyſtem, and have not yet been engaged, ſhould come to windward and join with their friends *a b* againſt that ſquadron of the enemy AB which is ſtill to windward and engaged; it ſeems almoſt inevitable but that the ſquadron AB muſt be deſtroyed by ſo great a ſuperiority, before it could receive any aſſiſtance from the ſhips to leeward between C *i* and F *i*. No doubt thoſe ſhips would endeavour to ſuccour their friends; but with reſpect to them, the ſquadron AB muſt be conſidered as placed in that part of the horizon which our author calls *croſſed and indirect*, and to which they would not be able to repair but by ſteering alternately the two cloſe hauled lines; and aſſiſtance brought by ſo tedious a courſe would come too late to be of eſſential ſervice. It is from this apparently well ſupported concluſion that the viſcount de Grenier deduces the propriety of his propoſed orders of ſailing and order of battle.

View of De Grenier's Tactics.

Of orders of ſailing, he thinks, there can be no occaſion for more than three; one, when a fleet is to paſs a ſtrait; another, when it ſteers in an open ſea, either looking for the enemy or trying to avoid him; and the third, when it has an extenſive cruiſe to perform, in which the ſhips ſhould be ſo diſpoſed as not to be ſurpriſed or cut off by the enemy. His firſt order of ſailing differs not from that in common uſe. It is and muſt be obſerved (ſays he) in any narrow road, whatever may be the occaſion of its narrowneſs, whether rocks or ſands.

141 Firſt order of ſailing.

142 Second order.

In the ſecond order of ſailing, when the fleet is looking for the enemy or trying to avoid him, the columns *a b*, *c d*, *e f*, are to be formed on three ſides of a regular lozenge, and ranged on the two cloſe-hauled lines. The ſhips of the two diviſions *c d*, *e f*, ſometimes to windward (as in fig. 56.), and ſometimes to leeward (as in fig. 57.), of the third diviſion *a b*, are to be formed on two parallels of one of the cloſe-hauled lines in the wakes of their reſpective headmoſt ſhips; and the third diviſion *a b* is to be ranged ahead or aſtern of the two others on the other cloſe-hauled line, and nevertheleſs to ſteer chequerwiſe the ſame courſe as the two diviſions *c d* and *e f*. When *a b* is to windward of *e d* and *e f* (fig. 57.), the viſcount calls that the *primitive* windward order of ſailing; and when to leeward (fig. 56.), the fleet is in the *leeward primitive* order of ſailing. The poſition of the three diviſions in the windward primitive order of ſailing is the ſame for the order of battle natural; for the order of retreat; and for the order of circumvallation, when the object is to ſeparate from the hoſtile fleet a part of its ſhips in order to engage the remainder with more advantage. The poſition of the three diviſions in the leeward primitive order of ſail is alſo the ſame for the order of battle inverted; for the order of chaſing; and for the order of convoy; ſo that in no poſſible caſe, when looking for the enemy or wiſhing to avoid him, need the admiral perplex himſelf with more than theſe two poſitions on the one or the other tack, whatever movements he may wiſh the fleet to make.

Plate cccxcviii.

143 Third order.

In the third order of ſailing, the diviſions *c d* and *e f* inſtead of bearing on the headmoſt and ſternmoſt ſhips of the diviſion *a b*, may be very conveniently placed at conſiderable diſtances from that diviſion, without the ſmalleſt danger of being ſurpriſed by the enemy, provided the ſhips of each of the diviſions keep always their reſpective poſitions in the two lines of bearing. For if we ſuppoſe the three diviſions to be in ſuch poſitions that *a b* and *e f* are at the diſtance of ſix leagues from each other (fig. 58), and that the two diviſions *c d* and *e f* reſt on the extremities of the baſe of the triangle STV, while the centre ſhip of the diviſion *a b* reſts on its ſummit T; none of the diviſions could be cut off by an enemy, however formidable, ſeen from its centre ſhip at the diſtance of ſix leagues. For if, upon the proper ſignal being thrown out, the diviſion *a b* ſhould ſteer from T towards X, on the courſe oppoſite to the cloſe-hauled line it ſteered before, and the two diviſions *c d* and *e f* ſteer from V and S towards X likewiſe; it is plain that each of theſe three diviſions would have only three leagues to run in order to join the other two in the windward primitive order of ſailing, which is the ſame with the order of battle natural; whilſt the enemy, which was firſt perceived at the diſtance of ſix leagues, muſt neceſſarily run nine before he could come up with the neareſt of theſe ſquadrons. And if frigates were placed ahead, and in the intervals between the diviſions, at the points *y y y* to windward and leeward of the fleet, the enemy might be ſeen at a ſtill greater diſtance, and the danger of ſurpriſe be ſtill ſo much leſs.

View of De Grenier's Tactics.

144 Order of battle.

We have ſaid, that the poſition of the three diviſions in the primitive orders of ſailing is the ſame with our author's propoſed order of battle; but there is this difference between them, that in the order of battle only the ſhips of one of the three diviſions ſtand in the wakes one of another, and that thoſe of the two other diviſions are ranged on two parallel lines, and ſteer chequerwiſe. So that if it be wanted to change a fleet from the windward primitive order of ſailing to this new order of battle on the other tack, the movement will be infinitely quicker than thoſe which, in former known tactics, are commonly preſcribed, to paſs from all the orders of ſailing either in one line, or on the obtuſe angle of chaſing or retreating, or in three or ſix diviſions, to the uſual order of battle. For it will be ſufficient for the ſhips of the three diviſions, ranged in the windward primitive order of ſailing, to heave in ſtays all together, and get on the other tack in the oppoſite line of bearing, and they will inſtantly find themſelves in this new propoſed order of battle (fig. 59.); and ſhould the fleet be in the leeward primitive order of ſailing, it would be ſufficient for the ſhips of the three diviſions all together to haul their wind on the ſame tack as they ſteer, and they would find themſelves in order of battle (fig. 60.)

145 Natural and inverted.

When the two columns *c d*, *e f*, are to leeward of the third diviſion *a b*, ranged in order of battle, our author calls *that* the order of battle *natural;* and when *c d* and *e f* are to windward of *a b*, the fleet is in the order of battle *inverted.* The former of theſe orders is calculated for a fleet combating to leeward, and the latter for a fleet which muſt combat to windward.

146 Advantages of theſe orders of ſailing and of battle.

That we may form ſome notion of the advantages which our author expects from drawing up a fleet for battle in the form of a lozenge, let us ſuppoſe the line AB, CD, EF, (fig. 61.) to repreſent the fleet of an enemy to windward in the ordinary order of battle on the cloſe-hauled line of bearing, and on the ſtarboard tack. Then the leeward line *a b* will repreſent one of the diviſions, in order of battle on the ſtarboard tack, of the fleet ranged according to the new natural order, which the enemy wiſhes to attack, and to which he believes himſelf ſuperior, becauſe that diviſion offers a front much inferior to his own. The two lines *c d*, *e f*, will repreſent the two other diviſions ſtanding on chequerwiſe on the ſame tack as the line of battle, and formed on the oppoſite cloſe-hauled line. On this ſuppoſition, if the diviſions AB, EF, of the hoſtile fleet, which have it not in their power to attack the ſhips of the line *a b*, wiſh to fall on the headmoſt ſhip *a* or the ſternmoſt *b* of that line, they will be obliged to bear away in order to attack the two ſhips *a* and *b*. To prevent this, each of the diviſions *c d*, *e f*, of the fleet ranged according to the new order, ſhould make the following evolutions, according to their reſpective ſituations and to the manœuvres of the enemy.

147 Evolutions to be performed when engaging, and

1ſt, The ſhips of the diviſion *a b* are to ſlacken as much as poſſible their headway, and form a very cloſe line, till the enemy makes a movement to attack the headmoſt or ſternmoſt ſhip of that diviſion.

2dly, The ſhips of the diviſion *c d* are to make ſail till they come under the ſecond or third ſhip of the rear of the line of battle *a b*, when they will take the ſame ſail as the ſhips of that diviſion, to preſerve that poſition until the hoſtile ſhips make their evolution to attack the rear ſhips of that diviſion. In this ſituation the ſhips of the diviſion *c d* will be able to obſerve the manœuvres of the enemy, in order to change tack and form themſelves in order of battle on the oppoſite board as ſoon as the hoſtile ſhips ſhall have, after their bearing away, run over a certain ſpace: becauſe the ſhips of the diviſion *c d*, ſteering afterwards cloſe-hauled in the wake of the ſternmoſt ſhip of the diviſion, *a b*, will be able to cover the rear ſhips of that diviſion, and get the weather gage of the hoſtile diviſions which are bearing away; rake their ſhips; run alongſide of them; double their rear-guard, and put it between two fires, if thoſe hoſtile ſhips are following in the wake of each other (c); divide it if they bear away chequerwiſe, or gain to windward, and put between two fires the enemy's diviſion CD, while it is engaged with the diviſion *a b*.

View of De Grenier's Tactics.

3dly, The ſhips of the diviſion *e f* may abandon their poſt and run chequerwiſe under a preſs of ſail, in the ſame courſe and in the ſame order they were formed, as ſoon as they perceive that the enemy falls ahead of the diviſion *a b*; in order that if the diviſion AB of that enemy makes any manœuvre to bear away and fall on the diviſion *e f*, or on the van of the diviſion *a b*, they may, by going about, ſteer in order of battle cloſe-hauled on the oppoſite line of bearing, and cover the headmoſt ſhip of the diviſion *a b*, double the hoſtile diviſion CD ahead, or divide the other hoſtile diviſion AB, which is running chequerwiſe on the oppoſite tack.

148 When the enemy is in a ſingle line not well formed.

The two diviſions *c d*, *e f*, might again manœuvre another way, in caſe the ſhips of the enemy were ranged in one ſingle line not well formed, or ſhould be in diſorder and leave too great a diſtance between them while they are engaged very cloſe with the diviſion *a b* (fig. 62.)

1ſt, By putting about the ſhips of the diviſion *e f*, and likewiſe the ſhip *a* headmoſt of the diviſion *a b*. 2dly, By making at the ſame time the ſhips of the diviſion *c d* tack, and likewiſe the ſhip *b* of the diviſion *a b*, to keep by the wind on the oppoſite cloſe-hauled line. 3dly, By making all the ſhips of the diviſion *a b* (which ſtood between the headmoſt *a* and the ſternmoſt *b*) bear away four points at the ſame time, and making them alſo take the ſame tack as the ſhips of the other two diviſions when they are on the beam of the ſternmoſt ſhips of thoſe two diviſions; becauſe, in that poſition, the ſhips of the two diviſions *c d*, *e f*, getting to windward on two parallels in order of battle, in the wake of the two headmoſt *a* and *b*, might put between two fires a part of the enemy's ſhips, which then would be obliged to take the ſame tack as theſe two diviſions, becauſe the ſhips of the diviſion *a b* (which are on the ſame tack as thoſe two diviſions) might prevent the ſhips of the enemy ſteering the courſe oppoſite to that tack.

From this ſuccinct expoſition it may be obſerved, that, in the firſt ſuppoſition, the way of thus diſpoſing the forces of a fleet is ſo much the more ſuitable to the defence of the headmoſt and ſternmoſt ſhips of a line of battle, as the ſhips of the diviſion *c d*, being covered by that line of battle, are able to manœuvre without any one ſhip of that diviſion being expoſed to the fire of the enemy; that the diviſion *e f*, the headmoſt ſhip of which is *e*, always preſents the ſide to the

(c) If the hoſtile ſhips which are not engaged with any of thoſe of the diviſion *a b* bear away in ſucceſſion in the wake of their headmoſt, in order to paſs to leeward of the diviſion *a b*, and to put it between two fires; then the ſhips of the diviſion *e f* muſt neceſſarily take the weather-gage of them, ſince the headmoſt of that diviſion *e f* is by her very ſituation already to windward of the headmoſt of the adverſe ſhips which are bearing away, and ſhe has the opportunity to come as cloſe as poſſible to the ſternmoſt ſhip *b* of the line of battle *a b*.

View of De Grenier's Tactics.

the enemy, without any one ship of that division being exposed to receive the fire of the enemy either ahead or astern, because they are not to range in a line of battle unless the enemy runs large or before the wind; and that, in the second supposition, the only ships which are liable to be raked astern, while they change tack, are the headmost and sternmost of the division in line of battle which cover the ships of the other two divisions.

149 How to know on what tack the fleet must be formed.

As it is of the utmost advantage to know, at first sight of the enemy, whether it be to windward or leeward of the fleet ranged lozenge-like, on what tack, and on what side the fleet must be formed, in order to defend itself or attack the enemy with advantage, it is to be observed, that in both the windward and leeward primitive orders of sailing the direction of the wind always traverses both the weathermost and leewardmost ships of the fleet (figs. 57. and 56.); that this leewardmost ship is always placed in the centre of an horizon, which is to be considered as the horizon of the whole fleet; and that it is from that ship you are to judge, by means of the rules which are known and practised in such cases, whether the lozenge-like fleet be to windward or to leeward of that of the enemy.

If you want to know, at sight of the enemy, seen either to windward or to leeward, on what side the line of battle is to be formed in order to be able to send one of the divisions on that side of the lozenge where there is none, it is the position of the enemy, with respect to the direction of the wind, which is to determine it; because, if the enemy is to windward of the fleet ranged in the windward primitive order of sailing, and if it bears down on that fleet, with the wind large or right aft, it belongs to its weathermost ship to observe what follows. If that ship, by setting the enemy, finds him to starboard of the direction of the wind, the division which is starboard of that direction of the wind is to take the starboard tack, and range in order of battle before the enemy is arrived within gunshot: if, on the contrary, the abovementioned ship finds the enemy to larboard, it belongs to the larboard division to assume the order of battle, and to take that tack, before the enemy can come to action. The old rule for choosing the proper tack is to be observed by a fleet in the leeward primitive order of sailing; observing, that it is the business of that fleet's leewardmost ship to determine it; and the point of the horizon which is opposite to that whence the wind blows, is the point towards which the observer is to be turned to judge on what side, whether starboard or larboard, the line of battle is to be formed; because, in that position, the starboard side must always be on his right hand and the larboard on his left.

By following this general rule, the line of battle will never be exposed to be too much lengthened either to windward or to leeward, in order to oppose all the ships of the adverse fleet formed in one single line, nor even to be surprised in disorder by that fleet while you are forming in orders of battle natural or inverted.

150 The orders of chasing, retreat, and convoy.

Our author's orders of CHASING, of RETREAT, and of CONVOY, are very easily formed. We have already said what they are; and the seaman, or even the landsman, who has any tolerable conception of his orders of SAILING and of BATTLE, will not stand in need of any farther description of them. It must, however, be observed, that in the order of chasing, the fleet in the lozenge-like position presents the obtuse angle of chasing, as when ranged according to the ordinary tactics; with this difference, that, in order to form themselves in order of battle, it is enough that, in this lozenge-like position, the ships of the second division should all keep the wind on the same board they were standing on, because they would afterwards find themselves in a line in the wake one of another; but, according to the usual tactics, the ships have a long space to run before they can execute the same evolution.

View of Mr Clerk's Tactics.

We shall conclude this short view of the Viscount de Grenier's tactics, with his directions for the most advantageous placing of the admiral's ship, the frigates, and transports, belonging to a lozenge-like fleet, whether it be ranged in the order of sailing or of battle, &c.

151 How the admiral's ship, the frigates, and transports, are to be placed.

In the order of sailing, the admiral A is to be placed ahead of the fleet, at a short distance from the headmost of the second division, and in the direction of the wind with the headmost of the first division (fig. 63.). Two of the frigates *f f* are to observe the same rule and the same position, with respect to the van ship of the third division and the sternmost of the first. In the order of battle, on the contrary, the admiral is to be in the centre of the lozenge, and two of the frigates on the fourth side of the lozenge. (fig. 64). As for the transports and store-ships, when there are any, their station is to be in one line on the side opposite to that of the enemy, when ranged in order of battle; and, if in order of sailing or convoy, they may occupy the space circumscribed by the lozenge. In any other circumstances these ships are to occupy the different stations appointed for them, that they may distinguish the signals and execute the commands of the admiral. Lastly, when the fleet shall pass from the order of battle to any other order whatever, or from any order to the order of battle, the admiral's ship is to bring to, and not to take any of the positions abovementioned till after the complete execution of the movement.

CHAP. II. *View of Mr Clerk's Tactics.*

WHETHER the Viscount de Grenier's order of battle and of sailing would be attended with all the advantages which he hopes from them, experienced seamen alone can judge; but we are now to introduce to our readers part of a system which has met with very great approbation from some of the ablest officers in the British navy, and which to us appears to be founded on principles self-evident. Mr Clerk, in the introduction to his Essay, informs us, that upon considering the great superiority displayed in the three last wars by the British seamen over their enemies, when engaged in single ships, and comparing it with the very little that, previous to Lord Rodney's glorious action, they had atchieved when engaged in fleets drawn up in line of battle, he was led to conclude, that there must be something wrong in the mode of making the attack. He turned his thoughts to the subject, and in 1790 published part of a large work, comprehending, 1. *A Theory of Attack from Windward;* 2. *A Theory of attack from Leeward; and,* 3. *An Historical Sketch of Naval Tactics.* We think it not much to the honour of his countrymen, that he has not yet had encouragement to publish more than the first part; but in hopes of exciting curiosity, we shall lay before our readers a distinct view of that part, beginning, as he begins, with

OBSERVATIONS OF THE PRESENT METHOD OF BRINGING SHIPS TO ACTION.

152 Disadvantages of bearing down directly on the enemy.

It has often, if not generally, been the practice, in the case of single ships, as well as in that of fleets, for the weather ship or fleet, when it is wished to bring the other to action, to steer directly down upon that ship or fleet, without reflecting that, by doing so, it gives the enemy an opportunity of completely disabling it, before it can attain its wished for station. For each ship in the lee line can use all the guns upon one side; whereas the ships in the wea-

View of Mr Clerk's Tactics.

ther-line, bearing directly down, have it only in their power to use their bow-chases. This method of attack appears, therefore, to be the worst possible for the weather-fleet, and the most advantageous for the lee fleet. For suppose a single ship of 80 guns to windward at B (fig. 65.), discovering an enemy's ship of equal force to leeward at F, to bear directly down upon her endwise, the receiving ship F, by lying to as in fig. 66. would present a broadside of 40 heavy guns bearing upon B during a course of two miles, in which every shot might take effect; while B, in this position, would have it in her power to bring only the two light guns of her forecastle or bow-chase to bear on F; a disadvantage greatly exceeding twenty to one. Besides, the receiving ship F, by lying broadside to, will have all her masts and rigging more open, and consequently will allow shot to pass with less effect than the ship B, which, coming endwise, is liable to be raked by every shot from stem to stern. The consequence of which must be, that B would be disabled in her rigging, &c. long before she could arrive at a proper position for annoying F; and when she had attained that position, F, by being entire in her rigging, would have it in her power to fight in any position, or to make off at pleasure.

153 Proper method of attack.

The method then is, B having the wind, should run down astern as *per* dotted line, and getting into the course, or near the wake of F, or a position that will bring her parallel to the course of F, at a proper distance, she should then run up close along side of F, upon equal terms, as in fig. 67; or otherwise, on shooting ahead, she may veer, and run down on the weather-bow of F, as in fig. 68. till she shall force F to bear away to leeward, keeping close by F on equal terms; but during the course, in both cases, carefully watching that F may not have it in her power to bring her broadside to bear upon B without retaliation.

154 Modes of attack by the British and French.

It having been often said that the French have made it a rule to throw the whole effect of their shot more particularly into the rigging of their enemy, and that the British, on the other hand, have been as attentive to point the force of their fire against the hull of the ship; it may be proper here to state the two cases, and compare the effect.

Let us suppose a ship of 80 guns wishing to avoid the effects of a close engagement, but at the same time lying to as at F (fig. 63.), intending to receive, with every advantage, an enemy B of equal force, coming down with an intention to fight her; and let us suppose that F, by aiming her fire at the rigging of B, shall have carried away any of the principal stays, eight or ten windward shrouds, or a foretopmast, or any other rigging, though of much less consequence, but, at the same time, without having wounded a single man of the ship B; and suppose a second ship, consort to F, receiving such another ship as B, and by firing at her hull only, shall, without other damage, have killed 30 or 40 of her men: In this critical juncture, when F and her consort are desirous of avoiding a close engagement, it is evident that the ship at B, which has lost part of her rigging, is more completely disabled from closing with them than the other ship, whose rigging is entire, though she may have lost 100 of her men.

155 No ship in the line of battle can be exposed to the fire of many at once.

It has been often said, that some particular ship has been exposed in battle to the cannonade of three, four, or even five ships, all extended in the enemy's line, and all bearing upon her at one and the same time; but this can never have been the case, but when the ship so exposed was at a very great distance. Let I, H, F, H, I, (fig. 70.) represent five ships extended in line of battle ahead at the distance of one cable's length, or 240 yards, from each other; let the length of each ship be 40 yards, so that the whole space between head and head of any two adjacent ships is 280 yards; and let the perpendicular line FK, proceeding right out from the beam of the middle ship F, to the distance of six cable's length or 1440 yards, be divided into six equal parts: It is evident, from inspection, that a ship stationed at the point E of the line FK, 720 yards distant, cannot for any length of time be exposed to the fire of more than the centre ship F of the fleet I, H, F, H, I. For supposing the ships H, K, ahead and astern of F, to be able to bring their broadsides to bear on E (a supposition which, if the line be close-hauled, cannot be made of the headmost of those ships), it is evident, that by putting themselves in positions proper for that purpose, the ships H, H, will not only disorder their own line, but also leave, the one her head, and the other her stern, exposed to a raking fire from their opposites B, B, in the enemy's line.

View of Mr Clerk's Tactics.

But if the opponent ship cannot well be exposed to the fire of the two ships H, H, at the point E, she must be still less exposed at the point C, 480 yards distant; and it will be almost impossible for the ships H, H, to touch her at the point G, 240 yards, or one cable's length, distant.

But one cable's length asunder is too small an allowance for accidents that may happen by the ships, I, H, F, H, I, extended in line of battle ahead. Therefore let us suppose the three ships, which are said to be at once upon a single opponent, to be stationed at I, F, I, at the distance of two cable's length or 480 yards from each other. Then it is evident that the opponent ship cannot now be more exposed at the point K, at the distance of 1440 yards, than she was, on the former supposition, at the point E, 720 yards distant; and if we suppose the line of battle to be formed at one and an half cable's length asunder, she must be at L, distant 1080 yards, before she can be annoyed even to this degree by the three hostile ships at once. Hence we may fairly conclude, that if one ship has at any time been exposed at once to the fire of five, four, or even three ships of the enemy's line, such ship must have been at a very great distance, and in no great danger.

156 Principles necessary for bringing fleets to action.

Having finished the above observations, our author proceeds to the principles necessary to be known for enabling us to judge of the different modes of bringing great fleets to action. For this purpose he supposes a fleet of 10, 20, or more ships, of 80 guns each, extended in line of battle, to leeward, and lying to at F (fig. 71.), with the intention of avoiding an attack; whilst another fleet at B, of equal number and force of ships, also extended in line of battle three or four miles to windward, is desirous of making an attack, and coming to close action on equal terms with the fleet F. In this disposition of the two fleets, should that to windward run down headlong ship for ship on its opponent, as in figs. 66. and 69. it is evident, from what has been said in the beginning of this chapter, that each individual ship of the weather-fleet might be completely disabled before it could possibly come to close action with the fleet to leeward. But let it be supposed that the commander of the weather fleet B, though his ships have been much disabled in their rigging during their course *a a a* from windward (fig. 72.), has made them bring to at a great distance, from whence he can hurt F; is it to be expected that F, whose desire has always been to avoid a close engagement, and who has already disabled the ships of B, will patiently lie still, or wait until B shall have time to disable him in his turn? No surely. While enveloped in his own smoke, as well as that of his enemy, he will bear away unhurt to a new station G, and there remain out of the reach of B's cannon-shot, who must repair his rigging before he can attempt a second attack.

Again, suppose that B, in place of going headlong and endwise down, were to run down in an angular course, or

lasking

View of Mr Clerk's Tactics.

laſking as it has been called; it is evident from fig. 73. that ſhould any ſhip in this angular line come to be crippled, her way being ſtopped, might of conſequence occaſion a confuſion among the ſhips next aſtern to her, ſome running to leeward and others to windward of the diſabled ſhip; and thus the time be loſt for affording the neceſſary ſupport to the ſhips ahead, and now ſo far ſeparated from their companions. Should it be ſaid, that a ſtoppage of one ſhip ahead will not neceſſarily produce a ſtoppage of every ſhip aſtern, becauſe they may go to leeward of the diſabled ſhip; we anſwer, that the ſhips ahead in the van A (fig. 74 n° 1.) may be now engaged, and of conſequence not having much headway, may be ſaid to be ſtationary; therefore every ſhip aſtern, if ſhe ſhall attempt to bear down, as at D, D, from being confined to a determined courſe, muſt be brought into the poſition of being raked when coming down before the wind, as in figs 76. and 69. and conſequently of being completely diſabled long before ſhe can get cloſe enough alongſide of the enemy.

Again, the headmoſt ſhips, or van of B, having attained their ſtation at A, that is, abreaſt of the van of F (fig. 74. n° 1.), and having begun the cannonade, may we not ſuppoſe that F, whoſe conduct or deſire has always been to ſave his ſhips, has inſtructed the commanders of thoſe in the van of his fleet to withdraw from danger as ſoon as they begin to feel the effects of a cannonade? and if ſo, may not thoſe ſhips, as ſoon as they have thrown in their fire upon the van of B, bear away in ſucceſſion as at H, followed indeed by the whole ſhips of F's fleet, which, having poured in their fire upon the van of B, may form a new line of battle two or three miles to leeward at II (fig. 74. n° 2.), and there be in readineſs to receive a ſecond attack, if B ſhall be ſo imprudent as to attempt it? And is it not farther evident, that if any one or more ſhips of the ſquadron of F ſhall be crippled, they will have it in their power to quit their ſtation, being covered with ſmoke, at any time, and to fall to leeward as at G, where they will be in ſafety?

Plate cccexcix.

In order to illuſtrate this ſtill farther, let B (fig. 75.) repreſent a fleet putting before the wind, each ſhip with an intent, when brought to at a determined diſtance at A, to take up her particular antagoniſt in the line of the enemy F to leeward; and, for argument's ſake, let F be ſuppoſed at reſt, without any motion ahead. There ſeems to be no difficulty in conceiving, that while the alternate ſhips of F's line, under cover of the ſmoke, withdraw from battle to GGG, the intermediate ſhips left behind them in the line will be ſufficient to amuſe even the whole of B's fleet, till the ſhips G ſhall form a new line HH as a ſupport from the leeward. In ſuch caſe B, after being diſabled, as he muſt be, and not having foreſeen the manœuvre, will neither be able to prevent the intermediate ſhips with which he is engaged from bearing away to join their friends, nor, were he able, would it be adviſable to follow them; for the ſame manœuvre with equal ſucceſs can again and again be repeated.

In order to ſhow the relative motion of both fleets, let F (fig. 76.) be a fleet conſiſting of twelve ſhips, drawn up in line of battle, at one cable's length or 120 fathoms aſunder; and let the length of each ſhip from the end of the jib-boom to the ſtern be 36⅔d fathoms; the whole fleet will then occupy a ſpace of two Engliſh miles; alſo, let its rate of ſailing be four knots an hour in the direction FG, ſo that in the ſpace of an hour it may have moved from F to G four miles diſtant from its former poſition.

Let B be the opponent fleet, conſiſting alſo of twelve ſhips, and four miles to windward; and let the point A be 440 yards, or one quarter of a mile, right to windward of the point G. Then if B, by bearing away in the direction BA, ſhall arrive at the point A at the ſame inſtant that F, the fleet to leeward, has arrived at the point G, the motion of the fleet B will have been at the rate of 5½ miles nearly per hour; and the angle contained between the direction of its line of bearing and preſent courſe 43° 9′, or nearly 4 points. For in the right-angled triangle ABM are given BM = 4 miles, and AM = 3¾ miles. Now BM=4 m. : AM=3¾m. : : R : tan. ABM=43° 9′, and R : ſec. ABM. 43° 9′ : : BM=4m. : AB=5.483 m.

View of Mr Clerk's Tactics.

Again, if F, as in fig. 77. by carrying more ſail, ſhall move at the rate of ſix miles an hour, that is, from F to G; then B, having his courſe made thereby the more ſlanting, will have juſt ſo much the greater difficulty of keeping his ſhips in line abreaſt while coming down to the attack: For the leading ſhip meeting with no obſtruction in her courſe, will puſh on; whereas every accident of obſtruction accumulating, as it happens to each ſhip progreſſively, the rear, being affected in the greateſt degree, will for that reaſon be left the farther aſtern. But, from the very form of this ſlanting courſe, every ſhip aſtern will be apt to get into the wake of the ſhip ahead. Therefore the whole fleet of B, van and rear, will not arrive in the ſame time at the line AD, ſo as to be in a perfect line abreaſt, and parallel with the fleet to leeward; but will have aſſumed the laſking form, as repreſented at the points M, N, and O, in the different parts of the courſe. In this caſe, the diſtance run by the van of B, from B to A, is 7,075 miles, or 7 miles and 132 yards, and the angle contained between the line of bearing and the diſtance BA is 32° 0′.

And again, as in fig. 78. if the fleet to leeward ſhall lie up one point higher, as FG, then the rears of the two fleets will thereby be removed at a much greater diſtance, and the van A of conſequence muſt be ſooner up with the enemy's van, and evidently ſo much the farther from ſupport; while F, by bringing up his ſhips in ſucceſſion, will have it in his power to diſable the van of A, and will afterwards bear away, as at H, unhurt and at pleaſure; while B, at this time, by the ſuppoſition, being crippled, or having his rear D obſtructed, and at a diſtance, will be unable to prevent him. And in all the three caſes, it is evident that the fleet B, ſo ſoon as he ſhall approach within reach of gun-ſhot, muſt be expoſed to the fire of F's whole line; for he will be abreaſt of B continually in every part of his courſe. But the difficulty of bringing the rear of the windward fleet to action will ſtill be more increaſed, if the ſternmoſt ſhips of the fleet to leeward, in place of keeping their wind, ſhall bear away occaſionally as at ML. All which being admitted, the difficulty of bringing adverſe fleets to cloſe engagement may be accounted for, without being obliged to have recourſe to that ſuppoſed inferiority in point of ſailing, imputed to Britiſh ſhips, compared to thoſe of the French.

Hence it appears, that a fleet B to windward, by extending his line of battle, with a deſign to ſtop and attack a whole line of enemy's ſhips to leeward, muſt do it at a great diſadvantage, and without hope of ſucceſs; for the receiving fleet F to leeward unqueſtionably will have the four following advantages over him: 1. The ſuperiority of a fire above 20 to 1 over the fleet B, while coming down to attack. 2. That when the ſhips of B are brought to at their reſpective ſtation, if it blows hard, the ſhot from F, by the lying along of the ſhips, will be thrown up into the air, and will have an effect at a much greater diſtance; whereas, on the other hand, the ſhot from B, from the ſame cauſe, will be thrown into the water, and the effect loſt. 3. That F, will have the power of directing and applying at pleaſure the fire of his whole line againſt the van of B, who is now

unable

View of Mr Clerk's Tactics.

unable to prevent it, his ships being disabled, separated, and therefore unsupported. 4. That F will also have a greater facility of withdrawing from battle the whole or any one of the disabled ships of his line.

If then, after a proper examination of the late (D) sea-engagements or rencounters, it shall be found that the French admirals have never once shewn a willingness to risk the making of the attack, but invariably have made choice of and earnestly courted, a leeward position; if invariably, upon seeing the British fleet disabled, they have made sail, and demolished the van in passing; if invariably, upon feeling the effect of the British fire, they have withdrawn at pleasure either a part or the whole of their fleet, and have formed a new line of battle to leeward; if the French repeatedly have done this upon every occasion:—and, on the other hand, if it shall be found that the British, from an irresistible desire of making the attack, as constantly and uniformly have courted the windward position; if, uniformly and repeatedly, they have had their ships so disabled and separated, by making the attack, that they have not once been able to bring them to close with, to follow up, or even to detain one ship of the enemy for a moment—shall we not have reason to believe, that the French have adopted and put in execution some system which, if the British have discovered, they have not yet profited by the discovery?

Our author therefore, instead of the usual mode of attack, which, by being made principally on the van, seems to be the result of a groundless expectation of being able to *take*, *destroy*, or *disable* the whole of the enemy's line, proposes

A new Mode of Attack from the Windward upon the Rear of the Enemy.

157 Mr Clerk's mode of attack upon the rear of the enemy.

Suppose, says he, a fleet of ten, twenty, or more ships, extended in line of battle at F (fig. 79.), endeavouring to avoid a close engagement, but at the same time keeping under an easy sail, with the intention of receiving the usual attack from another fleet of equal number, three or four miles to windward at B, sailing in any form, but let it be in three lines or divisions; it is required by what method shall B make the attack on F with advantage?

The improbability, or rather impossibility, of attacking and carrying the enemy's whole line of ships, having been demonstrated by every action which has been fought at sea, the next consideration will be, how many ships may be attacked and carried with advantage? Let it be supposed that the three sternmost ships only, and not exceeding the fourth, are possible to be *carried*; let a sufficient strength A be sent down to force an attack upon these three ships, disposed and supported according to the judgment of the admiral, while in the mean time he keeps to windward with the rest of his fleet, formed into such divisions as may best enable him to attend to the motions of the enemy and the effect of his attack; being himself so far disengaged from action, as to be able to make his observations, and give his orders, with some degree of tranquillity.

By placing the fleet B in such divisions as represented in the figure, when the attacking squadron comes up with the rear of the enemy, the whole will be so disposed, and so connected together, as to be able to give the support and attention that may be required to any ship, or any part of the fleet, and in preference to a long extended line of six or seven miles in length, where it must be impracticable to give the necessary support to such ships as may be disabled. The ships of the fleet F may, in general, be better sailers than the ships of the fleet B; but it is not conceivable but that the swiftest ships of B must come up alongside of the sternmost and dullest sailing ships of the enemy F; while, at the same time, F, by attempting to outsail B, must be thrown into the disorder of a downright flight: Therefore, of course, it must be admitted, that if the enemy F continues going off in line of battle, and endeavouring to avoid a close engagement, it will be impossible to prevent the fleet making the attack from getting into the position B A. But by this position, it is evident that the three ships at I of the fleet F will be in the power of the admiral of B; for, by keeping so many ships to windward, he will be enabled to send down fresh ships from time to time, either for the support, or to supply the station, of any of those that may be disabled in making the attack, while it may be imagined that the three ships in question, by being disabled, or being deprived of the wind now taken out of their sails by the ships to windward, will be prevented from following their friends. Hence the enemy ahead must either abandon his three sternmost ships, or he must double back to support them; which must be done either by tacking or veering. But let it be first examined what is naturally to be done by tacking; and for the greater satisfaction, let every possible case that can happen be examined separately.

View of Mr Clerk's Tactics.

158 Attack upon the enemy's three sternmost ships more particularly considered.

159 The enemy's attempt to support his three sternmost ships by tacking his fleet.

First, let us suppose that the enemy at F, fig. 80. has continued to protract his course in line of battle upon the same tack, and that the headmost ship H, with the three next astern of her, have tacked to windward, and that the whole remaining ships intend to tack the same way, but in succession; is it not evident that F has then left his three sternmost ships at I in the power of the ships at A; that he must also leave exposed his fourth and fifth ship G to another attack from another division of B at C, which will also be on equal terms as with his three sternmost at I; and lastly, if he prosecutes his intention of supporting his three ships, he will be obliged to begin a disadvantageous attack upon the admiral, with the main body of the fleet lying ready to receive him? The consequence of all which must be, that he will not only lose his three sternmost ships, but in all probability the fourth and fifth also, as at G; and will be forced to begin an attack, and close and mix ship with ship on equal terms; a situation which he at all times, with the greatest anxiety, hath avoided, and which B with equal anxiety has always courted.

Again, suppose that his three sternmost ships have been attacked, and that he has ordered his fleet to tack all at one time, as in fig. 81. The consequences will then be, that this movement, having required some time and some length of course, will have produced a considerable distance between his main body and his three ships; or, in other words, that these three ships have been deserted; for it will not be in their power to tack with the rest of their friends. He must also, in bringing his ships' heads round, expose the ships nearest his enemy to be raked by a dreadful cannonade; besides running the risk of having his fleet thrown into a general disorder, by many of his ships missing stays, veering, and running to leeward. Lastly, upon a supposition that his ships have all tacked, and none of them missed stays, still he

(D) This was written during the American war, and before Lord Rodney's decisive victory on the 12th of April 1782. That action, as well as the still more brilliant one of Lord Howe on the 1st of June 1794, we have heard the author distinguish from those battles which, with great propriety, he calls *sea-rencounters*, and do ample justice to the scientific manœuvres of both the noble admirals.

View of Mr Clerk's Tactics.

he muſt of neceſſity begin the attack, mix his ſhips, and come to a cloſe engagement, as in the former caſe.

160 The enemy's attempt to ſupport his three ſternmoſt ſhips by veering his fleet.

Having ſhewn the conſequences of an attempt to ſuccour the three ſternmoſt ſhips by tacking, let us alſo examine what may be expected from an attempt to do it by veering the fleet. Suppoſe the two fleets in the ſame poſition as in fig. 79. that is, the main body of the enemy extended in line of battle to leeward, his three ſternmoſt ſhips entangled with the fleet B, whoſe admiral, with the main body, keeps to windward to obſerve, with a rigid attention, the motions of the enemy. At the ſame time ſuppoſe that the admiral F has ordered his ſternmoſt ſhip G to veer (fig. 82.), and afterwards the whole line; and that he is now running upon a contrary tack to leeward, as at H, wiſhing to ſupport or bring off his three ſhips. From inſpection, it will be evident that this attempt may be more dangerous than the attempt to windward; for it will expoſe a number of his ſhips to a raking fire while in the act of veering; and the ſquadron, by getting ſo far to leeward, will be unable to give the proper ſupport to the three ſhips. It will open a gap for the fleet of B (who will immediately veer alſo and follow him) to break in, as at A, and cut off the three ſhips without hope of recovery. And if F ſhall ſtill perſiſt in the endeavour to recover his three ſhips, he will be obliged to begin the attack under all the uſual diſadvantages.

Again, upon another ſuppoſition, that the headmoſt ſhip of the enemy H (fig. 83.), with the four or five next aſtern, have wore, and are running upon a contrary tack, wiſhing, as before, to ſupport or bring off the three ſhips, the reſt of the fleet intending to wear alſo, and follow in ſucceſſion; it is evident that this movement, being more unſeaman-like, will be worſe than the laſt: It will expoſe an additional number of ſhips, particularly the laſt two, as at G; and will at the ſame time make an opening for the main body of B's fleet to fall in and cut off the three ſhips, as in the former caſe.

Again, ſhould the enemy F veer and bear away with his whole ſhips at one and the ſame time, it is evident that this movement muſt have the conſequence of a downright flight, with the certainty of loſing the three ſhips.

From what has been ſaid, it will appear, that a fleet B, keeping connected in a body to windward, may come up with and entangle the three ſternmoſt ſhips of an enemy F, extended in line of battle and going off to leeward, and at the ſame time be able to overawe the remaining main body of their fleet; and that, having forced the poſition, the whole conſequences, as already deſcribed, muſt follow; that is, F muſt ſubmit to the loſs of three ſhips.

What has been hitherto ſaid proceeds upon a ſuppoſition that the fleet F has kept on his courſe till the fleet B has come up with his rear. Let it then be examined what other attempts the enemy F can make to avoid coming to cloſe engagement upon equal terms.

161 The enemy endeavouring to avoid the attack upon his rear by veering and paſſing on contrary tacks to leeward.

Suppoſe a fleet of ſhips of the enemy ſtanding on the larboard tack to leeward, and going off as before at F, and a fleet of ſhips in a collected ſtate or poſition to windward, as at B (fig. 79.); and ſuppoſe that the enemy F, perceiving the fleet B pointing an attack againſt his rear, in place of keeping on his courſe upon the ſame tack, ſhould veer, and endeavour to paſs on contrary tacks to leeward (for it will not be admitted that he can get to windward); what will then be the effect?

Is it not evident, that the headmoſt ſhips of F muſt be forced to leeward by the fleet B obſtructing his line of direction, or the line of his courſe; that they muſt be forced to begin an attack at any diſtance B may chooſe? that they may receive ſuch damage as will ſtop their way? that their way being ſtopped, will of courſe be an obſtruction to the next aſtern; or that theſe ſubſequent ſhips, to prevent this ſtop, muſt bear away to leeward of their crippled ſhips, as at G (fig. 84.), which will not only prevent theſe ſhips from damaging the headmoſt ſhips of B, but will give time and opportunity to B to bring down his windward ſhips to fall in either ahead or aſtern, that is, to the right or left of his headmoſt ſhips A, and oppoſe ſhip for ſhip of the enemy upon equal terms? But ſhould none of the headmoſt ſhips of the ſquadron F be crippled, that is, ſhould F paſs B without reach of cannon ſhot, which undoubtedly he will do if he can; ſtill, while bearing away, he may be forced to ſuffer a diſtant cannonade, ſhip with ſhip on equal terms, whether he veers and gets back upon his former tack, as at G in fig. 85. or continues to run before the wind, as at P in fig. 86. But if F perſiſts to paſs on a contrary tack to leeward, and without reach of cannon ſhot, it is evident, whether he put right before the wind, or run off ſhip by ſhip as he beſt can, that B muſt at ſome time or other come up with his rear.

View of Mr Clerk's Tactics.

162 Effect produced by a change of wind during the action.

So far the attack has proceeded with the wind fixed in one and the ſame quarter. To make the propriety of it the more apparent, it will be neceſſary to inquire, What might be the effect produced by a change of wind, ſhould that take place during the action? For this purpoſe, let the opponent fleets be placed in ſome one of the preceding poſitions, repreſenting the attack upon the three ſternmoſt ſhips of the enemy, as in fig. 87.; in which the fleet deſirous of making the attack is repreſented in four diviſions, as at B, B, B, A, and F the fleet deſirous of avoiding the attack, at the hazard of abandoning his three ſternmoſt ſhips at G.

163 The wind ſhifting by degrees, and coming aft.

In the commencement of the attack, let us ſuppoſe the wind to be N. and the ſhips going two points free on the larboard tack, or ſtand E.; and ſoon after the commencement let the wind be ſuppoſed to veer round to the W.; then it is evident, by the diſpoſition of the two fleets, that the fleet F, by ſuch a change, will have acquired no advantage whatever; on the contrary, it will thereby be thrown juſt ſo much the farther to leeward.

164 The wind ſhifting by degrees round ahead.

Again, if the wind, by taking an oppoſite courſe, ſhall ſhift ahead and come round by the eaſtern quarter to L, the admiral of the fleet F will not have it in his power to avail himſelf of this circumſtance, provided the commander of B, continuing carefully to watch his motions, and feeling the impulſe of the veering wind, ſhall ſtretch his ſhips, as at OO, to the windward of the three ſhips at G, ſeparated from F's fleet, and at the ſame time to the leeward of the main body of that fleet. This will be apparent from figures 88. and 89. which exhibit the two fleets, after this manœuvre, both on the larboard and ſtarboard tack.

165 The wind continuing to veer round the compaſs.

Let the wind be ſuppoſed to veer round gradually from the E. towards the S. and from thence to the W. and then quite round the compaſs. Then F being ſuppoſed to have gained the wind, it will be in his power to maintain it, and make a circular courſe to windward of B; but as he can be attended all the while by the fleet B, who will cut him off to leeward, he never will be able to recover his three ſhips, ſuppoſed to be cut off. This is evident without the illuſtration of a figure.

166 The wind ſhifting inſtantly to the oppoſite points.

Laſtly, if the wind in changing ſhall in one inſtant ſhift in direct oppoſition to where it was when the attack began, that is, from north to ſouth; then and in that caſe, before it can be judged whether ſuch change ſhall be favourable for F or not, it will be neceſſary that the relative ſituation of the two fleets ſhould be determined, ſuch as it was when the change took place. For example, if the headmoſt ſhips of the fleet F, that is, if his van and centre ſhall have ſeparated at any conſiderable diſtance from his rear, and ſhall, in

con-

Partial Breezes of Wind.

conſequence of this mode of attack, have advanced to a poſition as repreſented in fig. 90. it is evident that F, though by this change he ſhall have got to windward, will yet not be able to avail himſelf of this ſeeming advantage, the fleet B having it ſtill in their power to cut him off from his three ſhips.

On the other hand, if this inſtantaneous change of wind, in direct oppoſition, ſhall have taken place more early in the action, that is, when the poſitions of the two fleets ſhall be ſuch as repreſented in fig. 87. (the fleet B in the poſition of four diviſions B, B, B, and A, and the enemy in the poſitions F and G); then F, who before was to leeward, by this inſtantaneous change of wind from the north to the ſouth, having now got to windward of every diviſion of the fleet B, is it not evident that it may be practicable for him to carry aſſiſtance to his three ſhips at G in the rear, and perhaps even to cut off ſome of B's ſhips at A, if they do not with all convenient ſpeed bear away to put themſelves under the protection of their friends B to leeward? But whether F ſhall attempt to effect this manœuvre, by veering his ſhips in the line, or, what ſeems moſt eligible, by making his ſhips tack, as it is to be preſumed that his three ſhips, which have been ſome time engaged, muſt be conſiderably crippled, and not able to make ſufficient ſail; while endeavouring to bring them off, it will be difficult for him to prevent being drawn into a general and cloſe engagement, which, by the ſuppoſition, he has all along endeavoured to avoid.

CHAP. III. *Of Partial Breezes of Wind.*

IT often happens at ſea, that when two ſhips are in ſight of each other, one of them will be ſailing at a conſiderable rate, being favoured with a breeze of wind; while the other at the ſame time is lying becalmed, having no other motion than what ſhe receives from the tide or a current, if any, or from the ſwell of the ſea. As this may be the caſe with reſpect to two adverſe fleets when in ſight of each other, that fleet which has the advantage of the wind will evidently uſe every poſſible method to proſecute the advantage that may reſult from it. Thus if the fleet deſirous of making the attack be favoured with a breeze of wind, while the other fleet at the ſame time is lying becalmed, it is evident that the commander of this fleet will endeavour to get as near the opponent fleet as poſſible; whereas, if the fleet wiſhing to avoid an engagement be favoured with the wind, the other lying becalmed, then that fleet will avail themſelves of this opportunity of making their eſcape.

167 The fleet purſued being favoured with a partial breeze after the attack upon his three ſternmoſt ſhips is commenced

If the attack upon the three ſternmoſt ſhips ſhall have commenced before this partial breeze in favour of the fleet purſued has taken place; then the variety of poſitions in which the two fleets may be affected is ſo great, and the reſulting conſequences ſo numerous, that it would be an endleſs taſk to give a ſeparate deſcription of each. In the mean time, therefore, as it is imagined nothing in ſuch inveſtigation will be found that can materially affect the general iſſue; and ſince no breeze whatever can favour the fleet F, ſo as to enable it to ſail round and round the fleet B, which all the while is ſuppoſed to be lying becalmed, it will

168 Of little advantage.

not be too much to ſay, that *this partial breeze in favour of the fleet F, taking place after the attack began, although it may facilitate the eſcape of his van and centre, will not avail him much in the recovery of the three ſhips in his rear*—perhaps not in any caſe as yet exhibited, excepting this one, where the the wind in one inſtant had changed in direct oppoſition.

Now let, as formerly, the attack be commenced before the partial breeze in favour of the fleet purſued has taken place, but that the wind has inſtantaneouſly ſhifted in direct oppoſition; then, even in this caſe, the ſame breeze which would favour F (fig. 87.) in the attempt to bring off his three ſhips, would at the ſame time favour the eſcape of the ſhips of B at A, as formerly deſcribed. That this partial breeze would require to be of conſiderable duration, otherwiſe F, in thus attempting to bring off his three ſhips, crippled as they will be, muſt hazard a general engagement, in like manner as already deſcribed.

Partial Breezes of Wind.

169 The wind ſhifting inſtantaneouſly in direct oppoſition.

Mr Clerk employs a ſection of his book to ſhow the propriety of his propoſed attack from windward, in places where the hoſtile fleets are liable to encounter winds blowing in contrary directions at the ſame inſtant; but as this is a caſe which does not ſurely often happen, we ſhall refer our readers to the work itſelf, and conclude this article with ſome other methods of attack, which have ſuggeſted as improvements of that which is commonly followed.

170 Of ſome other methods of attack.

1ſt, It has been propoſed that the attack ſhould be made with the greater part bearing down before the wind upon the ſix ſternmoſt ſhips of the enemy. It is, however, evident, that ſhips by making the attack in this manner muſt be expoſed, without a poſſibility of return, to as many broadſides from each of theſe ſix ſhips as can be got ready during a courſe of two miles. Hence, as the ſhips making the attack will aſſuredly be diſabled before they can have it in their power to hurt the enemy, this mode of attack cannot be proper.

2d, It has alſo been imagined, that ſome part of the force choſen to make the attack ſhould be ſent to leeward as well as to windward of the three ſhips determined to be attacked. But the danger ſuppoſed, of ſhot paſſing over the enemy's ſhips, and ſtriking thoſe of friends, may be an objection to this mode.

3d, Others have been of opinion, that the headmoſt ſhip choſen to make the attack ſhould come cloſe up alongſide of the ſternmoſt of the enemy, and having delivered her fire, puſh along the line as far as poſſible, which may be ſuppoſed to be the ſixth ſhip of the enemy; and as it is evident that this firſt ſhip may have received ſix broadſides, that is, a broadſide from every one of the ſix ſhips of the enemy during her courſe in paſſing them, it has been thought poſſible that the other five ſhips, by following cloſe after her, may attain their ſtations, each abreaſt of her oppoſite, without having received a greater number of broadſides than they have had it in their power to return; and therefore that by this mode the number of ſhips to be attacked will be determined: For as many ſhips as the leading ſhip will be able to reach, as many will the attacking fleet be able to carry.

4th, Again, let it be ſuppoſed, as in the former caſe, that the fleet making the attack has been brought up to action in a collected manner, but ſubdivided only ſo far as the ſervice may require, and that the leeward diviſion ſhall be more particularly deſtined for the immediate attack, while, at the ſame time, the body of the fleet keeping to windward ſhall be ſuppoſed attentive to give the neceſſary ſupport where required; then let it be ſuppoſed, that the headmoſt ſhip making the attack having been ſoon crippled, ſhall not have been able to puſh farther than the third or fourth ſhip of the enemy's line—is it not eaſy to conceive, it is aſked, that ſome one or more of the ſhips to windward, attentive to ſupport and ſupply her place, may bear down on the fourth ſhip of the enemy, under cover of the ſmoke, throw in her fire, and puſh on to the fifth or ſixth ſhip, or perhaps farther; and that ſo far as this freſh ſhip, or a ſecond freſh ſhip, may be able to puſh, ſo many ſhips of the enemy may be expected to be carried? For whatever ſhips of the enemy

Partial Breezes of Wind.

can be got abreaſt of, at a proper diſtance, *may be diſabled, and therefore commanded*, by the numerous freſh ſhips kept to windward for this purpoſe.

In all theſe various methods of attack, the fleet making the attack is ſuppoſed to ſail faſter than the other, or at leaſt to come up with it; and that ſo ſoon as the ſhips are engaged, their velocity will conſequently be diminiſhed. That being premiſed, a more proper mode of attack than any of the preceding will perhaps be as follows:

5th, The firſt or headmoſt of the ſhips intended to make the attack is to range alongſide of the enemy, and preſerve that ſtation. The ſecond ſhip is to make all poſſible ſail to luff up and paſs the firſt ſhip, which is now ſuppoſed to be engaged, and get alongſide of the laſt but one of the enemy, which ſhe is to engage. In like manner, the third of the attacking ſhips is to get alongſide of the laſt but two of the enemy, whom ſhe is to engage; and if it be deemed expedient, the fourth, &c. ſhip may be engaged. It is, however, evident that this method can only be practiſed when the wind is briſk, and that a calm, in conſequence of a vigorous cannonade, may render the attack upon more than three or four of the enemy's ſhips impoſſible.

Partial Breezes of Wind.

In all the different attacks upon the rear, it has by ſome been thought a great object, if practicable, to throw a raking fire into the rear of an enemy's line of battle, by ſhips detached for that purpoſe. For if ſhot, as has been ſaid, can take effect at a diſtance of two miles, from this poſition it will ſurely reach the ſixth ſhip, if the enemy's line ſhall be formed at two cable's length aſunder; and if formed at one cable's length aſunder, it may reach and may cripple the twelfth ſhip.

We have now given a curſory view of Naval Tactics in its preſent improved ſtate; and ſhall take leave of the ſubject, with earneſtly recommending to our nautical readers Mr Clerk's Eſſay, which, if allowance be made for the author's peculiarity of ſtyle, will ſurely meet the approbation of every officer who wiſhes to ſee the practice of naval war founded on principles of ſcience.

Tadcaſter ‖ Tænia.

TADCASTER, a town in the Weſt Riding of Yorkſhire, noted for the great plenty of limeſtone dug up near it; and for being one of the firſt places in which a building was erected for Sunday ſchools. It is nine miles from York, and 188 from London.

TADMOR. See PALMYRA.

TADPOLE, a young frog before it has diſengaged itſelf from the membranes that envelope it in its firſt ſtage of life.

TÆNIA, in zoology; a genus of animals belonging to the claſs of *vermes*, and order of *inteſtina*. The body is long, depreſſed, and jointed like a chain, and contains a mouth and viſcera in each joint. According to Gmelin, there are 92 ſpecies; all which inhabit the inteſtines of various animals, particularly of quadrupeds.

Seven ſpecies of tænia are peculiar to man. 1. The *viſceralis*, which is incloſed in a veſicle, broad in the fore-part, and pointed in the hinder part, inhabits the liver, the placenta uterina, and the ſack which contains the ſuperfluous fluid of dropſical perſons. 2. The *cellulofæ*, which is incloſed in a cartilaginous veſicle, inhabits the cellular ſubſtance of the muſcles; is about an inch long, half an inch broad, and one-fourth of an inch thick, and is very tenacious of life. 3. The *dentata*, has a pointed head; the large joints are ſtreaked tranſverſely, and the ſmall joints are all dilated; the oſculum or opening in the middle of both margins is ſomewhat raiſed. It is narrow, 10 or 12 feet long, and broad in the fore-parts; its ovaria are not viſible to the naked eye; and the head underneath reſembles a heart in ſhape. It inhabits the inteſtines. 4. The *lata*, is white, with joints very ſhort and knotty in the middle; the oſculum is ſolitary. It is from 18 to 120 feet long; its joints are ſtreaked tranſverſely; its ovaria are diſpoſed like the petals of a roſe. 5. The *vulgaris*, or common tape-worm, has two lateral mouths in each joint; it attaches itſelf ſo firmly to the inteſtines, that it can ſcarcely be removed by the moſt violent medicines; it is ſlender, and has the appearance of being membranaceous; it is ſomewhat pellucid, from 10 to 16 feet long, and about four and an half lines broad at one end. 6. The *truttæ*, which chiefly inhabits the liver of the trout, but is alſo to be found in the inteſtines of the human ſpecies. 7. The *ſolium*, has a marginal mouth, one on each joint.

The ſtructure and phyſiology of the tænia is curious, and it may be amuſing as well as inſtructive to conſider it with more attention. As the tænia is often the occaſion of diſeaſe, we may be apt to conſider it not only as uſeleſs, but even as naturally hurtful; but it is impoſſible to ſuppoſe that the Benevolent Father of mankind created a ſpecies of animals ſolely for the purpoſe of producing diſeaſe. The creation of the tænia is rather a ſtriking inſtance of that rule which the Deity ſeems to have laid down to himſelf, to leave no place deſtitute of living creatures where they could multiply their ſpecies. He has therefore not only covered the earth with animals, but the ſurface of animals with other animals; and has even peopled ſuch of their internal parts as could ſupply nouriſhment without diſadvantage. Perhaps therefore a certain proportion of theſe animals is conducive to health, juſt as a certain proportion of different fluids is ſo, tho' an exceſſive increaſe always produces diſeaſe. For there is in almoſt every different ſpecies of quadrupeds a different ſpecies of tænia, which is a full proof that theſe worms have their ſtructure and ſituation determined with as much attention and ſkill as any ſpecies of animals whatever. It is alſo a very curious fact, that thoſe ſpecies of tænia which are peculiar to the human race are alſo peculiar to particular countries. Thus the vulgaris is moſt common in Sweden, the lata in Switzerland and Ruſſia, and the ſolium in Great Britain, Saxony, and Holland.

Tænia.

The tænia appears deſtined to feed upon ſuch juices of animals as are already animalized, and is therefore moſt commonly found in the alimentary canal, and in the upper part, where there is the greateſt abundance of chyle; for chyle ſeems to be the natural food of the tænia. As it is thus ſupported by food which is already digeſted, it is deſtitute of the complicated organs of digeſtion. The tænia ſolium which is moſt frequent in this country, it may be proper to deſcribe more particularly:

It is from 3 to 30 feet long, ſome ſay 60 feet. It is compoſed of a head, in which is a mouth adapted to drink up fluids, and an apparatus for giving the head a fixed ſituation. The body is compoſed of a great number of diſtinct pieces articulated together, each joint having an organ whereby it attaches itſelf to the neighbouring part of the inner coat of the inteſtine. The joints neareſt the head are always ſmall, and they become gradually enlarged as they are farther removed from it; but towards the tail a few of the laſt joints again become diminiſhed in ſize. The extremity of the body is terminated by a ſmall ſemicircular joint, which has no opening in it.

The head of this animal is compoſed of the ſame kind of materials as the other parts of its body; it has a rounded

Tænia. opening at its extremity, which is conſidered to be its mouth. See Plate DI. fig. 1, 2. This opening is continued by a ſhort duct into two canals; theſe canals paſs round every joint of the animal's body, and convey the aliment (fig. 3.). Surrounding the opening of the mouth are placed a number of projecting radii, which are of a fibrous texture, whoſe direction is longitudinal. Theſe radii appear to ſerve the purpoſe of tentacula for fixing the orifice of the mouth, as well as that of muſcles to expand the cavity of the mouth, from their being inſerted along the brim of that opening: (See fig. 1.) After the rounded extremity or head has been narrowed into the neck, as is repreſented in fig. 2. the lower part becomes flatted, and has two ſmall tubercles placed upon each flatted ſide; the tubercles are concave in the middle, and appear deſtined to ſerve the purpoſe of ſuckers for attaching the head more effectually. The internal ſtructure of the joints compoſing the body of this animal is partly vaſcular and partly cellular; the ſubſtance itſelf is white, and ſomewhat reſembles in its texture the coagulated lymph of the human blood. The alimentary canal paſſes along each ſide of the animal, ſending a croſs canal over the bottom of each joint, which connects the two lateral canals together. See fig. 3.

Mr Carliſle, who gives the beſt account of the ſtructure and economy of the tænia which we have ſeen, injected with a coloured ſize by a ſingle puſh, with a ſmall ſyringe thee feet in length of theſe canals, in the direction from the mouth downwards. He tried the injection the contrary way, but it ſeemed to be ſtopped by valves. The alimentary canal is impervious at the extreme joint, where it terminates without any opening analogous to an anus. Each joint has a vaſcular joint occupying the middle part, which is compoſed of a longitudinal canal, from which a great number of lateral canals branch off at right angles. Theſe canals contain a fluid like milk.

The tænia ſeems to be one of the ſimpleſt vaſcular animals in nature. The way in which it is nouriſhed is ſingular; the food being taken in by the mouth, paſſes into the alimentary canal, and is thus made to viſit in a general way the different parts of the animal. As it has no excretory ducts, it would appear that the whole of its alimentary fluid is fit for nouriſhment; the decayed parts probably diſſolve into a fluid which tranſudes through the ſkin, which is extremely porous.

This animal has nothing reſembling a brain or nerves, and ſeems to have no organs of ſenſe but that of touch. It is moſt probably propagated by ova, which may eaſily paſs along the circulating veſſels of other animals. We cannot otherwiſe explain the phenomena of worms being found in the eggs of fowls, and in the inteſtines of a fœtus before birth, except by ſuppoſing their ova to have paſſed through the circulating veſſels of the mother, and by this means been conveyed to the fœtus.

The chance of an ovum being placed in a ſituation where it will be hatched, and the young find convenient ſubſiſtence, muſt be very ſmall; hence the neceſſity for their being very prolific. If they had the ſame powers of being prolific which they now have, and their ova were afterwards very readily hatched, then the multiplication of theſe animals would be immenſe, and become a nuiſance to the other parts of the creation.

Another mode of increaſe allowed to tænia (if we may call it increaſe) is by an addition to the number of their joints. If we conſider the individual joints as diſtinct beings, it is ſo; and when we reflect upon the power of generation given to each joint, it makes this conjecture the more probable. We can hardly ſuppoſe that an ovum of a tænia, which at its full growth is 30 feet long, and compoſed of 400 joints, contained a young tænia compoſed of this number of pieces; but we have ſeen young tænia not half a foot long, and not poſſeſſed of 50 joints, which ſtill were entire worms. We have alſo many reaſons to believe, that when a part of this animal is broken off from the reſt, it is capable of forming a head for itſelf, and becomes an independent being. The ſimple conſtruction of the head makes its regeneration a much more eaſy operation than that of the tails and feet of lizards, which are compoſed of bones and complicated veſſels; but this laſt operation has been proved by the experiments of Spallanzani and many other naturaliſts. Tænia ‖ Tagetes.

When inteſtinal worms produce a diſeaſed ſtate of the animal's body which they inhabit, various remedies are adviſed for removing them; many of which are ineffectual, and others very injurious by the violence of their operation. Draſtic purges ſeem to operate upon tænia, partly by irritating the external ſurface of their bodies, ſo as to make them quit their holds, and partly by the violent contractions produced in the inteſtine, which may ſometimes divide the bodies of tænia, and even kill them by bruiſing. Mr Carliſle propoſes the trial of a ſimple remedy, which (*à priori*) promiſes to be ſucceſsful; namely, ſmall ſhocks of electricity paſſed frequently through the regions of the abdomen; the lives of the lower orders of animals ſeeming to be eaſily deſtroyed by ſuch ſhocks of electricity as do not injure the larger and more perfect animals.

Plate DI. fig. 1. ſhows the head of the tænia magnified; the mouth is in the middle of the circular plane, where the body becomes flatted and broad; there are two hollow tubercles repreſented by the two dark-ſhaded ſpots. Fig. 2. is the ſame head, of its natural bigneſs, and which belonged to a tænia 20 feet in length. Fig. 3. ſhows the alimentary canals, in a portion of the ſame tænia, of their natural bigneſs. The dark-ſhaded undulating lines are the alimentary canals, which are ſeen to their full extent in this portion of the worm. Fig. 4. ſhows the middle ſyſtem of veſſels, in two joints, which are repreſented by the dark lines. Fig. 5. ſhows two joints, from one ſide of which a ſlip was torn down to ſhow the veſſels underneath, and alſo the direction of the fibres in the ſlip, which are accumulated into little faſciculi like muſcular fibres. Fig. 6. exhibits three joints, having the ducts leading from the lateral oſcula injected; the dark tranſverſe lines leading from each oſculum ſhow the ſize, direction, and extent of theſe ducts. Fig. 7. ſhows the edge of two joints turned forwards, and the appearance of the oſcula in this point of view. Fig. 8. repreſents the whole of theſe canals in their relative ſituations.

For a more complete account of the tænia, we muſt refer to Mr Carliſle's ingenious paper in the Linnæan Tranſactions.

TAFFETY or TAFFETA, in commerce, a fine ſmooth ſilken ſtuff, remarkably gloſſy. There are taffeties of all colours, ſome plain, and others ſtriped with gold, ſilver, &c. others chequered, others flowered, &c. according to the fancy of the workmen.

TAGARA, a city of ancient India, the metropolis of a large diſtrict called *Ariaca*, which comprehended the greateſt part of the Subah of Aurangabad, and the ſouthern part of Concan. Arrian ſays, that it was ſituated about ten days journey to the eaſtward of Pultanah; which, according to the rate of travelling in that country with loaded carts, might be about 100 Britiſh miles. This fixes its ſituation at Deoghir, a place of great antiquity, and famous through all India on account of the pagodas of Elouſa. It is now called *Doulet-abad.*

TAGETES, MARYGOLD, in botany: A genus of plants belonging to the claſs of *ſyngeneſia*, and order of *polygamia ſuperflua*; and in the natural ſyſtem ranging under the 49th order,

Tagetes ‖ Tail.

order, *Compoſitæ*. The receptacle is naked; the pappus conſiſts of five erect awns or beards; the calyx is monophyllous, quinquedentate, and tubular; and there are four perſiſtent florets of the ray. There are three ſpecies, the *patula*, *erecta*, and *minuta*; of which the two firſt have been cultivated in the Britiſh gardens, at leaſt ſince the year 1596, for it is mentioned in Gerard's Herbal, which was publiſhed that year. They are both natives of Mexico.

The *erecta*, or African marygold, has a ſtem ſubdivided and ſpreading, and has formed itſelf into a great many varieties: 1. Pale yellow, or brimſtone colour, with ſingle, double, and fiſtulous flowers. 2. Deep yellow, with ſingle, double, and fiſtulous flowers. 3. Orange-coloured, with ſingle, double, and fiſtulous flowers. 4. Middling African, with orange-coloured flowers. 5. Sweet-ſcented African. Theſe are all very ſubject to vary; ſo that unleſs the ſeeds are very carefully ſaved from the fineſt flowers, they are apt to degenerate: nor ſhould the ſame ſeeds be too long ſown in the ſame garden, for the ſame reaſon; therefore, thoſe who are deſirous to have theſe flowers in perfection ſhould exchange their ſeeds with ſome perſon of integrity at a diſtance, where the ſoil is of a different nature, at leaſt every other year. If this is done, the varieties may be continued in perfection. This plant is ſo well known as to need no deſcription. It flowers from the beginning of July till the froſt puts a ſtop to it.

The *patula* has a ſimple erect ſtem, and the peduncles are ſcaly and multiflorous.

It has been long in the Britiſh gardens, where it is diſtinguiſhed from the firſt by the title of *French marygold*. Of this there are ſeveral varieties, ſome of which have much larger flowers than others, and their colour varies greatly: there are ſome which are beautifully variegated, and others quite plain; but as theſe are accidents ariſing from culture, ſo they do not merit farther diſtinction; for we have always found that ſeeds ſaved from the moſt beautiful flowers will degenerate, eſpecially if they are ſown in the ſame garden for two or three years together, without changing the ſeed.

Theſe plants have a ſtrong diſagreeable ſcent, eſpecially when handled; for which reaſon they are not ſo greatly eſteemed for planting near habitations: but the flowers of the ſweet-ſcented ſort being more agreeable, are generally preferred, eſpecially for planting in ſmall gardens.

TAGUS, the largeſt river of Spain; which, taking its riſe on the confines of Arragon, runs ſouth-weſt through the provinces of New Caſtile and Eſtremadura; and paſſing by the cities of Aranjuez, Toledo, and Alcantara, and then croſſing Portugal, forms the harbour of Liſbon, at which city it is about three miles over; and about eight or ten miles below this it falls into the Atlantic ocean.

TAHOEREWA, one of the Sandwich iſlands. It is ſmall, deſtitute of wood, and its ſoil ſandy and unfertile. It is ſituated in north latitude 20° 38′, in eaſt longitude 203° 27′. See *Cook's Diſcoveries*, vol. v. n° 88. and *Sandwich-Iſlands*.

TAHOORA, one of the Sandwich iſlands in the South Sea. It is uninhabited, and lies in north latitude 21° 43′, and in eaſt longitude 199° 36′. See *Sandwich-Iſlands*.

TAJACU, or PECCARY, in zoology, a ſpecies of hog. See SUS.

TAI-OUAN, the Chineſe name of the iſland of Formoſa. See FORMOSA.—Tai-ouan is alſo the name of the capital of the iſland.

TAIL, the train of a beaſt, bird, or fiſh; which in land animals ſerves to drive away flies, &c. and in birds and fiſhes to direct their courſe, and aſſiſt them in aſcending or deſcending in the air or water.

Tail.

TAIL, or FEE-TAIL, in law, is a conditional eſtate or fee, oppoſed to *fee-ſimple*. See FEE.

A conditional fee, at the common law, was a fee reſtrained to ſome particular heirs excluſive of others: as to the heirs of a man's body, by which only his lineal deſcendants were admitted, in excluſion of collateral heirs; or to the heirs male of his body, in excluſion both of collaterals and lineal females alſo. It was called a *conditional fee*, by reaſon of the condition expreſſed or implied in the donation of it, that if the donee died without ſuch particular heirs, the land ſhould revert to the donor. For this was a condition annexed by law to all grants whatſoever, that on failure of the heirs ſpecified in the grant, the grant ſhould be at an end, and the land return to its ancient proprietor. Such conditional fees were ſtrictly agreeable to the nature of feuds, when they firſt ceaſed to be mere eſtates of life, and were not yet arrived to be abſolute eſtates in fee-ſimple.

With regard to the condition annexed to theſe fees by the common law, it was held, that ſuch a gift (to a man and the heirs of his body) was a gift upon condition that it ſhould revert to the donor if the donee had no heirs of his body; but if he had, it ſhould then remain to the donee. They therefore called it a *fee-ſimple* on condition that he had iſſue. Now we muſt obſerve, that when any condition is performed, it is thenceforth entirely gone; and the thing to which it was before annexed becomes abſolute and wholly unconditional. So that as ſoon as the grantee had any iſſue born, his eſtate was ſuppoſed to become abſolute by the performance of the condition; at leaſt for theſe three purpoſes: 1. To enable the tenant to alienate the land, and thereby to bar not only his own iſſue, but alſo the donor, of his intereſt in the reverſion. 2. To ſubject him to forfeit it for treaſon: which he could not do till iſſue born longer than for his own life, leſt thereby the inheritance of the iſſue and reverſion of the donor might have been defeated. 3. To empower him to charge the land with rents, commons, and certain other encumbrances, ſo as to bind his iſſue. And this was thought the more reaſonable, becauſe, by the birth of iſſue, the poſſibility of the donor's reverſion was rendered more diſtant and precarious: and his intereſt ſeems to have been the only one which the law, as it then ſtood, was ſolicitous to protect, without much regard to the right of ſucceſſion intended to be veſted in the iſſue. However, if the tenant did not in fact alienate the land, the courſe of deſcent was not altered by this performance of the condition: for if the iſſue had afterwards died, and then the tenant or original grantee had died, without making any alienation, the land, by the terms of the donation, could deſcend to none but the heirs of his body; and therefore, in default of them, muſt have reverted to the donor. For which reaſon, in order to ſubject the lands to the ordinary courſe of deſcent, the donees of theſe conditional fee-ſimples took care to alienate as ſoon as they had performed the condition by having iſſue; and afterwards repurchaſed the lands, which gave them a fee-ſimple abſolute, that would deſcend to the heirs general, according to the courſe of the common law. And thus ſtood the old law with regard to conditional fees: which things, ſays Sir Edward Coke, though they ſeem ancient, are yet neceſſary to be known, as well for the declaring how the common law ſtood in ſuch caſes, as for the ſake of annuities, and ſuch-like inheritances, as are not within the ſtatutes of entail, and therefore remain as the common law. The inconveniences which attended theſe limited and fettered inheritances were probably what induced the judges to give way to this ſubtle fineſſe (for ſuch it undoubtedly was), in order to ſhorten the duration of theſe conditional eſtates. But, on the other hand, the nobility, who were willing to perpetuate their

Tail. poſſeſſions in their own families, to put a ſtop to this practice, procured the ſtatute of Weſtminſter the ſecond (commonly called the ſtatute *de donis conditionalibus*) to be made; which paid a greater regard to the private will and intentions of the donor, than to the propriety of ſuch intentions, or any public conſiderations whatſoever. This ſtatute revived in ſome ſort the ancient feodal reſtraints which were originally laid on alienations, by enacting, that from thenceforth the will of the donor be obſerved; and that the tenements ſo given (to a man and the heirs of his body) ſhould at all events go to the iſſue, if there were any; or if none, ſhould revert to the donor.

Upon the conſtruction of this act of parliament, the judges determined that the donee had no longer a conditional fee ſimple, which became abſolute and at his own diſpoſal the inſtant any iſſue was born; but they divided the eſtate into two parts, leaving in the donee a new kind of particular eſtate, which they denominated a *fee-tail*; and veſting in the donor the ultimate fee-ſimple of the land, expectant on the failure of iſſue; which expectant eſtate is what we now call a *reverſion*. And hence it is that Littleton tells us, that tenant in fee-tail is by virtue of the ſtatute of Weſtminſter the ſecond. The expreſſion *fee-tail*, or *feodum talliatum*, was borrowed from the feudiſts (ſee Crag. *l. ſ. t.* 10. § 24, 25.), among whom it ſignified any mutilated or truncated inheritance, from which the heirs-general were cut off; being derived from the barbarous verb *taliare*, to cut; from which the French *tailler* and the Italian *tagliare* are formed, (Spelm. *Gloſſ.* 531.).

Having thus ſhown the original of eſtates-tail, we now proceed to conſider what things may or may not be entailed under the ſtatute *de donis*. Tenements is the only word uſed in the ſtatute: and this Sir Edward Coke expounds to comprehend all corporeal hereditaments whatſoever; and alſo all incorporeal hereditaments which ſavour of the realty, that is, which iſſue out of corporeal ones, or which concern or are annexed to or may be exerciſed within the ſame; as rents, eſtovers, commons, and the like. Alſo offices and dignities, which concern lands, or have relation to fixed and certain places, may be entailed. But mere perſonal chattels, which ſavour not at all of the reality, cannot be entailed. Neither can an office, which merely relates to ſuch perſonal chattels; nor an annuity, which charges only the perſon, and not the lands of the granter. But in theſe laſt, if granted to a man and the heirs of his body, the grantee hath ſtill a fee conditional at common law as before the ſtatute, and by his alienation may bar the heir or reverſioner. An eſtate to a man and his heirs for another's life cannot be entailed; for this is ſtrictly no eſtate of inheritance, and therefore not within the ſtatute *de donis*. Neither can a copyhold eſtate be entailed by virtue of the ſtatute; for that would tend to encroach upon and reſtrain the will of the lord: but, by the ſpecial cuſtom of the manor, a copyhold may be limited to the heirs of the body; for here the cuſtom aſcertains and interprets the lord's will.

As to the ſeveral ſpecies of eſtates-tail, and how they are reſpectively created; they are either general or ſpecial. Tail-general is where lands and tenaments are given to one, and the heirs of his body begotten: which is called *tail-general*; becauſe, how often ſoever ſuch donee in tail be married, his iſſue in general, by all and every ſuch marriage, is, in ſucceſſive order, capable of inheriting the eſtate-tail *per formam doni*. Tenant in *tail-ſpecial* is where the gift is reſtrained to certain heirs of the donee's body, and does not go to all of them in general. And this may happen ſeveral ways. We ſhall inſtance in only one; as where lands and tenements are given to a man and the heirs of his body, on Mary his now wife to be begotten. Here no iſſue can inherit but ſuch ſpecial iſſue as is engendered between them two; not ſuch as the huſband may have by another wife; and therefore it is called *ſpecial tail*. And here we may obſerve, that the words of inheritance (to him and his heirs) give him an eſtate in fee; but they being heirs to be by him begotten, this makes it a fee-tail; and the perſon being alſo limited, on whom ſuch heirs ſhall be begotten (viz. Mary his preſent wife), this makes it a fee-tail ſpecial. Tail.

Eſtates in general and ſpecial tail are farther diverſified by the diſtinction of ſexes in ſuch entails; for both of them may either be in tail male or tail female. As if lands be given to a man, and his heirs-male of his body begotten, this is an eſtate in tail male general; but if to a man, and the heirs female of his body on his preſent wife begotten, this is an eſtate in tail female ſpecial. And in caſe of an entail male, the heirs female ſhall never inherit, nor any derived from them; nor, *e converſo*, the heirs-male in caſe of a gift in tail female. Thus, if the donee in tail male hath a daughter, who dies leaving a ſon, ſuch grandſon in this caſe cannot inherit the eſtate-tail; for he cannot deduce his deſcent wholly by heirs-male. And as the heir-male muſt convey his deſcent wholly by males, ſo muſt the heir-female wholly by females. And therefore if a man hath two eſtates-tail, the one in tail male and the other in tail female, and he hath iſſue a daughter, which daughter hath iſſue a ſon; this grandſon can ſucceed to neither of the eſtates, for he cannot convey his deſcent wholly either in the male or female line.

As the word *heirs* is neceſſary to create a fee, ſo, in farther imitation of the ſtrictneſs of the feodal donation, the word *body*, or ſome other words of procreation, are neceſſary to make it a fee-tail, and aſcertain to what heirs in particular the fee is limited. If, therefore, either the words of inheritance or words of procreation be omitted, albeit the others are inſerted in the grant, this will not make an eſtate-tail. As if the grant be to a man and the iſſue of his body, to a man and his ſeed, to a man and his children or offſpring; all theſe are only eſtates for life, there wanting the words of inheritance, "his heirs." So, on the other hand, a gift to a man, and his heirs male or female, is an eſtate in fee-ſimple and not in fee-tail; for there are no words to aſcertain the body out of which they ſhall iſſue. Indeed, in laſt wills and teſtaments, wherein greater indulgence is allowed, an eſtate-tail may be created by a deviſe to a man and his ſeed, or to a man and his heirs-male, or by other irregular modes of expreſſion.

There is ſtill another ſpecies of entailed eſtates, now indeed grown out of uſe, yet ſtill capable of ſubſiſting in law; which are eſtates *in libero maritagio*, or FRANKMARRIAGE. See that article.

The incidents to a tenancy in tail, under the ſtatute Weſtminſter 2. are chiefly theſe: 1. That a tenant in tail may commit waſte on the eſtate tail, by felling timber, pulling down houſes, or the like, without being impeached or called to account for the ſame. 2. That the wife of the tenant in tail ſhall have her dower, or thirds, of the eſtate-tail. 3. That the huſband of a female tenant in tail may be tenant by the curteſy of the eſtate-tail. 4. That an eſtate-tail may be barred, or deſtroyed, by a fine, by a common recovery, or by lineal warranty deſcending with aſſets to the heir. See ASSETS.

Thus much for the nature of eſtates-tail: the eſtabliſhment of which family-law (as it is properly ſtyled by Pigott) occaſioned infinite difficulties and diſputes. Children grew diſobedient when they knew they could not be ſet aſide: farmers were ouſted of their leaſes made by tenants in tail; for if ſuch leaſes had been valid, then, under colour of long leaſes, the iſſue might have been virtually diſinherited: creditors were defrauded of their debts; for, if a tenant

Tail. a tenant in tail could have charged his eſtate with their payment, he might alſo have defeated his iſſue, by mortgaging it for as much as it was worth: innumerable latent entails were produced to deprive purchaſers of the lands they had fairly bought; of ſuits in conſequence of which, our ancient books are full: and treaſons were encouraged, as eſtates-tail were not liable to forfeiture longer than for the tenant's life. So that they were juſtly branded as the ſource of new contentions and miſchiefs unknown to the common law; and almoſt univerſally conſidered as the common grievance of the realm. But as the nobility were always fond of this ſtatute, becauſe it preſerved their family-eſtates from forfeiture, there was little hope of procuring a repeal by the legiſlature; and therefore, by the connivance of an active and politic prince, a method was deviſed to evade it.

About 200 years intervened between the making of the ſtatute *de donis*, and the application of common recoveries to this intent, in the 12th year of Edward IV.; which were then openly declared by the judges to be a ſufficient bar of an eſtate-tail. For though the courts had, ſo long before as the reign of Edward III. very frequently hinted their opinion that a bar might be effected upon theſe principles, yet it was never carried into execution; till Edward IV. obſerving (in the diſputes between the houſes of York and Lancaſter) how little effect attainders for treaſon had on families whoſe eſtates were protected by the ſanctuary of entails, gave his countenance to this proceeding, and ſuffered Taltarum's caſe to be brought before the court: wherein, in conſequence of the principles then laid down, it was in effect determined, that a common recovery ſuffered by tenant in tail ſhould be an effectual deſtruction thereof. Theſe common recoveries are fictitious proceedings, introduced by a kind of *pia fraus*, to elude the ſtatute *de donis*, which was found ſo intolerably miſchievous, and which yet one branch of the legiſlature would not then conſent to repeal: and that theſe recoveries, however clandeſtinely begun, are now become by long uſe and acquieſcence a moſt common aſſurance of lands; and are looked upon as the legal mode of conveyance, by which a tenant in tail may diſpoſe of his lands and tenements: ſo that no court will ſuffer them to be ſhaken or reflected on, and even acts of Parliament have by a ſide-wind countenanced and eſtabliſhed them.

This expedient having greatly abridged eſtates-tail with regard to their duration, others were ſoon invented to ſtrip them of other privileges. The next that was attacked was their freedom from forfeitures for treaſon. For, notwithſtanding the large advances made by recoveries, in the compaſs of about threeſcore years, towards unfettering theſe inheritances, and thereby ſubjecting the lands to forfeiture, the rapacious prince then reigning, finding them frequently reſettled in a ſimilar manner to ſuit the convenience of families, had addreſs enough to procure a ſtatute, whereby all eſtates of inheritance (under which general words eſtates-tail were covertly included) are declared to be forfeited to the king upon any conviction of high-treaſon.

The next attack which they ſuffered, in order of time, was by the ſtatute 32 Hen. VIII. c. 28. whereby certain leaſes made by tenants in tail, which do not tend to the prejudice of the iſſue, were allowed to be good in law, and to bind the iſſue in tail. But they received a more violent blow in the ſame ſeſſion of parliament, by the conſtruction put upon the ſtatute of fines, by the ſtatute 32 Hen. VIII. c. 36. which declares a fine duly levied by tenant in tail to be a complete bar to him and his heirs, and all other perſons claiming under ſuch entail. This was evidently agreeable to the intention of Henry VII. whoſe policy it was (before common recoveries had obtained their full ſtrength and authority) to lay the road as open as poſſible to the alienation of landed property, in order to weaken the overgrown power of his nobles. But as they, from the oppoſite reaſons, were not eaſily brought to conſent to ſuch a proviſion, it was therefore couched, in his act, under covert and obſcure expreſſions. And the judges though willing to conſtrue that ſtatute as favourably as poſſible for the defeating of entailed eſtates, yet heſitated at giving fines ſo extenſive a power by mere implication, when the ſtatute *de donis* had expreſsly declared that they ſhould not be a bar to eſtates-tail. But the ſtatute of Henry VIII. when the doctrine of alienation was better received, and the will of the prince more implicitly obeyed than before, avowed and eſtabliſhed that intention. Yet in order to preſerve the property of the crown from any danger of infringment, all eſtates tail created by the crown, and of which the crown has the reverſion, are excepted out of this ſtatute. And the ſame was done with regard to common recoveries, by the ſtatute 34 and 35 Hen. VIII. c. 20. which enacts, that no feigned recovery had againſt tenants in tail, where the eſtate was created by the crown, and the remainder or reverſion continues ſtill in the crown, ſhall be of any force and effect. Which is allowing, indirectly and collaterally, their full force and effect with reſpect to ordinary eſtates-tail, where the royal prerogative is not concerned.

Laſtly, by a ſtatute of the ſucceeding year, all eſtates-tail are rendered liable to be charged for payment of debts due to the king by record or ſpecial contract; as ſince, by the bankrupt-laws, they are alſo ſubjected to be ſold for the debts contracted by a bankrupt. And, by the conſtruction put on the ſtatute 43 Eliz. c. 4. an appointment by tenant in tail of the lands entailed to a charitable uſe is good without fine or recovery.

Eſtates-tail being thus by degrees unfettered, are now reduced again to almoſt the ſame ſtate, even before iſſue born, as conditional fees were in at common law, after the condition was performed by the birth of iſſue. For, firſt, the tenant in tail is now enabled to alienate his lands and tenements by fine, by recovery, or by certain other means; and thereby to defeat the intereſt as well of his own iſſue, though unborn, as alſo of the reverſioner, except in the caſe of the crown: ſecondly, he is now liable to forfeit them for high treaſon: and, laſtly, he may charge them with reaſonable leaſes, and alſo with ſuch of his debts as are due to the crown on ſpecialties, or have been contracted with his fellow ſubjects in a courſe of extenſive commerce.

TAILZIE, in Scots law, the ſame with Tail. See Law, N° clxxx. 9.

TALAPOINS or Talopins, prieſts of Siam.—They enjoy great privileges, but are enjoined celibacy and auſterity of life. They live in monaſteries contiguous to the temples: and what is ſingular, any one may enter into the prieſthood, and after a certain age may quit it to marry, and return to ſociety. There are talapoineſſes too, or nuns, who live in the ſame convents, but are not admitted till they have paſſed their fortieth year. The talapoins educate children; and at every new and full moon explain the precepts of their religion in their temples; and during the rainy ſeaſons they preach from ſix in the morning till noon, and from one in the afternoon till five in the evening. They dreſs in a very mean garb, go bareheaded and barefooted; and no perſon is admitted among them who is not well ſkilled in the Baly language.

They believe that the univerſe is eternal; but admit that certain parts of it, as this world, may be deſtroyed and again regenerated. They believe in a univerſal pervading ſpirit, and in the immortality and tranſmigration of the ſoul; but they extend this laſt doctrine, not only to all animals, but to vegetables and rocks. They have their good and

evil

Talc. evil genii, and particular local deities, who preſide over foreſts and rivers, and interfere in all ſublunary affairs.

For the honour of human nature, we are happy to find ſo pure a ſyſtem of morality prevail among theſe people: It not only forbids its followers to do ill, but enjoins the neceſſity of doing good, and of ſtifling every improper thought or criminal deſire.

Thoſe who wiſh to peruſe a more particular account of the talapoins, may conſult *Voyage de M. de la Loubere*; Sketches relating to the Hiſtory, &c. of the Hindoos; or Payne's Geography.

TALC, in mineralogy, a ſpecies of foſſil arranged under the magneſian earths. In Magellan's edition of Cronſtedt's Mineralogy, it is conſidered as a ſpecies of MICA, and has accordingly been mentioned by us under that article. On the other hand, Dr Kirwan has claſſed the mica under the ſiliceous earths, while he places talc under the magneſian. According to the analyſis of Dr Kirwan, "talc conſiſts of pure magneſia, mixed with nearly twice its weight of ſilex, and leſs than its own weight of argil." It is compoſed of broad, flat, and ſmooth lamina, or plates. There are two varieties of it, the Venetian talc and Muſcovy talc; for the difference of which, ſee the article MICA.

The Venetian talc has not derived its name from being a production of the territories of Venice (for it is not often to be met with in that country), but probably from being an article of Venetian commerce. It abounds in England, Norway, Hungary, Bohemia, Spain, and in many countries of Aſia. Venice talc, with half its weight of alkaline ſalt, may, in a ſtrong fire, be brought into perfect fuſion, though not to perfect tranſparency: with equal its weight, or leſs, of borax, it runs into a beautiful, pellucid, greeniſh yellow glaſs. Talc does not melt with any other earth, nor even bake or cohere with any but the argillaceous: Mixtures of it with them all are nevertheleſs brought into fuſion by a remarkably leſs quantity of ſaline matter than the ingredients ſeparately would require. Thus equal parts of talc and chalk, with only one fourth their weight of borax, melt in no very vehement heat into a fine tranſparent greeniſh glaſs, of conſiderable hardneſs and great luſtre. On ſubſtituting gypſeous earths to chalk, the fuſion was as eaſy, and the glaſs as beautiful; in colour not green, but yellow like the topaz. Talc, with half its weight of ſand, and a quantity of nitre equal to both, yielded alſo a tranſparent topaz yellow glaſs. Several farther experiments on talc may be ſeen in a memoir by Mr Pott in the *Mem. de l'Acad. de Berlin*, 1746.

Muſcovy talc, called alſo *lapis ſpecularis*, is found in many parts. The iſland of Cyprus abounds with it. It is very common alſo in Ruſſia, and has of late been diſcovered to abound in the Alps, the Apennines, and many of the mountains of Germany. It is imported in large quantities into England, and is uſed by the lanthorn-makers inſtead of horn in their nicer works; by the painters to cover miniature pictures; and by the microſcope-makers to preſerve ſmall objects for viewing by glaſſes. The ancients uſed it inſtead of glaſs in their windows. Some take the lapis ſpecularis to have been a ſpecies of gypſum, and compoſed of the acid of vitriol and calcareous earth. It came into uſe at Rome in the age of Seneca*; and ſoon after its introduction was applied not only to lighten apartments, but to protect fruit-trees from the ſeverity of the weather; and it is recorded, that the emperor Tiberius was enabled, principally by its means, to have cucumbers at his table during almoſt every month in the year. Dr Watſon apprehends it is ſtill uſed in ſome countries in the place of glaſs: however, it is well known, that it was ſo uſed in the time of Agricola; for he mentions† two churches in Saxony which were lighted by it.

Hill's Hiſt. of Foſſ. p. 72.

* Ep. 90.

† De Nat. Foſſ. lib. 5. p. 257.

Agricola eſteemed it to have been a ſpecies of plaſter-ſtone; and in ſpeaking of it he remarks, that though it could bear, without being injured, the heat of ſummer and the cold of winter, yet the largeſt maſſes of it were waſted by the rain. It differs from plaſter-ſtone in this property, that it does not, after being calcined and wetted with water, ſwell and concrete into a hard ſtony ſubſtance.*

Although we have treated of Muſcovy talc and lapis ſpecularis as the ſame, we are not ignorant that a diſtinction has been made between them by ſome chemiſts; but as we have found a greater degree of confuſion on this ſubject in ſeveral valuable ſyſtems of mineralogy than we had reaſon to expect, we continue the old names as formerly, till a more ſatisfactory analyſis make it proper to apply them differently.

* Watſon's Chem. Eſſ. vol. ii. p. 297, &c.

Talc is employed, in thoſe places where it is found in any conſiderable quantity, in compoſitions for earthen veſſels; and by ſome for teſts and cupels. From its ſmoothneſs, unctuoſity, and brightneſs, it has been greatly celebrated as a coſmetic; and the chemiſts have ſubmitted it to a variety of operations, for procuring from it oils, ſalts, tinctures, magiſteries, &c. for that intention. But all their labours have been in vain; and all the preparations ſold under the name of talc have either contained nothing of that mineral, or only a fine powder of it.

TALENT, ſignifies both a weight and a coin very common among the ancients, but very different among different nations. Talent.

The common Attic talent of weight contains 60 Attic minæ, or 6000 Attic drachmæ; and weighed according to Dr Arbuthnot, 56 lbs. 11 oz. 17$\frac{1}{7}$ gr. Engliſh troy weight. There was another Attic talent, by ſome ſaid to conſiſt of 80, by others of 100 minæ. The Egyptian talent was 80 minæ; the Antiochian alſo 80; the Ptolemaic of Cleopatra 86$\frac{2}{3}$; that of Alexandria 96; and the Inſular talent 120. In the valuation of money, the Grecian talent, according to Dr Arbuthnot, was equal to 60 minæ, or, reckoning the minæ at L. 3:4:7, equal to L. 193, 15s: The Syrian talent in this valuation conſiſted of 15 Attic minæ; the Ptolemaic of 20; the Antiochian of 60; the Euboic of 60; The Babylonic of 70; the Greater Attic of 80; The Tyrian of 80; the Eginean of 100; the Rhodian of 100; and the Egyptian of 80 minæ.

There is another talent much more ancient, which Dr Arbuthnot calls the *Homeric talent* of gold, which ſeems to have weighed ſix Attic drachms of three darics, a daric weighing very little more than a guinea. According to this talent, ſome reckon the treaſure of king David, particularly that mentioned 1 Chron. xxii. 14. which, according to the common reckoning, would amount in gold talents to the value of L. 547,500,000, and the ſilver to above L. 342,000,000; or, reckoning according to the decuple proportion of gold to ſilver, the two ſums would be equal. As David reigned in Judæa after the ſiege of Troy, it is not improbable but Homer and he might uſe the ſame numeral talent of gold.

Among the Romans there were two kinds of talents, the *little* and the *great* talent: the little was the common talent; and whenever they ſay ſimply *talentum*, they are to be underſtood of this. The little talent was 60 minæ or Roman pounds; the mina or pound eſtimated at 100 drachmæ or denarii: it was alſo eſtimated at 24 great ſeſterces, which amounted to 60 pounds.

The great talent exceeded the leſs by one-third part. Budæus computes, that the little talent of ſilver was worth L. 75 Sterling, and the greater L. 99:6:8 Sterling. The greater of gold was worth L. 1125 Sterling

TALENT, as a ſpecies or money, among the Hebrews, was

Taliacotius || Tally.

was ſometimes uſed for a gold coin, the ſame with the ſhekel of gold, called alſo *ſtater*, and weighing only 4 drachms. The Hebrews reckoned by theſe talents as we do by pounds, &c. Thus a million of gold, or million of talents of gold, among them, was a million of ſhekels or nummi; the nummus of gold being the ſame weight with the ſhekel, viz. four drachms.

But the Hebrew talent weight of ſilver, which they called *cicar*, was equivalent to that of 3000 ſhekels, or 113 lb. 10 oz. 1 dwt. $10\frac{2}{7}$ gr. Engliſh Troy weight, according to Arbuthnot's computation.

TALIACOTIUS (Gaſper), chief ſurgeon to the great duke of Tuſcany, was born at Bononia in Italy in 1553. He wrote a Latin treatiſe intitled *Chirurgia Nota de Curtis Membris*, in which he teaches the art of engrafting noſes, ears, lips, &c. giving repreſentations of the inſtruments and proper bandages; though many are of opinion that he never put his art in practice. However, his doctrine is not ſingular; for he ſhows that Alexander Benedictus, a famous chirurgical writer, deſcribed the operation before.

TALLIO *(lex talionis)*, a ſpecies of puniſhment in the Moſaic law, whereby an evil is returned ſimilar to that committed againſt us by another; hence that expreſſion, "Eye for eye, tooth for tooth." This law was at firſt inſerted in the 12 tables amongſt the Romans; but afterwards ſet aſide, and a power given to the prætor to fix upon a ſum of money for the damage done.

TALISMANS, magical figures cut or engraved with ſuperſtitious obſervations on the characteriſms and configurations of the heavens, to which ſome aſtrologers have attributed wonderful virtues, particularly that of calling down celeſtial influences. The taliſmans of Samothrace, ſo famous of old, were pieces of iron formed into certain images, and ſet in rings; theſe were eſteemed preſervatives againſt all kinds of evils. There were likewiſe taliſmans taken from vegetables, and others from minerals.

TALLAGE (*tallagium*), from the French *taillé*, is metaphorically uſed for a part or ſhare of a man's ſubſtance carved out of the whole, paid by way of tribute, toll, or tax.

TALLOW, in commerce, the fat of certain animals melted and clarified. It is procured from moſt animals, but chiefly from bullocks, ſheep, hogs, and bears. Some kinds of tallow are uſed as unguents in medicine, ſome for making ſoap and dreſſing leather, and ſome for making candles. See CHEMISTRY, n° 1429.

Tallow-Tree. See CROTON.

TALLY, is a ſtick cut in two parts, on each whereof is marked, with notches or otherwiſe, what is due between debtor and creditor, as now uſed by brewers, &c. And this was the ancient way of keeping all accounts, one part being kept by the creditor, the other by the debtor, &c. Hence the tallier of the exchequer, who is now called the *teller*. "But there are two kinds of tallies mentioned in our ſtatutes to have been long uſed in the exchequer. The one is termed *tallies of debt*, which are in the nature of an acquittance for debts paid to the king, on the payment whereof theſe tallies are delivered to the debtors, who carrying them to the clerk of the pipe-office, have there an acquittance in parchment for their full diſcharge. The other are *tallies of reward* or allowance, being made to ſheriffs of counties as a recompenſe for ſuch matters as they have performed to their charge, or ſuch money as is caſt upon them in their accounts of courſe, but not leviable, &c. In the exchequer there is a tally-court, where attend the two deputy chamberlains of the exchequer and the tally-cutter: and a tally is generally the king's acquittance for money paid or lent, and has written on it words proper to expreſs on what occaſion the money is received."

Tally-Man, a perſon that ſells or lets goods, clothes, &c. to be paid by ſo much a-week. Talmud.

TALMUD, a collection of Jewiſh traditions. There are two works which bear this name, the Talmud of Jeruſalem, and the Talmud of Babylon. Each of theſe are compoſed of two parts; the Miſhna, which is the text, and is common to both, and the Gemara or commentary. See MISHNA and GEMARA.

The Miſhna, which comprehends all the laws, inſtitutions, and rules of life which, beſide the ancient Hebrew Scriptures, the Jews thought themſelves bound to obſerve, was compoſed, according to the unanimous teſtimony of the Jews, about the cloſe of the ſecond century. It was the work of Rabbi Jehuda (or Juda) Hakkadoſh, who was the ornament of the ſchool at Tiberias, and is ſaid to have occupied him forty years. The commentaries and additions which ſucceeding Rabbins made were collected by Rabbi Jochanan Ben Eliezer, ſome ſay in the 5th, others ſay in the 6th, and others in the 7th century, under the name of *Gemara*, that is, *completion*; becauſe it completed the Talmud. A ſimilar addition was made to the Miſhna by the Babyloniſh doctors in the beginning of the 6th century according to Enfield, and in the 7th according to others.

The Miſhna is divided into ſix parts, of which every one which is intitled *order* is formed of treatiſes, every treatiſe is divided into chapters, and every chapter into miſhnas or aphoriſms. In the *firſt* part is diſcuſſed whatever relates to ſeeds, fruits, and trees: in the *ſecond* feaſts: in the *third* women, their duties, their diſorders, marriages, divorces, contracts, and nuptials: in the *fourth* are treated the damages or loſſes ſuſtained by beaſts or men, of things found, depoſits, uſuries, rents, farms, partnerſhips in commerce, inheritance, ſales and purchaſes, oaths, witneſſes, arreſts, idolatry; and here are named thoſe by whom the oral law was received and preſerved: in the *fifth* part are noticed what regards ſacrifices and holy things: and the *ſixth* treats on purifications, veſſels, furniture, clothes, houſes, leproſy, baths, and numerous other articles. All this forms the Miſhna.

As the learned reader may wiſh to obtain ſome notion of rabbinical compoſition and judgment, we ſhall gratify his curioſity ſufficiently by the following ſpecimen: "Adam's *body* was made of the earth of Babylon, his *head* of the land of Iſrael, his other *members* of other parts of the world. R. Meir thought he was compact of the earth gathered out of the whole earth; as it is written, *thine eyes did ſee my ſubſtance*. Now it is elſewhere written, *the eyes of the Lord are over all the earth*. R. Aha expreſsly marks the twelve hours in which his various parts were formed. His ſtature was from one end of the world to the other; and it was for his tranſgreſſion that the Creator, laying his hand in anger on him, leſſened him; for before (ſays R. Eleazer), 'with his hand he reached the firmament.' R. Jehuda thinks his ſin was hereſy; but R. Iſaac thinks that 'it was nouriſhing his foreſkin."

The Talmud of Babylon is moſt valued by the Jews; and this is the book which they mean to expreſs when they talk of the Talmud in general. An abridgment of it was made by Maimonides in the 12th century, in which he rejected ſome of its greateſt abſurdities. The Gemara is ſtuffed with dreams and chimeras, with many ignorant and impertinent queſtions, and the ſtyle very coarſe. The Miſhna is written in a ſtyle comparatively pure, and may be very uſeful in explaining paſſages of the New Teſtament where the phraſeology is ſimilar. This is indeed the only uſe to which Chriſtians can apply it; but this renders it valuable. Lightfoot has judiciouſly availed himſelf of ſuch information as he could derive from it. Some of the popes, with a barbarous

Talpa
&
Tamarindus.

barous zeal, and a timidity of ſpirit for the ſucceſs of the Chriſtian religion, which the belief of its divinity can never excuſe, ordered great numbers of the Talmud to be burned. Gregory IX. burned about 20 cart-loads, and Paul IV. ordered 12,000 copies of the Talmud to be deſtroyed.

The laſt edition of the Talmud of Babylon, printed at Amſterdam, is in 12 vols folio. The Talmud of Jeruſalem is in one large folio.

TALPA, the MOLE; a genus of quadrupeds belonging to the order of *feræ* and claſs of *mammalia*. It has ſix unequal foreteeth in the upper jaw, and eight in the lower; one tuſk on each ſide in each jaw; ſeven grinders on each ſide above, and ſix below. There are ſeven ſpecies; the European, the flava or American, the criſtata, longicaudata, fuſca, rubra, and aurea.

The European mole is the only ſpecies of this animal found in Britain. There are ſeveral varieties of it; the black, the variegated, the white, and the grey mole. This ſpecies inhabits the whole of Europe except Ireland, where it is ſaid no moles are found. It is alſo common in the northerly parts of Aſia and Africa. It chiefly frequents moiſt fields that are expoſed to the ſun, meadows, and gardens; through theſe it conſtructs ſubteraneous roads or galleries in every direction in ſearch of worms, on which and the larvæ of inſects it feeds, and not at all on vegetables, though it does great damage by looſening the roots of plants. It is moſt active in its operations before rain, becauſe then the worms are in motion. The penis of the male is exceedingly long in proportion; they ſeem to pair and propagate in ſpring, the female bringing four or five young at a birth, which are placed in neſts made of moſs, leaves, and dried graſs, under the largeſt hillocks of the field; theſe are conſtructed with wonderful ingenuity, conſiſting of an interior hillock, ſurrounded with a ditch, which communicates with ſeveral galleries, on purpoſe to carry off the moiſture; and the neſt is covered over with a dome of earth, like the flat arch of an oven. Moles are deſtroyed by means of a paſte compoſed of palma-chriſti and white hellebore, or by flooding the fields which they infeſt; though, in the latter caſe, they ſometimes eſcape by aſcending trees.

This ſpecies is five inches and three quarters in length, and its tail is about one inch long. It has a large head, without any external ears, and eyes ſo very ſmall and ſo completely hid in the fur as to make it vulgarly believed that it has none. As it lives entirely below ground, it has certainly no occaſion for eyes like other quadrupeds; and as it probably finds its food by its ſenſe of ſmell, which is acute, its eyes may ſerve merely as a ſafeguard to warn it when it happens to emerge from the ground to return to its ſubterraneous dwelling. This warning may be given by the light falling upon its eyes, which may produce a painful ſenſation. For the truth of this conjecture, however, we muſt refer to the anatomiſt, who might eaſily determine, from the ſtructure of the eyes, what purpoſe they are fitted to ſerve.

TAMANDAU, in zoology. See MYRMECOPHAGA.

TAMARINDUS, the TAMARIND-TREE, in botany: A genus of plants arranged by Linnæus under the claſs of *triandria* and order of *monogynia*; but Woodville, Schreber, and other late botaniſts, have found that it belongs to the claſs of *monodelphia* and order of *triandria*. In the natural ſyſtem it is ranked under the *lomentaceæ*. There is only one ſpecies, the *indica*, which is a native of both Indies, of America, of Arabia, and Egypt, and was cultivated in Britain before the year 1633. Tamarindus.

The tamarind-tree riſes to the height of 30 or 40 feet, ſending off numerous large branches, which ſpread to a conſiderable extent, and have a beautiful appearance; the trunk is erect, and covered with rough bark, of a greyiſh or aſh-colour; the leaves are ſmall and pinnated, and of a yellowiſh green colour: the flowers reſemble the papilionaceous kind, and grow in lateral cluſters: the calyx conſiſts of four leaves, and the corolla of three petals, which are of a yellowiſh hue, and are beautifully diverſified with red veins: the fruit is a pod of a roundiſh compreſſed form, from three to five inches long, containing two, three, or four ſeeds, lodged in a dark pulpy matter. The flowers appear, according to Jacquin, in October and November; but, according to Dr Wright, they continue during the whole of June and July, and then drop off.

The pulp of the tamarind, with the ſeeds connected together by numerous tough ſtrings or fibres, are brought to us freed from the outer ſhell, and commonly preſerved in ſyrup. According to Long, tamarinds are prepared for exportation at Jamaica in the following manner: "The fruit or pods are gathered (in June, July, and Auguſt) when full ripe, which is known by their fragility or eaſy breaking on ſmall preſſure between the finger and thumb. The fruit, taken out of the pod, and cleared from the ſhelly fragments, is placed in layers in a caſk; and boiling ſyrup, juſt before it begins to granulate, is poured in, till the caſk is filled: the ſyrup pervades every part quite down to the bottom, and when cool the caſk is headed for ſale." He obſerves, that the better mode of preſerving this fruit is with ſugar, well clarified with eggs, till a tranſparent ſyrup is formed, which gives the fruit a much pleaſanter flavour: but as a principal medicinal purpoſe of the pulp depends upon its acidity, which is thus counteracted by the admixture of ſugar, it would therefore be of more utility if always imported here in the pods. The fruit produced in the Eaſt Indies is more eſteemed than that of the Weſt, and eaſily to be diſtinguiſhed by the greater length of the pods, and the pulp being dryer and of a darker colour.

Uſes. This fruit, the uſe of which was firſt learned of the Arabians, contains a larger proportion of acid, with the ſaccharine matter, than is uſually found in the *fructus acido-dulcis*, and is therefore not only employed as a laxative, but alſo for abating thirſt and heat in various inflammatory complaints, and for correcting putrid diſorders, eſpecially thoſe of a bilious kind; in which the cathartic, antiſeptic, and refrigerant qualities of the fruit have been found equally uſeful. When intended merely as a laxative, it may be of advantage to join it with manna, or purgatives of a ſweet kind, by which its uſe is rendered ſafer and more effectual. Three drachms of the pulp are uſually ſufficient to open the body; but to prove moderately cathartic, one or two ounces are required. It is an ingredient in *electuarium e caſſia*, and *electuarium e ſenna* or lenitive electuary (A).

We are informed by Dr Wright, that preſerved tamarinds are kept in moſt houſes in Jamaica either as a ſweet-meat, or for occaſional uſe as a medicine. See PHARMACY, n° 394 and 395.

TAMARIX,

(A) "Tournefort relates, that an eſſential ſalt may be obtained from tamarinds, by diſſolving the pulp in water, and ſetting the filtered ſolution, with ſome oil upon the ſurface, in a cellar for ſeveral months; that the ſalt is of a ſouriſh taſte, and difficultly diſſoluble in water; and that a like ſalt is ſometimes found alſo naturally concreted on the branches of the tree. The ſalt, as Beaumé obſerves, may be obtained more expeditiouſly, by clarifying the decoction of the tamarinds

Tamarix ‖ Tamerlane.

TAMARIX, the TAMARISK, in botany: A genus of plants belonging to the claſs of *pentandria*, and order of *trigynia*; and in the natural ſyſtem ranging under the 13th order, *Succulentæ*. The calyx is quinquepartite; the petals are five; the capſule is unilocular and trivalvular, and the ſeeds pappous. There are only two ſpecies known; the *gallica* or French tamariſk, and the *germanica* or German tamariſk.

TAMBAC, in the materia medica. See EXCÆCANA.

TAMBOUR, in architecture, a term applied to the Corinthian and Compoſite capitals, as bearing ſome reſemblance to a drum which the French call *tambour*. Some chooſe to call it the *vaſe*, and others *campana* or the bell.

TAMBOUR is alſo uſed for a little box of timber work, covered with a ceiling, withinſide the porch of certain churches; both to prevent the view of perſons paſſing by, and to keep off the wind, &c. by means of folding-doors &c.

TAMBOUR, alſo denotes a round courſe of ſtone, ſeveral whereof form the ſhaft of a column, not ſo high as a diameter.

TAMBOUR, in the arts, is a ſpecies of embroidery. The tambour is an inſtrument of a ſpherical form, upon which is ſtretched, by means of a ſtring and buckle, or other ſuitable appendage, a piece of linen or thin ſilken ſtuff; which is wrought with a needle of a particular form, and by means of ſilken or gold and ſilver threads, into leaves, flowers, or other figures.

TAMBOURIN, is the name of a dance performed on the French ſtage. The air is lively, and the movements are quick.

TAMERLANE, or TIMUR BEK, a celebrated prince and conqueror. At the age of 25 he attained the higheſt dignities, with ſurpriſing courage, and an ambition aſtoniſhing to all the world. Endeavouring to perfect the great talents which he had received from nature, he ſpent nine years in different countries; where his great ſenſe and elevated genius appeared in councils and aſſemblies, while his intrepidity and valour, whether in perſonal combats or pitched battles, drew upon him the admiration of all mankind. He made himſelf maſter of the three empires of Jagatay Khân, Tuſhi Khân, and Hûlâkû Khân; ſo that his power, riches, and magnificence, were immenſe. There remain vaſt monuments of his grandeur in the cities, towns, caſtles, and walls, which he built; in the rivers and canals which he dug, as well as the bridges, gardens, palaces, hoſpitals, moſques, and monſteries, which he erected in divers part of Aſia in ſo great a number, that a king might be accounted very powerful and magnificent, who ſhould have employed 36 years only in building the great edifices which Timûr cauſed to be founded.

Timûr, according to the hiſtorian Arabſhâh, was in his perſon very corpulent and tall. He had a large forehead and big head. His countenance was agreeable, and his complexion fair. He wore a large beard, was very ſtrong, and well limbed; had broad ſhoulders, thick fingers, and long legs. His conſtitution was amazingly vigorous; but he was maimed in one hand and lame of the right ſide. His eyes appeared full of fire; his voice was loud and piercing; he feared nothing; and when far advanced in years, his underſtanding was ſound and perfect, his body vigorous and robuſt, his mind conſtant and unſhaken like a rock.

He did not like raillery, and could not bear a lie. There was no joking or fooling before him; for he loved the naked truth, even although it was to his own diſadvantage. He neither grieved if he miſcarried in any attempt, nor appeared overjoyed on any great ſucceſs. The device of his ſeal was, "I am ſincere and plain." He had a clear and ſolid underſtanding, was ſurpriſingly happy in his conjectures; vigilant, active, and unſhaken in his reſolutions. He took great delight in reading hiſtory, and was well verſed in the ſtate of countries provinces, and cities. He was penetrating, ſubtle, cloſe, and diſſembling; juſt by inclination, liberal from diſpoſition; but ambition had in a great meaſure extinguiſhed his humanity; war had familiarized him to blood; and his religious zeal had inſpired him with the moſt cruel, implacable, and pernicious fanaticiſm.

Tamerſine ‖ Tan.

He died on the 1ſt of April 1405, in the 71ſt year of his age and 36th of his reign. When he found death approaching, he ſent for his principal officers, declared his grandſon his heir, and made them ſwear to execute his will. Having recommended brotherly love and concord to the princes his children, he ordered one of the doctors to read the Koran at his bed's head, and often repeat the unity of God. At night he ſeveral times made profeſſion of his belief, "That there is no other God than God," and then expired. See MOGULS, n° 15, &c.

TAMTAM, a flat drum uſed by the Hindoos, reſembling a tabor, but it is larger, and ſounds louder.

TAMUS, BLACK BRIONY, in botany: A genus of plants belonging to the claſs of *diœcia*, and order of *hexandria*; and in the natural ſyſtem ranging under the 11th order, *Sarmentaceæ*. The male and female flowers are both ſexpartite; there is no corolla; the ſtyle is trifid; the berry is trilocular and inferior, and contains two ſeeds. There are only two ſpecies known; the elephantipes, which is a native of the Cape of Good Hope, and we believe was firſt deſcribed by L'Heritier; and the communis.

The *communis*, or common black briony, is a native of England, but has not been obſerved growing wild in Scotland. It has a large root, which ſends forth ſeveral long ſlender ſtems: the leaves are large, heart-ſhaped, dark green, and grow on long foot ſtalks: the flowers are greeniſh, and the berry red. It flowers from May to Auguſt, and is frequent in hedges.

TAN the bark of the oak after it has been ground and uſed by the tanner. The ſmaller ſort is generally made up in little ſquare cakes called *turf*, and ſold for firing. The coarſer ſort is ſometimes dried in the ſun, and uſed by bakers for heating their ovens, &c. but its chief uſe is for making of hot-beds to raiſe pine apples and other plants.—William III. introduced the uſe of it from Holland, for the purpoſe of raiſing orange trees; after which it was diſcontinued for many years: but about 1719, when *ananas* were firſt brought into England, it came into general uſe, and has ever ſince been in great eſtimation with gardeners for all the purpoſes of forcing, &c. on account of its ſtrong and laſting fermentation. The ſmaller the tan the quicker it heats; but the larger ſort acquires heat more gradually and retains it longer: the ſkilful gardener therefore uſes the one or the other, or a mixture of both, according to the time and purpoſe for which it is wanted. It is ſome time after the tan comes out of the tanner's pit before it begins to heat, and therefore it is not fit for immediate uſe; but having

---

rinds with whites of eggs, then filtering it, and evaporating it to a proper conſiſtence, and ſetting it to cool: the ſalt ſhoots into cryſtals of a brown colour and very acid taſte; but in diſſolving and cryſtallizing them again, or barely waſhing them with water, they loſe almoſt all their acidity, the acid principle of the tamarinds ſeeming not to be truly cryſtallizable." Vide *Lewis's Mat. Med.* p. 633.

Tanacetum ‖ Tangier.

ving laid a week or two, it enters into a ſtate of fermentation, and if put into hot-beds properly prepared, will retain a moderate heat for three or four months. When it becomes uſeleſs for the hot-houſe, it is ſaid by Miller and others to be an excellent manure for ſome kinds of land.

The word *tan* is ſometimes, though improperly, uſed for the *bark* itſelf, which is the chief ingredient in the tanning of leather. Oak bark, on account of its great aſtringency and gummy-reſinous properties, is preferred to all other ſubſtances for the purpoſe of tanning, as it not only preſerves the leather from rotting, but alſo, by condenſing the pores, renders it impervious to water. See TANNING.

TANACETUM, TANSY, in botany: A genus of plants belonging to the claſs of *ſyngeneſia*, and order of *polygamia ſuperflua*; and in the natural ſyſtem ranging under the 49th order, *Compoſitæ*. The receptacle is naked; the pappus ſomewhat emarginated; the calyx imbricated and hemiſpherical; the florets of the radius are trifid, and ſcarcely diſtinguiſhable. Gmelin has enumerated ſeven ſpecies; of which one only is a native of Britain, the *vulgare*.

The *vulgare*, or common tanſy, grows three or four feet high; the leaves are bipinnated and ſerrated; the flowers yellow, and terminate the branches in flat umbels. It is found ſometimes on the borders of fields and dry banks: it abounds at Wark, and Ford-caſtle in the neighbourhood of Kelſo, on the borders of Scotland; and on the ſide of Gareloch on the weſtern coaſt of Roſs-ſhire: it has alſo been found in Breadalbane. It flowers generally in Auguſt. Of this ſpecies there is a variety with curled leaves, which is therefore called *curled tanſy*. The tanſy has a bitter taſte, and an aromatic ſmell diſagreeable to many people.

Uſes. It is eſteemed good for warming and ſtrengthening the ſtomach; for which reaſon the young leaves have obtained a place among the culinary herbs, their juice being an ingredient in puddings, &c. It is rarely uſed in medicine, though extolled as a good emmenagogue. A drachm of the dried flowers has been found very beneficial in hyſteric diſorders ariſing from ſuppreſſion. The ſeeds and leaves were formerly in conſiderable eſteem for deſtroying worms in children, and are reckoned good in colics and flatulencies. In ſome parts of Sweden and Lapland, a bath with a decoction of this plant is made uſe of to aſſiſt parturition. See PHARMACY, n° 193.

TANÆCIUM, in botany: A genus of the *angioſperma* order, belonging to the *didynamia* claſs of plants; and in the natural method ranking under the 25th order, *Putamineæ*. The calyx is monophyllous, tubulated, truncated, and entire; the corolla long, monopetalous, and white; the tube cylindrical; the lymbi erect, ſpreading, and nearly equal; the fruit a berry covered with a thick bark, large, oblong, internally divided into two parts; in the pulp are contained a number of ſeeds. There are only two ſpecies of this genus; the *jaroba* and *paraſiticum*, both natives of Jamaica. They grow by the ſides of rivers, and climb on trees and buſhes.

TANAGRA, TANAGER, in ornithology, a genus of birds belonging to the order of *paſſeres*. The beak is conical, acuminated, emarginated, almoſt triangular at the baſe, and inclining a little towards the point. Dr Latham has deſcribed 44 ſpecies, all of which are of foreign extraction.

TANAIS, or DON. See DON.

TANGENT *of an* ARCH, is a right line drawn perpendicularly from the end of a diameter, paſſing to one extremity of the arch, and terminated by a right line drawn from the centre through the other end of that arch, and called the *ſecant*. See GEOMETRY.

TANGIER, a port-town of Africa, in the empire of Morocco and kingdom of Fez, ſituated at the entrance of the Straits of Gibraltar, in W. Long. 5. 50. N. Lat. 38. 49. In 1662, this place belonged to the Portugueſe, and was given to king Charles II. upon his marriage with the Infanta of Portugal: but he, growing weary of the charge of keeping it, cauſed it to be blown up and deſtroyed in 1684; ever ſince which time it has been only a poor fiſhing town. Anciently it was called *Tingis*, and gave name to the province of Mauritania Tingitana.

Tank ‖ Tanning.

TANK, in the language of Indoſtan, a place incloſed for receiving and retaining the rain. During the periodical rains the tanks are filled, and thus in the dry ſeaſon furniſh water for the rice fields and cattle. Some of them are of great extent, meaſuring 300 or 400 feet on the ſide; they are of a quadrangular form, and lined with granite, deſcending in regular ſteps from the margin to the bottom.

TANNER, one who dreſſes hides by tanning them. See TANNING.

TANNER (Dr Thomas), an Engliſh prelate and celebrated antiquarian, born in 1674. He was admitted of Queen's college Oxford, where a ſimilarity of taſte for antiquities produced a cloſe friendſhip between him and Edmund Gibſon afterwards biſhop of London. In 1697, he was choſen fellow of his college; and having already publiſhed ſome ſpecimens of his ſkill in the antiquarian way, ſoon after became known to Dr Moore biſhop of Norwich, who made him chancellor of his dioceſe. In 1722, he was made archdeacon of Norwich, and in 1731 biſhop of St Aſaph. He died at Oxford in 1735; and after his death was publiſhed an elaborate work, ſaid to have employed him for 40 years, under this title, *Bibliotheca Britannica Hibernica, ſive de Scriptoribus qui in Anglia, Scotia, et Hibernia, ad æculi* XVII. *initium floruerunt*, &c.

TANNING, the art of manufacturing leather from raw hides and ſkins.

Before we detail the proceſs, it may be proper to obſerve, that raw hides and ſkins being compoſed of minute fibres interſecting each other in every direction, the general operation of tanning conſiſts chiefly in expanding the pores, and diſſolving a ſort of greaſy ſubſtance contained in them; and then, by means of the aſtringency and gummy-reſinous properties of oak bark, to fill and reunite them, ſo as to give firmneſs and durability to the whole texture. But this theory has been controverted by ſome chemiſts, who ſuppoſe that the animal jelly contained in the ſkin is not diſſolved, but unites during the proceſs with the aſtringent principle of the bark, and forms a combination inſoluble in water.

1 Method of tanning.

The proceſs of tanning varies conſiderably, not only in different countries, but even in different parts of the ſame country. The following is the method moſt approved and practiſed in London and its vicinity, where the beſt leather is generally allowed to be manufactured.

The leather tanned in England conſiſts chiefly of three ſorts, known by the name of *butts* or *backs*, *hides*, and *ſkins*.

2 Butts.

Butts are generally made from the ſtouteſt and heavieſt ox hides, and are managed as follows: After the horns are taken off, the hides are laid ſmooth in heaps for one or two days in the ſummer, and for five or ſix in the winter: they are then hung on poles, in a cloſe room called a *ſmoke-houſe*, in which is kept a ſmouldering fire of wet tan; this occaſions a ſmall degree of putrefaction, by which means the hair is eaſily got off, by ſpreading the hide on a ſort of wooden horſe or beam, and ſcraping it with a crooked knife. The hair being taken off, the hide is thrown into a pit or pool of water to cleanſe it from the dirt, &c. which being done, the hide is again ſpread on the wooden beam, and the greaſe, looſe fleſh, extraneous filth, &c. carefully ſcrubbed

Tanning. scrubbed out or taken off; the hides are then put into a pit of ſtrong liquor called *ooze* or *wooze*, prepared in pits called *letches* or *taps* kept for the purpoſe, by infuſing ground bark in water; this is termed *colouring:* after which they are removed into another pit called a *ſcowering*, which conſiſts of water ſtrongly impregnated with vitriolic acid, or with a vegetable acid prepared from rye or barley. This operation (which is called *raiſing*), by diſtending the pores of the hides, occaſions them more readily to imbibe the ooze, the effect of which is to aſtringe and condenſe the fibres, and give firmneſs to the leather. The hides are then taken out of the ſcowering, and ſpread ſmooth in a pit commonly filled with water, called a *binder*, with a quantity of ground bark ſtrewed between each. After lying a month or ſix weeks, they are taken up; and the decayed bark and liquor being drawn out of the pit, it is filled again with ſtrong ooze, when they are put in as before, with bark between each hide. They now lie two or three months, at the expiration of which the ſame operation is repeated; they then remain four or five months, when they again undergo the ſame proceſs; and after being three months in the laſt pit, are completely tanned, unleſs the hides are ſo remarkably ſtout as to want an additional pit or layer.—The whole proceſs requires from 11 to 18 months, and ſometimes two years, according to the ſubſtance of the hide, and diſcretion of the tanner. When taken out of the pit to be dried, they are hung on poles; and after being compreſſed by a ſteel pin, and beat out ſmooth by wooden hammers called *beetles*, the operation is complete; and when thoroughly dry, they are fit for ſale. Butts are chiefly uſed for the ſoles of ſtout ſhoes.

3 Hides. The leather which goes under the denomination of *hides* is generally made from cow hides, or the lighter ox hides, which are thus managed. After the horns are taken off, and the hides waſhed, they are put into a pit of water ſaturated with lime, where they remain a few days when they are taken out, and the hair ſcraped off on a wooden beam, as before deſcribed; they are then waſhed in a pit or pool of water, and the looſe fleſh, &c. being taken off, they are removed into a pit of weak ooze, where they are taken up and put down (which is technically termed *handling*) two or three times a-day for the firſt week: every ſecond or third day they are ſhifted into a pit of freſh ooze, ſomewhat ſtronger than the former, till at the end of a month or ſix weeks they are put into a ſtrong ooze, in which they are handled once or twice a-week with freſh bark for two or three months. They are then removed into another pit, called a *layer*, in which they are laid ſmooth, with bark ground very fine ſtrewed between each hide. After remaining here two or three months, they are generally taken up, when the ooze is drawn out, and the hides put in again with freſh ooze and freſh bark; where, after lying two or three months more, they are completely tanned, except a few very ſtout hides, which may require an extra layer: they are then taken out, hung on poles, and being hammered and ſmoothed by a ſteel pin, are when dry, fit for ſale.

Theſe hides are called *crop hides;* they are from 10 to 18 months in tanning, and are uſed for the ſoles of ſhoes.

4 Skins. *Skins* is the general term for the ſkins of calves, ſeals, hogs, dogs, &c. Theſe, after being waſhed in water, are put into lime-pits, as before mentioned, where they are taken up and put down every third or fourth day, for a fortnight or three weeks, in order to dilate the pores and diſſolve the gelatinous parts of the ſkin. The hair is then ſcraped off, and the fleſh and excreſcences being removed, they are put into a pit of water impregnated with pigeon-dung (called a *grainer* or *maſhing*), forming a ſtrong alkaline ley, which in a week or ten days ſoaking out the lime, greaſe, and, ſaponaceous matter (during which period they are ſeveral times ſcraped over with a crooked knife to work out the dirt and filth), ſoftens the ſkins, and prepares them for the reception of the ooze. They are then put into a pit of weak ooze, in the ſame manner as the hides, and being frequently handled, are by degrees removed into a ſtronger and ſtill ſtronger liquor, for a month or ſix weeks, when they are put into a very ſtrong ooze, with freſh bark ground very fine, and at the end of two or three months, according to their ſubſtance, are ſufficiently tanned; when they are taken out, hung on poles, dried, and fit for ſale. Tanning.

Theſe ſkins are afterwards dreſſed and blacked by the currier; and are uſed for the upper-leathers of ſhoes, boots, &c.

The lighter ſort of hides, called *dreſſing hides*, as well as horſe-hides, are managed nearly in the ſame manner as ſkins; and are uſed for coach work, harneſs-work, &c. &c.

5 Schemes to ſhorten the proceſs and leſſen the expence. As the method of tanning above deſcribed and all others in general uſe, are extremely tedious and expenſive in their operation, various ſchemes have at different times been ſuggeſted to ſhorten the proceſs and leſſen the expence.—Though moſt of theſe ſchemes have ultimately proved unſucceſsful, yet in a work of this kind it may be expected that we ſhould not paſs them over wholly unnoticed.

Some have imagined, and perhaps juſtly, that cold water alone is not an adequate menſtruum for extracting the reſinous qualities of bark, however aſſiſted by the mucilage of the bark and of the ſkin; a decoction, inſtead of ſimple infuſion, has therefore been recommended as a more effectual mode of obtaining thoſe properties.

The late Dr Macbride of Dublin having been concerned in a leather manufactory, publiſhed in 1778 a new method of tanning. His projected improvements may be briefly claſſed under two heads: the one recommending the uſe of *vitriolic* inſtead of *vegetable* acid, brewed from rye or barley: the other ſubſtituting *lime-water*, for the purpoſe of extracting the virtues of the bark inſtead of the *water* commonly uſed by tanners. With reſpect to the firſt, it is generally acknowledged that the vitriolic acid is very proper for raiſing or diſtending the pores of the hides intended for butts, as its operation is not only more ſimple and certain than the acid formerly uſed, but as it tends more effectually to render the texture of the leather firm and durable: it is therefore ſtill preferred by the moſt ſkilful tanners. As to lime-water inſtead of water, it has been found inefficacious; and if the utmoſt care and attention be not obſerved, the leather is liable to ſuffer much injury. Even the ſhortening of the time and leſſening of the expence (which were its chief recommendations) being very problematical, it is now almoſt generally exploded.

A very ingenious chemiſt has obſerved, that it is neceſſary, on account of a chemical combination between the aſtringent principle and the animal ſubſtance in the proceſs of tanning, that free acceſs ſhould be given to the pure air; and therefore ſuppoſes that the proceſs could not be conducted properly in cloſe veſſels*.

The methods of tanning in different provinces of France are ſo various, ſo complicated, and ſo contrary to the acknowledged principles of the manufacture, that it would be an endleſs and uſeleſs taſk to endeavour to detail them: we ſhall therefore content ourſelves with a general reference to M. de la Lande's elaborate Treatiſe on this ſubject.

It has been ſaid, that every part of the oak tree contains a great portion of aſtringent, gummy-reſinous matter, and will therefore tan leather as effectually as the bark itſelf. This opinion, which was firſt publiſhed in 1674 by the Honourable Charles Howard (Phil. Tranſ. vol. ix.), has ſince been countenanced by the celebrated Buffon; who adds, that

* Phil. Tranſ. vol. lxviii. Bartholet.

Tanning.

the bark of birch will anſwer the purpoſe of tanning even ſole leather, which, it is well known, requires the ſtrongeſt and moſt penetrating materials †.

† Mem. Acad. Sc. Paris, 1786.

A long memoir, written by M. Gleditſch, recommends the leaves, branches, fruit, and flowers, of a vaſt number of plants as ſubſtitutes for oak bark. Heath dried and pulveriſed, gall nuts, and the bark of birch, are ſaid by M. Geſner to be uſed in different provinces of Germany. Abbé Nollet informs us, that the leaves of myrrh are uſed by the tanners in Naples. In Corſica they make uſe of the leaves of wild laurel dried in the ſun and beaten into powder, and in the iſland of St Kilda they tan with the tormentil root. In ſome parts of Italy leather is tanned with myrtle leaves. In Ruſſia, is is ſaid, that leather is tanned with the bark of willow: and it may here be obſerved, that a late writer has recommended the extract of bark to be made in America, in order to leſſen the expence of freight, &c. in conveying the bark itſelf to Europe.

In the year 1765, the Society of Arts, &c. granted a premium of L. 100 for the diſcovery of a method of tanning with oak ſaw-duſt; which method has been adopted in Germany: and the Reverend Mr Swaine has lately revived the exploded ſubſtitute (mentioned by Gleditſch and others) of oak leaves.

The following propoſal was communicated to the Bath Society for extracting the eſſence of oak bark:

Suppoſe (ſays the author) the operator has at hand a common family brew-houſe, with its neceſſary utenſils; let him procure a ton of good oak bark ground as uſual for the pit; and having placed a ſtrainer to the maſh-tub, fill it two-thirds with the bark; heat as much water, nearly boiling, as will ſufficiently moiſten it, and maſh it well together. After it has ſtood about two hours, draw it off clear, and put it into a caſk by itſelf. Make a ſecond extract with a ſmaller quantity of boiling water than before, ſo as to draw off a quantity nearly equal to the firſt, and put that alſo into the ſame caſk with the former.

Theſe two extracts will probably contain in them as much of the virtues of the bark as the quantity of liquid will abſorb.

A third extract, rather more in quantity than the other two, may be made from the ſame bark, and as ſoon as drawn off, ſhould be returned into the copper again when empty, and employed for the firſt and ſecond maſh of a quantity of freſh bark, as the three extracts may be ſuppoſed to have carried off the virtues of the firſt. Then proceed as before till all the bark is ſteeped, and a ſtrong liquid extract is drawn from it. The bark, when taken out of the copper, may be ſpread in the ſun to dry, and ſerve as fuel in the ſucceeding operations.

The next proceſs is, to evaporate the watery particles from the extract by a gentle heat, till it comes to the conſiſtence of treacle. This may be done either by the air and heat of the ſun, or by the ſtill or iron pan over the fire.

Anthony Day, Eſq; of London, obtained a patent, dated 17th July 1790, for a new method of tanning, "with half the bark in half the uſual time." This plan chiefly conſiſts in concentrating the bark into a ſtrong extract, and in ſome mechanical improvements in the conſtruction of the tan-yard. But neither the one nor the other have yet been adopted.

The 12th May 1795, a patent was granted to Mr Tucker of Wickham, Hants. He propoſes that the vat, made of wood, be incloſed in a metallic coating or copper pit, completely ſoldered, to prevent the eſcape of any of the fluid. This is to be ſurrounded with a caſe of brick-work, leaving an interſtice of a few inches; and a fire is to be made in a grate near the bottom of the pit, to keep the ooze moderately warm, and thus to ſhorten the proceſs. But the great expence of theſe triple pits and of the fuel, it is to be feared, will counterbalance any advantages which might otherwiſe be derived from this invention. Tanning, Tantalus.

Monſieur Seguin of Paris has lately ſubmitted to the French Convention a new method of tanning, which is ſaid to poſſeſs wonderful advantages. He has certainly exploded the ignorant and abſurd ſyſtems of the French tanners, which we have above hinted at, and has ſhown much ingenuity and chemical knowledge in the proſecution of his diſcoveries; but his leading principles ſeem, in fact, to be nearly ſimilar to thoſe which have been long known and practiſed in England.

An ingenious manufacturer in London has, by the application of warm air, conveyed by means of flues from ſtoves properly conſtructed, and by other contrivances not generally known, conſiderably abridged the uſual proceſs of tanning. Some experiments have likewiſe been lately made with the bark of aſh and of horſe-cheſnut.

A ſubſtitute for oak bark, the price of which has lately been enormous, is the grand *deſideratum* in the manufacture of leather. Moſt of thoſe above enumerated have hitherto been found ineffectual; but a patent, bearing date 16th January 1794, has been granted to Mr Aſhton of Sheffield, Yorkſhire, for his diſcovery of a cheap and expeditious method of tanning leather. This method chiefly conſiſts in applying a preparation of mineral ſubſtances inſtead of oak bark. Thoſe which, on account of their cheapneſs, are moſt to be preferred, are the droſs of coal-pits, called *ſulphur-ſtone* or *pyrites*, and the yellow ferruginous earth or red ochre; and, in general, all aſtringent, ſulphureous, or vitriolated ſubſtances.

If this diſcovery, which is yet in its infancy, ſhould prove ſucceſsful, it may cauſe a material alteration in the proceſs of this manufacture; and by reducing the expence may ultimately be of great advantage to the public. Many other experiments are now making in England for the improvement of tanning; and as there are many perſons of ingenuity and knowledge engaged in the leather manufacture, much may be expected from their induſtry and ſkill.

6

Acts of Parliament &c. reſpecting leather.

As the acts of parliament reſpecting leather, &c. are very numerous, and many of them almoſt obſolete, we ſhall refer our readers to Burn's Juſtice, or to the Statutes at Large. We cannot, however, help remarking, that the act of 1 James I. cap. 22. which preſcribes the mode and manner in which leather ſhall be tanned, the materials to be uſed, and the time to be employed, is ſo palpably abſurd and oppreſſive, that it ought to be immediately repealed.

The revenue ariſing from the duty on leather tanned in Great Britain (excluſive of oiled leather) is upwards of L. 200,000 *per annum*.

TANTALUS, in fabulous hiſtory, king of Phrygia and Paphlagonia, was the ſon of Jupiter and the nymph Plota. He one day entertained the gods at his table; when, to prove their divinity, he ſerved up his ſon Pelops cut in pieces. All the deities, except Ceres, perceived his cruelty and impiety, and would not touch his proviſions. That goddeſs, whoſe thoughts were ſolely employed about her daughter Proſerpine, inadvertently eat a part of his left ſhoulder. Pelops, however, was reſtored to life; and an ivory ſhoulder given him in the room of that which had been eaten; while Tantalus was thrown into Tartarus, where he was puniſhed with perpetual hunger and thirſt. He was chained in a lake; the water of which reached up to his chin, but retired when he attempted to drink. The branch of a tree loaded with fruit hung down even to his lips, but on his attempting to pluck the fruit the branch ſprung upwards.

Tantalus ‖ Taormina.

TANTALUS, in ornithology, a genus of birds belonging to the order of grallæ. The bill is long, ſubulated, and ſomewhat crooked; the face naked; the tongue ſhort; and the feet have four toes palmated on the under part. There are, according to Dr Latham, 23 ſpecies; of which the moſt remarkable is the *ibis*, the bird ſo much valued by the ancient Egyptians.

The ibis was formerly held in great veneration in Egypt, on account of its utility in freeing the country from ſerpents. Serpents muſt therefore have been numerous, or they could not have been very offenſive; and the ibis muſt have been numerous, or they could not have been uſeful. Yet we are aſſured by Mr Bruce, that the ibis is at preſent unknown in Egypt, and ſerpents are no nuiſance; and he thinks it impoſſible that a country, covered with water for five months of the year as Egypt is, could ever have abounded with ſerpents. He endeavours, however, to reconcile the accounts of ancient hiſtorians with the ſtate of Egypt.

In former times, when Egypt was in its flouriſhing ſtate, the inhabited country extended much farther than it does at preſent; reaching even a conſiderable way into the ſandy deſert of Libya, where ſerpents have their abode. Theſe parts were ſupplied with water by immenſe lakes, dug by the magnificent princes of thoſe times, and filled by the annual inundation of the Nile. Theſe frontier diſtricts would naturally be infeſted with vipers from the Libyan deſert, and the vaſt lakes would as naturally be ſupplied by numbers of water-fowl, of which the ibis is a ſpecies. This bird being likewiſe an enemy to ſerpents, the inhabitants would ſoon become acquainted with his uſe, and their ſuperſtition would ſoon reward him. In after ages, however, when the ancient improvements were loſt, and thoſe vaſt lakes dried up which brought the ibis thither, the ſerpents ceaſed to give any offence, becauſe there were none of the human ſpecies there whom they could annoy; and in conſequence of the want of water, the birds ceaſed to annoy them, retiring to their native place Ethiopia, where they continue to frequent the great ſtagnant pools which are common in that country.

Mr Bruce found a bird in Abyſſinia, which, after comparing it with the deſcription of the ancient writers, and the embalmed ibis of Egypt, he concludes is the ſame with the Egyptian ibis. It is called *abou Hannes*, ſignifying "father John," from its appearing annually on St John's day.

This bird is minutely deſcribed by Mr Bruce. It has a beak ſhaped like that of a curlew, two-thirds ſtraight, and the remaining third crooked; the upper part of a green horny ſubſtance, and the lower part black. It meaſures four inches and an half from the occiput to the place where it joins the beak. The leg, from the lower joint of the thigh to the foot, is ſix inches; the bone round and very ſtrong; and from the lower joint of the thigh to where it joins the body, is five inches and a half. The height of the body from the ſole to the middle of the back is 19 inches; the aperture of the eye one inch; the feet and legs black: three toes before armed with ſharp and ſtraight claws; and a toe behind. The head is brown, and the plumage of the ſame colour down to the back, or the place where the neck and back are joined. The throat is white, as well as the back, breaſt, and thighs; the largeſt feathers of the wing are of a deep black for 13 inches from the tail; and ſix inches up the back from the extremity of the tail is black likewiſe.

Tantalus's Cup. See HYDROSTATICS, n° 44.

TANZY, or TANSY, in botany. See TANACETUM.

TAORMINA, a town in Sicily, is ſituated on a rock which riſes to a conſiderable elevation above the level of the ſea, and is ſurrounded by other rocks, the height of which is ſtill more conſiderable. It is 88 miles ſouth of Meſſina, and was founded by a colony from Naxos, which were probably induced to chooſe the ſituation, not ſo much on account of its grandeur, as for the ſecurity which it would afford. It is alſo very wholeſome. The road to Taormina, up the north ſide of the hill on which it ſtands, is very ſteep and difficult of aſcent. Taormina ‖ Taper.

Of the origin of Taormina, as of other cities, almoſt nothing is known. A colony from the iſle of Naxos ſettled at the foot of Etna, at no great diſtance from the ſhore, and about a league or a league and an half from the preſent ſituation of Taormina. Dionyſius the Tyrant attacked this colony, and either took or ſet fire to the city. The inhabitants retired to the rocks of Mount Taurus; among which they found a tract of ground ſufficiently level, and of ſufficient extent, for them to raiſe habitations upon it. It was a ſituation in which they might be ſecure from every attack. Here, therefore, they built a city; which, after the mountain, they named *Tauromenium*. It was at length raiſed to a very flouriſhing ſtate by trade, and became celebrated as a ſeat of the arts. There are ſtill many remains to be ſeen, which ſhow that the fine arts muſt have been once ſucceſsfully cultivated at Tauromenium.

Among other remains of the ancient Tauromenium, ſtill to be ſeen at Taormina, there is a ſpacious theatre. Near the theatre is a tomb, and behind the tomb a large natural grotto. The grotto appears to have been anciently adorned within with artificial ornaments. It was poſſibly conſecrated by the Greeks to ſome rural deity, perhaps to the nymphs, to whom the ancient heathens uſed generally to conſecrate grottos. After the inhabitants of Taormina embraced Chriſtianity, they ſtill continued to viſit this grotto with devout veneration. Inſtead of the Pagan divinities to whom it had before been ſacred, they ſubſtituted a ſaint, the venerable St Leonard, inſtead of the ſportive nymphs. But St Leonard did not long draw crowds to this grotto; and the Chriſtians have either defaced its Pagan decorations, or ſuffered them to fall into decay by the injuries of time. It is now black and ſmoky; and it is with difficulty that any remains of the Greek paintings with which it was once ornamented can be diſtinguiſhed. Perhaps it might be ſacred to Pales rather than the nymphs: She was the protectreſs of flocks; and the circumjacent grounds are, and always have been, excellent for paſture.

There are alſo to be ſeen in the neighbourhood of Taormina a variety of tombs, the remains of a gymnaſium, with a number of other monuments which ſtill preſerve the memory of the ancient Tauromenium.

TAPE-WORM. See TÆNIA.

TAPER, TAPERING, is underſtood of a piece of timber, or the like, when thick at one end, and gradually diminiſhing to the other; as is the caſe in pyramids, cones, &c.

To meaſure Taper-Timber, &c. See *Sliding Rule*.

Taper Bored, is applied to a piece of ordnance when it is wider at the mouth than towards the breech.

TAPER, alſo denotes a kind of tall wax candle, placed in a candleſtick, and burnt at funeral proceſſions, and in other church ſolemnities.

Tapers are made of different ſizes; in ſome places, as Italy, &c. they are cylindrical; but in moſt other countries, as England, France, &c. they are conical or taper; whence poſſibly the name; unleſs we rather chooſe to derive taper, in the adjective ſenſe from the ſubſtantive taper, in the Saxon *tapen* or *tapon*, *cereus*, "wax-candle." Both kinds are pierced at bottom for a pin in the candleſtick to enter.—There are two ways of making tapers, the firſt with the ladle, the ſecond by hand; for which, ſee CANDLE.

Paſchal

Taper, Tapeſtry.

Paſchal TAPER, among the Romaniſts, is a large taper, whereon the deacon applies five bits of frankincenſe, in holes made for the purpoſe, in form of a croſs; and which he lights with new fire in the ceremony of Eaſter-Saturday.

The Pontifical makes Pope Zoſimus the author of this uſage; but Baronius will have it more ancient, and quotes a hymn of Prudentius to prove it. That pope he ſuppoſes to have only eſtabliſhed the uſe thereof in pariſh-churches, which, till then, had been reſtrained to greater churches.

F. Papebroch explains the original of the paſchal taper more diſtinctly, in his *Conatus Chronico-Hiſtoricus*, &c. It ſeems, though the council of Nice regulated the day whereon Eaſter was to be celebrated, it laid it on the patriarch of Alexandria to make a yearly canon thereof, and to ſend it to the pope. As all the other moveable feaſts were to be regulated by that of Eaſter, a catalogue of them was made every year; and this was written on a taper, *cereus*, which was bleſſed in the church with much ſolemnity.

This taper, according to the abbot Chaſtelain, was not a wax-candle made to be burnt; it had no wick, nor was it any thing more than a kind of column of wax, made on purpoſe to write the liſt of moveable feaſts on; and which would ſuffice to hold that liſt for the ſpace of a year.

For among the ancients, when any thing was to be written to laſt for ever, they engraved it on marble or ſteel; when it was to laſt a long while, they wrote it on Egyptian paper; and when it was only to laſt a ſhort time, they contented themſelves to write it on wax. In proceſs of time they came to write the moveable feaſts on paper, but they ſtill faſtened it to the paſchal taper. Such is the original of the benediction of the paſchal taper.

TAPESTRY, a kind of cloth made of wool and ſilk, adorned with figures of different animals, &c. and formerly uſed for lining the walls of rooms, churches, &c.

The art of weaving tapeſtry is ſuppoſed to have been borrowed from the Saracens; accordingly the workmen employed in this manufacture in France were formerly called *Sarazins* or *Sarazinois*. Guicciardini aſcribes the invention of tapeſtry hangings to the inhabitants of the Netherlands; but he has not mentioned at what time the diſcovery was made. This art was brought into England by William Sheldon, near the end of Henry VIII.'s reign. In 1619 a manufacture was eſtabliſhed at Mortlake in Surry by Sir Francis Crane, who received L. 2000 from King James to encourage the deſign. The firſt manufacture of tapeſtry at Paris was ſet up under Henry IV. in 1606 or 1607, by ſeveral artiſts whom that monarch invited from Flanders. Under Louis XIV. the manufacture of the Gobelins was inſtituted, which has introduced very beautiful cloths, remarkable for ſtrength, for elegance of deſign, and a happy choice of colours. The fineſt paintings are copied, and eminent painters have been employed in making deſigns for the work.

Tapeſtry-work is diſtinguiſhed by the workmen into two kinds, viz. that of high and that of low warp; though the difference is rather in the manner of working than in the work itſelf; which is in effect the ſame in both: only the looms, and conſequently the warps, are differently ſituated; thoſe of the low warp being placed flat and parallel to the horizon, and thoſe of the high warp erected perpendicularly. The Engliſh anciently excelled all the world in the tapeſtry of the high warp; and they ſtill retain their former reputation, though with ſome little change: their low warps are ſtill admired; but as for the high ones, they are quite laid aſide by the French. The French, before the Revolution, had three conſiderable tapeſtry manufactures beſides that of the Gobelins; the firſt at Aubuſſon in Auvergne, the ſecond at Felletin in the Upper Marche, and the third at Beauvais. They were all equally eſtabliſhed for the high and the low warp; but they had all laid aſide the high warp excepting the Gobelins. There were admirable low warps likewiſe in Flanders, generally exceeding thoſe of France; the chief and almoſt only Flemiſh manufactures were at Bruſſels, Antwerp, Oudenard, Liſle, Tournay, Bruges, and Valenciennes; but of the ſtate of theſe manufactures now we are ignorant. Tapeſtry.

The uſual widths of tapeſtry are from two ells to three ells Paris meaſure.

The Manufacture of Tapeſtry of the High Warp.—The loom on which it is wrought is placed perpendicularly: it conſiſts of four principal pieces; two long planks or cheeks of wood, and two thick rollers or beams. The planks are ſet upright, and the beams acroſs them, one at the top and the other at the bottom, or about a foot diſtance from the ground. They have each their trunnions, by which they are ſuſpended on the planks, and are turned with bars. In each roller is a groove, from one end to the other, capable of containing a long round piece of wood, faſtened therein with hooks. The uſe of it is to tie the ends of the warp to. The warp, which is a kind of worſted, or twiſted woollen thread, is wound on the upper roller; and the work, as faſt as wove, is wound on the lower. Withinſide the planks, which are ſeven or eight feet high, fourteen or fifteen inches broad, and three or four thick, are holes pierced from top to bottom, in which are put thick pieces of iron, with hooks at one end ſerving to ſuſtain the coat-ſtave: theſe pieces of iron have alſo holes pierced, by putting a pin in which the ſtave is drawn nearer or ſet farther off; and thus the coats or threads are ſtretched or looſened at pleaſure. The coat-ſtave is about three inches diameter, and runs all the length of the loom; on this are fixed the coats or threads, which make the threads of the warp croſs each other. It has much the ſame effect here as the ſpring-ſtave and treddles have in the common looms. The coats are little threads faſtened to each thread of the warp with a kind of ſliding knot, which forms a ſort of maſh or ring. They ſerve to keep the warp open for the paſſage of broaches wound with ſilks, woollens, or other matters uſed in the piece of tapeſtry. In the laſt place, there are a number of little ſticks of different lengths, but all about an inch in diameter, which the workman keeps by him in baſkets, to ſerve to make the threads of the warp croſs each other, by paſſing them acroſs; and, that the threads thus croſſed may retain their proper ſituation, a packthread is run among the threads above the ſtick.

The loom being thus formed, and mounted with its warp, the firſt thing the workman does is to draw on the threads of this warp the principal lines and ſtrokes of the deſign to be repreſented on the piece of tapeſtry; which is done by applying cartoons made from the painting he intends to copy to the ſide that is to be the wrong ſide of the piece, and then, with a black lead pencil, following and tracing out the contours thereof on the thread of the right ſide; ſo that the ſtrokes appear equally both before and behind.

As for the original deſign the work is to be finiſhed by, it is hung up behind the workmen, and wound on a long ſtaff, from which a piece is unrolled from time to time as the work proceeds.

Beſides the loom, &c. here deſcribed, there are three other principal inſtruments required for working the ſilk or the wool of the woof within the threads of the warp; theſe are a broach, a reed, and an iron needle. The broach is made of a hard wood, ſeven or eight inches long, and two-thirds of an inch thick, ending in a point with a little handle. This ſerves as a ſhuttle; the ſilks, woollens, gold, or ſilver, to be uſed in the work being wound on it. The

reed

Tapeſtry. reed or comb is alſo of wood, eight or nine inches long, and an inch thick on the back, whence it grows leſs and leſs to the extremity of the teeth, which are more or leſs apart, according to the greater or leſs degree of fineneſs of the intended work. Laſtly, the needle is made in form of the common needle, only bigger and longer. Its uſe is to preſs cloſe the wool and ſilks when there is any line or colour that does not fit well.

All things being prepared for the work, and the workman ready to begin, he places himſelf on the wrong ſide of the piece, with his back towards the deſign: ſo that he works as it were blindfold, ſeeing nothing of what he does, and being obliged to quit his poſt, and go to the other ſide of the loom whenever he would view and examine the piece, to correct it with his preſſing-needle. To put ſilk, &c. in the warp, he firſt turns and looks at the deſign; then, taking a broach full of the proper colour, he places it among the threads of the warp, which he brings croſs each other with his fingers, by means of the coats or threads faſtened to the ſtaff; this he repeats every time he is to change his colour. Having placed the ſilk or wool, he beats it with his reed or comb; and when he has thus wrought in ſeveral rows over each other, he goes to ſee the effects they have, in order to reform the contours with his needle, if there be occaſion. As the work advances, it is rolled upon the lower beam, and they unroll as much warp from the upper beam as ſuffices them to continue the piece: the like they do of the deſign behind them. When the pieces are wide, ſeveral workmen may be employed at once.

We have but two things to add: the firſt is, that the high warp tapeſtry goes on much more ſlowly than the low warp, and takes up almoſt twice the time and trouble. The ſecond is, that all the difference that the eye can perceive between the two kinds, conſiſts in this, that in the low warp there is a red fillet, about one-twelfth of an inch broad, running on each ſide from top to bottom, which is wanting in the high warp.

Manufacture of Tapeſtry of the Low Warp.—The loom or frame, whereon the low warp is wrought, is much like that of the weavers; the principal parts thereof are two ſtrong pieces of wood forming the ſides of the loom, and bearing a beam or roller at each end: they are ſuſtained at bottom with other ſtrong pieces of wood in manner of treſtes; and, to keep them the firmer, they are likewiſe faſtened to the floor with a kind of buttreſſes, which prevent any ſhaking, though there are ſometimes four or five workmen leaning on the fore-beam at once.

The rollers have each their trunnions, by which they are ſuſtained: they are turned by large iron pins three feet long. Along each beam runs a groove, wherein is placed the wich, a piece of wood of about two inches diameter, and almoſt of the length of the roller: this piece fills the groove entirely, and is faſtened therein, from ſpace to ſpace, by wooden pins. To the two wiches are faſtened the two extremities of the warp, which is wound on the farther roller, and the work, as it advances, on the nearer.

Acroſs the two ſides, almoſt in the middle of the loom, paſſes a wooden bar, which ſuſtains little pieces of wood, not unlike the beam of a balance: to theſe pieces are faſtened ſtrings, which bear certain ſpring-ſtaves, wherewith the workman, by means of two treddles under the loom whereon he ſets his feet, gives a motion to the coats, and makes the threads of the warp riſe and fall alternately. Each loom has more or fewer of theſe ſpring-ſtaves, and each ſtaff more or fewer coats, as the tapeſtry conſiſts of more or fewer threads.

The deſign or painting the tapeſtry man is to follow is placed underneath the warp; where it is ſuſtained from ſpace to ſpace with ſtrings, by means of which the deſign is brought nearer the warp. Tapeſtry ‖ Tar.

The loom being mounted, there are two inſtruments uſed in working it, viz. the reed and the flute. The flute does the office of the weaver's ſhuttle; it is made of an hard poliſhed wood, three or four lines thick at the ends, and ſomewhat more in the middle, and three or four inches long. On it are wound the ſilks or other matters to be uſed as the woof of the tapeſtry. The comb or reed is of wood or ivory; it has uſually teeth on both ſides; it is about an inch thick in the middle, but diminiſhes each way to the extremity of the teeth: it ſerves to beat the threads of the woof cloſe to each other, as faſt as the workman has paſſed and placed them with his flute among the threads of the warp.

The workman is ſeated on a bench before the loom, with his breaſt againſt the beam, only a cuſhion or pillow between them; and, in this poſture, ſeparating, with his fingers, the threads of the warp, that he may ſee the deſign underneath, and taking a flute, mounted with a proper colour, he paſſes it among the threads, after having raiſed or lowered them, by means of the treddles moving the ſpring-ſtaves and coats.

Laſtly, To preſs and cloſe the threads of the ſilk or yarn, &c. thus placed, he ſtrikes each courſe (*i. e.* what the flute leaves in its paſſing and coming back again) with the reed.

TAPIOCA, a ſpecies of ſtarch, which the Brazileans make from the roots of the caſſada plant, which is already deſcribed under its botanic name JATROPHA.

TAPIR, in zoology, a quadruped of the order of *belluæ*, reſembling the hippopotamus, has the fore-hoofs divided into four, and the hind-hoofs into three parts. The noſe of the male extends far beyond the lower jaw, is ſlender, and forms a ſort of proboſcis; it is capable of being contracted or extended at pleaſure, and its ſides are ſulcated. The extremities of both jaws end in a point, and there are ten cutting teeth in each. Between them and the grinders there is a vacant ſpace; and there are ten grinders in each jaw. The ears are erect, the eyes ſmall, and the body is ſhaped like that of a hog. The back is arched; the legs are ſhort; and the hoofs ſmall, black, and hollow. The tail is very ſmall. The animal grows to the ſize of a heifer half a year old. The hair is ſhort: when young, it is ſpotted with white; when old, of a duſky colour.—It inhabits the woods and rivers of the eaſtern ſide of South America, from the Iſthmus of Darien to the river of Amazon. It ſleeps during day in the darkeſt and thickeſt foreſt adjacent to the banks, and goes out in the night-time in ſearch of food. It lives on graſs, ſugar-canes, and on fruits. If diſturbed, it takes to the water; ſwims very well; or ſinks below, and, like the hippopotamus, walks on the bottom as on dry ground. It makes a ſort of hiſſing noiſe.—This is the largeſt of the American animals.

TAPPING, in general, the act of piercing a hole in a veſſel, and applying a tube or canula in the aperture, for the commodious drawing off the liquor contained therein.

TAPPING, in ſurgery. See SURGERY.

TAPROBANE, the ancient name of the iſland of Ceylon. See CEYLON.

TAR, a thick, black, unctuous ſubſtance obtained chiefly from old pines and fir-trees by burning them with a cloſe ſmothering heat. It is prepared in great quantities in Norway, Sweden, Germany, Ruſſia, and North America, and in other countries where the pine and fir abound. For the method of obtaining it, ſee the article PINUS, in Vol. XIV. page 765.

Becher, the celebrated chemiſt, firſt propoſed to make tar from pit-coal. Manufactures for this purpoſe have been eſtabliſhed many years ago in the biſhopric of Liege, and in

Taranto ‖ Targionia.

in ſeveral parts of England. In the year 1781, the earl of Dundonald obtained a patent for extracting tar from pit-coal by a new proceſs of diſtillation (ſee COAL, page 89.); Great hopes were entertained of the value of this diſcovery, but we have not heard that it has anſwered expectation.

Tar, which is well known for its economical uſes, is properly an empyreumatic oil of turpentine, and has been much uſed as a medicine both internally and externally (ſee PHARMACY-*Index*). Tar-water, or water impregnated with the more ſoluble parts of tar, was formerly a popular remedy. See PHARMACY, n° 405.

TARANTO, the ancient TARENTUM, a ſea port town of Italy, in the kingdom of Naples, and in the Terra de Otranto. It is a ſtrong and populous place, with an archbiſhop's ſee, and the title of a principality. It is ſeated on a peninſula, and is defended by a ſtrong caſtle; but the harbour is choaked up. E. Long. 17. 29. N. Lat. 40. 35.

TARANTULA, a ſpecies of Aranea, ſo called from Taranto, the place where they are ſaid to abound. See ARANEA, ſpecies 13.

TARASCON, an ancient, populous, and handſome town of France, in the department of the Mouths of the Rhone, and late province of Provence, with a well-built caſtle, ſeated on the river Rhone, oppoſite Beaucaire, with which it communicates by a bridge of boats. Its commerce conſiſts in oil, brandy, ſtarch, and ſtuffs that are much worn, one ſort being of coarſe ſilk, and the other of the ſame material and wool. It is 10 miles north of Arles, and 375 ſouth by eaſt of Paris. E. Long. 4. 45. N. Lat. 43. 46.

TARAZONA, a ſtrong town of Spain, in the kingdom of Arragon, and on the frontiers of Old Caſtile, with a biſhop's ſee. It is ſeated partly on a rock, and partly in a fertile plain, on the river Chiles. It was taken from the Moors in 1110. W. Long. 1. 26. N. Lat. 42. 10.

TARCHONANTHUS, FLEA-BANE, in botany: A genus of plants belonging to the claſs of *ſyngeneſia*, and to the order of *polygymia æqualis*; and in the natural ſyſtem ranging under the 49th order, *Compoſitæ*. The receptacle is villous, and the pappus plumy: the calyx is monophyllous, turbinated, and half divided into ſeven ſegments. There are only three ſpecies known; the *camphoratus*, *glaber*, and *ericoides*.

TARE, is an allowance for the outſide package that contains ſuch goods as cannot be unpacked without detriment; or for the papers, threads, bands, &c. that incloſe or bind any goods imported looſe; or though imported in caſks, cheſts, &c. yet cannot be unpacked and weighed neat.

TARE, or VETCH. See VICIA.

TARGET, a kind of ſhield or weapon of defence made uſe of by the ancients.

TARGIONIA, in botany; a genus of plants belonging to the claſs of *cryptogamia*, and natural order of *algæ*. The calyx is bivalved, including a globular body. There is only one ſpecies; the *hypophylla*, which it a native of Great Britain. The hypophylla, or vetch targionia, has leaves about a quarter of an inch long, of a heart-ſhape, inverted, and growing proſtrate in a clump together: their upper ſurface is green, covered with whitiſh papillæ, and their lower ſurface is black. The fructification grows at the great end of the leaf on the lower ſide, and conſiſts of two concave valves or hemiſpheres, of a reddiſh black colour, incloſing a chocolate-coloured globule, reſembling the ſeed of a tare or vetch, full of a yellow powder. The leaves increaſe by ſhooting out young offſets from their ſides like the polypus. This plant is found in the north of England, and near the Tarbet of Cantire in Scotland.

TARGUM, a name given to the Chaldee paraphraſes of the books of the Old Teſtament. They are called *paraphraſes* or *expoſitions*, becauſe they are rather comments and explications than literal tranſlations of the text. They are written in the Chaldee tongue, which became familiar to the Jews after the time of their captivity in Babylon, and was more known to them than the Hebrew itſelf. So that when the Hebrew text was read in the ſynagogue, or in the temple, they generally added to it an explication in the Chaldee tongue for the ſervice of the people, who had but a very imperfect knowledge of the Hebrew tongue. It is probable, that even from the time of Ezra this cuſtom began, ſince this learned ſcribe, reading the law to the people in the temple, explained it, with the other prieſts that were with him, to make it underſtood by the people (Nehem. viii. 7—9.). Targum

But though the cuſtom of making theſe ſorts of expoſitions in the Chaldee language be very ancient among the Hebrews, yet have they no written paraphraſes or targums before the era of Onkelos and Jonathan, who lived about the time of our Saviour. Jonathan is placed about 30 years before Chriſt, under the reign of Herod the Great. Onkelos is ſomething more modern. The targum of Onkelos is the moſt of all eſteemed, and copies are to be found in which it is inſerted verſe for verſe with the Hebrew. It is ſo ſhort and ſo ſimple, that it cannot be ſuſpected of being corrupted. This paraphraſt wrote only upon the books of Moſes; and his ſtyle approaches nearly to the purity of the Chaldee, as it is found in Daniel and Ezra. This targum is quoted in the Miſna, but was not known either to Euſebius, St Jerome, or Origen.

The targum of Jonathan ſon of Uziel is upon the greater and leſſer prophets. He is much more diffuſe than Onkelos, and eſpecially upon the leſſer prophets, were he takes great liberties, and runs on in allegories. His ſtyle is pure enough, and approaches pretty near to the Chaldee of Onkelos. It is thought that the Jewiſh doctors who lived about 700 years after him made ſome additions to him.

The targum of Joſeph the Blind is upon the Hagiographa. This author is much more modern, and leſs eſteemed than thoſe we have now mentioned. He has written upon the Pſalms, Job, the Proverbs, the Canticles, Eccleſiaſtes, Ruth, and Eſther. His ſtyle is a very corrupt Chaldee, with a great mixture of words from foreign languages.

The targum of Jeruſalem is only upon the Pentateuch; nor is that entire or perfect. There are whole verſes wanting, others tranſpoſed, others mutilated; which has made many of opinion that this is only a fragment of ſome ancient paraphraſe that is now loſt. There is no targum upon Daniel, or upon the books of Ezra and Nehemiah.

Theſe targums are of great uſe for the better underſtanding not only of the Old Teſtament, on which they are written, but alſo of the New. As to the Old Teſtament, they ſerve to vindicate the genuineneſs of the preſent Hebrew text, by proving it to be the ſame that was in uſe when theſe targums were made, contrary to the opinion of thoſe who think the Jews corrupted it after our Saviour's time. They help to explain many words and phraſes in the Hebrew original, and they hand down to us many of the ancient cuſtoms of the Jews. And ſome of them, with the phraſeologies, idioms, and peculiar forms of ſpeech, which we find in them, do in many inſtances help as much for the better illuſtration and better underſtanding of the New Teſtament as of the Old; the Jeruſalem Chaldee dialect, in which they are written, being the vulgar language of the Jews in our Saviour's time. They alſo very much ſerve the Chriſtian cauſe againſt the Jews, by interpreting many of the prophecies of the Meſſiah in the Old Teſtament in the ſame

manner

Tarif ‖ Tartary.

manner as the Chriſtians do. Many inſtances are produced to this purpoſe by Dr Prideaux in his *Connect. of the Hiſt. of the Old and New Teſt.* vol. iv. p. 777, &c.

Theſe targums are publiſhed to the beſt advantage in the ſecond edition of the great Hebrew Bible ſet forth at Baſil by Buxtorf the father, *anno* 1610; for he has rectified the Chaldee text, and reformed the vowel pointings in it: the targums having at firſt been written without vowel points, which were afterwards added very erroneouſly by ſome Jews.

TARIF, a table or catalogue containing the names of different ſorts of merchandize, with the duties to be paid as ſettled by authority amongſt trading nations.

TARPA (Spurius Mecius), a Latin critic in the time of Julius Cæſar and Auguſtus. He had his tribunal in the temple of Apollo, where, with four aſſiſtants, he paſſed ſentence on the works of the poets. Cicero and Horace make honourable mention of this critic.

TARPAULIN, a piece of canvaſs, well tarred over, to keep off the rain from any place. The term is alſo often applied in a burleſque ſenſe to a perſon that has been all his life bred to the ſea.

TARPEIAN, in Roman antiquity, an appellation given to a ſteep rock in Rome; whence, by the law of the twelve tables, thoſe guilty of certain crimes were precipitated. It took its name from Tarpeia, a veſtal virgin, who was killed by the Sabines, as related under the article ROME, n° 24.

TARQUIN *the* ELDER, king of Rome, ſucceeded Ancus Martius 615 B.C. See ROME, n° 35—40.

TARQUIN the Proud, a tyrant and uſurper. See the article ROME, n° 49—51, &c.

TARRAGON, or DRAGON-WORT. See ARTEMISIA.

TARROCK, in ornithology, a ſpecies of LARUS.

TARSHISH, or TARTESSUS, a town frequently mentioned by ancient authors, the ſituation of which it is difficult to aſcertain. See the opinions of Mr Bruce and Dr Droig on this ſubject under the article OPHIR.

TARTAN, in ſea language, a ſmall coaſting veſſel navigated in the Mediterranean ſea, and having only one maſt and a bowſprit, the principal ſail, which is extremely large, being extended by a lateen-yard. When tartans put up a ſquare ſail, it is called a *ſail of fortune*.

TARTAR, a hard ſolid ſubſtance which ſeparates from wine after complete fermentation, and adheres to the top and ſides of the caſks. See the *Index* to CHEMISTRY and PHARMACY.

TARTARY, a very large country of Aſia, ſituated between 57° and 160° of E. Long. reckoning from the weſt end of the iſle of Ferro, and between 37° and 55° of Lat. It is bounded on the north by Siberia, or that part of Aſia which belongs to Ruſſia; on the weſt by the rivers Don, Wolga, and Kama, which ſeparate it from Ruſſia; on the ſouth by the Euxine and Caſpian Seas, Karaſm, the two Bukharias, China, and Korea; and on the eaſt, by the Oriental or Tartarian ocean. It extends from eaſt to weſt the ſpace of 104 degrees in longitude, or 4145 geographical miles; but its breadth is not proportionable, being not above 960 miles where broadeſt, and where narroweſt 330.

This vaſt region is divided into two great parts; the one called the *Weſtern*, the other the *Eaſtern Tartary*.

Weſtern Tartary, which is much more extenſive than the Eaſtern, containing 139 degrees of longitude out of 161, is inhabited by a great number of nations, or tribes of people, who are called *Mungls* or *Mungals*, by themſelves; and *Moguls* or *Tartars*, indifferently, by other nations.

The principal mountains, or rather chains of mountains, found in this part of Great Tartary, may be divided into three claſſes: firſt, thoſe which run along the northern borders of it; and though perhaps not always contiguous, or of the ſame denomination, go under the general name of *Ulug Tâg*, or *Dag*, that is, the *Great Mountain*. Secondly, thoſe which make the ſouthern bounds, and are called *Kichug Tâg*, or the *Leſſer Mountain*. The third great chain is called *Mount Altay*, lying nearly in the middle, between the Caſpian Sea and Eaſtern Tartary, and extending between the other two, in about the 110th degree of longitude. Tartary.

The principal rivers of Weſtern Tartary, beſides the Dnieper, Don, and Wolga, are the Jaik or Yaik, and Yem, both deſcending from the Ulug Tag, and falling into the Caſpian Sea on the north ſide: the river Ili or Khonghis, which riſes out of the Kichug Tag, on the borders of Little Bukharia, and runs north-weſt into the lake Palkaſi, which is about forty miles long, and 30 broad, in latitude 48°, longitude 97°, reckoning from the iſle of Ferro: on this river the khan of the Eluths or Kalmucks uſually reſides; the river Irtiſh, Irtis, or Erchis, which riſes in Mount Altay, and runs weſtward, inclining to the north, between two branches of it, into the lake Sayſan, Saſſan, or Iſan, called alſo *Honhotu-Nor*, 90 miles long from weſt to eaſt, and 40 broad, in latitude 47° 30′, longitude 104°; from whence iſſuing again, it paſſes north-weſt, through part of Siberia, and falls into the Oby, which has its ſource in the ſame mountain, about one degree to the north of that of the Irtiſh; and ſeven or eight degrees to the north-eaſt riſes the Kem or Jeniſea, which runs weſtward for the ſpace of ſeven or eight degrees, and then turning northward enters Siberia. The next river of note is the Selinga, which riſes out of the lake Kofogol, Hutuktu or Khutuktu, which is 70 miles long from ſouth to north, and 20 broad, in latitude 52°, longitude 118°, not far from the ſource of the Jeniſea, and taking a ſweep ſouthward, round by the eaſt, falls northward into the lake Baykal in Siberia, about 30 leagues north-weſt of the city Selinghinſkoy, which ſtands upon it. Into the Selinga runs the Orkon, coming from the ſouth-weſt; and into the Orkon the Tula, riſing eaſtward in Mount Kentey. On the ſame mountain riſes alſo two other rivers, *viz.* the Onon, called alſo by the Tartars *Saghalian Ula*, or the Dragon river, and by the Ruſſians *Amur*; which running north-eaſtward, and then taking a large ſweep by the ſouth, rolls along the bounds of Eaſtern Tartary, and falls into the Eaſtern Ocean. On its banks ſtand two cities; Nerchinſkoy or Nipchew, a frontier of the Ruſſians, almoſt due north of Pekin in China; and Saghalian Ula, poſſeſſed by the Chineſe. Another large river is the Kerlon or Kerulon, which running north-eaſtward, falls into the lake Kulon or Dalay, which is 60 miles long from ſouth-weſt to north-eaſt, and 27 broad, in latitude 48° 30′, longitude 135°, and iſſuing out again under the name of *Ergona* or *Argun*, joins the Saghalian Ula, about 170 miles beyond Nerchinſkoy. To theſe let us add the river Kalka, from whence, though ſmall, the Kalka-Moguls or Mongols take their name. It riſes in the mountains, ſeparating Eaſtern from Weſtern Tartary, and, running eaſtward, falls into the lake Puir, and then into that of Kulon, before ſpoken of.

In the middle of a deſert, on the banks of the river Irtiſh, is a remarkable piece of antiquity called SEDMY PALATY, or *the ſeven palaces*.

Above the Sedmy Palaty, towards the ſource of the Irtiſh, grows the beſt rhubarb in the world, without the leaſt culture. In the plain of this country alſo, about eight or ten days journey from Tomſky in Siberia, are found many

Tartary. tombs and burying-places of ancient heroes, who in all probability fell in battle. Theſe tombs are eaſily diſtinguiſhed by the mounds of earth and ſtone raiſed over them. The Tartars ſay, Tamerlane had many engagements in this country with the Kalmucks, whom he in vain endeavoured to conquer. Many perſons go from Tomſky, and other parts, every ſummer, to theſe graves, which they dig up, and find among the aſhes of the dead conſiderable quantities of gold, ſilver, braſs, and ſome precious ſtones, but particularly hilts of ſwords and armour. They find alſo ornaments of ſaddles and bridles, and other trappings for horſes; and ſometimes thoſe of elephants. Whence it appears, that when any general or perſon of diſtinction was interred, all his arms, his favourite horſe and ſervant, were buried with him in the ſame grave; this cuſtom privails to this day among the Kalmucks and other Tartars, and ſeems to be of great antiquity. It appears from the number of graves, that many thouſands muſt have fallen in thoſe places; for the people have continued to dig for treaſure many years and ſtill find it unexhauſted. They are, indeed, ſometimes interrupted, and robbed of all their booty, by parties of Kalmucks, who abhor diſturbing the aſhes of the dead. Armed men on horſeback, caſt in braſs of no mean deſign and workmanſhip, with the figures of deer caſt in pure gold, have been dug out of theſe tombs. They once diſcovered an arched vault, where they found the remains of a man, with his bow, lance, and other arms, laying on a ſilver table. On touching the body, it fell to duſt. The value of the table and arms was very conſiderable. For the manners and cuſtoms of theſe Tartars, ſee KALMUCKS.

Great quantities of a kind of ivory, called by the natives *Mammons-horn*, are found in this country and in Siberia, on the banks of the Oby. They are commonly found on the banks of rivers that have been waſhed by floods. Some of them are very entire and freſh, like the beſt ivory in all reſpects, excepting only the colour which is of a yellowiſh hue. In Siberia they make ſnuff-boxes, combs, and divers ſorts of turnery ware of them. Some have been found weighing above 100 pounds Engliſh.

The moſt conſiderable tribes in Weſtern Tartary, next to the Kalmucks, are the Kalkas and Mungls, or Mongals, properly ſo called. The country of the Kalkas extends eaſtward, from mount Altay to the ſource of the river Kalka, whence they derive their name, in the borders of Eaſtern Tartary and 139th degree of longitude. The territories of the Mungls or Mongalia, lie to the ſouth of thoſe of the Kalkas, between them and the great will of China, to which empire both nations are ſubject. Beſides theſe tribes, who are idolaters of the religion of the Delay Lama, there are others, who poſſeſs that part of Weſtern Tartary called *Turkeſtan*, the original country of the Turks and Turkmans, ſituated to the north of Great Bukharia and Karaſm, between thoſe countries and the dominions of the Eluths. Under Weſtern Tartary alſo is comprehended Tibet, Thibet, or Tobbut, ſubject to the Delay Lama, or great high-prieſt of the Pagan Tartars and Chineſe.

In all the vaſt region of Weſtern Tartary, there are but few towns, moſt of the inhabitants living under tents, eſpecially in ſummer, and moving from place to place with their flocks and herds. They generally encamp near ſome river for the convenience of water.

The air of this country is temperate, wholeſome, and pleaſant, being equally removed from the extremes of heat and cold. As to the ſoil though there are many mountains, lakes, and deſerts in it, yet the banks of the rivers, and the plains, ſome of which are of great extent, are exceeding fertile. The mountains, woods, and deſerts, abound with veniſon, game, and wild fowl; and the rivers and lakes both with fiſh and fowl. In particular, here are wild mules, horſes, and dromedaries, wild boars, ſeveral kinds of deer, a ſpecies of goats with yellow hair, ſquirrels, foxes; an animal called *hautehan*, reſembling an elk; another called *chulon* or *cheliſon*, that ſeems to be a ſort of lynx; and a creature called *tael-pe*, as ſmall as an ermine, of whoſe ſkins the Chineſe make mantles to keep out the cold. Among other birds of extraordinary beauty, bred in this country, there is one called the *ſhonkar*, which is all over white except the beak, wings, and tail, which are of a very fine red. Notwithſtanding the ſoil in many parts of Tartary is ſo luxuriant, yet we are told it does not produce a ſingle wood of tall trees of any kind whatever, excepting in ſome few places towards the frontiers; all the wood that is found in the heart of the country conſiſting of ſhrubs, which never exceed the height of a pike, and even theſe are rare. Tartary.

It is remarkable, that in all the vaſt dominions of Mongalia, there is not ſo much as a ſingle houſe to be ſeen. All the people, even the prince and high-prieſt, live conſtantly in tents, and remove their cattle from place to place as conveniency requires. Theſe people do not trouble themſelves with ploughing or digging the ground in any faſhion, but are content with the produce of their flocks, though the ſoil is exceedingly fine, and capable, by proper culture, of producing grain of ſeveral ſorts.

In the country of the Mongals the graſs is very thick and rank, and would with little labour make excellent hay. This graſs is often ſet on fire by the Mongals in the ſpring during high winds. At ſuch times it burns moſt furiouſly, running like wild-fire, and ſpreading its flames to the diſtance of perhaps 10 or 20 miles, till its progreſs is interrupted by ſome river or barren hill. The rapidity of thoſe flames, their ſmoke, and crackling noiſe, cannot eaſily be conceived by thoſe who have not ſeen them. When any perſon finds himſelf to the leeward of them, the only method by which he can ſave himſelf from their fury, is to kindle immediately the graſs where he ſtands, and follow his own fire. For this purpoſe every perſon is provided with flints, ſteel, and tinder. The reaſon why the Mongals ſet fire to the graſs, is to procure early paſture to their cattle. The aſhes left upon the ground ſink into the earth at the melting of the ſnow, and prove an excellent manure; ſo that the graſs in the ſpring riſes on the lands which have been prepared in this manner as thick as a field of wheat. Caravans, travellers with merchandiſe, but eſpecially armies, never encamp upon this rank graſs; and there are ſeveral inſtances of conſiderable bodies of men being put in confuſion, and even defeated, by the enemy's ſetting fire to the graſs.

Eaſtern Tartary, according to the limits uſually aſſigned it by hiſtorians and geographers, is bounded to the weſt by Weſtern Tartary, or by that part poſſeſſed by the proper Mungls and Kalkas; on the north by Siberia; on the eaſt by that part of the Oriental Ocean called the *Tartarian Sea*; and on the ſouth by the ſame ſea, the kingdom of Korea, and the Yellow Sea, which ſeparates it from China. It is ſituated between the 137th and 160th degrees of longitude, being about 900 miles long from ſouth to north, and near as many in breadth from weſt to eaſt, yet but thinly peopled. This large region is at preſent divided into three great governments, all ſubject to the Chineſe, viz. Shing-yang or Mugden, Kurin-ula, and Tſitſikar.

The government of Shing-yang, containing all the ancient Lyau-tong or Quan-tong, is bounded on the ſouth by the great wall of China and the Yellow Sea; on the eaſt, north, and weſt, it is incloſed by a wooden paliſade, ſeven or eight feet high, fitter to mark its bounds and keep out petty robbers than to oppoſe an army.

The

Tartary. The lands of this province are for the general very fertile, producing abundance of wheat, millet, roots, and cotton. They alſo afford paſture to great numbers of ſheep and oxen, which are rarely ſeen in any of the provinces of China. They have indeed but little rice; yet, to make amends, there is plenty of apples, pears, hazel nuts, filberds, and chefnuts, even in the foreſts. The eaſtern part, which borders on the ancient country of the Manchews and kingdom of Korea, is full of deſerts and bogs. The principal cities of this government are Shing-yang or Mugden, Fong-whang ching, Inden, Ichew, and Kingchew. This country was the original ſeat of the Tartar tribe of the Manchews, who have been maſters of China above 100 years.

The government of Kirin-ula-hotun is bounded weſtward by the paliſade of Lyau-tong; on the eaſt, by the Eaſtern Ocean; ſouthward, by the kingdom of Korea; and on the north by the great river Saghalian; ſo that it extends no fewer than 12 degrees, and almoſt 20 degrees in longitude being 750 miles in length and 600 in breadth.

This vaſt country abounds in millet and oats, with a ſort of grain unknown in Europe, called by the Chineſe *may-ſem-mi*, as being of a middle kind between wheat and rice. It is wholeſome, and much uſed in thoſe cold regions. There is but little wheat or rice here; but whether that is the fault of the ſoil or the inhabitants, we cannot aſſert. The cold begins much ſooner in theſe parts than at Paris, whoſe latitude is near 50 degrees. The foreſts, which are very thick and large the nearer you advance to the Eaſtern Ocean, contribute not a little to bring it on and keep it up. The banks of the rivers here, in ſummer, are enamelled with a variety of flowers common in Europe, excepting the yellow lilies, which are of a moſt lively colour, in height and ſhape exactly reſembling our white lilies, but are of a much weaker ſcent. But the plant which is moſt eſteemed, and draws a great number of herbaliſts into theſe deſerts, is the gin-ſeng*, called by the Manchews *orhota*, that is, the chief or queen of plants. It is highly valued for its virtues in curing ſeveral diſeaſes, and all decays of ſtrength proceeding from exceſſive labour of body or mind. For this reaſon it has always been the principal riches of Eaſtern Tartary; what is found in the north of Korea being conſumed in that kingdom.

* See Panax.

Formerly the Chineſe uſed to get into the gin-ſeng country among the mandarins and ſoldiers continually paſſing; but in 1700 the emperor Kang-hi, that his Manchews might reap this advantage, ordered 10,000 of his ſoldiers, encamped without the great wall, to go and gather it, on condition that each ſhould give him two ounces of the beſt, and take an equal weight of fine ſilver for the remainder: by which means the emperor got in that year 20,000 pounds of it for leſs than one fourth of the price it bears at Pekin. The root is the only part that is uſed medicinally. Its value is enhanced by its age for the largeſt and firmeſt are the beſt. This country abounds alſo in fine ſables, grey ermines, and black foxes.

One of the tribes of Tartars inhabiting this country are called the *Yu-pi Tartars*, whoſe manner of life is ſomewhat extraordinary. All the ſummer they ſpend in fiſhing: one part of what they catch is laid up to make oil for their lamps; another ſerves for their daily food; and the reſt, which they dry in the ſun, without ſalting, for they have no ſalt, is laid up for their winter's proviſions, whereof both men and cattle eat when the rivers are frozen. Notwithſtanding this diet, a great deal of ſtrength and vigour appears in moſt of theſe poor people. Their raiment conſiſts of the ſkins of fiſh, which after dreſſing and dyeing of three or four colours, they ſhape and ſew in ſo delicate a manner, that one would imagine they made uſe of ſilk, till, on ripping a ſtitch or two, you perceive an exceeding fine thong, cut out of a very thin ſkin. When the rivers are frozen, their ſledges are drawn by dogs trained up for the purpoſe, and highly valued. Tartary.

Although the Manchew language is as much uſed at the court of Pekin as the Chineſe, and all public acts are drawn up in the one as well as the other; yet it began to decline, and would probably have been loſt, had not the Tartars taken great pains to preſerve it, by tranſlating Chineſe books, and compiling dictionaries, under the emperor's patronage. Their language is ſingular in this reſpect, that the verb differs as often as the ſubſtantive governed by it; or, which is the ſame thing, to every different ſubſtantive they uſe a different verb; as for inſtance, when they would ſay, *make a verſe, a picture, a ſtatue;* for though the repetition of the ſame verb in diſcourſe might be excuſable, it is with them unpardonable in writing, as making a monſtrous grating to their ears.

Another ſingularity of their language is the copiouſneſs of it; for inſtance, beſides names for each ſpecies of animals, they have words to expreſs their ſeveral ages and qualities. *Judagon* is the general name for a dog; but *tayha* ſignifies a dog who has very long and thick hair both on his ears and tail; and *yolo*, a dog with a long thick muzzle and tail, large ears, and hanging lips. The horſe, as more ſerviceable to them, has 20 times more names than the dog; almoſt every motion of him giving occaſion to a different name. Where they could get that aſtoniſhing multitude of names and terms, is not eaſy to determine.

This country is but thinly peopled, and contains only four cities, namely, Kirinula-hotun or Khotun, Pedne or Petuna, Ninguta, and Putay-ula-hotun, which are very ill-built, and encompaſſed with no better than mud-walls. The firſt ſtands on the river Songari, and is the reſidence of the Manchew general, who has all the privileges of a viceroy, and commands the mandarines as well as the troops. Ninguta, which the family now reigning in China conſiders as its ancient patrimony, is ſituated on the Hurkapira, which runs northward into the Songari. Its name is compounded of two Tartarian words which ſignify ſeven chiefs, to expreſs the riſe of the Manchew kingdom, which was firſt eſtabliſhed by ſeven brothers of the late emperor Kanghi's great-grandfather's father.

The tribe of the Manchews, who inhabit a part of Eaſtern Tartary, and are lords of all the other inhabitants thereof, are called by the Ruſſians *Bogdoy*, and the emperor of China *Bogdoy Khan* and *Amulon Bogdoy Khan*.

The third government into which Eaſtern Tartary is divided, is that of Tſitſikar. It is 740 miles long and 600 broad; and belongs partly to China and partly to Ruſſia. The people are great hunters, dexterous archers, and pay their tribute in ſable-ſkins; each family being aſſeſſed two or three, or more a-year, according to the number of able perſons.

This province is inhabited chiefly by three ſorts of Tartars, the Manchews, the Solons, and Taguri, of whom the firſt are maſters. The Taguri are a large robuſt people, but not very numerous. They live in houſes or huts, and cultivate barley, oats, and millet. Their cattle are principally horſes, dromedaries, oxen, cows, and ſheep. They make much uſe of their oxen to ride on.

The Solons alſo are a brave robuſt people. Their dreſs is a ſhort jacket of wolves ſkins, with a cap of the ſame; and they have long cloaks made of fox or tigers ſkins, to defend them againſt the cold, eſpecially of the night. They hang their bows at their backs. Their women ride on horſeback, drive the plough, hunt ſtags and other game.

Beſides the country towns or villages, there are three ci-

Tartary. ties in the province of Tſitſikar, namely, Tiſitſikar, Merghen, and Saghalian-ula-hotun. The garriſon of Tſitſikar, the capital, conſiſts of Manchews; but the inhabitants are moſtly Chineſe. According to their own account, they are all ſhammams, or conjurors, and invoke the devil with frightful cries. They give their dead two burials, firſt leaving a hole at top of the grave, where the relations daily bring victuals, which they convey to the mouth of the deceaſed with a ſpoon, and leave drink in ſmall tin cups ſtanding round the grave. This ceremony holds for ſeveral weeks, after which they burry the body deeper in the ground.

Several rivers in this country produce pearls, which, though much cried up by the Tartars, would be little valued by Europeans, on account of their defects in ſhape and colour.

The kingdoms or countries of Corea, Lyau-tong, and Nyu-che, forming a part of Katay, Kitay, or Cathay, and by ſome included under Eaſtern Tartary, are more properly provinces of China, though they lie without the great wall.

Uſbeck TARTARY. To the north and north-eaſt of Perſia lie the countries of Karaſm, and great and Little Bukharia, which being moſtly ſubject to and inhabited by the tribe of Uſbeck Tartars, are commonly known by the general name of *Uſbeck Tartary*.

The kingdom of Karaſm was known to the ancient Greeks, as appears from Herodotus, Ptolemy, and other authors of that nation, by the name of *Khoraſmia*. At preſent it is bounded on the north by the country of Turkeſtan, and the dominions of the great khan of the Eluths or Kalmucks; on the eaſt, by Great Bukharia, from which it is ſeparated partly by the mountains of Irdar, and partly by the deſerts of Karak and Gaznah; on the ſouth, by the provinces of Aſterabad and Khoraſſan, belonging to Iran or Perſia at large, from which it is divided by a river Jihun or Amu, and ſundry deſerts of a vaſt extent; and on the weſt by the Caſpian Sea.

It may be about 440 miles in length from ſouth to north, and 300 from weſt to eaſt; being ſituated between the 39th and 46th degrees of north latitude, and the 71ſt and 77th degrees of eaſt longitude. The country conſiſts, for the moſt part, of vaſt ſandy plains, ſome of which are barren deſerts, but others afford excellent paſture. There is good land in ſeveral of the provinces where vines grow, and wine is made; but water being ſcarce, a great part of the country turns to no account.

Karaſm owes all its fertility to three rivers and a lake. The rivers are the Amu, Kheſil, and Sir. The Amu, as it is called by the Uſbecks and Perſians, is the Jihun of the Arabs, and Oxus of the ancient Greeks. It has its ſource in thoſe high mountains which ſeparate Little Bukharia from the dominions of the Great Mogul; and, after paſſing through Great Bukharia and Karaſm, divides into two branches, one of which falls into the Kheſil, and the other into the Caſpian Sea, towards the borders of the province of Aſtarabad. The Amu abounds with all ſorts of excellent fiſh, and its banks are the moſt charming in the world. Along them grow thoſe excellent melons and other fruits ſo much eſteemed in Perſia, the Indies, and Ruſſia.

The river Khefil riſes in the mountains to the north-eaſt of the province of Samarkant, and falls into the lake of Aral or Eagles, 50 or 60 miles below its junction with a branch of the Amu. Its banks are exceeding fertile wherever they are cultivated.

The Sir or Daria riſes in the mountains to the eaſt of Little Bukharia, and after a long courſe weſtward, along the borders of the Bukharias and Karaſm, falls at laſt into the lake Aral.

Karaſm is at preſent inhabited by three ſorts of people, the Sarts, Turkmans, and Uſbeck Tartars. With regard to the firſt of theſe, we are told, that they are the ancient inhabitants of the country, or thoſe who were ſettled there before the Uſbecks became maſters of it; and that they ſupport themſelves like the Turkmans by their cattle and huſbandry. The Turkmans or Turkomans came originally from Turkeſtan or the parts of Tartary to the north of Karaſm and Great Bukharia, towards the 11th century. They divided into two parties; one of which went round the north ſide of the Caſpian Sea, and ſettled in the weſtern parts of the Greater Armenia, from thence called *Turkomania*, or *the country of the Turkomans*. The ſecond party turned ſouth, and reſted about the banks of the river Amu and the ſhores of the Caſpian Sea, where they ſtill poſſeſs a great many towns and villages, in the countries of Karaſm and Aſtarabad. Tartary.

The name of *Uſbecks*, which the ruling tribe of the Tartars of Karaſm and Great Bukharia bear at preſent, is derived from one of their khans. The Uſbecks of Karaſm are divided into ſeveral hords, and live for the moſt part by rapine; reſembling in all reſpects thoſe of Great Bukharia, excepting that they are much more rude and uncivilized. Like the Turkmans, they dwell in winter in the towns and villages which are towards the middle of Karaſm; and in ſummer the greater part of them encamp in the neighbourhood of the Amu, or in other places where they can meet with paſture for their cattle, always watching for ſome convenient opportunity to rob and plunder. They never ceaſe making incurſions upon the adjacent territories of Perſia or Great Bukharia, and are to be reſtrained by no treaties or engagements whatſoever. Although they have fixed habitations, yet, in travelling from one place to another, they carry with them all their effects of value, conformable to the way of living in uſe among their anceſtors before they had ſettled dwellings.

Theſe Tartars, it is ſaid, never ride without their bows, arrows, and ſwords, although it be in hawking or taking any other diverſion. They have no arts or ſciences among them, neither do they till or ſow. They are great devourers of fleſh, which they cut in ſmall pieces, and eat greedily by handfuls, eſpecially horſe fleſh.

Their chief drink is ſour mare's milk, like that in uſe with the Nogays. They eat their victuals upon the ground, ſitting with their legs double under them, which is their poſture alſo when they pray.

All theſe tribes have abundance of camels, horſes, and ſheep, both wild and tame. Their ſheep are extraordinary large, with great tails weighing 60 or 80 pounds. There are many wild horſes in the country, which the Tartars frequently kill with their hawks. Theſe birds are taught to ſeize upon the head or neck of the beaſt; which being tired with toiling to get rid of this cruel enemy, the hunter, who follows his game, comes up and kills him. Some travellers tell us, that the inhabitants of this country have not the uſe of gold, ſilver, or any other coin, but barter their cattle for neceſſaries. Others tell us, that they have money, particularly a piece of ſilver called *tanga*, the value near the fourth part of a crown. It is round, and has on one ſide the name of the country, and on the other that of the khan, with the year of the hegira. There are alſo, it is ſaid ſmall pieces of copper of different ſizes, which anſwer to our pence, halfpence, and farthings.

As to the government of Karaſm, the Uſbecks being maſters, it is commonly veſted in divers princes of that tribe of the ſame houſe; of whom, notwithſtanding, only one has the title of *khan*, with a kind of ſuperiority over the others.

This

Tartary. This khan has no ſort of dependence on him of Great Bukharia, or any other prince.

Bukharia, *Bokharia*, *Bokaria*, *Bogaria*, or *Boharia*, is the name given to all that region or tract of land lying between Karaſm and the Great Kobi, or Sandy Deſert, bordering on China. It is divided into the Great and Little Bukharia. For an account of which, ſee the article BUKHARIA.

The inhabitants of theſe different countries, which are known by the name of *Tartary*, have a tradition among themſelves that they are all ſprung from one common ſtock, and that they are of the moſt remote antiquity. To this tradition much credit is due; for they are known to be the deſcendants of the ancient Scythians. But when M. Bailly contends that the Tartars are the moſt ancient of nations, and the civilizers of mankind, he writes without authority, and advances a paradox at which every mind muſt recoil. Among the Tartars there are no hiſtorical monuments of antiquity of any credit; for all their writings extant, even thoſe in the Mogul dialect, are long ſubſequent to the time of Mohammed; nor is it poſſible, ſays Sir William Jones, to diſtinguiſh their traditions from thoſe of the Arabs, whoſe religious opinions they have in general adopted. M. Bailly diſplays indeed great learning and ingenuity in his attempt to derive civilization from this ſource; but the greateſt learning and acuteneſs, together with the charms of a moſt engaging ſtyle, can hardly render tolerable a ſyſtem, which places an earthly paradiſe, the gardens of *Heſperus*, the iſlands of the *Macares*, the groves of Elyſium, if not of Eden, the heaven of INDRA, the Periſtan or fairy-land of the Perſian poets, with its city of diamonds and its country of *Shadcam*, ſo named from Pleaſure and Love, not in any climate which the common ſenſe of mankind conſiders as the ſeat of delights, but beyond the mouth of the Oby, in the Frozen Sea, in a region equalled only by that where the wild imagination of Dante led him to fix the worſt of criminals in a ſtate of puniſhment after death, and of which he could not, he ſays, even think without ſhivering.

Before the era of Mohammed the Tartars had no literature. The magnificent Chengiz, whoſe empire included an area of near 80 ſquare degrees, could find none of his own Mongals, as the beſt authors inform us, able to write his diſpatches; and TIMUR or TAMERLANE, a ſavage of ſtrong natural parts, and paſſionately fond of hearing hiſtories read to him, could himſelf neither write nor read. It is true, that by ſome Arabian writers mention is made of a ſet of Tartarian characters, ſaid to conſiſt of 41 letters; but from the deſcription of theſe characters, Sir William Jones, with much plauſibility, ſuſpects them to have been thoſe of Tibet.

Aſiatic Reſearches, vol. ii. "From ancient monuments therefore (continues the learned preſident) we have no proof that the Tartars were themſelves well inſtructed, much leſs that they inſtructed the world; nor have we any ſtronger reaſon to conclude from their general manners and character, that they had made an early proficiency in arts and ſciences; even of poetry, the moſt univerſal and moſt natural of the fine arts, we find no genuine ſpecimens aſcribed to them, except ſome horrible war-ſongs expreſſed in Perſian by Ali of Yezd, and poſſibly invented by him. After the conqueſt of Perſia by the Mongals, their princes indeed encouraged learning, and even made aſtronomical obſervations at Samarkand; as the Turks became poliſhed by mixing with the Perſians and Arabs, though *their very nature*, as one of their own writers confeſſes, *had before been like an incurable diſtemper, and their minds clouded with ignorance:* thus alſo the Manchew monarchs of China have been patrons of the learned and ingenious, and the emperor Tien-Long is, if he be now living, a fine Chineſe poet. In all theſe inſtances the Tartars have reſembled the Romans, who, before they had ſubdued Greece, were little better than tigers in war, and Fauns or Sylvans in ſcience and art. Tartary ‖ Taſſo.

"We may readily believe thoſe who aſſure us, that ſome tribes of wandering Tartars had real ſkill in applying herbs and minerals to the purpoſes of medicine, and pretended to ſkill in magic: but the general character of their nation ſeems to have been this; they were profeſſed hunters or fiſhers, dwelling, on that account, in foreſts or near great rivers, under huts or rude tents, or in waggons drawn by their cattle from ſtation to ſtation; they were dexterous archers, excellent horſemen, bold combatants, appearing often to flee in diſorder for the ſake of renewing their attack with advantage; drinking the milk of mares, and eating the fleſh of colts; and thus in many reſpects reſembling the old Arabs, but in nothing more than in their love of intoxicating liquors, and in nothing leſs than in a taſte for poetry and the improvement of their language."

Krim TARTARY. See CRIMEA.

TASSEL, a ſort of pendant ornament at the corners of a cuſhion or the like. In building, taſſels denote thoſe pieces of board that lie under the ends of the mantlet trees.

TASSO (Torquato), a juſtly celebrated Italian poet, was born at Sorrento in the kingdom of Naples, in 1544. He was the ſon of Bernardo Taſſo, the author of ſeveral ingenious compoſitions both in verſe and proſe; and of Portia de Roſſi, a lady of an illuſtrious family of Naples.

His father being obliged to accompany the prince of Salerno to the emperor Charles V. upon a deputation from Naples to remonſtrate againſt erecting the inquiſition there, committed the care of his ſon, then three years old, to Angeluzza, a man of great learning; who, we are told, at this tender age began to teach him grammar: at four he was ſent to the Jeſuit's college, and at ſeven was well acquainted with Latin and Greek. At 12 years of age he went from Rome to Mantua, where his father had entered into the ſervice of the duke Guglielmo Gonzago: he had then completed his knowledge of the Latin and Greek languages; he was well acquainted with rhetoric and poetry, and a maſter of Ariſtotle's ethics; he had alſo ſtudied the precepts of Mauritio Cataneo with particular attention, and ever after reverenced him as a ſecond father.

He was ſoon after ſent to the univerſity of Padua; and, in his 18th year, publiſhed his Rinaldo, a poem written upon the plan of Homer's Odyſſey. This extended his reputation throughout all Italy; but greatly diſpleaſed his father, who foreſaw that it would ſeduce him from ſtudies of more advantage. He went to Padua, to remonſtrate againſt his apparent purpoſe of giving himſelf up to philoſophy and poetry, and made uſe of many very harſh expreſſions, which Taſſo heard with a patience and tranquillity that made the old gentleman ſtill more angry: "Of what uſe is that philoſophy on which you value yourſelf ſo much?" "It has enabled me (replied Taſſo) to endure the harſhneſs of your reproofs."

He ſoon after went to Bologna, by the invitation of the city and college; but in a little time returned to Padua at the preſſing inſtances of Scipio Gonzaga, who had been elected prince of the academy that had been eſtabliſhed in that city by the name of the *Ætherei*. He was incorporated into this ſociety, and took upon himſelf the name of *Pentito*.

In this retreat he formed the deſign of his *Jeruſalem Delivered*, invented the fable, diſpoſed the parts, and determined to dedicate it to the houſe of Eſte; but whether to Alphonſo II the laſt duke of Ferrara, or his brother the cardinal Luigi, to whom he had already dedicated his *Rinaldo*, he was yet in doubt. Being preſſed by both the brothers to reſide with them at Ferrara, he conſented. The

duke

Taſſo. duke gave him an apartment in his palace, where he lived in peace and affluence, and proſecuted his work; which he now determined to dedicate to the duke, and which was publiſhed by his patrons, book by book, as he finiſhed them.

When he was about 27, he publiſhed a paſtoral comedy called *Aminta*; which was received with univerſal applauſe, as a maſterpiece in its kind, and is the original of the *Paſtor Fido* and *Filli di Sciro*.

In the 30th year of his age he finiſhed his *Jeruſalem*, and the whole was reprinted and publiſhed together: the ſucceſs of it was aſtoniſhing; it was tranſlated into Latin, French, Spaniſh, and even the Oriental languages, almoſt as ſoon as it appeared.

But it was Taſſo's fate to become wretched from the moment that he gained the ſummit of reputation: very ſoon after his *Jeruſalem* was publiſhed he loſt his father, who died at Oſtia upon the Po, the government of which place had been given him by the duke of Mantua; his *Jeruſalem* was attacked by a ſwarm of ignorant but petulant critics, who gave the preference to the rhapſodies of Pulci and Boyardo; and the perfidy of a friend drew upon him much greater misfortunes.

This friend was a gentleman of Ferrara, to whom Taſſo had indiſcreetly communicated ſome tranſactions of a very delicate nature concerning his patron the duke, with whom he lived. This ſecret being betrayed, Taſſo reproached, his friend for his treachery; and this reproach was retorted in ſuch a manner as provoked Taſſo to ſtrike him. A challenge immediately enſued, and the opponents met and engaged; but during the rencounter, three brothers of Taſſo's antagoniſt came up, and all fell upon him together: Taſſo defended himſelf ſo well, that he wounded two them, and kept his ground againſt the others till ſome people came up and parted them. This made a grear noiſe at Ferrara, where nothing was talked of but the valour of Taſſo; and it became a kind of proverb, "That Taſſo, with his pen and his ſword, was ſuperior to all men."

The duke being informed of the quarrel, baniſhed the brothers from his dominions, confiſcated their eſtates, and Taſſo himſelf he ſhut up in priſon, under pretence of ſecuring him from any future attacks of his enemies.

Taſſo found means to eſcape from this confinement, after having ſuffered it about a year; and, being now about 34 years of age, retired to Turin, where he was ſoon known and recommended to the duke of Savoy, who ſhowed him many marks of eſteem and affection: but Taſſo, fearing that the duke of Ferrara would require him to be delivered up, and that the duke of Savoy would chooſe rather to comply than forfeit the friendſhip of that prince, precipitately ſet out for Rome alone, and without proper neceſſaries for ſuch a journey.

He got ſafe, however, to Rome; where he went directly to his friend Mauritio Cataneo, who received him with great kindneſs, and the whole city ſeemed to rejoice at the preſence of ſo extraordinary a perſon. He was viſited by princes, cardinals, prelates, and all the learned in general. But being impatient of exile, he took meaſures to make his peace with the duke, and ſucceeded.

The duke received him with great appearance of ſatisfaction, and gave him freſh marks of his eſteem. But Taſſo having made ſome attempts on the princeſs Leonora, whom he has celebrated in ſeveral of his verſes, the duke her brother, believing, or pretending to believe, that his ill conduct proceeded from a diſordered underſtanding, cauſed him to be ſtrictly confined in the hoſpital of St Anne. Taſſo applied to the duke, by every friend he had, to releaſe him from this confinement; but the duke coldly anſwered, that inſtead of endeavouring to procure the enlargement of a perſon in his condition, they ought rather to exhort him to ſubmit patiently to ſuch remedies as were judged proper for him. Taſſo was certainly diſordered in his mind, whether as the effect or cauſe of this confinement: he was conſcious that he laboured under ſome diſtemper, and he believed the cauſe of it to be ſupernatural, and fancied himſelf haunted by a ſpirit that continually diſordered his books and papers; to which, however, the tricks played him by his keepers might contribute. He continued, notwithſtanding, to ſolicit the interpoſition of all the powers in Italy, to whom he could find means to apply, particularly the emperor and the pope; but without ſucceſs. At laſt, after he had been a priſoner ſeven years, Vincentio Gonzaga prince of Mantua came to Ferrara among other great perſonages, during the feſtivals and rejoicings that were held there on the marriage of Cæſar of Eſte with Virginia of Medicis, procured his liberty, and took him with him to Mantua, he being then in the 42d year of his age. Taſſo.

At Mantua he lived about a year in great favour with the prince, and in all the ſplendour and affluence which the favour of great princes confers: but he was weary of a ſtate of dependence, however ſplendid and luxurious; and therefore reſolved to go to Naples, and endeavour to recover his mother's jointure, which had been ſeized by her relations when he went into exile with his father Bernardo. With this view he procured letters of recommendation to the viceroy; and having taken leave of the prince of Mantua, he went firſt to Bergamo, where he ſtaid ſome time, and from thence proceeded to Naples.

At Naples he immediately commenced a ſuit at law for the recovery of his right, and divided his time between a proſecution of that and his ſtudies. But during the ſummer he retired to Biſaccio with one Giovanni Batiſta Manſo, with whom he had contracted an intimate friendſhip.

Taſſo, who was now in his 45th year, appeared to Manſo, while they were at Biſaccio, to be affected with a melancholy, which had very ſingular effects; he therefore very frequently queſtioned him about them; and Taſſo told him that he had a familiar ſpirit; with whom he frequently and freely converſed. Manſo treated this as an illuſion, but Taſſo ſtill affirmed it to be real; and telling him that the ſpirit would meet and converſe with him the next day, invited him to be preſent. Manſo coming at the hour appointed, ſaw Taſſo fix his eyes with great earneſtneſs upon a window, and perceiving him to continue without motion, he called him ſeveral times by his name. Taſſo made no reply; but at length cried out with great vehemence, "There is the friendly ſpirit that is come to converſe with me; look, and be convinced that what I have ſaid is true." Manſo looked, not without ſome ſurpriſe, but ſaw nothing except the ſun-beams which ſhone through the window. He was juſt going to aſk where the pretended ſpirit was, when he was prevented by Taſſo's ſpeaking with great earneſtneſs to ſome imaginary being ſometimes putting queſtions, and ſometimes giving anſwers, in a manner ſo pleaſing, and with ſuch elevation of expreſſion, that Manſo had no deſire to interrupt him: the converſation at laſt ended by the ſuppoſed departure of the ſpirit; when Taſſo turning round to his friend, aſked if his doubts were removed? To which he made no reply, being ſo much amazed that he gladly waved all farther converſation on the ſubject.

Finding his law-ſuit not likely to be ſoon determined, he went from Naples to Rome, where he continued about a year in high favour with Pope Sextus Quintus; and then went to Florence, at the preſſing invitation of Ferdinando grand duke of Tuſcany, who had been cardinal at Rome when Taſſo firſt reſided there.

Having

Taſſo, Taſte.

Having ſpent about another year at Florence, he returned again to Naples; and there applied himſelf to correct his *Jeruſalem Delivered*. Soon after the publication of this work, Hippolito Aldrobandini ſucceeded Sextus Quintus to the papacy, by the name of *Clement the VIIth*; and his two nephews, Cynthio and Pietro Aldrobandini, were created cardinals. Cynthio, who was a great patron of learning and genius, and had known Taſſo when he laſt reſided at Rome, prevailed with him once more to leave his retreat at Naples, and live with him in that city. Here he continued till his 50th year; and being then again weary of his ſituation, and deſirous to proſecute his law-ſuit, he obtained permiſſion to retire once more to Naples, where he took up his abode with the Benedictine fathers in the convent of St Severin. Cardinal Cynthio, however, found means to recal him again to Rome, after a very ſhort abſence, by having prevailed with the Pope to confer upon him the honour of being publicly and ſolemnly crowned with laurel in the Capitol.

He ſet out from Naples to receive this honour, with a preſage that he ſhould never return; and arrived at Rome in the beginning of the year 1595, being then about 51 years old: he was met at the entrance of the city by many prelates and perſons of diſtinction, and was introduced by the two cardinals to the pope, who complimented him by ſaying, "That his merit would confer as much honour on the laurel he was about to receive, as the laurel had formerly conferred on others." Orders were immediately given to decorate not only the pope's palace and the Capitol, but all the principal ſtreets through which the proceſſion was to paſs: but Taſſo, whether from an habitual dejection of mind, or a ſecret ſenſation of the firſt approaches of a diſeaſe which he apprehended would be fatal, declared that all theſe pompous preparations would be in vain.

It happened, that while they were waiting for fair weather to celebrate the ſolemnity, cardinal Cynthio fell ſick; and, before he was perfectly recovered, Taſſo himſelf was taken ill, and died on the 15th day of his ſickneſs, aged 51. His poems have acquired him an immortal reputation. The principal of them are, 1. Jeruſalem Delivered. 2. Jeruſalem Conquered. 3. Rinaldo. 4. The Seven Days of the Creation. 5. The Tragedy of Torimond. 6. Aminta, &c. All Taſſo's works were printed together at Florence in 1724, in ſix volumes folio, with the pieces for and againſt his Jeruſalem Delivered. A ſplendid edition of this laſt poem was printed at Venice in 1745, in folio. The beſt edition of Mirebaud's French tranſlation is that of Paris in 1735, in two vols 12mo. His *Aminta* and *Gieruſalemme Liberata* have been tranſlated into Engliſh.

TASTE, a certain ſenſation, or claſs of ſenſations, excited in the mind by certain bodies, which are called *ſapid*, applied to the tongue and palate, and moiſtened with the ſaliva. This is the original and proper meaning of the word *taſte* (ſee METAPHYSICS, n° 46); but as the qualities of bodies which produce theſe ſenſations are unknown, they have in all languages got the names of the ſenſations themſelves, by that figure of ſpeech which ſubſtitutes the cauſe for the effect. Hence we talk of the taſtes of ſugar, wormwood, honey, vinegar, &c.; and ſay, that the taſte of ſugar is ſweet, and of vinegar ſour. Taſtes have been divided into ſimple and compound; and philoſophers have to very little purpoſe eadeavoured to aſcertain the number of each ſpecies. Attempts have likewiſe been made to determine from their taſtes the effects of different ſubſtances on the human body, taken into the ſtomach as food or phyſic; but by ſtating the reſults of the various inquiries, we ſhould be more likely to miſlead the unlearned reader, than to communicate uſeful information to readers of any deſcription. Whoever is deſirous of information on the ſubject may conſult *Phil. Tranſ.* N° 280, 299; and *Abercromb. Nov. Med. Clavis*. Taſte.

TASTE is likewiſe uſed in a figurative ſenſe, to denote that faculty of the mind by which we perceive and enjoy whatever is beautiful or ſublime in the works of nature or of art. Like the taſte of the palate, this faculty reliſhes ſome things, is diſguſted with others, and to many is indifferent; and from theſe obvious analogies between it and the external ſenſe it has obtained its name. It has likewiſe been called an internal *ſenſe*, and by one philoſopher * a *reflex ſenſe*; whilſt others have conſidered it, not as a diſtinct faculty or ſenſe, but as the joint exertion of perception and judgment in ſome caſes, and as a play of the imagination in others. * Dr Hutcheſon.

To decide among theſe different opinions, it will be neceſſary to aſcertain, if we can, what are the objects of this faculty; for we hardly think that every thing which is beautiful, either in nature or art, can with propriety be called an object of taſte. *Scarlet*, *blue*, *green*, and *yellow*, are all beautiful colours, and a *cube* and a *ſphere* are beautiful figures; but it does not appear to us, that a man could be ſaid to have either a good or a bad taſte for reliſhing the perception of a *ſcarlet* more than that of a *yellow* colour, or a *ſpherical* more than a *cubical* figure. A native of Africa conſiders thick lips and a flat noſe as eſſential to female beauty; whilſt the inhabitant of Europe prefers to all other forms of the noſe that which is called *Grecian*, and is diſguſted with lips either very thick or very thin. But upon what principles can we ſay that the African has a bad, and the European a good, taſte?

With reſpect to the objects of the external ſenſe, we are generally ſo conſtituted by nature as to reliſh, in the higheſt degree, thoſe kinds of food which are moſt wholeſome; and ſuch a taſte, which we believe is always found in infants, is juſtly ſaid to be ſound and uncorrupted. It is in the higheſt perfection too at firſt; for it depends not upon culture of any kind, and is incapable of improvement. The reverſe of all this is the caſe with reſpect to internal taſte; of which the variety is obvious to the moſt careleſs obſerver, and is found, on examination, to be ſtill greater in reality than it is in appearance. Every voice is indeed united in applauding elegance, propriety, ſimplicity, ſpirit in writing; and in blaming ſuſtian, affectation, coldneſs, and a falſe brilliancy: but when critics come to particulars, this ſeeming unanimity vaniſhes; and it is found that they had affixed very different meanings to the ſame expreſſions. Perhaps no man ever attentively beheld the riſing or the ſetting ſun without feeling ſome emotions of pleaſure which filled his mind; or went for the firſt time into ſuch a building as the cathedral church of York, without being ſtruck with a pleaſing, though ſolemn, reverence. Yet it is certain, that the emotions of the clown, however acute he may be by nature, and perfect in all his faculties, are not the ſame, at leaſt in degree, with thoſe of the poet or philoſopher when contemplating the riſing or ſetting ſun; or of the ſcientific mechanic when viewing the ſtructure of the pillars and roof of the Gothic cathedral. We are not indeed ſure that the pleaſure of the clown on theſe occaſions riſes above that of mere ſenſation. Any bright and beautiful object preſented to the eye, gives a pleaſing ſenſation to the mind, in conſequence of that peculiar agitation which ſuch objects communicate to the optic nerves and the brain; and to us it appears, that the clown feels nothing more than this from the view of the riſing ſun or the magnificent church. Perhaps he may compare the ſenſations which he feels on theſe occaſions with others which he has formerly felt in ſome degree ſimilar to them, and have his pleaſure heightened by the

exerciſe

Taſte. exerciſe of that faculty of which the province is to judge upon compariſon; but we have no reaſon to ſuppoſe, that from the riſing ſun he receives any emotions different in kind from what he would receive from a blazing heath, were it accompanied with the ſame varying tints of colour; or that the church impreſſes on his fancy more than that wonder with which he would view any other building equally large and equally novel, though of a form very different. In poetry and painting the vulgar are always delighted with the melody of the verſe and the brilliancy of the colours; and think of nothing elſe as beauties, either in the one or in the other, unleſs the painting be the picture of ſome known object, and the poem deſcribe ſcenes or actions in which they may be ſelfiſhly intereſted. Hence it is that the vulgar are more captivated by the ſplendor of the Venetian ſtyle of painting, than by the ſimple grandeur of the Roman and Bolognian Schools; for the art of the former, which has been carried to the higheſt degree of perfection, is to give pleaſure to the eye or the ſenſe; that of the latter is to fill the imagination. The powers exerted in the former ſchool Sir Joſhua Reynolds calls the *language* of painters, which he compares to an *empty tale told by an idiot, full of ſound and fury, ſignifying nothing.* The compoſitions of the latter ſchools may be compared to the ſublimity of Milton's ſentiments, which would be diſgraced by thoſe petty ornaments to which it leaves not the reader at leiſure to attend.

If this be ſo, the pleaſures which the vulgar derive from what are called objects of taſte are merely gratifications of the ſenſes; or if any of theſe objects ever intereſt their higher faculties, it muſt be by inſpiring them with confidence or dread; confidence of their own ſafety, for inſtance, if the building which they admire appear to them to be ſtable; and dread, if they have formed of it a contrary opinion. Very different is the pleaſure which the man of cultivated taſte derives from the beauties either of nature or of art: when he beholds the riſing or the ſetting ſun, he has indeed the pleaſing ſenſation, which is all that the rude man feels; but along with this ariſes in his imagination a train of ideas, which hurries him beyond the object before him to its beneficent effects and its Almighty Creator: and if he has been much converſant with the works of deſcriptive poets, a number of pleaſing ideas treaſured up in his memory will, by the principle of aſſociation, paſs in review before him, though they be not connected either with one another, or with the riſing or ſetting ſun, by a relation ſo cloſe as that of cauſe and effect. In like manner, when the ſcientific architect views the Gothic cathedral, he muſt admire its ſolemn magnificence, though with leſs wonder than it excites in the breaſt of the clown; but he feels an additional pleaſure, derived from a ſource to which the other has no acceſs. He perceives the many contrivances diſplayed in its ſtructure for uniting ſtability with lightneſs; and from contemplating the building, he is inſtantly led by a natural train of thought to admire the ſkill of the builder.

The nature of any perſon's taſte, therefore, is generally determined from the character of his imagination and the ſoundneſs of his judgment. When any object either of ſublimity or beauty is preſented to the mind, every man is conſcious of a train of thought being immediately awakened in his imagination, analogous to the character or expreſſion of the original object. The ſimple perception of the object we frequently find is inſufficient to excite theſe emotions, unleſs it is accompanied with this operation of mind; unleſs, according to common expreſſion, our imagination is ſeized, and our fancy buſied in the purſuit of all thoſe trains of thought which are allied to this character or expreſſion. Thus, when we feel either the beauty or ſublimity of natural ſcenery, the gay luſtre of a morning in ſpring, or the mild radiance of a ſummer evening, the ſavage majeſty of a wintry ſtorm, or the wild magnificence of a tempeſtuous ocean, we are conſcious of a variety of images in our minds, very different from thoſe which the objects themſelves can preſent to the eye. Trains of pleaſing or of ſolemn thought ariſe ſpontaneouſly within our minds; our hearts ſwell with emotions, of which the objects before us ſeem to afford no adequate cauſe; and we are never ſo much ſatiated with delight, as when, in recalling our attention, we are unable to trace either the progreſs or the connection of thoſe thoughts which have paſſed with ſo much rapidity through our imagination. Taſte.

If the mind is in ſuch a ſtate as to prevent this freedom of imagination, the emotion, whether of ſublimity or beauty, is unperceived. In ſo far as the beauties of art or nature affect the external ſenſes, their effect is the ſame upon every man who is in poſſeſſion of theſe ſenſes. But to a man in pain or in grief, whoſe mind by theſe means is attentive only to one object or conſideration, the ſame ſcene or the ſame form will produce no feeling of admiration, which, at other times, when his imagination was at liberty, would have produced it in its fulleſt perfection. It is upon the vacant and the unemployed, accordingly, that the objects of taſte make the ſtrongeſt impreſſion. It is in ſuch hours alone that we turn to the compoſitions of muſic or of poety for amuſement. The ſeaſons of care, of grief, or of buſineſs, have other occupations, and deſtroy, for the time at leaſt, our ſenſibility to the beautiful or the ſublime, in the ſame proportion that they produce a ſtate of mind unfavourable to the indulgence of imagination.

There are many objects of taſte, however, which produce not their full effect on the imagination, but through the medium of the judgment. We have given one inſtance in architecture, and ſhall give another in ſculpture. The beauty of the Farneſe Hercules is one kind of beauty; that of the gladiator in the palace of Chighi another; and that of the Apollo of Belvidere a third. Each of theſe figures is acknowledged to be perfect in its kind; and yet Sir Joſhua Reynolds affirms, that the higheſt perfection of the human figure is not to be found in any one of them, but in that form which might be taken from them all, and would partake equally of the activity of the gladiator, of the delicacy of the Apollo, and of the muſcular ſtrength of the Hercules. If the judgment of this eminent artiſt be admitted, the perfection of theſe ſtatues cannot conſiſt in any thing which is the immediate object of ſenſe, either external or internal; but in ſomething which, being perceived by the eye, is referred by the underſtanding to what we know of the characters of Hercules, Apollo, and the Gladiator, and which we believe it was the intention of the ſtatuaries to expreſs. Nay, there are objects of which taſte is ſometimes ſaid to judge, though they have little or no effect whatever on the imagination. A book of abſtract ſcience, written in a prolix and intricate ſtyle, might be ſaid to be in a bad taſte; and had Swift, in his clear and ſimple ſtyle, written *An Eſſay on the Human Underſtanding*, his work, ſuppoſing him maſter of the ſubject, would undoubtedly have diſplayed more taſte than Locke's, in which the terms are ſometimes vague, and the periods often encumbered. This is actually the caſe of Berkeley, whom every man admits to have been a writer of good taſte, though neither *The Principles of Human Knowledge*. *The Dialogues on Matter*, nor the beautiful work entitled *The Minute Philoſopher*, is capable of affording pleaſure to the ſenſes or the imagination. His beauty conſiſts merely in the perſpicuity of his ſtyle, of which the underſtanding alone is the judge. The metaphyſical

Taſte. phyſical writings of Dr Reid poſſeſs in an eminent degree the ſame beauty; and no man of true taſte can read them without admiring the elegant ſimplicity of the compoſition as much as the ſtrength of the reaſoning, and feeling from the whole a pleaſure which the poetical ſtyle of Shafteſbury cannot communicate.

If this be a juſt account of the pleaſures of taſte, that faculty cannot be properly conſidered as a mere internal ſenſe, ſince to its enjoyments a well-ſtored fancy is neceſſary in ſome caſes, and the reaſoning power in all; and the poet and the painter who wiſh to excel in their reſpective profeſſions, muſt not content themſelves, the one with filling the ear of the reader with melliſluous ſounds, and the other with dazzling or deceiving the eye of the ſpectator by the brilliancy of his colours, but both muſt ſtrive for fame by captivating the imagination; whilſt the architect, who aſpires to a ſimilar celebrity, muſt make the purpoſe of his ornaments obvious to every perſon capable of judging. The landſcapes of Claude Lorrain, the muſic of Handel, the poetry of Milton, excite feeble emotions in our minds, when our attention is confined to the qualities they preſent to our ſenſes, or when it is to ſuch qualities of their compoſition that we turn our regard. It is then only we feel the ſublimity or beauty of their productions, when our imaginations are kindled by their power, when we loſe ourſelves amid the number of images that paſs before our minds, and when we waken at laſt from this play of fancy as from the charm of a romantic dream.

* Diſcourſe delivered at the Royal Academy, Dec. 14. 1770.

It is well obſerved by Sir Joſhua Reynolds,* that taſte is ſometimes praiſed in ſuch terms by orators and poets, who call it *inſpiration*, and *a gift from heaven*, that though a ſtudent by ſuch praiſe may have his attention rouſed, and a deſire excited of obtaining this gift, he is more likely to be deterred than encouraged in the purſuit of his object. "He examines his own mind, and perceives *there* nothing of that divine inſpiration with which he is told ſo many others have been favoured. He never travelled to heaven to gather new ideas; and he finds himſelf poſſeſſed of no other qualifications than what mere common obſervation and a plain underſtanding are able to confer. Thus he becomes gloomy amidſt the ſplendour of figurative declamation, and thinks it hopeleſs to purſue an object which he ſuppoſes out of the reach of human induſtry. But on this, as on many other occaſions, we ought to diſtinguiſh how much is to be given to enthuſiaſm, and how much to common ſenſe; taking care not to loſe in terms of vague admiration that ſolidity and truth of principle upon which alone we can reaſon." Whoever poſſeſſes the ordinary powers of perception, ſenſibility of heart, good ſenſe, and an imagination capable of being rouſed by the ſtriking objects of nature and of art, may, without inſpiration, become, by mere experience, a man of fine taſte in the objects of which he aſpires to be a critical judge.

This being the caſe, we may eaſily account for the variety of taſtes which prevail among men, not only as individuals but as nations. We have already mentioned the difference in one inſtance between the European taſte and the African reſpecting female beauty; and we may now affirm, as we hope to prove our affirmation, that the one taſte is equally correct with the other. The charms of female beauty exiſt not in the mere external form and colour conſidered by themſelves (for then the inanimate ſtatue of the Venus de Medicis would give more delight to the European beholder than the fineſt woman that ever lived); but we aſſociate external beauty with ſweetneſs of diſpoſition, and with all the train of endearments which take place in the union of the ſexes; and it is this aſſociation which delights the man of taſte, as giving refinement to an appetite which in itſelf is groſs and ſenſual. A ſimilar aſſociation muſt be formed in the breaſt of the African who has any taſte; and as he never knew feminine ſoftneſs, or any of the endearing qualities of the ſex, but as united with thick lips, a flat noſe, a black ſkin, and woolly hair—a ſable beauty of that deſcription muſt excite in his breaſt the ſame emotions that are excited in the breaſt of an European by the fair woman with Grecian features. Taſte.

But is there not an ideal or perfect beauty of the human form? There certainly is, as of every other natural object; but it cannot be the ſame in Europe as in Africa, unleſs to a Being who is acquainted with all the peculiarities of form, national and individual, that are to be found among the inhabitants of the whole earth. It has been ſuppoſed, and we think completely proved, by one of the beſt writers that we have on the philoſophy of taſte,* that the ſublimity or beauty of forms ariſes altogether from the aſſociations we connect with them, or the qualities of which they are expreſſive to us. The qualities expreſſed by the male and female forms are very different; and we would by no means think the woman beautiful who ſhould have the form of the Farneſe Hercules, or admire the ſhapes of the hero who ſhould be formed like the Venus de Medicis; becauſe the proportions of ſuch a woman would indicate ſtrength and intrepidity, where we wiſh to find only gentleneſs and delicacy; and the delicate form of the hero would indicate ſoftneſs and effeminacy, where the oppoſite qualities only can be eſteemed. As we aſſociate with the female form many deſirable qualities, every woman is eſteemed more or leſs beautiful as her figure and features indicate a greater or ſmaller number of theſe qualities; and the ſame is the caſe with reſpect to the qualities which adorn the male character, and the form and features by which they are expreſſed. Upon comparing a number of human beings with one another, we find, that with reſpect to every feature and limb, there is one central form to which nature always tends, though ſhe be continually deviating from it on the right hand and on the left: (See Nose). This form therefore is conſidered as the moſt perfect form of the ſpecies, and moſt expreſſive of the qualities for which that ſpecies is valued; but in Africa, the central form, with reſpect to the proportions of the human body and the features of the human face, is very different from what it is in Europe; and therefore the ideal or perfect beauty of the human form and features cannot be the ſame in both countries. No doubt, if a man could examine the limbs and features of every individual of the human race, he would diſcover one central form belonging to the whole, and be led to eſteem it the ſtandard of beauty; but as this is obviouſly impoſſible, the common idea or central form belonging to each great claſs of mankind muſt be eſteemed the ſtandard of beauty in that claſs, as indicating moſt completely the qualities for which individuals are eſteemed. Thus there is a common form in childhood and a common form in age; each of which is the more perfect as it is the more remote from peculiarities: but though age and childhood have ſomething in common, we ſhould not deem the child beautiful who was formed exactly like the moſt handſome man, nor the man handſome who was formed exactly like the moſt beautiful child. This doctrine is well illuſtrated by Sir Joſhua Reynolds,* who has applied it to every object eſteemed beautiful in nature; and proved, that the ſuperiority of Claude Lorrain over the landſcape-painters of the Dutch and Flemiſh ſchools, ariſes chiefly from his having generalized his conceptions, and formed his pictures by compounding together the various draughts which he had previouſly made from various beautiful ſcenes and proſpects. "On the whole (ſays he), it ſeems to me that there is but one preſiding principle which regulates and

* Mr Alliſon.

Taſte. gives ſtability to every art. The works, whether of poets, painters, moraliſts, or hiſtorians, which are built upon general nature, live for ever; while thoſe which depend for their exiſtence on particular cuſtoms and habits, a particular view of nature, or the fluctuation of faſhion, can only be coeval with that which firſt raiſed them from obſcurity. All the individual objects which are exhibited to our view by nature, upon cloſe examination, will be found to have their blemiſhes and defects. The moſt beautiful forms have ſomething about them like weakneſs, minuteneſs, or imperfection. But it is not every eye that perceives theſe blemiſhes: It muſt be an eye long uſed to the contemplation and compariſon of theſe forms; which alone can diſcern what any ſet of objects of the ſame kind has in common, and what each wants in particular."

From theſe reaſonings the ſame great artiſt concludes, that the man who is ambitious of the character of poſſeſſing a correct taſte, ought to acquire a "habit of comparing and digeſting his notions. He ought not to be wholly unacquainted with that part of philoſophy which gives him an inſight into human nature, and relates to the manners, characters, paſſions, and affections. He ought to know *ſomething* concerning the *mind*, as well as a great deal concerning the *body*, and the various external works of nature and of art; for it is only the power of diſtinguiſhing right from wrong that is properly denominated *taſte*.

"Genius and taſte, in their common acceptation, appear to be very nearly related; the difference lies only in this, that genius has ſuperadded to it a habit or power of execution. Or we may ſay, that taſte, when this power is added, changes its name, and is called *genius*. They both, in the popular opinion, pretend to an entire exemption from the reſtraint of rules. It is ſuppoſed that their powers are intuitive; that under the name of *genius* great works are produced, and under the name of *taſte* an exact judgment is given, without our knowing why, and without being under the leaſt obligation to reaſon, precept, or experience.

"One can ſcarce ſtate theſe opinions without expoſing their abſurdity; yet they are conſtantly in the mouths of men, and particularly of illiterate and affected connoiſſeurs. The natural appetite, or taſte of the human mind, is for *truth*; whether that truth reſults from the real agreement or equality of original ideas among themſelves, from the agreement of the repreſentation of any object with the thing repreſented, or from the correſpondence of the ſeveral parts of any arrangement with each other. It is the very ſame taſte which reliſhes a demonſtration in geometry, that is pleaſed with the reſemblance of a picture to an original, and touched with the harmony of muſic.

"But beſides *real*, there is alſo *apparent* truth, or opinion, or prejudice. With regard to real truth, when it is known, the taſte which conforms to it is and muſt be uniform. With regard to the ſecond ſort of truth, which may be called *truth upon ſufferance*, or *truth by courteſy*, it is not fixed but variable. However, whilſt theſe opinions and prejudices on which it is founded continue, they operate as truth; and the art, whoſe office it is to pleaſe the mind as well as inſtruct it, muſt direct itſelf according to *opinion*, or it will not attain its end. In proportion as theſe prejudices are known to be generally diffuſed or long received, the taſte which conforms to them approaches nearer to certainty, and to a ſort of reſemblance to real ſcience, even where opinions are found to be no better than prejudices. And ſince they deſerve, on account of their duration and extent, to be conſidered as really true, they become capable of no ſmall degree of ſtability and determination by their permanent and uniform nature.

"Of the judgment which we make on the works of art, and the preference that we give to one claſs of art over another, if a reaſon be demanded, the queſtion is perhaps evaded by anſwering, I judge from my taſte; but it does not follow that a better anſwer cannot be given, though for common gazers this may be ſufficient. Every man is not obliged to inveſtigate the cauſes of his approbation or diſlike. The arts would lie open for ever to caprice and caſualty, if thoſe who are to judge of their excellencies had no ſettled principles by which they are to regulate their deciſions, and the merit or defect of performances were to be determined by unguided fancy. And indeed we may venture to aſſert, that whatever ſpeculative knowledge is neceſſary to the artiſt, is equally and indiſpenſably neceſſary to the critic and the connoiſſeur. Taſte, Tate.

"The firſt idea that occurs in the conſideration of what is fixed in art or in taſte, is that preſiding principle which we have already mentioned, the general idea of nature. The beginning, the middle, and the end of every thing that is valuable in taſte, is compriſed in the knowledge of what is truly nature; for whatever ideas are not conformable to thoſe of nature or univerſal opinion, muſt be conſidered as more or leſs capricious; the idea of nature comprehending not only the forms which nature produces, but alſo the nature and internal fabric and organization, as I may call it, of a human mind and imagination. General ideas, beauty, or nature, are but different ways of expreſſing the ſame thing, whether we apply theſe terms to ſtatues, poetry, or picture. Deformity is not nature, but an accidental deviation from her accuſtomed practice. This general idea therefore ought to be called *nature*; and nothing elſe, correctly ſpeaking, has a right to that name. Hence it plainly appears, that as a work is conducted under the influence of general ideas, or partial, it is principally to be conſidered as the effect of a good or a bad taſte."

Upon the whole, we may conclude that the real ſubſtance, as it may be called, of what goes under the name of *taſte*, is fixed and eſtabliſhed in the nature of things; that there are certain and regular cauſes by which the imagination and paſſions of men are affected; and that the knowledge of theſe cauſes is acquired by a laborious and diligent inveſtigation of nature, and by the ſame ſlow progreſs as wiſdom or knowledge of every kind, however inſtantaneous its operations may appear when thus acquired. A man of real taſte is always a man of judgment in other reſpects; and thoſe inventions which either diſdain or ſhrink from reaſon, are generally more like the dreams of a diſtempered brain than the exalted enthuſiaſm of a ſound and true genius. In the midſt of the higheſt flights of fancy or imagination, reaſon ought to preſide from firſt to laſt; and he who ſhall decide on the beauties of any one of the fine arts by an imaginary innate ſenſe or feeling, will make as ridiculous an appearance as the connoiſſeur mentioned by Dr Moor, who praiſed as a work of the divine Raphael the wretched daubing by a Swiſs copyiſt. The reader who wiſhes for further inſtruction in the philoſophy of taſte, may conſult Gerard's Eſſay on Taſte, with the diſſertations of Voltaire, d'Alembert, and Monteſquieu; Dr Blair's Lectures on the Belles Lettres; Dr Reid's Eſſays on the Intellectual Powers of Man; Aliſon's Eſſays on the Nature and Principles of Taſte; and Sir Joſhua Reynolds' Diſcourſes delivered in the Royal Academy.

TATE (Nahum), an Engliſh poet, born about the middle of the reign of Charles II. in Ireland, where he received his education. He was made poet-laureat to King William upon the death of Shadwell, and held that place until the reign of George I. whoſe firſt birth-day ode he lived

Tatian ‖ Taunton.

lived to write, and executed it with unuſual ſpirit. He died in the mint in 1716, and was ſucceeded in the laurel by Mr Euſden. He was the author of nine dramatic performances, a great number of poems, and a verſion of the Pſalms in conjunction with Dr Nicholas Brady.

TATIAN, a writer of the primitive church in the ſecond century. He was born in Aſſyria, and trained up in the heathen religion and learning. Coming over to Chriſtianity, he became the diſciple of Juſtin Martyr, whom he attended to Rome. While Juſtin lived, he continued ſteadily orthodox: but after Juſtin's death he made a ſchiſm, and became the author of a new ſect, condemning marriage, enjoining abſtinence from wine and animal-food, and ſuffering only water to be uſed in the holy myſteries; whence his followers were called *Encratitæ* and *Hydroparaſtatæ*. None of his works are now extant but his piece againſt the Gentiles; or, as it is uſually intitled, his *Oration to the Greeks*.

TATIUS (Achilles), a native of Alexandria, was the author of a book on the ſphere, which father Petau tranſlated into Latin. There is alſo attributed to him a Greek romance on the loves of Leucippe and Clitophon, of which Salmaſius has given a beautiful edition in Greek and Latin, with notes. Suidas ſays, that this Achilles Tatius was a Pagan, but that he afterwards embraced the Chriſtian religion, and became a biſhop. Photius mentions him in his Bibliotheca.

TATONNEUR, in zoology. See LEMUR.

TATTOOING, or TATTOWING, an operation in uſe among the iſlanders in the South Sea for marking their bodies with figures of various kinds which they conſider as ornamental. It is performed by puncturing the ſkin, and rubbing a black colour into the wounds. The inſtrument uſed ſomewhat reſembles a comb, the teeth of which are repeatedly ſtruck into the ſkin by means of a ſmall mallet. It is very painful; but the children are forced by their relations to ſubmit to it.

TATTOU, a beat of a drum at night to advertiſe the ſoldiers to retreat, or repair to their quarters in the garriſon, or to their tents in a camp.

TAVERNIER (John Baptiſt), a famous French traveller, was born in 1605. In the courſe of 40 years he travelled ſix times to Turkey, Perſia, and the Eaſt Indies, and viſited all the countries in Europe, travelling moſtly on foot. His travels have been frequently reprinted in ſix vols 12mo. He died on his ſeventh journey to the eaſt, at Moſcow, in 1669.

TAVIRA, or TAVILA, a conſiderable town of Portugal, and capital of the province of Algarve, with a handſome caſtle, and one of the beſt harbours in the kingdom, defended by a fort. It is ſeated in a pleaſant fertile country, at the mouth of the river Gilaon, between Cape Vincent and the Strait of Gibraltar, 100 miles weſt by north of Cadiz. W. Long 7. 46. N. Lat. 37. 18.

TAVISTOCK, a town of Devonſhire in England, ſituated on the river Tavey or Tave, W. Long. 4. 12. N. Lat. 50. 37. It ſends two members to parliament, and gives the title of *marquis* to the noble family of Ruſſel duke of Bedford.

TAUNTON, a large, elegant, and well built town of Somerſetſhire, 146 miles from London. It conſiſts principally of four ſtreets paved and lighted; the market-place is ſpacious, and has a handſome market-houſe, with a town hall over it, which was finiſhed in 1773. It has an extenſive woollen manufactory; and in 1780 a ſilk manufactory was introduced. Its caſtle, the ruins of which remain, was in 1645 defended for the parliament by colonel Blake againſt an army of 10,000 men under lord Goring, but was diſmantled by Charles II. In 1685 the duke of Monmouth made this place his head-quarters. Its church, which is large and beautiful, is a fine ſpecimen of the florid Gothic ſtyle of architecture. The tower, which is lofty, is of excellent workmanſhip, crowned at the top with four ſtately pinnacles, 32 feet high. The whole perhaps is not equalled in the kingdom. Taunton is pleaſantly ſeated on the river Tone, which is navigable to Bridgewater; is reckoned the beſt town in the county; and ſends two members to parliament. W. Long. 3. 17. N. Lat. 50. 59.

Tauris ‖ Tawing.

TAURIS, or TEBRIS, a town of Perſia, and capital of Aderbeitzan. It was formerly the capital of Perſia, and is now the moſt conſiderable next to Iſpahan; for it contains 15,000 houſes, beſides many ſeparate ſhops, and about 200,000 inhabitants. It is about five miles in circumference, and carries on a prodigious trade in cotton, cloth, ſilks, gold and ſilver brocades, fine turbans, and ſhagreen leather. There are 300 caravanſeras, and 250 moſques. Some travellers ſuppoſe it to be the ancient Ecbatana; but of this there is no certainty. It is ſeated in a delightful plain, ſurrounded with mountains, from whence a ſtream iſſues, which runs through the city. E. Long. 47. 50. N. Lat. 38. 18.

TAURUS, a great chain of mountains in Aſia, which begin at the eaſtern part of Little Carimania, and extend very far into India. In different places they have different names.

TAURUS, in aſtronomy, one of the 12 ſigns of the zodiac.

TAUTOLOGY, a needleſs repeating of the ſame thing in different words.

TAWING, the art of dreſſing ſkins in white, ſo as to be fit for divers manufactures, particularly gloves, &c.

All ſkins may be tawed; but thoſe chiefly uſed for this purpoſe are lamb, ſheep, kid, and goat ſkins.

The method of tawing is this: Having cleared the ſkins of wool or hair by means of lime, they are laid in a large vatt of wood or ſtone, ſet on the ground full of water, in which quicklime has been ſlaked; wherein they are allowed to lie a month or ſix weeks, according as the weather is more or leſs hot, or as the ſkins are required to be more or leſs ſoft and pliant.

While they are in the vatt, the water and lime is changed twice, and the ſkins are taken out and put in again every day: and when they are taken out for the laſt time, they are laid all night to ſoak in a running water, to get out the greateſt part of the lime; and in the morning are laid together by ſixes one upon another, upon a wooden leg, and are ſcraped ſtoutly one after another, to get the fleſh off from the fleſhy ſide, with a cutting two-handled inſtrument called a *knife*; and then they cut off the legs (if they are not cut off before) and other ſuperfluous parts about the extremes. Then they are laid in a vatt or pit with a little water, where they are fulled with wooden peſtles for the ſpace of a quarter of an hour; and then the vatt is filled up with water, and they are rinſed in it.

In the next place, they are thrown on a clean pavement to drain and afterwards caſt into a freſh pit of water, out of which they rinſe them well, and are laid again on the wooden leg, ſix at a time, with the hair ſide outermoſt: over which they rub a kind of whetſtone very briſkly, to ſoften and fit them to receive four or five more preparations, given them on the leg both on the fleſh-ſide and the hair-ſide, with the knife, after the manner abovementioned.

After this they are put into a pit of water and wheaten-bran, and ſtirred about in it with wooden poles, till the bran is perceived to ſtick to them, and then they are left: as they riſe of themſelves to the top of the water by a kind of fermentation, they are plunged down again to the bottom; and at the ſame time fire is ſet to the liquor, which burns as

Tawing, Tax.

eaſily as if it were brandy, but goes out the moment the ſkins are all covered.

They repeat this operation as often as the ſkins riſe above the water; and when they have done riſing they take them out, lay them on the wooden leg, the fleſhy ſide outwards, and paſs the knife over them to ſcrape off the bran.

Having thus cleared them of the bran, they lay the ſkins in a large baſket, and load them with huge ſtones to promote their draining: and when they have drained ſufficiently, they give them their feeding; which is performed after the manner following:

For 100 of large ſheep ſkins, and for ſmaller in proportion, they take eight pounds of alum and three of ſea-ſalt, and melt the whole with water in a veſſel over the fire, pouring the ſolution out, while yet lukewarm, into a kind of trough, in which is twenty pounds of the fineſt wheat-flower, with the yolks of eight dozen of eggs; of all which is formed into a kind of paſte, a little thicker than children's pap; which, when done, is put into another veſſel, to be uſed in the following manner.

They pour a quantity of hot water into the trough in which the paſte was prepared, mixing two ſpoonfuls of the paſte with it; to do which they uſe a wooden ſpoon, which contains juſt as much as is required for a dozen of ſkins: and when the whole is well diluted, two dozen of the ſkins are plunged into it; but they take care that the water be not too hot, which would ſpoil the paſte and burn the ſkins.

After they have lain ſome time in the trough they take them out, one after another, with the hand, and ſtretch them out; this they do twice: and after they have given them all their paſte, they put them into tubs, and there full them afreſh with wooden peſtles.

Then they put them into a vatt, where they are ſuffered to lie for five or ſix days, or more; then they take them out in fair weather, and hang them to dry on cords or racks: and the quicker they are dried the better; for if they be too long a-drying, the ſalt and alum within them are apt to make them riſe in a grain, which is an eſſential fault in this kind of dreſſing.

When the ſkins are dry, they are made up into bundles, and juſt dipt in fair water, and taken out and drained: they are then thrown into an empty tub; and after having lain ſome time are taken out and trampled under foot.

Then they draw them over a flat iron inſtrument, the top of which is round like a battledore, and the bottom fixed into a wooden block, to ſtretch and open them; and having been opened, they are hung in the air upon cords to dry; and being dry, they are opened a ſecond time, by paſſing them again over the ſame inſtrument.

In the laſt place, they are laid on a table, pulled out, and laid ſmooth, and are then fit for ſale.

TAX (*Taxa*, from the Greek ταξις, i. e. *ordo, tributum*), a tribute or impoſition laid upon the citizen or ſubject for the ſupport of government. See REVENUE.

"It is the ancient indiſputable privilege and right of the Britiſh houſe of commons, that all grants of ſubſidies or parliamentary aids do begin in that houſe, and are firſt beſtowed by them; although their grants are not effectual to all intents and purpoſes until they have the aſſent of the other two branches of the legiſlature. See COMMONS. The general reaſon given for this excluſive privilege of the houſe of commons is, that the ſupplies are raiſed upon the body of the people, and therefore it is proper that they alone ſhould have the right of taxing themſelves. This reaſon would be unanſwerable, if the commons taxed none but themſelves: but it is notorious, that a very large ſhare of property is in the poſſeſſion of the houſe of lords; that this property is equally taxable, and taxed, as the property of the commons; and therefore the commons, not being the ſole perſons taxed, this cannot be the reaſon of their having the ſole right of raiſing and modelling the ſupply. The true reaſon, ariſing from the ſpirit of the conſtitution, ſeems to be this. The lords being a permanent hereditary body, created at pleaſure by the king, are ſuppoſed more liable to be influenced by the crown, and when once influenced to continue ſo, than the commons, who are a temporary elective body, freely nominated by the people. It would therefore be extremely dangerous to give the lords any power of framing new taxes for the ſubject; it is ſufficient that they have a power of rejecting, if they think the commons too laviſh or improvident in their grants. But ſo reaſonably jealous are the commons of this valuable privilege, that herein they will not ſuffer the other houſe to exert any power but that of rejecting. They will not permit the leaſt alteration or amendment to be made by the lords to the mode of taxing the people by a money-bill: under which appellation are included all bills by which money is directed to be raiſed upon the ſubject, for any purpoſe or in any ſhape whatſoever; either for the exigencies of government, and collected from the kingdom in general, as the land-tax; or for private benefit, and collected in any particular diſtrict, as by turnpikes, pariſh-rates, and the like. Yet Sir Matthew Hale mentions one caſe, founded on the practice of parliament in the reign of Henry VI. wherein he thinks the lords may alter a money-bill: and that is, if the commons grant a tax, as that of tonnage and poundage, for four years; and the lords alter it to a leſs time, as for two years: here, he ſays, the bill need not be ſent back to the commons for their concurrence, but may receive the royal aſſent without farther ceremony; for the alteration of the lords is conſiſtent with the grant of the commons. But ſuch an experiment will hardly be repeated by the lords, under the preſent improved idea of the privilege of the houſe of commons; and, in any caſe where a money bill is remanded to the commons, all amendments in the mode of taxation are ſure to be rejected.

Tax.

"The commons, when they have voted a ſupply to his majeſty, and ſettled the *quantum* of that ſupply, uſually reſolve themſelves into what is called *a committee of ways and means*, to conſider the ways and means of raiſing the ſupply ſo voted. And in this committee every member (though it is looked upon as the peculiar province of the chancellor of the exchequer) may propoſe ſuch ſcheme of taxation as he thinks will be leaſt detrimental to the public. The reſolutions of this committee (when approved by a vote of the houſe) are in general eſteemed to be (as it were) final and concluſive. For though the ſupply cannot be actually raiſed upon the ſubject till directed by an act of the whole parliament, yet no monied man will ſcruple to advance to the government any quantity of ready caſh, on the credit of a bare vote of the houſe of commons, though no law be yet paſſed to eſtabliſh it.

"The taxes which are raiſed upon the ſubject are either annual or perpetual.

"I. The uſual annual taxes are thoſe upon land and malt. See LAND and MALT.

"II. The perpetual are, 1. The cuſtoms. 2. The exciſe-duty. 3. The ſalt-duty. 4. The poſt-office. 5. The ſtamp-duty. 6. Houſe and window duty. 7. The duty on hackney-coaches and chairs. 8. That on offices and penſions.—See the articles CUSTOMS, EXCISE, POST, STAMP, HOUSE, HACKNEY, and *OFFICES and Penſions*.

"As to the application of all theſe, ſee the articles REVENUE, *NATIONAL Debt*, FUNDS, and *Civil List*."

TAX-

Taxation, Taxus.

TAXATION. See REVENUE, TAX, and *FEODAL Syſtem*.

TAXUS, the YEW TREE, in botany: A genus of plants belonging to the claſs of *diœcia*, and order of *monodelphia*; and in the natural ſyſtem ranging under the 51ſt order, *Coniferæ*. The male calyx is triphyllous, gemmaceous, and imbricated: there is no corolla; the ſtamina are numerous; the antheræ peltated and octofid. The female calyx reſembles the male; there is no corolla nor ſtyle, and only one ſeed with a calycle reſembling a berry very entire. There are only two ſpecies mentioned by Linnæus, the baccata and nucifera. M. Sonnerat has added a third, called *capenſis*; and Sir Charles Thunberg has inſerted two more, the macrophylla and verticillata, in his *Flora Japonica*.

The *baccata*, or common yew tree, is a native of Britain, France, Switzerland, &c. and of North America. It is diſtinguiſhed from the other ſpecies by linear leaves which grow very cloſe, and by the receptacles of the male flowers being ſubgloboſe. The wood is reddiſh, full of veins, and flexible, very hard and ſmooth, and almoſt incorruptible. Its hardneſs renders it very proper for turners and cabinet-makers. It produces berries which are red, mucilaginous, and have a ſweet mawkiſh taſte. They are often eaten by birds, and are therefore not poiſonous: But it is a common opinion that the leaves are poiſonous to cattle, and many facts are mentioned of horſes and cows having died by eating them. Others, however, deny theſe facts. It is found in ſeveral parts of the Highlands of Scotland in a wild ſtate. At Glenlure, near Glen-Creran, in Upper-Lorn, are the remains of an old wood of it. The place takes its name from the trees which grow in it; for *Glenlure* in the Gaelic language is no other than a corruption of *Gleaniuir*, *i. e.* "The valley of yew trees." It is of no great height, but the trunk grows to a large ſize. Mr Pennant has taken notice of a very remarkable decayed one in Fortingal church-yard, the remains of which meaſured 56 feet and an half in circumference.

The yew is at preſent almoſt peculiar to church-yards; hence ſome naturaliſts ſuſpect that it is an exotic. Several reaſons have been aſſigned for its frequency in church-yards. The firſt is, that before the invention of gunpowder the warrior might never be at a loſs for a bow. This is an opinion for which we have found no hiſtorical evidence; and till ſome be produced it is conſidered merely as a conjecture. There are ſeveral laws enacted by our forefathers for encouraging archery, but none of them mention the cultivation of the yew. The bows uſed in England were indeed made frequently of yew, but it was yew of foreign growth. In the reign of Elizabeth, a bow of the beſt foreign yew ſold for 6s. 8d. while one made of Engliſh yew ſold only for 2s. In 12 Edw. IV. it was ordained that every foreign merchant that ſhould convey any goods from any country from which bow ſtaves had formerly been brought to England, ſhould for every ton of goods bring four bow ſtaves. A ſimilar law was framed in the time of Richard III. It appears therefore that the church-yards did not ſupply the nation with bows.

A ſecond opinion concerning the introduction of yew trees into church-yards is, that they were intended to defend the church againſt ſtorms. But there are many other trees that would have anſwered this purpoſe much better; for the yew is of ſo ſlow a growth, that it would be long before it could be of any ſervice at all, and is ſo low that it could never be a ſufficient ſhelter. A third opinion is, that being an evergreen, it is an emblem of immortality. This is a pretty idea; but the misfortune is, that yew is always conſidered as a tree of baleful influence. This opinion is as old as Statius, who ſays, *metuenda ſucco taxus*. A fourth opinion is, that when anciently it was the cuſtom, as it ſtill is in Catholic countries, to carry palms on Palm Sunday, the yew was ſubſtituted on ſuch occaſions for the palm. Two or three trees, the uſual number growing in church-yards, were ſufficient for ſuch purpoſes. This is the only opinion which receives any countenance from hiſtory. The following extract from Caxton's Direction for keeping Feaſts all the year, printed in 1483, will probably be conſidered as deciſive on this ſubject. It is taken out of the lecture for Palm-Sunday; where the writer, after giving the ſcriptural account of our Saviour's triumphant entrance into Jeruſalem, proceeds thus: "Wherefore holy chirche this day makyth ſolempne proceſſyon, in mynd of the proceſſyon that Cryſt made this day. But for encheſion that we have non olyue that berith grene leef, algate therefore *we take ewe in ſtede of palme and olyue*, and beren about in proceſſyon, and ſo is thys day callyd Palme Sonday." As a confirmation of this fact, we may add, that the yews in the church-yards of Eaſt Kent are at this day called *palms*.

Tay.

TAY, called by the Romans *Tavus* or *Taus*, the largeſt river in Scotland. It riſes in Braidalbane, on the frontiers of Lorn; and having in the paſſage of a few miles augmented its ſtream by the acceſſion of ſeveral ſmall rills, ſpreads itſelf into a Lake called *Loch Dochart*; out of which having run but a little ſpace, it expands itſelf again. Leaving this ſecond lake, it rolls ſome miles with a conſiderable body of water, and then diffuſes itſelf abroad in the ſpacious Loch Tay; which, reckoning from the ſources of the river, is 24 miles in length, though, ſtrictly ſpeaking, the lake is but 13: almoſt as ſoon as it iſſues from hence, it receives the river Lyon, coming out of Loch Lyon, and running through Glen Lyon; which, having travelled in a manner parallel to it, from its ſource, for a ſpace of 25 miles, at length joins the Tay as it enters Athol, which it next traverſes, and, directing its courſe in a manner due eaſt, receives almoſt all the waters of that country. Bending then to the ſouth, at the diſtance of ſix miles, it reaches Dunkeld; which, in the ancient language ſignifies "the hill of hazels," was the very centre of the old Caledonia, and is at preſent eſteemed the heart of the Highlands. The river is very broad here, inſomuch that there is a ferry-boat over it at each end of the town. Declining ſtill to the ſouth-eaſt, with a winding courſe, for above 12 miles, the Tay receives a large ſupply of waters from the county of Angus; and then running ſouth-weſt for eight miles more, is joined in that ſpace by ſeveral rivers, the moſt conſiderable of which is the Almond. Turning then to the ſouth-eaſt, at the diſtance of about three miles, this copious river comes with a ſwelling ſtream to Perth, or St Johnſton's, which is the capital of the ſhire of that name.

The Tay, continuing ſtill a ſouth-eaſt courſe, receives, a few miles below Perth, the river Erne; which, iſſuing from a loch of the ſame name, traverſes the county of Strathern, and paſſes by Abernethy, once the capital of the Pictiſh kingdom; ſwelled by the waters of this laſt river, the Tay, running next directly eaſt, enlarges itſelf till it becomes about three miles broad; but contracts again before the town of Dundee; ſoon after which it opens into the German ocean. At the entrance of the frith, there are ſands both on the north and on the ſouth ſide: the former ſtyled *Goa*, the latter *Aberlay* and *Drumlan*: and before theſe, in the very mouth of the frith, thoſe which are called the *Croſs Sands*. At Buttonneſs, which is the northern promontory, there are two light-houſes. The ſpace between the north and the ſouth ſands may be near a mile, with about three fathoms water; but being within the frith, it grows deeper, and in the road of Dundee is full ſix fathoms. The frith

of

Taylor. of Tay is not indeed ſo large or ſo commodious as that of Forth, but from Buttonneſs to Perth it is not leſs than 40 miles; and the whole may be, without any great impropriety, ſtyled a harbour, which has Fife on one ſide, and the ſhires of Perth and Angus on the other, both very fertile and pleaſant countries.

TAYLOR (Dr Jeremy), biſhop of Down and Connor in Ireland, was the ſon of a barber at Cambridge, and there had his education. Upon entering into orders, he became divinity lecturer of St Paul's in London: and was, by the intereſt of archbiſhop Laud, elected fellow of All Soul's college, Cambridge, in 1636. Two years after he became one of the chaplains of the archbiſhop, who beſtowed on him the rectory of Uppingham in Rutlandſhire. In 1642 he was chaplain to the king; and a frequent preacher before him and the court at Oxford. He afterward attended in the king's army in the condition of a chaplain. Upon the declining of his majeſty's cauſe, he retired into Wales, where he was permitted to officiate as miniſter, and to keep a ſchool, in order to maintain himſelf and his children. In this retirement he wrote ſeveral of his works. Having ſpent ſeveral years there, his family was viſited with ſickneſs; and he loſt three ſons of great hopes within the ſpace of two or three months. This affliction touched him ſo ſenſibly, that it made him deſirous to leave the country; and, going to London, he for a time officiated in a private congregation of loyaliſts to his great hazard. At length meeting with Edward lord Conway, that nobleman carried him over with him into Ireland, and ſettled him at Portmore, where he wrote his *Ductor Dubitantium*. Upon the Reſtoration he returned to England; ſoon after, he was advanced to the biſhopric of Down and Connor in Ireland; and had the adminiſtration of the ſee of Dromore granted to him. He was likewiſe made privy-counſellor and vice-chancellor of the univerſity of Dublin; which place he held till his death. He died of a fever at Liſnegarvy in 1667, and was interred in a chapel which he himſelf had built on the ruins of the old cathedral of Dromore.

TAYLOR (Dr Brook), was born at Edmonton, Auguſt 18th 1685. He was the ſon of John Taylor, Eſq; of Biſron's-houſe in Kent, by Olivia, daughter of Sir Nicholas Tempeſt, of Durham, Baronet. His grandfather, Nathaniel Taylor, was one of thoſe puritans whom "Cromwell thought fit to elect by a letter, dated June 14th 1653, to repreſent the county of Bedford in parliament." The character of his father partook in no ſmall degree of the auſterity that had been tranſmitted to him in the line of his anceſtors, and by the ſpirit of the times in which they lived; and to this cauſe may be aſcribed the diſaffection which ſometimes ſubſiſted between the father and even ſuch a ſon as is the ſubject of this article. The old gentleman's moroſe temper, however, yielded to the powers of muſic; and the moſt eminent profeſſors of the art in that period were hoſpitably welcomed in his houſe. His ſon Brook was induced by his natural genius, and by the diſpoſition of his father, which he wiſhed by all the means in his power to conciliate, to direct his particular attention to muſic; and he became in very early life a diſtinguiſhed proficient in it.—"In a large family-piece, he is repreſented at the age of 13 ſitting in the centre of his brothers and ſiſters; the two elder of whom, Olivia and Mary, crown him with laurel, bearing the inſignia of harmony."

To muſic he added another accompliſhment, in which he equally excelled. "His drawings and paintings, of which ſome are ſtill preſerved, require not thoſe allowances for error or imperfection with which we ſcan the performances of even the ſuperior *dilettanti*:—they will bear the teſt of ſcrutiny and criticiſm from artiſts themſelves, and thoſe of the firſt genius and profeſſional abilities." Though he was eminent in the culture and practice both of muſic and drawing in his early youth, his whole attention was not occupied by theſe faſcinating arts. His claſſical education was conducted at home under a private tutor; and his proficiency in the ordinary branches of the languages and the mathematics was ſo great, that he was deemed qualified for the univerſity at the early age of 15. Taylor.

In 1701 he was entered a Fellow Commoner of St John's College, Cambridge. At that period mathematics engaged more particularly the attention of the univerſity; and the examples of eminence in the learned world, derived from that branch of ſcience, attracted the notice and rouſed the emulation of every youth poſſeſſed of talents and of application. We may preſume, that Brook Taylor, from the very hour of his admiſſion at college, adopted the courſe of ſtudy which a Machin, a Keil, and, above all, a Newton, had opened to the mind of man, as leading to diſcoveries of the celeſtial ſyſtem.—That he applied early to theſe ſtudies, and without remiſſion, is to be inferred from the early notice and kind attention with which he was honoured by thoſe eminent perſons, and from the extraordinary progreſs which he made in their favourite ſcience."

In 1708 he wrote his treatiſe On the Centre of Oſcillation, which was not publiſhed in the Philoſophical Tranſactions till ſome years afterwards. In 1709, he took his degree of Bachelor of Laws. In 1712, he was choſen a Fellow of the Royal Society. During the interval between theſe two periods, he correſponded with Profeſſor Keil on ſeveral of the moſt abſtruſe ſubjects of mathematical diſquiſition. Sir William Young informs us, that he has in his poſſeſſion a letter, dated in 1712, addreſſed to Mr Machin, which contains at length a ſolution of Kepler's problem, and marking the uſe to be derived from that ſolution. In this year he preſented to the Royal Society three different papers; one On the Aſcent of Water between two Glaſs Planes; a ſecond, On the Centre of Oſcillation; and a third, On the Motion of a ſtretched ſtring. It appears from his correſpondence with Keil, that in 1713 he preſented a paper on his favourite ſubject of Muſic: but this is not preſerved in the Tranſactions.

His diſtinguiſhed proficiency in thoſe branches of ſcience, which engaged the particular attention of the Royal Society at this period, and which embroiled them in conteſts with foreign academies, recommended him to the notice of its moſt illuſtrious members; and in 1714 he was elected to the office of ſecretary. In this year he took at Cambridge his degree of Doctor of Laws; and at this time he tranſmitted, in a letter to Sir Hans Sloane, An Account of ſome curious Experiments relative to Magnetiſm; which, however, was not delivered to the Society till many years afterward, when it was printed in the Tranſactions. His application to thoſe ſtudies to which his genius inclined was indefatigable: for we find that in 1715 he publiſhed in Latin his *Methodus Incrementorum*; alſo a curious eſſay preſerved in the Philoſophical Tranſactions, entitled An Account of an Experiment for the Diſcovery of the Laws of Magnetic Attraction; likewiſe a treatiſe well known to mathematicians, and highly valued by the beſt judges, On the Principles of Linear Perſpective. In the ſame year (ſuch were his admirable talents, and ſo capable were they of being directed to various ſubjects), he conducted a controverſial correſpondence with the Count Raymond de Montmort, on the Tenets of Malebranche; which occaſioned his being particularly noticed in the eulogium pronounced by the French academy on the deceaſe of that eminent metaphyſician.

The new philoſophy of Newton (as it was then called) en-

Taylor. engaged the attention of mathematicians and philoſophers both at home and abroad. At Paris it was in high eſtimation; and the men of ſcience in that city were deſirous of obtaining a perſonal acquaintance with the learned ſecretary of the Royal Society, whoſe reputation was ſo generally acknowledged, and who had particularly diſtinguiſhed himſelf in the Leibnitzian or German controverſy as we may denominate it, of that period. In conſequence of many urgent invitations, he determined to viſit his friends at Paris in the year 1716. He was received with every poſſible token of affection and reſpect; and had an opportunity of diſplaying many traits of character, which mark the general ſcholar and accompliſhed gentleman, as well as the profound mathematician. His company was courted by all "who had temper to enjoy, or talents to improve, the charms of ſocial intercourſe." Beſides the mathematicians, to whom he had always free acceſs, he was here introduced to Lord Bolingbroke, the Count de Caylus, and Biſhop Boſſuet. "He inſpired partiality on his firſt addreſs; he gained imperceptibly on acquaintance; and the favourable impreſſions which he made from genius and accompliſhments, he fixed in further intimacy by the fundamental qualities of benevolence and integrity."

Among the ladies who honoured Dr Brook Taylor with a particular regard, we may mention the names of Marcilly de Villette, and of Miſs Brunton, the beautiful and accompliſhed niece of Sir Iſaac Newton.

Early in 1717 he returned to London, and compoſed three treatiſes, which were preſented to the Royal Society, and publiſhed in the 30th volume of the Tranſactions. About this time his intenſe application had impaired his health to a conſiderable degree; and he was under the neceſſity of repairing, for relaxation and relief, to Aix-la-Chapelle. Having likewiſe a deſire of directing his attention to ſubjects of moral and religious ſpeculation, he reſigned his office of ſecretary to the Royal Society in 1718.

After his return to England in 1719, he applied to ſubjects of a very different kind from thoſe that had employed the thoughts and labours of his more early life. Among his papers of this date, Sir William Young has found detached parts of A Treatiſe on the Jewiſh Sacrifices, and a diſſertation of conſiderable length On the Lawfulneſs of eating Blood. He did not, however, wholly neglect his former ſubjects of ſtudy, but employed his leiſure hours in combining ſcience and art; with this view he reviſed and improved his treatiſe on Linear Perſpective. Drawing continued to be his favourite amuſement to his lateſt hour; and it is not improbable, that his valuable life was ſhortened by the ſedentary habits which this amuſement, ſucceeding his ſeverer ſtudies, occaſioned.

"He drew figures with extraordinary preciſion and beauty of pencil. Landſcape was yet his favourite branch of deſign. His original landſcapes are moſtly painted in water colours, but with all the richneſs and ſtrength of oils. They have a force of colour, a freedom of touch, a varied diſpoſition of planes of diſtance, and a learned uſe of aerial as well as linear perſpective, which all profeſſional men who have ſeen theſe paintings have admired. Some pieces are compoſitions; ſome are drawn from nature; and the general characteriſtic of their effect may be exemplified, in ſuppoſing the bold fore-grounds of Salvator Roſa to be backed by the ſucceſſion of diſtances, and mellowed by the ſober harmony, which diſtinguiſhed the productions of Gaſpar Pouſſin. The ſmall figures interſperſed in the landſcapes would not have diſgraced the pencil of the correct and claſſic Nicholas."

The work of Dr Brook Taylor in linear perſpective was cenſured by Bernoulli, in a treatiſe publiſhed in the Acts of Leipſic, as "abſtruſe to all, and as unintelligible to artiſts for whom it was more eſpecially written." Taylor. It muſt be acknowledged that this excellent work, for ſo it deſerves to be called, was not level to the apprehenſions of practitioners in the art of drawing and deſign: but it was much eſteemed by mathematicians. Three editions of it have been publiſhed; and as it is now ſcarce, a republication of it in its moſt improved and perfect ſtate would be very acceptable. Mr Kirby, however, has made it more plain and popular, in his treatiſe entitled "Brook Taylor's Perſpective made eaſy;" and this book, detailing and illuſtrating the principles of the original work, has been the *vade mecum* of artiſts. Dr Brook Taylor was incenſed by the invidious attacks of Bernoulli; and he publiſhed An Apology againſt J. Bernoulli's Objections, which may be ſeen in the 30th volume of the Philoſophical Tranſactions. Bernoulli, with his uſual envy of Britiſh mathematicians, had diſputed our author's right to his own work. We have no reaſon to doubt Dr Taylor's claims to the undecided diſcovery of the method which he deſcribes, though he is not an original inventor. This method was long before publiſhed by Guido Ubaldi, in his Perſpective, printed at Peſaro in 1600; where it is delivered very clearly, and confirmed by moſt elegant demonſtrations; and where it is actually applied to the art of delineating the ſcenes of a theatre.

Toward the end of the year 1720, Dr Brook Taylor accepted the invitation of Lord Bolingbroke to ſpend ſome time at La Source, a country-ſeat near Orleans, which he held in right of his wife, the widow of the Marquis de Villette, nephew of Madame de Maintenon. During his reſidence at this beautiful ſpot, he fixed and cemented a friendſhip with its noble owners which terminated only with life.

In the next year he returned to England, and publiſhed the laſt paper which appears with his name in the Philoſophical Tranſactions, entitled, An Experiment made to aſcertain the Proportion of Expanſion of Liquor in the Thermometer, with regard to the degree of Heat.

In 1721, Dr Brook Taylor married Miſs Bridges of Wallington in the county of Surry, a young lady of good family, but of ſmall fortune; and this marriage occaſioned a rupture with his father, whoſe conſent he had never obtained. The death of this lady in 1725, and that of an infant ſon, whom the parents regarded as the preſage and pledge of reconciliation with the father, and who actually proved ſuch, deeply affected the ſenſibility of Dr Taylor. However, during the two ſucceeding years he reſided with his father at Bifrons, where "the muſical parties, ſo agreeable to his taſte and early proficiency, and the affectionate attentions of a numerous family welcoming an amiable brother, ſo long eſtranged by paternal reſentment, not only ſoothed his ſorrows, but ultimately engaged him to a ſcene of country retirement, and domeſticated and fixed his habits of life. He could no more recur to the deſultory reſources and cold ſolace of ſociety, which caſual viſits, ſlight acquaintance, and diſtant friendſhips, afford the man—who hath *none to make, and cheer a conſtant home.*"

In 1725 he formed a new connection; and with the full approbation of his father and family, married Sabetta, daughter of John Sawbridge, Eſq; of Olantigh, in Kent. In 1729, on the death of his father, he ſucceeded to the family eſtate of Bifrons. In the following year he loſt his wife in child-bed. The daughter whoſe birth occaſioned this melancholy event ſurvived and became the mother of Sir William Young, to whom we owe theſe memoirs of his grandfather.

In the interval that elapſed between the years 1721 and 1730, no production by Brook Taylor appears in the Philoſophical

Taylor, Tea.

lofophical Tranfactions; nor did he publifh in the courfe of that time any work. His biographer has found no traces of his learned labour, excepting a Treatife of Logarithms, which was committed to his friend Lord Paifley (afterward Abercorn), in order to be prepared for the prefs; but which probably was never printed. His health was now much impaired; relaxation became neceffary, and he was diverted by new connections from the habit of fevere ftudy, which had diftinguifhed the early period of his life, and which had contributed to contract the duration of it. Happy in the focial circle of domeftic enjoyment, and devoting his attention to bufinefs or amufement as they occurred, his application and his literary emulation feem to have declined. He did not long furvive the lofs of his fecond wife; and his remaining days were days of increafing imbecillity and forrow.

"The eflay entitled *Contemplatio Philofophica*, publifhed by Sir William Young, 1793, appears to have been written about this time, and probably with a view to abftract his mind from painful recollections and regret. It was the effort of a ftrong mind, and is a moft remarkable example of the clofe logic of the mathematician applied to metaphyfics. But the blow was too deep at heart for ftudy to afford more than temporary relief. The very refource was hurtful, and intenfe ftudy but accelerated the decline of his health. His friends offered every comfort; in particular Lord Bolingbroke preffed his confolation, and fought to call his mind from regret of domeftic endearments to focial friendfhip at Dawley.

The attention and kindnefs of his friends, however, could not ward off the approaches of diffolution. "Having furvived his fecond wife little more than a year, Dr Brook Taylor died of a decline in the 46th year of his age, December the 29th 1731, and was buried in the church-yard of St Ann's, Soho. I am fpared (fays his defcendant) the neceffity of clofing this biographical fketch with a prolix detail of his character: in the beft acceptation of duties relative to each fituation of life in which he was engaged, his own writings, and the writings of thofe who beft knew him, prove him to have been the finifhed Chriftian, gentleman, and fcholar."

Taylor (Dr John), a learned diffenting minifter, born in Lancafhire. He fettled firft at Kirkftead in Lincolnfhire, where he preached to a fmall congregation, and taught a grammar-fchool for near 20 years. Afterwards he removed to Norwich, where he preached many years in great repute, until he was invited to fuperintend the academy formed at Warrington in Lancafhire: but a few idle differences on formal punctilios and uncertain doctrines kindled into fuch a flame there, as fubjected him to much fcurrility and ill treatment, and endangered the very being of the academy. He died in 1761; and among feveral other judicious performances, his Hebrew and Engliſh Concordance, 2 vols folio, will remain a monument of his critical fkill and indefatigable induftry.

TEA, the dried leaves of the tea plant.—A commodity with which we are fo well acquainted, which affords a beverage fo generally ufed and fo generally agreeable, and which forms fo conſiderable an article of commerce, muft excite the curiofity of the public at large to know fomething of its hiftory, and of the nature of the plant from which it is obtained. We are forry that we can neither gratify their curiofity nor our own completely. We have conſulted all the botanical books to which we had acceſs, and we believe we have had acceſs to the beſt, yet we have not been able to diſcover with certainty whether there be various ſpecies of the tea plant; or whether all the different kinds of tea, ſo unlike to one another in their flavour, and ſtrength, and colour, be derived from one ſingle ſpecies. As an apology for this imperfection in botanical knowledge, it is proper to obſerve, that the country of which the tea plant is a native is hidden from the exploring eye of the philoſopher; that it is jealous of Europeans, and ſeldom gives them an opportunity of ſtudying its productions. While we apologize for the ignorance of Europeans in this point, and ſincerely regret it, we ſhall be careful to ſelect every important fact, that we may preſent our readers with as accurate and complete an account as our materials can ſupply. Tea.

The tea plant is a native of Japan, China, and Tonquin, and has not, as far as we can learn, been found growing ſpontaneouſly in any other parts of the world. Linnæus arranged it under the claſs of *polyandria*, and order of *monogynia*. We are told he was led into this miſtake from having no ſpecimens of the flower to examine but ſuch as were dried. If Linnæus has in this arrangement fallen into error, it is ſurpriſing that he has not been corrected by one who had the beſt opportunity of examining the matter. Sir Charles Thunberg, one of the moſt diſtinguiſhed pupils of that illuſtrious botaniſt, who reſided 16 months in Batavia and Japan, has given a full botanical deſcription of the tea plant; and having claſſed it in the ſame manner as his maſter, ſays expreſsly that it has only one ſtyle. Several of the Britiſh botaniſts, on the other hand, refer it to the order of *trigynia*; deriving their authority from a plant in the Duke of Northumberland's garden at Sion-houſe, which had three ſtyles.

Linnæus ſays that there are two ſpecies of the tea plant; the *bohea*, the corolla of which has ſix petals; and the *viridis* or green tea, which has nine petals. Thunberg makes only one ſpecies, the bohea, conſiſting of two varieties: the one with broad and the other with narrow leaves. This botaniſt's authority is deciſive reſpecting the Japaneſe tea plants; but as China has not yet been explored, we cannot determine what number of ſpecies there are in that country. Of the bohea plant we have been favoured with a beautiful drawing, and an accurate botanical deſcription, by a learned gentleman, which we ſhall here preſent to our readers.

Calyx. K, fig. 1, 2, 3, 10. a perianthium quinquepartite, very ſmall, flat, the ſegments round, obtuſe, permanent. Fig. 1. K.

Corolla. C, fig. 1, 3, 4, 5, 7, 8. the petals ſix, roundiſh, concave; two exterior (fig. 4, 7.) CC; leſs, unequal, incloſing the flower before fully blown (fig. 3.) C; four interior (fig. 5, 6.) CCCC; large, equal, before they fall off recurvate (fig. 8.) CC; (A).

Stamens. *f*, fig. 6, 9, 10, 11. the filaments numerous (B) fig. 6, 9. *f a*; about 200; filiform, white, ſhorter than the corolla, and inſerted in the receptacle; *a*, the antheras cordate; and didymous (fig. 10, 11.) *, magnified (C).

Piſtillum. Fig. 1, 10, 12. * magnified; *g*, the germen, three globular bodies joined in a triangular form; *s*, the ſtyles, three, connected at their baſe (fig. 12.); ſubulate, re-

(A) Thunberg ſays, that three of the petals are exterior and three inferior.
(B) In a flower received from J. Ellis, Eſq; upwards of 280 filaments were told.
(C) Kempfer deſcribes the antheras as ſingle.

The tea plant, which is an evergreen, grows to the height of five or ſix feet; Le Compte ſays ten or twelve. The leaves, which are the only valuable part of it, are about an inch and a half long, narrow, indented, and tapering to a point, like thoſe of the ſweet briar, and of a dark green colour. The root is like that of the peach tree, and its flowers reſemble thoſe of the white wild roſe. The ſtem ſpreads into many irregular branches. The wood is hard, of a whitiſh green colour, and the bark is of a greeniſh colour, with a bitter, nauſeous, and aſtringent taſte. The fruit is ſmall, and contains ſeveral round blackiſh ſeeds, about the bigneſs of a bean or large pea.

This plant delights in valleys, is frequent on the ſloping ſides of mountains and the banks of rivers, where it enjoys a ſouthern expoſure. It flouriſhes in the northern latitudes of Pekin as well as round Canton, but attains the greateſt perfection in the mild temperate regions of Nankin. It is ſaid only to be found between the 30th and 45th degree of north latitude. In Japan it is planted round the borders of fields, without regard to the ſoil; but as it is an important article of commerce with the Chineſe, whole fields are covered with it, it is by them cultivated with care. The Abbé Rochen ſays, it grows equally well in a poor as in a rich ſoil; but that there are certain places where it is of a better quality. The tea which grows in rocky ground is ſuperior to that which grows in a light ſoil; and the worſt kind is that which is produced in a clay ſoil. It is propagated by ſeeds; from ſix to twelve are put into a hole about five inches deep, at certain diſtances from each other. The reaſon why ſo many ſeeds are ſown in the ſame hole is ſaid to be, that only a fifth part vegetate. Being thus ſown, they grow without any other care. Some, however, manure the land, and remove the weeds; for the Chineſe are ſo fond of good tea, and take as much pains to procure it of an excellent quality, as the Europeans do to procure excellent wine.

The leaves are not fit for being plucked till the ſhrub be of three years growth. In ſeven years it riſes to a man's height; but as it then bears but few leaves, it is cut down to the ſtem, and this produces a new crop of freſh ſhoots the following ſummer, every one of which bears nearly as many leaves as a whole ſhrub. Sometimes the plants are not cut down till they are ten years old. We are informed by Kœmpfer, that there are three ſeaſons in which the leaves are collected in the iſles of Japan, from which the tea derives different degrees of perfection. Tea.

The firſt gathering commences at the end of February or beginning of March. The leaves are then ſmall, tender, and unfolded, and not above three or four days old: theſe are called *ficki-tſiaa*, or "tea in powder," becauſe it is pulveriſed; it is alſo called *imperial tea*, being generally reſerved for the court and people of rank; and ſometimes alſo it is named *bloom tea*. It is ſold in China for 20 d. or 2 s. *per* pound. The labourers employed in collecting it do not pull the leaves by handfuls, but pick them one by one, and take every precaution that they may not break them. However long and tedious this labour may appear, they gather from 4 to 10 or 15 pounds a day.

The ſecond crop is gathered about the end of March or beginning of April. At this ſeaſon part of their leaves have attained their full growth, and the reſt are not above half their ſize. This difference does not, however, prevent them from being all gathered indiſcriminately. They are afterwards picked and aſſorted into different parcels, according to their age and ſize. The youngeſt, which are carefully ſeparated from the reſt, are often ſold for leaves of the firſt crop, or for imperial tea. Tea gathered at this ſeaſon is called *too-tſiaa*, or "Chineſe tea," becauſe the people of Japan infuſe it, and drink it after the Chineſe manner.

The third crop is gathered in the end of May or in the month of June. The leaves are then very numerous and thick, and have acquired their full growth. This kind of tea, which is called *Ben-tſiaa*, is the coarſeſt of all, and is reſerved for the common people. Some of the Japaneſe collect their tea only at two ſeaſons of the year, which correſpond to the ſecond and third already mentioned; others confine themſelves to one general gathering of their crop, towards the month of June: however, they always form afterwards different aſſortments of their leaves.

The fineſt and moſt celebrated tea of Japan is that which grows near Ud-ſi, a ſmall village ſituated cloſe to the ſea, and not far diſtant from Meaco. In the diſtrict of this village is a delightful mountain, having the ſame name, the climate of which is ſaid to be extremely favourable to the culture of tea; it is therefore incloſed by a hedge, and ſurrounded with wide ditches, which prevent all acceſs to it. The tea ſhrubs that grow on this mountain are planted in regular order, and are divided by different avenues and alleys.

The care of this place is entruſted to people who are ordered to guard the leaves from duſt, and to defend them from the inclemency of the weather. The labourers who are appointed to collect the tea abſtain from every kind of groſs food for ſome weeks before they begin, that their breath and perſpiration may not in the leaſt injure the leaves. They gather them with the moſt ſcrupulous nicety, and never touch them but with very fine gloves. When this choice tea has undergone the proceſs neceſſary for its

(D) It was this circumſtance that led Linnæus to place it under the order monogynia.

(E) No author has hitherto remarked this obvious circumſtance; even Kœmpfer ſays the leaves terminate in a ſharp point.

Tea. preparation, it is eſcorted by the ſuperintendant of the mountain and a ſtrong guard to the emperor's court, and reſerved for the uſe of the imperial family.

As the tea ſhrub grows often on the rugged banks of ſteep mountains, acceſs to which is dangerous, and ſometimes impracticable, the Chineſe, in order to come at the leaves, make uſe of a ſingular ſtratagem: Theſe ſteep places are generally frequented by great numbers of monkeys, which being irritated and provoked, to revenge themſelves tear off the branches, and ſhower them down upon thoſe who have inſulted them. The Chineſe immediately collect theſe branches, and ſtrip them of their leaves.

When the tea leaves have been collected, they are expoſed to the ſteam of boiling water; after which they are put upon plates of copper, and held over the fire until they become dry and ſhrivelled, and appear ſuch as we have them here. According to the teſtimony of Kœmpfer, tea is prepared in the ſame manner in the iſles of Japan. "There are to be ſeen there (ſays this traveller) public buildings erected for the purpoſe of preparing the freſh gathered tea. Every private perſon who has not ſuitable conveniences, or who is unacquainted with the operation, may carry his leaves thither as they dry. Theſe buildings contain a great number of ſmall ſtoves raiſed about three feet high, each of which has a broad plate of iron fixed over its mouth. The workmen are ſeated round a large table covered with mats, and are employed in rolling the tea leaves which are ſpread out upon them. When the iron plates are heated to a certain degree by the fire, they cover them with a few pounds of freſh gathered leaves, which being green and full of ſap crackle as ſoon as they touch the plate. It is then the buſineſs of the workman to ſtir them with his naked hands as quickly as poſſible, until they become ſo warm that he cannot eaſily endure the heat. He then takes off the leaves with a kind of ſhovel, and lays them upon mats. The people who are employed in mixing them, take a ſmall quantity at a time, roll them in their hands always in the ſame direction; while others keep continually ſtirring them, in order that they may cool ſooner, and preſerve their ſhrivelled figure the longer. This proceſs is repeated two or three times, and even oftener, before the tea is depoſited in the warehouſes. Theſe precautions are neceſſary to extract all the moiſture from the leaves."

The people of Japan and China generally keep their tea a year before uſing it, becauſe, when quite freſh and newly gathered, it poſſeſſes a narcotic quality which hurts the brain. Imperial tea is generally preſerved in porcelain vaſes, or in leaden or tin caniſters covered with fine mats made of bamboo. Common tea is kept in narrow-mouthed earthen pots; and coarſe tea, the flavour of which is not ſo eaſily injured, is packed up in baſkets of ſtraw.

An infuſion of tea is the common drink of the Chineſe: and indeed when we conſider one circumſtance in their ſituation, we muſt acknowledge that Providence has diſplayed much goodneſs in ſcattering this plant with ſo much profuſion in the empire of China. The water is ſaid to be unwholeſome and nauſeous, and would therefore perhaps, without ſome corrective, be unfit for the purpoſes of life. The Chineſe pour boiling water over their tea, and leave it to infuſe, as is done here; but they drink it without any mixture, and even without ſugar. The people of Japan reduce theirs to a fine powder, which they dilute with warm water until it has acquired the conſiſtence of thin ſoup. Their manner of ſerving tea is as follows: They place before the company the tea equipage, and the box in which this powder is contained; they fill the cups with warm water, and taking from the box as much powder as the point of a knife can contain, throw it into each of the cups, and ſtir it with a tooth-pick until the liquor begins to foam: it is then preſented to the company, who ſip it while it is warm. According to F. du Halde, this method is not peculiar to the Japaneſe; it is alſo uſed in ſome of the provinces of China. Tea.

The firſt European writer who mentions tea is Giovanni Botero, an eminent Italian author, who publiſhed a treatiſe about the year 1590, Of the Cauſes of the Magnificence and Greatneſs of Cities. He does not indeed mention its name, but deſcribes it in ſuch a manner that it is impoſſible to miſtake it. "The Chineſe (ſays he) have an herb out of which they preſs a delicate juice, which ſerves them for drink inſtead of wine: it alſo preſerves their health, and frees them from all thoſe evils which the immoderate uſe of wine produces among us *."

* Anderſon's Commerce, vol. ii. p. 138.

Tea was introduced into Europe in the year 1610 by the Dutch Eaſt India Company. It is generally ſaid, that it was firſt imported from Holland into England, in 1666, by the lords Arlington and Oſſory, who brought it into faſhion among people of quality. But it was uſed in coffee-houſes before this period, as appears from an act of parliament made in 1660, in which a duty of 8 d. was laid on every gallon of the infuſion ſold in theſe places. In 1666 it was ſold in London for 60 s. *per* pound, though it did not coſt more than 2 s. 6 d. or 3 s. 6 d. at Batavia. It continued at this price till 1707. In 1715 green tea began to be uſed; and as great quantities were then imported, the price was leſſened, and the practice of drinking tea deſcended to the lower ranks.† In 1720 the French began to ſend it to us by a clandeſtine commerce. Since that period the demand has been increaſing yearly, and it has become almoſt a neceſſary of life in ſeveral parts of Europe, and among the loweſt as well as the higheſt ranks.

† Hanway's Journal.

The following table will give an idea of the quantity of tea imported annually into Great Britain and Ireland ſince 1717:

From 1717 to 1726	-	700,000 lbs.
1732 to 1742	-	1,200,000
1755 near	-	4,000,000
1766 -	-	6,000,000
1785 about	-	12,000,000
1794 from	-	16 to 20,000,000

Beſides theſe immenſe quantities imported into Britain and Ireland, much has been brought to Europe by other nations. In 1766 the whole tea imported into Europe from China amounted to 17 millions of pounds; in 1785 it was computed to be about 19 millions of pounds.‡

‡ Raynal, vol. i. and Robertſon's India.

Several reſearches have been made in Europe to determine whether the tea plant grows ſpontaneouſly; but theſe reſearches have been hitherto in vain. When Captain Cook viſited Teneriffe in his laſt voyage, Mr Anderſon his ſurgeon was informed by a gentleman of acknowledged veracity, that a ſhrub is common near Santa Cruz which agrees exactly with the deſcription given of the tea-plant by Linnæus. It is conſidered as a weed, and large quantities are rooted out of the vineyards every year: But the Spaniards who inhabit the iſland ſometimes make uſe of it, and aſcribe to it all the qualities of the tea imported from China.

Many attempts have been made to introduce this valuable plant into Europe; but from want of proper precautions moſt of theſe attempts have miſcarried. The ſeeds, being of an oily nature, are apt to grow rancid during a long voyage, unleſs proper care is taken to preſerve them. There are two methods of preſerving theſe ſeeds: The firſt is, to incloſe them in wax after they have been dried in the ſun; the ſecond is, to leave them in their huſks, and ſhut them up cloſely in a box made of tin: but neither of theſe methods has been attended with general ſucceſs, whatever

care

Tea. care has been taken to obtain freſh ſeeds, or to preſerve them. The beſt method would be, to ſow freſh ſeeds in fine light earth immediately on leaving Canton, and to cover them with wire to ſecure them from rats and other animals that might attack them. The boxes ought not to be too much expoſed to the air, nor to that kind of dew which riſes from the ſea. The earth in the boxes muſt neither be hard nor dry, and ſhould from time to time be gently watered with freſh or rain water; and when the ſhoots begin to appear, they ought to be kept in a ſlight moiſture, and ſheltered from the ſun. The tea-plants to be found in England have been procured by theſe means only; and though ſeveral of the young riſing roots periſhed, the laſt method propoſed is probably that which may be followed with greateſt ſucceſs.

The fineſt tea-plant known in England was raiſed in Kew gardens; it was carried thither by Sir J. Ellis, who brought it from ſeed: but the firſt that ever flouriſhed in Europe was one belonging to the Duke of Northumberland at Sion, from a drawing of which our engraving is taken. The plants which are cultivated in the gardens near London thrive well in the green-houſe during winter, and ſome ſtand that ſeaſon in the open air. Linnæus, who obtained this ſhrub in its growing ſtate, contrived to preſerve it in the open air in the northern latitude of Sweden. France has alſo procured ſome plants. There can be no doubt but they would ſucceed in many countries of Europe, if proper care were paid to their cultivation till they became inured to the climate. It will be a great advantage if we can rear that plant, which can never ſuffer ſo much from change of ſoil as from growing muſty during the long voyage from China. Beſides, the demand for tea is now become ſo great, that the Chineſe find it neceſſary, or at leaſt profitable, to adulterate it. Bad tea is now become an univerſal complaint. The Abbé Groſier tells us, that there is a kind of moſs which grows in the neighbourhood of the little city of Mang-ing-hien, which is ſold as a delicate ſpecies of tea. If this delicious commodity is adulterated in China, can we flatter ourſelves that none comes to us but what is pure and unmixed? How would our fine ladies like to be told, that inſtead of tea they drink nothing but the infuſion of moſs from the rocks of Mang-ing-hien (F)?

Of the chemical qualities and effects of tea on the conſtitution, many various and oppoſite opinions have been formed. About a century ago, Bontikoe, a Dutch phyſician, beſtowed extravagant encomiums on the benefits of tea. With him it was good for every thing; and any quantity might be drunk, even to the amount of 200 diſhes in a day. Whether Bontikoe in this caſe acted as a phyſician, or, being a Dutchman, was eager to encourage the ſale of an important article of his country's commerce, is not eaſy to ſay. On the other hand, the pernicious effects of tea upon the nervous ſyſtem have been often repeated, and very oppoſite effects have been aſcribed to it. Some affirm that green tea is mildly aſtringent; others ſay it is relaxing: Some ſay it is narcotic, and procures ſleep; while others contend, that taken before bed-time it aſſuredly prevents it. Tea.

Dr Lettſom, who has written the Natural Hiſtory of the Tea Tree, made ſeveral experiments to determine its chemical qualities. He found an infuſion of it preſerved beef freſh; it is therefore antiſeptic: and from its ſtriking a purple colour with the ſalt (ſulphate) of iron, he juſtly concludes that it is aſtringent. He concludes alſo, that the eſſential qualities of tea reſide in its fragrant and volatile parts.

We have heard much of the bad effects of tea, but we have neither felt nor obſerved it. If it were ſo pernicious as it has been repreſented by ſome, its effects muſt certainly be evident in China, where it is drunk by all ranks; yet ſo far from being thought hurtful in that country, it is in high eſtimation. The preſent emperor has compoſed a kind of eloge on the virtues of tea. We are told by thoſe who have written the hiſtory of China, that inflammatory diſeaſes are leſs frequent there than in many other countries, which is aſcribed ſolely to the liberal uſe of tea. It muſt be obſerved by all, that tea is an antidote againſt intemperance, and that he who reliſhes the one ſeldom runs into the other. Raynal ſays, that tea has contributed more to the ſobriety of this nation than the ſevereſt laws, the moſt eloquent harangues of Chriſtian orators, or the beſt treatiſes of morality. We have no doubt but it may be hurtful to ſome conſtitutions in particular circumſtances; but we ſuſpect that the nervous diſorders ſo often attributed to tea, are rather owing to hereditary diſeaſes, to want of exerciſe, and to irregularity in food or ſleep, than to tea. "Weak tea drunk too hot (ſays Dr Leake) will enervate, and if very ſtrong, may prove equally pernicious by affecting the head or ſtomach. But when it is drunk in moderation, and not too warm, with a large addition of milk, I believe it will ſeldom prove hurtful, but, on the contrary, ſalutary. After ſtudy or fatigue it is a moſt refreſhing and grateful repaſt; it quenches thirſt, and cheers the ſpirits, without heating the blood; and the pleaſing ſociety, in which we ſo often partake of it, is no inconſiderable

(F) There is very good reaſon to believe, that the adulteration of tea is not confined to China. It is practiſed, and often with too much ſucceſs, among ourſelves. Mr Twining, a conſiderable tea-dealer in London, publiſhed a pamphlet ſome years ago, in which he has expoſed this infamous traffic. The information (he ſays) was obtained from a gentleman who had made very accurate inquiries into this ſubject.

The ſmouch for mixing with black teas is made of the leaves of the aſh. When gathered, they are firſt dried in the ſun, then baked: they are next put upon a floor, and trod upon until the leaves are ſmall, then ſifted and ſteeped in copperas with ſheeps dung; after which, being dried on a floor, they are fit for uſe. There is alſo another mode: When the leaves are gathered, they are boiled in a copper with copperas and ſheeps dung; when the liquor is ſtrained off, they are baked and trod upon, until the leaves are ſmall, after which they are fit for uſe. The quantity manufactured at a ſmall village, and within eight or ten miles thereof, cannot be aſcertained, but is ſuppoſed to be about 20 tons in a year. One man acknowledges to have made 600 weight in every week for ſix months together. The fine is ſold at 4 l. 4 s. *per* cwt. equal to 9d. *per* lb. The coarſe is ſold at 2 l. 2 s. *per* cwt. equal to 4½d. *per* lb. Elder buds are manufactured in ſome places to repreſent fine teas.

For the honour of human nature, we hope ſuch a traffic as this is not very common; but if it be, thoſe concerned in it deſerve exemplary puniſhment. The only way (Mr Twining ſays) to eſcape this adulterated tea, is never to purchaſe from thoſe who offer their teas to ſale at lower prices than genuine teas can be afforded; but to purchaſe them only from perſons of character.

Tea, Teachers.

addition to its value; for whatever affords rational pleasure to the mind, will always contribute to bodily health.

In this country teas are generally divided into three kinds of green, and five of bohea: The former are, 1. Imperial or bloom tea, with a large loose leaf, light green colour, and a faint delicate smell. 2. Hyson, so called from the name of the merchant who first imported it; the leaves of which are closely curled and small, of a green colour, verging to a blue: And, 3. Singlo tea, from the name of the place where it is cultivated. The boheas are, 1. Souchong, which imparts a yellow green colour by infusion. 2. Camho, so called from the place where it is made; a fragrant tea, with a violet smell: its infusion pale. 3. Congo, which has a larger leaf than the following, and its infusion somewhat deeper, resembling common bohea in the colour of the leaf. 4. Pekoe tea; this is known by the appearance of small white flowers mixed with it. 5. Common bohea, whose leaves are of one colour. There are other varieties, particularly a kind of green tea, done up in roundish balls, called *gun-powder tea*.

Tea-Tree of New Zealand, is a species of myrtle, of which an infusion was drunk by Captain Cook's people in their voyages round the world. Its leaves were finely aromatic, astringent, and had a particular pleasant flavour at the first infusion; but this went off at the next filling up of the tea-pot, and a great degree of bitterness was then extracted; for which reason it was never suffered to be twice infused. In a fine soil in thick forests this tree grows to a considerable size; sometimes 30 or 40 feet in height, and one foot in diameter. On a hilly and dry exposure it degenerates into a shrub of five or six inches; but its usual size is about eight or ten feet high, and three inches in diameter. In that case its stem is irregular and unequal, dividing very soon into branches, which rise at acute angles, and only bear leaves and flowers at top. The flowers are white, and very ornamental to the whole plant.

Mr White, in his Journal of a Voyage to New South Wales, mentions a shrub which he calls a *tea-tree*, merely from its being used by the convicts as a succedaneum for tea; for he had not seen the flower, nor did he know to what genus it belonged. It is a creeping kind of a vine, running to a great extent along the ground; the stalk slender; the leaf not so large as the common bay leaf; the taste sweet, exactly like the liquorice root of the shops.

TEACHERS, persons employed in conducting the education of the young.

"We will venture to say, that there is no class of men to whom a nation is so much indebted as to those employed in instructing the young: For if it be education that forms the only distinction between the civilized and the savage, much certainly is due to those who devote themselves to the office of instruction. It must be the duty therefore of every state to take care that proper encouragement be given to those who undertake this office. There ought to be such a salary as would render it an object of ambition to men of abilities and learning, or at least as would keep the teacher respectable. In Scotland, the office of a schoolmaster was formerly much more lucrative than at present, and most of that class had received liberal education; and this is the reason why the common people in Scotland have been famous, even to a proverb, for their learning. But at present the salary of a country schoolmaster, independent of fees for scholars, is not greater than a ploughman can earn, being seldom more than L. 8 : 6 : 8, the consequence of which is, that this, which is in fact an honourable, because an useful profession, is now sinking into contempt. It is no longer an object to a man of learning; and we must soon be satisfied with schoolmasters that can read, write, and cast accounts, a little better, than the lowest of the people, or who from some natural deformity are unable to exercise a trade. And what in this case must become of the minds of the common people? They must be totally uncultivated. Teachers; Trees.

"We have observed a great difference between the cultivation of the common people in one part of Scotland compared with another; and we have found, that wherever a schoolmaster is looked upon as a mean profession, there is scarcely a duly qualified person to be found to undertake the office; and in those places the common people are lamentably ignorant. In other places again, where the schoolmaster is considered as one of the principal persons in the parish, there men of a liberal education, young divines, and preachers, do not think themselves disgraced by exercising this profession; and there the common people show a degree of acuteness, knowledge, and observation, and possess such polished manners, as raise them very high above those of their own rank in other parts of the country.

"Many and keen have been the debates about a reform of government of late years; but little attention has been paid to the formation of the minds of the common people, who constitute the greater part of the nation; of course they are ready to join the standard of every seditious demagogue who sounds the alarm of oppression; and should they at length be roused, their cruelty and barbarity, like the common people of France, would be exactly in proportion to their ignorance and want of principle.

"We are willing to hope, then, that the government and the monied men of the nation, who alone have property to lose and money to bestow, will at length find it to be their interest to patronize schoolmasters."

TEAL, in ornithology. See ANAS.

TEARS, a lymph or aqueous humour, which is limpid, and a little saltish: it is separated from the arterial blood by the lachrymal glands and small glandulous grains on the inside of the eyelids.

TEASELS, a plant cultivated in the west of England for the use of clothiers. See DIPSACUS.

TEBETH, the tenth month of the Jewish ecclesiastical year, and fourth of the civil. It answers to our month of December.

TECKLENBURG, a town of Germany, in the circle of Westphalia, capital of a county of the same name, with a castle built on a hill. It was bought by the king of Prussia in 1707. E. Long. 8. 2. N. Lat. 52. 20.

TECHNICAL, expresses somewhat relating to arts or sciences: in this sense we say technical terms. It is also particularly applied to a kind of verses wherein are contained the rules or precepts of any art, thus digested to help the memory to retain them; an example whereof may be seen in the article MEMORY.

TECTONA, in botany; a genus of plants belonging to the class of *pentandria*, and order of *monogynia*. The stigma is dentate; the fruit a dry spongy plum within an inflated calyx; and the nucleus is trilocular. There is only one species, the *grandis*, Indian oak, or teak wood, which is a native of India.

TE DEUM, the name of a celebrated hymn, used in the Christian church, and so called because it begins with these words, *Te Deum laudamus*, We praise thee, O God. It is sung in the Romish church with great pomp and solemnity upon the gaining of a victory, or other happy event; and is believed to be the composition of St AMBROSE bishop of *Milan*.

TEES, a river which rises on the confines of Cumberland,

Teeth || Teff.

land, and running eaſtward, divides the county of Durham from Yorkſhire, and falls into the German ſea below Stockton.

TEETH, the bones placed in the jaws for chewing food, that it may be the more eaſily digeſted in the ſtomach. The anatomical ſtructure of theſe has already been deſcribed under ANATOMY and COMPARATIVE ANATOMY. The diſeaſes to which they are liable, as well as the moſt ſucceſsful remedies for removing them, are fully detailed under MEDICINE and SURGERY, to which we refer the reader.

Much attention has been paid to the beauty and preſervation of the teeth among moſt nations. The Romans rubbed and waſhed them with great care; and when they loſt them, ſupplied their place with artificial teeth made of ivory; and ſometimes, when looſe, bound them with gold. Ligatures of wire have been found to hurt the natural teeth with which the artificial are connected: whereas ſilken twiſt cannot affect them to any conſiderable degree for ſeveral years.

Guilleman gives us the compoſition of a paſte for making artificial teeth, which ſhall never grow yellow: the compoſition is white wax granulated, and melted with a little gum elemi, adding powder of white maſtich, coral and pearl.

When ſeveral teeth are out in the ſame place, it is beſt to make a ſet, or the number wanted, out of one piece, all adhering together, which may be faſtened to the two next of the ſound or natural teeth. And even a whole ſet of artificial teeth may be made for one or both jaws, ſo well fitted to admit of the neceſſary motions, and ſo conveniently retained in the proper ſituation by means of ſprings, that they will anſwer every purpoſe of natural teeth, and may be taken out, cleaned and replaced, by the patient himſelf with great eaſe.

The common trick of mountebanks and other ſuch practitioners, is to uſe various waſhes for the teeth, the ſudden effects of which, in cleaning and whitening the teeth, ſurpriſe and pleaſe people; but the effects are very pernicious. All the ſtrong acid ſpirits will do this. As good a mixture as any thing can be, on this occaſion, is the following: take plantane-water an ounce, honey of roſes two drams, muriatic acid ten drops; mix the whole together, and rub the teeth with a piece of linen rag dipped in this every day till they are whitened. The mouth ought to be well waſhed with cold water after the uſe of this or any other acid liquor; and indeed the beſt of all teeth-waſhes is cold water, with or without a little ſalt; the conſtant uſe of this will keep them clean and white, and prevent them from aching.

After all the numerous cures which have been propoſed for preventing the toothach, we will venture to recommend the keeping the teeth clean as the moſt efficacious, and avoiding every kind of hot food, eſpecially hot liquids, as tea, &c. They who are conſtantly uſing powders generally deſtroy their teeth altogether, as the valetudinarian does his health.

TEETHING in children. See MEDICINE.

TEFF, a kind of grain, ſown all over Abyſſinia, from which is made the bread commonly uſed throughout the country. We have no deſcription of this plant but from Mr Bruce, who ſays that it is herbaceous; and that from a number of weak leaves ſurrounding the root proceeds a ſtalk of about 28 inches in length, not perfectly ſtraight, ſmooth but jointed or knotted at particular diſtances. This ſtalk is not much thicker than that of a carnation or jellyflower. About eight inches from the top, a head is formed of a number of ſmall branches, upon which it carries the fruit and flowers; the latter of which is ſmall, of a crimſon colour, and ſcarcely perceptible by the naked eye but from the oppoſition of that colour. The piſtil is divided into two, ſeemingly attached to the germ of the fruit, and has at each end ſmall capillaments forming a bruſh. The ſtamina are three in number; two on the lower ſide of the piſtil, and one on the upper. Theſe are each of them crowned with two oval ſtigmata, at firſt green, but after crimſon. The fruit is formed in a capſula, conſiſting of two conical hollow leaves, which, when cloſed, ſeem to compoſe a ſmall conical pod, pointed at the top. The fruit or ſeed is oblong, and is not ſo large as the head of the ſmalleſt pin; yet it is very prolific, and produces theſe ſeeds in ſuch quantity as to yield a very abundant crop in the quantity of meal. Teff, Tefflis.

Our author, from the ſimilarity of the names, conjectures it to be the *tipha* mentioned, but not deſcribed, by Pliny; but this conjecture, which he acknowledges to be unſupported, is of very little importance.

There are three kinds of meal made from teff, of which the beſt (he ſays) is as white as flour, exceedingly light, and eaſily digeſted; the ſecond is of a browner colour; and the laſt, which is the food of ſoldiers and ſervants, is nearly black. This variety he imagines to ariſe entirely from the difference of ſoils in which the ſeeds are ſown, and the different degrees of moiſture to which the plant is expoſed when growing. The manner of making the meal or flour into bread is by taking a broad earthen jar, and having made a lump of it with water, they put it into the earthen jar at ſome diſtance from the fire, where it remains till it begins to ferment or turn ſour; they then bake it into cakes of a circular form, and about two feet in diameter: it is of a ſpongy ſoft quality, and not a diſagreeable ſouriſh taſte. Two of theſe cakes a-day, and a coarſe cotton cloth once a-year, are the wages of a common ſervant.

At their banquets of raw meat, the fleſh being cut in ſmall bits, is wrapt up in pieces of this bread, with a proportion of foſſil ſalt and Cayenne pepper. Before the company ſits down to eat, a number of theſe cakes of different qualities are placed one upon the other, in the ſame manner as our plates, and the principal people ſitting firſt down, eat the white teff; the ſecond or coarſer ſort ſerves the ſecond rate people that ſucceed them, and the third is for the ſervants. Every man, when he has done, dries or wipes his fingers upon the bread which he is to leave for his ſucceſſor, for they have no towels; and this is one of the moſt beaſtly cuſtoms among them.

Of this teff bread the natives make a liquor, by a proceſs which our author deſcribes in the following words: The bread, when well toaſted, is broken into ſmall pieces, which are put into a large jar, and have warm water poured upon them. It is then ſet by the fire, and frequently ſtirred for ſeveral days, the mouth of the jar being cloſe covered. After being allowed to ſettle three or four days, it acquires a ſouriſh taſte, and is what they call *bouza*, or the common beer of the country. The bouza in Atbara is made in the ſame manner, only inſtead of teff, cakes of barley-meal are employed. Both are very bad liquors, but the worſt is that made of barley.

TEFFLIS, or TIFFLIS, a town of Aſia, in Georgia, one of the ſeven nations between the Black Sea and the Caſpian. It is the capital of that country, the place of reſidence of its ſovereign, and is called by the inhabitants *Thilis-Cabar*, "warm town," from the warm baths in its neighbourhood. Though its circumference does not exceed two Engliſh miles, it contains 20,000 inhabitants, of which more than one half are Armenians; the remainder are principally Georgians, with ſome Tartars. According to Major Rennel, it has 20 Armenian and 15 Greek churches, and three metſheds. But Mr Coxe, on the authority of Profeſſor Gul-

Tefflis || Telegraph.

Guldenſtaedt, ſtates the places of worſhip to be one Roman Catholic, 13 Greek, and ſeven Armenian churches. There are ſome magnificent caravanſeras, bazars, and palaces in the city, but no moſques; for the Georgians, though living under a Mohammedan government, have always riſen up in arms as often as any attempts have been made to erect ſuch places of Mohammedan worſhip. Many of the Romiſh miſſionaries live here in diſguiſe under the denomination of phyſicians, ſurgeons, and chemiſts; and the great cures which they perform procure them much eſteem, though they are ſometimes expoſed to the inſults of the people when they attempt to make any proſelytes to their church. All the houſes are of ſtone, with flat roofs, which ſerve, according to the cuſtom of the Eaſt, as walks for the women. They are neatly built; the rooms are wainſcotted, and the floors ſpread with carpets. The ſtreets ſeldom exceed ſeven feet in breadth; and ſome are ſo narrow as ſcarcely to allow room for a man on horſeback: they are conſequently very filthy.

Tefflis is a place of conſiderable trade, eſpecially in furs, which are conveyed hence to Conſtantinople by the way of Erzerum. As for the ſilks of this country, they are bought up on the ſpot by the Armenians, and conveyed to Smyrna and other ports of the Mediterranean; but the greateſt part is firſt ſent to Erzerum to be manufactured, the Georgians being very ignorant and unſkilful in that reſpect. From hence, likewiſe, great quantities of a root called *bøya* is ſent to Erzerum and Indoſtan for the uſe of the linen dyers. Here is likewiſe a foundery, at which are caſt a few cannon, mortars, and balls, all of which are very inferior to thoſe of the Turks. The gunpowder made here is very good. The Armenians have likewiſe eſtabliſhed in this town all the manufactures carried on by their countrymen in Perſia: the moſt flouriſhing is that of printed linens. Tefflis is ſeated on the river Kur, at the foot of a mountain; and on the ſouth ſide of it ſtands a large caſtle or fortreſs, built by the Turks in 1576, when they made themſelves maſters of the city and country, under the command of the famous Muſtapha Pacha. It is 125 miles weſt of Terki. E. Long. 63. 3. N. Lat. 41. 59.

TEGERHY, a principal town in Fezzan, in Africa, about 80 miles ſouth-weſt of the capital. It collects from its lands little other produce than dates and Indian corn. In this, as in every town in Fezzan, a market for butcher-meat, corn, fruit, and vegetables, is regularly held. Mutton and goat's fleſh are ſold by the quarter without weighing; the uſual price is from 32 to 40 grains of gold-duſt, or four or five ſhillings Engliſh money. The fleſh of the camel, which is much more highly valued, is commonly ſold at a dearer rate, and is divided into ſmaller lots. Agriculture and paſturage ſeem to be the principal occupations.

TEGUMENT, any thing that ſurrounds or covers another.

TEIND in Scots law. See Law, N° clxx.

Commiſſion of Teinds. See Commission.

TEINTS, and Semiteints, in painting, denote the ſeveral colours uſed in a picture, conſidered as more or leſs high, bright, deep, thin, or weakened and diminiſhed, &c. to give the proper relievo, ſoftneſs, or diſtance, &c. of the ſeveral objects.

TELEGRAPH (derived from τηλε and γραφω), is the name very properly given to an inſtrument, by means of which information may be almoſt inſtantaneouſly conveyed to a conſiderable diſtance.

The telegraph, though it has been generally known and uſed by the moderns only for a few years, is by no means a modern invention. There is reaſon to believe that amongſt the Greeks there was ſome ſort of telegraph in uſe. The burning of Troy was certainly known in Greece very ſoon after it happened, and before any perſon had returned from thence. Now that was altogether ſo tedious a piece of buſineſs, that conjecture never could have ſupplied the place of information. A Greek play begins with a ſcene, in which a watchman deſcends from the top of a tower in Greece, and gives the information that Troy was taken. "I have been looking out theſe ten years (ſays he) to ſee when that would happen, and this night it is done." Of the antiquity of a mode of conveying intelligence quickly to a great diſtance, this is certainly a proof. Telegraph.

The Chineſe, when they ſend couriers on the great canal, or when any great man travels there, make ſignals by fire from one day's journey to another, to have every thing prepared; and moſt of the barbarous nations uſed formerly to give the alarm of war by fires lighted on the hills or riſing grounds.

Polybius calls the different inſtruments uſed by the ancients for communicating information πυρσειαι *pyrſiæ*, becauſe the ſignals were always made by means of fire. At firſt they communicated information of events merely by torches; but this method was of little uſe, becauſe it was neceſſary before-hand to fix the meaning of every particular ſignal. Now as events are exceedingly various, it was impoſſible to expreſs the greater number of them by any premeditated contrivance. It was eaſy, for inſtance, to expreſs by ſignals that a fleet had arrived at ſuch a place, becauſe this had been foreſeen, and ſignals accordingly had been agreed upon to denote it; but an unexpected revolt, a murder, and ſuch accidents, as happen but too often, and require an immediate remedy, could not be communicated by ſuch ſignals; becauſe to foreſee them was impoſſible.

Æneas, a contemporary of Ariſtotle, who wrote a treatiſe on the duties of a general, endeavoured to correct thoſe imperfections, but by no means ſucceeded. "Thoſe (ſays he) who would give ſignals to one another upon affairs of importance, muſt firſt prepare two veſſels of earth, exactly equal in breadth and depth; and they need be but four feet and a half deep, and a foot and a half wide. They then muſt take pieces of cork, proportioned to the mouth of theſe veſſels, but not quite ſo wide, that they may be let down with eaſe to the bottom of theſe veſſels. They next fix in the middle of this cork a ſtick, which muſt be of equal ſize in both theſe veſſels. This ſtick muſt be divided exactly and diſtinctly, by ſpaces of three inches each, in order that ſuch events as generally happen in war may be writ on them, For example, on one of theſe ſpaces the following words may be writ: 'A body of horse are marched into the country.' On another, 'A body of infantry, heavily armed, are arrived hither.' On a third, 'Infantry lightly armed.' On a fourth, 'Horse and foot.' On another, 'Ships,' then 'Provisions;' and ſo on till all the events which may probably happen in the war that is carrying on are writ down in theſe intervals. Polybius, book x. chap. 40.

"This being done, each of the two veſſels muſt have a little tube or cock of equal bigneſs, to let out the water in equal proportion. Then the two veſſels muſt be filled with water; the pieces of cork, with their ſticks thruſt through them, muſt be laid upon them, and the cocks muſt be opened. Now, it is plain, that as theſe veſſels are equal, the corks will ſink, and the ſticks deſcend lower in the veſſels, in proportion as they empty themſelves. But to be more certain of this exactneſs, it will be proper to make the experiment firſt, and to examine whether all things correſpond and agree together, by an uniform execution on both ſides. When they are well aſſured of this, the two veſſels muſt be carried to the two places where the ſignals are to be made

Telegraph. and obſerved: water is poured in, and the corks and ſticks are put in the veſſels. When any of the events which are written on the ſticks ſhall happen, a torch or other light is raiſed, which muſt be held aloft till ſuch time as another is raiſed by the party to whom it is directed. (This firſt ſignal is only to give notice that both parties are ready and attentive.) Then the torch or other light muſt be taken away, and the cocks ſet open. When the interval, that is, that part of the ſtick where the event of which notice is to be given or written, ſhall be fallen to a level with the veſſels, then the man who gives the ſignal lifts up his torch; and on the other ſide, the correſpondent ſignal-maker immediately turns the cock of his veſſel, and looks at what is writ on that part of the ſtick which touches the mouth of the veſſel: on which occaſion, if every thing has been executed exactly and equally on both ſides, both will read the ſame thing."

This method was defective, becauſe it could not convey any other intelligence except what was written on the ſticks, and even that not particularly enough. With regard to all unforeſeen events, it was quite uſeleſs.

Polybius, ibid. A new method was invented by Cleoxenus (others ſay by Democlitus), and very much improved by Polybius, as he himſelf informs us. He deſcribes this method as follows: Take the letters of the (Greek) alphabet, and divide them into five parts, each of which will conſiſt of five letters, except the laſt diviſion, which will have only four. Let theſe be fixed on a board in five columns. The man who is to give the ſignals is then to begin by holding up two torches, which he is to keep aloft till the other party has alſo ſhown two. This is only to ſhow that both ſides are ready. Theſe firſt torches are then withdrawn. Both parties are provided with boards, on which the letters are diſpoſed as formerly deſcribed. The perſon then who gives the ſignal is to hold up torches on the left to point out to the other party from what column he ſhall take the letters as they are pointed out to him. If it is to be from the firſt column, he holds up one torch; if from the ſecond, two; and ſo on for the others. He is then to hold up torches on the right, to denote the particular letter of the column that is to be taken. All this muſt have been agreed on before-hand. The man who gives the ſignals muſt have an inſtrument (διοπτραν), conſiſting of two tubes, and ſo placed as that, by looking through one of them, he can ſee only the right ſide, and through the other only the left, of him who is to anſwer. The board muſt be ſet up near this inſtrument; and the ſtation on the right and left muſt be ſurrounded with a wall (παραπεφραχθαι) ten feet broad, and about the height of a man, that the torches raiſed above it may give a clear and ſtrong light, and that when taken down they may be completely concealed. Let us now ſuppoſe that this information is to be communicated—*A number of the auxiliaries, about a hundred, have gone over to the enemy.* In the firſt place, words muſt be choſen that will convey the information in the feweſt letters poſſible; as *A hundred Cretans have deſerted,* Κρητες εκατον απ' ημων υπομολησαν. Having written down this ſentence, it is conveyed in this manner. The firſt letter is a κ, which is in the ſecond column; two torches are therefore to be raiſed on the left hand to inform the perſon who receives the ſignals to look into that particular column. Then five torches are to be held up on the right, to mark the letter *k*, which is the laſt in the column. Then four torches are to be held up on the left to point out the ρ *(r)*, which is in the fourth column, and two on the right to ſhow that it is the ſecond letter of that column. The other letters are pointed out in the ſame manner.—Such was the *pyrſia* or telegraph recommended by Polybius.

But neither this nor any other method mentioned by the ancients ſeems ever to have been brought into general uſe; nor does it appear that the moderns had thought of ſuch a machine as a *telegraph* till the year 1663, when the Marquis of Worceſter, in his CENTURY OF INVENTIONS, affirmed that he had diſcovered "a method by which, at a window, as far as eye can diſcover black from white, a man may hold diſcourſe with his correſpondent, without noiſe made or notice taken; being according to occaſion given or means afforded, *ex re nata*, and no need of proviſion before hand; though much better if foreſeen, and courſe taken by mutual conſent of parties." This could be done only by means of a telegraph, which in the next ſentence is declared to have been rendered ſo perfect, that by means of it the correſpondence could be carried on "by night as well as by day, though as dark as pitch is black." Telegraph.

About 40 years afterwards M. Amontons propoſed a new telegraph. His method was this: Let there be people placed in ſeveral ſtations, at ſuch a diſtance from one another, that by the help of a teleſcope a man in one ſtation may ſee a ſignal made in the next before him; he muſt immediately make the ſame ſignal, that it may be ſeen by perſons in the ſtation next after him, who are to communicate it to thoſe in the following ſtation, and ſo on. Theſe ſignals may be as letters of the alphabet, or as a cipher, underſtood only by the two perſons who are in the diſtant places, and not by thoſe who make the ſignals. The perſon in the ſecond ſtation making the ſignal to the perſon in the third the very moment he ſees it in the firſt, the news may be carried to the greateſt diſtance in as little time as is neceſſary to make the ſignals in the firſt ſtation. The diſtance of the ſeveral ſtations, which muſt be as few as poſſible, is meaſured by the reach of a teleſcope. Amontons tried this method in a ſmall tract of land before ſeveral perſons of the higheſt rank at the court of France.

It was not, however, till the French revolution that the telegraph was applied to uſeful purpoſes. Whether M. Chappe, who is ſaid to have invented the telegraph firſt uſed by the French about the end of 1793, knew any thing of Amontons's invention or not, it is impoſſible to ſay; but his telegraph was conſtructed on principles nearly ſimilar. The manner of uſing this telegraph was as follows: At the firſt ſtation, which was on the roof of the palace of the Louvre at Paris, M. Chappe, the inventor, received in writing, from the committee of public welfare, the words to be ſent to Liſle, near which the French army at that time was. An upright poſt was erected on the Louvre, at the top of which were two tranſverſe arms, moveable in all directions by a ſingle piece of mechaniſm, and with inconceivable rapidity. He invented a number of poſitions for theſe arms, which ſtood as ſigns for the letters of the alphabet; and theſe, for the greater celerity and ſimplicity, he reduced in number as much as poſſible. The grammarian will eaſily conceive that ſixteen ſigns may amply ſupply all the letters of the alphabet, ſince ſome letters may be omitted not only without detriment but with advantage. Theſe ſigns, as they were arbitrary, could be changed every week; ſo that the ſign of B for one day might be the ſign of M the next; and it was only neceſſary that the perſons at the extremities ſhould know the key. The intermediate operators were only inſtructed generally in theſe ſixteen ſignals; which were ſo diſtinct, ſo marked, ſo different the one from the other, that they were eaſily remembered. The conſtruction of the machine was ſuch, that each ſignal was uniformly given in preciſely the ſame manner at all times: It did not depend on the operator's manual ſkill; and the poſition of the arm could never, for any one ſignal, be a degree higher or a degree lower, its movement being regulated mechanically.

M. Chappe having received at the Louvre the ſentence

Telegraph. to be conveyed, gave a known ſignal to the ſecond ſtation, which was Mont Martre, to prepare. At each ſtation there was a watch tower, where teleſcopes were fixed, and the perſon on watch gave the ſignal of preparation which he had received, and this communicated ſucceſſively through all the line, which brought them all into a ſtate of readineſs. The perſon at Mont Martre then received, letter by letter, the ſentence from the Louvre, which he repeated with his own machine; and this was again repeated from the next height, with inconceivable rapidity, to the final ſtation at Liſle.

Engliſh Review. June 1796.

The firſt deſcription of the telegraph was brought from Paris to Frankfort on the Maine by a former member of the parliament of Bourdeaux, who had ſeen that which was erected on the mountain of Belville. As given by Dr Hutton from ſome of the Engliſh papers, it is as follows. AA is a beam or maſt of wood placed upright on a riſing ground (fig. 1. Plate DII.), which is about 15 or 16 feet high. BB is a beam or balance moving upon the centre AA. This balance-beam may be placed vertically or horizontally, or any how inclined, by means of ſtrong cords, which are fixed to the wheel D, on the edge of which is a double groove to receive the two cords. This balance is about 11 or 12 feet long, and nine inches broad, having at the ends two pieces of wood CC, which likewiſe turn upon angles by means of four other cords that paſs through the axis of the main balance, otherwiſe the balance would derange the cords; the pieces C are each about three feet long, and may be placed either to the right or left, ſtraight or ſquare, with the balance-beam. By means of theſe three the combination of movement is very extenſive, remarkably ſimple, and eaſy to perform. Below is a ſmall wooden gouge or hut, in which a perſon is employed to obſerve the movements of the machine. In the mountain neareſt to this another perſon is to repeat theſe movements, and a third to write them down. The time taken up for each movement is 2c ſeconds; of which the motion alone is four ſeconds, the other 16 the machine is ſtationary. Two working models of this inſtrument were executed at Frankfort, and ſent by Mr W. Playfair to the Duke of York; and hence the plan and alphabet of the machine came to England.

Various experiments were in conſequence tried upon telegraphs in that country; and one was ſoon after ſet up by government in a chain of ſtations from the admiralty-office to the ſea-coaſt. It conſiſts of ſix octagonal boards, each of which is poiſed upon an axis in a frame, in ſuch a manner that it can be either placed vertically, ſo as to appear with its full ſize to the obſerver at the neareſt ſtation, as in fig. 2. or it becomes inviſible to him by being placed horizontally, as in fig. 3. ſo that the narrow edge alone is expoſed, which narrow edge is from a diſtance inviſible. Fig. 2. is a repreſentation of this telegraph, with the parts all ſhut, and the machine ready to work. T, in the officer's cabin, is the teleſcope pointed to the next ſtation. Fig. 3. is a repreſentation of the machine not at work, and with the ports all open. The opening of the firſt port (fig. 2.) expreſſes *a*, the ſecond *b*, the third *c*, the fourth *d*, the fifth *e*, and the ſixth *f*, &c.

Six boards make 36 changes, by the moſt plain and ſimple mode of working; and they will make many more if more were neceſſary: but as the real ſuperiority of the telegraph over all other modes of making ſignals conſiſts in its making letters, we do not think that more changes than the letters of the alphabet, and the ten arithmetical ciphers, are neceſſary; but, on the contrary, that thoſe who work the telegraphs ſhould avoid communicating by words or ſigns agreed upon to expreſs ſentences; for that is the ſure method never to become expert at ſending unexpected intelligence accurately.

Telegraph

This telegraph is without doubt made up of the beſt number of combinations poſſible; five boards would be inſufficient, and ſeven would be uſeleſs. It has been objected to it, however, that its form is too clumſy to admit of its being raiſed to any conſiderable height above the building on which it ſtands; and that it cannot be made to change its direction, and conſequently cannot be ſeen but from one particular point.

Several other telegraphs have been propoſed to remedy theſe defects, and perhaps others to which the inſtrument is ſtill liable. The dial plate of a clock would make an excellent telegraph, as it might exhibit 134 ſigns ſo as to be viſible at a great diſtance. A telegraph on this principle, with only ſix diviſions inſtead of twelve, would be ſimple and cheap, and might be raiſed 20 or 30 feet high above the building without any difficulty; it might be ſupported on one poſt, and therefore turn round, and the contraſt of colours would always be the ſame.

Supplement for 1794.

A very ingenious improvement of the telegraph has been propoſed in the Gentleman's Magazine. It conſiſts of a ſemicircle to be properly elevated, and fixed perpendicularly on a ſtrong ſtand. The radius 12 feet; the ſemicircle conſequently ſomewhat more than 36. This to be divided into 24 parts. Each of theſe will therefore compriſe a ſpace of 18 inches, and an arch of 7° 30′ on the circumference. Theſe 24 diviſions to be occupied by as many circular apertures of ſix inches diameter; which will leave a clear ſpace of ſix inches on each ſide between the apertures. Theſe apertures, beginning from the left, to denote the letters of the alphabet, omitting K, J conſonant, V, X, and Q, as uſeleſs for this purpoſe. There are then 21 letters. The four other ſpaces are reſerved for ſignals. The inſtrument to have an index moveable by a windlaſs on the centre of the ſemicircle, and having two tops, according as it is to be uſed in the day or night; one, a circular top of lacquered iron or copper, of equal diameter with the apertures (and which conſequently will eclipſe any of them againſt which it reſts); the other, a ſpear or arrow-ſhaped top, black and highly poliſhed, which, in ſtanding before any of the apertures in the day-time, will be diſtinctly viſible. In the night, the apertures to be reduced by a diaphragm fitting cloſe to each, ſo as to leave an aperture of not more than two inches diameter. The diaphragm to be of well-poliſhed tin; the inner rim lacquered black half an inch. All the apertures to be illuminated, when the inſtrument is uſed in the night-time, by ſmall lamps; to which, if neceſſary, according to circumſtances, convex lenſes may be added, fitted into each diaphragm, by which the light may be powerfully concentrated and increaſed. Over each aperture one of the five priſmatic colours leaſt likely to be miſtaken (the remaining two being leſs diſtinguiſhable, and not wanted, are beſt omitted) to be painted; and, in their natural order, on a width of eighteen inches and a depth of four, red, orange, yellow, green, blue; or, ſtill to heighten the contraſt, and render immediately ſucceſſive apertures more diſtinguiſhable, red, green, orange, blue, yellow. The whole inner circle beneath and between the apertures to be painted black.

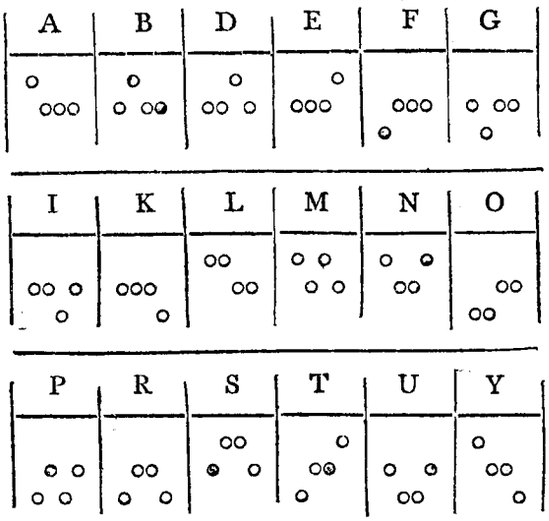
When the inſtrument is to be uſed, the index to be ſet to the ſignal apertures on the right. All the apertures to be covered or dark when it begins to be uſed, except that which is to give the ſignal. A ſignal gun to be fired to appriſe the obſerver. If the index is ſet to the firſt aperture, it will denote that words are to be expreſſed; if to the ſecond, that figures; if to the third, that the figures ceaſe; and that the intelligence is carried on in words. When figures are to be expreſſed, the alternate apertures from the left are taken in their order, to denote from 1 to 10 inclu-

ſively;

Telegraph. fively; the ſecond from the right denotes 100; the fifth 1000. This order, and theſe intervals, are taken to prevent any confuſion in ſo peculiarly important an article of the intelligence to be conveyed.

Perhaps, however none of the telegraphs hitherto offered to the public exceeds the following, either in ſimplicity, cheapneſs, or facility in working, and it might perhaps, with a few trifling additions, be made exceedingly diſtinct. It is thus deſcribed in the Repertory of Arts and Manufactures: For a nocturnal telegraph, let there be four large patent reflectors, lying on the ſame plane, parallel to the horizon, placed on the top of an obſervatory. Let each of theſe reflectors be capable, by means of two winches, either of elevation or depreſſion to a certain degree. By elevating or depreſſing one or two of the reflectors, eighteen very diſtinct arrangements may be produced, as the following ſcheme will explain (A).

Vol. I. p. 382.



For the ſake of example, the above arrangements are made to anſwer to the moſt neceſſary letters of the alphabet; but alterations may be made at will, and a greater number of changes produced, without any addition to the reflectors. In the firſt obſervatory there need only be a ſet of *ſingle* reflectors; but in the others each reflector ſhould be double, ſo as to face both the preceding and ſubſequent obſervatory; and each obſervatory ſhould be furniſhed with two teleſcopes. The proper diameter of the reflectors, and their diſtance from each other, will be aſcertained by experience.

To convert this machine into a diurnal telegraph, nothing more is neceſſary than to inſert, in the place of the reflectors, gilt balls, or any other conſpicuous bodies.

Were telegraphs brought to ſo great a degree of perfection, that they could convey information ſpeedily and diſtinctly; were they ſo much ſimplified, that they could be conſtructed and maintained at little expence—the advantages which would reſult from their uſe are almoſt inconceivable. Not to ſpeak of the ſpeed with which information could be communicated and orders given in time of war, by means of which misfortunes might be prevented or inſtantly repaired, difficulties removed, and diſputes precluded, and by means of which the whole country could be prepared in an inſtant to oppoſe an invading enemy; it might be uſed by commercial men to convey a commiſſion cheaper and ſpeedier than an expreſs can travel. The capitals of diſtant nations might be united by chains of poſts, and the ſettling of thoſe diſputes which at preſent take up months or years might then be accompliſhed in as many hours. An eſtabliſhment of telegraphs might then be made like that of the poſt; and inſtead of being an expence, it would produce a revenue. Until telegraphs are employed to convey information that occurs very frequently, the perſons who are ſtationed to work them will never become expert, and conſequently will neither be expeditious nor accurate, though, with practice, there is no doubt but they will attain both in a degree of perfection of which we can as yet have but little conception. Telegraph. Telemachus.

TELEMACHUS, the ſon of Ulyſſes and Penelope, was ſtill in the cradle when his father went with the reſt of the Greeks to the Trojan war. At the end of this celebrated war, Telemachus, anxious to ſee his father, went to ſeek him; and as the place of his reſidence, and the cauſe of his long abſence, were then unknown, he viſited the court of Menelaus and Neſtor to obtain information. He afterwards returned to Ithaca, where the ſuitors of his mother Penelope had conſpired to murder him, but he avoided their ſnares; and by means of Minerva he diſcovered his father, who had arrived in the iſland two days before him, and was then in the houſe of Eumæus. With this faithful ſervant and Ulyſſes Telemachus concerted how to deliver his mother from the importunities of her ſuitors, and it was effected with great ſucceſs. After the death of his father, Telemachus went to the iſland of Ææa, where he married Circe, or, according to others, Caſſiphone the daughter of Circe, by whom he had a ſon called *Latinus*. He ſome time after had the misfortune to kill his mother-in-law Circe, and fled to Italy, where he founded Cluſium. Telemachus was accompanied in his viſit to Neſtor and Menelaus by the goddeſs of wiſdom under the form of Mentor. It is ſaid that, when a child, Telemachus fell into the ſea, and that a dolphin brought him ſafe to ſhore, after he had remained ſome time under water. From this circumſtance Ulyſſes had the figure of a dolphin engraved on the ſeal which he wore on his ring.

From theſe ſtories, collected from Homer and the other poets of antiquity, the celebrated Fenelon archbiſhop of Cambray took the idea of his well-known *Adventures of Telemachus*; which, though not compoſed in verſe, is juſtly intitled to be eſteemed a poem. "The plan of the work (ſays Dr Blair) is in general well contrived; and is deficient neither in epic grandeur nor unity of object. The author has entered with much felicity into the ſpirit and ideas of the ancient poets, particularly into the ancient mythology, which retains more dignity, and makes a better figure in his hands than in thoſe of any other modern poet. His deſcriptions are rich and beautiful; eſpecially of the ſofter and calmer ſcenes, for which the genius of Fenelon was beſt ſuited; ſuch as the incidents of paſtoral life, the pleaſures of virtue, or a country flouriſhing in peace. There is an inimitable ſweetneſs and tenderneſs in ſeveral of the pictures of this kind which he has given:" and his meaſured proſe, which is remarkably harmonious, gives the ſtyle nearly as much elevation as the French language is capable of ſupporting even in regular verſe. Lectures on Rhetoric and the Belles Lettres.

According to the ſame eminent critic, "the beſt executed part of the work is the firſt ſix books, in which Telemachus recounts his adventures to Calypſo. The narration throughout them is lively and intereſting. Afterwards, eſpecially in the laſt twelve books, it becomes more tedious and languid; and in the warlike adventures which are attempted,

(A) Each reflector, after every arrangement, muſt be reſtored to its place.

Telefcope. compared, there is a great defect of vigour. The chief objection againſt this work being claſſed with epic poems, ariſes from the minute details of virtuous policy, into which the author in ſome places enters; and from the diſcourſes and inſtructions of Mentor, which recur upon us too often, and too much in the ſtrain of common-place morality. Though theſe were well ſuited to the main deſign of the author, which was to form the mind of a young prince, yet they ſeem not congruous to the nature of epic poetry; the object of which is to improve us by means of actions, characters, and ſentiments, rather than by delivering profeſſed and formal inſtruction." Telefcope.

TELEPHIUM, TRUE ORPINE, in botany: A genus of plants belonging to the claſs of *pentandria*, and order of *trigynia*; and in the natural ſyſtem ranging under the 54th order, *Miſcellaneæ*. The calyx is pentaphyllous; there are five petals, which are inſerted into the receptacle; the capſule is unilocular and trivalvular. There are two ſpecies, the *imperati* and *oppoſitifolia*.

TELESCOPE, an optical inſtrument for viewing diſtant objects; ſo named by compounding the Greek words τηλε *far off*, and σκοπειν *to look at* or *contemplate*. This name is commonly appropriated to the larger ſizes of the inſtrument, while the ſmaller are called PERSPECTIVE-GLASSES, SPY-GLASSES, OPERA-GLASSES. A particular kind, which is thought to be much brighter than the reſt, is called a NIGHT-GLASS.

To what has been ſaid already with reſpect to the inventor of this moſt noble and uſeful inſtrument in the article OPTICS, we may add the two following claims.

Mr Leonhard Digges, a gentleman of the laſt century of great and various knowledge, poſitively aſſerts in his *Stratoticos*, and in another work, that his father, a military gentleman, had an inſtrument which he uſed in the field, by which he could bring diſtant objects near, and could know a man at the diſtance of three miles. He ſays, that when his father was at home he had often looked through it, and could diſtinguiſh the waving of the trees on the oppoſite ſide of the Severn. Mr Digges reſided in the neighbourhood of Briſtol.

Francis Fontana, in his *Celeſtial Obſervations*, publiſhed at Naples in 1646, ſays, that he was aſſured by a Mr Hardy, advocate of the parliament of Paris, a perſon of great learning and undoubted integrity, that on the death of his father, there was found among his things an old tube, by which diſtant objects were diſtinctly ſeen; and that it was of a date long prior to the teleſcope lately invented, and had been kept by him as a ſecret.

It is not at all improbable, that curious people, handling ſpectacle glaſſes, of which there were by this time great varieties, both convex and concave, and amuſing themſelves with their magnifying power and the ſingular effects which they produced in the appearances of things, might ſometimes chance ſo to place them as to produce diſtinct and enlarged viſion. We know perfectly, from the table and ſcheme which Sirturus has given us of the tools or diſhes in which the ſpectacle-makers faſhioned their glaſſes, that they had convex lenſes formed to ſpheres of 24 inches diameter, and of 11 inferior ſizes. He has given us a ſcheme of a ſet which he got leave to meaſure belonging to a ſpectacle-maker of the name of *Rogette* at Corunna in Spain; and he ſays that this man had tools of the ſame ſizes for concave glaſſes. It alſo appears, that it was a general practice (of which we do not know the preciſe purpoſe) to uſe a convex and concave glaſs together. If any perſon ſhould chance to put together a 24-inch convex and a 12-inch concave (wrought on both ſides) at the diſtance of 6 inches, he would have diſtinct viſion, and the object would appear of double ſize. Concaves of 6 inches were not uncommon, and one ſuch combined with the convex of 24, at the diſtance of 9 inches, would have diſtinct viſion, and objects would be quadrupled in diameter. When ſuch a thing occurred, it was natural to keep it as a curioſity, although the *rationale* of its operation was not in the leaſt underſtood. We doubt not but that this happened much oftener than in theſe two inſtances. The chief wonder is, that it was not frequent, and taken notice of ſome writer. It is pretty plain that Galileo's firſt teleſcope was of this kind, made up of ſuch ſpectacle-glaſſes as he could procure; for it magnified only three times in diameter: a thing eaſily procured by ſuch glaſſes as he could find with every ſpectacle-maker. And he could not but obſerve, in his trials of their glaſſes, that the deeper concaves and flatter convexes he employed, he produced the greater amplification; and then he would find himſelf obliged to provide a tool not uſed by the ſpectacle-makers, viz. either a much flatter tool for a convex ſurface, or a much ſmaller ſphere for a concave: and, notwithſtanding his telling us that it was by reflecting on the nature of refraction, and without any inſtruction, we are perſuaded that he proceeded in this very way. His next teleſcope magnified but five times. Now the ſlighteſt acquaintance with the obvious laws of refraction would have directed him at once to a very ſmall and deep concave, which would have been much eaſier made, and have magnified more. But he groped his way with ſuch ſpectacle-glaſſes as he could get, till he at laſt made tools for very flat object-glaſſes and very deep eye-glaſſes, and produced a teleſcope which magnified about 25 times. Sirturus ſaw it, and took the meaſures of it. He afterwards ſaw a ſcheme of it which Galileo had ſent to a German prince at Inſpruch who had it drawn (that is, the circles for the tools) on a table in his gallery. The object-glaſs was a plano-convex, a portion of a ſphere, of 24 inches diameter; the eye-glaſs was a double concave of 2 inches diameter: the focal diſtances were therefore 24 inches and 1 inch nearly. This muſt have been a very lucky operation, for Sirturus ſays it was the beſt teleſcope he had ſeen; and we know that it requires the very beſt work to produce this magnifying power with ſuch ſmall ſpheres. Teleſcopes continued to be made in this way for many years; and Galileo, though keenly engaged in the obſervation of Jupiter's ſatellites, being candidate for the prize held out by the Dutch for the diſcovery of the longitude, and therefore much intereſted in the advantage which a convex eye-glaſs would have given him, never made them of any other form. Kepler publiſhed his Dioptrics in 1611; in which he tells us, all that he or others had diſcovered of the law of refraction, viz. that in very ſmall obliquities of incidence, the angle of refraction was nearly $\frac{1}{3}$d of the angle of incidence. This was indeed enough to have pointed out with ſufficient exactneſs, the conſtruction of every optical inſtrument that we are even now poſſeſſed of; for this proportionality of the angles of incidence and refraction is aſſumed in the conſtruction of the optical figure for all of them; and the deviation from it is ſtill conſidered as the *refinement* of the art, and was not brought to any rule till 50 years after by Huyghens, and called by him ABERRATION. Yet even the ſagacious Kepler ſeems not to have ſeen the advantage of any other conſtruction of the teleſcope; he juſt ſeems to acknowledge the poſſibility of it: and we are ſurpriſed to ſee writers giving him as the author of the aſtronomical teleſcope, or even as hinting as its conſtruction. It is true, in the laſt propoſition he ſhows how a teleſcope may be made *apparently* with a convex eye-glaſs: but this is only a frivolous fancy;

Teleſcope. fancy; for the eye-glaſs is directed to be made convex externally, and a very deep concave on the inſide; ſo that it is, in fact, a meniſcus with the concavity prevalent. In the 86th propoſition, he indeed ſhows that it is poſſible ſo to place a convex glaſs behind another convex glaſs, that an eye ſhall ſee objects diſtinct, magnified, and inverted; and he ſpeaks very ſagaciouſly on the ſubject. After having ſaid that an eye placed behind the point of union of the firſt glaſs will ſee an object inverted, he ſhows that a ſmall part only will be ſeen; and then he ſhows that a convex glaſs, duly proportioned and properly placed, will ſhow more of it. But in ſhowing this, he ſpeaks in a way which ſhows evidently that he had formed no diſtinct notions of the manner in which this effect would be produced, only ſaying vaguely that the convergency of the ſecond glaſs would counteract the divergency beyond the focus of the firſt. Had he conceived the matter with any tolerable diſtinctneſs, after ſeeing the great advantage of taking in a field greater in almoſt any proportion, he would have eagerly catched at the thought, and enlarged on the immenſe improvement. Had he but drawn one figure of the progreſs of the rays through two convex glaſſes, ſuch as fig. 12. of Pl. CCCLXIV. the whole would have been open to his view.

This ſtep, ſo eaſy and ſo important, was reſerved for Father Scheiner, as has been already obſerved in the article OPTICS; and the conſtruction of this author, together with that of Janſen, are the models on which all refracting teleſcopes are now conſtructed; and in all that relates to their magnifying power, brightneſs, and field of viſion, they may be conſtructed on Kepler's principle, that the angles of refraction are in a certain given proportion to the angles of incidence.

But after Huyghens had applied his elegant geometry to the diſcovery of Snellius, viz. the proportonality, not of the angles, but of the ſines, and had aſcertained the aberrations from the foci of infinitely ſlender pencils, the reaſons were clearly pointed out why there were ſuch narrow limits affixed by nature to the performance of optical inſtruments, in conſequence of the indiſtinctneſs of viſion which reſulted from conſtructions where the magnifying power, the quantity of light, or the field of viſion, were extended beyond certain moderate bounds. The theory of aberrations, which that moſt excellent geometer eſtabliſhed, has enabled us to diminiſh this indiſtinctneſs ariſing from any of theſe cauſes; and this diminution is the ſole aim of all the different conſtructions which have been contrived ſince the days of Galileo and Scheiner.

THE deſcription which has been already given of the various conſtructions of teleſcopes in the article OPTICS, is ſufficient for inſtructing the reader in the general principles of their conſtruction, and with moderate attention will ſhow the manner in which the rays of light proceed, in order to enſure the different circumſtances of amplification, brightneſs, and extent of field, and even diſtinctneſs of viſion, in as far as this depends on the proper intervals between the glaſſes. But it is inſufficient for giving us a knowledge of the improvements which are aimed at in the different departures from the original conſtructions of Galileo and Scheiner, the advantage of the double eye-glaſs of Huyghens, and the quintuple eye glaſs of Dolland: ſtill more is it inſufficient for ſhowing us why the higheſt degrees of amplification and moſt extenſive field cannot be obtained by the mere proportion of the focal diſtances of the glaſſes, as Kepler had taught. In ſhort, without the Huyghenian doctrine of aberrations, neither can the curious reader learn the limits of their performance, nor the artiſt learn why one teleſcope is better than another, or in what manner to proceed to make a teleſcope differing in any particular from thoſe which he ſervilely copies. Teleſcope.

Although all the improvements in the conſtruction of teleſcopes ſince the publication of Huyghens's Dioptrics have been the productions of Britain, and although Dr Smith of Cambridge has given the moſt elegant and perſpicuous account of this ſcience that has yet appeared, we do not recollect a performance in the Engliſh language (except the Optics of Emerſon) which will carry the reader beyond the mere ſchoolboy elements of the ſcience, or enable a perſon of mathematical ſkill to underſtand or improve the conſtruction of optical inſtruments. The laſt work on this ſubject of any extent (Dr Prieſtley's Hiſtory of Viſion) is merely a parlour book for the amuſement of half-taught dilettanti, but is totally deficient in the mathematical part, although it is here that the ſcience of optics has her chief claim to preeminence, and to the name of a DISCIPLINA ACCURATA. But this would have been *ultra crepidam;* and the author would in all probability have made as poor a figure here as he has done in his attempts to degrade his ſpecies in his Commentaries on the *Vibratiunculæ* of Hartley; motions which neither the author nor his amplificater were able to underſtand or explain. We truſt that our readers, jealous as we are of every thing that ſinks us in the ſcale of nature's works, will pardon this tranſient ejaculation of ſpleen, when our thoughts are called to a ſyſtem which, of *abſolute and unavoidable neceſſity*, makes the DIVINE MIND nothing but a quivering of *that matter* of which it is the AUTHOR and unerring DIRECTOR. *Sed miſſum faciamus.*

We think therefore that we ſhall do the public ſome ſervice, by giving ſuch an account of this *higher branch* of optical ſcience as will at leaſt tend to the complete underſtanding of this noble inſtrument, by which our conceptions of the extent of almighty power, and wiſdom, and beneficence, are ſo wonderfully enlarged. In the proſecution of this we hope that many general rules will emerge, by which artiſts who are not mathematicians may be enabled to conſtruct optical inſtruments with intelligence, and avoid the many blunders and defects which reſult from mere ſervile imitation.

The general aim in the conſtruction of a teleſcope is, to form, by means of mirrors or lenſes, an image of the diſtant object, as large, as bright, and as extenſive as is poſſible, conſiſtently with diſtinctneſs; and then to view the image with a magnifying glaſs in any convenient manner. This gives us an arrangement of our ſubject. We ſhall firſt ſhow the principles of conſtruction of the object glaſs or mirror, ſo as that it ſhall form an image of the diſtant object with theſe qualities; and then ſhow how to conſtruct the magnifying glaſs or eye-piece, ſo as to preſerve them unimpaired.

This indiſtinctneſs which we wiſh to avoid ariſes from two cauſes; the ſpherical figures of the refracting and reflecting ſurfaces, and the different refrangibility of the differently coloured rays of light. The firſt may be called the SPHERICAL and the ſecond the CHROMATIC indiſtinctneſs; and the deviations from the foci, determined by the elementary theorem (OPTICS, p. 289), may be called the SPHERICAL and the CHROMATIC aberrations.

The limits of a Work like this will not permit us to give any more of the doctrine of aberrations than is abſolutely neceſſary for the conſtruction of achromatic teleſcopes; and we muſt refer the reader for a general view of the whole to Euler's *Dioptrics*, and other works of that kind. Dr Smith has given as much as was neceſſary for the compariſon of the merits of different glaſſes of ſimilar conſtruction, and this in a very plain and elegant manner.

We ſhall begin with the aberration of colour, becauſe it is the moſt ſimple.

Teleſcope. Let white or compounded light fall perpendicularly on the flat ſide PQ (fig. 1.) of a plano-convex lens PVQ, whoſe axis is CV and vertex V. The white ray *p* P falling on the extremity of the lens is diſperſed by refraction at the point P of the ſpherical ſurface, and the red ray goes to the point *r* of the axis, and the violet ray to the point *v*. In like manner the white ray *q* Q is diſperſed by refraction at Q, the red ray going to *r*, and the violet to *v*. The red ray P *r* croſſes the violet ray Q *v* in a point D, and Q *r* croſſes P *v* in a point E; and the whole light refracted and diſperſed by the circumference, whoſe diameter is PQ, paſſes through the circular area, whoſe diameter is DE. Suppoſing that the lens is of ſuch a form that it would collect red rays, refracted by its whole ſurface in the point *r*, and violet in the point *v*; then it is evident that the whole light which occupies the ſurface of the lens will paſs through this little circle, whoſe diameter is DE. Therefore white light iſſuing from a point ſo diſtant that the rays may be conſidered as parallel, will not be collected in another point or focus, but will be diſperſed over the ſurface of that little circle; which is therefore called the *circle of chromatic diſperſion*; and the radiant point will be repreſented by this circle. The neighbouring points are in like manner repreſented by circles; and theſe circles encroaching on and mixing with each other, muſt occaſion hazineſs or confuſion, and render the picture indiſtinct. This indiſtinctneſs will be greater in the proportion of the number of circles which are in this manner mixed together. This will be in the proportion of the room that is for them; that is, in proportion to the area of the circle, or in the duplicate proportion of its diameter. Our firſt buſineſs therefore is, to obtain meaſures of this diameter, and to mark the connection between it and the aperture and focal diſtance of the lens.

Plate DII.

Let *i* be to *r* as the ſine of incidence in glaſs to the ſine of refraction of the red rays; and let *i* be to *v* as the ſine of incidence to the ſine of refraction of the violet rays. Then we ſay, that when the aperture PQ is moderate, $v-r : v+r-2i = DE : PQ$, very nearly. For let DE, which is evidently perpendicular to V *r*, meet the parallel incident rays in K and L and the radii of the ſpherical ſurface in G and H. It is plain that GKP is equal to the angle of incidence on the poſterior or ſpherical ſurface of the lens; and GP *r* and GP *v* are the angles of refraction of the red and the violet rays; and that GK, GD, and GE, are very nearly as the ſines of thoſe angles, becauſe the angles are ſuppoſed to be ſmall. We may therefore inſtitute this proportion $DE : KD = v-r : r-i$; then, by doubling the conſequents $DE : 2KD = v-r : 2r-2i$. Alſo $DE : 2KD+DE = v-r : 2r-2i+v-r, = v-r : r+v-2i$. But 2KD + DE is equal to KL or PQ. Therefore we have $DE : PQ = v-r : r+v-2i$. *Q. E. D.*

Cor. 1. Sir Iſaac Newton, by moſt accurate obſervation, found, that in common glaſs the ſines of refraction of the red and violet rays were 77 and 78 where the ſine of incidence was 50. Hence it follows, that $v-r$ is to $v+r-2i$ as 1 to 55; and that the diameter of the ſmalleſt circle of diſperſion is $\frac{1}{55}$th part of that of the lens.

2. In like manner may be determined the circle of diſperſion that will comprehend the rays of any particular colour or ſet of colours. Thus all the orange and yellow will paſs through a circle whoſe diameter is $\frac{1}{280}$th of that of the lens.

3. In different ſurfaces, or plano-convex lenſes, the angles of aberration *r* P *v* are as the breadth PQ directly, and as the focal diſtance VF inverſely; becauſe any angle DPE is as its ſubtenſe DE directly and radius DP inverſely. *N. B.* we call VF the focal diſtance, becauſe at this diſtance, or at the point F, the light is moſt of all conſtipated. If we examine the focal diſtance by holding the lens to the ſun, we judge it to be where the light is drawn into the ſmalleſt ſpot. Teleſcope.

When we reflect that a lens of $5\frac{1}{2}$ inches in diameter has a circle of diſperſion $\frac{1}{10}$th of an inch in diameter, we are ſurpriſed that it produces any picture of an object that can be diſtinguiſhed. We ſhould not expect greater diſtinctneſs from ſuch a lens than would be produced in a camera obſcura without a lens, by ſimply admitting the light through a hole of $\frac{1}{10}$th of an inch in diameter. This, we know, would be very hazy and confuſed. But when we remark the ſuperior vivacity of the yellow and orange light in compariſon with the reſt, we may believe that the effect produced by the confuſion of the other colours will be much leſs ſenſible. But a ſtronger reaſon is, that the light is much denſer in the middle of the circle of diſperſion, and is exceedingly faint towards the margin. This, however, muſt not be taken for granted; and we muſt know diſtinctly the manner in which the light of different colours is diſtributed over the circle of chromatic diſperſion, before we pretend to pronounce on the immenſe difference between the indiſtinctneſs ariſing from colour and that ariſing from the ſpherical figure. We think this the more neceſſary, becauſe the illuſtrious diſcoverer of the chromatic aberration has made a great miſtake in the compariſon, becauſe he did not conſider the diſtribution of the light in the circle of ſpherical diſperſion. It is therefore proper to inveſtigate the chromatic diſtribution of the light with the ſame care that we beſtowed on the ſpherical diſperſion in Optics, n° 251. &c.; and we ſhall then ſee that the ſuperiority of the reflecting teleſcope is incomparably leſs than Newton imagined it to be.

Therefore let EB (fig. 2.) repreſent a plano-convex lens, of which C is the centre and C *r* the axis. Let us ſuppoſe it to have no ſpherical aberration, but to collect rays occupying its whole ſurface to ſingle points in the axis. Let a beam of white or compounded light fall perpendicularly on its plane ſurface. The rays will be ſo refracted by its curved ſurface, that the extreme red rays will be collected at *r*, the extreme violet rays at *w*, and thoſe of intermediate refrangibility at intermediate points, *o*, *y*, *g*, *b*, *p*, *v*, of the line *r w*, which is nearly $\frac{1}{28}$th of *r* C. The extreme red and violet rays will croſs each other at A and D; and AD will be a ſection or diameter of the circle of chromatic diſperſion, and will be about $\frac{1}{55}$th of EB. We may ſuppoſe *wr* to be biſected in *b*, becauſe *w b* is to *b r* very nearly in the ratio of equality (for $r b : r C = b A : c E, = b A : c B, = w b : w C$). The line *r w* will be a kind of priſmatic ſpectrum, red from *r* to *o*, orange-coloured from *o* to *y*, yellow from *y* to *g*, green from *g* to *b*, blue from *b* to *p*, purple from *p* to *v*, and violet from *v* to *w*.

The light in its compound ſtate muſt be ſuppoſed uniformly denſe as it falls upon the lens; and the ſame muſt be ſaid of the rays of any particular colour. Newton ſuppoſes alſo, that when a white ray, ſuch as *e* E, is diſperſed into its component coloured rays by refraction at E, it is uniformly ſpread over the angle DEA. This ſuppoſition is indeed gratuitous; but we have no argument to the contrary, and may therefore conſider it as juſt. The conſequence is, that each point *w*, *v*, *p*, *b*, &c. of the ſpectrum is not only equally luminous, but alſo illuminates uniformly its correſponding portion of AD: that is to ſay, the coating (ſo to term it) of any particular colour, ſuch as purple, from the point *p*, is uniformly denſe in every part of AD on which it falls. In like manner, the colouring of yellow, intercepted by a part of AD in its paſſage to the point *y*, is uniformly denſe in all its parts. But the denſity of the different colours in AD is extremely different: for ſince the radiation in *w* is equally denſe with that in *p*, the denſity of the violet colouring, which radiates from *w*, and is

ſpread

Teleſcope. ſpread over the whole of AD, muſt be much leſs than the denſity of the purple colouring, which radiates from p, and occupies only a part of AD round the circle b. Theſe denſities muſt be very nearly in the inverſe proportion of wb^2 to pb^2.

Hence we ſee, that the central point b will be very intenſely illuminated by the blue radiating from $p\,b$ and the green intercepted from $b\,g$. It will be more faintly illuminated by the purple radiating from $v\,p$, and the yellow intercepted from $g\,y$; and ſtill more faintly by the violet from $w\,v$, and the orange and red intercepted from $y\,r$. The whole colouring will be a white, tending a little to yellowneſs. The accurate proportion of theſe colourings may be computed from our knowledge of the poſition of the points o, y, g, &c. But this is of little moment. It is of more conſequence to be able to determine the proportion of the total intenſity of the light in b to its intenſity in any other point I.

For this purpoſe draw r I R, I w W, meeting the lens in R and W. The point I receives none of the light which paſſes through the ſpace RW: for it is evident that b I : CR = b A : CE, = 1 : 55, and that CR = CW; and therefore, ſince all the light incident on EB paſſes through AB, all the light incident on RW paſſes through I i ($b\,i$ being made = b I). Draw o I O, y I Y, g I G, I p P, I v V. It is plain, that I receives red light from RO, orange from OY, yellow from YG, green from GE, a little blue from BP, purple from PV, and violent from VW. It therefore wants ſome of the green and of the blue.

That we may judge of the intenſity of theſe colours at I, ſuppoſe the lens covered with paper pierced with a ſmall hole at G. The green light only will paſs through I; the other colours will paſs between I and b, or between I and A, according as they are more or leſs refrangible than the particular green at I. This particular colour converges to g, and therefore will illuminate a ſmall ſpot round I, where it will be as much denſer than it is at G as this ſpot is ſmaller than the hole at G. The natural denſity at G, therefore, will be to the increaſed denſity at I, as $g\,I^2$ to $g\,G^2$, or as $g\,b^2$ to $g\,C^2$, or as $b\,I^2$ to CG^2. In like manner, the natural denſity of the purple coming to I through an equal hole at P will be to the increaſed denſity at I as $b\,I^2$ to CP^2. And thus it appears, that the intenſity of the differently coloured illuminations of *any* point of the circle of diſperſion, is inverſely proportional to the ſquare of the diſtance from the centre of the lens to the point of its ſurface through which the colouring light comes to this point of the circle of diſperſion. This circumſtance will give us a very eaſy, and, we think, an elegant ſolution of the queſtion.

Biſect CE in F, and draw FL perpendicular to CE, making it equal to CF. Through the point L deſcribe the hyperbola KLN of the ſecond order, that is, having the ordinates EK, FL, RN, &c. inverſely proportional to the ſquares of the abſciſſæ CE, CF, CR, &c.; ſo that FL : RN $= \frac{1}{CF^2} : \frac{1}{CR^2}$, or = $CR^2 : CF^2$, &c. It is evident that theſe ordinates are proportional to the denſities of the ſeverally coloured lights which go from them to any points whatever of the circle of diſperſion.

Now the total denſity of the light at I depends both on the denſity of each particular colour and on the number of colours which fall on it. The ordinates of this hyperbola determine the firſt; and the ſpace ER meaſures the number of colours which fall on I, becauſe it receives light from the whole of ER, and of its equal BW. Therefore, if ordinates be drawn from any point of ER, their ſum will be as the whole light which goes to I; that is, the total denſity of the light at I will be proportional to the area NREK. Now it is known that CE × EK is equal to the infinitely extended area lying beyond EK; and CR × RN is equal to the infinitely extended area lying beyond RN. Therefore the area NREK is equal to CR × RN — CE × EK. But RN and EK are reſpectively equal to $\frac{CF^3}{CR^2}$ and $\frac{CF^3}{CE^2}$. Therefore the denſity at I is proportional to $CF^3 \times \left(\frac{CR}{CR^2} - \frac{CE}{CE^2}\right)$, $= CF^3 \times \left(\frac{1}{CR} - \frac{1}{CE}\right)$, $= CF^3 \times \frac{CE - CR}{CE \times CR}$, $= CF^3 \times \frac{ER}{CE \times CR}$, $= \frac{CF^3}{CE} \times \frac{ER}{CR}$. But becauſe CF is $\frac{1}{2}$ of CE, $\frac{CF^3}{CE}$ is $= \frac{CF^3}{2CF}$, $= \frac{CF^2}{2}$, a conſtant quantity. Therefore the denſity of the light at I is proportional to $\frac{ER}{CR}$, or to $\frac{AI}{bI}$, becauſe the points R and I are ſimilarly ſituated in EC and Ab.

Farther, if the ſemi-aperture CE of the lens be called 1, $\frac{CF^2}{2}$ is $= \frac{1}{8}$, and the denſity at I is $= \frac{AI}{8bI}$.

Here it is proper to obſerve, that ſince the point R has the ſame ſituation in the diameter EB that the point I has in the diameter AD of the circle of diſperſion, the circle deſcribed on EB may be conceived as the magnified repreſentation of the circle of diſperſion. The point F, for inſtance, repreſents the point f in the circle of diſperſion, which biſects the radius b A; and f receives no light from any part of the lens which is nearer the centre than F, being illuminated only by the light which comes through EF and its oppoſite BF'. The ſame may be ſaid of every other point.

In like manner, the denſity of the light in f, the middle between b and A, is meaſured by $\frac{EF}{CF}$, which is $= \frac{EF}{EF}$, or 1. This makes the denſity at this point a proper ſtandard of compariſon. The denſity there is to the denſity at I as 1 to $\frac{AI}{bI}$, or as bI to AI; and this is the ſimpleſt mode of compariſon. The denſity half way from the centre of the circle of diſperſion is to the denſity at any point I as b I to IA.

Laſtly, through L deſcribe the common rectangular hyperbola k L n, meeting the ordinates of the former in k, L, and n: and draw $k\,h$ parallel to EC, cutting the ordinates in g, f, r, &c. Then CR : CE = Ek : Rn, and CR : CE — CR = Ek : Rn — Ek, or CR : RE = Ek : $r\,n$, and b I : IA = Ek : $r\,n$. And thus we have a very ſimple expreſſion of the denſity in any point of the circle of diſperſion. Let the point be anywhere, as at I. Divide the lens in R as AD is divided in I, and then $r\,n$ is as the denſity in I.

Theſe two meaſures were given by Newton; the firſt in his *Treatiſe de Mundi Syſtemate*, and the laſt in his *Optics*; but both without demonſtration.

If the hyperbola k L n be made to revolve round the axis CQ, it will generate a ſolid ſpindle, which will meaſure the whole quantity of light which paſſes through different portions of the circle of diſperſion. Thus the ſolid produced by the revolution of L $k\,f$ will meaſure all the light which occupies the outer part of the circle of diſperſion lying without the middle of the radius. This ſpace is $\frac{3}{4}$ths of the whole circle; but the quantity of light is but $\frac{1}{4}$th of the whole.

A ſtill more ſimple expreſſion of the whole quantity of light paſſing through different portions of the circle of chromatic diſperſion may now be obtained as follows:

It has been demonſtrated, that the denſity of the light at

I is

Teleſcope. I is as $\frac{AI}{bI}$, or as $\frac{ER}{CR}$. Suppoſe the figure to turn round the axis. I or R deſcribe circumferences of circles; and the whole light paſſing through this circumference is as the circumference, or as the radius, and as the denſity jointly. It is therefore as $\frac{ER}{CR} \times CR$, that is, as ER. Draw any ſtraight line E m, cutting RN in s, and any other ordinate FL in x R s. The whole light which illuminates the circumference deſcribed by I is to the whole light which illuminates the centre b as ER to EC, or as R s to C m. In like manner, the whole light which illuminates the circumference deſcribed by the point f in the circle of diſperſion is to the whole light which illuminates the centre b, as F x to C m. The lines C m, R S, F x, are therefore proportional to the whole light which illuminates the correſponding circumferences in the circle of diſperſion. Therefore the whole light which falls on the circle whoſe radius is b I, will be repreſented by the trapezium in CRS; and the whole light which falls on the ring deſcribed by IA, will be repreſented by the triangle E s R; and ſo of any other portions.

By conſidering the figure, we ſee that the diſtribution of the light is exceedingly unequal. Round the margin it has no ſenſible denſity; while its denſity in the very centre is incomparably greater than in any other point, being expreſſed by the aſymptote of a hyperbola. Alſo the circle deſcribed with the radius $\frac{Ab}{2}$ contains $\frac{1}{4}$ths of the whole light. No wonder then that the confuſion cauſed by the mixture of theſe circles of diſperſion is leſs than one ſhould expect; beſides, it is evident that the moſt lively or impreſſive colours occupy the middle of the ſpectrum, and are there much denſer than the reſt. The margin is covered with an illumination of deep red and violet, neither of which colours are brilliant. The margin will be of a dark claret colour. The centre revives all the colours, but in a proportion of intenſity greatly different from that in the common priſmatic ſpectrum, becauſe the radiant points L, p, b, g, &c. by which it is illuminated, are at ſuch different diſtances from it. It will be white; but we apprehend not a pure white, being greatly overcharged with the middle colours.

Theſe conſiderations ſhow that the coloured fringes, which are obſerved to border very luminous objects ſeen on a dark ground through optical inſtruments, do not proceed from the object-glaſs of a teleſcope or microſcope, but from an improper conſtruction of the eye-glaſſes. The chromatic diſperſion would produce fringes of a different colour, when they produce any at all, and the colours would be differently diſpoſed. But this diſperſion by the object-glaſs can hardly produce any fringes: its effect is a general and almoſt uniform mixture of circles all over the field, which produces an uniform hazineſs, as if the object were viewed at an improper diſtance, or out of its focus, as we vulgarly expreſs it.

We may at preſent form a good gueſs at the limit which this cauſe puts to the performance of a teleſcope. A point of a very diſtant object is repreſented, in the picture formed by the object-glaſs, by a little circle, whoſe diameter is at leaſt $\frac{1}{100}$th of the aperture of the object-glaſs, making a very full allowance for the ſuperior brilliancy and denſity of the central light. We look at this picture with a magnifying eye-glaſs. This magnifies the picture of the point. If it amplify it to a ſuch a degree as to make it an object individually diſtinguiſhable, the confuſion is then ſenſible. Now this can be computed. An object ſubtending one minute of a degree is diſtinguiſhed by the dulleſt eye, even although it be a dark object on a bright ground. Let us therefore ſuppoſe a teleſcope, the object-glaſs of which is of ſix feet focal diſtance, and one inch aperture. The diameter of the circle of chromatic diſperſion will be $\frac{1}{100}$th of an inch, which ſubtends at the centre of the object-glaſs an angle of about $9\frac{1}{2}$ ſeconds. This, when magnified ſix times by an eye-glaſs, would become a diſtinguiſhable object; and a teleſcope of this length would be indiſtinct if it magnified more than ſix times, if a point were thus ſpread out into a ſpot of uniform intenſity. But the ſpot is much leſs intenſe about its margin. It is found experimentally that a piece of engraving, having fine croſs hatches, is not ſenſibly indiſtinct till brought ſo far from the limits of perfectly diſtinct viſion, that this indiſtinctneſs amounts to 6′ or 5′ in breadth.—Therefore ſuch a teleſcope will be ſenſibly diſtinct when it magnifies 36 times; and this is very agreeable to experience. Teleſcope.

We come, in the ſecond place, to the more arduous taſk of aſcertaining the error ariſing from the ſpherical figure of the ſurfaces employed in optical inſtruments.—Suffice it to ſay before we begin, that although geometers have exhibited other forms of lenſes which are totally exempt from this error, they cannot be executed by the artiſt; and we are therefore reſtricted to the employment of ſpherical ſurfaces.

Of all the determinations which have been given of ſpherical aberration, that by Dr Smith, in his Optics, which is an improvement of the fundamental theorem of that moſt elegant geometer Huyghens, is the moſt perſpicuous and palpable. Some others are more conciſe, and much better fitted for after uſe, and will therefore be employed by us in the proſecution of this article. But they do not keep in view the optical facts, giving the mind a picture of the progreſs of the rays, which it can contemplate and diſcover amidſt many modifying circumſtances. By ingenious ſubſtitutions of analytical ſymbols, the inveſtigation is rendered expeditious, conciſe, and certain; but theſe are not immediate ſymbols of things, but of operations of the mind; objects ſufficiently ſubtile of themſelves, and having no need of ſubſtitutions to make us loſe ſight of the real ſubject; and thus our occupation degenerates into a proceſs almoſt without ideas. We ſhall therefore ſet out with Dr Smith's fundamental Theorem.

1. *In Reflections.*

Let AVB (fig. 3.) be a concave ſpherical mirror, of which C is the centre, V the vertex, CV the axis, and F the focus of an infinitely ſlender pencil of parallel rays paſſing through the centre. Let the ray a A, parallel to the axis, be reflected in AG, croſſing the central ray CV in f. Let AP be the ſine of the ſemi-aperture AV, AD its tangent, and CD its ſecant.

The aberration F f from the principal focus of central rays is equal to $\frac{1}{2}$ of the exceſs VD of the ſecant above the radius, or very near equal to $\frac{1}{2}$ of VP, the verſed ſine of the ſemi-aperture.

For becauſe AD is perpendicular to CA, the points C, A, D, are in a circle, of which CD is the diameter; and becauſe A f is equal to C f, by reaſon of the equality of the angles f AC, f CA, and CA a, f is the centre of the circle through C, A, D, and f D is $= \frac{1}{2}$ CD. But FC is $= \frac{1}{2}$ CV. Therefore F f is $\frac{1}{2}$ of VD.

But becauſe DV : VP = DC : VC, and DC is very little greater than VC when the aperture AB is moderate, DV is very little greater than VP, and F f is very nearly equal to $\frac{1}{2}$ of VP.

Cor. 1. The longitudinal aberration is $= \frac{AV^2}{4CV}$, for PV is very nearly $= \frac{AV^2}{2CV}$.

Cor. 2.

Telescope. *Cor.* 2. The lateral aberration FG is $= \frac{AV^3}{2CV^2}$. For $FG : Ff = AP : Pf, = AV : \frac{1}{2}$ CV nearly, and therefore $FG = \frac{AV^3}{4CV} \times \frac{2}{CV} = \frac{AV^3}{2CV^2}$.

2. *In Refractions.*

Let AVB (fig. 4. A or B) be a ſpherical ſurface ſeparating two refracting ſubſtances, C the centre, V the vertex, AV the ſemi aperture, AP its ſine, PV its verſed ſine, and F the focus of parallel rays infinitely near to the axis. Let the extreme ray *a* A, parallel to the axis, be refracted into AG, croſſing CF in *f*, which is therefore the focus of extreme parallel rays.

The rectangle of the ſine of incidence, by the difference of the ſines of incidence and refraction, is to the ſquare of the ſine of refraction, as the verſed ſine of the ſemi-aperture is to the longitudinal abberration of the extreme rays.

Call the ſine of incidence *i*, the ſine of refraction *r*, and their difference *d*.

Join CA, and about the centre *f* deſcribe the arch AD.

The angle ACV is equal to the angle of incidence, and CA *f* is the angle of refraction. Then, ſince the ſine of incidence is to the ſine of refraction as VF to CF, or as A *f* to C*f*, that is, as D *f* to C*f*, we have

CF : FV = C*f* : *f* D
by converſion CF : CV = C*f* : CD
altern. conver. CF—C*f* : CV—CD = CF : CV
or - F*f* : VD = CF : CV, = *r* : *d*.

Now $PV = \frac{AP^2}{CP+CV}, = \frac{AP^2}{2CV}$ nearly, and $PD = \frac{AP^2}{fP+fV} = \frac{AP^2}{2fV}$ nearly, $= \frac{AP^2}{2FV}$ nearly. Therefore PV : PD = FV : CV, and DV : PV = CF : FV nearly.

we had above F*f* : VD = *r* : *d*;
and now - VD : PV = CF : FV, = *r* : *i*;
therefore - F*f* : PV = $r^2 : di$,

and $Ff = \frac{r^2}{di} \times PV$. *Q. E. D.*

The aberration will be different according as the refraction is made towards or from the perpendicular; that is, according as *r* is leſs or greater than *i*. They are in the ratio of $\frac{r^2}{di}$ to $\frac{i^2}{dr}$, or of r^3 to i^3. The abberration therefore is always much diminiſhed when the refraction is made from a rare into a denſe medium. The proportion of the ſines for air and glaſs is nearly that of 3 to 2. When the light is refracted into the glaſs, the aberration is nearly $\frac{4}{3}$ of PV; and when the light paſſes out of glaſs into air, it is about $\frac{2}{3}$ of PV.

Cor. 1. $Ff = \frac{r^2}{di} \times \frac{AP^2}{2CV}$ nearly, and it is alſo $= \frac{r^2}{d^2} \times \frac{AP^2}{2FV}$, becauſe $PV = \frac{AP^2}{2CV}$ nearly, and $i : d = FV : CV$.

Cor. 2. Becauſe *f* P : PA = F*f* : FG
or FV : AV = F*f* : FG nearly,

we have FG, the lateral aberration, $= Ff \times \frac{AV}{FV}, = \frac{r^2}{d^2} \times \frac{AV^3}{2FV^2}, = \frac{r^2}{i^2} \times \frac{AV^3}{2CV^2}$.

Cor. 3. Becauſe the angle F·A*f* is proportional to $\frac{FG}{FV}$ very nearly, we have the angular aberration $FA\,f = \frac{r^2}{d^2} \times \frac{AV^3}{2FV^3} = \frac{r^2}{i^2} \times \frac{AV^3}{2CV^3}$.

In general, the longitudinal aberrations from the focus of central parallel rays are as the ſquares of the apertures directly, and as the focal diſtances inverſely; and the lateral aberrations are as the cubes of the apertures directly, and the ſquares of the focal diſtances inverſely; and the angular aberrations are as the cubes of the aperture directly, and the cubes of the focal diſtances inverſely. Telescope.

The reader muſt have obſerved, that to ſimplify the inveſtigation, ſome ſmall errors are admitted. PV and PD are not in the exact proportion that we aſſumed them, nor is D *f* equal to FV. But in the ſmall apertures which ſuffice for optical inſtruments, theſe errors may be diſregarded.

This ſpherical aberration produces an indiſtinctneſs of viſion, in the ſame manner as the chromatic aberration does, *viz.* by ſpreading out every mathematical point of the object into a little ſpot in its picture; which ſpots, by mixing with each other, confuſe the whole. We muſt now determine the diameter of the circle of diffuſion, as we did in the caſe of chromatic diſperſion.

Let a ray $\beta\,\alpha$ (fig. 5.) be refracted on the other ſide of the axis, into α H φ, cutting A *f* G in H, and draw the perpendicular EH. Call AV *a*, α V α, V *f* (or VF, or V φ, which in this compariſon may be taken as equal) = *f*, F*f* = *b*, and *f* E = $\varphi\,x$. Plate DIII.

$AV^2 : \alpha V^2 = Ff : F\varphi$ (already demonſtrated) and $F\varphi = \frac{\alpha^2}{a^2} b$, and $Ff - F\varphi$, (or $f\varphi$) $= b - \frac{\alpha^2}{a^2} b, = \frac{a^2 b - \alpha^2 b}{a^2}$, $= \frac{b}{a^2} \times a^2 - \alpha^2, = \frac{b}{a^2} \times \overline{a+\alpha} \times \overline{a-\alpha}$. Alſo P*f* : PA = *f*E : EH, or $f : a = x : \frac{ax}{f}$, = EH. And $P\pi : P\varphi =$ EH : E φ, or $\alpha : f = \frac{ax}{f} : \frac{ax}{\alpha}$, = E φ. Therefore $f\varphi = \frac{ax}{\alpha} + x, = \frac{\overline{a+\alpha}x}{\alpha}, = \frac{x}{\alpha} \times \overline{a+\alpha}$. Therefore $\frac{x}{\alpha} \times \overline{a+\alpha} = \frac{b}{a^2} \times \overline{a+\alpha} \times \overline{a-\alpha}$, and $\frac{x}{\alpha} = \frac{b}{a^2} \times \overline{a-\alpha}$, and $x = \frac{b}{a^2} \times \alpha\,(a-\alpha)$. Therefore x is greateſt when $\alpha \times \overline{a-\alpha}$ is greateſt; that is, when $\alpha = \frac{1}{2}a$. Therefore EH is greateſt when $P\pi$ is equal to the half of AP. When this is the caſe, we have at the ſame time $\frac{b}{a^2} \times \alpha\,(a-\alpha) = \frac{b}{a^2} \times \frac{1}{4}a^2$, and $x = \frac{1}{4}b$, or $EH = \frac{1}{4}$ FG. That is, the diameter of the circle of aberration through which the whole of the refracted light muſt paſs, is $\frac{1}{4}$ of the diameter of the circle of aberration at the focus of parallel central rays. In the chromatic aberration it was $\frac{1}{2}$; ſo that in this reſpect the ſpherical aberration does not create ſo great confuſion as the chromatic.

We are now able to compare them, ſince we have now the meaſure of both the circles of aberration.

It has not been found poſſible to give more than four inches of aperture to an object glaſs of 100 feet focal diſtance, ſo as to preſerve ſufficient diſtinctneſs. If we compute the diameter of the circle EH correſponding to this aperture, we ſhall find it not much to exceed $\frac{1}{120,000}$ of an inch. If we reſtrict the circle of chromatic diſperſion to $\frac{1}{250}$ of the aperture, which is hardly the fifth part of the whole diſperſion in it, it is $\frac{1}{62\frac{1}{2}}$ of an inch, and is about 1900 times greater than the other.

The circle of ſpherical abberration of a plano-convex lens, with the plane ſide next the diſtant object, is equal to the circle of chromatic diſperſion when the ſemi-aperture is about

Teleſcope. about 15°: For we ſaw formerly that EH is $\frac{1}{4}$ of FG, and that FG is $= \frac{r^2}{i^2} \frac{AP^3}{2AC^2}$, and therefore $EG = \frac{r^2}{i^2} \times \frac{AP^3}{8AC^2}$. This being made $= \frac{AP}{55}$, gives us $AP = \sqrt{\frac{8i^2AC^2}{55r^2}}$, which is nearly $\frac{AC}{4}$, and correſponds to an aperture of 30° diameter, if r be to i as 3 to 2.

Sir Iſaac Newton was therefore well entitled to ſay, that it was quite needleſs to attempt figures which ſhould have leſs aberration than ſpherical ones, while the confuſion produced by the chromatic diſperſion remained uncorrected. Since the indiſtinctneſs is as the ſquares of the diameters of the circles of aberration, the diſproportion is quite beyond our imagination, even when Newton has made ſuch a liberal allowance to the chromatic diſperſion. But it muſt be acknowledged, that he has not attended to the diſtribution of the light in the circle of ſpherical aberration, and has haſtily ſuppoſed it to be like the diſtribution of the coloured light, indefinitely rare in the margin, and denſer in the centre.

We are indebted to Father Boſcovich for the elegant determination of this diſtribution, which we have given in the article Optics. From this it appears, that the light in the margin of the circle of ſpherical aberration, inſtead of being incomparably rarer than in the ſpaces between it and the centre, is incomparably denſer. The indiſtinctneſs therefore produced by the interſection of theſe luminous circumferences is vaſtly great, and increaſes the whole indiſtinctneſs exceedingly. By a groſs calculation which we made, it appears to be increaſed at leaſt 500 times. The proportional indiſtinctneſs therefore, inſtead of being 1900^2 to 1, is only $\frac{1900^2}{500}$, or nearly 7220 to 1; a proportion ſtill ſufficently great to warrant Newton's preference of the reflecting teleſcope of his invention. And we may now obſerve, that the reflecting teleſcope has even a great advantage over a refracting one of the ſame focal diſtance with reſpect to its ſpherical aberration: For we have ſeen (*Cor.* 2.) that the lateral aberration is $\frac{r^2}{i^2} \frac{AV^3}{2CV^2}$. This for a plano-convex glaſs is nearly $\frac{9}{4} \frac{AV^3}{2CV^2}$. And the diameter of the circle of aberration is one-fourth of this, or $\frac{9}{16} \times \frac{AV^3}{2CV^2}$. In like manner, the lateral aberration of a concave mirror is $\frac{AV^3}{2CV^2}$; and the diameter of the circle of diſperſion is $\frac{AV^3}{8CV^2}$; and therefore if the ſurfaces were portions of the ſame ſphere, the diameter of the circle of aberration of refracted rays would be to that of the circle of aberration of reflected rays as $\frac{9}{16}$ to $\frac{1}{4}$, or as 9 to 4. But when the refracting and reflecting ſurfaces, in the poſition here conſidered, have the ſame focal diſtance, the radius of the refracting ſurface is four times that of the reflecting ſurface. The proportion of the diameters of the circles of ſpherical aberration is that of 9×4^2 to 4, or of 144 to 4, or 36 to 1. The diſtinctneſs therefore of the reflector is 36×36, or 1296 times greater than that of a plano-convex lens (placed with the plane ſide next the diſtant object) of the ſame breadth and focal diſtance, and will therefore admit of a much greater magnifying power. This compariſon is indeed made in circumſtances moſt favourable to the reflector, becauſe this is the very worſt poſition of a plano-convex lens. But we have not as yet learned the aberration in any other poſition. In another poſition the refraction and Teleſcope. conſequent aberration of both ſurfaces are complicated.

Before we proceed to the conſideration of this very difficult ſubject, we may deduce from what has been already demonſtrated ſeveral general rules and maxims in the conſtruction of teleſcopes, which will explain (to ſuch readers as do not wiſh to enter more deeply into the ſubject), and juſtify the proportion which long practice of the beſt artiſts has ſanctioned.

Indiſtinctneſs proceeds from the commixture of the circles of aberration on the retina of the eye: For any one *ſenſible* point of the retina, being the centre of a circle of aberration, will at once be affected by the admixture of the rays of as many different pencils of light as there are ſenſible points in the area of that circle, and will convey to the mind a mixed ſenſation of as many viſible points of the object. This number will be as the area of the circle of aberrations, whatever be the ſize of a ſenſible point of the retina. Now in viſion with teleſcopes, the diameter of the circle of aberration on the retina is as the *apparent* magnitude of the diameter of the correſponding circle in the focus of the eye-glaſs; that is, as the angle ſubtended by this diameter at the centre of the eye-glaſs; that is, as the diameter itſelf directly, and as the focal diſtance of the eye-glaſs inverſely. And the area of that circle on the retina is as the area of the circle in the focus of the eye-glaſs directly, and as the ſquare of the focal diſtance of the eye-glaſs inverſely. And this is the meaſure of the apparent indiſtinctneſs.

Cor. In all ſorts of teleſcopes, and alſo in compound microſcopes, an object is ſeen equally diſtinct when the focal diſtance of the eye-glaſſes are proportional to the diameters of the circles of aberration in the focus of the object-glaſs.

Here we do not conſider the trifling alteration which well conſtructed eye-glaſſes may add to the indiſtinctneſs of the firſt image.

In refracting teleſcopes, the apparent indiſtinctneſs is as the area of the object-glaſs directly, and as the ſquare of the focal diſtance of the eye-glaſs inverſely. For it has been ſhown, that the area of the circle of diſperſion is as the area of the object-glaſs, and that the ſpherical aberration is inſignificant when compared with this.

Therefore, to make reflecting teleſcopes equally diſtinct, the diameter of the object-glaſs muſt be proportional to the focal diſtance of the eye-glaſs.

But in reflecting teleſcopes, the indiſtinctneſs is as the ſixth power of the aperture of the object-glaſs directly, and as the fourth power of the focal diſtance of the object-glaſs and ſquare of the focal diſtance of the eye-glaſs inverſely. This is evident from the dimenſions of the circle of aberration, which was found proportional to $\frac{AV^3}{CV^2}$.

Therefore, to have them equally diſtinct, the cubes of the apertures muſt be proportional to the ſquares of the focal diſtance multiplied by the focal diſtance of the eye-glaſs.

By theſe rules, and a ſtandard teleſcope of approved goodneſs, an artiſt can always proportion the parts of any inſtrument he wiſhes to conſtruct. Mr. Huyghens made one, of which the object-glaſs had 30 feet focal diſtance and three inches diameter. The eye-glaſs had 3,3 inches focal diſtance. And its performance was found ſuperior to any which he had ſeen; nor did this appear owing to any chance goodneſs of the object-glaſs, becauſe he found others equally good which were conſtructed on ſimilar proportions. This has therefore been adopted as a ſtandard.

It does not at firſt appear how there can be any difficul-

Teleſcope. ty in this matter, becauſe we can always diminiſh the aperture of the object-glaſs, or ſpeculum till the circle of aberration is as ſmall as we pleaſe. But by diminiſhing this aperture, we diminiſh the light in the duplicate ratio of the aperture. Whatever be the aperture, the brightneſs is diminiſhed by the magnifying power, which ſpreads the light over a greater ſurface in the bottom of the eye. The apparent brightneſs muſt be as the ſquare of the aperture of the teleſcope directly, and the ſquare of the amplification of the diameter of an object inverſely. Objects therefore will be ſeen equally bright if the apertures of the teleſcopes be as the focal diſtances of the object-glaſſes directly, and the focal diſtances of the ſingle eye-glaſs (or eye-glaſs equivalent to the eye piece) inverſely. Therefore, to have teleſcopes equally diſtinct and equally bright, we muſt combine theſe proportions with the former. It is needleſs to go farther into this ſubject, becauſe the conſtruction of refracting teleſcopes has been ſo materially changed by the correction of the chromatic aberration, that there can hardly be given any proportion between the object-glaſs and eye-glaſſes. Every thing now depends on the degree in which we can correct the aberrations of the object-glaſs. We have been able ſo far to diminiſh the chromatic aberration, that we can give very great apertures without its becoming ſenſible. But this is attended with ſo great an increaſe of the aberration of figure, that this laſt becomes a ſenſible quality. A lens which has 30° for its ſemi-aperture, has a circle of aberration equal to its chromatic aberration. Fortunately we can derive from the very method of contrary refractions, which we employ for removing the chromatic aberration, a correction of the other. We are indebted for this contrivance alſo to the illuſtrious Newton.

We call this Newton's contrivance, becauſe he was the firſt who propoſed a conſtruction of an object-glaſs in which the aberration was corrected by the contrary aberrations of glaſs and water.

Huyghens had indeed ſuppoſed, that our all-wiſe Creator had employed in the eyes of animals many refractions in place of one, in order to make the viſion more diſtinct; and the invidious detractors from Newton's fame have catched at this vague conjecture as an indication of his knowledge of the poſſibility of deſtroying the aberration of figure by contrary refractions. But this is very ill-founded. Huyghens has acquired ſufficient reputation by his theory of aberrations. The ſcope of his writing in the paſſage alluded to, is to ſhow that, by dividing any intended refraction into parts, and producing a certain convergence to or divergence from the axis of an optical inſtrument by means of two or three lenſes inſtead of one, we diminiſh the aberrations four or nine times. This conjecture about the eye was therefore in the natural train of his thoughts. But he did not think of deſtroying the aberration altogether by oppoſite refractions. Newton, in 1669, ſays, that opticians need not trouble themſelves about giving figures to their glaſſes other than ſpherical. If this figure were all the obſtacle to the improvement of teleſcopes, he could ſhow them a conſtruction of an object-glaſs having ſpherical ſurfaces where the aberration is deſtroyed; and accordingly gives the conſtruction of one compoſed of glaſs and water, in which this is done completely by means of contrary refractions.

The general principle is this: When the radiant point R (fig. 5. B), or focus of incident rays, and its conjugate focus F of refracted central rays, are on oppoſite ſides of the refracting ſurface or lens V, the conjugate focus f of marginal rays is nearer to R than F is. But when the focus of incident rays R′ lies on the ſame ſide with its conjugate focus F′ for central rays, R′f′ is greater than R′ F′.

Now fig. 5. C repreſents the contrivance for deſtroying Teleſcope. the colour produced at F, the principal focus of the convex lens V, of crown glaſs, by means of the contrary refraction of the concave lens v of flint glaſs. The incident parallel rays are made to converge to F by the firſt lens. This convergence is diminiſhed, but not entirely deſtroyed, by the concave lens v, and the focus is formed in F. F and F′ therefore are conjugate foci of the concave lens. If F be the focus of V for central rays, the marginal rays will be collected at ſome point f nearer to the lens. If F be now conſidered as the focus of light incident on the centre of v, and F′ be the conjugate focus, the marginal ray p F would be refracted to ſome point f′ lying beyond F′. Therefore the marginal ray $p f$ may be refracted to F′, if the aberration of the concave be properly adjuſted to that of the convex.

This brings us to the moſt difficult part of our ſubject, the compounded aberrations of different ſurfaces. Our limits will not give us room for treating this in the ſame elementary and perſpicuous manner that we employed for a ſingle ſurface. We muſt try to do it in a compendious way, which will admit at once the different ſurfaces and the different refractive powers of different ſubſtances. This muſt naturally render the proceſs more complicated; but we hope to treat the ſubject in a way eaſily comprehended by any perſon moderately acquainted with common algebra; and we truſt that our attempt will be favourably received by an indulgent public, as it is (as far as we know) the only diſſertation in our language on the conſtruction of achromatic inſtruments. We cannot but expreſs our ſurpriſe at this indifference about an invention which has done ſo much honour to Britain, and which now conſtitutes a very lucrative branch of its manufacture. Its artiſts infinitely ſurpaſs all the performances of foreigners in this branch, and ſupply the markets of Europe without any competition; yet it is from the writings on the continent that they derive their ſcientific inſtruction, and particularly from the diſſertations of Clairaut, who has wonderfully ſimplified the analyſis of optical propoſitions. We ſhall freely borrow from him, and from the writings of Abbé Boſcovich, who has conſiderably improved the firſt views of Clairaut. We recommend the originals to the curious reader. Clairaut's diſſertations are to be found in the Memoirs of the Academy of Paris, 1756, &c.; thoſe of Boſcovich in the Memoirs of the Academy of Bologna, and in his five volumes of *Opuſcula*, publiſhed at Baſſano in 1785. To theſe may be added D'Alembert and Euler. The only thing in our language is the tranſlation of a very imperfect work by Schærfer.

Lemma 1. In the right-angled triangle MXS (fig. 6), of which one ſide MX is very ſmall in compariſon of either of the others; the exceſs of the hypothenuſe MS, above the ſide XS, is very nearly equal to $\frac{MX^2}{2MS}$ or to $\frac{MX^2}{2XS}$. For if about the centre S, with the radius SM, we deſcribe the ſemicircle AMO, we have AX × XO = MX². Now AX = MS − SX, and XO, is nearly equal to 2MS or 2XS; on the other hand, MS is nearly equal to $XS + \frac{MX^2}{2XS}$; and in like manner MG is nearly equal to $\frac{MX^2}{2XG} + XG$, and MH is nearly equal to $\frac{MX^2}{2XH} + XH$.

Prop. I. Let the ray m M, incident on the ſpherical ſurface AM, converge to G; that is, let G be the focus of inci-

Telescope. incident rays. It is required to find the focus F of refracted rays?

Let m express the ratio of the sine of incidence and refraction; that is, let m be to 1 as the sine of incidence to the sine of refraction in the substance of the sphere.

Then - MG : GS = sin. MSH : sin. SMG,
and - m : 1 = sin. SMG : sin. SMH;
therefore $m \times$ MG : GS = sin. MSH : sin. SMH.
Now S, MSH : S, SMH = MH : HS. Therefore, finally,
m. MG : GS = MH : HS.

Now let MS, the radius of the refracting surface, be called a. Let AG, the distance of the focus of incident rays from the surface, be called r. And let AH, the focal distance of refracted rays, be called x. Lastly, let the line MX of the semi-aperture be called e. Observe, too, that a, r, x, are to be considered as positive quantities, when AS, AG, AH, lie from the surface in the direction in which the light is supposed to move. If therefore the refracting surface be concave, that is, having the centre on that side from which the light comes; or if the incident rays are divergent, or the refracted rays are divergent; then a, r, x, are negative quantities.

It is plain that $HS = x - a$; $GS = r - a$; also $AX = \frac{e^2}{2a}$ nearly. $HX = a - \frac{e^2}{2a}$. $GX = r - \frac{e^2}{2a}$. Now add to HX and to GX their differences from MH and MG, which (by the Lemma) are $\frac{e^2}{2x}$ and $\frac{e^2}{2r}$. We get $MH = x - \frac{e^2}{2a} + \frac{e^2}{2x}$, and $MG = r - \frac{e^2}{2a} + \frac{e^2}{2r}$. In order to shorten our notation, make $k = \frac{1}{a} - \frac{1}{r}$. This will make $MG = r - \frac{ke^2}{2}$.

Now substitute these values in the final analogy at the top of this column, viz. MH : HS = m. MG : GS; it becomes $x - \frac{e^2}{2a} + \frac{e^2}{2x} : x - a = mr - \frac{mke^2}{2} : r - a$ (or ark), because $k = \frac{r-a}{ar}$, and $ark = r - a$. Now multiply the extreme and mean terms of this analogy. It is evident that it must give us an equation which will give us a value of x or AH, the quantity sought.

But this equation is quadratic. We may avoid the solution by an approximation which is sufficiently accurate, by substituting for x in the fraction $\frac{e^2}{2x}$ (which is very small in all cases of optical instruments), an approximate value very easily obtained, and very near the truth. This is the focal distance of an infinitely slender pencil of rays converging to G. This we know by the common optical theorem to be $\frac{amr}{m-1r=a}$. Let this be called φ; if we substitute k in place of $\frac{1}{a} - \frac{1}{r}$, this value of φ becomes $= \frac{am}{m-ak}$.

This gives us, by the by, an easily remembered expression (and beautifully simple) of the refracted focus of an infinitely slender pencil, corresponding to any distance r of the radiant point. For since $\varphi = \frac{am}{m-ak}$, $\frac{1}{\varphi}$ must be $= \frac{m-ak}{am}$, $= \frac{m}{am} - \frac{ak}{am}$, $= \frac{1}{a} - \frac{k}{m}$. We may even express it more simply, by expanding k, and it becomes $\frac{1}{\varphi} = \frac{1}{a} - \frac{1}{ma} - \frac{1}{mr}$.

Now put this value of $\frac{1}{\varphi}$ in place of the $\frac{1}{x}$ in the analogy employed above. The first term of the analogy becomes $x - \frac{e^2}{2a} + \frac{e^2}{2a} - \frac{ke^2}{2m}$, or $x - \frac{ke^2}{2m}$. The analogy now becomes $x - \frac{ke^2}{2m} : xa = mr - \frac{mke^2}{2} : ark$. Hence we obtain the linear equation $mrx - \frac{mke^2x}{2} - mra + \frac{mkae^2}{2} = ark x - \frac{arke^2}{2m}$; from which we finally deduce

$$x = \frac{mra - \frac{1}{2}makee^2 - \frac{ark^2e^2}{2m}}{mr - ark - \frac{1}{2}mke^2}$$

We may simplify this greatly by attending to the elementary theorem in fluxions, that the fraction $\frac{x+\dot{x}}{y+\dot{y}}$ differs from the fraction $\frac{x}{y}$ by the quantity $\frac{\dot{y}x - x\dot{y}}{y^2}$; this being the fluxion of $\frac{x}{y}$. Therefore $\frac{x+\dot{x}}{y+\dot{y}} = \frac{x}{y} + \frac{\dot{y}x - x\dot{y}}{y^2}$. Now the preceding formula is nearly in this situation. It may be written thus; $\frac{mra \quad \left(-\frac{1}{2}makee^2 - \frac{ark^2e^2}{2m}\right)}{mr - ark \quad -mke^2}$, when the last terms of the numerator and denominator are very small in comparison with the first, and may be considered as the $\dot{x}$ and $\dot{y}$, while mra is the x, and $mr - ark$ is the y. Treating it in this way, it may be stated thus:

$$x = \frac{mra}{mr - ark} + \frac{(mra)\frac{1}{2}mke^2 - (mr - ark)\left(\frac{1}{2}makee^2 + \frac{ark^2e^2}{2m}\right)}{r^2(m-ak)^2}$$

$$\text{or } x = \frac{mra}{r(m-ak)} + \frac{(mra)mk - (mr-ark)\left(mka + \frac{ark^2}{m}\right)}{r^2(m-ak)^2} \times \tfrac{1}{2}e^2.$$

The first term $\frac{mra}{r(m-ak)}$, or $\frac{ma}{m-ak}$, is evidently $= \varphi$, the focal distance of an infinitely slender pencil. Therefore the aberration is expressed by the second term, which we must endeavour to simplify.

If we now perform the multiplications indicated by $-(mr - ark) \times \left(mka - \frac{ark^2}{m}\right)$, it is plain that $-mr \times mka$ destroys the first term $mra \times mk$ of the numerator of our small fraction, and there remains of this numerator $\left(ma^2rk^2 - ar^2k^3 + \frac{a^2r^2k^3}{m}\right)\frac{1}{2}e^2$, which is equal to $m^2a^2\left(\frac{rk^2}{m} - \frac{r^2k^3}{m^2a} + \frac{r^2k^3}{m^3}\right)\frac{1}{2}e^2$.

The denominator was $r^2(m-ak)^2$, and the fraction now becomes $\frac{m^2a^2}{(m-ak)^2}\left(\frac{k^2}{mr} - \frac{k^3}{m^2a} + \frac{k^3}{m^3}\right)\frac{1}{2}e^2$, which is evidently $= \varphi^2\left(\frac{k^2}{mr} - \frac{k^3}{m^2a} + \frac{k^3}{m^3}\right)\frac{e^2}{2}$. Now recollect that $k = \frac{1}{a} - \frac{1}{r}$. Therefore $\frac{k^3}{m^3} = \frac{k^2}{m^2}\left(\frac{1}{a} - \frac{1}{r}\right) = \frac{k^2}{m^2a} - \frac{k^2}{m^2r}$. Therefore, instead of $-\frac{k^3}{m^2a}$, write $\frac{-k^3}{m^3} - \frac{k^2}{m^2r}$, and we get the fraction $\varphi^2\left(\frac{k^3}{m^3} - \frac{k^3}{m^2} - \frac{k^2}{m^2r} + \frac{k^2}{mr}\right)\frac{e^2}{2} = \varphi^2\left(\frac{k^3}{m} - \frac{mk^3}{m^3} -$

Telescope. $\frac{mk^2}{m^3 r} + \frac{m^2 k^2}{m^3 r}\Big)\frac{e^2}{2}$, which is equal to $\varphi^2 \frac{1-m}{m^3}\left(k^3 - \frac{mk^2}{r}\right)\frac{e^2}{2}$, and finally to $-\varphi^2 \frac{m-1}{m^3}\left(k^3 - \frac{mk^2}{r}\right)\frac{e^2}{2}$.

Therefore the focal diſtance of refracted rays is $x = \varphi - \varphi^2 \frac{m-1}{m^3}\left(k^3 - \frac{mk^2}{r}\right)\frac{e^2}{2}$.

This conſiſts of two parts. The firſt φ is the focal diſtance of an infinitely ſlender pencil of central rays, and the other $-\varphi^2 \frac{m-1}{m^3}\left(k^3 - \frac{mk^2}{r}\right)\frac{e^2}{2}$ is the aberration ariſing from the ſpherical figure of the refracting ſurface.

Our formula has thus at laſt put on a very ſimple form, and is vaſtly preferable to Dr Smith's for practice.

This aberration is evidently proportional to the ſquare of the ſemi-aperture, and to the ſquare of the diſtance φ: but, in order to obtain this ſimplicity, ſeveral quantities were neglected. The aſſumption of the equality of AX to $\frac{e^2}{2a}$ is the firſt ſource of error. A much more accurate value of it would have been $\frac{2ae^2}{4a^2+e^2}$, for it is really $= \frac{e^2}{2a-AX}$. If for AX we ſubſtitute its approximated value $\frac{e^2}{2a}$, we ſhould have $AX = \frac{e^2}{2a-\frac{e^2}{2a}}, = \frac{2ae^2}{4a^2-e^2}$. To have uſed this value would not have much complicated the calculus; but it did not occur to us till we had finiſhed the inveſtigation, and it would have required the whole to be changed. The operation in page 346. col. 2. par. 2. is another ſource of error. But theſe errors are very inconſiderable when the aperture is moderate. They increaſe for the moſt part with an increaſe of aperture, but not in the proportion of any regular function of it; ſo that we cannot improve the formula by any manageable proceſs, and muſt be contented with it. The errors are preciſely the ſame with thoſe of Dr Smith's theorem, and indeed with thoſe of any that we have ſeen, which are not vaſtly more complicated.

As this is to be frequently combined with ſubſequent operations, we ſhorten the expreſſion by putting θ for $\frac{m-1}{m^3}\left(k^3 - \frac{mk^2}{r}\right)\frac{e^2}{2}$. Then $\varphi^2\theta$ will expreſs the aberration of the firſt refraction from the focal diſtance of an infinitely ſlender pencil; and now the focal diſtance of refracted rays is $f = \varphi - \varphi^2\theta$.

If the incident rays are parallel, r becomes infinite, and $\theta = \frac{m-1}{m^3}k^3\frac{e^2}{2}$. But in this caſe k becomes $= \frac{1}{a}$, and $\frac{1}{\varphi} = \frac{m-1}{ma}$, and $\varphi = \frac{ma}{m-1}$, and $\varphi^2\theta$ becomes $\frac{m^2a^2}{(m-1)^2} \times \frac{m-1}{m^3} \times \frac{1}{a^3} \times \frac{e^2}{2}, = \frac{e^2}{2(m-1)ma}$. This is the aberration of extreme parallel rays.

We muſt now add the refraction of another ſurface.

Lemma 2. If the focal diſtance AG be changed by a ſmall quantity Gg, the focal diſtance AH will alſo be changed by a ſmall quantity Hh, and we ſhall have

$$m \cdot AG^2 : AH^2 = Gg : Hh.$$

Draw Mg, Mh, and the perpendiculars Gi, Hk. Then, becauſe the ſines of the angles of incidence are in a conſtant ratio to the ſines of the angles of refraction, and the increments of theſe ſmall angles are proportional to the increments of the ſines, theſe increments of the angles are in the ſame conſtant ratio. Therefore,

We have the angle CMg to HMh as m to 1 Telescope.

Now $Gg : Gi = AG : AM$,
and $Gi : hk = m \cdot AG : HA$,
and $hk : Hh = MA : AH$:
therefore $Gg : Hh = m \cdot AG^2 : AH^2$.

The eaſieſt and moſt perſpicuous method for obtaining the aberration of rays twice refracted, will be to conſider the firſt refraction as not having any aberration, and determine the aberration of the ſecond refraction. Then conceive the focus of the firſt refraction as ſhifted by the aberration. This will produce a change in the focal diſtance of the ſecond refraction, which may be determined by this Lemma.

Prop. II. Let AM, BN (fig. 7.) be two ſpherical ſurfaces, including a refracting ſubſtance, and having their centres C and c in the line AG. Let the ray aA paſs through the centres, which it will do without refraction. Let another ray mM, tending to G, be refracted by the firſt ſurface into MH, cutting the ſecond ſurface in N, where it is farther refracted into NI. It is required to determine the focal diſtance BI?

It is plain that the ſine of incidence on the ſecond ſurface is to the ſine of refraction into the ſurrounding air as 1 to m. Alſo BI may be determined in relation to BH, by means of BH, Nx, Bc, and $\frac{1}{m}$, in the ſame way that AH was determined in relation to AG, by means of AG, MX, AC, and m.

Let the radius of the ſecond ſurface be b, and let e ſtill expreſs the ſemi-aperture, (becauſe it hardly differs from Nx). Alſo let α be the thickneſs of the lens. Then obſerve, that the focal diſtance of the rays refracted by the firſt ſurface, (neglecting the thickneſs of the lens and the aberration of the firſt ſurface, is the diſtance of the radiant point for the ſecond refraction, or is the focal diſtance of rays incident on the ſecond ſurface. In place of r therefore we muſt take φ; and as we made $k = \frac{1}{a} - \frac{1}{r}$, in order to abbreviate the calculus, let us now make $l = \frac{1}{b} - \frac{1}{\varphi}$; and make $\frac{1}{f} = \frac{1}{b} - ml$, as we made $\frac{1}{\varphi} = \frac{1}{a} - \frac{k}{m}$. Laſtly, in place of $\theta = \frac{m-1}{m^3}\left(k^3 - \frac{mk^2}{r}\right)\frac{e^2}{2}$, make $\theta' = \left(\frac{1}{m} - 1\right)m^3\left(l^3 - \frac{l^2}{m\varphi}\right)\frac{e^2}{2}, = -\frac{m-1}{m}\left(m^3l^3 - \frac{m^2l^2}{\varphi}\right)\frac{e^2}{2}$.

Thus we have got an expreſſion ſimilar to the other; and the focal diſtance BI, after two refractions, becomes $BI = f - f^2\theta'$.

But this is on the ſuppoſition that BH is equal to φ, whereas it is really $\varphi - \varphi^2\theta - \alpha$. This muſt occaſion a change in the value juſt now obtained of BI. The ſource of the change is twofold. 1ſt, Becauſe, in the value $\frac{1}{b} - \frac{1}{\varphi}$, we muſt put $\frac{1}{b} - \frac{1}{\varphi - \varphi^2\theta - \alpha}$, and becauſe we muſt do the ſame in the fraction $\frac{m^2l^2}{\varphi}$. In the ſecond place, when the value of BH is diminiſhed by the quantity $\varphi^2\theta + \alpha$, BI will ſuffer a change in the proportion determined by the 2d Lemma. The firſt difference may ſafely be neglected, becauſe the value of θ is very ſmall, by reaſon of the coefficient $\frac{e^2}{2}$ being very ſmall, and alſo becauſe the variation bears a very ſmall ratio to the quantity itſelf, when the true value of φ differs

Teleſcope. differs but little from that of the quantity for which it is employed. The chief change in BI is that which is determined by the lemma. Therefore take from BI the variation of BH, multiplied by $\frac{m\,BI^2}{BH^2}$, which is very nearly $= \frac{mf^2}{\varphi^2}$. The product of this multiplication is $mf^2\theta + \frac{mf^2\alpha}{\varphi^2}$. This being taken from f, leaves us for the value of BI $f - \frac{f^2 m\alpha}{\varphi^2} - f^2(m\theta + \theta')$.

In this value f is the focal diſtance of an infinitely ſlender pencil of rays twice refracted by a lens having no thickneſs, $\alpha\frac{mf^2}{\varphi}$ is the ſhortening occaſioned by the thickneſs, and $f^2(m\theta + \theta')$ is the effect of the two aberrations ariſing from the aperture.

It will be convenient, for ſeveral collateral purpoſes, to exterminate from theſe formula the quantities k, l, and φ. For this purpoſe make $\frac{1}{n} = \frac{1}{a} - \frac{1}{b}$. We have already $k = \frac{1}{a} - \frac{1}{r}$; and $\frac{1}{\varphi} = \frac{1}{a} - \frac{1}{ma} + \frac{1}{mr}$; and $l = \frac{1}{b} - \frac{1}{\varphi}, = \frac{1}{b} - \frac{1}{a} + \frac{1}{ma} - \frac{1}{mr}$. Now for $\frac{1}{b} - \frac{1}{a}$ write $-\frac{1}{n}$, and we get $l = \frac{1}{ma} - \frac{1}{mr} - \frac{1}{n}$. Therefore $\frac{1}{f} = \frac{1}{b} - ml$ (by conſtruction, page 347. Prop. II.) becomes $= \frac{1}{b} - \frac{1}{a} + \frac{1}{r} + \frac{m}{n}, = \frac{m}{n} + \frac{1}{r} - \frac{1}{n}, = \frac{m-1}{n} + \frac{1}{r}$.

This laſt value of $\frac{1}{f}$ (the reciprocal of the focus of a ſlender pencil twice refracted), viz. $\frac{m-1}{n} + \frac{1}{r}$, is the ſimpleſt that can be imagined, and makes n as a ſubſtitute for $\frac{1}{a} - \frac{1}{b}$; a moſt uſeful ſymbol, as we ſhall frequently find in the ſequel. It alſo gives a very ſimple expreſſion of the focal diſtance of parallel rays, which we may call the principal focal diſtance of the lens, and diſtinguiſh it in future by the ſymbol p; for the expreſſion $\frac{1}{f} = \frac{m-1}{n} + \frac{1}{r}$, becomes $\frac{1}{p} = \frac{m-1}{n}$ when the incident light is parallel. And this gives us another very ſimple and uſeful meaſure of f; for $\frac{1}{f}$ becomes $= \frac{1}{p} + \frac{1}{r}$. Theſe equations $\frac{1}{f} = \frac{m-1}{n} + \frac{1}{r}, \frac{1}{p} = \frac{m-1}{n}$, and $\frac{1}{f} = \frac{1}{p} + \frac{1}{r}$, deſerve therefore to be made very familiar to the mind.

We may alſo take notice of another property of n. It is half the radius of an iſoſceles lens, which is equivalent to the lens whoſe radii are a and b: for ſuppoſe the lens to be iſoſceles, that is, $a = b$; then $n = \frac{1}{a} - \frac{1}{a}$. Now the ſecond a is negative if the firſt be poſitive, or poſitive if the firſt be negative. Therefore $\frac{1}{a} - \frac{1}{b} = \frac{1+b}{a^2} = \frac{a+a}{a^2} = \frac{2}{a}$, and $\frac{1}{n} = \frac{2}{a}$, and $n = \frac{a}{2}$. Now the focal diſtance of this lens is $\frac{m-1}{n}$, and ſo is that of the other, and they are equivalent.

But, to proceed with our inveſtigation, recollect that we Teleſcope had $\theta = \frac{m-1}{m^3}\left(k^3 - \frac{mk^2}{r}\right)\frac{e^2}{2}$. Therefore $m\theta = \frac{m-1}{m}\left(\frac{k^3}{m} - \frac{k^2}{r}\right)\frac{e^2}{2}$. And θ' was $= \frac{m-1}{m}\left(-m^3 l^3 + \frac{ml^2}{\varphi}\right)\frac{e^2}{2}$. Therefore $m\theta + \theta'$, the aberration (neglecting the thickneſs of the lens) is $f^2\frac{m-1}{m}\left(\frac{k^3}{m} - \frac{k^2}{r} - m^3 l^3 + \frac{ml^2}{\varphi}\right)\frac{e^2}{2}$.

If we now write for k, l, and φ, their values as determined above, performing all the neceſſary multiplications, and arrange the terms in ſuch a manner as to collect in one ſum the coefficients of a, n, and r, we ſhall find 4 terms for the value of $m\theta$, and 10 for the value of θ'. The 4 are deſtroyed by as many with contrary ſigns in the value of θ', and there remain 6 terms to expreſs the value of $m\theta + \theta'$, which we ſhall expreſs by one ſymbol 9; and the equation ſtands thus:

$$q = \frac{m-1}{m}\left(\frac{m^3}{n^3} - \frac{2m^2+m}{an^2} + \frac{m+2}{a^2n} + \frac{3m^2+m}{rn^2} - \frac{4m+4}{arn} + \frac{3m+2}{r^2n}\right)\frac{e^2}{2}.$$

The focal diſtance therefore of rays twice refracted, reckoned from the laſt ſurface, or BI, corrected for aberration, and for the thickneſs of the lens, is $f - f\frac{2m\alpha}{\varphi^2} - f^2 q$, conſiſting of three parts, viz. f, the focal diſtance of central rays; $f^2\frac{m\alpha}{\varphi^2}$, the correction for the thickneſs of the lens; and $f^2 q$, the aberration.

The formula in the 2d par. of this col. appears very complex, but is of very eaſy management, requiring only the preparation of the ſimple numbers which form the numerators of the fractions included in the parentheſis. When the incident rays are parallel, the terms vaniſh which have r in the denominator, ſo that only the three firſt terms are uſed.

We might here point out the caſes which reduce the aberration expreſſed in the formula laſt referred to, to nothing; but as they can ſcarcely occur in the object-glaſs of a teleſcope, we omit it for the preſent, and proceed to the combination of two or more lenſes.

Lemma 3. If AG be changed by a ſmall quantity Gg, BI ſuffers a change Ii, and $Gg : Ii = AG^2 : BI^2$. For it is well known that the ſmall angles GMg and INi are equal; and therefore their ſubtenſes Gk, In are proportional to MG, NI, or to AG, AI nearly, when the aperture is moderate. Therefore we have (nearly)

$$Gk : In = AG : BI$$
$$In : Ii = AM : BI$$
$$Gg : Gk = AG : AM$$
$$\text{Therefore } Gg : Ii = AG^2 : BI^2$$

Prop. III. To determine the focal diſtance of rays refracted by two lenſes placed near to each other on a common axis.

Let AM, BN (fig. 8.) be the ſurfaces of the firſt lens, and CO, DP be the ſurfaces of the ſecond, and let β be the thickneſs of the ſecond lens, and δ the interval between them. Let the radius of the anterior ſurface of the ſecond lens be a', and the radius of its poſterior ſurface be b'. Let m' be to 1 as the ſine of incidence to the ſine of refraction in the ſubſtance of the ſecond lens. Laſtly, let p' be the principal focal diſtance of the ſecond lens. Let the extreme or marginal ray meet the axis in L after paſſing thro' both lenſes, ſo that DL is the ultimate focal diſtance, reckoned from the laſt ſurface.

It is plain that DL may be determined by means of a', b', m', p', and CI, in the ſame manner that BI was determined by means of a, b, m, p, and AG.

The

Teleſcope. The value of BI is $f - m\alpha\frac{f^2}{\varphi^2} - f^2 q$. Take from this the interval δ, and we have CI $= f - m\alpha\frac{f^2}{\varphi^2} - \delta - f^2 q$. Let the ſmall part $-m\alpha\frac{f^2}{\varphi^2} - \delta - f^2 q$ be neglected for the preſent, and let CI be ſuppoſed $= f$. As we formed φ, f, and q, by means of a, b, m, n, and r, let us now form φ', f', and q', for the ſecond lens, by means of a', b', m', n', $\left(=\frac{1}{a'}-\frac{1}{b'}\right)$, and r'. φ' will be the focal diſtance of a ſlender pencil refracted by the firſt ſurface, f will be the focal diſtance of this pencil after two refractions, and q' will be the coefficient of the aberration, neglecting the thickneſs and interval of the lenſes.

Proceeding in this way, DL will be $= f' - m\beta\frac{f'^2}{\varphi'} - f'^2 q$. But becauſe CI is really leſs than f, by the quantity $m\alpha\frac{f^2}{\varphi'^2} + \delta + f^2 q'$, we muſt (by Lemma 3.) ſubtract the product of this quantity, multiplied by $\frac{\mathrm{DL}}{\mathrm{BI}^2}$, (which is nearly $\frac{f'^2}{f^2}$), from $f' - m\beta\frac{f'^2}{\varphi'^2} - f'^2 q'$.

By this proceſs we ſhall have

$$\mathrm{DL} = f' - f'^2\left(\frac{m\alpha}{\varphi^2} + \frac{\delta}{f^2} + \frac{m'\beta}{\varphi'^2}\right) - f'^2(q + q').$$

The firſt term f' of this value of DI is the focal diſtance of a ſlender pencil of central rays refracted by both lenſes, neglecting their thickneſs and diſtance; the ſecond term, $-f'^2\left(\frac{m\alpha}{\varphi^2} + \frac{\delta}{f^2} + \frac{m'\beta}{\varphi'^2}\right)$ is the correction neceſſary for theſe circumſtances; and the third term, $-f'^2(q + q')$, is the correction for the aperture $2e$. And it is evident that q' is a formula preciſely ſimilar to q, containing the ſame number of terms, and differing only by the m', a', n', and r', employed in place of m, a, n, and r.

It is alſo evident, that if there be a third lens, we ſhall obtain its focal diſtance by a proceſs preciſely ſimilar to that by which we obtained DL; and ſo on for any number of lenſes.

Thus have we obtained formulæ by which the foci of rays are determined in the moſt general terms; and in ſuch a manner as ſhall point out the connection of the curvatures, thickneſſes, and diſtances of the lenſes, with their ſpherical aberrations, and with the final aberration of the compound lens, and give the aberrations in ſeparate ſymbols, ſo that we can treat them by themſelves, and ſubject them to any conditions which may enable us to correct one of them by another.

We alſo ſee in general, that the correction for the thickneſs and diſtance of the lenſes are exhibited in terms which involve only the focal diſtances of central rays, and have very little influence on the aberrations, and ſtill leſs on the ratio of the aberrations of the different lenſes. This is a moſt convenient circumſtance; for we may neglect them while we are determining q and q', and in determining the ratio of the focal diſtances of the ſeveral lenſes, on which the correction of the chromatic aberration chiefly depends. Therefore, in the conſtruction of a compound lens for uniting the different colours, we may neglect this correction for the thickneſs and diſtance till the end of the proceſs. When we apply it, we ſhall find that it chiefly affects the final focal diſtance, making it ſomewhat longer, but has hardly any influence either on the chromatic or ſpherical aberration. We do not heſitate to ſay, that the final formulæ here given are abundantly accurate, while they are vaſtly more manageable than thoſe employed by Euler or D'Alembert. We have calculated trigonometrically the progreſs of the rays through one of the glaſſes, which will be given as an example, giving it a very extravagant aperture, that the errors of the formulæ might be very remarkable. We found the real aberration exceed the aberration aſſigned by the formula by no more than $\frac{1}{59}$th part, a difference which is quite inſignificant. The proceſs here given derives its ſimplicity from the frequent occurrence of harmonic proportions in all optical theorems. This enabled Mr Clairaut to employ the reciprocals of the radii and diſtances with ſo much ſimplicity and generality. Teleſcope.

We conſider it as another advantage of Mr Clairaut's method, that it gives, by the way, formulæ for the more ordinary queſtions in optics, which are of wonderful ſimplicity, and moſt eaſily remembered. The chief problems in the elementary conſtruction of optical inſtruments relate to the focal diſtances of central rays. This determines the focal diſtances and arrangement of the glaſſes. All the reſt may be called the refinement of optics; teaching us how to avoid or correct the indiſtinctneſs, the colours, and the diſtortions, which are produced in the images formed by theſe ſimple conſtructions. We ſhall mention a few of theſe formulæ which occur in our proceſs, and tend greatly to abbreviate it when managed by an experienced analyſt.

Let m be to 1 as the ſine of incidence to the ſine of refraction; let a and b be the radii of the anterior and poſterior ſurfaces of a lens; let r be the diſtance of the radiant point, or the focus of incident central rays, and f the diſtance of the conjugate focus; and let p be the principal focal diſtance of the lens, or the focal diſtance of parallel rays. Make $\frac{1}{n}$ equal to $\frac{1}{a} - \frac{1}{b}$; let the ſame letters a', b', r', &c. expreſs the ſame things for a ſecond lens; and a'', b'', r'', &c. expreſs them for a third; and ſo on. Then we have $\frac{1}{f} = \frac{m-1}{n} + \frac{1}{r}$; $\frac{1}{f'} = \frac{m'-1}{n'} + \frac{1}{r'}$; $\frac{1}{f''} = \frac{m''-1}{n''} + \frac{1}{r''}$, &c.

Therefore when the incident light is parallel, and r infinite, we have $\frac{1}{p} = \frac{m-1}{n}$; $\frac{1}{p'} = \frac{m'-1}{n'}$; $\frac{1}{p''} = \frac{m''-1}{n''}$, &c.

And when ſeveral lenſes are contiguous, ſo that their intervals may be neglected, and therefore $\frac{1}{f}$, belonging to the firſt lens, becomes $\frac{1}{r}$, belonging to the ſecond, we have

1. $\frac{1}{r'} = \frac{1}{f}, = \frac{m-1}{n} + \frac{1}{r}, = \frac{1}{p} + \frac{1}{r}$.
2. $\frac{1}{r''} = \frac{1}{f'}, = \frac{m'-1}{n'} + \frac{m-1}{n} + \frac{1}{r}, = \frac{1}{p'} + \frac{1}{p} + \frac{1}{r}$.
3. $\frac{1}{f''} = \frac{m''-1}{n''} + \frac{m'-1}{n} + \frac{m-1}{n} + \frac{1}{r}, = \frac{1}{p''} + \frac{1}{p'} + \frac{1}{p} + \frac{1}{r}$.

Nothing can be more eaſily remembered than theſe formulæ, how numerous ſo ever the glaſſes may be.

Having thus obtained the neceſſary analyſis and formulæ, it now remains to apply them to the conſtruction of achromatic lenſes; in which it fortunately happens, that the employment of ſeveral ſurfaces, in order to produce the union of the differently refrangible rays, enables us at the ſame time to employ them for correcting each other's ſpherical aberration.

In the article Optics we gave a general notion of the principle on which we may proceed in our endeavours to unite the differently refrangible rays. A white or compounded ray is ſeparated by refraction into its component coloured rays, and they are diffuſed over a ſmall angular ſpace. Thus it appears, that the glaſs uſed by Sir Iſaac Newton

Telescope. Newton in his experiments diffused a white ray which was incident on its posterior surface in an angle of 30°, in such a manner that the extreme red ray emerged into air, making an angle of 50° 21$\frac{1}{5}'$ with the perpendicular; the extreme violet ray emerged in an angle of 51° 15$\frac{3}{5}'$; and the ray which was in the confines of green and blue, emerged in an angle of 50° 48$\frac{1}{5}'$. If the sine of the angle 30° of incidence be called 0,5, which it really is, the sine of the emergence of the red ray will be 0,77; that of the violet ray will be 0,78; and that of the intermediate ray will be 0,77$\frac{1}{2}$, an exact mean between the two extremes. This ray may therefore be called the mean refrangible ray, and the ratio of 77$\frac{1}{2}$ to 50, or of 1,55 to 1, will very properly express the mean refraction of this glass; and we have for this glass $m = 1{,}55$. The sine of refraction, being measured on a scale, of which the sine of incidence occupies 100 parts, will be 154 for the red ray, 155 for the mean ray, and 156 for the violet ray. This number, or its ratio to unity, is commonly taken to represent the refractive power of the glass. There is some impropriety in this, unless we consider ratios as measured by their logarithms: for if n be 1, the substance does not refract at all. The refractive power can be properly measured only by the refraction which it produces; that is, by the change which it makes in the direction of the light, or the angle contained between the incident and refracted rays. If two substances produce such deviations always in one proportion, we should then say that their refractive powers are in that proportion. This is not true in any substances; but the sines of the angles, contained between the refracted ray and the perpendicular are always in one proportion when the angle of incidence in both substances is the same. This being a cognisable function of the real refraction, has therefore been assumed as the only convenient measure of the refractive powers. Although it is not strictly just, it answers extremely well in the most usual cases in optical instruments: the refractions are moderate; and the sines are very nearly as the angles contained between the rays and the perpendicular; and the real angles of refraction, or deflections of the rays, are almost exactly proportional to $m-1$. The most natural and obvious measure of the refractive powers would therefore be $m-1$. But this would embarrass some very frequent calculations; and we therefore find it best, on the whole, to take m itself for the measure of the refractive power.

The separation of the red, violet, and intervening rays, has been called *dispersion*; and although this arises merely from a difference of the refractive power in respect of the different rays, it is convenient to distinguish this particular modification of the refractive power by a name, and we call it the Dispersive Power of the refracting substance.

It is susceptible of degrees; for a piece of flint-glass will refract the light, so that when the sine of refraction of the red ray is 77, the sine of the refraction of the violet ray is nearly 78$\frac{1}{2}$; or if the sine of refraction of the red ray, measured on a particular scale, is 1,54, the sine of refraction of the violet ray is 1,57. The dispersion of this substance, being measured by the difference of the extreme sines of refraction, is greater than the dispersion of the other glass, in the proportion of 3 to 2.

But this alone is not a sufficient measure of the absolute dispersive power of a substance. Although the ratio of 1,54 to 1,56 remains constant, whatever the real magnitude of the refractions of common glass may be, and though we therefore say that its dispersive power is constant, we know, that by increasing the incidence and the refraction, the absolute dispersion is also increased. Another substance shows the same properties, and in a particular case may produce the same dispersion; yet it has not for this sole reason the same dispersive power. If indeed the incidence and the refraction of the mean ray be also the same, the dispersive power cannot be said to differ; but if the incidence and the refraction of the mean ray be less, the dispersive power must be considered as greater, though the actual dispersion be the same; because if we increase the incidence till it becomes equal to that in the common glass, the dispersion will now be increased. The proper way of conceiving the dispersion therefore is, to consider it as a portion of the whole refraction; and if we find a substance making the same dispersion with half the general refraction, we must say that the dispersive quality is double; because by making the refraction equal, the dispersion will really be double. Telescope.

If therefore we take m as a symbol of the separation of the extreme rays from the middle ray, $\frac{m}{m-1}$ is the natural measure of the dispersive power. We shall express this in the Leibnitzian notation, thus $\frac{dm}{m-1}$, that we may avoid the indistinctness which the Newtonian notation would occasion when m is changed for m' or m''.

It is not unusual for optical writers to take the whole separation of the red and violet rays for the measure of the dispersive power, and to compare this with the refracting power with respect to one of the extreme rays. But it is surely better to consider the mean refraction as the measure of the refracting power: and the deviation of either of the extremes from this mean is a proper enough measure of the dispersion, being always half of it. It is attended with this convenience, that being introduced into our computations as a quantity infinitely small, and treated as such for the ease of computation, while it is really a quantity of sensible magnitude; the errors arising from this supposition are diminished greatly, by taking one half of the deviation and comparing it with the mean refraction. This method has, however, this inconvenience, that it does not exhibit at once the refractive power in all substances respecting any particular colour of light; for it is not the ray of any particular colour that suffers the mean refraction. In common glass it is the ray which is in the confines of the yellow and blue; in flint glass it is nearly the middle blue ray; and in other substances it is a different ray. These circumstances appear plainly in the different proportions of the colours of the prismatic spectrum exhibited by different substances. This will be considered afterwards, being a great bar to the perfection of achromatic instruments.

The way in which an achromatic lens is constructed is, to make use of a contrary refraction of a second lens to destroy the dispersion or spherical aberration of the first.

The first purpose will be answered if $\frac{dm}{n}$ be equal to $-\frac{dm'}{n'}$. For, in order that the different coloured rays may be collected into one point by two lenses, it is only necessary that $\frac{1}{f'}$, the reciprocal of the focal distance of rays refracted by both, may be the same for the extreme and mean rays, that is, that $\frac{m-1}{n} + \frac{dm}{n} + \frac{m'-1}{n'} + \frac{dm'}{n'} + \frac{1}{r}$ be of the same value with $\frac{m-1}{n} + \frac{m'-1}{n'} + \frac{1}{r}$; which must happen if $\frac{dm}{n} + \frac{dm'}{n'}$ be $= 0$, or $\frac{dm}{n} = -\frac{dm'}{n}$. This may be seen in another way, more comprehensible by such as are not versant in these discussions. In order

Telescope. der that the extreme colours which are separated by the first lens may be rendered parallel by the second; we have shown already that n and n' are proportional to the radii of the equivalent isosceles lenses, being the halves of these radii. They are therefore (in these small refractions) inversely proportional to the angles formed by the surfaces at the edges of the lenses. n' may therefore be taken for the angle of the first lens, and n for that of the second. Now the small refraction by a prism, whose angle (also small) is n', is $\overline{m-1} \times n'$. The dispersive power being now substituted for the refractive power, we have for this refraction of the prism $dm \times n'$. This must be destroyed by the opposite refraction of the other prism $dm' \times n$. Therefore $dm \times n' = dm' \times n$, or $\frac{dm}{n} = -\frac{dm'}{n'}$. In like manner, this effect will be produced by three lenses if $\frac{dm}{n} + \frac{dm'}{n'} + \frac{dm''}{n''}$ be $= 0$, &c.

Lastly, the errors arising from the spherical figure, which we expressed by $-R^2(q+q')$ will be corrected if $q+q'$ be $= 0$. We are therefore to discover the adjustments of the quantities employed in the preceding formulæ, which will insure these conditions. It will render the process more perspicuous if we collect into one view the significations of our various symbols, and the principal equations which we are to employ.

1. The ratios to unity of the fines of mean incidence in the different media are - m, m', m''
2. The ratio of the differences of the fines of the extremes - - - $\frac{dm}{dm'} = u$.
3. The ratio $\frac{m-1}{m'-1}$ - - $= c$.
4. The radii of the surfaces - $a, b; a', b'; a'', b''$.
5. The principal focal distances, or the focal distances of parallel central rays, - p, p', p''.
6. The focal distance of the compound lens P.
7. The distance of the radiant point, or of the focus of incident rays on each lens r, r', r''.
8. The focal distance of the rays refracted by each lens - - $f, f' f''$.
9. The focal distance of rays refracted by ths compound lens - - F.
10. The half breadth of the lens e.

Also the following subsidiary values:

1. $\frac{1}{n} = \frac{1}{a} - \frac{1}{b}$; $\frac{1}{n'} = \frac{1}{a'} - \frac{1}{b'}$; $\frac{1}{n''} = \frac{1}{a''} - \frac{1}{b''}$.

2. $q = \frac{m-1}{m}\left(\frac{m'^3}{n^3} - \frac{2m^2+m}{an^2} + \frac{m+2}{a^2 n} + \frac{3m^2+m}{rn^2} - \frac{4(m+1)}{arn} + \frac{3m+2}{r^2 n}\right)\frac{e^2}{2}$. And q' and q'' must be formed in the same manner from m', a', n', r'; and from m'', a'', n'', r'', as q is formed from m, a, n, r.

3. Also, because in the case of an object-glass, r is infinitely great, the last term $\frac{1}{r}$ in all the values of $\frac{1}{f}, \frac{1}{f'}, \frac{1}{f''}$, $\frac{1}{r'}, \frac{1}{r''}$, will vanish, and we shall also have $F = P$.

Therefore in a double object-glass $\frac{1}{P} = \frac{m'-1}{n'} + \frac{m-1}{n}$, $= \frac{1}{p} + \frac{1}{p'}$.

And in a triple object-glass $\frac{1}{P} = \frac{m''-1}{n''} + \frac{m'-1}{n'} + \frac{m-1}{n}$, $= \frac{1}{p''} + \frac{1}{p'} + \frac{1}{p}$.

Also, in a double object-glass, the correction of spherical Telescope aberration requires $q + q' = v$.

And a triple object-glass requires $q + q' + q'' = v$. For the whole error is multiplied by F^2, and by $\frac{1}{2}e^2$; and therefore the equation which corrects this error may be divided by $F^2 \frac{1}{2} e^2$.

This equation in the preceding column, 11th line from the bottom, giving the value of q, q', q'', may be much simplified as follows: In the first place, they may be divided by m, m', or m'', by applying them properly to the terms within the parenthesis, and expunging them from the denominator of the general factors $\frac{m-1}{m}, \frac{m'-1}{m'}, \frac{m''-1}{m''}$. This does not alter the values of q, q', and q''. In the second place the whole equations may be afterwards divided by $m'-1$. This will give the values of $\frac{q}{m'-1}, \frac{q'}{m'-1}$, and $\frac{q''}{m'-1}$, which will still be equal to nothing if $q + q' + q''$ be equal to nothing.

This division reduces the general factor $\frac{m'-1}{m'}$ of q' to $\frac{1}{m'}$. And in the equation for q we obtain, in place of the general factor $\frac{m-1}{m}$, the factor $\frac{m-1}{m'-1}$, or c. This will also be the factor of the value of q'' when the third lens is of the same substance with the first, as is generally the case. And, in the third place, since the rays incident on the first lens are parallel, all the terms vanish from the value of q in which $\frac{1}{r}$ is found, and there remain only the three first, viz. $\frac{m^3}{n^3} - \frac{2m^2+m}{an^2} + \frac{m+2}{a^2 n}$.

Performing these operations, we have

$$\frac{q}{m'-1} = c\left(\frac{m^3}{n^3} - \frac{2m+1}{an^2} + \frac{m+2}{ma^2 n}\right)\frac{e^2}{2}$$

$$\frac{q'}{m'-1} = \left(\frac{m'^2}{n'^3} - \frac{2m'+1}{a'n'^2} + \frac{m'+2}{m'a'^2 n'} + \frac{3m'+1}{r'n'^2} - \frac{4(m'+1)}{m'a'r'n'} + \frac{3m'+2}{m'r'^2 n'}\right)\frac{e^2}{2}$$

$$\frac{q''}{m'-1} = c\left(\frac{m^3}{n^3} - \frac{2m+1}{a''n''^2} + \frac{m+2}{m''a''^2 n''} + \frac{3m+1}{r''n''^2} + \frac{4(m+1)}{m''a''r''n''} + \frac{3m+2}{m''r''^2 n''}\right)\frac{e^2}{2}$$

Let us now apply this investigation to the construction of an object-glass; and we shall begin with a double lens.

Construction of a Double Achromatic Object-glass.

Here we have to determine four radii a, b, a', and b'. Make $n = 1$. This greatly simplifies the calculus, by exterminating it from all the denominators. This gives for the equation $\frac{dm}{n} + \frac{dm'}{n'} = 0$, the equation $dm + \frac{dm'}{n'} = 0$, or $dm = -\frac{dm'}{n'}$, and $\frac{1}{n'} = -\frac{dm}{dm'}$, $= -u$. Also we have r', the focal distance of the light incident on the second lens, the same with the principal focal distance p of the first lens (neglecting the interval, if any). Now $\frac{1}{p} = \frac{m-1}{n}$, which in the present case is $= m-1$. Also $\frac{1}{p'}$ is $= -u(m'-1)$, and $\frac{1}{P} = m - 1 - u(m'-1) = u'$.

Make these substitutions in the values of $\frac{q}{m-1}$ and $\frac{q'}{m'-1}$, and we obtain the following equation:

Telescope.

$$c\,m^2 - \frac{c(2m+1)}{a} + \frac{c(m+2)}{m\,a^2} - u^3 m'^2 - \frac{u^2(2m'+1)}{a'} - \frac{u(m'+2)}{m'\,a'^2} + u^2(3m'+1)(m-1) + \frac{4u(m'+1)(m-1)}{m'\,a'} - \frac{u(3m'+2)(m-1)^2}{m'} = 0.$$

Arrange these terms in order, according as they are factors of $\frac{1}{a^2}$, $\frac{1}{a}$, $\frac{1}{a'^2}$, $\frac{1}{a'}$, or independent quantities. It puts on this form:

$$\frac{c(m+2)}{m} \times \frac{1}{a^2} - c'(2m+1) \times \frac{1}{a} - \frac{u(m'+2)}{m'} \times \frac{1}{a'^2} - \left(u^2(2m'+1) - \frac{4u(m'+1)(m-1)}{m'}\right) \times \frac{1}{a'} + cm^2 + u^2(3m'+1)(m-1) - u^3 m'^2 - \frac{u(3m'+2)(m-1)^2}{m'} = 0.$$

Let A be the coefficient of $\frac{1}{a^2}$, B that of $\frac{1}{a}$, C that of $\frac{1}{a'^2}$, D that of $\frac{1}{a'}$, and E the sum of the independent quantity; that is, let A be $= \frac{c(m+2)}{m}$, $B = c(2m+1)$, $C = \frac{u(m'+2)}{m'}$, $D = u^2(2m'+2) - \frac{4u(m'+1)(m-1)}{m'}$, and $E = cm^2 + u^2(3m'+1)(m-1) - u^3 m'^2 - \frac{u(3m'+2)(m-1)^2}{m'}$.

Our final equation becomes

$$\frac{A}{a^2} - \frac{B}{a} - \frac{C}{a'^2} - \frac{D}{a'} + E = 0.$$

The coefficients of this equation and the independent quantity are all known, from our knowledge of m, m' $d\,m$, $d\,m'$; and we are to find the values of a and a', and from them and $n = 1$ to find the values of b and b'.

But it is evidently an indeterminate equation, because there are two unknown quantities; so that there may be an infinity of solutions. It must be rendered determinate by means of some other conditions, to which it may be subjected. These conditions must depend on some other circumstances which may direct our choice.

One circumstance occurs to us which we think of very great consequence. In the passage of light from one substance to another, there is always a considerable portion reflected from the posterior surface of the first and from the anterior surface of the last; and this reflection is more copious in proportion to the refraction. This loss of light will therefore be diminished by making the internal surfaces of the lenses to coincide; that is, by making $b = a'$. This will be attended with another advantage. If we put between the glasses a substance of nearly the same refracting power, we shall not only completely prevent this loss of light, but we shall greatly diminish the errors which arise from an imperfect polish of the surfaces. We have tried this, and find the effect very surprising. The lens being polished immediately after the figure has been given it, and while it was almost impervious to light by reason of its roughness, which was still sensible to the naked eye, performed as well as when finished in the finest manner.

N. B. This condition, by taking away one refraction, obliges us to increase those which remain, and therefore increases the spherical aberrations. And since our formulæ do not fully remove those (by reason of the small quantities neglected in the process), it is uncertain whether this condition be the most eligible. We have, however, no direct argument to the contrary.

Let us see what determination this gives us.

In this case $\frac{1}{a'} = \frac{1}{b}$, $= \frac{1}{a} - 1$. For because $\frac{1}{n} = \frac{1}{a} - \frac{1}{b}$ and $n = 1$, we have $1 + \frac{1}{b} = \frac{1}{a}$, and $\frac{1}{b} = \frac{1}{a} - 1$. Therefore $\frac{1}{a'^2} = \frac{1}{a^2} - \frac{2}{a} + 1$. Therefore in our final equation, put $\frac{1}{a^2} - \frac{2}{a} + 1$ in place of $\frac{1}{a'^2}$, and $\frac{1}{a} - 1$ in place of $\frac{1}{a'}$, and it becomes $\frac{A-C}{a^2} - \frac{B+D-2C}{a} + E + D - C = 0$.

Thus have we arrived at a common affected quadratic equation, where $\frac{1}{a}$ is the unknown quantity. It has the common form $px^2 + qx + r = 0$, where p is $= A - C$, q is equal to $2C - B - D$, r is equal to $E + D - C$, and x is equal to $\frac{1}{a}$.

Divide the equation by p, and we have $x^2 + \frac{q}{p}x + \frac{r}{p} = 0$. Make $s = \frac{q}{p}$ and $t = \frac{r}{p}$, and we have $x^2 + sx + t = 0$.

This gives us finally $\frac{1}{a}$, or $x = -\frac{1}{2}s \pm \sqrt{\frac{1}{4}s^2 - t}$.

This value of $\frac{1}{a}$ is taken from a scale of which the unit is half the radius of the isosceles lens which is equivalent to the first lens, or has the same focal distance with it. We must then find (on the same scale) the value of b, *viz.* $\frac{1}{a} - 1$, which is also the value of a'. Having obtained a', we must find b' by means of the equation $\frac{1}{n'} = \frac{1}{a'} - \frac{1}{b'}$ and therefore $\frac{1}{b} = \frac{1}{a'} - \frac{1}{n'}$. But $\frac{1}{n'} = u$. Therefore $\frac{1}{b'} = \frac{1}{a'} + u$, $= \frac{1}{a} + u - 1$.

Thus is our object-glass constructed; and we must determine its focal distance, or its reciprocal $\frac{1}{P}$. This is $= m - 1 - u(m'-1)$.

All these radii and distances are measured on a scale of which n is the unit. But it is more convenient to measure every thing by the focal distance of the compound object-glass. This gives us the proportion which all the distances bear to it. Therefore, calling P unity, in order to obtain $\frac{1}{a}$ on this scale, we have only to state the analogy $m - 1 - u(m'-1) : 1 = \frac{1}{a} : \frac{1}{A}$, and A is the radius of our first surface measured on a scale of which P is the unit.

If, in the formula which expresses the final equation for $\frac{1}{a}$, the value of t should be positive, and greater than $\frac{1}{4}s^2$, the equation has imaginary roots; and it is not possible with the glasses employed, and the conditions assumed, to correct both the chromatic and spherical aberrations.

If t is negative and equal to $\frac{1}{4}s^2$, the radical part of the value is $= 0$, and $\frac{1}{a} = -\frac{1}{2}s$. But if it be negative or positive, but less than $\frac{1}{4}s^2$, the equation has two real roots, which will give two constructions. That is to be preferred which gives the smallest curvature of the surfaces; because, since in our formulæ which determine the spherical aberration some quantities are neglected, these quantities are always

Telescope. ways greater when a large arch (that is, an arch of many degrees) is employed. No radius ſhould be admitted which is much leſs than $\frac{1}{3}$ of the focal diſtance.

All this proceſs will be made plain and eaſy by an example.

Very careful experiments have ſhown, that in common crown-glaſs the ſine of incidence is to the ſine of refraction as 1,526 is to 1, and that in the generality of flint-glaſs it is as 1,604 to 1. Alſo that $\frac{dm}{dm'} = 0{,}6054 = u$. Therefore $m - 1 = 0{,}526$; $m' - 1 = 0{,}604$; $c = \frac{m-1}{m'-1'} = 0{,}87086$. By theſe numbers we can compute the coefficients of our final equation. We ſhall find them as follows:

$$\begin{aligned} A &= 2{,}012 \\ B &= 3{,}529 \\ C &= 1{,}360 \\ D &= -0{,}526 \\ E &= 1{,}8659 \end{aligned}$$

The general equation (p. 352. l. 17.), when ſubjected to the aſſumed coincidence of the internal ſurfaces, is $\frac{A-C}{a^2} - \frac{B+D-2C}{a} + E + D - C = 0$. $A - C$ is $= 0{,}652$; $B + D - 2C$ is $= 0{,}283$; and $E + D - C$ is $= -0{,}020$; and the equation with numerical coefficients is $\frac{0{,}652}{a^2} - \frac{0{,}283}{a} - 0{,}020 = 0$, which correſponds to the equation $px^2 + qx + r = 0$. We muſt now make $s = \frac{q}{p} = \frac{0{,}283}{0{,}652} = 0{,}434$, and $t = \frac{r}{p} = \frac{0{,}02}{0{,}652} = 0{,}0307$. This gives us the final quadratic equation $\frac{1}{a^2} - \frac{0{,}434}{a} - 0{,}0307 = 0$. To ſolve this, we have $-\frac{1}{2}s = 0{,}217$, and $\frac{1}{4}s^2 = 0{,}0471$. From this take t, which is $= -0{,}0307$ (that is, to 0,0471 add 0,0307), and we obtain 0,0778, the ſquare root of which is $= 0{,}2789$. Therefore, finally, $\frac{1}{a} = 0{,}2170 \pm 0{,}2789$, which is either 0,4959 or $-0{,}0619$. It is plain that the firſt muſt be preferred, becauſe the ſecond gives a negative radius, or makes the firſt ſurface of the crown-glaſs concave. Now as the convergence of the rays is to be produced by the crown-glaſs, the other ſurface muſt become very convex, and occaſion great errors in the computed aberration. We therefore retain 0,4959 for the value of $\frac{1}{a}$, and a is $= \frac{1}{0{,}4959} = 2{,}0166$.

To obtain b, uſe the equation $\frac{1}{b} = \frac{1}{a} - 1$, which gives $\frac{1}{b} = -0{,}5041$, and therefore a convex ſurface. b is therefore $= \frac{1}{0{,}5041} = 1{,}9837$.

a' is the ſame with b, and $\frac{1}{a'} = -0{,}5041$.

To obtain b', uſe the equation $\frac{1}{b'} = \frac{1}{a'} + u$. Now $u = 0{,}6054$, and $\frac{1}{a'} = -0{,}5041$. The ſum of theſe is 0,1013; and ſince it is poſitive, the ſurface is concave. $b' = \frac{1}{,1013}$ Teleſcope. $= 9{,}872$.

Laſtly, $\frac{1}{P} = m - 1 - u(m' - 1) = 0{,}1603$, and $P = \frac{1}{0{,}1603} = 0{,}2383$.

Now to obtain all the meaſures in terms of the focal diſtance P, we have only to divide the meaſures already found by 6,2383, and the quotients are the meaſures wanted.

$$\begin{aligned} \text{Therefore } a &= \frac{2{,}0\,66}{6{,}2383} = 0{,}32325 \\ b &= \frac{1{,}9837}{6{,}2383} = -0{,}31798 \\ a' &= \text{ - } \cdot \text{ - } = -0{,}31798 \\ b' &= \frac{9{,}872}{6{,}2383} = 1{,}5825 \\ P &= \text{ - } 1. \end{aligned}$$

If it be intended that the focal diſtance of the object-glaſs ſhall be any number n of inches or feet, we have only to multiply each of the above radii by n, and we have their lengths in inches or feet.

Thus we have completed the inveſtigation of the conſtruction of a double object-glaſs. Although this was intricate, the final reſult is abundantly ſimple for practice, eſpecially with the aſſiſtance of logarithms. The only troubleſome thing is the preparation of the numerical coefficients A, B, C, D, E of the final equation. Strict attention muſt alſo be paid to the poſitive and negative ſigns of the quantities employed.

We might propoſe other conditions. Thus it is natural to prefer for the firſt or crown-glaſs lens ſuch a form as ſhall give it the ſmalleſt poſſible aberration. This will require a ſmall aberration of the flint-glaſs to correct it. But a little reflection will convince us that this form will not be good. The focal diſtance of the crown-glaſs muſt not exceed one-third of that of the compound glaſs; theſe two being nearly in the proportion of $dm' - dm$ to dm'. Therefore if this form be adopted, and a be made about $\frac{1}{5}$th of b, it will not exceed $\frac{1}{15}$th of P. Therefore, although we may produce a moſt accurate union of the central and marginal rays by oppoſite aberrations, there will be a conſiderable aberration of ſome rays which are between the centre and the margin.

It is abſolutely impoſſible to collect into one point the whole rays (though the very remoteſt rays are united with the central rays), except in a very particular caſe, which cannot obtain in an object-glaſs; and the ſmall quantities which are neglected in the formula which we have given for the ſpherical aberration, produce errors which do not follow any proportion of the aperture which can be expreſſed by an equation of a manageable form. When the aperture is very large, it is better not to correct the aberration for the whole aperture, but for about $\frac{3}{5}$ths of it. When the rays correſponding to this diſtance are made to coincide with the central rays by means of oppoſite aberrations, the rays which are beyond this diſtance will be united with ſome of thoſe which are nearer to the centre, and the whole diffuſion will be conſiderably diminiſhed. Dr Smith has illuſtrated this in a very perſpicuous manner in his theory of his Catoptric Microſcope.

But although we cannot adopt this form of an object-glaſs, there may be other conſiderations which may lead us

Tel-ſcope. to prefer ſome particular form of the crown-glaſs, or of the flint-glaſs. We ſhall therefore adapt our general equation $\frac{A}{a^2} - \frac{B}{a} - \frac{C}{a'^2} - \frac{D}{a'} + E = 0$ to this condition.

Therefore let b expreſs this ſelected ratio of the two radii of the crown-glaſs, making $\frac{a}{b} = b$ (remembering always that a is poſitive and b negative in the caſe of a double convex, and b is a negative number).

With this condition we have $\frac{1}{b} = \frac{b}{a}$. But when we make n the unit of our formula of aberration, $\frac{1}{b} = \frac{1}{a} - 1$. Therefore $1 = \frac{1}{a} - \frac{b}{a}$, and $\frac{1}{a} = \frac{1}{1-b}$. Now ſubſtitute this for $\frac{1}{a}$ in the general equation, and change all the ſigns (which ſtill preſerves it $= 0$), and we obtain

$$\frac{C}{a'^2} + \frac{D}{a} - E - \frac{A}{(1-b)^2} + \frac{B}{1-b} = 0.$$

By this equation we are to find $\frac{1}{a}$, or the radius of the anterior ſurface of the flint-glaſs. The equation is of this form $p x^2 + q x + r = 0$, and we muſt again make $s = \frac{q}{p}$, and $t = \frac{r}{p}$. Therefore $s = \frac{D}{C}$, and $t = \frac{1}{C} \times \left(\frac{B}{1-b} - \frac{A}{(1-b)^2} - E\right)$. Then, finally,

$$\frac{1}{a'} = -\tfrac{1}{2}s \pm \sqrt{\tfrac{1}{4}s^2 - t}.$$

It may be worth while to take a particular caſe of this condition. Suppoſe the crown glaſs to be of equal convexities on both ſides. This has ſome advantages: We can tell with preciſion whether the curvatures are preciſely equal, by meaſuring the focal diſtance of rays reflected back from its poſterior ſurface. Theſe diſtances will be preciſely equal. Now it is of the utmoſt importance in the conſtruction of an object-glaſs which is to correct the ſpherical aberration, that the forms be preciſely ſuch as are required by our formulæ.

In this caſe of a lens equally convex on both ſides $\frac{1}{a}$ is $= -\frac{1}{b}$, $= \frac{1}{2}$. Subſtitute this value for $\frac{1}{a}$ in the general equation $\frac{A}{a^2} - \frac{B}{a} - \frac{C}{a'^2} - \frac{D}{a'} + E = 0$, and then $\frac{A}{a^2} = \frac{A}{4}$; $\frac{B}{a}$ becomes $\frac{B}{2}$. Now change all the ſigns, and we have $\frac{C}{a'^2} + \frac{D}{a'} - E - \frac{A}{4} + \frac{B}{2} = 0$, by which we are to find a'. This in numbers is $\frac{1,360}{a'^2} - \frac{0,526}{a'} - 0,6044 = 0$. Then $s = \frac{-0,526}{1,360}$, $= 0,3867$, and $t = \frac{-0,6044}{1,360}$, $= -0,4444$. Then $-\frac{1}{2}s = 0,1933$; $\frac{1}{4}s^2 = 0,0374$; and $\sqrt{\frac{1}{4}S^2 - t} = \pm 0,6941$; ſo that $\frac{1}{a'} = 0,1933 \pm 0,6941$. This gives two real roots, viz. 0,8874, and $-0,5008$. If we take the firſt, we ſhall have a convex anterior ſurface for the flint-glaſs, and conſequently a very deep concave for the poſterior ſurface. We therefore take the ſecond or negative root $-0,5008$.

We find $\frac{1}{b'}$, as before, by the equation $\frac{1}{b'} = \frac{1}{a'} + u$, $=$ Teleſcope. $0,1046$, which will give a large value of b'.

We had $\frac{1}{a} = \frac{1}{2}$

and $\frac{1}{b} = -\frac{1}{2}$

and $\frac{1}{P}$ is the ſame as in the former caſe, viz. 0,1603.

Having all theſe reciprocals, we may find a, b, a'', b', and P; and then dividing them by P, we obtain finally

$a = 0,3206$
$b = -0,3206$
$a' = -0,3201$
$b' = 1,533$
$P = 1,$

By comparing this object-glaſs with the former, we may remark, that diminiſhing a a little increaſes b, and in this reſpect improves the lens. It indeed has diminiſhed b', but this being already conſiderable, no inconvenience attends this diminution. But we learn, at the ſame time, that the advantage *muſt* be very ſmall; for we cannot diminiſh a much more, without making it as ſmall as the ſmalleſt radius of the object-glaſs. This proportion is therefore very near the maximum, or beſt poſſible; and we know that in ſuch caſes, even conſiderable changes in the radii will make but ſmall changes in the reſult: for theſe reaſons we are diſpoſed to give a ſtrong preference to the firſt conſtruction, on account of the other advantages which we ſhowed to attend it.

As another example, we may take a caſe which is very nearly the general practice of the London artiſts. The radius of curvature for the anterior ſurface of the convex crown-glaſs is $\frac{5}{6}$ths of the radius of the poſterior ſurface, ſo that $b = \frac{5}{6}$. This being introduced into the determinate equation, gives

$a = 0,2938$ $a' = -0,3443$
$b = -0,3526$ $b = 1,1474$

As another condition, we may ſuppoſe that the ſecond or flint-glaſs is of a determined form.

This caſe is ſolved much in the ſame manner as the former. Taking b to repreſent the ratio of a' and b', we have $\frac{1}{a'} = \frac{1}{1-b}$. This value being ſubſtituted in the general equation $\frac{A}{a^2} - \frac{B}{a} - \frac{C}{a'^2} - \frac{D}{a'} + E = 0$, gives us $\frac{A}{a^2} - \frac{B}{a} + E - \frac{C}{(1-b)^2} - \frac{D}{1-b} = 0$. This gives for the final equation $x^2 + s x + t = 0$, $s = \frac{B}{A}$, and $t = \frac{1}{A} \times \left(E - \frac{C}{(1-b)^2} - \frac{D}{1-b}\right)$ and $\frac{1}{a} = -\frac{1}{2}s \pm \sqrt{\frac{1}{4}s^2 - t}$.

We might here take the particular caſe of the flint-glaſs being equally concave on both ſides. Then, becauſe $\frac{1}{a'} = -u$, and in the caſe of equal concavities $\frac{2}{a'} = \frac{1}{n'}$, $= -u$, it is ſufficient to put $-\frac{1}{2}u$ for $\frac{1}{a'}$. This being done, the equation becomes $\frac{A}{a} - \frac{B}{a} - \frac{C u^2}{4} + \frac{D u}{2} + E = 0$. This gives $s = \frac{B}{A}$, and $t = \frac{1}{A} \times \left(\frac{4 D u - 2 C u^2}{8} + E\right)$.

We

Telescope. We imagine that these cases are sufficient for showing the management of the general equation; and the example of the numerical solution of the first case affords instances of the only niceties which occur in the process, viz. the proper employment of the positive and negative quantities.

We have oftener than once observed, that the formula is not perfectly accurate, and that in very large apertures errors will remain. It is proper therefore, when we have obtained the form of a compound object glass, to calculate trigonometrically the progress of the light through it; and if we find a considerable abberration, either chromatic or spherical, remaining, we must make such changes in the curvatures as will correct them. We have done this for the first example; and we find, that if the focal distance of the compound object-glass be 100 inches, there remains of the spherical aberration nearly $\frac{1}{60}$ of an inch, and the aberration of colour is over corrected above $\frac{1}{9}$th of an inch. The first aberration has been diminished about 6 times, and the other about 30 times. Both of the remaining errors will be diminished by increasing the radius of the inner surfaces. This will diminish the aberration of the crown-glass, and will diminish the dispersion of the flint more than that of the crown. But indeed the remaining error is hardly worth our notice.

It is evident to any person conversant with optical discussions, that we shall improve the correction of the spherical aberration by diminishing the refractions. If we employ two lenses for producing the convergency of the rays to a real focus, we shall reduce the aberration to $\frac{1}{4}$th. Therefore a better achromatic glass will be formed of three lenses, two of which are convex and of crown-glass. The refraction being thus divided between them, the aberrations are lessened. There is no occasion to employ two concave lenses of flint-glass; there is even an advantage in using one. The aberration being considerable, less of it will serve for correcting the aberration of the crown-glass, and therefore such a form may be selected as has little aberration. Some light is indeed lost by these two additional surfaces: but this is much more than compensated by the greater apertures which we can venture to give when the curvature of the surface is so much diminished. We proceed therefore to

The Construction of a Triple Achromatic Object-glass

It is plain that there are more conditions to be assumed before we can render this a determinate problem, and that the investigation must be more intricate. At the same time, it must give us a much greater variety of constructions, in consequence of our having more conditions necessary for giving the equation this determinate form. Our limits will not allow us to give a full account of all that may be done in this method. We shall therefore content ourselves with giving one case, which will sufficiently point out the method of proceeding. We shall then give the results in some other eligible cases, as rules to artists by which they may construct such glasses.

Let the first and second glasses be of equal curvatures on both sides; the first being a double convex of crown-glass, and the second a double concave of flint-glass.

Still making n the unit of our calculus, we have in the first place $a = -b, = -a', = b'$. Therefore $\frac{1}{a'} - \frac{1}{b'} = -\left(\frac{1}{a} - \frac{1}{b}\right)$, or $\frac{1}{n'} = -\frac{1}{n} = -1$. Therefore the equation $\frac{dm}{n} + \frac{dm'}{n'} + \frac{dm''}{n''} = 0$ becomes $u - 1 + \frac{u}{n''} = 0$, or $\frac{1}{n''} = \frac{1}{u} - 1$. Let us call this value u'.

We have $\frac{1}{p} = m - 1$; $\frac{1}{p'} = -(m' - 1)$; $\frac{1}{p''} = u'(m - 1)$; $\frac{1}{P} = \frac{1}{p} + \frac{1}{p'} + \frac{1}{p''}, = m - m' + u'(m - 1)$. And if we make $m' - m = C'$, we shall have $\frac{1}{P} = -C, + u'(m - 1)$. Also $\frac{1}{r'} = m - 1$; $\frac{1}{r''} = m - 1 - (m' - 1), = m - m', = -C'$.

The equality of the two curvatures of each lens gives $\frac{1}{a} = \frac{1}{2n}$. Therefore $\frac{1}{a} = -\frac{1}{b}, = -\frac{1}{a'}, = \frac{1}{b'}, = \frac{1}{2}$; and $\frac{1}{b''} = \frac{1}{a''} - \frac{1}{n''}, = \frac{1}{a''} - u'$.

Substituting these values in the equation (p. 351. col. 2. par. 5.), we obtain the three formulæ,

1. $c m^2 - \frac{1}{2} c (2m + 1) + \frac{c(m+2)}{4m}$

2. $-m' 2 + \frac{1}{2}(2m' + 1) - \frac{m' + 2}{4m'} + (3m' + 1)(m - 1) - \frac{2(m' + 1)(m - 1)}{m'} - \frac{(3m' + 2)(m - 1)^2}{m'}$

3. $c u' 3 m^2 - \frac{c u'^2 (2m + 1)}{a''} + \frac{c u' (m + 2)}{m a''^2} - c c' u'^2 (3m + 1) + \frac{4 c c' u' (m + 1)}{m a''} + \frac{c c'^2 u' (3m + 2)}{m} = 0$.

Now arrange these quantities according as they are coefficients of $\frac{1}{a''^2}$ and of $\frac{1}{a''}$, or independent quantities. Let the coefficient of $\frac{1}{a''^2}$ be A, that of $\frac{1}{a''}$ be B, and the independent quantity be C, we have

$A = \frac{c u' (m + 2)}{m}$; $B = c u'^2 (2m + 1) - \frac{4 c c' u' (m + 1)}{m}$,

and $C = c m^2 + \frac{c(m+2)}{4m} + \frac{1}{2}(2m' + 1) + (3m' + 1)(m - 1) + c u'^3 m^3 + \frac{c c'^2 u' (3m + 2)}{m} - \frac{1}{2} c (2m + 1) - m'^2 - \frac{m' + 2}{4m} - \frac{2(m' + 1)(m - 1)}{m'} - \frac{(3m' + 2)(m - 1)^2}{m'} - c c' u'^2 (3m + 1)$.

Our equation now becomes $\frac{A}{a''^2} - \frac{B}{a''} + C = 0$.

This reduced to numbers, by computing the values of the coefficients, is $\frac{1,312}{a''^2} - \frac{1,207}{a''} - 0,3257 = 0$.

This, divided by 1,312, gives $s = -0,92$; and $t = -0,2482$; $-\frac{1}{2} s = 0,46$; $\frac{1}{4} s^2 = 0,2116$; and $\sqrt{\frac{1}{4} s^2 - t} = \pm 0,6781$.

And, finally, $\frac{1}{a''} = 0,46 \pm 0,6781$.

This has two roots, viz. 0,2181 and $-1,1381$. The last would give a very small radius, and is therefore rejected.

Now, proceeding with this value of $\frac{1}{a''}$ and the $\frac{1}{n''}$, we get the other radius b'', and then, by means of u', we get the other radius which is common to the four surfaces. Then, by $\frac{1}{P} = \frac{1}{p''} - c'$, we get the value of P.

The radii being all on the scale of which n is the unit, they must be divided by P to obtain their value on the scale which has P for its unit. This will give us

Teleſcope.

$a = -b, = -a', = b', = 0{,}530$
$a'' = 1{,}215$
$b'' = -0{,}3046$
$P = 1.$

This is not a very good form, becauſe the laſt ſurface has too great curvature.

We thought it worth while to compute the curvatures for a caſe where the internal ſurfaces of the lenſes coincide, in order to obtain the advantages mentioned on a former occaſion. The form is as follows:

The middle lens is a double concave of flint-glaſs; the laſt lens is of crown-glaſs, and has equal curvatures on both ſides. The following table contains the dimenſions of the glaſſes for a variety of focal diſtances. The firſt column contains the focal diſtances in inches; the ſecond contains the radii of the firſt ſurface in inches; the third contains the radii of the poſterior ſurface of the firſt lens and anterior ſurface of the ſecond; and the fourth column has the radii of the three remaining ſurfaces.

P	a	b, a'	b', a'', b''
12	9,25	6,17	12,75
24	18,33	12,25	25,5
36	27,33	18,25	38,17
48	36,42	24,33	50,92
60	45,42	30,33	63,58
72	54,5	36,42	76,33
84	63,5	42,5	89,
96	72,6	48,5	101,75
108	81,7	54,58	114,42
120	90,7	60,58	127,17

We have had an opportunity of trying glaſſes of this conſtruction, and found them equal to any of the ſame length, although executed by an artiſt by no means excellent in his profeſſion as a glaſs-grinder. This very circumſtance gave us the opportunity of ſeeing the good effects of interpoſing a tranſparent ſubſtance between the glaſſes. We put ſome clear turpentine varniſh between them, which completely prevented all reflection from the internal ſurfaces. Accordingly theſe teleſcopes were ſurpriſingly bright; and although the roughneſs left by the firſt grinding was very perceptible by the naked eye before the glaſſes were put together, yet when joined in this manner it entirely diſappeared, even when the glaſſes were viewed with a deep magnifier.

The aperture of an object glaſs of this conſtruction of 30 inches focal diſtance was $3\frac{1}{5}$th inches, which is conſiderably more than any of Mr Dollond's that we have ſeen.

If we ſhould think it of advantage to make all the three lenſes iſoſceles, that is, equally curved on both ſurfaces, the general equation will give the following radii:

$a = +0{,}639 \quad a' = -0{,}5285 \quad a'' = +0{,}6413$
$b = -0{,}639 \quad b' = +0{,}5285 \quad b'' = -0{,}6413$

This ſeems a good form, having large radii.

Should we chooſe to have the two crown-glaſs lenſes iſoſceles and equal, we muſt make

$a = +0{,}6412 \quad a' = -0{,}5227 \quad a'' = +0{,}6412$
$b = -0{,}6412 \quad b' = +0{,}5367 \quad b'' = -0{,}6412$

This form hardly differs from the laſt.

Our readers will recollect that all theſe forms proceed on certain meaſures of the refractive and diſperſive powers of the ſubſtances employed, which are expreſſed by m, m', dm, and dm': and we may be aſſured that the formulæ are ſufficiently exact, by the compariſon (which we have made in one of the caſes) of the reſult of the formula and the trigonometrical calculation of the progreſs of the rays. The error was but $\frac{1}{60}$th of the whole, ten times leſs than another error, which unavoidably remains, and will be conſidered preſently. Theſe meaſures of refraction and diſperſion were carefully taken; but there is great diverſity, particularly in the flint-glaſs. We are well informed that the manufacture of this article has conſiderably changed of late years, and that it is in general leſs refractive and leſs diſperſive than formerly. This muſt evidently make a change in the forms of achromatic glaſſes. The proportion of the focal diſtance of the crown-glaſſes to that of the flint muſt be increaſed, and this will occaſion a change in the curvatures, which ſhall correct the ſpherical aberration. We examined with great care a parcel of flint-glaſs which an artiſt of Edinburgh got lately for the purpoſe of making achromatic object-glaſſes, and alſo ſome very white crown-glaſs made in Leith; and we obtained the following meaſures:

$m = 1{,}529 \qquad \frac{dm}{dm'} = \frac{142}{219} = 0{,}64841.$
$m' = 1{,}578$

We computed ſome forms for triple object-glaſſes made of theſe glaſſes, which we ſhall ſubjoin as a ſpecimen of the variations which this change of data will occaſion.

If all the three lenſes are made iſoſceles, we have

$a = +0{,}796 \quad a' = -0{,}474 \quad a'' = +0{,}502$
$b = -0{,}796 \quad b' = +0{,}474 \quad b'' = -0{,}502$

Or

$a = 0{,}504 \quad a' = -0{,}475 \quad a'' = +0{,}793$
$b = -0{,}504 \quad b' = 0{,}475 \quad b'' = -0{,}793$

If the middle lens be iſoſceles, the two crown-glaſs lenſes may be made of the ſame form and focal diſtance, and placed the ſame way. This will give us

$a = +0{,}705 \quad a' = -0{,}475 \quad a'' = +0{,}705$
$b = -0{,}547 \quad b' = +0{,}475 \quad b'' = -0{,}547$

N. B. This conſtruction allows a much better form, if the meaſures of refraction and diſperſion are the ſame that we uſed formerly. For we ſhall have

$a = +0{,}628 \quad a' = -0{,}579 \quad a'' = +0{,}628$
$b = -0{,}749 \quad b' = +0{,}579 \quad b'' = -0{,}749$

And this is pretty near the practice of the London opticians.

We may here obſerve, upon the whole, that an amateur has little chance of ſucceeding in theſe attemps. The diverſity of glaſſes, and the uncertainty of the workman's producing the very curvatures which he intends, is ſo great, that the object-glaſs turns out different from our expectation. The artiſt who makes great numbers acquires a pretty certain gueſs at the remaining error; and having many lenſes, intended to be of one form, but unavoidably differing a little from it, he tries ſeveral of them with the other two, and finding one better than the reſt, he makes uſe of it to complete the ſet.

The great difficulty in the conſtruction is to find the exact proportion of the diſperſive powers of the crown and flint glaſs. The crown is pretty conſtant; but there is hardly two pots of flint-glaſs which have the ſame diſperſive power. Even if conſtant, it is difficult to meaſure it accurately: and an error in this greatly affects the inſtrument, for the focal diſtances of the lenſes muſt be nearly as their diſperſive powers. The method of examining this circumſtance, which we found moſt accurate, was as follows:

The ſun's light, or that of a brilliant lamp, paſſed through a ſmall hole in a board, and fell on another board pierced alſo with a ſmall hole. Behind this was placed a fine prism A (fig. 10.), which formed a ſpectrum ROV on a ſcreen pierced with a ſmall hole. Behind this was placed a priſm B of the ſubſtance under examination. The ray which was refracted by it fell on the wall at D, and the diſtance of its illumination from that point to C, on which an unrefracted ray would have fallen, was carefully meaſured. This ſhowed the refraction of that colour. Then, in order that we might be certain that we always compared the refraction of the

Teleſcope.

Teleſcope. the ſame preciſe colour by the different priſms placed at B, we marked the preciſe poſition of the priſm A when the ray of a particular colour fell on the priſm B. This was done by an index AG attached to A, and turning with it, when we cauſed the different colours of the ſpectrum formed by A to fall on B. Having examined one priſm B with reſpect to all the colours in the ſpectrum formed by A, we put another B in its place. Then bringing A to all its former poſitions ſucceſſively, by means of a graduated arch HGK, we were certain that when the index was at the ſame diviſion of the arch it was the very ray which had been made to paſs through the firſt priſm B in a former experiment. We did not ſolicitouſly endeavour to find the very extreme red and violet rays; becauſe, although we did not learn the whole diſperſions of the two priſms, we learned their proportions, which is the circumſtance wanted in the conſtruction of achromatic glaſſes. It is in vain to attempt this by meaſuring the ſpectrums themſelves; for we cannot be certain of ſelecting the very ſame colours for the compariſon, becauſe they ſucceed in an inſenſible gradation.

The intelligent reader will readily obſerve, that we have hitherto proceeded on the ſuppoſition, that when, by means of contrary refractions, we have united the extreme red and violet rays, we have alſo united all the others. But this is quite gratuitous. Sir Iſaac Newton would, however, have made the ſame ſuppoſition; for he imagined that the different colours divided the ſpectrum formed by all ſubſtances in the proportions of a muſical canon. This is a miſtake. When a ſpectrum is formed by a priſm of crown-glaſs, and another of preciſely the ſame length is formed by the ſide of it by a priſm of flint-glaſs, the confine between the green and blue will be found preciſely in the middle of the firſt ſpectrum, but in the ſecond it will be conſiderably nearer to the red extremity. In ſhort, different ſubſtances do not diſperſe the colours in the ſame proportion.

The effect of this irrationality (ſo to call it) of diſperſion, will appear plainly, we hope, in the following manner: Let A (fig. 9. A) repreſent a ſpot of white ſolar light falling perpendicularly on a wall. Suppoſe a priſm of common glaſs placed behind the hole through which the light is admitted, with its refracting angle facing the left hand. It will refract the beam of light to the right, and will at the ſame time diſperſe this heterogeneous light into its component rays, carrying the extreme red ray from A to R, the extreme orange from A to O, the extreme yellow from A to Y, &c. and will form the uſual priſmatic ſpectrum ROYGBPVC. If the whole length RC be divided into 1000 parts, we ſhall have (when the whole refraction AR is ſmall) RO very nearly 125, RY=200, RG=333, RB=500, RP=667, RV=778, and RC=1000; thus being the proportion obſerved in the difference of the ſines of refraction by Sir Iſaac Newton.

Perhaps a refracting medium may be found ſuch, that a priſm made of it would refract the white light from A′, in the upper line of this figure, in ſuch a manner that a ſpectrum R′O′Y′G′B′P′V′C′ ſhall be formed at the ſame diſtance from A′, and of the ſame length, but divided in a different proportion. We do not know that ſuch a medium has been found; but we know that a priſm of flint-glaſs has its refractive and diſperſive powers ſo conſtituted, that if A′H′ be taken about $\frac{1}{3}$d of AR, a ſpot of white light, formed by rays falling perpendicularly at H′, will be ſo refracted and diſperſed, that the extreme red ray will be carried from H′ to R′, and the extreme violet from H′ to C′, and the intermediate colours to intermediate points, forming a ſpectrum reſembling the other, but having the colours more conſtipated towards R′, and more dilated towards C; ſo that the ray which the common glaſs carried to the middle point B of the ſpectrum RC is now in a point B′ of the Teleſcope. ſpectrum R′C′, conſiderably nearer to R′.

Dr Blair has found, on the other hand, that certain fluids, particularly ſuch as contain the muriatic acid, when formed into a priſm, will refract the light from H″ (in the lower line) ſo as to form a ſpectrum R″C″ equal to RC, and as far removed from A″ as RC is from A, but having the colours more dilated toward R″, and more conſtipated toward C, than is obſerved in RC; ſo that the ray which was carried by the priſm of common glaſs to the middle point B is carried to a point B″, conſiderably nearer to C″.

Let us now ſuppoſe that, inſtead of a white ſpot at A, we have a priſmatic ſpectrum AB (fig. 9. B), and that the priſm of common glaſs is applied as before, immediately behind the priſm which forms the ſpectrum AB. We know that this will be refracted ſidewiſe, and will make a ſpectrum ROYGBPC, inclined to the plane of refraction in an angle of 45°; ſo that drawing the perpendicular RC′, we have RC′=C′C.

We alſo know that the priſm of flint-glaſs would refract the ſpectrum formed by the firſt priſm on EHF, in ſuch a manner that the red ray will go to R, the violet to C, and the intermediate rays to points *o*, *y*, *g*, *b*, *p*, *v*, ſo ſituated that O′ *o* is = R O′ of the other figure; *Y y* is = R′ Y′ of that figure, G *g* = R′G′, &c. Theſe points muſt therefore lie in a curve R *o y g b p v* C, which is convex toward the axis R′C′.

In like manner we may be aſſured that Dr Blair's fluid will form a ſpectrum R *o′y′g′b′p′*, *v′* C, concave toward R′C.

Let it be obſerved by the way, that this is a very good method for diſcovering whether a medium diſperſes the light in the ſame proportion with the priſm which is employed for forming the firſt ſpectrum AB or EF. It diſperſes in the ſame or in a different proportion, according as the oblique ſpectrum is ſtraight or crooked; and the exact proportion correſponding to each colour is had by meaſuring the ordinates of the curves R *b* C or R *b′* C.

Having formed the oblique ſpectrum RBC by a priſm of common glaſs, we know that an equal priſm of the ſame glaſs, placed in a contrary poſition, will bring back all the rays from the ſpectrum RBC to the ſpectrum AB, laying each colour on its former place.

In like manner, having formed the oblique ſpectrum R *b* C by a priſm of flint-glaſs, we know that another priſm of flint-glaſs, placed in the oppoſite direction, will bring all the rays back to the ſpectrum EHF.

But having formed the oblique ſpectrum RBC by a priſm of common glaſs, if we place the flint-glaſs priſm in the contrary poſition, it will bring the colour R back to E, and the colour C to F; but it will not bring the colour B to H, but to a point *b*, ſuch that B *b* is equal to *b* H, and *b* B to *b* H. In like manner, the other colours will not be brought back to the ſtraight line EHF, but to a curve E *b* F, forming a crooked ſpectrum.

In like manner, the fluids diſcovered by Dr Blair, when employed to bring back the oblique ſpectrum RBC formed by common glaſs, will bring its extremities back to E and F, and form the crooked ſpectrum E *b′* F lying beyond EHF.

This experiment evidently gives us another method for examining the proportionality of the diſperſion of different ſubſtances.

Having, by common glaſs, brought back the oblique ſpectrum formed by common glaſs to its natural place AB, ſuppoſe the original ſpectrum at AB to contract gradually (as Newton has made it do by means of a lens), it is plain that the oblique ſpectrum will alſo contract, and ſo will the

Teleſcope. ſecond ſpectrum at AB; and it will at laſt coaleſce into a white ſpot. The effect will be equivalent to a gradual compreſſion of the whole figure, by which the parallel lines AR and BC gradually approach, and at laſt unite.

In like manner, when the oblique ſpectrum formed by flint-glaſs is brought back to EHF by a flint-glaſs priſm, and the figure compreſſed in the ſame gradual manner, all the colours will coaleſce into a white ſpot.

But when flint-glaſs is employed to bring back the oblique ſpectrum formed by common glaſs, it forms the crooked ſpectrum E *h* F. Now let the figure be compreſſed. The curve E *h* F will be doubled down on the line H *h*, and there will be formed a compound ſpectrum H *h*, quite unlike the common ſpectrum, being purple or claret coloured at H by the mixture of the extreme red and violet, and green edged with blue at *h* by the mixture of the green and blue. The fluid priſms would in like manner form a ſpectrum of the ſame kind on the other ſide of H.

This is preciſely what is obſerved in achromatic object-glaſſes made of crown-glaſs and flint: for the refraction from A to R correſponds to the refraction of the convex crown-glaſs; and the contrary refraction from R to E correſponds to the contrary refraction of the concave flint-glaſs, which ſtill leaves a part of the firſt refraction, producing a convergence to the axis of the teleſcope. It is found to give a purple or wine coloured focus, and within this a green one, and between theſe an imperfect white. Dr Blair found, that when the eye-glaſs was drawn out beyond its proper diſtance, a ſtar was ſurrounded by a green fringe, by the green end of the ſpectrum, which croſſed each other within the focus; and when the eye-glaſs was too near the object-glaſs, the ſtar had a wine coloured fringe. The green rays were ultimately moſt refracted. *N. B.* We ſhould expect the fringe to be of a blue colour rather than a green. But this is eaſily explained: The extreme violet rays are very faint, ſo as hardly to be ſenſible; therefore when a compound glaſs is made as achromatic as poſſible to our ſenſes, in all probability (nay certainly) theſe almoſt inſenſible violet rays are left out, and perhaps the extreme colours which are united are the red and the middle violet rays. This makes the green to be the mean ray, and therefore the moſt outſtanding when the diſperſions are not proportional.

Dr Blair very properly calls theſe ſpectrums, H *h* and H *h'*, *ſecondary ſpectrums*, and ſeems to think that he is the firſt who has taken notice of them. But Mr Clairault was too accurate a mathematician, and too careful an obſerver, not to be aware of a circumſtance which was of primary conſequence to the whole inquiry. He could not but obſerve that the ſucceſs reſted on this very particular, and that the proportionality of diſperſion was indiſpenſably neceſſary.

This ſubject was therefore touched on by Clairault; and *fully* diſcuſſed by Boſcovich, firſt in his Diſſertations publiſhed at Vienna in 1759; then in the *Comment. Bononienſis*; and, laſtly, in his *Opuſcula*, publiſhed in 1785. Dr Blair, in his ingenious Diſſertation on Achromatic Glaſſes, read to the Royal Society of Edinburgh in 1793, ſeems not to have known of the labours of theſe writers; ſpeaks of it as a new diſcovery; and exhibits ſome of the conſequences of this principle in a ſingular point of view, as ſomething very paradoxical and inconſiſtent with the uſually received notions on theſe ſubjects. But they are by no means ſo. We are, however, much indebted to his ingenious reſearches, and his ſucceſsful endeavours to find ſome remedy for this imperfection of achromatic glaſſes. Some of his contrivances are exceedingly ingenious; but had the Doctor conſulted theſe writers, he would have ſaved himſelf a good deal of trouble.

Boſcovich ſhows how to unite the two extremes with the moſt outſtanding colour of the ſecondary ſpectrum, by means of a third ſubſtance. When we have done this, the aberration occaſioned by the ſecondary ſpectrums muſt be prodigiouſly diminiſhed; for it is evidently equivalent to the union of the points H and *h* of our figure. Whatever cauſe produces this muſt diminiſh the curvature of the arches E *h* and *h* F: but even if theſe curvatures were not diminiſhed, their greateſt ordinates cannot exceed $\frac{1}{4}$th of H *h*; and we may ſay, without heſitation, that by uniting the mean or moſt outſtanding ray with the two extremes, the remaining diſperſion will be as much leſs than the uncorrected colour of Dollond's achromatic glaſs, as this is leſs than four times the diſperſion of a common object-glaſs. It muſt therefore be altogether inſenſible. Teleſcope.

Boſcovich aſſerts, that it is not poſſible to unite more than two colours by the oppoſite refraction of two ſubſtances, which do not diſperſe the light in the ſame proportions. Dr Blair makes light of this aſſertion, as he finds it made in general terms in the vague and paltry extract made by Prieſtley from Boſcovich in his Eſſay on the Hiſtory of Optics; but had he read this author in his own diſſertations, he would have ſeen that he was perfectly right. Dr Blair, however, has hit on a very ingenious and effectual method of producing this union of three colours. In the ſame way as we correct the diſperſion of a concave lens of crown-glaſs, by the oppoſite diſperſion of a concave lens of flint-glaſs, we may correct the ſecondary diſperſion of an achromatic convex lens by the oppoſite ſecondary diſperſion of an achromatic concave lens. But the intelligent reader will obſerve, that this union does not contradict the aſſertion of Boſcovich, becauſe it is *neceſſarily* produced by means of three refracting ſubſtances.

The moſt eſſential ſervice which the public has received at the hands of Dr Blair is the diſcovery of fluid mediums of a proper diſperſive power. By compoſing the lenſes of ſuch ſubſtances, we are at once freed from the irregularities in the refraction and diſperſion of flint-glaſs, which the chemiſts have not been able to free it from. In whatever way this glaſs is made, it conſiſts of parts which differ both in refractive and diſperſive power; and when taken up from the pot, theſe parts mix in threads, which may be diſſeminated through the maſs in any degree of fineneſs. But they ſtill retain their properties; and when a piece of flint-glaſs has been formed into a lens, the eye, placed in its focus, ſees the whole ſurface occupied by gliſtening threads or broader veins running acroſs it. Great rewards have been offered for removing this defect, but hitherto to no purpoſe. We beg leave to propoſe the following method: Let the glaſs be reduced to powder, and then melted with a great proportion of alkaline ſalt, ſo as to make a liquor ſilicum. When precipitated from this by an acid, it muſt be in a ſtate of very uniform compoſition. If again melted into glaſs we ſhould hope that it would be free from this defect; if not, the caſe ſeems to be deſperate.

But by uſing a fluid medium, Dr Blair was freed from all this embarraſſment; and he acquired another immenſe advantage, that of adjuſting at pleaſure both the refractive and diſperſive powers of his lenſes. In ſolid lenſes, we do not know whether we have taken the curvatures ſuited to the refractions till our glaſs is finiſhed; and if we have miſtaken the proportions, all our labour is loſt. But when fluids are uſed, it is enough that we know nearly the refractions. We ſuit our focal diſtances to theſe, and then ſelect our curvatures, ſo as to remove the aberration of figure, preſerving the focal diſtances. Thus, by properly tempering the fluid mediums, we bring the lens to agree

preciſely

Telescope. precisely with the theory, perfectly achromatic, and the aberration of figure as much corrected as is possible.

Dr Blair examined the refractive and dispersive powers of a great variety of substances, and found great varieties in their actions on the different colours. This is indeed what every well informed naturalist would expect. There is no doubt now among naturalists about the mechanical connection of the phenomena of nature; and all are agreed that the chemical actions of the particles of matter are perfectly like in kind to the action of gravitating bodies; that all these phenomena are the effects of forces like those which we call attractions and repulsions, and which we observe in magnets and electrified bodies; that light is refracted by forces of the same kind, but differing chiefly in the small extent of their sphere of activity. One who views things in this way will expect, that as the actions of the same acid for the different alkalis are different in degree, and as the different acids have also different actions on the same alkali, in like manner different substances differ in their general refractive powers, and also in the proportion of their action on the different colours. Nothing is more unlikely therefore than the proportional dispersion of the different colours by different substances; and it is surprising that this inquiry has been so long delayed. It is hoped that Dr Blair will oblige the public with an account of the experiments which he has made. This will enable others to cooperate in the improvement of achromatic glasses. We cannot derive much knowledge from what he has already published, because it was chiefly with the intention of giving a popular, though not an accurate, view of the subject. The constructions which are there mentioned are not those which he found most effectual, but those which would be most easily understood, or demonstrated by the slight theory which is contained in the dissertation; besides, the manner of expressing the difference of refrangibility, perhaps chosen for its paradoxical appearance, does not give us a clear notion of the characteristic differences of the substances examined. Those rays which are ultimately most deflected from their direction, are said to have become the most refrangible by the combination of different substances, although, in all the particular refractions by which this effect is produced, they are less refracted than the violet light. We can just gather this much, that common glass disperses the rays in such a manner, that the ray which is in the confine of the green and blue occupies the middle of the prismatic spectrum; but in glasses, and many other substances, which are more dispersive, this ray is nearer to the ruddy extremity of the spectrum. While therefore the straight line RC′ (fig. 9. B) terminates the ordinates O o', YY′, G g', &c. which represent the dispersion of common glass, the ordinates which express the dispersions of these substances are terminated by a curve passing through R and C′, but lying below the line RC′. When therefore parallel heterogeneous light is made to converge to the axis of a convex lens of common glass, as happens at F in fig. 5. C, the light is dispersed, and the violet rays have a shorter focal distance. If we now apply a concave lens of greater dispersive power, the red and violet rays are brought to one focus F′; but the green rays, not being so much refracted away from F, are left behind at g, and have now a shorter focal distance. But Dr Blair afterwards found that this was not the case with the muriatic acid, and some solutions in it. He found that the ray which common glass caused to occupy the middle of the spectrum was much nearer to the blue extremity when refracted by these fluids. Therefore a concave lens formed of such fluids which united the red and violet rays in F′, refracted the green rays to f'. Telescope.

Having observed this, it was an obvious conjecture, that a mixture of some of these fluids might produce a medium, whose action on the intermediate rays should have the same proportion that is observed on common glass; or that two of them might be found which formed spectra similarly divided, and yet differing sufficiently in dispersive power to enable us to destroy the dispersion by contrary refractions, without destroying the whole refraction. Dr Blair accordingly found a mixture of solutions of ammoniacal and mercurial salts, and also some other substances, which produced dispersions proportional to that of glass, with respect to the different colours.

And thus has the result of this intricate and laborious investigation corresponded to his utmost wishes. He has produced achromatic telescopes which seem as perfect as the thing will admit of; for he has been able to give them such apertures, that the *incorrigible* aberration arising from the spherical surfaces becomes a sensible quantity, and precludes farther amplification by the eye glasses. We have examined one of his telescopes: The focal distance of the object-glass did not exceed 17 inches, and the aperture was fully $3\frac{1}{2}$ inches. We viewed some single and double stars and some common objects with this telescope; and found, that in magnifying power, brightness, and distinctness, it was manifestly superior to one of Mr Dollond's of 42 inches focal length. It also gave us an opportunity of admiring the dexterity of the London artists, who could work the glasses with such accuracy. We had most distinct vision of a star when using an erecting eye-piece, which made this telescope magnify more than a hundred times; and we found the field of vision as uniformly distinct as with Dolloud's 42 inch telescope magnifying 46 times. The intelligent reader must admire the nice figuring and centering of the very deep eye-glasses which are necessary for this amplification.

It is to be hoped that Dr Blair will extend his views to *glasses* of different compositions, and thus give us object-glasses which are solid; for those composed of fluids have inconveniences which will hinder them from coming into general use, and will confine them to the museums of philosophers. We imagine that antimonial glasses bid fair to answer this purpose, if they could be made free of colour, so as to transmit enough of light. We recommend this dissertation to the careful perusal of our readers. Those who have not made themselves much acquainted with the delicate and abstruse theory of aberrations, will find it exhibited in such a popular form as will enable them to understand its general aim; and the well-informed reader will find many curious indications of inquiries and discoveries yet to be made.

We now proceed to consider the eye-glasses or glasses of telescopes. The proper construction of an eye-piece is not less essential than that of the object-glass. But our limits will not allow us to treat this subject in the same detail. We have already extended this article to a great length, because we do not know of any performance in the English language which will enable our readers to understand the construction of achromatic telescopes; an invention which has completed the discoveries of the illustrious Newton, and reflects honour on his country. Our readers will find abundant information in Dr Smith's Optics concerning the eye-glasses, chiefly deduced from Huyghen's fine theory of aberration (A). At the same time, we must again pay Mr Dollond

(A) While we thus repeatedly speak of the theory of spherical aberration as coming from Mr Huyghens, we must not omit

Telescope. Dollond the merited compliment of saying, that he was the first who made any scientific application of this theory to the compound eye-piece for erecting the object. His eye-pieces of five and six glasses are very ingenious reduplications of Huyghens's eye-piece of two glasses, and would probably have superseded all others, had not his discovery of achromatic object-glasses caused opticians to consider the chromatic dispersion with more attention, and pointed out methods of correcting it in the eye-piece without any compound eye-glasses. They have found that this may be more conveniently done with four eye-glasses, without sensibly diminishing the advantages which Huyghens showed to result from employing many small refractions instead of a lesser number of great ones. As this is a very curious subject, we shall give enough for making our readers fully acquainted with it, and content ourselves with merely mentioning the principles of the other rules for constructing an eye-piece.

Such readers as are less familiarly acquainted with optical discussions will do well to keep in mind the following consequences of the general focal theorem (Optics n° 141. Cor. 5.).

If AB (fig. 10. B) be a lens, R a radiant point or focus of incident rays, and a the focus of parallel rays coming from the opposite side; then,

1. Draw the perpendicular $a\,a'$ to the axis, meeting the incident ray in a', and a' A to the centre of the lens. The refracted ray BF is parallel to a' A: for R a' : a'A (= Ra : aA) = RB : BF (= RA : AF), which is the focal theorem.

2. An oblique pencil BPb proceeding from any point P which is not in the axis, is collected to the point f, where the refracted ray BF cuts the line PA f drawn from P through the centre of the lens: for P a' : a' A = PB : Bf, which is also the focal theorem.

The Galilean telescope is susceptible of so little improvement, that we need not employ any time in illustrating its performance.

The simple astronomical telescope is represented in fig. 11. The beam of parallel rays, inclined to the axis, is made to converge to a point G, where it forms an image of the lowest point of a very distant object. These rays decussating from G fall on the eye-glass; the ray from the lowest point B of the object-glass falls on the eye-glass at b; and the ray from A falls on a; and the ray from the centre O falls on o. These rays are rendered parallel, or nearly so by refraction through the eye-glass, and take the direction $b\,i'$, o I, $a\,i$. If the eye be placed so that this pencil of parallel rays may enter it, they converge to a point of the retina, and give distinct vision of the lowest point of the object. It appears inverted, because the rays by which we see its lowest point come in the direction which in simple vision is connected with the upper point of an object. They come from above, and therefore are thought to proceed from above. We see the point as if situated in the direction I o. In like manner the eye placed at I, sees the upper point of the object in the direction IP, and its middle in the direction IE. The proper place for the eye is I: if brought much nearer the glass, or removed much farther from it, some, or the whole, of this extreme pencil of rays will not enter the pupil. It is therefore of importance to determine this point. Because the eye requires parallel rays for distinct vision, it is plain that F must be the principal focus of the eye-glass. Therefore, by the common focal theorem (Optics, n° 141. Cor. 5.), OF : OE = OE : OI, or OF : FE = OE : EI. Telescope.

The magnifying power being measured by the magnitude of the visual angle, compared with the magnitude of the visual angle with the naked eye, we have $\frac{o\,I\,p}{o\,O\,p}$, or $\frac{o\,IF}{o\,OF}$ for the measure of the magnifying power. This is very nearly $= \frac{OE}{EI}$, or $\frac{OF}{FI}$.

As the line OE, joining the centres of the lenses, and perpendicular to their surfaces, is called the axis of the telescope, so the ray OG is called the axis of the oblique pencil, being really the axis of the cone of light which has the object-glass for its base. This ray is through its whole course the axis of the oblique pencil; and when its course is determined, the amplification, the field of vision, the apertures of the glasses, are all determined. For this purpose we have only to consider the centre of the object-glass as a radial point, and trace the process of a ray from this point through the other glasses: this will be the axis of some oblique pencil.

It is evident, therefore, that the field of vision depends on the breadth of the eye-glass. Should we increase this, the extreme pencil will pass through I, because O and I are still the conjugate foci of the eye-glass. On the other hand, the angle resolved on for the extent or field of vision gives the breadth of the eye-glass.

We may here observe, by the way, that for all optical instruments there must be two optical figures considered. The first shows the progress of a pencil of rays coming from one point of the object. The various focuses of this pencil show the places of the different images, real or virtual. Such a figure is formed by the three rays AG $a\,i'$, OG o I, BG $b\,i$.

The second shows the progress of the axes of the different pencils, proceeding through the centre of the object-glass. The focuses of this pencil of axes show the places where an image of the object-glass is formed; and this pencil determines the field of vision, the apertures of the lenses, and the amplification or magnifying power. The three rays OG o I, OFEI, OHPI, form this figure.

See also fig. 17. where the progress of both sets of pencils is more diversified.

The perfection of a telescope is to represent an object in its proper shape, distinctly magnified, with a great field of vision, and sufficiently bright. But there are limits to all these qualities; and an increase of one of them, for the most part, diminishes the rest. The brightness depends on the aperture of the object-glass, and will increase in the same proportion (because $i\,i'$ will always be to AB in the proportion of EF to FO), till the diameter of the emergent pencil is equal to that of the pupil of the eye. Increasing the object-glass any more, can send no more light into the eye. But we cannot make the emergent pencil nearly so large

---

omit giving a due share of the honour of it to Dr Barrow and Mr James Gregory. The first of these authors, in his Optical Lectures delivered at Cambridge, has given every proposition which is employed by Huyghens, and has even prosecuted the matter much further. In particular, his theory of oblique slender pencils is of immense consequence to the perfection of telescopes, by showing the methods for making the image of an extended surface as flat as possible. Gregory, too, has given all the fundamental propositions in his *Optica Promota*. But Huyghens, by taking the subject together, and treating it in a system, has greatly simplified it: and his manner of viewing the principal parts of it is incomparably more perspicuous than the performances of Barrow and Gregory.

Teleſcope. large as this when the teleſcope magnifies much; for the great aperture of the object-glaſs produces an indiſtinct image at GF, and its indiſtinctneſs is magnified by the eye-glaſs.

A great field of viſion is incompatible with the true ſhape of the object; for it is not ſtrictly true that all rays flowing from O are refracted to I. Thoſe rays which go to the margin of the eye-glaſs croſs the axis between E and I; and therefore they croſs it at a greater angle than if they paſſed through I. Now had they really paſſed through I, the object would have been repreſented in its due proportions. Therefore ſince the angles of the marginal parts are enlarged by the aberration of the eye-glaſs, the marginal parts themſelves will appear enlarged, or the object appear diſtorted. Thus a cheſs board viewed through a reading glaſs appears drawn out at the corners, and the ſtraight lines are all changed into curves, as is repreſented in fig. 13.

The circumſtance which moſt peremptorily limits the extent of field is the neceſſary diſtinctneſs. If the viſion be indiſtinct, it is uſeleſs, and no other quality can compenſate this defect. The diſtortion is very inconſiderable in much larger angles of viſion than we can admit, and is unworthy of the attention paid to it by optical writers. They have been induced to take notice of it, becauſe the means of correcting it in a conſiderable degree are attainable, and afford an opportunity of exhibiting their knowledge; whereas the indiſtinctneſs which accompanies a large field is a ſubject of moſt difficult diſcuſſion, and has hitherto baffled all their efforts to expreſs by any intelligible or manageable formulæ.

Quæque tractata niteſcere poſſe
Deſperat relinquit.

This ſubject muſt, however, be conſidered. The image at GF of a very remote object is not a plain ſurface perpendicular to the axis of the teleſcope, but is nearly ſpherical, having O for its centre. If a number of pencils of parallel rays croſſing each other in I fall on the eye-glaſs, they will form a picture on the oppoſite ſide, in the focus F. But this picture will by no means be flat, nor nearly ſo, but very concave towards E. Its exact form is of moſt difficult inveſtigation. The elements of it are given by Dr Barrow; and we have given the chief of them in the article Optics, when conſidering the foci of infinitely ſlender pencils of oblique rays. Therefore it is impoſſible that the picture formed by the object-glaſs can be ſeen diſtinctly in all its parts by the eye-glaſs. Even if it were flat, the points G and H (fig. 11.) are too far from the eye-glaſs when the middle F is at the proper diſtance for diſtinct viſion. When, therefore, the teleſcope is ſo adjuſted that we have diſtinct viſion of the middle of the field, in order to ſee the margin diſtinctly we muſt puſh in the eye-glaſs: and having ſo done, the middle of the field becomes indiſtinct. When the field of viſion exceeds 12 or 15 degrees, it is not poſſible by any contrivance to make it tolerably diſtinct all over; and we muſt turn the teleſcope ſucceſſively to the different parts of the field that we may ſee them agreeably.

The cauſe of this indiſtinctneſs is, as we have already ſaid, the ſhortneſs of the lateral foci of lateral and oblique pencils refracted by the eye-glaſs. We have ſhown (in Optics, n° 252) how to determine theſe in all the caſes which occur. But the determination is not complete, and relates only to thoſe rays which are in a plane paſſing through the axis of the lens. But the oblique pencil *b* G *a*, by which an eye placed at I ſees the point G of the image, is a cone of light, having a circular baſe on the eye-glaſs; of which circle *a b* is one of the diameters. There is a diameter perpendicular to this, which, in this figure is repreſented by the point *c*. Fig 12. repreſents the baſe of the cone as ſeen by an eye placed in the axis of the teleſcope, with the object-glaſs as appearing behind it. The point *b* is formed by a ray which comes from the loweſt point B of the object-glaſs, and the point *a* is illuminated by a ray from A. The point *c* at the right hand of the circular baſe of this cone of light came from the point C on the left ſide of the object-glaſs; and the light comes to *d* from D. Now the laws of optics demonſtrate, that the rays which come through the points *c* and *d* are more convergent after refraction than the rays which come through *a* and *b*. The analogies, therefore, which aſcertain the foci of rays lying in planes paſſing thro' the axis do not determine the foci of the others. Of this we may be ſenſible by looking through a lens to a figure on which are drawn concentric circles croſſed by radii. When the teleſcope is ſo adjuſted that we ſee diſtinctly the extremity of one of the radii, we ſhall not ſee diſtinctly the circumference which croſſes the extremity with equal diſtinctneſs, and *vice verſa*. This difference, however, between the foci of the rays which come through *a* and *b*, and thoſe which come through *c* and *d*, is not conſiderable in the fields of viſion, which are otherwiſe admiſſible. But the ſame difference of foci obtains alſo with reſpect to the diſperſion of light, and is more remarkable. Both d'Alembert and Euler have attempted to introduce it into their formulæ; but they have made them uſeleſs for any practical purpoſe by their inextricable complication. Teleſcope.

This muſt ſerve as a general indication of the difficulties which occur in the conſtruction of teleſcopes, even although the object-glaſs were perfect, forming an image without the ſmalleſt confuſion or diſtortion.

There is yet another difficulty or imperfection. The rays of the pencil *a* G *b*, when refracted through the eye-glaſs, are alſo ſeparated into their component colours. The edge of the lens muſt evidently perform the office of a priſm, and the white ray G *b* will be ſo diſperſed that if *b i'* be the path of its red ray, the violet ray, which makes another part of it, will take ſuch a courſe *b n* that the angle *i' b n* will be nearly $\frac{1}{27}$th of G' *b i'*. The ray G *a* paſſing through a part of the lens whoſe ſurfaces are leſs inclined to each other will be leſs refracted, and will be leſs diſperſed in the ſame proportion very nearly. Therefore the two violet rays will be very nearly parallel when the two red rays are rendered parallel.

Hence it muſt happen, that the object will appear bordered with coloured fringes. A black line ſeen near the margin on a white ground, will have a ruddy and orange border on the outſide and a blue border within: and this confuſion is altogether independent on the object-glaſs, and is ſo much the greater as the viſual angle *b* I E is greater.

Such are the difficulties: They would be unſurmountable were it not that ſome of them are ſo connected that, to a certain extent, the diminution of one is accompanied by a diminution of the other. Our readers will recollect, that in the article Optics we gave ſome account of what are called the *Cauſtic curves* (Optics n° 252), and ſhowed that theſe curves are the geometrical loci of the foci of infinitely ſlender pencils. Conſequently the point G is very nearly in the cauſtic formed by a beam of light conſiſting of rays parallel to I *o*, and occupying the whole ſurface of the eye-glaſs, becauſe the pencil of rays which are collected at G is very ſmall. Any thing therefore that diminiſhes the mutual inclination of the adjoining rays, puts their concourſe farther off. Now this is preciſely what we want: for the point G of the image formed by the object-glaſs is already beyond the focus of the oblique ſlender pencil of parallel rays *i a* and *i b*; and therefore, if we could make this focus go a little farther from *a* and *b*, we ſhall bring it nearer to G, and obtain more diſtinct viſion of this point of the object. Now

Telescope. let it be recollected, that in moderate refractions through prisms, two rays which are inclined to each other in a small angle are, after refraction, inclined to each other in the same angle. Therefore, if we can diminish the aberration of the ray *a i*, or *o* I, or *b i'*, we diminish their mutual inclination; and consequently the mutual inclination of the rays G *a*, G *o*, G *b'*, and therefore lengthen the focus, and get more distinct vision of the point G. Therefore we at once correct the distortion and the indistinctness: and this is the aim of Mr Huyghens's great principle of dividing the refractions. See Optics, n° 100.

The general method is as follows: Let *o* be the object-glass (fig. 14. A) and E the eye-glass of a telescope, and F their common focus, and FG the image formed by the object-glass. The proportion of their focal distances is supposed to be such as gives as great a magnifying power as the perfection of the object-glass will admit. Let BI be the axis of the emergent pencil. It is known by the focal theorem that GE is parallel to BI: therefore BGE is the whole refraction or deflection of the ray OHB from its former direction. Let it be proposed to diminish the aberrations by dividing this into two parts by means of two glasses D and *e*, so as to make the ultimate angle of vision *b i e* equal to BIE, and thus retain the same magnifying power and visible field. Let it be proposed to divide it into the parts BGC and CGE.

From G draw any line GD to the axis towards O; and draw the perpendicular DH, cutting OG in H; draw H *c* parallel to GC, cutting GD in *g*; draw *g f* perpendicular to the axis, and *g e* parallel to GE; draw *e b* perpendicular to the axis, draw D *d* parallel to GC, and *d d* perpendicular to the axis.

Then if there be placed at D a lens whose focal distance is D *d*, and another at *e* whose focal distance is *e f*, the thing is done. The ray OH will be refracted into H *b*, and this into *b i* parallel to BI.

The demonstration of this construction is so evident by means of the common focal theorem, that we need not repeat it, nor the reasons for its advantages (see Optics 100). We have the same magnifying power, and the same field of vision; we have less aberration, and therefore less distortion and indistinctness; and this is brought about by a lens HD of a smaller aperture and a greater focal distance than BE. Consequently, if we are contented with the distinctness of the margin of the field with a single eye-glass, we may greatly increase the field of vision: for if we increase DH to the size of EB we shall have a greater field, and much greater distinctness in the margin; because HD is of a longer focal distance, and will bear a greater aperture, preserving the same distinctness at the edge. On this account the glass HD is commonly called the *Field-glass*.

It must be observed here, however, that although the distortion of the object is lessened, there is a real distortion produced in the image *f g*. But this, when magnified by the glass *e*, is smaller than the distortion produced by the glass E, of greater aperture and shorter focus, on the undistorted image GF. But because there is a distortion in the second image *f g*, this construction cannot be used for the telescopes of astronomical quadrants, and other graduated instruments; because then equal divisions of the micrometer would not correspond to equal angles.

But the same construction will answer in this case, by taking the point D on that side of F which is remote from O (fig. 14 B). This is the form now employed in the telescopes of all graduated instruments.

The exact proportion in which the distortion and the indistinctness at the edges of the field are diminished by this construction, depends on the proportion in which the angle BGE is divided by GC; and is of pretty difficult investigation. But it never deviates far (never $\frac{1}{8}$th in optical instruments) from the proportion of the squares of the angles. We may, without any sensible error, suppose it in this proportion. This gives us a practical rule of easy recollection, and of most extensive use. When we would diminish an aberration by dividing the whole refraction into two parts, we shall do it most effectually by making them equal. In like manner, if we divide it into three parts by means of two additional glasses, we must make each $= \frac{1}{3}$d of the whole; and so on for a greater number. Telescope.

This useful problem, even when limited, as we have done, to equal refractions, is as yet indeterminate; that is, susceptible of an infinity of solutions: for the point D, where the field glass is placed, was taken at pleasure: yet there must be situations more proper than others. The aberrations which produce distortion, and those which produce indistinctness, do not follow the same proportions. To correct the indistinctness, we should not select such positions of the lens HD as will give a small focal distance to *b e*; that is, we should not remove it very far from F. Huyghens recommends the proportion of 3 to 1 for that of the focal distances of the lens HD and *e b*, and says that the distance D*e* should be $= 2$ F*e*. This will make *e i* $= \frac{1}{4}$ *e* F, and will divide the whole refraction into two equal parts, as any one will readily see by constructing the common optical figure. Mr Short, the celebrated improver of reflecting telescopes, generally employed this proportion; and we shall presently see that it is a very good one.

It has been already observed that the great refractions which take place on the eye-glasses occasion very considerable dispersions, and disturb the vision by fringing every thing with colours. To remedy this, achromatic eye-glasses may be employed, constructed by the rules already delivered. This construction, however, is incomparably more intricate than that of object-glasses: for the equations must involve the distance of the radiant point, and be more complicated: and this complication is immensely increased on account of the great obliquity of the pencils.

Most fortunately the Huyghenian construction of an eye-piece enables us to correct this dispersion to a great degree of exactness. A heterogeneous ray is dispersed at H, and the red ray belonging to it falls on the lens *b e* at a greater distance from the centre than the violet ray coming from H. It will therefore be less refracted (cæteris paribus) by the lens *b e*; and it is possible that the difference may be such that the red and violet rays dispersed at H may be rendered parallel at *b*, or even a little divergent, so as to unite accurately with the red ray at the bottom of the eye. How this may be affected, by a proper selection of the places and figures of the lenses, will appear by the following proposition, which we imagine is new, and not inelegant.

Let the compound ray OP (fig. 15. A) be dispersed by the lens PC; and let PV, PR be its violet and red rays, cutting the axis in G and *g*. It is required to place another lens RD in their way, so that the emergent rays R *r*, V*v*, shall be parallel.

Produce the incident ray OP to Z. The angles ZPR, ZPV, are given, (and RPV is nearly $= \frac{\text{ZPR}}{27}$) and the intersections G and *g* with the axis. Let F be the focus of parallel red light coming through the lens RD in the opposite direction. Then (by the common optical theorem), the perpendicular F ρ will cut PR in such a point ρ, that ρF will be parallel to the emergent ray R *r* (see Optics, n° 252—256), and to V*v*. Therefore if ρD cut PV in *u*, and *u f* be drawn perpendicular to the axis, we shall have (also by the common theorem) the point *f* for the focus of violets,

Telescope. violet rays, and DF : Df = Dρ : Du = 28 : 27 nearly, or in a given ratio.

The problem is therefore reduced to this, "To draw from a point D in the line CG a line Dρ, which shall be cut by the lines PR and PV in the given ratio.

The following construction naturally offers itself: Make GM : g M in the given ratio, and draw MK parallel to Pg. Through *any* point D of CG draw the straight line PDK, cutting MK in K. Join GK, and draw Dρ parallel to KG. This will solve the problem; and, drawing ρ F perpendicular to the axis, we shall have F for the focus of the lens RD for parallel red rays.

The demonstration is evident: for MK being parallel to Pg, we have GM : g M = GK : HK, = ρ D : u D, = FD f D, in the ratio required.

This problem admits of an infinity of solutions; because the point D may be taken anywhere in the line CG. It may therefore be subjected to such conditions as may produce other advantages.

1. It may be restricted by the magnifying power, or by the division which we choose to make of the whole refraction which produces this magnifying power. Thus, if we have resolved to diminish the aberrations by making the two refractions equal, we have determined the angle RrD. Therefore draw GK, making the angle MGK equal to that which the emergent pencil must make with the axis, in order to produce this magnifying power. Then draw MK parallel to Pg, meeting GK in K. Then draw PK, cutting the axis in D, and Dρ parallel to GK, and ρ F perpendicular to the axis. D is the place, and DF the focal distance of the eye-glass.

2. Particular circumstances may cause us to fix on a particular place D, and we only want the focal distance. In this case the first construction suffices.

3. We may have determined on a certain focal distance DF, and the place must be determined. In this case let

$$\begin{aligned} GF : F\rho &= 1 : \text{tan. } G \\ F\rho : fu &= 1 : m, \ m \text{ being} = \tfrac{27}{28} \\ fu : fg &= \text{tan. } g : 1 \end{aligned}$$

then $GF : fg = \text{tan. } g : m \text{ tan. } G$

then $GF - fg : GF = \text{tan. } g - m \text{ tan. } G : \text{tan. } g$

or $Gg + Ff : GF = \text{tan. } g - m \text{ tan. } G : \text{tan. } g$;

and $$GF = Gg + Ff \frac{\text{tan. } g}{\text{tan. } g - m. \text{ tan. } G},$$ and is therefore given, and the place of F is determined; and since FD is given by supposition, D is determined.

The application of this problem to our purpose is difficult, if we take it in the most general terms; but the nature of the thing makes such limitations that it becomes very easy. In the case of the dispersion of light, the angle GPg is so small that MK may be drawn parallel to PG without any sensible error. If the ray OP were parallel to CG, then G would be the focus of the lens PC, and the point M would fall on C; because the focal distance of red rays is to that of violet rays in the same proportion for every lens, and therefore CG : Cg = DF : Df. Now, in a telescope which magnifies considerably, the angle at the object-glass is very small and CG hardly exceeds the focal distance; and CG is to Cg very nearly in the same proportion of 28 to 27. We may therefore draw through C (fig. 15. B) a line CK parallel to PG: then draw GK' perpendicular to the axis of the lens, and join PK'; draw K'BE parallel to CG, cutting PK in B; draw BHI parallel to GK, cutting GK' in H: Join HD and PK. It is evident that CG is bisected in F', and that K'B = 2 F'D: also K'H : HG = K'B : BE, = CD : DG. Therefore DH is parallel to CK', or to PG. But because PF = F'K', PD is = DB, and IH = HB. Therefore ρ D = HB, and FD = K'B, = 2 F'D; and FD is bisected in F'. Therefore CD = $\frac{CG+FD}{2}$. Telescope.

That is, in order that the eye-glass RD may correct the dispersion of the field-glass PC, *the distance between them must be equal to the half sum of their focal distances* very nearly. More exactly, *the distance between them must be equal to the half sum of the focal distance of the eye glass, and the distance at which the field-glass would form an image of the object glass.* For the point G is the focus to which a ray coming from the centre of the object-glass is refracted by the field-glass.

This is a very simple solution of this important problem. Huyghens's eye-piece corresponds with it exactly. If indeed the dispersion at P is not entirely produced by the refraction, but perhaps combined with some previous dispersion, the point M (fig. 15. A) will not coincide with C, (fig. 15. B), and we shall have GC to GM, as the natural dispersion at P to the dispersion which really obtains there. This may destroy the equation CD = $\frac{CG+FD}{2}$.

Thus, in a manner rather unexpected, have we freed the eye-glasses from the greatest part of the effect of dispersion. We may do it entirely by pushing the eye-glass a little nearer to the field-glass. This will render the violet rays a little divergent from the red, so as to produce a perfect picture at the bottom of the eye. But by doing so we have hurt the distinctness of the whole picture, because F is not in the focus of RD. We remedy this by drawing both glasses out a little, and the telescope is made perfect.

This improvement cannot be applied to the construction of quadrant telescopes, such as fig. 14. B. Mr Ramsden has attempted it, however, in a very ingenious way, which merits a place here, and is also instructive in another way. The field-glass HD (fig. 14. B) is a plano-convex, with its plane side next the image GF. It is placed very near this image. The consequence of this disposition is, that the image GF produces a vertical image $g f$, which is much less convex towards the glass. He then places a lens on the point C, where the red ray would cross the axis. The violet ray will pass on the other side of it. If the focal distance of this glass be fc, the vision will be distinct and free from colour. It has, however, the inconveniency of obliging the eye to be close to the glass, which is very troublesome.

This would be a good construction for a magic-lanthorn, or for the object-glass of a solar microscope, or indeed of any compound microscope.

We may presume that the reader is now pretty familiar with the different circumstances which must be considered in the construction of an eye-piece, and proceed to consider those which must be employed to erect the object.

This may be done by placing the lens which receives the light from the object-glass in such a manner that a second image (inverted with respect to the first) may be formed beyond it, and this may be viewed by an eye-glass. Such a construction is represented in fig. 16. But, besides many other defects, it tinges the object prodigiously with colour. Plate DIV. The ray $o d$ is dispersed at d into the red ray $d r$, and the violet $d v$, v being farther from the centre than r, the refracted ray $v v'$ crosses $r r'$ both by reason of spherical aberration and its greater refrangibility.

But the common day telescope, invented by F. Rheita, has, in this respect, greatly the advantage of the one now described. See Optics, n° 266. The rays of compound light are dispersed at e and f. (Plate CCCLXIV. fig. 13.). The violet ray proceeding from f, falls without the red ray at g, but is accurately collected with it at the focus E, as we shall demonstrate by and by. Since they cross each

Teleſcope. other in E, the violet ray muſt fall within the red ray at *i*, and be leſs refracted than if it had fallen on the ſame point with the red ray. Had it fallen there it would have ſeparated from it; but by a proper diminution of its refraction, it is kept parallel to it, or nearly ſo. And this is one excellence of this teleſcope: when conſtructed with three eye-glaſſes perfectly equal, the colour is ſenſibly diminiſhed, and by uſing an eye-glaſs ſomewhat ſmaller, it may be removed entirely.—We ſay no more of it at preſent, becauſe we ſhall find its conſtruction included in another, which is ſtill more perfect.

It is evident at firſt ſight that this teleſcope may be improved, by ſubſtituting for the eye-glaſs *i k* (fig. 13.) the Huyghenian double eye-glaſs, or field glaſs and eye-glaſs repreſented in fig. 14. A, and fig. 14. B; and that the firſt of theſe may be improved and rendered achromatic. This will require the two glaſſes *e f* and *g h* to be increaſed from their preſent dimenſions to the ſize of a field glaſs, ſuited to the magnifying power of the teleſcope, ſuppoſing it an aſtronomical teleſcope. Thus we ſhall have a teleſcope of four eye-glaſſes. The three firſt will be of a conſiderable focal diſtance, and two of them will have a common focus at *h*. But this is conſiderably different from the eye piece of four glaſſes which are now uſed, and are far better. We are indebted for them to Mr Dollond, who was a mathematician as well as an artiſt, and in the courſe of his reſearch diſcovered reſources which had not been thought of. He had not then diſcovered the achromatic object-glaſs, and was buſy in improving the eye-glaſſes by diminiſhing their ſpherical aberration. His firſt thought was to make the Huyghenian addition at both the images of the day teleſcope. This ſuggeſted to him the following eye-piece of five glaſſes.

Plate DIV. Fig. 17. repreſents this eye-piece, but there is not room for the object-glaſs at its proper diſtance. A pencil of rays coming from the upper point of the object is made to converge (by the object-glaſs) to G, where it would form a picture of that part of the object. But it is intercepted by the lens A *a* and its axis is bent towards the axis of the teleſcope in the direction *a b*. At the ſame time the rays which converged to G converge to *g*, and there is formed an inverted picture of the object at *g f*. The axis of the pencil is again refracted at *b*, croſſes the axis of the teleſcope in H, is refracted again at *c*, at *d*, and at *e*, and at laſt croſſes the axis in I. The rays of this pencil, diverging from *g*, are made leſs diverging, and proceed as if they came from *g'*, in the line B *g g'*. The lens *c* C cauſes them to converge to *g'*, in the line G' C *g'*. The lens *d* D makes them converge ſtill more to G", and there they form an erect picture G" F"; diverging from G", they are rendered parallel by the refraction at *e*.

At H the rays are nearly parallel. Had the glaſs B *b* been a little farther from A, they would have been accurately ſo, and the object-glaſs, with the glaſſes A and B, would have formed an aſtronomical teleſcope with the Huyghenian eye-piece. The glaſſes C, D, and E, are intended merely for bending the rays back again till they again croſs the axis in I. The glaſs C tends chiefly to diminiſh the great angle BH *b*; and then the two glaſſes D and E are another Huyghenian eye-piece.

The art in this conſtruction lies in the proper adjuſtment of the glaſſes, ſo as to divide the whole bending of the pencil pretty equally among them, and to form the laſt image in the focus of the eye-glaſs, and at a proper diſtance from the other glaſs. Bringing B nearer to A would bend the pencil more to the axis. Placing C farther from B would do the ſame thing; but this would be accompanied with more aberration, becauſe the rays would fall at a greater diſtance from the centres of the lenſes. The greateſt bending is made at the field-glaſs D; and we imagine that the teleſcope would be improved, and made more diſtinct at the edges of the field, by employing another glaſs of great focal diſtance between C and D. Teleſcope.

There is an image formed at H of the object-glaſſes, and the whole light paſſes through a ſmall circle in this place. It is uſual to put a plate here pierced with a hole which has the diameter of this image. A ſecond image of the object-glaſs is formed at I, and indeed wherever the pencils croſs the axis. A lens placed at H makes no change in any of the angles, nor in the magnifying power, and affects only the place where the images are formed. And, on the other hand, a lens placed at *f*, or F", where a real image is formed, makes no change in the places of the images, but affects the mutual inclination of the pencils. This affords a reſource to the artiſt, by which he may combine properties which ſeem incompatible.

The aperture of A determines the viſible field and all the other apertures.

We muſt avoid forming a real image, ſuch as *f g*, or F" G", on or very near any glaſs. For we cannot ſee this image without ſeeing along with it every particle of duſt and every ſcratch on the glaſs. We ſee them as making part of the object when the image is exactly on the glaſs, and we ſee them confuſedly, and ſo as to confuſe the object, when the image is near it. For when the image is on or very near any glaſs, the pencil of light occupies a very ſmall part of its ſurface, and a particle of duſt intercepts a great proportion of it.

It is plain that this conſtruction will not do for the teleſcope of graduated inſtruments, becauſe the micrometer cannot be applied to the ſecond image *f g*, on account of its being a little diſtorted, as has been obſerved of the Huyghenian eye-piece.

Alſo the interpoſition of the glaſs C makes it difficult to correct the diſperſion.

By proper reaſoning from the correction in the Huyghenian eye-piece, we are led to the beſt conſtruction of one with three glaſſes; which we ſhall now conſider, taking it in a particular form, which ſhall make the diſcuſſion eaſy, and make us fully maſters of the principles which lead to a better form. Therefore let PA (fig. 18.) be the glaſs which firſt receives the light proceeding from the image formed by the object-glaſs, and let OP be the axis of the extreme pencil. This is refracted into PR, which is again refracted into R *r* by the next lens B *r*. Let *b* be the focus of parallel rays of the ſecond lens. Draw PB *r*. We know that A *b* : *b* B = PB : B *r*, and that rays of one kind diverging from P will be collected at *r*. But if PR, PV be a red and a violet ray, the violet ray will be more refracted at V, and will croſs the red ray in ſome intermediate point *g* of the line R *r*. If therefore the firſt image had been formed preciſely on the lens PA, we ſhould have a ſecond image at *f g* free from all coloured fringes.

If the refractions at P and R are equal (as in the common day teleſcope), the diſperſion at V muſt be equal to that at P, or the angle *v* V *r* = VPR. But we have ultimately RPV : R *r* V = BC : AB, (= B *b* : A *b* by the focal theorem). Therefore *g* V *r* : *g r* V (or *g r* : *g* V, or C *f* : *f* B) = B *b* : A *b*, and AB : A *b* = R *r* : R *g*.

This ſhows by the way the advantage of the common day teleſcope. In this AB = 2A *b*, and therefore *f* is the place of the laſt image which is free from coloured fringes. But this image will not be ſeen free from coloured fringes through the eye-glaſs C *r*, if *f* be its focus: For had *g r*, *g v* been both red rays, they would have been parallel after refraction; but *g v* being a violet ray, will be more refracted. It

will

Telescope. will not indeed be so much deflected from parallelism as the violet ray, which naturally accompanies the red ray to r, because it falls nearer the centre. By computation its dispersion is diminished about $\frac{1}{7}$th.

In order that $g\,v$ may be made parallel to $g\,r$ after refraction, the refraction at r must be such that the dispersion corresponding to it may be of a proper magnitude. How to determine this is the question. Let the dispersion at g be to the dispersion produced by the refraction at r (which is required for producing the intended magnifying power) as 1 to 9. Make $9 : 1 = ff' : f'\,C$, $= f\,C : CD$, and draw the perpendicular $D\,r'$ meeting the refracted ray $r\,r'$ in r'. Then we know by the common focal theorem, that if f' be the focus of the lens $C\,r$, red rays diverging from g will be united in r'. But the violet ray $g\,v$ will be refracted into $v\,v'$ parallel to $r\,r'$. For the angle $v\,r'\,r : v\,g\,r =$ (ultimately) $f\,C : CD$, $= 9 : 1$. Therefore the angle $v\,r'\,r$ is equal to the dispersion produced at r, and therefore equal to $r'\,v\,v'$, and $v\,v'$ is parallel to $r\,r'$.

But by this we have destroyed the distinct vision of the image formed at $f\,g$, because it is no longer at the focus of the eye-glass. But distinct vision will be restored by pushing the glasses nearer to the object-glass. This makes the rays of each particular pencil more divergent after refraction through A, but scarcely makes any change in the directions of the pencils themselves. Thus the image comes to the focus f', and makes no sensible change in the dispersions.

In the common day telescope, the first image is formed in the anterior focus of the first eye-glass, and the second image is at the anterior focus of the last eye-glass. If we change this last for one of half the focal distance, and push in the eye-piece till the image formed by the object glass is half way between the first eye-glass and its focus, the last image will be formed at the focus of the new eye-glass, and the eye-piece will be achromatic. This is easily seen by making the usual computations by the focal theorem. But the visible field is diminished, because we cannot give the same aperture as before to the new eye-glass; but we can substitute for it two eye-glasses like the former, placed close together. This will have the same focal distance with the new one, and will allow the same aperture that we had before.

On these principles may be demonstrated the correction of colour in eye-pieces with three glasses of the following construction.

Let the glasses A and B be placed so that the posterior focus of the first nearly coincides with the anterior focus of the second, or rather so that the anterior focus of B may be at the place where the image of the object-glass is formed, by which situation the aperture necessary for transmitting the whole light will be the smallest possible. Place the third C at a distance from the second, which exceeds the sum of their focal distances by a space which is a third proportional to the distance of the first and second, and the focal distance of the second. The distance of the first eye-glass from the object-glass must be equal to the product of the focal distance of the first and second divided by their sum.

Let O o, A a, B b, C c, the focal distances of the glasses, be O, a, b, c. Then make $AB = a + b$ nearly; $BC = b + c + \frac{b^2}{b+c}$; $OA = \frac{b\,c}{b+c}$. The amplification or magnifying power will be $= \frac{o\,b}{a\,c}$; the equivalent eye-glass $= \frac{a\,c}{b}$; and the field of vision $= 3438' \times \frac{\text{Aperture of A}}{\text{foc. dist. ob. gl.}}$

These eye-pieces will admit the use of a micrometer at the place of the first image, because it has no distortion. Telescope.

Mr Dollond was anxious to combine this achromatism of the eye-pieces with the advantages which he had found in the eye-pieces with five glasses. This eye-piece of three glasses necessarily has a very great refraction at the glass B, where the pencil which has come from the other side of the axis must be rendered again convergent, or at least parallel to it. This occasions considerable aberrations. This may be avoided by giving part of this refraction to a glass put between the first and second, in the same way as he has done by the glass B put between A and C in his five glass eye-piece. But this deranges the whole process. His ingenuity, however, surmounted this difficulty, and he made eye-pieces of four glasses, which seem as perfect as can be desired. He has not published his ingenious investigation; and we observe the London artists work very much at random, probably copying the proportions of some of his best glasses, without understanding the principle, and therefore frequently mistaking. We see many eye-pieces which are far from being achromatic. We imagine therefore that it will be an acceptable thing to the artists to have precise instructions how to proceed, nothing of this kind having appeared in our language, and the investigations of Euler, D'Alembert, and even Boscovich, being so abstruse as to be inaccessible to all but experienced analysts. We hope to render it extremely simple.

It is evident, that if we make the rays of different colours unite on the surface of the last eye-glass but one, commonly called the *field-glass*, the thing will be done, because the dispersion from this point of union will then unite with the dispersion produced by this glass alone; and this increased dispersion may be corrected by the last eye-glass in the way already shown.

Therefore let A, B (fig. 19.) be the stations which we have fixed on for the first and second eye-glasses, in order to give a proper portion of the whole refraction to the second glass. Let b be the anterior focus of B. Draw P B r through the centre of B. Make $A\,b : b\,B = AB : BK$. Draw the perpendicular $K\,r$, meeting the refracted ray in r. We know by the focal theorem, that red rays diverging from P will converge to r; but the violet ray PV, being more refracted, will cross R r in some point g. Drawing the perpendicular $f\,g$, we get f for the proper place of the field glass. Let the refracted ray R r, produced backwards, meet the ray OP coming from the centre of the object glass in O. Let the angle of dispersion RPV be called p, and the angle of dispersion at V, that is, $r\,V\,v$, be v, and the angle $V\,r\,R$ be r.

It is evident that $OR : OP = p : v$, because the dispersions are proportional to the sines of the refractions, which in this case, are very nearly as the refractions themselves.

Let $\frac{OP}{OR}$ $\left(\text{or } \frac{o\,p}{p\,B} \text{ or } \frac{p\,B}{b\,B}\right)$ be made $= m$. Then $v = m\,p$; also $p : r = BK : AB$, $= b\,B : A\,b$, and $r = p.\frac{A\,b}{b\,B}$, or, making $\frac{A\,b}{B\,b} = n$, $r = n\,p$; therefore $v : r = m : n$, $= \frac{p\,B}{b\,B} : \frac{A\,b}{b\,B}$, $= p\,B : A\,b$.

The angle $R\,g\,V = g\,V\,r + g\,r\,V = p.\overline{m+n}$; and $R\,g\,V : R\,r\,v = R\,r : R\,g$, or $m + n : n = R\,r : R\,g$, and $R\,g = R\,r\,\frac{n}{m+n}$. But $R\,r$ is ultimately $= BK = AB$

Telescope. $\frac{b\,B}{A\,b} = \frac{AB}{a}$. Therefore $R\,g = \frac{AB}{n} \times \frac{n}{m+n} = \frac{AB}{m+n}$, and $B\,f = \frac{AB}{m+n}$.

This value of $B\,f$ is evidently $= b\,B \times \frac{AB}{p\,B + A\,b}$. Now $b\,B$ being a conſtant quantity while the glaſs B is the ſame, the place of union varies with $\frac{AB}{p\,B + A\,b}$. If we remove B a little farther from A, we increaſe AB, and $p\,B$, and $A\,b$, each by the ſame quantity. This evidently diminiſhes $B\,f$. On the other hand, bringing B nearer to A increaſes $B\,f$. If we keep the diſtance between the glaſſes the ſame, but increaſe the focal diſtance $b\,B$, we augment $B\,f$, becauſe this change augments the numerator and diminiſhes the denominator of the fraction $\frac{b\,B \times A\,B}{p\,B + A\,b}$.

In this manner we can unite the colours at what diſtance we pleaſe, and conſequently can unite them in the place of the intended field-glaſs, from which they will diverge with an increaſed diſperſion, viz. with the diperſion competent to the refraction produced there, and the diſperſion $p \times m + n$ conjoined.

It only remains to determine the proper focal diſtances of the field-glaſs and eye glaſs, and the place of the eye-glaſs, ſo that this diſperſion may be finally corrected.

This is an indeterminate problem, admitting of an infinity of ſolutions. We ſhall limit it by an equal diviſion of the two remaining refractions, which are neceſſary in order to produce the intended magnifying power. This conſtruction has the advantage of diminiſhing the aberration. Thus we know the two refractions, and the diſperſion competent to each; it being nearly $\frac{1}{177}$th of the refraction. Call this q. The whole diſperſion at the field-glaſs conſiſts of q, and of the angle K g V of fig. 19. which we alſo know to be $= p \times m+n$. Call their ſum s.

Let fig. 20. n° 1. repreſent this addition to the eye-piece. C g is the field-glaſs coming in the place of $f g$ of fig. 19. and R g w is the red ray coming from the glaſs BR. Draw $g\,s$ parallel to the intended emergent pencil from the eye-glaſs; that is, making the angle C s g with the axis correſpond to the intended magnifying power. Biſect this angle by the line g K. Make $s\,g : g\,q = s : q$, and draw q K, cutting C g in t. Draw $t\,\delta$ D, cutting $g\,k$ in δ, and the axis in D. Draw $\delta\,d$ and D r perpendicular to the axis. Then a lens placed in D, having the focal diſtance D d, will deſtroy the diſperſion at the lens $g\,c$, which refracts the ray $g\,w$ into $g\,r$.

Let $g\,v$ be the violet ray, making the angle $v\,g\,r = s$. It is plain, by the common optical theorem, that $g\,r$ will be refracted into $r\,r'$ parallel to δ D. Draw g D r' meeting $r\,r'$, and join $v\,r'$. By the focal theorem two red rays $g\,r$, $g\,v$, will be united in r'. But the violet ray $g\,v$ will be more refracted, and will take the path $v\,v'$, making the angle of diſperſion $r'\,v\,v' = q$, very nearly, becauſe the diſperſion at v does not ſenſibly differ from that at r. Now, in the ſmall angles of refraction which obtain in optical inſtruments the angles $r\,r'\,v$, $r\,g\,v$ are very nearly as $g\,r$ and $r\,r'$, or as g D and D r', or as CD and DT; which, by the focal theorem, are as C d and d D; that is, $D\,d : d\,c = r\,g\,v : r\,r'\,v$. But $D\,d : d\,C = D\,\delta : \delta t, = s\,g : g\,q, = s : q$. But $r\,g\,v = s$; therefore $r\,r'\,v = q, = r'\,v\,v'$, and $v\,v'$ is parallel to $r\,r'$, and the whole diſperſion at g is corrected by the lens D r. The focal diſtance C c of C g is had by drawing C $\varkappa$ parallel to K g, meeting R g in $\varkappa$, and drawing $\varkappa\,c$ perpendicular to the axis.

It is eaſy to ſee that this (not inelegant) conſtruction is not limited to the equality of the refractions $v\,g\,r$, K $r\,r'$. Telescope. In whatever proportion the whole refraction $v\,g\,s$ is divided, we always can tell the proportion of the diſperſions which the two refractions occaſion at g and r, and can therefore find the values of s and q. Indeed this ſolution includes the problem in p. 365. col. 1. par. 2.; but it had not occurred to us till the preſent occaſion. Our readers will not be diſpleaſed with this variety of reſource.

The intelligent reader will ſee, that in this ſolution ſome quantities and ratios are aſſumed as equal which are not ſtrictly ſo, in the ſame manner as in all the elementary optical theorems. The parallelism, however, of $v\,v'$ and $r\,r'$ may be made accurate, by puſhing the lens D r nearer to C g, or retiring it from it. We may alſo, by puſhing it ſtill nearer, induce a ſmall divergency of the violet ray, ſo as to produce accurate viſion in the eye, and may thus make the viſion through a teleſcope more perfect than with the naked eye, where diſperſion is by no means avoided. It would therefore be an improvement to have the eye glaſs in a ſliding tube for adjuſtment. Bring the teleſcope to diſtinct viſion; and if any colour be viſible about the edges of the field, ſhift the eye-glaſs till this colour is removed. The viſion may now become indiſtinct: but this is corrected by ſhifting the place of the whole eye-piece.

We have examined trigonometrically the progreſs of a red and a violet ray through many eye-pieces of Dollond's and Ramſden's beſt teleſcopes; and we have found in all of them that the colours are united on or very near the field-glaſs; ſo that we preſume that a theory ſomewhat analogous to ours has directed the ingenious inventors. We meet with many made by other artiſts, and even ſome of theirs, where a conſiderable degree of colour remains, ſometimes in the natural order and often in the contrary order. This muſt happen in the hands of mere imitators, ignorant of principle. We preſume that we have now made this principle ſufficiently plain.

Fig. 20 N° 2. repreſents the eye-piece of a very fine ſpy-glaſs by Mr Ramſden; the focal length of its object-glaſs is $8\frac{1}{2}$ inches, with $1\frac{1}{10}$th of aperture, 2° 05′ of viſible field, and 15,4 magnifying power. The diſtances and focal lengths are of their proper dimenſions, but the apertures are $\frac{1}{2}$ larger, that the progreſs of a lateral pencil might be more diſtinctly drawn. The dimenſions are as follow:

Foc. lengths $Aa = 0{,}775$ $Bb = 1{,}025$ $Cc = 1{,}01$ $Dd = 0{,}79$

Diſtances $AB = 1{,}18$ $BC = 1{,}83$ $CD = 1{,}105$.

It is perfectly achromatic, and the colours are united, not preciſely, at the lens C g, but about $\frac{1}{20}$th of an inch nearer the eye-glaſs.

It is obvious that this combination of glaſſes may be uſed as a microſcope; for if, inſtead of the image formed by the object-glaſs at FG, we ſubſtitute a ſmall object, illuminated from behind, as in compound microſcopes; and if we draw the eye-piece a very ſmall way from this object, the pencils of parallel rays emergent from the eye-glaſs D will become convergent to very diſtant points, and will there form an inverted and enlarged picture of the object, which may be viewed by a Huyghenian eye-piece; and we may thus get high magnifying powers without uſing very deep glaſſes. We tried the eye-piece of which we have given the dimenſions in this way, and found that it might be made to magnify 180 times with very great diſtinctneſs. When uſed as the magnifier of a ſolar microſcope, it infinitely ſurpaſſes every thing we have ever ſeen. The picture formed by a ſolar microſcope is generally ſo indiſtinct, that it is fit only for amuſing ladies; but with this magnifier it ſeemed perfectly ſharp. We therefore recommend this to the artiſts as a valuable article of their trade.

The only thing which remains to be conſidered in the theory

Teleſcope. theory of refracting teleſcopes is the forms of the different lenſes. Hitherto we have had no occaſion to conſider any thing but their focal diſtances; but their aberrations depend greatly on the adjuſtment of their forms to their ſituations. When the conjugate focuſes of a lens are determined by the ſervice which it is to perform, there is a certain form or proportion between the curvatures of their anterior and poſterior ſurfaces, which will make their aberrations the ſmalleſt poſſible.

It is evident that this proportion is to be obtained by making the fluxion of the quantity within the parentheſis in the formula of par. 2. col. 2. p. 348, equal to nothing. When this is done we obtain this formula for a, the radius of curvature for the anterior ſurface of a lens. $\frac{1}{a}=\frac{2m^2+m}{2m+4}+\frac{4m+4}{2(m+4)r}$, where m is the ratio of the ſine of incidence to the ſine of refraction, and r is the diſtance of the focus of incident rays, poſitive or negative, according as they converge or diverge, all meaſured on a ſcale of which the unit is n, = half of the radius of the equivalent iſoſceles lens.

It will be ſufficiently exact for our purpoſe to ſuppoſe $m=\frac{3}{2}$, though it is more nearly $\frac{31}{20}$. In this caſe $\frac{1}{a}=\frac{b}{7}+\frac{10}{7r}=\frac{42r+70}{49r}$. Therefore $a=\frac{49r}{42r+70}$. And $\frac{1}{b}=\frac{1}{a}-1=\frac{1-a}{a}$.

As an example, let it be required to give the radii of curvature in inches for the eye-glaſs be of page 362. col. 1. par. 2. which we ſhall ſuppoſe of $1\frac{1}{2}$ inches focal diſtance, and that ec $(=r)$ is $3\frac{3}{4}$th inches.

The radius of curvature for the equivalent iſoſceles lens is 1,5, and its half is 0,75. Therefore $r=\frac{3\frac{3}{4}}{0,75}=5$; and our formula is $a=\frac{49\times5}{42\times5+70}=\frac{245}{280}=0,875$; and $\frac{1}{b}=\frac{1-a}{a}=\frac{0,125}{0,875}$, and $b=\frac{0,875}{0,125}=7$.

Theſe values are parts of a ſcale, of which the unit is 0,75 inches. Therefore

a, in inches, $=0,875\times0,75=0,65525$
b, in inches, $=7\times0,75=5,25$.

And here we muſt obſerve that the poſterior ſurface is concave: for b is a poſitive quantity, becauſe $1-a$ is a poſitive quantity as well as a; therefore the centre of ſphericity of both ſurfaces lies beyond the lens.

And this determination is not very different from the uſual practice, which commonly makes this lens a plano convex with its flat ſide next the eye: and there will not be much difference in the performance of theſe two lenſes; for in all caſes of maxima and minima, even a pretty conſiderable change of the beſt dimenſions does not make a ſenſible change in the reſult.

The ſame conſideration leads to a rule which is very ſimple, and ſufficiently exact for ordinary ſituations. This is to make the curvatures ſuch, that the incident and emergent pencils may be nearly equally inclined to the ſurfaces of the lens. Thus in the eye-piece with five glaſſes, A and B ſhould be moſt convex on their anterior ſides; C ſhould be moſt convex on the poſterior ſide; D ſhould be nearly iſoſceles; and E nearly plano convex.

But this is not ſo eaſy a matter as appears at firſt ſight. The lenſes of an eye-piece have not only to bend the ſeveral pencils of light to and from the axis of the teleſcope; they have alſo to form images on the axes of theſe pencils. Theſe offices frequently require oppoſite forms, as mentioned in par. 3. col. 2. p. 362. Thus the glaſs A of fig. 20. n° 2. ſhould be moſt convex on the ſide next the object, that it may produce little diſtortion of the pencils. But it ſhould be moſt convex next the eye, that it may produce diſtinct viſion of the image FG, which is very near it. This image ſhould have its concavity turned towards A, whereas it is towards the object-glaſs. We muſt therefore endeavour to make the vertical image fg flatter, or even convex. This requires a glaſs very flat before and convex behind. For ſimilar reaſons the object-glaſs of a microſcope and the ſimple eye-glaſs of an aſtronomical teleſcope ſhould be formed the ſame way.

This is a ſubject of moſt difficult diſcuſſion, and requires a theory which few of our readers would reliſh; nor does our limits afford room for it. The artiſts are obliged to grope their way. The proper method of experiment would be, to make eye-pieces of large dimenſions, with extravagant apertures to increaſe the aberrations, and to provide for each ſtation A, B, C, and D, a number of lenſes of the ſame focal diſtance, but of different forms: and we would adviſe making the trial in the way of a ſolar microſcope, and to have two eye-pieces on trial at once. Their pictures can be formed on the ſame ſcreen, and accurately compared; whereas it is difficult to keep in remembrance the performance of one eye-piece, and compare it with another.

We have now treated the theory of refracting teleſcopes with conſiderable minuteneſs, and have perhaps exceeded the limits which ſome readers may think reaſonable. But we have long regretted that there is not any theory on this ſubject from which a curious perſon can learn the improvements which have been made ſince the time of Dr Smith, or an artiſt learn how to proceed with intelligence in his profeſſion. If we have accompliſhed either of theſe ends, we truſt that the public will receive our labours with ſatisfaction.

We cannot add any thing to what Dr Smith has delivered on the theory of reflecting teleſcopes. There appears to be the ſame poſſibility of correcting the aberration of the great ſpeculum by the contrary aberration of a convex ſmall ſpeculum, that we have practiſed in the compound object-glaſs of an achromatic refracting teleſcope. But this cannot be, unleſs we make the radius of the convex ſpeculum exceedingly large, which deſtroys the magnifying power and the brightneſs. This therefore muſt be given up. Indeed their performance, when well executed, does already ſurpaſs all imagination. Mr Herſchel has found great advantages in what he calls the *front view*, not uſing a plane mirror to throw the pencils to one ſide. But this cannot be practiſed in any but teleſcopes ſo large, that the loſs of light, occaſioned by the interpoſition of the obſerver's head, may be diſregarded.

NOTHING remains but to deſcribe the mechaniſm of ſome of the moſt convenient forms.

To deſcribe all the varieties of ſhape and accommodation which may be given to a teleſcope, would be a taſk as trifling as prolix. The artiſts of London and of Paris have racked their inventions to pleaſe every fancy, and to ſuit every purpoſe. We ſhall content ourſelves with a few general maxims, deduced from the ſcientific conſideration of a teleſcope, as an inſtrument by which the viſual angle ſubtended by a diſtinct object is greatly magnified.

The chief conſideration is to have a ſteady view of the diſtant object. This is unattainable, unleſs the axis of the inſtrument be kept conſtantly directed to the ſame point of it: for when the teleſcope is gently ſhifted from its poſition, the object *ſeems to move* in the ſame or in the oppoſite direction, according as the teleſcope inverts the object or

Does

Teleſcope. ſhows it erect. This is owing to the magnifying power, becauſe the apparent angular motion is greater than what we naturally connect with the motion of the teleſcope.

This does not happen when we look through a tube without glaſſes.

All ſhaking of the inſtrument therefore makes the object dance before the eye; and this is diſagreeable, and hinders us from ſeeing it diſtinctly. But a tremulous motion, however ſmall, is infinitely more prejudicial to the performance of a teleſcope, by making the object quiver before us. A perſon walking in the room prevents us from ſeeing diſtinctly; nay, the very pulſation in the body of the obſerver, agitates the floor enough to produce this effect, when the teleſcope has a great magnifying power: For the viſible motion of the object is then an imperceptible tremor, like that of an harpſichord wire, which produces an effect preciſely ſimilar to optical indiſtinctneſs; and every point of the object is diffuſed over the whole ſpace of the angular tremor, and appears coexiſtent in every part of this ſpace, juſt as a harpſichord wire does while it is ſounding. The more rapid this motion is, the indiſtinctneſs is the more complete. Therefore the more firm and elaſtic and well bound together the frame-work and apertures of our teleſcope is, the more hurtful will this conſequence be. A mounting of lead, were it practicable, would be preferable to wood, iron, or braſs. This is one great cauſe of the indiſtinctneſs of the very fineſt reflecting teleſcopes of the uſual conſtructions, and can never be totally removed. In the Gregorian form it is hardly poſſible to damp the elaſtic tremor of the ſmall ſpeculum, carried by an arm ſupported at one end only, even though the tube were motionleſs. We were witneſſes of a great improvement made on a four-feet reflecting teleſcope, by ſupporting the ſmall ſpeculum by a ſtrong plate of lead placed acroſs the tube, and led by an adjuſting ſcrew at each end. But even the great mirror may vibrate enough to produce indiſtinctneſs. Refracting teleſcopes are free from this inconveniency, becauſe a ſmall angular motion of the object-glaſs round one of its own diameters has no ſenſible effect on the image in its focus. They are affected only by an angular motion of the axis of the teleſcope or of the eye-glaſſes.

This ſingle conſideration gives us great help towards judging of the merits of any particular apparatus. We ſhould ſtudy it in this particular, and ſee whether its form makes the tube readily ſuſceptible of ſuch tremulous motions. If it does, the firmer it is and the more elaſtic it is, the worſe. All forms therefore where the tube is ſupported only near the middle, or where the whole immediately or remotely depend on one narrow joint, are defective.

Reaſoning in this way, we ſay with confidence, that of all the forms of a teleſcope apparatus, the old faſhioned ſimple ſtand repreſented in fig. 21. is by far the beſt, and that others are ſuperior according as the diſpoſition of the points of ſupport of the tube approaches to this. Let the pivots A, B, be fixed in the lintel and ſole of a window. Let the four braces terminate very near to theſe pivots. Let the teleſcope lie on the pin F *f*, reſting on the ſhoulder round the eye-piece, while the far end of it reſts on one of the pins 1, 2, 3, &c.; and let the diſtance of theſe pins from F very little exceed the length of the teleſcope. The trembling of the axis, even when conſiderable, cannot affect the poſition of the tube, becauſe the braces terminate almoſt at the pivots. The tremor of the brace CD does as little harm, becauſe it is nearly perpendicular to the tube. And if the object-glaſs were cloſe at the upper ſupporting pin, and the focus at the lower pin F, even the bending and trembling of the tube will have no effect on its optical axis. The inſtrument is only ſubject to horizontal tremors. Theſe may be almoſt annihilated by having a ſlender rod coming Teleſcope. from a hook's joint in the ſide of the window, and paſſing through ſuch another joint cloſe by the pin F. We have ſeen an inſtrument of this form, having AB parallel to the earth's axis. The whole apparatus did not coſt 50 ſhillings, and we find it not in the leaſt ſenſible manner affected by a ſtorm of wind. It was by obſervations with this inſtrument that the tables of the motions of the Georgium Sidus, publiſhed in the Edinburgh Tranſactions, were conſtructed, and they are as accurate as any that have yet appeared. This is an excellent equatorial.

But this apparatus is not portable, and it is ſadly deficient in elegance. The following is the beſt method we have ſeen of combining theſe circumſtances with the indiſpenſable requiſites of a good teleſcope.

The pillar VX (fig. 22.) rises from a firm ſtand, and has a horizontal motion round a cone which completely fills it. This motion is regulated by a rack-work in the box at V. The ſcrew of this rack-work is turned by means of the handle P, of a convenient length, and the ſcrew may be diſengaged by the click or detent V, when we would turn the inſtrument a great way at once. The teleſcope has a vertical motion round the joint Q placed near the middle of the tube. The lower end of the tube is ſupported by the ſtay OT. This conſiſts of a tube RT, faſtened to the pillar by a joint T, which allows the ſtay to move in a vertical plane. Within this tube ſlides another, with a ſtiff motion. This tube is connected with the teleſcope by another joint O, alſo admitting motion in a vertical plane. The ſide M of this inner tube is formed into a rack, in which works a pinion fixed to the top of the tube RT, and turned by the flat finger-piece R. The reader will readily ſee the advantages and the remaining defects of this apparatus. It is very portable, becauſe the teleſcope is eaſily diſengaged from it, and the legs and ſtay fold up. If the joint Q were immediately under A, it would be much freer from all tremor in the vertical plane. But nothing can hinder other tremors ariſing from the long pillar and the three ſpringy legs. Theſe communicate all external agitations with great vigour. The inſtrument ſhould be ſet on a ſtone pedeſtal, or, what is better, a caſk filled with wet ſand. This pedeſtal, which neceſſity perhaps ſuggeſted to our ſcientific navigators, is the beſt that can be imagined.

Fig. 23. is the ſtand uſually given to reflecting teleſcopes. The vertical tube FBG is faſtened to the tube by finger ſcrews, which paſs through the ſlits at F and G. This arch turns round a joint in the head of the divided pillar, and has its edge cut into an oblique rack, which is acted on by the horizontal ſcrew, furniſhed with the finger-piece A. This ſcrew turns in a horizontal ſquare frame. This frame turns round a horizontal joint in the off-ſide, which cannot be ſeen in this view. In the ſide of this frame next the eye there is a finger-ſcrew *a*, which paſſes through the frame, and preſſes on the round horizontal plate D. By ſcrewing down this finger-ſcrew, the frame is brought up, and preſſes the horizontal ſcrew to the rack. Thus the elevation of the teleſcope is fixed, and may be nicely changed by the finger applied to A and turning this ſcrew. The horizontal round plate D moves ſtiffly round on another plate of nearly equal diameter. This under plate has a deep conical hollow ſocket, which is nicely fitted by grinding to a ſolid cone formed on the top of the great upright pillar, and they may be firmly fixed in any poſition by the finger-ſcrew E. To the under plate is faſtened a box *c*, containing a horizontal ſcrew C, which always works in a rack cut in the edge of the upper plate, and cannot be diſengaged from it. When a great vertical or horizontal motion is wanted, the ſcrews *a* and E are ſlacked, and by tightening them the teleſcope may be

fixed

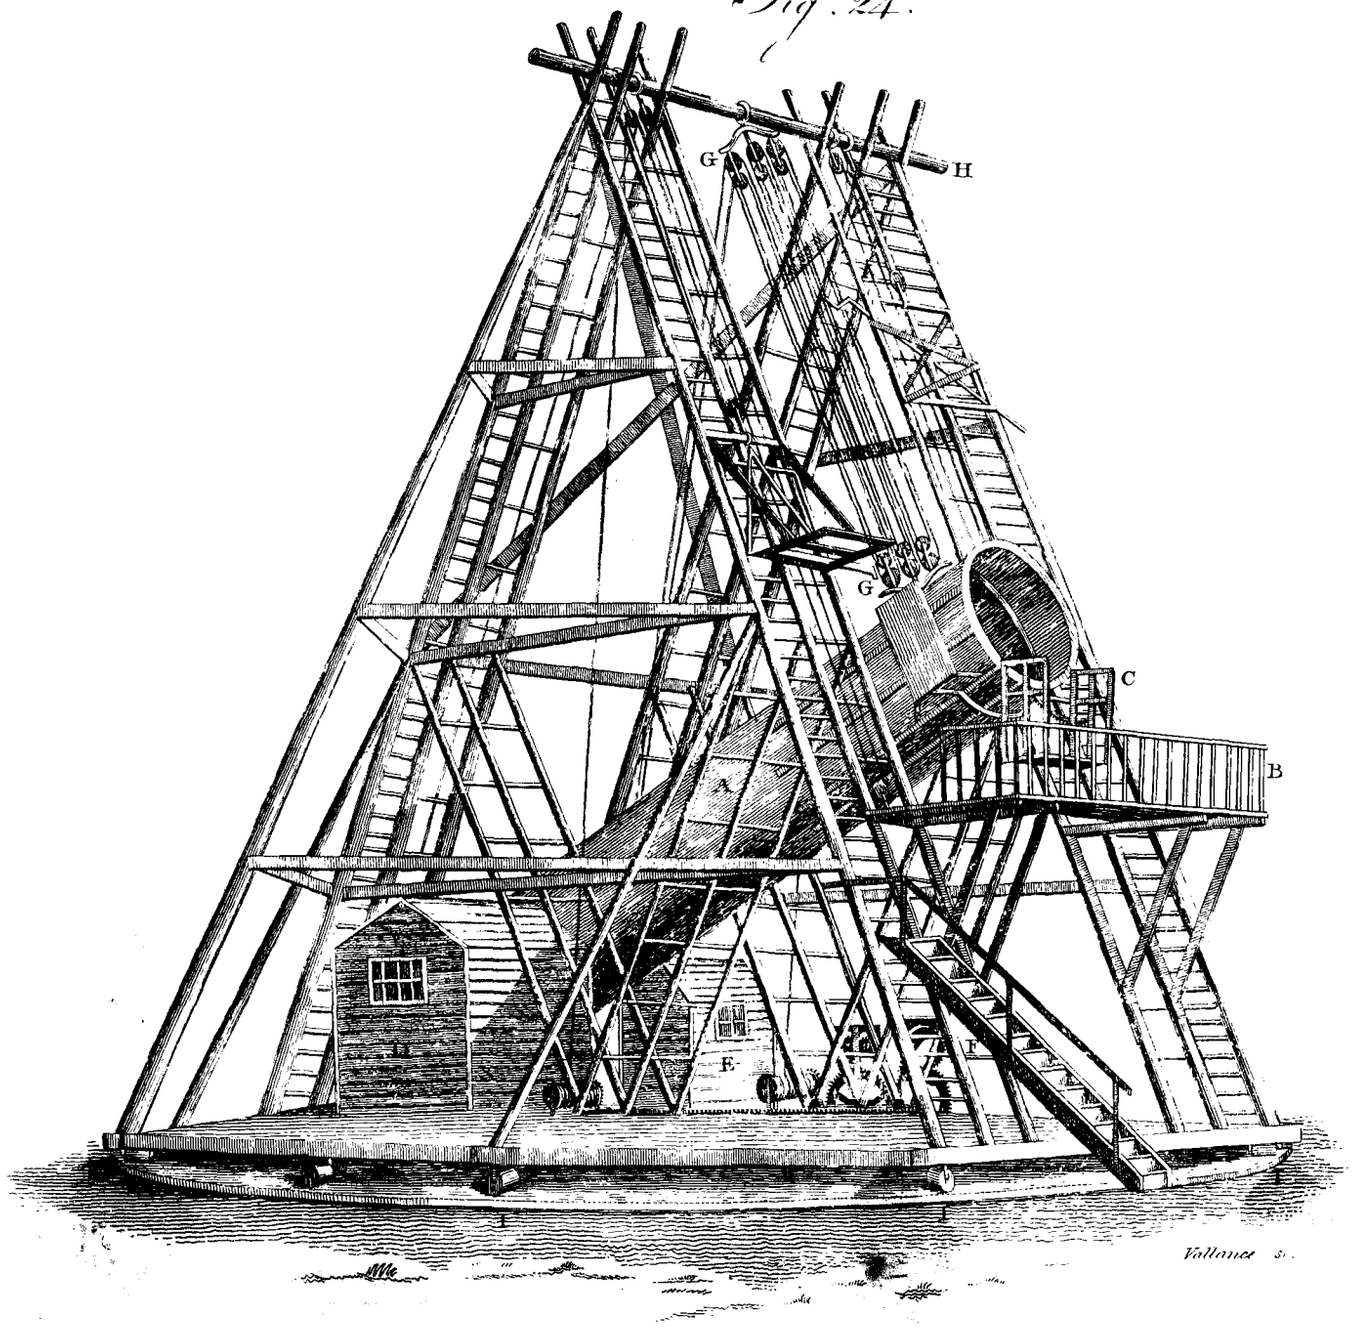
HERSCHEL'S GRAND TELESCOPE. Plate IV.

Fig. 24.



Teleſcope. fixed in any poſition, and then any ſmall movements may be given it by the finger plates A and C.

This ſtand is very ſubject to briſk tremor, either from external agitation of the pedeſtal, or from the immediate action of the wind; and we have ſeldom ſeen diſtinctly through teleſcopes mounted in this manner, till one end of the tube was preſſed againſt ſomething that was very ſteady and unelaſtic. It is quite aſtoniſhing what a change this produces. We took a very fine teleſcope made by James Short, and laid the tube on a great lump of ſoft clay, preſſing it firmly down into it. Several perſons, ignorant of our purpoſe, looked through it, and read a table of logarithms at the diſtance of 310 yards. We then put the teleſcope on its ſtand, and pointed it to the ſame object; none of the company could read at a greater diſtance than 235 yards, although they could perceive no tremor. They thought the viſion as ſharp as before; but the incontrovertible proof of the contrary was, that they could not read at ſuch a diſtance.

If the round plates were of much greater dimenſions; and if the lower one, inſtead of being fixed to the pillar, were ſupported on four ſtout pillars ſtanding on another plate; and if the vertical arch had a horizontal axis turning on two upright frames firmly fixed to the upper plate—the inſtrument would be much freer from tremor. Such ſtands were made formerly; but being much more bulky and inconvenient for package, they have gone into diſuſe.

The high magnifying powers of Dr Herſchel's teleſcopes made all the uſual apparatus for their ſupport extremely imperfect. But his judgment, and his ingenuity and fertility in reſource, are as eminent as his philoſophical ardour. He has contrived for his reflecting teleſcopes ſtands which have every property that can be deſired. The tubes are all ſupported at the two ends. The motions, both vertical and horizontal, are contrived with the utmoſt ſimplicity and firmneſs. We cannot more properly conclude this article than with a deſcription of his 40 feet teleſcope, the nobleſt monument of philoſophical zeal and of princely munificence that the world can boaſt of.

Plate DV. repreſents a view of this inſtrument in a meridional ſituation, as it appears when ſeen from a convenient diſtance by a perſon placed to the ſouth-weſt of it. The foundation in the ground conſiſts of two concentric circular brick walls, the outermoſt of which is 42 feet in diameter, and the inſide one 21 feet. They are two feet ſix inches deep under ground; two feet three inches broad at the bottom, and one foot two inches at the top; and are capped with paving ſtones about three inches thick, and twelve and three quarters broad. The bottom frame of the whole apparatus reſts upon theſe two walls by twenty concentric rollers III, and is moveable upon a pivot, which gives a horizontal motion to the whole apparatus, as well as to the teleſcope.

The tube of the teleſcope A, though very ſimple in its form, which is cylindrical, was attended with great difficulties in the conſtruction. This is not to be wondered at, when its ſize, and the materials of which it is made, are conſidered. Its length is 39 feet four inches; it meaſures four feet ten inches in diameter; and every part of it is of iron. Upon a moderate computation, the weight of a wooden tube muſt have exceeded an iron one at leaſt 3000 pounds; and its durability would have been far inferior to that of iron. It is made of rolled or ſheet iron, which has been joined together without rivets, by a kind of ſeaming well known to thoſe who make iron-funnels for ſtoves.

Very great mechanical ſkill is uſed in the contrivance of the apparatus by which the teleſcope is ſupported and directed. In order to command every altitude, the point of ſupport is moveable; and its motion is effected by mechaniſm, ſo that the teleſcope may be moved from its moſt backward point of ſupport to the moſt forward, and, by means of the pulleys GG ſuſpended from the great beam H, be ſet to any altitude, up to the very zenith. The tube is alſo made to reſt with the point of ſupport in a pivot, which permits it to be turned ſidewiſe. Teleſcope. Tell.

The concave face of the great mirror is 48 inches of poliſhed ſurface in diameter. The thickneſs, which is equal in every part of it, remains now about three inches and a half; and its weight, when it came from the caſt was 2118 pounds, of which it muſt have loſt a ſmall quantity in poliſhing. To put this ſpeculum into the tube, it is ſuſpended vertically by a crane in the laboratory, and placed on a ſmall narrow carriage, which is drawn out, rolling upon planks, till it comes near the back of the tube; here it is again ſuſpended and placed in the tube by a peculiar apparatus.

The method of obſerving by this teleſcope is by what Dr Herſchel calls the *front view*; the obſerver being placed in a ſeat C, ſuſpended at the end of it, with his back towards the object he views. There is no ſmall ſpeculum, but the magnifiers are applied immediately to the firſt focal image.

From the opening of the teleſcope, near the place of the eye-glaſs, a ſpeaking pipe runs down to the bottom of the tube, where it goes into a turning joint; and after ſeveral other inflections, it at length divides into two branches, one going into the obſervatory D, and the other into the work-room E. By means of the ſpeaking-pipe the communications of the obſerver are conveyed to the aſſiſtant in the obſervatory, and the workman is directed to perform the required motions.

In the obſervatory is placed a valuable ſideral time-piece, made by Mr Shelton. Cloſe to it, and of the ſame height, is a polar diſtance-piece, which has a dial-plate of the ſame dimenſions with the time-piece: this piece may be made to ſhow polar diſtance, zenith diſtance, declination or altitude, by ſetting it differently. The time and polar diſtance pieces are placed ſo that the aſſiſtant ſits before them at a table, with the ſpeaking-pipe riſing between them; and in this manner obſervations may be written down very conveniently.

This noble inſtrument, with proper eye-glaſſes, magnifies above 6000 times, and is the largeſt that has ever been made. Such of our readers as wiſh for a fuller account of the machinery attached to it, viz. the ſtairs, ladders, and platform B, may have recourſe to the ſecond part of the Tranſactions of the Royal Society for 1795: in which, by means of 18 plates and 63 pages of letter-preſs, an ample detail is given of every circumſtance relating to joiner's work, carpenter's work, and ſmith's work, which attended the formation and erection of this teleſcope. It was completed on Auguſt the 28th 1789, and on the ſame day was the ſixth ſatellite of Saturn diſcovered.

TELL (William), an illuſtrous Swiſs patriot, chief inſtrument of the revolution which delivered the Swiſs cantons from the German yoke in 1307. Griſler, the governor of theſe provinces for the emperor Albert, having ordered him, under pain of death, to ſhoot at an apple placed on the head of one of his children; he had the dexterity, though the diſtance was very conſiderable, to ſtrike it off without hitting the child. The tyrant, perceiving he had another arrow concealed under his cloak, aſked him for what purpoſe? To which he boldly replied, "To have ſhot you through the heart, if I had had the misfortune to kill my ſon." The enraged governor now ordered him to be hanged; but his fellow-citizens, animated by his fortitude and

Tell
Temper.

patriotism, flew to arms; attacked and vanquished Grisler, who was shot to death by Tell; and the association for the independency took place that instant.

Tell-Tale, a name sometimes given to the *Perpetual-Log*. See that article.

"TELLER, an officer of the exchequer, in ancient records called *tallier*. There are four of these officers, whose duty is to receive all sums due to the king, and to give the clerk of the pells a bill to charge him therewith. They likewise pay all money due from the king, by warrant from the auditor of the receipt; and make weekly and yearly books both of their receipts and payments, which they deliver to the lord treasurer."

TELLINA, in natural history, a genus of animals belonging to the class of *vermes*, and order of *testaceæ*. The animal is a tethys; the shell is bivalve, generally sloping to one side, with three teeth at the hinge. Gmelin reckons about 90 species.

The tellinæ bury themselves in the mud or sand at the bottom of the sea, keeping a communication with the water above by means of short tubes or pipes.

TEMISSA, a large town in Africa, about 120 miles north-east of Mourzouk, the capital of Fezzan. Here the caravan of pilgrims from Bornou and Nigritia, which takes its departure from Mourzouk, and travels by the way of Cairo to Mecca, usually provides the stores of corn and dates, and dried meat, that are requisite for its dreary passage.

TEMPE (anc. geog.), a most pleasant place or valley of Thessaly. That it was there, appears from the epithets *Thessalica* (Livy), *Thessala* (Ovid); but in what particular district is the question. From the Phthiotica of Catullus, it should seem to be of Phthiotis: but the Peneus, which ran through Tempe, was at too great a distance, being separated from it by Mount Othrys and others. First, however, we shall define Tempe, previous to the determining the particular district in which it lay. The Peneus, according to Pliny, running down between Ossa to the south and Olympus to the north for 500 stadia, is for half that space navigable: in the direction of this course lies what is called *Tempe*, extending in length for five miles, in breadth for almost an acre and an half, with gentle convexities rising on the right and left beyond ken of human sight. Within glides the Peneus in its verdant light, green in its pebbles, charming in the grass on its banks, harmoniously vocal with the music of birds. In this description Strabo and Ælian agree; the last adding, that it has an agreeable variety of places of retreat; and that it is not the work of man's hand, but the spontaneous production of nature; and Strabo says, that formerly the Peneus formed a lake in this spot, being checked in its course by the higher grounds about the sea; but that an opening being made by an earthquake, and Mount Ossa torn from Olympus, the Peneus gained a free course between them. But Livy, who calls Tempe a grove, remarks a degree of horror rather than amenity, with which the Roman army was struck on marching over the narrow pass; for, besides the defile, difficult to go over, which runs on for five miles, there are steep rocks on each hand, down which the prospect is apt to cause a dizziness, heightened by the noise and depth of the interfluent Peneus. Hence it appears that Tempe was in the Pelasgiotis, whose extremity was formerly the Peneus, but afterwards, as is probable, allotted to Magnesia; and thus Pliny places the mouth of the Peneus not in Thessaly itself, but in the Magnesia of Thessaly.

TEMPER, in a mechanical sense. See TEMPERING.

TEMPER, in a moral sense, the disposition of mind whether natural or acquired. The word is seldom used by good writers without an epithet, as a *good* or *bad* temper; though one of the most beautiful poems in our language is entitled *The Triumphs of Temper*. Temper, Temperament.

It is well observed by an elegant essayist, that more constant uneasiness arises from ill temper than from ill fortune; as a bad temper embitters every sweet, and converts a paradise into a place of torment. For subduing the heart to softness, and preserving a due balance of the passions, a proper culture of the understanding and of the taste is the best method. He who employs his time in the studies of elegant literature, or the fine arts, has almost always a good temper; whilst the man who is absorbed in the pursuits of profound science is apt to acquire a severity of disposition, little less disagreeable, though generally much less pernicious, than the capriciousness of the idler. Music, painting, and poetry, teach the mind to select the agreeable parts of those objects which surround us, and by habituating it to a pure and permanent delight, gradually superinduce an habitual good humour. It is of infinite importance to happiness to accustom the mind, from infancy, to turn from deformed and painful scenes, and to contemplate whatever can be found of moral and natural beauty.

So much of the happiness of private life depends on the government of the temper, that the temper ought to be a principal object of regard in a well-conducted education. The suffering of children to tyrannize without control over servants and inferiors, is the ruin of many an amiable disposition. The virtues of humanity, benevolence, humility, cannot be too early enforced; at the same time, care should be taken that an infant of two or three years old should never be beaten or spoken to harshly for any offence which it can possibly commit.

TEMPERAMENT, among physicians, the same with constitution, or a certain disposition of the solids and fluids of the human body, by which it may be properly denominated strong, weak, lax, &c.

In every person there are appearances of a temperament peculiar to himself, though the ancients only took notice of four, and some have imagined these were deduced from the theories of the four humours or four cardinal qualities; but it is more probable that they were first founded on observation, and afterwards adapted to those theories, since we find that they have a real existence, and are capable of receiving an explanation. The two that are most distinctly marked are the sanguineous and melancholic, viz. the temperaments of youth and age.

1. *Sanguineous.* Here there is laxity of solids, discoverable by the softness of hair and succulency; large system of arteries, redundancy of fluids, florid complexion; sensibility of the nervous power, especially to pleasing objects; irritability from the plethora; mobility and levity from lax solids. These characters are distinctly marked, and are proved by the diseases incident to this age, as hæmorrhagies, fevers, &c. but these, as they proceed from a lax system, are more easily cured.

2. *Melancholic Habit.* Here greater rigidity of solids occurs, discoverable by the hardness and crispature of the hair; small proportion of the fluids, hence dryness and leanness; small arteries, hence pale colour; venous plethora, hence turgescency of these, and lividity; sensibility, frequently exquisite; moderate irritability, with remarkable tenacity of impressions; steadiness in action and slowness of motion, with great strength; for excess of this constitution in maniacs gives the most extraordinary instance of human strength we know. This temperament is most distinctly marked in old age, and in males. The sanguineous tempera-

ment

Temperament, Temperance.

ment of youth makes us not diſtinguiſh the melancholic till the decline of life, when it is very evident, from diſeaſes of the veins, hemorrhoids, apoplexy, cachexy, obſtructions of the viſcera, particularly of the liver, dropſies, affections of the alimentary canal, chiefly from weaker influence of the nervous power. So much for the ſanguineous and melancholic temperaments; the other two are not ſo eaſily explained. The choleric temperament takes place between youth and manhood. In the

3. *Choleric*, the diſtribution of the fluids is more exactly balanced; there is leſs ſenſibility, and leſs obeſity, with more irritability, proceeding from greater tenſion, leſs mobility and levity, and more ſteadineſs in the ſtrength of the nervous power. As to the

4. *Phlegmatic*. This temperament cannot be diſtinguiſhed by any characters of age or ſex. It agrees with the ſanguineous in laxity and ſucculency. It differs from that temperament, and the melancholic, by the more exact diſtribution of the fluids. Again, it differs from the ſanguineous, by having leſs ſenſibility, irritability, mobility, and perhaps ſtrength, though ſometimes indeed this laſt in found to be great.

Theſe are the ancient temperaments. The temperaments, indeed, are much more various; and very far from being eaſily marked and reduced to their genera and ſpecies, from the great variety which is obſervable in the conſtitutions of different men.

TEMPERAMENT, in muſic, is defined by Rouſſeau to be an operation which, by means of a ſlight alteration in the intervals, cauſes the difference between two contiguous ſounds to diſappear, makes each of theſe ſounds ſeem identical with the other, which, without offending the ear, may ſtill preſerve their reſpective intervals or diſtances one from the other. By this operation the ſcale is rendered more ſimple, and the number of ſounds which would otherwiſe be neceſſary retrenched. Had not the ſcale been thus modified, inſtead of twelve ſounds alone, which are contained in the octave, more than ſixty would be indiſpenſably required to form what we properly call *modulation* in every tone.

It is proved by computation, that upon the organ, the harpſichord and every other inſtrument with keys, there is not, and there ſcarcely can be, any chords properly in tune, ſave the octave alone. The cauſe is this, that though three thirds major, or four thirds minor, ought to form a juſt octave, thoſe are found to ſurpaſs, and theſe not to reach it.

TEMPERANCE, that virtue which a man is ſaid to poſſeſs who moderates and reſtrains his ſenſual appetites. It is often, however, uſed in a much more general ſenſe, as ſynonymous with moderation, and is then applied indiſcriminately to all the paſſions.

Temperance (ſays Mr Nelſon) is the virtue that bridles our irregular deſires; it is nearly allied to prudence, and has a cloſe connection with juſtice; it calms revenge, and quenches the fire of unjuſt reſentment; it checks the Epicure, and ſtops the riotous hand of the Bacchanalian; it extinguiſhes or abates the flames of luſt, and baniſhes every lawleſs action; it ſilences the flippant detracting tongue, and gives in its ſtead a pleaſing moderation of ſpeech; it ſhuts the door againſt avarice, and proves experimentally, that happineſs does not conſiſt in the eager purſuit or acquiſition of riches, but in a contented mind; it curbs the ſtrongeſt of all other paſſions, gaming, and diſtinguiſhes juſtly the abſurdity and folly of making that a dangerous trade, which was only deſigned as a relaxation and an amuſement: temperance, in a word, is the parent of many virtues; the parent of peace, proſperity, health, and joy.

Nothing can be more ſtrange to all obſervation than the practice of forſaking temperance; ſince every day's experience proves to us, that intemperance produces the oppoſite to what we ſeek. Suppoſe, when a child is born, we aſk the parents what it is they wiſh in that child; they will anſwer, life. But as life alone, that is, mere exiſtence, may, by infirmity or other accidents, be very wretched, they will naturally wiſh for health and happineſs. Well then, life, health, and happineſs, are the general wiſhes of parents for their children. Now let us ſee how their wiſhes are likely to ſucceed. Their firſt ſtep is uſually a ſhameful neglect of the food of nature, the breaſt; the next, a blind gratification of their will; the third, an almoſt total neglect of their manners; and a fourth, the cheriſhing them in every irregular affection. Where then is the wonder that parents are diſappointed? Life and health depend on proper food and other judicious management on one part; and if ſick, an obedience to remedies on the other part; and happineſs eſſentially depends in the firſt place on health; in the next, on the due government of our ſenſes, affections, and paſſions. See here how much mankind deviate from themſelves; how far they depart from their own principles. But what is the remedy? Nothing more obvious. Let parents exerciſe their reaſon in all the ſteps they take for their children's welfare; let them examine right and wrong; let them not only avoid paſſion, but labour to correct their own errors of judgment, that they may be the better enabled to prevent them in their children; but, particularly, let them fix in them the knowledge, love, and habit, of temperance.

Temperance || Templars.

TEMPERING, in the mechanic arts, the preparing of ſteel and iron, ſo as to render them more compact, hard, and firm; or even more ſoft and pliant, according to their reſpective occaſions. See IRON and STEEL.

TEMPESTA. See MOLYN.

TEMPLARS, TEMPLERS, or *Knights of the Temple*, a religious order inſtituted at Jeruſalem in the beginning of the 12th century, for the defence of the holy ſepulchre and the protection of Chriſtian pilgrims. They were firſt called *The poor of the Holy City*, and afterwards aſſumed the appellation of *Templers*, becauſe their houſe was near the temple. The order was founded by Baldwin II. then king of Jeruſalem, with the concurrence of the pope; and the principal articles of their rule were: That they ſhould hear the holy office throughout every day; or that, when their military duties ſhould prevent this, they ſhould ſupply it by a certain number of pater noſters: that they ſhould abſtain from fleſh four days in the week, and on Fridays from eggs and milk-meats: that each knight might have three horſes, and one eſquire: and that they ſhould neither hunt nor fowl. After the ruin of the kingdom of Jeruſalem about 1186, they ſpread themſelves through Germany and other countries of Europe, to which they were invited by the liberality of the Chriſtians. In the year 1228, this order acquired ſtability, by being confirmed in the council of Troyes, and ſubjected to a rule of dicipline drawn up by St Bernard. In every nation they had a particular governor, called *maſter of the Temple*, or of the *militia of the Temple*. The grand-maſter had his reſidence at Paris.

The order of Templars flouriſhed for ſome time, and acquired, by the valour of its knights, immenſe riches and an eminent degree of military renown: but as their proſperity increaſed, their vices were multiplied, and their arrogance, luxury, and cruelty roſe at laſt to ſuch a monſtrous height, that their privileges were revoked, and their order ſuppreſſed with the moſt terrible circumſtances of infamy and ſeverity. Their accuſers were two of their own body, and their chief proſecutor Philip the Fair of France, who addreſſed his com-

Templars. plaints to Clement V. The pope, though at firſt unwilling to proceed againſt them, was under a neceſſity of complying with the king's deſire; ſo that, in the year 1307, upon an appointed day, and for ſome time afterwards, all the knights, who were diſperſed throughout Europe, were ſeized and impriſoned, and many of them, after trials for capital crimes, were convicted and put to death. In 1312 the whole order was ſuppreſſed by the council of Vienne. A part of the rich revenues they poſſeſſed was beſtowed upon other orders, eſpecially on the knights of St John, now of Malta, and the reſt confiſcated to the reſpective treaſuries of the ſovereign princes in whoſe dominions their poſſeſſions lay.—The knights Templars, in order to juſtify the ſeverity with which they were treated, were charged with apoſtaſy to the Saracens, and holding correſpondence with them, with inſulting the majeſty of God, turning into deriſion the Goſpel of Chriſt, and trampling upon the obligation of all laws human and divine. Candidates, it is ſaid upon admiſſion to this order, were commanded to ſpit, in token of contempt, upon an image of Chriſt, and after admiſſion to worſhip either a cat or a wooden head crowned with gold. It is farther affirmed, that, among them, the odious and unnatural act of ſodomy was a matter of obligation; and they are charged with other crimes too horrible to be mentioned, or even imagined. However, though there be reaſon to believe, that in this order, as well as others of the ſame period, there were ſhocking examples of impiety and profligacy; yet that the whole order was thus enormouſly corrupt, there is no reaſon to believe. The pope indeed, though he acted with ſeverity, acted with juſtice. He ſent two cardinals to Paris, who, publiſhing his bull againſt the order, condemned thoſe Templars who had made the voluntary confeſſion to be burnt by a ſlow fire. The criminals recanted their former confeſſions, but acknowleged themſelves worthy of death, becauſe they had unjuſtly accuſed the order of crimes of which they were innocent. Several authors of thoſe times wrote in defence of the order; and Boccace alleges, that its extirpation was owing to the avarice of the king of France, who coveted the rich poſſeſſions the Templars then enjoyed in France.

The king of Arragon was much preſſed to treat the Templars in his kingdom as they had been treated in France; but his conſtant anſwer was, "We muſt be firſt convinced of their guilt, and it will be then time enough to talk of their puniſhment." The people, however, were in general ſo provoked againſt them, that they were compelled to ſhut themſelves up in the fortreſſes belonging to their order, to prevent their being torn in pieces; which precaution was repreſented to the king of Arragon as an act of rebellion. He marched, therefore, with a corps of troops againſt one of theſe fortreſſes. The knight who commanded ſurrendered immediately, and told the king the truth, aſſuring him that they deſired nothing but a fair trial; with which declaration the king was extremely moved, took the whole order into his protection, and forbade any to abuſe or inſult them under the heavieſt penalties. At the ſame time he declared, he was ready to receive any informations againſt them that were ſupported by proofs; but if the informers failed therein, he would puniſh them as they deſerved.

Theſe facts plead ſtrongly for the innocence of the Templars, or at leaſt they prove that their guilt muſt have been exaggerated; and if we add, that many of the accuſations advanced againſt them flatly contradict each other, and that many members of this unfortunate order ſolemnly avowed their innocence while languiſhing under the ſevereſt tortures, and even with their dying breath—it would ſeem probable, that king Philip ſet on foot this bloody tragedy, with a view to gratify his avarice, and glut his reſentment againſt the Templars and eſpecially againſt their grand-maſter, who had highly offended him. The principal cauſe of his invincible hatred againſt them was, that in his quarrel with Boniface VIII. the knights eſpouſed the cauſe of the pope, and furniſhed him with money to carry on the war. They originally wore a white habit, with red croſſes ſewed upon their cloaks as a mark of diſtinction. Templars.

TEMPLE (Sir William), was born in London in the year 1628. The family from which he ſprung was ancient, and is ſaid to have aſſumed the ſurname of Temple from the manor of Temple, in the hundred of Sparken-Hall, in Leiceſterſhire. He was firſt ſent to ſchool at Penſehurſt, in Kent, under the care of his uncle, the celebrated Dr Hammond, then miniſter of that pariſh; but at the age of ten he was removed thence to a ſchool at Biſhop-Stortford, in Hertfordſhire. When he had acquired a ſufficient knowledge of the Greek and Latin, he returned home at the age of fifteen; and, two years after, he went to Cambridge, where he was placed under the tuition of the learned Dr Cudworth, then fellow of Emanuel College. His father, Sir John Temple, being a ſtateſmen, ſeems to have deſigned him for the ſame way of life; and on this account, after reſiding at Cambridge two years, which were principally ſpent in acquiring a competency of French and Spaniſh, both languages exceedingly uſeful for his intended purſuits, he was ſent abroad to finiſh his education.

Mr Temple began his travels by viſiting France in 1648. As he choſe to paſs through the Iſle of Wight, where his majeſty was detained a priſoner, he there accidentally met with the ſecond daughter of Sir Peter Oſborn of Chickſand, in Bedfordſhire, then governor of Guernſey for the king; and this lady being on a journey with her brother to St Maloes, where their father then was, our young traveller joined their party. This gave riſe to an honourable amour, which, at the end of ſeven years, concluded in a happy marriage. Having reſided two years in France, and learned the French language perfectly, Mr Temple made a tour through Holland, Flanders, and Germany, during which he became completely maſter of the Spaniſh. In 1654 he returned from the continent, and, marrying Miſs Oſborn, paſſed his time in retirement with his father, his two brothers, and a ſiſter, then in Ireland, happy in that perfect harmony which has been ſo often remarked in their family.

As he rejected all offers made him of employment under Cromwell, the five years which he lived in Ireland were ſpent chiefly in improving himſelf in hiſtory and philoſophy; but at the Reſtoration, in 1660, being choſen a member of the convention there, while others were trying to make their court to the king, Mr Temple oppoſed the poll-bill with ſo much ſpirit, that his conduct ſoon attracted the attention of the public, and brought him into notice. In the ſucceeding parliament, in 1661, he was elected with his father for the country of Carlow; and, in the year following, he was choſen one of the commiſſioners to be ſent from that parliament to the king, which gave him an opportunity of waiting on the duke of Ormond, the new lord lieutenant, then at London. Soon after he went back to Ireland, but with a reſolution of quitting that kingdom, and of removing with his family to England.

On his return he met with a very favourable reception from the duke of Ormond; and ſoon acquired ſuch a conſiderable ſhare in his eſteem, that the duke complained of him as the only man in Ireland that had never aſked any thing from him. When he mentioned his deſign of carrying his family to England, his grace ſaid, that he hoped he would

Temple. would at leaſt give him leave to write in his favour to the two great miniſters, Clarendon then lord chancellor, and the earl of Arlington, who was ſecretary of ſtate. This the duke did in ſuch ſtrong terms, as procured him the friendſhip of theſe two noblemen, as well as the good opinion of the king. Mr Temple, however, made no other uſe of this advantage than to tell lord Arlington, that if his majeſty had any employment abroad, which he was fit for, he ſhould be happy to undertake it; but, at the ſame time, he requeſted that he might not be ſent into any of the northern climates, to which he had a very great averſion. Lord Arlington replied, he was very ſorry he had made ſuch an objection, as there was no other employment then undiſpoſed of except that of going envoy to Sweden. However, in 1665, about the beginning of the firſt Dutch war, lord Arlington ſent a meſſenger to acquaint him that he muſt immediately come to his houſe; which he did, and found that his lordſhip's buſineſs was to tell him, that the king had occaſion to ſend ſome perſon abroad upon an affair of the utmoſt importance, and that he had reſolved to make him the firſt offer; but that he muſt know, without delay, and without telling him what it was, whether he would accept of it, and that he muſt be ready to ſet out in two or three days, without mentioning it to any of his friends. After a little conſideration, Mr Temple told his lordſhip, that, as he took him to be his friend, and as he had adviſed him not to refuſe, as it would be an entrance into his majeſty's ſervice, he ſhould conſult no farther. This buſineſs was to carry a ſecret commiſſion to the biſhop of Munſter; which he ſet out with on the ſecond of Auguſt, and executed ſo much to the ſatisfaction of Charles II. that, on his return to Bruſſels, his majeſty appointed him reſident there, and created him a baronet. As Bruſſels was a place which he had long wiſhed to reſide at, in April 1666 he ſent for his family; but, before their arrival, he had been again obliged to depart upon buſineſs to the prelate's court: for the biſhop having liſtened to terms of accommodation with France, Sir William wrote two letters to diſſuade him from that alliance; and theſe not having the deſired effect, he went in diſguiſe to Munſter, where, though he arrived too late to ſecure the prince in his firſt engagement, yet he prevailed on him to permit five or ſix thouſand of his beſt troops to enter into the Spaniſh ſervice. In this journey he paſſed for a Spaniſh envoy, having twenty Spaniſh guards to attend him. In this manner he firſt went to Duſſeldorp, where the duke of Newburgh, though in the French intereſt, gave him a guard to Dortmund; but when he reached that place, finding the gates ſhut, he was forced to proceed to a village, at the diſtance of a league, which, being full of Brandenburg troops, he was under the neceſſity of lodging in a barn, upon a ſtraw bed, with his page for a pillow. Next day he was entertained at a caſtle belonging to the biſkop of Munſter, by one Gorges a Scotch lieutenant-general in that prelate's ſervice, with what he calls a very epiſcopal way of drinking. The general coming to the large hall, in which ſtood a great many flaggons ready charged, he called for wine to drink the king's health. A ſilver bell, that might hold about two quarts, was upon this brought him; and, as ſoon as he received it, he pulled out the clapper, and giving it to Sir William, to whom he intended to drink, ordered the bell to be filled. When this was done, he drank off the contents to his majeſty's health; and aſking Sir William for the clapper, put it on, and turning down the bell, rang it, to ſhew that he had drank fair, and left nothing in it. He then took out the clapper, deſired Sir William to give it to whomſoever he pleaſed; and, ordering the bell to be filled again, preſented it to Sir William: but as the latter ſeldom uſed to drink, he had generally ſome gentleman with him to ſupply his place in this reſpect whenever it might be neceſſary. Having finiſhed his buſineſs at Munſter, he returned to Bruſſels, where he paſſed a year with great pleaſure and ſatisfaction. Temple.

Two months after the concluſion of the peace with the Dutch at Breda, Sir William's ſiſter, who reſided with him at Bruſſels, being very deſirous of ſeeing Holland, he went thither incognito to gratify her deſire: but while he was at the Hague, he paid a private viſit to Mr De Witt, in which he laid the foundation of that cloſe intimacy which afterwards ſubſiſted between them.

In the ſpring of 1667, a new war breaking out between France and Spain, which expoſed Bruſſels to the danger of falling into the hands of the former, Sir William ſent his lady and family to England; but he himſelf remained there with his ſiſter till the Chriſtmas following, when he was ordered by the king to come over privately to London. Taking the Hague in his way, he paid another viſit to De Witt, and, purſuant to his inſtructions, propoſed thoſe overtures to him which produced the triple alliance. Soon after his arrival at the Britiſh court, he returned, on the 16th of January 1668, with the character of envoy extraordinary and plenipotentiary to Holland; where a conference being opened, he brought that treaty to a perfect concluſion in the ſhort ſpace of five days. The ratifications of this alliance being exchanged on the 15th of February, he repaired to Bruſſels; and a treaty being ſet on foot between France and Spain at Aix la-Chapelle, he ſet out for that place on the 24th of April in quality of his majeſty's ambaſſador extraordinary and mediator. Here he arrived on the 27th; and it was chiefly owing to his aſſiſtance that the Spaniards were brought to ſign the articles of that peace on the ſecond of May. This ſervice being completed, he returned to Bruſſels, with a view of remaining there in his former ſtation of reſident; but he received letters from the earl of Arlington, with the king's order to continue as ambaſſador, and to ſerve his country in that quality in Holland, as, on account of the late alliances, his majeſty was reſolved to renew a character which the crown of England had diſcontinued there ſince the time of king James. Sir William being now left at liberty to return to England, embraced the opportunity; and upon his arrival at London, he was received with every poſſible demonſtration of favour both by the king and the court.

Setting out again for Holland, with his new character of the king's ambaſſador, he arrived at the Hague in the end of Auguſt 1668. Here he enjoyed the confidence of that great miniſter De Witt, and lived in great intimacy with the prince of Orange, who was then only eighteen years of age; but, in September 1669, he was hurried back to England by lord Arlington, who ordered him to put his foot in the ſtirrup as ſoon as he ſhould receive his letter. When Sir William waited on the earl, he found that he had not one word to ſay to him; for, after making him attend a long time, he only aſked him a few indifferent queſtions reſpecting his journey. Next day he was received as coolly by the king; but the ſecret ſoon came out, and he was preſſed to return to the Hague, and pave the way for a war with Holland. This, however, he excuſed himſelf from having any hand in; which ſo much provoked the lord treaſurer Clifford, that he refuſed to pay him an arrear of two thouſand pounds due from his embaſſy. Diſguſted with Arlington's behaviour, which was ſo unlike the friendſhip he had formerly profeſſed, Sir William now retired to his houſe at Sheen near Richmond, in Surry; and in this retreat, when free from the hurry of buſineſs, he wrote his Obſervations on the United Provinces, and one part of his Miſcellanies, in the

time

Temple. time of the ſecond Dutch war. About the end of ſummer, however, 1673, the king wiſhing to put an end to the war, ſent for Sir William, and deſired him to go to Holland to negotiate a peace; but powers having been ſent from thence at this time to the Marquis de Freſno, the Spaniſh ambaſſador at London, Sir William was ordered to confer with him; and a treaty was accordingly concluded in three days, and the point carried reſpecting the ſuperiority of the Britiſh flag, which had been ſo long conteſted. In June 1674 he was again ſent ambaſſador to Holland to offer the king's mediation between France and the confederates, then at war, which was accepted not long after; Lord Berkeley, Sir William Temple, and Sir Leoline Jenkins, being declared ambaſſadors and mediators; and Nimeguen, which Sir William had propoſed, was at length agreed upon by all parties to be the place of treaty. During his ſtay at the Hague, the prince of Orange, who was fond of the Engliſh language, and of the plain Engliſh way of eating, conſtantly dined and ſupped once or twice a week at his houſe; and by this familiarity he ſo much gained the prince's confidence and eſteem, that he had a conſiderable hand in his marriage with the Princeſs Mary, daughter of James II.

In July 1676 he removed his family to Nimeguen, where he ſpent the remainder of that year without making any progreſs in the treaty; and the year following his ſon was ſent over with letters from the lord treaſurer, ordering him to return, and ſucceed Mr Coventry as ſecretary of ſtate. In conſequence of this order, Sir William went over to England in the ſpring of 1677; and though the affair of the ſecretary's place was dropped at his deſire, he did not return to Nimeguen that year. About this time, the prince having the king's leave to come over, he ſoon after married the Princeſs Mary; and this gave occaſion for a new coolneſs between lord Arlington and Sir William, as he and the lord treaſurer Oſborn, who was related to Sir William's lady, were only privy to that affair. After the prince and princeſs were gone to Holland, as the court always ſeemed inclined to favour France, the king wiſhed to engage Sir William in ſome negotiations with that crown: but he was ſo ill ſatisfied with this propoſal, that he offered to give up all pretenſions to the office of ſecretary; and deſiring the lord treaſurer to acquaint his majeſty with his intentions, retired to Sheen, in hopes of being taken at his word. Upon a diſcovery, however, of the French deſigns not to evacuate the Spaniſh towns agreed by the treaty to be delivered up, the king commanded him to go upon a third embaſſy to the ſtates; with whom he concluded a treaty: by which England engaged, in caſe France refuſed to evacuate the towns in forty days, to declare war immediately againſt that nation: but before half that time was elapſed, one Du Croſs was ſent from the Engliſh court to Holland upon a buſineſs which damped all the good humour excited by the treaty there, and which produced ſuch ſudden and aſtoniſhing changes in this country, as gave Sir William a diſtaſte for all public employments.

In 1679 he went back to Nimeguen, where the French delayed to ſign the treaty till the laſt hour; but having concluded it, he returned to the Hague, whence he was ſoon after ſent for to enter upon the ſecretary's office, which Mr Coventry at length reſolved to reſign. He accordingly went over, and went to court, as all his friends hoped, with a full intention of aſſuming his office; but he ſtarted ſome difficulty, becauſe he had not a ſeat in the houſe of commons, thinking that, by his not being a member, the public buſineſs would ſuffer at ſuch a critical time, when the conteſts between the two parties ran ſo high that the king thought fit to ſend the duke of York into Flanders, and the parliament to put the lord treaſurer Danby into the Tower. After th's his majeſty ſtill preſſed Sir William to be ſecretary of ſtate; uſing as an argument for his compliance, that he had nobody to conſult with at a time when he had the greateſt need of the beſt advice. Notwithſtanding all this, Sir William declined the king's offer, adviſing him to chooſe a council in whom he could confide, and upon whoſe abilities he could depend. This advice the king followed; and the choice of the perſons being concerted between his majeſty and Sir William, the old council was diſſolved four days after, and the new one eſtabliſhed, of which the latter was a member. Temple.

In 1680 the councils began again to be changed, on the king's illneſs, at the end of ſummer, and the duke of York's return privately to court. In this juncture Sir William, endeavouring to bring to the king's favour and buſineſs ſome perſons to whom his majeſty had taken a diſlike, if not an averſion, he met with ſuch treatment from them as gave him a freſh diſtaſte to the court, at which he ſeldom made his appearance; ſo that he reſided principally at Sheen. Soon after this the king ſent for him again; and having propoſed that he ſhould go as ambaſſador into Spain, Sir William conſented: but when his equipage was almoſt ready, and part of the money paid down for it, the king changed his mind, and told him that he would have him defer his journey till the end of the ſeſſion of parliament, in which he was choſen a member for the univerſity of Cambridge. In this ſeſſion the ſpirit of party ran ſo high that it was impoſſible to bring the houſe to any kind of temper. The duke was ſent into Scotland; but this would not ſatisfy them, nor any thing but a bill of excluſion; which Sir William ſtrenuouſly oppoſed, ſaying, that "His endeavour ever would be to unite the royal family, and that he ſhould never enter into any councils to divide them." Not long after this period, the parliament being diſſolved by his majeſty, without the advice of his privy council, and contrary to what he had promiſed, Sir William made a bold ſpeech againſt it; for which he was very ill uſed by ſome of thoſe friends who had been moſt earneſt in promoting the laſt change in the miniſtry. Upon this he grew quite tired of public buſineſs, declined the offer he had of again ſerving for the univerſity in the next parliament, that was ſoon after called, and met at Oxford; and ſeeing his majeſty reſolved to govern without his parliament, and to ſupply his treaſury through another channel, he retired to Sheen a few days after, whence he ſent word by his ſon, that "he would paſs the reſt of his days like a good ſubject, but would never more meddle with public affairs." From that time Sir William lived at this place till the end of that reign and for ſome time in the next; when having purchaſed a ſmall ſeat, called *Moor Park*, near Farnham in Surry, which he conceived a great fondneſs for on account of its ſolitude and retirement, and its healthy and pleaſant ſituation, and being much afflicted with the gout, and broken with age and infirmities—he reſolved to ſpend the remainder of his life in this agreeable retreat. In his way thither, therefore, he waited on king James, who was then at Windſor, and begged his favour and protection to one "that would always live as a good ſubject, but, whatever might happen, never again enter upon any public employment;" deſiring his majeſty to give no credit to any thing he might hear to the contrary. The king, who uſed to ſay that Sir William Temple's character was always to be believed, promiſed him whatever he deſired, gently reproached him for not entering into his ſervice, which, he ſaid, was his own fault; and kept his word as faithfully to Sir William as Sir William did to his majeſty, during the ſurpriſing turn of affairs that ſoon after followed by the arrival of the prince of Orange. At the time of this happy revolution, in 1688, Moor-Park becoming unſafe,

Temple. safe, as it lay in the way of both armies, he went back to the house at Sheen, which he had given up to his son; to whom he refused leave, though importunately begged, to go and meet the prince of Orange at his landing: but after king James's abdication, when the Prince reached Windsor, he went thither to wait upon his highness, and carried his son along with him. The prince pressed him to enter into his service, and to be secretary of state; but his age and infirmities confirming him in the resolution he had made not to meddle any more with public affairs, he was satisfied that his son alone should enjoy his majesty's favour. Mr John Temple was upon this appointed secretary at war; but he had hardly been a week in that office, when he resolved to put an end to his own existence; which he did on the 14th of April 1689, by throwing himself out of a boat, hired for that purpose, in shooting London-bridge; having first put stones into his pocket to make him sink speedily.

In 1694 Sir William had the misfortune to lose his lady, who was a very extraordinary woman, as well as an affectionate wife. He was then considerably turned of sixty; at which age he practised what he had so often declared to be his opinion, that "an old man ought then to consider himself of no farther use in the world except to himself and his friends." After this he lived four years, very much afflicted with the gout; and his strength and spirits being worn out by the infirmities of age, he expired in the month of January 1698. He died at Moor-Park, where his heart was buried in a silver box under the sun dial in his garden, opposite to a window from which he used to contemplate and admire the works of nature, with his sister the ingenious lady Gifford. This was according to his will; in pursuance of which his body was privately interred in Westminster Abbey, and a marble monument erected in 1722, after the death of lady Gifford, who resembled him in genious as well as in person, and left behind her the character of one of the best and most constant friends in the world.

Sir William Temple's principal works are, 1. Memoirs from 1672 to 1692: They are very useful for those who wish to be acquainted with the affairs of that period. 2. Remarks upon the State of the United Provinces. 3. An Introduction to the History of England: This is a Sketch of a General History. 4. Letters written during his last embassies. And, 5. Miscellanies, which contain a great many curious pieces that display considerable depth of thought. He was an accomplished gentleman, a sound politician, a patriot, and a great scholar. And if this great idea should perchance be shaded by some touches of *vanity* and *spleen*, the reader will be so candid as to consider, that the greatest, wisest, and the best of men, have still some failings and imperfections which are inseparable from human nature.

TEMPLE, *templum*, a public building, erected in honour of some deity, either true or false; and wherein the people meet to pay religious worship to the same. The word is formed from the Latin *templum*, which some derive from the Greek τεμενος, signifying the same thing; and others from τεμνω, *abscindo*, "I cut off, I separate," in regard a temple is a place separated from common uses; others with more probability derive it from the old Latin word *templare*, "to contemplate." It is certain the ancient augurs gave the name *templa* to those parts of the heavens which were marked out for the observation of the flight of birds. Their formula was this: *Templa tesqua sunto*. Temples were originally all open, and hence received their name. See Phil. Transf. n° 471. sect. 5. where we have an account of an ancient temple in Ireland of the same sort as the famous Stonehenge. The word *templum*, in its primary sense among the old Romans, signified nothing more than a place set apart and consecrated by the augurs, whether inclosed or open, in the city or in the fields. Temple.

Clemens Alexandrinus and Eusebius refer the origin of temples to the sepulchres built for the dead. This notion has been lately illustrated and confirmed by a variety of testimonies by Mr Farmer in his Treatise on the Worship of Human Spirits, p. 373, &c. Herodotus and Strabo will have the Egyptians to have been the first who built temples to the gods. The first erected in Greece is ascribed to Deucalion, by Apollonius, Argonaut. lib. iii. In antiquity we meet with many people who would not build any temples to their gods for fear of confining them to too narrow bounds. They performed their sacrifices in all places indifferently, from a persuasion that the whole world is the temple of God, and that he required no other. This was the doctrine of the magi, followed by the Persians, the Scythians, the Numidians, and many other nations mentioned by Herodotus, lib. i. Strabo, lib. xv. and Cicero in his second oration against Verres.

The Persians, who worshipped the sun, believed it would wrong his power to inclose him in the walls of a temple, who had the whole world for his habitation; and hence, when Xerxes ravaged Greece, the magi exhorted him to destroy all the temples he met with.

The Sicyonians would build no temple to their goddess Coronis; nor the Athenians, for the like reason, erect any statue to Clemency, who, they said, was to live in the hearts of men, not within stone walls.

The Bithynians had no temples but the mountains to worship on; nor had the ancient Germans any other but the woods.

Even some philosophers have blamed the use and building of temples, particularly Diogenes, Zeno, and his followers the Stoics. But it may be said, that if God hath no need of temples, men have need of places to meet in for the public offices of religion: accordingly temples may be traced back even into the remotest antiquity. See *Hospinian de Origine Templorum*.

The Romans had several kinds of temples; whereof those built by the kings, &c. consecrated by the augurs, and wherein the exercise of religion was regularly performed, were called, by way of eminence, *templa*, "temples." Those that were not consecrated, were called *ædes*. The little temples, that were covered or roofed, they called *ædiculæ*. Those open, *sacella*. Some other edifices, consecrated to particular mysteries of religion, they called *fana* and *delubra*.

All these kinds of temples, Vitruvius tells us, had other particular denominations, according to the form and manner of their construction, as will be hereafter specified.

Indeed the Romans outdid all nations with regard to temples: they not only built temples to their gods, to their virtues, to their diseases, &c. but also to their emperors, and that in their life time: instances whereof we meet with in medals, inscriptions, and other monuments. Horace compliments Augustus hereupon, and sets him above Hercules and all the heroes of fable; because those were admitted into temples only after their death, whereas Augustus had his temples and altars while living.

Præsenti tibi maturos largimur honores;
Jurandasque tuum per nomen ponimus aras.

Epist. ad Aug.

Suetonius, on this occasion, gives an instance of the modesty of that emperor, who would allow of no *temples* being erected to him in the city; and even in the provinces, where he knew it was usual to raise temples to the very proconsuls, refused

Temple. refuſed any but thoſe erected in the name of Rome as well as his own.

The moſt celebrated temples among the Romans were the Capitol and Pantheon. They had alſo the temple of Saturn, which ſerved for the public treaſury; and the temple of Janus.

The temple at Jeruſalem was ſimilar in its plan to the TABERNACLE. The firſt temple was begun by Solomon about the year of the world 2992, and before Chriſt 1012 according to ſome chronologers, and finiſhed in eight years. Great miſtakes have been committed reſpecting the dimenſions of this temple, by confounding the emblematical deſcription of Ezekiel with the plain account of it in the books of Kings and Chronicles. It conſiſted of the holy of holies, the ſanctuary, and a portico. The holy of holies was a ſquare room of 20 cubits; the ſanctuary, or holy place, was 40 cubits long and 20 broad, conſequently the length of both theſe together was 60 cubits. The portico, which ſtood before the ſanctuary, was 20 cubits long and 10 cubits broad. Whether the portico was ſeparated by a wall from the reſt of the temple or not, is not mentioned in Scripture. If it was, the whole length of the temple, computing the cubit at 22 inches, did not exceed 110 feet in length and 36 feet 8 inches in breadth. In the portico ſtood the two brazen pillars called *Jachin* and *Boaz*, which, upon comparing and reconciling the ſeemingly different account in different places, appear to have been 40 cubits high and about 4 cubits diameter. The court probably at firſt extended all round the temple. Now we are told, that the court about the tabernacle was 100 cubits long and 50 broad; and as Solomon made every part of the temple about twice as large as the correſponding part in the tabernacle, we have reaſon to conclude, that the court around the temple was 200 cubits long and 100 broad. According to this deſcription, which is taken from the Scripture hiſtory, the temple of Solomon was by no means ſo large as it is commonly repreſented. Still, however, it was very magnificent in ſize and ſplendid in ornament. It was plundered of its treaſures in the reign of Rehoboam, and repaired by Joaſh; it was again ſpoiled in the time of Ahaz and of Hezekiah; and after being reſtored by Joſiah, was demoliſhed by Nebuchadnezzar in the year of the world 3416, after it had ſtood 476 years according to Joſephus, and according to Uſher 428 years.

The ſecond temple was built by the Jews, after their return from the Babyloniſh captivity, under the direction and influence of Zerubbabel their governor, and of Joſhua the high-prieſt, with the leave and encouragement of Cyrus the Perſian emperor, to whom Judea was now become a tributary kingdom. According to the Jews, this temple was deſtitute of five remarkable appendages, which were the chief glory of the firſt temple; viz. the ark and mercy-ſeat, the Shechinah, the holy fire on the altar, which had been firſt kindled from heaven, the urim and thummim, and the ſpirit of prophecy. This temple was plundered and profaned by Antiochus Epiphanes, who alſo cauſed the public worſhip in it to ceaſe; and afterwards purified by Judas Maccabæus, who reſtored the divine worſhip; and after having ſtood five hundred years, rebuilt by Herod, with a magnificence approaching to that of Solomon's. Tacitus calls it *immenſæ opulentiæ templum;* and Joſephus ſays, it was the moſt aſtoniſhing ſtructure he had ever ſeen, as well on account of its architecture as its magnitude, and likewiſe the richneſs and magnificence of its various parts and the reputation of its ſacred appurtenances. This temple, which Herod began to build about ſixteen year before the birth of Chriſt, and ſo far completed in nine years and a half as to be fit for divine ſervice, was at length deſtroyed by the Romans on the ſame month and day of the month on which Solomon's temple was deſtroyed by the Babylonians. Temple.

The Indian temples, or pagodas, are ſometimes of a prodigious ſize. They are commonly erected near the banks of the Ganges, Kiſtna, or other ſacred rivers, for the benefit of ablution in the purifying ſtream. Where no river flows near the foot of the pagoda, there is invariably in the front of it a large tank or reſervoir of water. Theſe are, for the moſt part, of a quadrangular form, are lined with freeſtone or marble, have ſteps regularly deſcending from the margin to the bottom, and Mr Crauford obſerved many between three and four hundred feet in breadth. At the extrance of all the more conſiderable pagodas there is a portico, ſupported by rows of lofty columns, and aſcended by a handſome flight of ſtone ſteps; ſometimes, as in the inſtance of Tripetti*, to the number of more than a hundred. Under this portico, and in the courts that generally incloſe the whole building, an innumerable multitude aſſemble at the riſing of the ſun; and, having bathed in the ſtream below, and, in conformity to an immemorial cuſtom over all the Eaſt, having left their ſandals on the border of the tank, impatiently await the unfolding of the gates by the miniſtring brahmin. The gate of the pagoda univerſally fronts the eaſt, to admit the ray of the ſolar orb; and, opening, preſents to the view an edifice partitioned out, according to M. Thevenot in his account of Chitanagar, in the manner of the ancient cave-temples of Elora, having a central nave or body; a gallery ranging on each ſide; and, at the farther end, a ſanctuary, or chapel of the deity adored, ſurrounded by a ſtone balluſtrade to keep off the populace. Thoſe who wiſh to peruſe a more particular account of the Indian temples may conſult Maurice's Indian Antiquities. See alſo PAGODA and SERINGHAM.

Maurice's Indian Antiquities, vol. iii. p. 352.

Crauford's Sketches, vol. i. p. 160.

* Voyage des Indes, tom. iii.

TEMPLE, in architecture. The ancient temples were diſtinguiſhed, with regard to their conſtruction, into various kinds; as, *Temple in antæ*, *Ædes in antis*. Theſe, according to Vitruvius, were the moſt ſimple of all temples, having only angular pilaſters, called *antæ* or *paraſtatæ*, at the corners, and two Tuſcan columns on each ſide of the doors. *Temple, tetraſtyle*, or ſimple *tetraſtyle*, was a temple that had four columns in front and as many behind. Such was the temple of Fortuna Virilis at Rome. *Temple, proſtyle*, that which had only columns in its front or fore ſide; as that of Ceres at Eleuſis in Greece. *Temple, amphiproſtyle*, or *double proſtyle*, that which had columns both before and behind, and which was alſo tetraſtyle. *Temple, periptere*, that which had four rows of inſulated columns around, and was hexaſtyle, *i. e.* had ſix columns in front; as the temple of Honour at Rome. *Temple, diptere*, that which had two wings and two rows of columns around, and was alſo octoſtyle, or had eight columns in front; as that of Diana at Epheſus.

TEMPLES, among us denote two inns of court in London, thus called, becauſe anciently the dwelling-houſe of the knights-templars. At the ſuppreſſion of that order, they were purchaſed by the profeſſors of the common law, and converted into *hoſpitia* or inns. They are called the *inner* and *middle temple*, in relation to Eſſex-houſe; which was alſo a part of the houſe of the templars, and called the *outer temple*, becauſe ſituated without Temple-Bar. In the middle temple, during the time of the templars, the king's treaſure was kept; as was alſo that of the kings of France in the houſe templars at Paris. The chief officer was the maſter of the temple, who was ſummoned to parliament in 47. Hen. III. and from him the chief miniſter of the temple church is ſtill called *maſter of the temple*.

TEMPLES, in anatomy, a double part of the head, reaching from the forehead and eyes to the two ears. The temples are chiefly formed of two bones called *oſſa temporis*.

Theſe

Temporal ‖ Tenacity.

These parts, according to phyſicians, were called *tempora*, from their ſhowing the age or time of a man by the colour of the hair, which turns white in this part before any other; which Homer ſeems to have been aware of, by his calling men *poliocrotaphi*, *q. d.* "grey-templed."

TEMPORAL, a term generally uſed for ſecular, as a diſtinction from eccleſiaſtical. Thus we ſay temporal lords, and ſpiritual or eccleſiaſtical lords.

TEMPORALTIES *of Bishops*, are the revenues, lands, tenements, and lay-fees, belonging to biſhops, as they are barons and lords of parliament.

The cuſtody of the temporalties of biſhops forms a branch of the king's ordinary revenues (ſee REVENUE.).—Theſe, upon the vacancy of the biſhopric, are immediately the right of the king, as a conſequence of his prerogative in church matters; whereby he is conſidered as the founder of all archbiſhoprics and biſhoprics, to whom, during the vacancy, they revert. And for the ſame reaſon, before the diſſolution of abbeys, the kings had the cuſtody of the temporalties of all ſuch abbeys and priories as were of royal foundation (but not of thoſe founded by ſubjects), on the death of the abbot or prior. Another reaſon may alſo be given why the policy of the law hath veſted this cuſtody in the king; becauſe, as the ſucceſſor is not known, the lands and poſſeſſions of the ſee would be liable to ſpoil and devaſtation if no one had a property therein. Therefore the law has given the king, not the temporalties themſelves, but the cuſtody of the temporalties, till ſuch time as a ſucceſſor is appointed; with power of taking to himſelf all the intermediate profits, without giving any account to the ſucceſſor; and with the right of preſenting (which the crown very frequently exerciſes) to ſuch benefices and other preferments as fall within the time of vacation. This revenue is of ſo high a nature, that it could not be granted out to a ſubject, before or even after it accrued: but now, by the ſtatute 15 Edw. III. ſt. 4. c. 4 & 5. the king may, after the vacancy, leaſe the temporalties to the dean and chapter; ſaving to himſelf all advowſons, eſcheats, and the like. Our ancient kings, and particularly William Rufus, were not only remarkable for keeping the biſhoprics a long time vacant, for the ſake of enjoying the temporalties, but alſo committed horrible waſtes on the woods and other parts of the eſtate; and to crown all, would never, when the ſee was filled up, reſtore to the biſhop his temporalties again, unleſs he purchaſed them at an exorbitant price. To remedy which, king Hen. I. granted a charter at the beginning of his reign, promiſing neither to ſell, nor let to farm, or take any thing from, the domains of the church, till the ſucceſſor was inſtalled. And it was made one of the articles of the great charter, that no waſte ſhould be committed in the temporalties of biſhoprics, neither ſhould the cuſtody of them be ſold. The ſame is ordained by the ſtatute of Weſtminſter the firſt; and the ſtatute 14 Edw. III. ſtat. 4. c. 4. (which permits a leaſe to the dean and chapter) is ſtill more explicit in prohibiting the other exactions. It was alſo a frequent abuſe, that the king would, for trifling or no cauſes, ſeize the temporalties of biſhops, even during their lives, into his own hands: but this is guarded againſt by ſtatute 1 Edw. III. ſt. 2. c. 2.

Blackſt. Comment. vol. i.

This revenue of the king, which was formerly very conſiderable, is now by a cuſtomary indulgence almoſt reduced to nothing: for, at preſent, as ſoon as the new biſhop is conſecrated and confirmed, he uſually receives the reſtitution of his temporalties quite entire and untouched from the king; and then, and not ſooner, he has a fee-ſimple in his biſhopric, and may maintain an action for the profits.

TENACITY, in natural philoſophy, that quality of bodies by which they ſuſtain a conſiderable preſſure or force of any kind without breaking. It is the quality oppoſite to fragility or brittleneſs. See *Strength of Material*.

Tenaculum ‖ Tenelos.

TENACULUM, in ſurgery, an inſtrument uſed in amputation, for pulling out bleeding veſſels that are to be tied by ligatures. See SURGERY.

TENAILLES and TENAILLIONS. } See FORTIFICATION, Sect. I. § 3. and 5.

TENANT, one that holds lands or tenements of ſome lord or landlord, by rent, fealty, &c. See TENURE.

TENAWWIT. See LOXIA, ſpecies 13.

TENCH, in ichthyology. See CYPRINUS, ſpecies 3.

TENDER, a ſmall ſhip in the ſervice of men of war, for carrying men, proviſions, or any thing elſe that is neceſſary.

TENDONS, in anatomy, are white, firm, and tenacious parts, contiguous to the muſcles, and uſually forming their extremities. See ANATOMY, n° 85.

TENEBRIO, in natural hiſtory, a genus of inſects belonging to the order of *Coleoptera*. The antennæ are moniliform, the laſt joint being roundiſh; the thorax is plano-convex and marginated; the head projecting, and the elytra are ſomewhat ſtiff. Gmelin enumerates about 63 ſpecies. The larvæ of ſome live in damp places under ground among rubbiſh; of others in flour and different kinds of food, where they undergo their metamorphoſis. The perfect inſects are very troubleſome in houſes; eating bread, meat, &c. They precipitately avoid the light; reſorting in troops to dark damp cellars, where putrefaction allures and nouriſhes them. They are all of a very dark gloomy appearance, from which circumſtance they take their name.

TENEDOS (anc. geog.), an iſland on the coaſt of Troas, at the diſtance of 40 ſtadia from the continent, and 80 in compaſs; with a cognominal Æolian town, and a temple of Apollo Smintheus. Its origin is derived from Tennes or Tenes, who being expoſed in a coffer or bog by his father Cygnus the Thracian, at the inſtigation of the mother-in-law, was by fate carried to this iſland, made king of it, and at length worſhipped as a god on account of his virtues. The iſland was famous for its earthen ware, for which purpoſe it had an excellent red clay; and hence Bochart would derive the appellation from *tinedom*, a "red clay." *Tenedia ſecuris*, is a proverbial ſaying to denote ſeverity; from a law there paſſed, that perſons found in the act of adultery ſhould be put to death; a ſeverity executed on the king's ſon; and therefore, in the coins of Tenedos, on one are two heads in memorial of the king and his ſon, and on the reverſe an axe, (Ariſtotle). This iſland ſtill retains its ancient name; and is one of the ſmalleſt iſlands of the Archipelago, ſituated near the coaſt of Leſſer Aſia, weſt of the ruins of Troy. It is chiefly rocky, but fertile, being remarkable for producing the beſt Muſcadine wine in the Levant; and its poſition, thus near the mouth of the Helleſpont, has given it importance in all ages; veſſels bound towards Conſtantinople finding ſhelter in its port, or ſafe anchorage in the road, during the Eteſian or contrary winds, and in foul weather. The emperor Juſtinian erected a magazine to receive the cargoes of the corn-ſhips from Alexandria, when detained there. This was a lofty building, two hundred and eighty feet long and ninety broad. The voyage from Egypt was rendered leſs precarious, and the grain preſerved until it could be tranſported to the capital. Afterwards, during the troubles of the Greek empire, Tenedos experienced a variety of fortune. The pirates, who infeſted theſe ſeas, made it for many years their place of rendezvous; and Othman ſeized it in 1302, procured veſſels, and thence ſubdued the other iſlands of the Archipelago. It has continued in the poſſeſſion of the Turks ever ſince:

Teneriff. and on the eaſtern ſide is a pretty large town, ſeated at the foot of a mountain, with a fine harbour commanded by a caſtle. E. Long. 27. 0. N Lat. 29. 30.

TENERIFF, an iſland of Africa, and one of the Canaries, being the moſt conſiderable for riches, trade, and extent. It lies to the ſouth of the iſland of Salvages, to the weſt of the Grand Canary, to the north of the iſland of Gomera, and to the eaſt of that of Palma. It is of a triangular form, being about 45 miles in length and 20 in breadth; and in the centre is the famous *peak*, called by the natives *El Pico de Teyde*, which in clear weather may be ſeen at the diſtance of 120 miles, like a thin blue vapour very little darker than the ſky.

The moſt frequented harbour is called *Santa Cruz*, which is on the ſouth ſide of the iſland, and where ſhips with good anchors and cables may be ſafe in all weathers. At this port is the principal commercial town in the iſland, called alſo *Santa Cruz*, in the middle of which is a mole, built at a vaſt expence for the convenience of landing; between the mole and the town is a fort called *St Philips*; and near it is a ſteep rocky den or valley, beginning at the ſea ſhore, and running far inland, which would render the attack of an enemy very difficult; there are alſo other forts for its defence, all joined together by a thick ſtone wall, and mounted with cannon.

Glas's Hiſtorical Account of the Canary Iſlands.

Santa Cruz is a large town, containing ſeveral churches and convents, an hoſpital, and the beſt conſtructed private buildings of any in the Canary iſlands. It contains about 7000 inhabitants; it is not fortified on the land ſide, and all the country near it is dry, ſtony, and barren.

About four leagues to the ſouth of Santo Cruz, cloſe to the ſea, there is a cave, with a chapel called the *chapel of our Lady of Candelarie*, in which is an image of the Virgin Mary, that is held in as much reverence here as that of Diana was at Epheſus. This chapel is endowed with ſo many ornaments that it is the richeſt place in all the ſeven iſlands. At a certain ſeaſon of the year almoſt all the inhabitants go thither on pilgrimage, and innumerable and incredible ſtories are related and univerſally believed concerning this image.

About four miles inland from Santa Cruz ſtands the city of St Chryſtobal de la Laguna, which is the metropolis of the iſland, and contains two pariſh churches and five convents, but has no trade, being inhabited principally by the gentry of the iſland; the inhabitants are numerous, yet nobody is ſeen in the ſtreets, which are ſolitary and deſolate, ſo that graſs grows in thoſe that are moſt frequented. There are many other towns in the iſland which contain a great number of people, but none are more than three leagues from the ſea.

All the fertile ground within a league of the ſea is covered with vines; that of the next league is ſown with corn, the third is adorned with woods, and above the woods are the clouds, for the iſland gradually aſcends from the ſea, riſing on all ſides till it terminates in the peak, which is the centre.

On the ſouth-eaſt of the iſland inland from *Candelaria* is a town called *Guimar*, where there are ſome families which know themſelves to be the genuine unmixed offſpring of the original natives; but they know nothing of the manners of their anceſtors, nor have they preſerved any remains of their language. They are fairer than the Spaniards of Andaluſia.

Teneriff contains about 96,000 perſons, ſuppoſed to be equal to the number of inhabitants of all the reſt of the ſeven iſlands put together. The peaſants in general are wretchedly clothed; when they do appear better, they are habited in the Spaniſh faſhion. The men, in a genteeler line, dreſs very gayly, and are ſeldom ſeen without long ſwords. It is remarked, that few of them walk with dignity and eaſe; which may be attributed to the long cloaks they uſually wear. The women wear veils: thoſe worn by the lower ranks are of black ſtuff, thoſe of the higher of black ſilk; and ſuch among the latter as have any claim to beauty are far from being over careful in concealing their faces by them. The young ladies wear their fine long black hair plaited, and faſtened with a comb or a riband on the top of the head.

Teneriff. White's Voyage to New South Wales, p. 18.

The common people, and in this they reſemble the inhabitants of moſt of the iſlands in the Pacific Ocean lately diſcovered, have in them a ſtrong tendency to thieving; they are beſides lazy, and the moſt importunate beggars in the world. "I obſerved likewiſe (ſays Mr White) that the itch was ſo common among them, and had attained ſuch a degree of virulence, that one would almoſt be led to believe it was epidemic there. Some of the women are ſo abandoned and ſhameleſs, that it would be doing an injuſtice to the proſtitutes met with in the ſtreets of London to ſay they are like them. The females of every degree are ſaid to be of an amorous conſtitution, and addicted to intrigue; for which no houſes could be better adapted than thoſe in Teneriff.

"The manufactures carried on here are very few, and the product of them little more than ſufficient for their own conſumption. They conſiſt of taffeties, gauze, coarſe linens, blankets, a little ſilk, and curious garters. The principal dependence of the inhabitants is on their wine (their ſtaple commodity), oil, corn, and every kind of ſtock for ſhipping. With theſe the iſland abounds: and, in their ſeaſon, produces not only the tropical fruits, but the vegetable productions of the European gardens, in the greateſt plenty. Teneriff enjoys an agreeable and healthful mediocrity of climate. Indeed none ſeems better adapted for the reſtoration of a valetudinarian; as, by going into the mountains, he may graduate the air, and chooſe that ſtate of it which beſt ſuits his complaint. But although the inhabitants are thus healthy, and have ſo little occaſion for medical aid, they loudly complain of the want of knowledge in the profeſſional gentlemen of the iſland."

The height of the peak of Teneriff has been ſo variouſly eſtimated and calculated by different travellers and geographers, that we can only take the mean between the two extremes of their deciſions. Dr Halley allows but two miles and a quarter from the level of the ſea to the ſummit of the ſugar-loaf, whilſt the Spaniſh account of the Canary iſlands, tranſlated by Mr Glas in 1763, makes it no leſs than five miles; and others have aſſigned a height different from both theſe. That it is an extinguiſhed volcano is univerſally known; and we are perſuaded that the following account of the crater, and of ſome experiments made on its brink by M. Mongez on the 24th of Auguſt 1785, will prove not unacceptable to our chemical readers.

Rye's Excurſion to the Peak of Teneriff.

"The crater of the peak of Teneriff (ſays he) is a true ſulphur-pit, ſimilar to thoſe of Italy. It is about 50 fathoms long and 40 broad, riſing abruptly from eaſt to weſt. At the edges of the crater, particularly on the under ſide, are many ſpiracles, or natural chimneys, from which there exhale aqueous vapours and ſulphureous acids, which are ſo hot as to make the thermometer riſe from 9° to 34° of Reaumur. The inſide of the crater is covered with yellow, red, or white, argillaceous earth, and blocks of lava partly decompoſed. Under theſe blocks are found ſuperb cryſtals of ſulphur; theſe are eight ſided rhomboidal cryſtals, ſometimes an inch in length, and, I ſuppoſe, they are the fineſt cryſtals of volcanic ſulphur that have ever been found. The water that exhales from the ſpiracles is perfectly pure, and not in the leaſt acid, as I was convinced by ſeveral experiments.

Journal de Phyſique.

"The

Teneriff. "The elevation of the peak above the level of the sea is near 1900 toises; which induced me to make several chemical experiments in order to compare the phenomena with those that occur in our laboratories. I shall here confine myself merely to the results.

"The volatilization and cooling of liquors were here very considerable. Half a minute was sufficient for the dissipation of a pretty strong dose of æther. The action of acids on metals, earths, and alkalis, was slow; and the bubbles which escaped during the effervescence were much larger than ordinary. The production of vitriols was attended with very singular phenomena. That of iron assumed all at once a very beautiful violet colour, and that of copper was suddenly precipitated of a very bright blue colour. I examined the moisture of the air by means of the hygrometer, of pure alkali, and of vitriolic acid; and I thence concluded, as well as from the direction of the aqueous vapours, that the air was very dry; for at the end of three hours the vitriolic acid had suffered hardly any change either in colour or weight; the fixed alkali remained dry, except near the edges of the vessel that contained it, where it was a little moist; and Saussure's hygrometer pointed to 64°, as nearly as the impetuous wind which then blew would permit us to judge.

"Liquors appeared to us to have lost nothing of their smell or strength at this height; a circumstance which contradicts all the tales that have hitherto been related on this head: volatile alkali, ether, spirit of wine, retained all their strength; the smoking spirit of Boyle was the only one that seemed to have lost any sensible portion of its energy. Its evaporation, however, was not the less quick; in 30 seconds, a quantity which I had poured into a cup was entirely volatilized; and nothing remained but the sulphur which tinged the rims and the bottom. When I poured the vitriolic acid on this liquor, there happened a violent detonation, and the vapours that arose had a very sensible degree of heat. I tried to form volatile alkali by decomposing sal ammoniac with the fixed alkali; but the production was slow and hardly sensible, while at the level of the sea this process, made with the same substances, in the same proportions, succeeded very readily and in abundance.

"As I was curious to investigate the nature of the vapours that exhale from the crater, and to know whether they contained inflammable air, fixed air, and marine acid, I made the following experiments: I exposed on the edge of one of the spiracles a nitrous solution of silver in a cup; it remained more than an hour in the midst of the vapours which were continually exhaling, but without any sensible alteration; which sufficiently shews that no vapours of marine acid exhale from the crater. I then poured into it some drops of marine acid, when a precipitation of luna cornea immediately ensued: but instead of being white, as that precipitate generally is, it was of a fine dark violet colour, which quickly became grey, and it assumed the form of small scaly crystals. These were very distinct when looked at with a glass, and they were even visible to the naked eye. I think myself justifiable in attributing this alteration of colour to the vapours of inflammable air, according to some experiments that I have made on the precipitation of luna cornea in such air. Lime-water, exposed for three hours on the margin of the crater, and in the neighbourhood of a spiracle, was not covered with any calcareous pellicle, nor even hardly with any filmy appearance; which proves, in my opinion, not only that no vapours of fixed air exhale from the crater, but that the atmospheric air, which rests upon it, contains very little of that air, and that the inflammable vapours and sulphureous acids alone are sensible and considerable. The electricity of the atmosphere was pretty considerable, for Saussure's electrometer, when held in the hand at the height of about five feet, indicated three degrees, while on the ground it pointed only to one and a half. The electricity was positive." W. Long. 16. 18. N. Lat. 28. 29. Tenesmus ‖ Tenison.

TENESMUS, in medicine, a name given by medical writers to a complaint which is a continual desire of going to stool, but without any stool being ready to be voided. This is properly no primary disease, but merely a symptomatic one, and differs in degree according to the disease on which it is an attendant. See MEDICINE, n° 111.

TENIERS (David), the Elder, a Flemish painter, born at Antwerp in 1582. He received the first rudiments of his art from the famous Rubens, who highly esteemed him for his promising genius, and with great satisfaction examined and commended his designs. From the school of that celebrated painter Teniers went to finish his studies at Rome. He attached himself to Adam Elsheimer for six years; and from the instructions of two such incomparable masters, he formed to himself a peculiar style, which his son cultivated so happily afterward as to bring it to the utmost perfection. His pictures were small; and his subjects usually shops, elaboratories, humorous conversations, and rural festivities. The demand for his pieces was universal; and even his master Rubens thought them an ornament to his cabinet. He died at Antwerp in 1649.

TENIERS (David) the Younger, also an admirable painter, was the son of the former, and was born at Antwerp in 1610. He obtained the name of *Ape of Painting*, from his imitating the manner of different painters with such exactness as to deceive even the nicest judges. He improved greatly under his father, and obtained such reputation as introduced him to the favour of the great. The archduke Leopold William made him gentleman of his bed-chamber; and all the pictures of his gallery were copied by Teniers, and engraved by his direction. The king of Spain and Don Juan of Asturia set so high a value on his pictures, that they built a gallery on purpose for them. William prince of Orange honoured him with his friendship; and Rubens not only esteemed his works, but assisted him with his advice. His principal talent lay in landscapes adorned with small figures. He also painted men drinking and smoking, chemists elaboratories, country fairs, and the like. His small figures are superior to his large ones. He died in 1694.

The works of the father and son are thus distinguished: The latter discover a finer touch and fresher pencil, greater variety of attitudes, and a better disposition of the figures. The father retained something of the tone of Italy in his colouring, which was stronger than the son's; besides, the son used to put at the bottom of his pictures, David Teniers, junior.

Abraham, another son of David the Elder, was equal, if not superior, to his father and brother in the expression of his characters, and his understanding the *claro obscuro*; though he was inferior in the sprightliness of his touch, and the lightness of his pencil.

TENISON (Dr Thomas), archbishop of Canterbury, was born at Cottenham in Cambridgeshire in 1636: and studied at Corpus Christi college in Cambridge. In his youth, while the fanatical government lasted, he applied himself to physic; but afterward went into orders, and was some time minister of St Andrew's church, Cambridge; where he attended the sick during the plague in 1665, which his parishioners acknowledged by the present of a piece of plate. He showed himself very active against the growth of Popery by his writings both in king Charles and king James's reigns: in 1680 he was presented to the vicarage of St Martin's in the Fields, London, to which parish he made several donations; and among others, endowed

Tennis. a free ſchool, and built a handſome library, which he furniſhed with uſeful books. King William and queen Mary, in 1689, preſented him to the archdeaconry of London; in 1691, he was nominated to the ſee of Lincoln, and in 1694 he ſucceeded Dr Tillotſon as archbiſhop of Canterbury. He performed all the duties of a good primate for 20 years, and died in 1715.

TENNIS, a play at which a ball is driven by a racket.

As many perſons would become players at tennis, provided they could eaſily underſtand the rudiments of the game, ſo as to form ſome judgment of the players, or at leaſt to know who wins and who loſes, we have here attempted to give ſo plain a deſcription of it, that no one can be at a loſs, if ever he ſhould bett or play. As to the executive part, it requires great practice to make a good player, ſo that nothing can be done without it; all we preſume to do is to give an inſight into the game, whereby a perſon may not ſeem a total ſtranger to it when he happens to be in a tennis court.

Heylè's Games improved by Beaufort.

The game of tennis is played in moſt capital cities in Europe, particularly in France, from whence we may venture to derive its origin. It is eſteemed with many to be one of the moſt ancient games in Chriſtendom, and long before king Charles I.'s time it was played in England.

This game is as intricate as any game whatever; a perſon who is totally ignorant of it may look on for a month together, without being able to make out how the game is decided. Therefore we ſhall begin by deſcribing the court in which it is played.

The ſize of a tennis court is generally about 96 or 97 feet by 33 or 34, there being no exact dimenſions aſcribed to its proportition, a foot more or leſs in length or width being of no conſequence. A line or net hangs exactly acroſs the middle, over which the ball muſt be ſtruck, either with a racket or board to make the ſtroke good. Upon the entrance of a tennis-court, there is a long gallery which goes to the dedans, that is, a kind of front gallery, where ſpectators uſually ſtand, into which, whenever a ball is ſtruck, it tells for a certain ſtroke. This long gallery is divided into different compartments or galleries, each of which has its particular name, as follows; from the line towards the dedans are the *firſt gallery*, *door*, *ſecond gallery*, and the *laſt gallery*, which is called the *ſervice ſide*. From the dedans to the laſt gallery are the figures 1, 2, 3, 4, 5, 6, at a yard diſtance each, by which the chaces are marked, and is one of the moſt eſſential parts of the game, as will appear in the following deſcription.

On the other ſide of the line are alſo the *firſt gallery*, *door*, *ſecond gallery*, and *laſt gallery*; which is called the *hazard-ſide*. Every ball ſtruck into the laſt gallery on this ſide reckons for a certain ſtroke the ſame as the dedans. Between the ſecond and this laſt gallery are the figures 1, 2, to mark the chaces on the hazard-ſide. Over this long gallery, or theſe compartments, is a covering, called the pent-houſe, on which they play the ball from the ſervice-ſide, in order to begin a ſet of tennis, from which it is called a *ſervice*. When they miſs putting the ball (ſo as to rebound from the pent-houſe) over a certain line on the ſervice-ſide, it is deemed a fault, two of which are reckoned for a ſtroke. If the ball rolls round the pent-houſe, on the oppoſite ſide of the court, ſo as to fall beyond a certain line deſcribed for that purpoſe, it is called *paſſe*, reckons for nothing on either ſide, and the player muſt ſerve again.

On the right-hand ſide of the court from the dedans is what they call the *tambour*, a part of the wall which projects, and is ſo contrived in order to make a variety in the ſtroke, and render it more difficult to be returned by the adverſary; for when a ball ſtrikes the *tambour*, it varies its direction, and requires ſome extraordinary judgment to return it over the line. The laſt thing on the right hand ſide is called the *grill*, wherein if the ball is ſtruck, it is alſo 15, or a certain ſtroke. Tennis.

The game of tennis is played by what they call *ſets*; a ſet of tennis conſiſts of ſix games: but if they play what is called an advantage-ſet, two above five games muſt be won on one ſide or the other ſucceſſively, in order to decide; or, if it comes to ſix games all, two games muſt ſtill be won on one ſide to conclude the ſet; ſo that an advantage-ſet may laſt a conſiderable time: for which kind of ſets the court is paid more than for any other.

We muſt now deſcribe the uſe of the chaces, and by what means theſe chaces decide or interfere ſo much in the game. When the player gives his ſervice at the beginning of a ſet, his adverſary is ſuppoſed to return the ball; and wherever it falls after the firſt rebound untouched, the chace is called accordingly; for example, if the ball falls at the figure 1, the chace is called at a yard, that is to ſay, at a yard from the dedans: this chace remains till a ſecond ſervice is given; and if the player on the ſervice ſide lets the ball go after his adverſary returns it, and if the ball falls on or between any of theſe figures or chaces, they muſt change ſides, there being two chaces; and he who then will be on the hazard ſide, muſt play to win the firſt chace; which if he wins by ſtriking the ball ſo as to fall, after its firſt rebound, nearer to the dedans than the figure 1, without his adverſary's being able to return it from its firſt hop, he wins a ſtroke, and then proceeds in like manner to win the ſecond chace, wherever it ſhould happen to be. If a ball falls on the line with the firſt gallery door, ſecond gallery, or laſt gallery, the chace is likewiſe called at ſuch or ſuch a place, naming the gallery, door, &c. When it is juſt put over the line, it is called a chace at the line. If the player on the ſervice-ſide returns a ball with ſuch force as to ſtrike the wall on the hazard-ſide ſo as to rebound, after the firſt hop over the line, it is alſo called a chace at the line.

The chaces on the hazard-ſide proceed from the ball being returned either too hard or not quite hard enough; ſo that the ball after its firſt rebound falls on this ſide of the blue line, or line which deſcribes the hazard-ſide chaces; in which caſe it is a chace at 1, 2, &c. provided there is no chace depending. When they change ſides, the player, in order to win this chace, muſt put the ball over the line anywhere, ſo that his adverſary does not return it. When there is no chace on the hazard-ſide, all balls put over the line from the ſervice ſide, without being returned, reckon for a ſtroke.

As the game depends chiefly upon the marking, it will be neceſſary to explain it, and to recommend thoſe who play at tennis to have a good and unbiaſſed marker, for on him the whole ſet may depend: he can mark in favour of the one and againſt the other in ſuch a manner, as will render it two to one at ſtarting, though even players. Inſtead of which the marker ſhould be very attentive to the chaces, and not be anyway partial to either of the players.

This game is marked in a very ſingular manner, which makes it at firſt ſomewhat difficult to underſtand. The firſt ſtroke is called 15, the ſecond 30, the third 40, and the fourth game, unleſs the players get four ſtrokes each; in that caſe, inſtead of calling it 40 all, it is called *deuce*; after which, as ſoon as any ſtroke is got, it is called *advantage*; and in caſe the ſtrokes become equal again, *deuce* again, till one or the other gets two ſtrokes following, which win the game; and as the games are won, ſo they are marked and called; as one game love, two games to one, &c. towards the ſet, of which ſo many of theſe games it conſiſts.

Although but one ball at a time is played with, a number of balls are made uſe of at this game to avoid trouble, and are handed to the players in baſkets for that purpoſe: by which

Tennis. which means they can play as long as they pleaſe, without ever having occaſion to ſtoop for a ball.

As to the odds at tennis, they are by no means fixed, but are generally laid as follows:

Upon the firſt ſtroke being won between even players, that is, fifteen love, the odds are of the ſingle game - - - 7 to 4

Thirty love - -	4	1
Forty love - -	8	1
Thirty fifteen - -	2	1
Forty fifteen - -	5	1
Forty thirty - -	3	1
The odds of a four game ſet when the firſt game is won, are -	7	4
When two games love -	4	1
Three games love - -	8	to 1
When two games to one -	2	1
Three games to one - -	5	1
The odds of a ſix game ſet when the firſt game is won, are -	3	2
When two games love -	2	1
Three games love - -	4	1
Four games love -	10	1
Five games love - -	21	1
When two games to one -	8	5
Three games to one - -	5	2
Four games to one -	5	1
Five games to one -	15	1
When three games to two -	7	4
Four games to two - -	4	1
Five games to two -	10	1
When four games to three -	2	1
Five games to three -	5	1
The odds of an advantage ſet when the firſt game is won, are	5	4
When two games love -	7	4
Three games love -	3	1
Four games love - -	5	1
Five games love -	15	1
When two games to one -	4	3
Three games to one -	2	1
Four games to one -	7	2
Five games to one -	10	1
When three games to two	3	2
Four games to two -	3	1
Five games to two -	8	1
When four games to three - -	8	5
Five games to three -	3	1
When five games to four -	2	1
When ſix games to five -	5	2

The foregoing odds, as beforeſaid, are generally laid, but the chaces interfering makes the odds very precarious; for example, when there is a chace at half a yard, and a ſet is five games all, and in every other reſpect equal, the odds are a good five to four; and if it were ſix games to five, and forty thirty with the ſame chace, the odds then would be a guinea to a ſhilling; ſo that it is plain that the odds at this game differ from thoſe of any other: for one ſtroke will reduce a ſet, ſuppoſing the players to be five games all, from an even wager to three to two, and ſo on in proportion to the ſtage of the ſet.

There are various methods of giving odds at tennis, in order to make a match equal; and that they may be underſtood, we ſhall give the following liſt of them, with their meanings, ſo that any perſon may form a judgment of the advantage received or given.

The loweſt odds that can be given, excepting the choice of the ſides, is what they call a *biſque*, that is, a ſtroke to be taken or ſcored whenever the player, who receives the advantage, thinks proper: for inſtance, ſuppoſe a critical game of the ſet to be forty thirty, by taking the *biſque*, he who is forty becomes game, and ſo in reſpect of two *biſques*, &c. Tennis ‖ Tent.

The next greater odds are *fifteen*, that is, a certain ſtroke given at the beginning of each game.

After theſe, *half thirty*, that is, fifteen one game, and thirty the next. Then follow the whole *thirty*, *forty*, &c.

There are alſo the following kind of odds which are given, viz.

Round ſervices; thoſe are ſervices given round the penthouſe, ſo as to render it eaſy for the *ſtriker out* (the player who is on the hazard ſide) to return the ball.

Half court, that is, being obliged or confined to play into the adverſary's half-court; ſometimes it is played ſtraightwiſe, and at other times acroſs; both which are great advantages given by him ſo confined, but the ſtrait half-court is the greateſt.

Touch-no-wall, that is, being obliged to play within the compaſs of the walls, or ſides of the court. This is a conſiderable advantage to him who receives it; as all the balls muſt be played gently, and conſequently they are much eaſier to take than thoſe which are played hard, or according to the uſual method of play.

Barring the hazards, that is, barring the dedans, tambour, grill, or the laſt gallery on the hazard-ſide, or any particular one or more of them.

Theſe are the common kind of odds or advantages given; but there are many others, which are according to what is agreed by the players: ſuch as playing with *board* againſt *racket*, *cricket-bat* againſt *racket*, &c.

The game of tennis is alſo played by four perſons, two partners on each ſide. In this caſe, they are generally confined to their particular quarters, and one of each ſide appointed to ſerve and ſtrike out; in every other reſpect, the game is played in the ſame manner as when two only play.

Any thing more to be ſaid upon this ſubject would be needleſs, as nothing can be recommended, after reading this ſhort account of tennis, but practice and attention, without which no one can become a proficient at the game.

TENOR, or TENOUR, the purport or content of a writing or inſtrument in law, &c.

TENOR, in muſic, the firſt mean, or middle part, or that which is the ordinary pitch of the voice, when neither raiſed to a treble nor lowered to a baſs.

TENSE, in grammar, an inflection of verbs, whereby they are made to ſignify or diſtinguiſh the circumſtance of time in what they affirm. See GRAMMAR.

TENT, in war, a pavilion or portable houſe. Tents are made of canvas, for officers and ſoldiers to lie under when in the field. The ſize of the officers tents is not fixed; ſome regiments have them of one ſize and ſome of another: a captain's tent and marquee is generally 10½ feet broad, 14 deep, and 8 high: the ſubalterns are a foot leſs; the major's and lieutenant-colonel's a foot larger; and the colonel's two feet larger. The ſubalterns of foot lie two in a tent, and thoſe of horſe but one. The tents of private men are 6½ feet ſquare, and 5 feet high, and hold five ſoldiers each. The tents for horſe are 7 feet broad and 9 feet deep: they hold likewiſe five men and their horſe accoutrements.—The word is formed from the Latin *tentorium*, of *tendo* "I ſtretch," becauſe tents are uſually made of canvas ſtretched out, and ſuſtained by poles, with cords and pegs.

TENT, in ſurgery, a roll of lint made into the ſhape of a nail with a broad flat head, chiefly uſed in deep wounds and ulcers. They are of ſervice, not only in conveying medicines to the moſt intimate receſſes and ſinuſes of the wound, but to prevent the lips of the wound from uniting before it

is

Tenter ‖ Tenths.

is healed from the bottom; and by their aſſiſtance grumous blood, ſordes, &c. are readily evacuated.

TENTER, TRIER, or *Prover*, a machine uſed in the cloth manufactory, to ſtretch out the pieces of cloth, ſtuff, &c. or only to make them even and ſet them ſquare.

It is uſually about 4½ feet high, and for length exceeds that of the longeſt piece of cloth. It conſiſts of ſeveral long ſquare pieces of wood, placed like thoſe which form the barriers of a manege; ſo, however, as that the lower croſs pieces of wood may be raiſed or lowered as is found requiſite, to be fixed at any height by means of pins. Along the croſs pieces, both the upper and under one, are hooked nails, called *tenter-hooks*, driven in from ſpace to ſpace.

To put a piece of Cloth on the TENTER. While the piece is yet quite wet, one end is faſtened to one of the ends of the tenter; then it is pulled by force of arms towards the other end, to bring it to the length required: that other end being faſtened, the upper liſt is hooked on to the upper croſs piece, and the loweſt liſt to the loweſt croſs-piece, which is afterwards lowered by force, till the piece have its deſired breadth. Being thus well ſtretched, both as to length and breadth, they bruſh it with a ſtiff hair bruſh, and thus let it dry. Then they take it off; and, till they wet it again, it will retain the length and breadth the tenter gave it.

TENTHREDO, the SAW-FLY; a genus of inſects belonging to the order of *hymenoptera*. The mouth is furniſhed with jaws, which are horny, arched, dentated within; the right jaw being obtuſe at the apex: the lip cylindrical, trifid: there are four feelers, unequal and filiform: the wings are plain and turned: the ſting conſiſts of two ſerrated laminæ, and the ſcutellum of two grains placed at a diſtance. Gmelin mentions 143 ſpecies. Theſe inſects are not very ſhy. Some, by means of their ſaw, depoſit in the buds of flowers, others on the twigs of trees or ſhrubs, eggs from which are produced caterpillars. The implement with which they are armed is nowiſe formidable; as it appears only deſtined to the purpoſe of depoſiting their eggs.

TENTHS, and *FIRST FRUITS of Spiritual Preferments*, in England, a branch of the king's revenue. See REVENUE.

"Theſe were originally a part of the Papal uſurpations over the clergy of this kingdom; firſt introduced by Pandulph the pope's legate, during the reigns of king John and Henry III. in the ſee of Norwich; and afterwards attempted to be made univerſal by the popes Clement V. and John XXII. about the beginning of the 14th century. The firſt fruits, *primitiæ* or *annates*, were the firſt year's whole profits of the ſpiritual preferment, according to a rate or *valor* made under the direction of pope Innocent IV. by Walter biſhop of Norwich in 38 Hen. III. and afterwards advanced in value by commiſſion from pope Nicholas III. A. D. 1292, 20 Edw. I.; which valuation of pope Nicholas is ſtill preſerved in the exchequer. The tenths, or *decimæ*, were the tenth part of the annual profit of each living by the ſame valuation; which was alſo claimed by the holy ſee, under no better pretence than a ſtrange miſapplication of that precept of the Levitical law, which directs, that the Levites "ſhould offer the tenth part of their tithes as a heave-offering to the Lord, and give it to Aaron the high-prieſt." But this claim of the pope met with vigorous reſiſtance from the Engliſh parliament; and a variety of acts were paſſed to prevent and reſtrain it, particularly the ſtatute 6 Hen. IV. c. 1. which calls it a *horrible miſchief and damnable cuſtom*. But the Popiſh clergy, blindly devoted to the will of a foreign maſter, ſtill kept it on foot; ſometimes more ſecretly, ſometimes more openly and avowedly: ſo that in the reign of Henry VIII. it was computed, that in the compaſs of 50 years 800,000 ducats had been ſent to Rome for firſt fruits only. And as the clergy expreſſed this willingneſs to contribute ſo much of their income to the head of the church, it was thought proper (when in the ſame reign the papal power was aboliſhed, and the king was declared the head of the church of England) to annex this revenue to the crown; which was done by ſtatute 26 Hen. VIII. c. 3. (confirmed by ſtatute 1 Eliz. c. 4); and a new *valor beneficiorum* was then made, by which the clergy are at preſent rated.

Blackſt. Comment. vol. i.

Tenths, Tenure.

"By theſe laſt mentioned ſtatutes all vicarages under ten pounds a year, and all rectories under ten marks, are diſcharged from the payment of firſt fruits: and if, in ſuch livings as continue chargeable with this payment, the incumbent lives but half a year, he ſhall pay only one quarter of his firſt fruits; if but one whole year, then half of them; if a year and a half, three quarters; and if two years, then the whole, and not otherwiſe. Likewiſe by the ſtatute 27 Hen. VIII. c. 8. no tenths are to be paid for the firſt year, for then the firſt fruits are due: and by other ſtatutes of queen Anne, in the fifth and ſixth years of her reign, if a benefice be under L. 50 *per annum* clear yearly value, it ſhall be diſcharged of the payment of firſt fruits and tenths.

"Thus the richer clergy being, by the criminal bigotry of their Popiſh predeceſſors, ſubjected at firſt to a foreign exaction, were afterwards, when that yoke was ſhaken off, liable to a like miſapplication of their revenues through the rapacious diſpoſition of the then reigning monarch; till at length the piety of queen Anne reſtored to the church what had been thus indirectly taken from it. This ſhe did, not by remitting the tenths and firſt fruits entirely; but, in a ſpirit of the trueſt equity, by applying theſe ſuperfluities of the larger benefices to make up the deficiencies of the ſmaller. And to this end ſhe granted her royal charter, which was confirmed by the ſtatute 2 Ann. c. 11. whereby all the revenue of firſt fruits and tenths is veſted in truſtees for ever, to form a perpetual fund for the augmentation of poor livings. This is uſually called *Queen Anne's bounty*; which has been ſtill farther regulated by ſubſequent ſtatutes."

TENURE, in law, ſignifies the manner whereby lands or tenements are held, or the ſervice that the tenant owes to his lord.

Of Britain almoſt all the real property is by the policy of the laws ſuppoſed to be granted by, dependent upon, and holden of, ſome ſuperior lord, by and in conſideration of certain ſervices to be rendered to the lord by the tenant or poſſeſſor of this property. The thing holden is therefore ſtyled a *tenement*, the poſſeſſors thereof *tenants*, and the manner of their poſſeſſion a *tenure*. Thus all the lands in the kingdom is ſuppoſed to be holden, mediately or immediately, of the king; who is ſtyled the *lord paramount*, or above all. Such tenants as held under the king immediately, when they granted out portions of the lands to inferior perſons, became alſo lords with reſpect to thoſe inferior perſons, as they were ſtill tenants with reſpect to the king; and, thus partaking of a middle nature, were called *meſne* or *middle lords*. So that if the king granted a manor to A, and he granted a portion of the land to B, now B was ſaid to hold of A, and A of the king; or, in other words, B held his lands immediately of A, but mediately of the king. The king therefore was ſtyled *lord paramount*: A was both tenant and lord, or was a meſne lord; and B was called *tenant paravail*, or the *loweſt tenant*, being he who was ſuppoſed to make avail, or profit of the land. In this manner are all the lands of the kingdom holden which are in the hands of ſubjects: for, according to Sir Edward Coke, in the law of England we have not properly *allodium*, which is the name by which the feudiſts abroad diſtinguiſh

Blackſt. Comment. vol. ii.

ſuch

Tenure. ſuch eſtates of the ſubject as are not holden of any ſuperior. So that at the firſt glance we may obſerve, that the lands are either plainly feuds, or partake very ſtrongly of the feodal nature.

All tenures being thus derived, or ſuppoſed to be derived, from the king, thoſe that held immediately under him, in right of his crown and dignity, were called his *tenants in capite*, or *in chief*; which was the moſt honourable ſpecies of tenure, but at the ſame time ſubjected the tenants to greater and more burdenſome ſervices than inferior tenures did. And this diſtinction ran through all the different ſorts of tenure.

There ſeem to have ſubſiſted among our anceſtors four principal ſpecies of lay-tenures, to which all other may be reduced: the grand criteria of which were the natures of the ſeveral ſervices or renders that were due to the lords from their tenants. The ſervices, in reſpect of their quality were either *free* or *baſe* ſervices: in reſpect of their quantity and the time of exacting them were either *certain* or *uncertain*. Free ſervices were ſuch as were not unbecoming the character of a ſoldier or a freeman to perform; as to ſerve under his lord in the wars, to pay a ſum of money, and the like. Baſe ſervices were ſuch as were fit only for peaſants or perſons of a ſervile rank; as to plough the lord's land, to make his hedges, to carry out his dung, or other mean employments. The certain ſervices, whether free or baſe, were ſuch as were ſtinted in quantity, and could not be exceeded on any pretence; as, to pay a ſtated annual-rent, or to plough ſuch a field for three days. The uncertain depended upon unknown contingencies; as, to do military ſervice in perſon, or pay an aſſeſſment in lieu of it when called upon; or to wind a horn upon the appearance of invaders; which are free ſervices; or to do whatever the lord ſhould command; which is a baſe or villein ſervice.

From the various combinations of theſe ſervices have ariſen the four kinds of lay-tenure which ſubſiſted in England till the middle of the laſt century; and three of which ſubſiſt to this day. Of theſe Bracton (who wrote under Henry the Third) ſeems to give the cleareſt and moſt compendious account of any author ancient or modern; of which the following is the outline or abſtract: "Tenements are of two kinds, *frank-tenement*, and *villenage*. And of frank-tenements, ſome are held freely in conſideration of homage and knight-ſervice; others in free-ſocage, with the ſervice of fealty only. And again, of villenages, ſome are *pure*, and others *privileged*. He that holds in pure villenage ſhall do whatſoever is commanded him, and always be bound to an uncertain ſervice. The other kind of villenage is called *villein-ſocage*; and theſe villein-ſocmen do villein-ſervices, but ſuch as are certain and determined." Of which the ſenſe ſeems to be as follows; firſt, where the ſervice was free, but uncertain, as military ſervice with homage, that tenure was called the *tenure in chivalry*, *per ſervitium militare*, or by knight-ſervice. Secondly, where the ſervice was not only free, but alſo certain, as by fealty only, by rent and fealty, &c. that tenure was called *liberum ſocagium*, or *free ſocage*. Theſe were the only free holdings or tenements; the others were villenous or ſervile: as, thirdly, where the ſervice was baſe in its nature, and uncertain as to time and quantity, the tenure was *purum villenagium*, abſolute or pure villenage. Laſtly, where the ſervice was baſe in its nature, but reduced to a certainty, this was ſtill villenage, but diſtinguiſhed from the other by the name of *privileged villenage*, *villenagium privilegiatum*; or it might be ſtill called *ſocage* (from the certainty of its ſervices), but degraded by their baſeneſs into the inferior title of *villanum ſocagium*, villein-ſocage.

1. The military tenure, or that by knight-ſervice, was done away by ſtat. 12 Car. II. For an account of this ſpecies of tenure ſee *Feodal Syſtem*, and *Knight-Service*; and for its incidents, ſee Relief, Primer-seisin, Wardship, Marriage, Fines, and Escheat. Tenure.

2. The ſecond ſpecies of tenure or free-ſocage, not only ſubſiſts to this day, but has in a manner abſorbed and ſwallowed up (ſince the ſtatute of Charles the Second) almoſt every other ſpecies of tenure. See Socage.

The other grand diviſion of tenure, mentioned by Bracton, is that of villenage, as contradiſtinguiſhed from *liberum tenementum*, or frank-tenure. And this (we may remember) he ſubdivides into two claſſes, pure and privileged villenage: from whence have ariſen two other ſpecies of the modern tenures.

3. From the tenure of pure villenage have ſprung the preſent copyhold tenures, or tenure by copy of court-roll at the will of the lord; in order to obtain a clear idea of which, it will be previouſly neceſſary to conſult the articles Manor and Villenage.

As a farther conſequence of what has been there explained, we may collect theſe two main principles, which are held to be the ſupporters of a copyhold-tenure, and without which it cannot exiſt; 1. That the lands be parcel of and ſituate within that manor under which it is held. 2. That they have been demiſed, or demiſable, by copy of court-roll immemorially. For immemorial cuſtom is the life of all tenures by copy; ſo that no new copyhold can, ſtrictly ſpeaking, be granted at this day.

In ſome manors, where the cuſtom hath been to permit the heir to ſucceed the anceſtor in his tenure, the eſtates are ſtyled *copyholds of inheritance*; in others, where the lords have been more vigilant to maintain their rights, they remain copyholds for life only; for the cuſtom of the manor has in both caſes ſo far ſuperſeded the will of the lord, that, provided the ſervices be performed or ſtipulated for by fealty, he cannot in the firſt inſtance refuſe to admit the heir of his tenant upon his death; nor, in the ſecond, can he remove his preſent tenant ſo long as he lives, though he holds nominally by the precarious tenure of his lord's will.

The fruits and appendages of a copyhold-tenure, that it hath in common with free tenures, are fealty, ſervices (as well in rents as otherwiſe), reliefs, and eſcheats. The two latter belong only to copyholds of inheritance; the former to thoſe for life alſo. But, beſides theſe, copyholds have alſo heriots, wardſhip, and fines. Heriots, which are agreed to be a Daniſh cuſtom, are a render of the beſt beaſt or other good (as the cuſtom may be) to the lord on the death of the tenant. This is plainly a relic of villein tenure; there being originally leſs hardſhip in it, when all the goods and chattles belonged to the lord, and he might have ſeized them even in the villein's lifetime. Theſe are incident to both ſpecies of copyhold; but wardſhip and fines to thoſe of inheritance only. Wardſhip, in copyhold-eſtates, partakes both of that in chilvalry and that in ſocage. Like that in chivalry, the lord is the legal guardian, who uſually aſſigns ſome relation of the infant tenant to act in his ſtead: and he, like guardian in ſocage, is accountable to his ward for the profits. Of fines, ſome are in the nature of primer-ſeiſins, due on the death of each tenant, others are mere fines for alienations of the lands; in ſome manors, only one of thoſe ſorts can be demanded, in ſome both, and in others neither. They are ſometimes arbitrary and at the will of the lord, ſometimes fixed by cuſtom; but, even when arbitrary, the courts of law, in favour of the liberty of copyholders, have tied them down to be reaſonable in their extent; otherwiſe they might amount to diſheriſon of the eſtate. No fine therefore is allowed to be taken upon deſcents and alienations (unleſs in particular circumſtances) of

more

Tenure. more than two years improved value of the eſtate. From this inſtance we may judge of the favourable diſpoſition that the law of England (which is a law of liberty) hath always ſhown to this ſpecies of tenants, by removing, as far as poſſible, every real badge of ſlavery from them, however ſome nominal ones may continue. It ſuffered cuſtom very early to get the better of the expreſs terms upon which they held their lands; by declaring, that the will of the lord was to be interpreted by the cuſtom of the manor; and, where no cuſtom has been ſuffered to grow up to the prejudice of the lord, as in this caſe of arbitrary fines, the law itſelf interpoſes in an equitable method, and will not ſuffer the lord to extend his power ſo far as to diſinherit the tenant.

4. There is yet a fourth ſpecies of tenure, deſcribed by Bracton, under the name ſometimes of *privileged villenage*, and ſometimes of *villein-ſocage*. See *Privileged* VILLENAGE.

Having in the preſent article and thoſe referred to, taken a compendious view of the principal and fundamental points of the doctrine of tenures, both ancient and modern, we cannot but remark the mutual connection and dependence that all of them have upon each other. And upon the whole it appears, that, whatever changes and alterations theſe tenures have in proceſs of time undergone, from the Saxon era to the 12 Car. II. all lay-tenures are now in effect reduced to two ſpecies; free tenure in common ſocage, and baſe tenure by copy of court-roll. But there is ſtill behind one other ſpecies of tenure, reſerved by the ſtatute of Charles II. which is of a ſpiritual nature, and called the tenure in *FRANK-Almoign*; ſee that article.

A particular account of the ancient tenures would to many perſons be highly amuſing. We can only ſelect a few of the moſt ſingular, referring the curious reader for more information to Anderſon's Origin of Commerce, Henry's Hiſtory of Britain, and Blount's *Fragmenta Antiquitates*.

In the 19th of Henry III. Walter Gately held the manor of Weſtcourt, in Bedington in Surry, yielding yearly to the king one croſs-bow, *baliſtam*, value twelve pence.

Anno tertio Edw. I. Oſbert de Lonchamp, knight, held his lands of Ovenhelle in Kent, for perſonally guarding the king forty days into Wales at his own expence, with one horſe of five ſhillings value, one ſack worth ſix-pence, and one broch for that ſack. *N. B.* All perſonal ſervices, or attendances on Engliſh kings in thoſe times, were limited to forty days, at their own expence.

The like the ſame year of Laurence de Broke, who for his hamlet of Renham in Middleſex, found the king one ſoldier, a horſe worth five ſhillings, a ſack worth fivepence, and a broch worth twopence (this broch was a kind of cup, jug, pot, or baſon), for forty days, at his own expence, wherever his army ſhall be within the four ſeas. This was ſettled (ſays Mr Blount) at the Stone Croſs, which ſtood near the May-pole in the Strand, London, where the judges itinerant uſed in old times to ſit.

Robert Maunſel's tenure of lands in Peverel paid the ſame ſervice, and the horſe, ſack, and broch, of the ſame prices.

13*mo* Edw. I. Henry de Averning's tenure of the manor of Morton in Eſſex, was to find a man, a horſe worth ten ſhillings, four horſe-ſhoes, a leather ſack, and an iron broch.

The year following, three perſons held thirty acres of land in Carleton in Norfolk, by the ſervice of bringing the king, whenever he ſhall be in England, twenty-four paſties of freſh herrings, at their firſt coming in.

Another held his manor in Norfolk of that king, by annually ſupplying him at his exchequer with two veſſels, called *mues*, of wine made of pearmains. "Here (ſays our author) it is worth obſerving, that in King Edward the Firſt's time pearmain cyder was called *wine*." This therefore ſeems to account for the mention of vineyards in old times in Kent, Suſſex, and other parts of England, which has ſo often puzzled many people to elucidate. Tenure ‖ Tercery.

Another perſon, in the 21ſt of the ſaid king, held thirty acres of land, valued at ten ſhillings yearly in the exchequer, or fourpence *per* acre, in Cambridgeſhire, for furniſhing a truſs of hay for the king's neceſſary-houſe or privy, whenever he ſhall come into that county.

Another, in the 34th of that king, held a manor in Kent, for providing a man to lead three greyhounds when the king ſhall go into Gaſcony, ſo long as a pair of ſhoes of fourpence ſhould laſt.

And that we may not again recur to theſe old tenures, we ſhall further add, from the ſame author, that in the firſt year of king Edward II. Peter Spileman made fine to the king for his lands by ſerjeanty, to find one to ſerve as a ſoldier for forty days in England, with a coat of mail; alſo to find ſtraw for the king's bed, and hay for his horſe.

This article of ſtraw for the king's bed we did not ſo much wonder at, when we found it in an article in William the Conqueror's time; but it is ſomewhat more remarkable ſo late as the days of king Edward the Second.

Several others, we find, held their lands of the crown in thoſe times by very different tenures. One, by paying two white capons annually; another, by carrying the king's ſtandard whenever he happens to be in the county of Suſſex; another, by carrying a rod or batoon before the king on certain occaſions; another, by ſerving the office of chamberlain of the exchequer, a very good place at preſent; another, by building and upholding a bridge; another, by being marechal (*meretricum*), *i. e.* as Mr Blount tranſlates it, of the laundreſſes in the king's army; another, by acting as a ſerjeant at arms for the king's army whilſt in England; one ſupplies a ſervant for the king's larder; another, for his wardrobe; others, to find ſervants for this or that foreſt; another, a hawk; one preſents the king a pair of ſcarlet hoſe annually; others are bound to ſupply ſoldiers with armour for certain days, for the keeping this or that caſtle; one, viz. for the manor of Elſton in Nottinghamſhire, pays yearly rent of one pound weight of cummin ſeed, two pair of gloves, and a ſteel needle; another, is to repair the iron-work of the king's ploughs; Ela Counteſs of Warwick, in the 13th year of king Edward I. held the manor of Hokenorton in Oxfordſhire, in the barony of D'Oyly, by the ſerjeanty of carving at the king's table on his birth-day, and ſhe to have the knife the king then uſes at table.

TEOS, one of the twelve Ionian cities, was ſituated on the ſouth ſide of the Ionian peninſula, and diſtinguiſhed by being the place where the poet Anacreon and the hiſtorian Hecatæus were born.

TERAPHIM, or THERAPHIM, a word in the Hebrew language, which has exerciſed much the ingenuity of the critics. It occurs 13 or 14 times in the Old Teſtament, and is commonly interpreted *idols*. We will not trouble our readers with the numerous conjectures which have been formed reſpecting the meaning of this word. The only way to determine it, if it be at all poſſible, would be to examine and compare all the paſſages in which it occurs, and to conſult the ancient tranſlations. Conjectures are uſeleſs; every man may make a new one, which will have juſt as good a title to belief as thoſe which have been already propoſed.

TERCERY, one of the largeſt iſlands of the Azores, or Weſtern Iſlands, lying in the Atlantic Ocean. It is about 40 miles in circumference; and ſurrounded with craggy rocks, which render it almoſt inacceſſible. The ſoil is

ſertile,

Terebella || Teredo.

fertile, abounding in corn, wine, and fruits; and they have such plenty of cattle, that they ſupply the ſhips therewith that call there. However, their principal trade is wood. The inhabitants are lively and well made; and they pretend to a great deal of religion and gallantry at the ſame time. They pique themſelves upon points of honour, and are extremely revengeful. It is their cuſtom to rove about in the night-time in queſt of intrigues, and ſeldom fail in finding women for their purpoſe. It is ſubject to Portugal; and Angra is the capital town. W. Long. 27. 1. N. Lat. 28. 45.

TEREBELLA, the Piercer, in natural hiſtory, a genus of inſects belonging to the claſs of *vermes*, and order of *molluſca*. The body is filiform, the mouth placed before; the preputium puts forth a pedunculated tubulous gland. There are ſeveral capillary tentacula about the mouth. There are ten ſpecies.

Terebinthine Electuary. See Pharmacy, n° 599.

TEREBINTHUS, in botany. See Pistacia.

TEREDO, in natural hiſtory, a genus of *vermes* belonging to the order of *teſtacea*. The animal is a terebella; there are two valves, calcareous, hemiſpherical, and cut off before, and two lanceolated. The ſhell is tapering, bending, and capable of penetrating wood. There are only three ſpecies; the *navalis*, *utriculus*, and *clava*.

The *navalis*, or ſhip-worm, which has a very ſlender ſmooth cylindrical ſhell, inhabits the Indian ſeas, whence it was imported into Europe. It penetrates eaſily into the ſtouteſt oak-planks, and produces dreadful deſtruction to the ſhips by the holes it makes in their ſides and it is to avoid the effects of this inſect that veſſels require ſheathing.

The head of this creature is well prepared by nature for the hard offices which it has to undergo, being coated with a ſtrong armour, and furniſhed with a mouth like that of the leech; by which it pierces wood, as that animal does the ſkin; a little above this it has two horns which ſeem a kind of continuation of the ſhell; the neck is as ſtrongly provided for the ſervice of the creature as the head, being furniſhed with ſeveral ſtrong muſcles; the reſt of the body is only covered by a very thin and tranſparent ſkin, through which the motion of the inteſtines is plainly ſeen by the naked eye; and by means of the microſcope ſeveral other very remarkable particulars become viſible there. This creature is wonderfully minute when newly excluded from the egg, but it grows to the length of four or ſix inches, and ſometimes more.

When the bottom of a veſſel, or any piece of wood which is conſtantly under water, is inhabited by theſe worms, it is full of ſmall holes; but no damage appears till the outer parts are cut away: Then their ſhelly habitations come into view; in which there is a large ſpace for incloſing the animal, and ſurrounding it with water. There is an evident care in theſe creatures never to injure one another's habitations; by this means each caſe or ſhell is preſerved entire; and in ſuch pieces of wood as have been found eaten by them into a ſort of honeycomb, there never is ſeen a paſſage or communication between any two of the ſhells, tho' the woody matter between them often is not thicker than a piece of writing-paper.

They penetrate ſome kinds of wood much more eaſily than others. They make their way moſt quickly into fir and alder, and grow to the greateſt ſize. In the oak they make ſmall progreſs, and appear ſmall and feeble, and their ſhells much diſcoloured. Terence, Term.

Since each of theſe animals is lodged in a ſolitary cell, and has no acceſs to thoſe of its own ſpecies, it has been matter of ſurpriſe how they ſhould increaſe to ſo vaſt a multitude. Upon diſſecting them, it appears that every individual has the parts of both ſexes, and is therefore ſuppoſed to propagate by itſelf.

The ſea-worms, which are pernicious to our ſhipping, appear to have the ſame office allotted them in the waters which the termites have on the land (ſee Termes). They will appear, on a very little conſideration, to be moſt important beings in the great chain of creation, and pleaſing demonſtrations of that infinitely wiſe and gracious Power which formed, and ſtill preſerves, the whole in ſuch wonderful order and beauty: for if it was not for the rapacity of theſe and ſuch animals, tropical rivers, and indeed the ocean itſelf, would be choked with the bodies of trees which are annually carried down by the rapid torrents, as many of them would laſt for ages, and probably be productive of evils, of which, happily, we cannot in the preſent harmonious ſtate of things form any idea (A); whereas now being conſumed by theſe animals, they are more eaſily broken in pieces by the waves; and the fragments which are not devoured become ſpecifically lighter, and are conſequently more readily and more effectually thrown on ſhore, where the ſun, wind, inſects, and various other inſtruments, ſpeedily promote their entire diſſolution. Phil. Tranſ. for 1781.

TERENCE, or Publius Terentius Afer, a celebrated comic poet of ancient Rome, was born at Carthage in Africa. He was ſlave to Terentius Lucanus the ſenator; who gave him his liberty on account of his wit, his good mien, and great abilities. Terence, on his becoming a freed man, applied himſelf to the writing of comedies; in the execution of which he imitated Menander and the other celebrated comic poets of Greece. Cicero gives him the moſt pompous eulogiums, both for the purity of his language and the perſpicuity and beauty of his compoſitions, which he conſiders as the rule and ſtandard of the Latin tongue; and obſerves, that they were eſteemed ſo fine and elegant, that they were thought to have been written by Scipio and Lelius, who were then the greateſt perſonages and the moſt eloquent of the Roman people. Terence died while on a voyage into Greece, about the 15th year before the Chriſtian era. There are ſix of his comedies extant, of which the beſt editions are the Elzevir one 1635. 12mo; that *cum integris notis Donati, et ſelectis variorum*, 1686, 8vo; Weſterhovius's, in two vols 4to 1726; and that of Bentley the ſame year 4to. Madam Dacier has given a beautiful French verſion of this author; and a very good Engliſh tranſlation was publiſhed in 4to, 1768, by Mr Colman.

TERM, in law, is generally taken for a limitation of time or eſtate; as, a leaſe for term of life or years.

Term, however, is more particularly uſed for that time wherein our courts of juſtice are open; in oppoſition to which, the reſt of the year is called *vacation*.

Term, in grammar, denotes ſome word or expreſſion in a language.

The word *term*, *terminus*, is borrowed metaphorically, by the grammarians and philoſophers, from the meaſurers or ſurveyors

(B) That wood will endure in water for many centuries, is apparent from the oak ſtakes which were driven into the bed of the river Thames on the invaſion of Britain by Julius Cæſar, one of which is to be ſeen in Sir Athion Lever's muſeum, and likewiſe from thoſe bodies of trees which are daily found in the bogs and Moraſſes of Great Britain and Ireland, which after a duration, the former of eighteen hundred, the latter of upwards of two thouſand years are found in a perfect ſtate of preſervation.

Terms. veyors of lands: as a field is defined and diſtinguiſhed by its *termini*, or limits, ſo is a thing or matter ſpoken of by the word or term it is denoted by.

Term in the Arts, or *Term of Art*, is a word which, beſides the literal and popular meaning which it has or may have in common language, bears a further and peculiar meaning in ſome art or ſcience.

Terms, the ſeveral times or ſeaſons of the year, wherein the tribunals, or courts of judicature, are open to all who think fit to complain of wrong, or to ſeek their rights by due courſe of law, or action; and during which the courts in Weſtminſter-hall ſit and give judgment. But the high court of parliament, the chancery, and inferior courts do not obſerve the terms; only the courts of king's-bench, common-pleas, and exchequer, which are the higheſt courts at common law. In contradiſtinction to theſe, the reſt of the year is called *vacation*.

Of theſe terms there are four in every year, during which time matters of juſtice are diſpatched. *Hilary-term*, which, at London, begins the 23d day of January, or if that be Sunday, the next day after; and ends the 12th of February following. *Eaſter-term*, which begins the Wedneſday fortnight after Eaſter-day, and ends the Monday next after Aſcenſion-day. *Trinity-term*, beginning the Friday next after Trinity-Sunday, and ending the Wedneſday fortnight after. *Michaelmas-term*, which begins the ſixth day of November, and ends the 28th of November following. Each of theſe terms have alſo their returns. Theſe terms are ſuppoſed by Mr Selden to have been inſtituted by William the Conqueror; but Sir H. Spelman hath ſhewn, that they were gradually formed from the canonical conſtitutions of the church; being no other than thoſe leiſure ſeaſons of the year which were not occupied by the great feſtivals or faſts, or which were not liable to the general avocations of rural buſineſs. Throughout all Chriſtendom, in very early times, the whole year was one continual term for hearing and deciding cauſes. For the Chriſtian magiſtrates, in order to diſtinguiſh themſelves from the heathens, who were very ſuperſtitious in the obſervation of their *dies faſti* and *nefaſti*, adminiſtered juſtice upon all days alike; till at length the church interpoſed, and exempted certain holy ſeaſons from being profaned by the tumult of forenſic litigations; as, particularly, the time of Advent and Chriſtmas, which gave riſe to the winter vacation; the time of Lent and Eaſter, which created that in the ſpring; the time of Pentecoſt, which produced the third; and the long vacation, between midſummer and Michaelmas, which was allowed for the hay-time and harveſt. All Sundays alſo, and ſome peculiar feſtivals, as the days of the purification, aſcenſion, &c. were included in the ſame prohibition, which was eſtabliſhed by a canon of the church, A. D. 517, and fortified by an imperial conſtitution of the younger Theodoſius, comprized in the Theodoſian code. Afterwards, when our own legal conſtitution was eſtabliſhed, the commencement and duration of our law terms were appointed, with a view to theſe canonical prohibitions; and it was ordered by the laws of king Edward the Confeſſor, that from Advent to the octave of the Epiphany, from Septuageſima to the octave of Eaſter, from the Aſcenſion to the octave of Pentecoſt, and from three in the afternoon of all Saturdays till Monday morning, the peace of God and holy church ſhall be kept throughout the whole kingdom.

And ſo extravagant was afterwards the regard paid to theſe holy times, that though the author of the Mirror mentions only one vacation of conſiderable length, containing the months of Auguſt and September, yet Britton ſays, that in the reign of king Edward I. no ſecular plea could be held, nor any man ſworn on the Evangeliſts, in the time of Advent, Lent, Pentecoſt, harveſt, and vintage, the days of the great litanies, and all ſolemn feſtivals. He adds, that the biſhops and prelates granted diſpenſations for taking aſſizes and juries in ſome of theſe holy ſeaſons, upon reaſonable occaſions; and ſoon after a general diſpenſation was eſtabliſhed in parliament by ſtat. Weſtm. 1. 3. Edw. I. cap. 51. that aſſizes of novel diſſeiſin, *mort d' anceſtor*, and darrein preſentment, ſhould be taken in Advent, Septuageſima, and Lent, as well as inqueſts; at the ſpecial requeſt of the king to the biſhops. The portions of time that were not included within theſe prohibited ſeaſons fell naturally into a fourfold diviſion; and from ſome feſtival, or ſaint's day, that immediately preceded their commencement, were denominated the terms of *St Hilary*, of *Eaſter*, of the *Holy Trinity*, and of *St Michael*: which terms have been ſince regulated and abbreviated by ſeveral acts of parliament; particularly Trinity-term by ſtat. 32 Hen. VIII. cap. 2. and Michaelmas-term by ſtat. 16 Car. I. cap. 6. and again by ſtat. 24 Geo. II. cap. 48. Terms, Termes.

Terms, *Oxford*. Hilary or Lent-term begins January 14th, and ends the Saturday before Palm-Sunday. Eaſter-term begins the tenth day after Eaſter, and ends the Thurſday before Whitſunday. Trinity-term begins the Wedneſday after Trinity-Sunday, and ends after the act, or 6th of July, ſooner or later, as the vice-chancellor and convocation pleaſe. Michaelmas-term begins October the 10th, and ends December the 17th.

Terms, *Cambridge*. Lent term begins January the 14th, and ends Friday, before Palm-Sunday. Eaſter-term begins the Wedneſday after Eaſter-week, and ends the week before Whitſunday. Trinity-term begins the Wedneſday after Trinity-Sunday, and ends the Friday after the commencement, or 2d of July. Michaelmas-term begins October the 10th, and ends December the 16th.

Terms, *Scottiſh*. The court of ſeſſion has two terms, the winter and ſummer. The winter begins on 12th November, and ends 11th March, only there is a receſs of three weeks at Chriſtmas. The ſummer term commences 12th May, and ends 11th July. The court of exchequer has four terms: 1. Candlemas term begins 15th January, and ends 3d February; 2. Whitſuntide term begins 12th May, and ends 2d June; 3. Lammas term begins 17th June, and ends 5th July; 4. Martinmas term begins 24th November, and ends 20th December.

Terms, *Iriſh*. In Ireland the terms are the ſame as at London, except Michaelmas-term, which begins October the 13th, and adjourns to November the 3d, and thence to the 6th.

TERMES, in etymology; a genus of inſects belonging to the order of *aptera*, according to Linnæus, but by others it is arranged more properly under the *neuroptera*. The mouth has two horny jaws; the lip is horny and quadrifid, the laciniæ being linear and acute: there are four feelers, which are equal and filiform. The antennæ are moniliform in moſt ſpecies, and the eyes two. There are eight ſpecies, according to Gmelin; the *fatale*, *deſtructor*, *arda*, *mordax*, *capenſe*, *fatidicum*, *pulſatorium*, and *divinatorium*. But as Gmelin has followed the claſſification of Linnæus in arranging the termes under the order of aptera, it is not improbable that ſeveral of theſe which are mentioned as ſpecies of the termes may belong to a different genus. It will be ſufficient, in the preſent article, to deſcribe the fatale, which we are enabled to do from very accurate information.

The *termes fatale*, *bellicoſus*, or white ant, is of a yellow colour above; the wings alſo yellowiſh; the coſta is ferruginous; the ſtemmata are near the eyes, the central point being ſomewhat prominent. Of the white ant we have a very curious and intereſting deſcription, in the Philoſophical

Termes. sophical Tranſactions for 1781, by Mr Henry Smeathman of Clement's Inn. According to this account, the works of theſe inſects ſurpaſs thoſe of the bees, waſps, beavers, and other animals, as much at leaſt as thoſe of the moſt poliſhed European nations excel thoſe of the leaſt cultivated ſavages. And even with regard to man, his greateſt works, the boaſted pyramids, fall comparatively far ſhort, even in ſize alone, of the ſtructures raiſed by theſe inſects. The labourers among them employed in this ſervice are not a quarter of an inch in length; but the ſtructures which they erect riſe to 10 or 12 feet and upwards above the ſurface of the earth. Suppoſing the height of a man to be ſix feet, the author calculates, that the buildings of theſe inſects may be conſidered, relatively to their ſize and that of a man, as being raiſed to near five times the height of the greateſt of the Egyptian pyramids; that is, correſponding with conſiderably more than half a mile. We may add, that, with reſpect to the interior conſtruction, and the various members and diſpoſitions of the parts of the building, they appear greatly to exceed that or any other work of human conſtruction.

The moſt ſtriking parts of theſe ſtructures are, the royal apartments, the nurſeries, magazines of proviſions, arched chambers and galleries, with their various communications; the ranges of Gothic ſhaped arches, projected, and not formed by mere excavation, ſome of which are two or three feet high, but which diminiſh rapidly, like the arches of ailes in perſpectives; the various roads, ſloping ſtaircaſes, and bridges, conſiſting of one vaſt arch, and conſtructed to ſhorten the diſtance between the ſeveral parts of the building, which would otherwiſe communicate only by winding paſſages. In ſome parts near Senegal, their number, magnitude, and cloſeneſs of ſituation, make them appear like the villages of the natives. But theſe and many other curious inſtances of the great ſagacity and powers of theſe inſects cannot be underſtood, without viewing the plates in which their feeble frames, and comparatively ſtupendous works, are delineated. See Phil. Tranſ. above referred to.

The economy of theſe induſtrious inſects appears to have been very attentively obſerved by the ingenious author, as well as their buildings. There are three diſtinct ranks or orders among them, conſtituting a well-regulated community. Theſe are, firſt, the *labourers*, or working inſects; next the *ſoldiers*, or fighting order, who do no kind of labour, and are about twice as long as the former, and equal in bulk to about 15 of them; and laſtly, the winged or perfect inſects, which may be called the *nobility* or *gentry* of the ſtate; for they neither labour nor fight, being ſcarcely capable even of ſelf-defence. "Theſe only are capable of being elected *kings* or *queens*; and nature has ſo ordered it, that they emigrate within a few weeks after they are elevated to this ſtate, and either eſtabliſh new kingdoms, or periſh within a day or two."

The firſt order, the working inſects, are moſt numerous, being in the proportion of 100 to 1 of the ſoldiers. In this ſtate they are about $\frac{1}{4}$ of an inch long, and 25 of them weigh about a grain, ſo that they are not ſo large as ſome of our ants. See Plate DI. fig. 1. and 2.

The ſecond order, or ſoldiers, have a very different form from the labourers, and have been by ſome authors ſuppoſed to be the males, and the former neuters; but they are, in fact, the ſame inſects as the foregoing, only they have undergone a change of form, and approached one degree nearer to the perfect ſtate. They are now much larger, being half an inch long, and equal in bulk to fifteen of the labourers, (fig. 3. and 4.)

The third order or the inſect in its perfect ſtate, varies its form ſtill more than ever. The head, thorax, and abdomen, differ almoſt entirely from the ſame parts in the labourers and ſoldiers; and, beſides this, the animal is now furniſhed with four fine large browniſh, tranſparent, wings, with which it is at the time of emigration to wing its way in ſearch of a new ſettlement. It differs ſo much from the other two, that they have not hitherto been ſuppoſed to belong to the ſame community. In fact, they are not to be diſcovered in the neſt till juſt before the commencement of the rainy ſeaſon; when they undergo the laſt change, which is preparative to the formation of new colonies. They are equal in bulk to two ſoldiers or about 30 labourers (ſee fig. 5.), and by means of the wings with which they are furniſhed they roam about for a few hours; at the end of which time they loſe their wings, and become the prey of innumerable birds, reptiles, and inſects: while probably not a pair out of many millions of this unhappy race get into a place of ſafety, fulfil the firſt law of nature, and lay the foundation of a new community. In this ſtate many fall into the neighbouring waters, and are eaten with avidity by the Africans. The author found them delicate, nouriſhing, and wholeſome, without ſauce or other help from cookery than merely roaſting them in the manner of coffee.

The few fortunate pairs who happen to ſurvive this annual maſſacre and deſtruction, are repreſented by the author as being caſually found by ſome of the labourers, that are continually running about on the ſurface of the ground, and are elected kings and queens of new ſtates. Thoſe who are not ſo elected and preſerved certainly periſh, and moſt probably in the courſe of the following day. By theſe induſtrious creatures the king and queen elect are immediately protected from their innumerable enemies, by incloſing them in a chamber of clay; where the buſineſs of propagation ſoon commences. Their "voluntary ſubjects" then buſy themſelves in conſtructing wooden nurſeries, or apartments entirely compoſed of wooden materials, ſeemingly joined together with gums. Into theſe they afterwards carry the eggs produced from the queen, lodging them there as faſt as they can obtain them from her. The author even furniſhes us with plauſible reaſons to believe, that they here form a kind of garden for the cultivation of a ſpecies of microſcopical muſhroom; which Mr Konig (in an Eſſay on the Eaſt Indian Termites, read before the Society of Naturaliſts of Berlin) conjectures to be the food of the young inſects. But perhaps the moſt wonderful, and at the ſame time beſt authenticated, part of the hiſtory of theſe ſingular inſects, is that which relates to the queen or mother of the community in her pregnant ſtate.

After impregnation, a very extraordinary change begins to take place in her perſon, or rather in her abdomen only. It gradually increaſes in bulk, and at length becomes of ſuch an enormous ſize as to exceed the bulk of the reſt of her body 1500 or 2000 times. She becomes 1000 times heavier than her conſort, and exceeds 20,000 or 30,000 times the bulk of one of the labourers. In this ſtate, the matrix has a conſtant periſtaltic or undulating motion; the conſequence of which is (as the author has counted them) (fig. 8.) the protruſion of 80,000 eggs in 24 hours.

Theſe eggs, ſays the author, "are inſtantly taken from her body by her attendants (of whom there always are, in the royal chamber and the galleries adjacent, a ſufficient number in waiting) and carried to the nurſeries, which are ſometimes four or five feet diſtant in a ſtraight line.—Here, after they are hatched, the young are attended and provided with every thing neceſſary, until they are able to ſhift for themſelves, and take their ſhare of the labours of the community."

Many curious and ſtriking particulars are related of the

Termes. great devaſtations committed by this powerful community; which conſtruct roads, or rather covered ways, diverging in all directions from the neſt, and leading to every object of plunder within their reach. Though the miſchiefs they commit are very great, ſuch is the economy of nature, that it is probably counterbalanced by the good produced by them; in quickly deſtroying dead trees and other ſubſtances, which, as the author obſerves, would, by a tedious decay, ſerve only to encumber the face of the earth. Such is their alacrity and diſpatch in this office, that the total deſtruction of deſerted towns is ſo effectually accompliſhed, that in two or three years a thick wood fills the ſpace; and not the leaſt veſtigate of a houſe is to be diſcovered.

From the many ſingular accounts here given of the police of theſe inſects, we ſhall mention one reſpecting the different functions of the labourers and ſoldiers, or the civil and military eſtabliſhments in this community, on an attempt to examine their neſt or city.

On making a breach in any part of the ſtructure with a hoe or pick-axe, a ſoldier immediately appears, and walks about the breach, as if to ſee whether the enemy is gone, or to examine whence the attack proceeds. In a ſhort time he is followed by two or three others, and ſoon afterwards by a numerous body, who ruſh out as faſt as the breach will permit them; their numbers increaſing as long as any one continues to batter the building. During this time they are in the moſt violent buſtle and agitation; while ſome of them are employed in beating with their forceps upon the building, ſo as to make a noiſe that may be heard at three or four feet diſtance. On ceaſing to diſturb them, the ſoldiers retire, and are ſucceeded by the labourers, who haſten in various directions towards the breach, each with a burden of mortar in his mouth ready tempered. Though there are millions of them, they never ſtop or embarraſs each other; and a wall gradually ariſes that fills up the chaſm. A ſoldier attends every 600 or 1000 of the labourers, ſeemingly as a director of the works; for he never touches the mortar, either to lift or carry it. One in particular places himſelf cloſe to the wall which they are repairing, and frequently makes the noiſe abovementioned; which is conſtantly anſwered by a loud hiſs from all the labourers within the dome: and at every ſuch ſignal, they evidently redouble their pace, and work as faſt again.

The work being completed, a renewal of the attack conſtantly produces the ſame effects. The ſoldiers again ruſh out, and then retreat, and are followed by the labourers loaded with mortar, and as active and diligent as before. "Thus, ſays the author, the pleaſure of ſeeing them come out to fight or to work alternately may be obtained as often as curioſity excites or time permits: and it will certainly be found, that the one order never attempts to fight, or the other to work, let the emergency be ever ſo great." The obſtinacy of the ſoldiers is remarkable. "They fight to the very laſt, diſputing every inch of ground ſo well as often to drive away the negroes, who are without ſhoes, and make white people bleed plentifully through their ſtockings."

Such is the ſtrength of the buildings erected by theſe puny inſects, that when they have been raiſed to little more than half their height, it is always the practice of the wild bulls to ſtand as centinels upon them, while the reſt of the herd is ruminating below. When at their full height of 10 or 12 feet, they are uſed by the Europeans as places to look out from over the top of the graſs, which here grows to the height of 13 feet upon an average. The author has ſtood with four men on the top of one of theſe buildings, in order to get a view of any veſſel that might come in ſight. Termes.

It may appear ſurpriſing how a Being perfectly good ſhould have created animals which ſeem to ſerve no other end but to ſpread deſtruction and deſolation wherever they go. But let us be cautious in ſuſpecting any imperfection in the Father of the Univerſe. What at firſt ſight may ſeem only productive of miſchief, will, upon mature deliberation, be found worthy of that wiſdom which planned the moſt beautiful parts of the world. Many poiſons are valuable medicines; the ſtorms are beneficial; and diſeaſes often promote life. Theſe termites, indeed, are frequently pernicious to mankind, but they are alſo very uſeful and even neceſſary; one valuable purpoſe which they ſerve is, to deſtroy decayed trees and other ſubſtances, which, if left on the ſurface of the ground in hot climates, would in a ſhort time pollute the air. In this reſpect they reſemble very much the common flies, which are regarded by mankind in general as noxious, and at beſt as uſeleſs beings in the creation; but this is certainly for want of conſideration. There are not probably in all nature animals of more importance; and it would not be difficult to prove, that we ſhould feel the want of one or two ſpecies of large quadrupeds much leſs than of one or two ſpecies of theſe deſpicable-looking inſects. Mankind in general are ſenſible that nothing is more diſagreeable, or more peſtiferous, than putrid ſubſtances; and it is apparent to all who have made obſervation, that thoſe little inſects contribute more to the quick diſſolution and diſperſion of putreſcent matter than any other. They are ſo neceſſary in all hot climates, that even in the open fields a dead animal or ſmall putrid ſubſtance cannot be laid upon the ground two minutes before it will be covered with flies and their maggots, which inſtantly entering quickly devour one part, and perforating the reſt in various directions, expoſe the whole to be much ſooner diſſipated by the elements. Thus it is with the termites; the rapid vegetation in hot climates, of which no idea can be formed by any thing to be ſeen in this, is equalled by as great a degree of deſtruction from natural as well as accidental cauſes (A). It ſeems apparent that when any thing whatever is arrived at its laſt degree of perfection, the Creator has decreed it ſhall be totally deſtroyed as ſoon as poſſible, that the face of nature may be ſpeedily adorned with freſh productions in the bloom of ſpring or the pride of ſummer: ſo when trees, and even woods, are in part deſtroyed by tornadoes or fire, it is wonderful to obſerve how many agents are employed in haſtening the total diſſolution of the reſt; but in the hot climates there are none ſo expert, or who do their buſineſs ſo expeditiouſly and effectually, as theſe inſects, who in a few weeks deſtroy and carry away the bodies of large trees, without leaving a particle behind, thus clearing the place for other vegetables, which ſoon fill up every vacancy; and in places where two or three years before there has been a populous town, if the inhabitants, as is frequently the caſe, have choſen to abandon it, there ſhall be a very thick wood, and not the veſtige of a poſt to be ſeen, unleſs the wood has been of a ſpecies which, from its hardneſs, is called *iron wood*.

Fig.

(A) The Guinea graſs, which is ſo well known and ſo much eſteemed by the planters in the Weſt Indies, grows in Africa, as we have already mentioned, thirteen feet high upon an average, which height it attains in about five or ſix months; and the growth of many other plants is as quick.

Terminalia || Ternſtromia.

Fig. 1. repreſents a labourer. Fig. 2. a labourer magnified. Fig. 3. a ſoldier. Fig. 4. a ſoldier, forceps, and part of his head magnified. Fig. 5. a perfect termes bellicoſus. Fig. 6. the head of a perfect inſect magnified. Fig. 7. a head with ſtemmata magnified. Fig. 8. a queen. Fig. 9. a king. Fig. 10. is a ſection of the building raiſed by theſe inſects, as it would appear on being cut down through the middle from the top a foot lower than the ſurface of the ground. AA, an horizontal line from A on the left, and a perpendicular line from A at the bottom, will interſect each other at the royal chamber. The darker ſhades near it are the empty apartments and paſſages, which it ſeems are left ſo for the attendants on the king and queen, who, when old, may require near 100,000 to wait on them every day. The parts which are the leaſt ſhaded and dotted are the nurſeries, ſurrounded, like the royal chamber, by empty paſſages, on all ſides, for the more eaſy acceſs to them with the eggs from the queen, the proviſion for the young, &c. *N. B.* The magazines of proviſions are ſituated without any ſeeming order among the vacant paſſages which ſurround the nurſeries. B, the top of the interior building, which often ſeems, from the arches carrying upward, to be adorned on the ſides with pinnacles. C, the floor of the area or nave. DDD, the large galleries which aſcend from under all the buildings ſpirally to the top. EE, the bridges.

TERMINALIA, in antiquity, feaſts celebrated by the Romans in honour of the god Terminus.

TERMINALIA, in botany; a genus of plants belonging to the claſs of *polygamia*, and order of *monœcia*. The male calyx is quinquepartite; there is no corolla; the ſtamina are ten in number. The hermaphrodite flower is the ſame with that of the male; there is one ſtyle; the fruit, which is a drupe or plum, is below, and ſhaped like a boat. There are two ſpecies; the catappa, and anguſtifolia or benzoin. This ſpecies does not, however, yield benzoin. See STYRAX.

TERMINI, in architecture, denotes a kind of ſtatues or columns, adorned on the top with the figure of a man's, woman's, or ſatyr's head, as a capital; and the lower part ending in a kind of ſheath or ſcabbard.

TERMINUS, in Pagan worſhip, an ancient deity among the Romans, who preſided over the ſtones or land marks, called *termini*, which were held ſo ſacred, that it was accounted ſacrilege to move them; and as the criminal became devoted to the gods, it was lawful for any man to kill him. The worſhip of this deity was inſtituted by Numa Pompilius, who, to render land marks, and conſequently the property of the people, ſacred, erected a temple on the Tarpeian mount to Terminus.

TERN, in ornithology. See STERNA.

TERNATE, the moſt northerly of the Molucca or Clove Iſlands in the Eaſt Indies. It abounds in cocoa-nuts, bananas, citrons, oranges, almonds, and other fruit proper to the torrid zone; but cloves are the moſt valuable produce. It is in the poſſeſſion of the Dutch. Malaya is the capital town. E. Long. 129. 0. N. Lat 1. 0.

TERNI, a town of Italy in the Pope's territories, and in the duchy of Spoletto, with a biſhop's ſee. It is but a ſmall place; though there are very beautiful ruins of antiquity, it having been a very conſiderable Roman colony. It is ſituated on the top of a high mountain, and to the weſt of it are fields which are extremely fertile. E. Long. 12. 40. N. Lat. 42. 34.

TERNSTROMIA, in botany; a genus of plants belonging to the claſs of *polyandria*, and order of *monogynia*. The calyx is monophyllous and quinquepartite: the corolla is monopetalous, quinquepartite or ſexpartite, globular, and bell-ſhaped: the berry is dry, bilocular, and valveleſs. There is only one ſpecies, the meridionalis.

Terpander, Terra.

TERPANDER, a celebrated Greek poet and muſician. The Oxford marbles tell us that he was the ſon of Derdeneus of Leſbos, and that he flouriſhed in the 381ſt year of theſe records; which nearly anſwers to the 27th Olympiad, and 671ſt year B. C. The marbles inform us likewiſe, that he taught the *nomes*, or airs, of the lyre and flute, which he performed himſelf upon this laſt inſtrument, in concert with other players on the flute. Several writers tell us that he added three ſtrings to the lyre, which before his time had but four; and in confirmation of this, Euclid and Strabo quote two verſes, which they attribute to Terpander himſelf.

The tetrachord's reſtraint we now deſpiſe,
The ſeven-ſtring'd lyre a nobler ſtrain ſupplies.

Among the many ſignal ſervices which Terpander is ſaid to have done to muſic, none was of more importance than the notation that is aſcribed to him for aſcertaining and preſerving melody, which before was traditional, and wholly dependent on memory. The invention, indeed, of muſical characters has been attributed by Alypius and Gaudentius, two Greek writers on muſic, and upon their authority by Boethius, to Pythagorus, who flouriſhed full two centuries after Terpander. But Plutarch, from Heraclides of Pontus, aſſures us that Terpander, the inventor of nomes for the cithara, in hexameter verſe, ſet them to muſic, as well as the verſes of Homer, in order to ſing them at the public games: And Clemens Alexandrinus, in telling us that this muſician wrote the laws of Lycurgus in verſe, and ſet them to muſic, makes uſe of the ſame expreſſion as Plutarch; which ſeems clearly to imply a written melody.

After enumerating the airs which Terpander had compoſed, and to which he had given names, Plutarch continues to ſpeak of his other compoſitions; among which he deſcribes the proems, or hymns for the cithara, in heroic verſe. Theſe were uſed in after times by the Rhapſodiſts, as prologues or introductions to the poems of Homer and other ancient writers. But Terpander rendered his name illuſtrious, no leſs by his performances both upon the flute and cithara than by his compoſitions. This appears by the marbles already mentioned; by a paſſage in Athenæus, from the hiſtorian Hellanicus, which informs us that he obtained the firſt prize, in the muſical conteſts at the Carnean games; and by the teſtimony of Plutarch, who ſays, that "no other proof need be urged of the excellence of Terpander in the art of playing upon the cithara, than what is given by the regiſter of the Pythic games, from which it appears that he gained four prizes ſucceſſively at thoſe ſolemnities.

Of the works of this poet only a few fragments are now remaining.

TERRA AUSTRALIS INCOGNITA, a name for a large unknown continent, ſuppoſed to lie towards the South Pole, and which for a long time was ſought after by navigators. The late voyages of Captain Cook have aſcertained this matter as much as it probably ever will be. (See *South-Sea, Cook's Diſcoveries*, n° 47, 48, 68, 69. and AMERICA, n° 4). On this ſubject Captain Cook expreſſes himſelf as follows: "I had now made the circuit of the Southern Ocean in a high latitude, and traverſed it in ſuch a manner as to leave not the leaſt room for the poſſibility of there being a continent, unleſs near the pole, and out of the reach of navigation. By twice viſiting the tropical ſea, I had not only ſettled the ſituation of ſome old diſcoveries, but made there many new ones, and left, I conceive, very little more to be done even in that part. Thus I flatter myſelf, that

Terra. that the intention of the voyage has in every reſpect been fully anſwered; the ſouthern hemiſphere ſufficiently explored; and a final end put to the ſearching after a ſouthern continent, which has at times engroſſed the attention of ſome of the maritime powers for near two centuries paſt, and been a favourite theory amongſt the geographers of all ages. That there may be a continent, or large tract of land near the pole, I will not deny: on the contrary, I am of opinion there is; and it is probable that we have ſeen a part of it. The exceſſive cold, the many iſlands, and vaſt floats of ice, all tend to prove that there muſt be land to the ſouth; and for my perſuaſion that this ſouthern land muſt lie or extend fartheſt to the north, oppoſite to the Southern Atlantic and Indian Oceans, I have already aſſigned ſome reaſons; to which I may add, the greater degree of cold experienced by us in theſe ſeas than in the Southern Pacific Ocean under the ſame parallels of latitude."

Terra Firma, in geography, is ſometimes uſed for a continent, in contradiſtinction to iſlands.

Terra Firma, otherwiſe called *New Caſtile* or *Caſtella del Oro*, a country of America, bounded on the north by the North Sea and part of the Atlantic Ocean, by the ſame ſea and Guiana on the eaſt, by the country of the Amazons and Peru on the ſouth, and by the Pacific Ocean and Veragua on the weſt. It lies between 62 and 83 degrees of weſt longitude, and between the equator and 12 degrees of north latitude; being upwards of 1200 miles in length from eaſt to weſt, and 800 in breadth from north to ſouth. It had the name of *Caſtella del Oro* from the quantities of gold found in the diſtricts of Uraba and other parts; and was firſt diſcovered by the celebrated Columbus in his third voyage.

The climate is neither pleaſant nor healthy; the inhabitants one part of the year being ſcorched by the moſt intenſe and burning heat, and the other almoſt drowned with perpetual floods of rain, pouring from the ſky with ſuch violence as if a general deluge was to enſue.

In ſo large a tract of country the ſoil muſt neceſſarily vary. Accordingly, in ſome parts it is a barren ſand, or drowned mangrove land, that will ſcarce produce any kind of grain; in others it yields Indian corn, balms, gums, and drugs, almoſt all manner of Fruits as well of Old as of New Spain, ſugar, tobacco, Braſil wood, and ſeveral other kinds of dyeing woods; a variety of precious ſtones, particularly emeralds and ſapphires; veniſon and other game. The plantations of cacao, or chocolate nuts, in the diſtrict of the Caraccas, are eſteemed the beſt in America. The mountains abound with tygers, and, according to ſome, with lions, and great numbers of other wild beaſts. The rivers, ſeas, and lakes, teem with fiſh, and alſo with alligators; and the bowels of the earth were once furniſhed with the richeſt treaſures, now almoſt exhauſted. The ſame may be ſaid of the pearl-fiſheries on the coaſt, which are far from being ſo profitable now as formerly.

Terra Firma is a very mountainous country. Terra Firma Proper, in particular, conſiſts of prodigious high mountains, and deep valleys flooded more than half the year. The Terra. mountains in the provinces of Carthagena and St Martha, according to Dampier, are the higheſt in the world; being ſeen at ſea 200 miles off: from theſe run a chain of hills of almoſt equal height, quite through South America, as far as the Straits of Magellan, called the *Cordilleras des Andes*. The province of Venezuela alſo, and diſtrict of the Caraccas, the moſt northerly parts of South America, are almoſt a continued chain of hills, ſeparated by ſmall valleys, pointing upon the coaſt of the North Sea. A chain of barren mountains, almoſt impaſſable, runs through the province of Popayan from north to ſouth, ſome whereof are volcanoes; but towards the ſhores of the Pacific Ocean it is a low country, flooded great part of the year.

The principal rivers of Terra Firma are, the Darien, Chagtre, Santa Maria, Conception, Rio Grande or Magdalena, Maricaibo, and Oroonoko.

Terra Firma contains the provinces of Terra Firma Proper or Darien, of Carthagena, St Martha, Rio de la Hacha, Venezuela, Comana, New Andaluſia or Paria, New Granada, and Popayan.

Terra Firma Proper lies in the form of a creſcent, about the ſpacious bay of Panama, being the iſthmus which joins South and North America; and extending in length between the two ſeas 300 miles, but in breadth, where the iſthmus is narroweſt, only 60. Here are found gold mines, gold ſands, and fine pearls; and though the land is generally rough, there are ſome fruitful valleys, watered by rivers, brooks, and ſprings. The chief places are Panama and Porto Bello.

The inhabitants of Terra Firma have never been thoroughly ſubdued, and in all probability never will; as they are a brave and warlike people, have retreats inacceſſible to Europeans, and bear an inveterate enmity to the Spaniards. See Darien.

Terra Japonica, more commonly called *catechu*, a drug formerly ſuppoſed to be an extract from the ſeeds of the areca catechu, but lately diſcovered by Mr Kerr, aſſiſtant ſurgeon to the civil hoſpital at Bengal, to be obtained from the *mimoſa catechu*. Mr Kerr gives the following account of the manner in which the extract is made: "After felling the trees, the manufacturer carefully cuts off all the exterior white part of the wood. The interior coloured wood is cut Med. Obſ. into chips, with which he fills a narrow-mouthed unglazed and Inquiearthen pot, pouring water upon them until he ſees it ries, vol. v. among the upper chips; when this is half evaporated by boiling, the decoction, without ſtraining, is poured into a flat earthen pot, and boiled to one third part; this is ſet in a cool place for one day, and afterwards evaporated by the heat of the ſun, ſtirring it ſeveral times in the day. When it is reduced to a conſiderable thickneſs, it is ſpread upon a mat or cloth, which has previouſly been covered with the aſhes of cow-dung; this maſs is divided into ſquare or quadrangular pieces by a ſtring, and completely dried by turning them frequently in the ſun until they are fit for ſale (A)."

This extract is called *cutt* by the natives, by the Engliſh

(A) "In making the extract, the pale brown wood is preferred, as it produces the fine whitiſh extract; the darker the wood is, the blacker the extract, and of leſs value. They are very careful in drying their pots upon the fire before they are uſed; but very negligent in cutting their chips upon the ground, and not ſtraining the decoction; by which, and the dirty aſhes they uſe, there muſt be a conſiderable quantity of earth in the extract, beſides what avarice may prompt them to put into it.

"The antiſeptic quality of catechu appears from the experiments made by Sir John Pringle. Huxham employed it ſucceſsfully in caſes where a putrid diſſolved ſtate of the blood prevailed. This extract is the principal ingredient in an ointment of great repute in India, compoſed of catechu four ounces, alum nine drams, white reſin four ounces; theſe are reduced

Terra ‖ Terraſſon.

liſh *catch*, and by different authors *terra japonica*, *catechu*, *khaath*, *cate*, *cachou*, &c. "In its pureſt ſtate it is a dry pulverable ſubſtance, outwardly of a reddiſh colour, internally of a ſhining dark brown, tinged with a reddiſh hue; in the mouth it diſcovers conſiderable aſtringency, ſucceeded by a ſweetiſh mucilaginous taſte." According to Lewis, "it diſſolves almoſt totally in water, excepting the impurities; which are uſually of the ſandy kind, and amounting in the ſpecimens I examined to about one eighth of the maſs. Of the pure matter, rectified ſpirit diſſolves about ſeven eighths into a deep red liquor: the part which it leaves undiſſolved is an almoſt inſipid mucilaginous ſubſtance." Woodville's Medical Botany, vol. ii.

Uſes. Catechu may be uſefully employed for moſt purpoſes where an aſtringent is indicated, provided the moſt powerful be not required. But it is particularly uſeful in alvine fluxes; and where theſe require the uſe of aſtringents, we are acquainted with no one equally beneficial. Beſides this, it is employed alſo in uterine profluvia, in laxity and debility of the viſcera in general, in catarrhal affections, and various other diſeaſes where aſtringents are neceſſary. It is often ſuffered to diſſolve leiſurely in the mouth, as a topical aſtringent for laxities and exulcerations of the gums, for aphthous ulcers in the mouth, and ſimilar affections. This extract is the baſis of ſeveral fixed formulæ in our pharmacopœias, particularly of a tincture and an electuary: but one of the beſt forms under which it can be exhibited, is that of a ſimple infuſion in warm water, with a proportion of cinnamon or caſſia; for by this means it is at once freed from its impurities, and improved by the addition of the aromatic.

Terra Puzzolana. See Puzzolana.

Terræ Filius, Son of the Earth, a ſtudent of the univerſity of Oxford, formerly appointed in public acts to make ſatirical and jeſting ſpeeches againſt the members thereof, to tax them with any growing corruptions, &c.

Terra Sigillata Lemnia. See Adansonia.

TERRACE, a walk or bank of earth, raiſed in a garden or court to a due elevation for a proſpect. The name is alſo given to the roofs of houſes that are flat, and whereon we may walk.

TERRAQUEOUS, in geography, a name given to our globe, becauſe conſiſting of land and water.

TERRAS, or Traas, in mineralogy, a ſpecies of argillaceous earth. It differs but little in its principles from puzzolana, but is much more compact and hard, porous and ſpungy. It is generally of a whitiſh yellow colour, and contains more heterogeneous particles, as ſpar, quartz, ſhoerl, &c. and ſomething more of calcareous earth; it effervеſces with acids, is magnetic, and fuſible *per ſe*. When pulverized, it ſerves as a cement, like puzzolana. It is found in Germany and Sweden. Kirwan's Mineralogy.

A ſpecies of red earth has been found in the pariſh of St Elizabeth in Jamaica, which turns out to be an excellent ſubſtitute for terras or puzzolana earth, and may therefore be of great value to the inhabitants of the Weſt Indies. Society for Arts, &c. vol. v.

One meaſure of this earth, mixed with two of well ſlaked lime and one of ſand, form a cement that anſwers extremely well for building any dam or bridge, or any ſtructure in water, for it will ſoon harden and become like a ſtone.

TERRASSON (Abbé John), a French writer born at Lyons in 1669. He diſtinguiſhed himſelf in the diſpute concerning Homer, between La Motte and Madam Dacier, by writing a *Diſſertation contre l'Iliade*. He wrote a political and moral romance called *Sethos*, full of learning and philoſophy; and another capital work of his is a French tranſlation of Diodorus Siculus. He died in 1750. Terre ‖ Tertullian.

TERRE *Verte*, in the colour-trade, the name of a green earth much uſed by painters, both ſingly for a good ſtanding green, and in mixture with other colours. The name is French, and ſignifies "green earth."

It is an indurated clay, of a deep bluiſh green colour, and is found in the earth, not in continued ſtrata or beds, as moſt of the other earths are, but in large flat maſſes of different ſizes, imbedded in other ſtrata; theſe break irregularly in the cutting, and the earth is generally brought out of the pit in lumps of different ſizes. It is of a fine, regular, and even ſtructure, and not very hard. It is of an even and gloſſy ſurface, very ſmooth to the touch, and in ſome degree reſembling the morochthus or French chalk, but adhering firmly to the tongue. It does not ſtain the hands in touching it; but being drawn along a rough ſurface, it leaves an even white line, with a greeniſh caſt.

It does not ferment with acids, and it burns to a duſky brown colour. It is dug in the iſland of Cyprus, and in many parts of France and Italy. That from the neighbourhood of Verona has been eſteemed the beſt in the world; but of late there has been ſome dug in France that equals it. There is alſo an earth dug on Mendip Hills, in the ſinking for coal, which, though wholly unobſerved, is nearly, if not wholly, of equal value. When ſcraped, and the finer parts ſeparated, it is ready to be made up with oil for the uſe of the painters, and makes the moſt true and laſting green of any ſimple body they uſe.

TERRESTRIAL, ſomething partaking of the nature of earth, or belonging to the globe of earth; thus we ſay, the terreſtrial globe, &c.

TERRIER, a ſmall hound to hunt the fox or badger; ſo called becauſe he creeps into the ground, as ferrets do into the coney-burrows, after the fox, &c.

TERRITORY, in geography, denotes an extent or compaſs of land, within the bounds or belonging to the juriſdiction of any ſtate, city, or other ſubdivinon of a country.

TERROR. See Fear and Fright.

TERTIAN FEVER. See Medicine, n° 126.

TERTULLIAN, or Quintus Septimus Florens Tertullianus, a celebrated prieſt of Carthage, was the ſon of a centurion in the militia, who ſerved as proconſul of Africa. He was educated in the Pagan religion; but being convinced of its errors, embraced Chriſtianity, and became a zealous defender of the faith. He married, it is thought, after his baptiſm. Afterwards he took orders, and went to Rome; where, during the perſecution under the emperor Severus, he publiſhed his Apology for the Chriſtians, which is, in its kind, a maſterpiece of eloquence and learning; and at the beginning of the third century he embraced the ſect of the Montaniſts. He lived to a very great age, and died under the reign of Antoninus Caracalla, about the year 216. Many of his works are ſtill extant, in all of which he diſcovers a great knowledge of the Holy Scriptures, a lively imagination, a ſtrong, elevated, and impetuous ſtyle, great eloquence and ſtrength of reaſoning; but is ſome-

---

reduced to a fine powder, and mixed with the hand, adding olive oil ten ounces, and a ſufficient quantity of water, to bring the maſs to the conſiſtence of an ointment. To all ſores and ulcers in warm climates aſtringent applications of this kind are found to be peculiarly uſeful."

Teruncius ‖ Teſſera.

ſometimes obſcure. His Apology and Preſcriptions are moſt eſteemed. The beſt editions of his works are thoſe of Rigault; eſpecially that of Venice in 1746, folio. Pamelius and Alix, Mr Thomas, and the Sieur du Foſſé, have written his life; and Rigault, M. de l'Aube Epine, Father Petau, and other learned men, have publiſhed notes on his works.

TERUNCIUS, in antiquity, a very ſmall braſs coin in uſe among the Romans.

The inconvenience of ſuch very ſmall pieces being ſoon found, the teruncius became diſuſed, but its name is ſtill retained in reckoning, and thus it became a money of account. The teruncius at firſt was a quarter of the as, or libra; hence, as the as contained twelve ounces, the teruncius contained three, whence the name, which is formed of the Latin *tres unciæ*. Teruncius was alſo uſed for the quarter of the denarius; ſo that when the denarius was at ten aſes, the teruncius was worth two and a half; and when the denarius was riſen to ſixteen, the teruncius was worth four. See DENARIUS.

TESSELATED PAVEMENTS, thoſe of rich Moſaic work made of curious ſquare marbles, bricks, or tiles, called *teſſelæ* from their reſembling dice.

TESSERA, in Roman antiquity, denoted in its primary ſenſe a cube or die; ſo called from the Greek word τεσσαρα, or τεσσερα, *four*; reſpect being had to its number of ſides, diſtinct from the two horizontal planes above and below. And it was thus diſtinguiſhed from the talus, which being round at each end, contained only four planes or faces on which it could ſtand; and therefore when thrown had no more than two ſide faces in view. Hence *ludere talis et ludere teſſeris* are ſpoken of by Roman writers as two different games. The ſyllable TES. occurs often in Roman inſcriptions. The word *teſſera* was applied to many other things, not ſo much from a ſimilitude in the figure, as from the relation they bore to ſome other thing of which they were the ſign or token; as the points on the upper plane of the die denoted the good or ill ſucceſs of the caſt.

The *teſſera hoſpitalis* was either public or private. As to the former, we find among the inſcriptions publiſhed by Gruter inſtances of two municipal towns which put themſelves under the patronage of the Roman governor; and the reciprocal engagement between them, engraved on two copper plates, in the form of an oblong ſquare, with a pediment at the top, is called in both *teſſera hoſpitalis*. The deſign of it was to cultivate or maintain a laſting friendſhip between private perſons and their families; and gave a mutual claim to the contracting parties and their deſcendants of a reception and kind treatment at each other's houſes, as occaſion offered. For which end thoſe teſſeræ were ſo contrived as beſt to preſerve the memory of that tranſaction to poſterity. And one method of doing this was by dividing one of them lengthwiſe into two equal parts; upon each of which one of the parties wrote his name, and interchanged it with the other. From this cuſtom came the prevailing expreſſion *teſſeram hoſpitalem confringere*, applied to perſons who violated their engagements.

The *teſſeræ frumentariæ* were ſmall tallies given by the emperors to the populace at Rome, entitling them to the reception of a quantity of corn from the public at ſtated ſeaſons. The perſon who had the inſpection of theſe was called *teſſerarius*. They were made of wood and of ſtone.

There was another kind of teſſera which intitled perſons to a ſight of the public games and other diverſions, uſually made in the form of an oblong ſquare.

The *teſſera militaris* was a ſignal given by the general, or chief commander of an army, as a direction to the ſoldiers for executing any duty or ſervice required of them. This, upon urgent occaſions, was only vocal; but, in ordinary caſes, it was written on a tablet, commonly made of wood. Beſide theſe civil and military teſſeræ, there are others which relate to religious affairs, and may be called *ſacred*.

Teſſon ‖ Teſt.

TESSON, or TESTON. See TESTER.

TESSOUWA, a conſiderable town in Africa, ſituated eaſt of Mourzouk, the capital of the kingdom of Fezzan. Near this town a deep and rapid ſtream is ſaid to have exiſted, but was overwhelmed by the moving ſands ſo frequent in Africa.

TEST, a veſſel uſed in metallurgy for abſorbing the ſcoriæ of metallic bodies when melted. See CUPEL.

Some of the German writers recommend, both for teſts and cupels, a ſort of friable opake ſtone, called *white ſpath*, which appears to be a ſpecies of gypſum, or of the ſtones from which plaſter of Paris is prepared. The ſpath is directed to be calcined with a gentle fire, in a covered veſſel, till the ſlight crackling, which happens at firſt, has ceaſed, and the ſtone has fallen in part into powder: the whole is then reduced into ſubtle powder, which is paſſed through a fine ſieve, and moiſtened with ſo much of a weak ſolution of green vitriol as is ſufficient for making it hold together. Gellert, however, finds, that if the ſtone is of the proper kind, which can be known only by trials, calcination is not neceſſary. Scheffer obſerves, that theſe kinds of teſts are liable to ſoften or fall aſunder in the fire, and that this inconvenience may be remedied by mixing with the uncalcined ſtone ſomewhat leſs than equal its weight, as eight-ninths of ſuch as has been already uſed and is penetrated by the ſcoria of the lead, taking only that part of the old teſt which appears of a green-grey colour, and rejecting the red cruſt on the top. Teſts or cupels made of the ſpath are ſaid not to require ſo much caution in nealing and heating them as the common ones; it appears, however, from Scheffer's account, that they are leſs durable than thoſe made of the aſhes of bones, though greatly ſuperior to thoſe of wood-aſhes. Vegetables aſhes, which ſtand pretty well the teſting of ſilver, can ſcarcely bear any great quantity of gold, this metal requiring a conſiderably ſtronger fire than the other; but bone-aſhes anſwer ſo effectually, and are among us ſo eaſily procurable, that it is not needful for the refiner to ſearch for any other materials; though thoſe who work off large quantities of lead, in order to gain a little ſilver or gold contained in it, may poſſibly, in places remote from populous cities, avail themſelves of ſubſtances ſimilar to the ſpath abovementioned.

The teſt, for its greater ſecurity, is fixed in the mould in which it was formed; which is ſometimes a ſhallow veſſel made of crucible earth or caſt-iron, more commonly an iron hoop, with three bars arched downwards acroſs the bottom, about two inches deep, and of different widths, from three or four inches to fifteen or more, according to the quantity of metal to be teſted at once. The aſhes or earthy powder, moiſtened as for making cupels, are preſſed down in the mould ſo as to completely fill it or riſe a little above the ſides; with care to make the maſs equally ſolid, and to put in at once, or at leaſt after the bottom has been preſſed cloſe, as much of the matter as will be ſufficient for the whole; for any additional quantity will not unite thoroughly with the reſt, but be apt to part from it in the fire. The edges are pared ſmooth, and a portion cut out from the middle with a bent knife, ſo as to leave a proper cavity, which is ſmoothed by ſtrewing ſome dry powder on the ſurface, and rolling on it a wooden, or rather a glaſs ball.

The proceſs of teſting is often performed in the ſame

Teſt. manner as that of cupellation: but where great quantities of baſe metal are to be worked off from a little gold, recourſe is had to a more expeditious method, that of teſting before the bellows.

An oval teſt is placed in a cavity, made in a hearth of a convenient height, and ſome moiſtened ſand or aſhes preſſed round it to keep it ſteady: the noſe of a bellows is directed along its ſurface, in ſuch a manner, that if aſhes are ſprinkled in the cavity of the teſt, the bellows may blow them completely out: ſome have an iron plate fixed before the bellows, to direct the blaſt downwards. To keep the ſurface of the teſt from being injured in putting in the metal, ſome cloths or pieces of paper are interpoſed. The fuel conſiſts of billets of barked oak laid on the ſides of the teſt, with others laid croſswiſe on theſe: the bellows impel the flame on the metal, clear the ſurface of aſhes or ſparks of coal, haſten the ſcorification of the lead, and blow off the ſcoria, as faſt it forms, to one end of the teſt, where it runs out through a notch made for that purpoſe. About two-thirds of the ſcorified lead may thus be collected; the reſt being partly abſorbed by the teſt, and partly diſſipated by the action of the bellows. Care muſt be taken not to urge the blaſt too ſtrongly, leſt ſome portion of the gold ſhould be carried away by the fumes impetuouſly forced off from the lead, and ſome minute particles of it entangled and blown off with the ſcoriæ.

Test-Act, in law, is the ſtatute 25 Car. II. cap. 2. which directs all officers, civil and military, to take the oaths, and make the declaration againſt tranſubſtantiation, in the court of King's Bench or Chancery, the next term, or at the next quarter-ſeſſions, or (by ſubſequent ſtatutes) within ſix months after their admiſſion; and alſo within the ſame time to receive the ſacrament of the Lord's Supper, according to the uſage of the church of England, in ſome public church, immediately after divine ſervice or ſermon, and to deliver into court a certificate thereof, ſigned by the miniſter and church warden, and alſo to prove the ſame by two credible witneſſes, upon forfeiture of 500l. and diſability to hold the ſaid office.

The avowed object of this act was to exclude from places of truſt all members of the church of Rome; and hence the diſſenters of that age, if they did not ſupport the bill when paſſing through the two houſes of parliament, gave it no oppoſition. For this part of their conduct they have been often cenſured with ſeverity, as having betrayed their rights from reſentment to their enemies. But is this a fair ſtate of the caſe? Were any rights in reality betrayed? That the dread of a popiſh ſucceſſor and of popiſh influence was the immediate and urgent cauſe of paſſing the *teſt-act*, is indeed true; but that the legiſlature, when guarding againſt an impending evil, had not likewiſe a retroſpect to another from which they had ſo recently been delivered, is not ſo evident. If it be proper to ſupport an eſtabliſhed church as a branch of the conſtitution, and if the teſt-act be calculated to afford that ſupport to the church of England, it is probable that the deliberations of parliament were as much influenced by the dread of puritanic fury, and a renewal of the covenant, as by apprehenſions of a perſecution from a popiſh king and popiſh councils. That the members of the church eſtabliſhed by law in England had as much reaſon to dread the effects of power in the hands of Puritans as in the hands of Papiſts, no impartial man will controvert, who is not a ſtranger to that period of our national hiſtory; and that it was the duty of the legiſlature by every method in their power to provide for the ſecurity of the conſtitution againſt the machinations of both its enemies, will be admitted by all but ſuch as are in love with anarchy on the one hand, or with deſpotiſm on the other. Teſt.

Many people, when they talk or write of the *teſt-act*, ſeem to think that it was framed in oppoſition to the *religious* opinions of the church of Rome; and finding the Proteſtant diſſenters, who abhor theſe opinions, deprived by it of their civil *rights*, they ſpeak with indignation of a law which confounds the innocent with the guilty. But all this proceeds from a palpable miſtake of the purpoſe of the teſt. As the legiſlature had no authority to make laws againſt *any opinions whatever*, on account of their being falſe in theology; ſo it is not to be ſuppoſed that, in their deliberations on the TEST-ACT, the members of that auguſt body took into their conſideration the comparative orthodoxy of the diſtinguiſhing tenets of the Catholics and Puritans. As a religious ſect they might eſteem the latter much more than the former; but if they found that both had combined with their theological doctrines opinions reſpecting civil and eccleſiaſtical government, inconſiſtent with the fundamental principles of the Engliſh conſtitution, they had an undoubted right to enact a law, by which none ſhould be admitted to offices, in the execution of which they could injure the conſtitution, without previouſly giving ſecurity that their adminiſtration ſhould ſupport it in all its branches. It had not then been doubted, nor is there reaſon to doubt yet, (ſay the advocates for the Church of England), that an eſtabliſhed religion is neceſſary, in conjunction with civil government, to preſerve the peace of ſociety; and therefore in every well regulated ſtate an eſtabliſhed religion muſt be ſupported, not becauſe it is the duty of the civil magiſtrate to conduct his ſubjects to future happineſs, but becauſe he cannot without ſuch an eſtabliſhment preſerve among them preſent tranquillity. The eſtabliſhment which muſt beſt anſwer this purpoſe, is that which, teaching the great and unchangeable duties of morality, is moſt acceptable in its government and forms of worſhip to the majority of the people; and therefore in giving a legal eſtabliſhment to one conſtitution of the church in preference to all others, it is only this circumſtance, and not the comparative purity of the rival churches, viewed merely as eccleſiaſtical corporations, to which it is the buſineſs of the legiſlature to pay attention. At the time when the *teſt-act* paſſed the two houſes of parliament, the eſtabliſhed church of England was certainly more acceptable to the great body of the people and to all ranks in the ſtate, than any one of the ſects, whether Catholic or Proteſtant, which diſſented from her; and therefore it was the duty of the legiſlature to preſerve to that church all her privileges and immunities, and to prevent thoſe hoſtile ſectaries from doing her injury in the diſcharge of any civil office with which they might be entruſted. It was with this view that the *teſt-act* was formed; and it is with the ſame view that the legiſlature has hitherto rejected every petition for its repeal. In doing ſo, it deprives no man of his *rights*, far leſs of rights which *conſcience* calls upon him to maintain at every hazard; for the rights of individuals to hold civil offices are not inherent, but derived from the legiſlature, which of courſe muſt be the judge upon what terms they are to be held. The legiſlature of England has excluded from many offices, civil and military, every man who will not give ſecurity, that in the diſcharge of his public duty he will ſupport the church eſtabliſhed by law; and as the teſt of his intention, it requires him, before he enters upon his office, to renounce the doctrine of tranſubſtantiation, and receive the ſacrament of the Lord's Supper in ſome public church, according to the liturgy of the church or England. Whether this be the moſt proper teſt that could have been exacted, may well be queſtioned; but

Teſt. that in a country abounding with ſectaries of various denominations, who agree in nothing but venomous hoſtility to the religious eſtabliſhment, *ſome* teſt is neceſſary, ſeems incontrovertible, if it be the buſineſs of the legiſlature to preſerve the public peace.

To this it will be replied, That the public peace in Scotland is preſerved without a teſt, and that therefore a teſt cannot be neceſſary in England. This is plauſible, but not concluſive. For forty years after the Revolution, there was in Scotland no denomination of Chriſtians but thoſe of the Preſbyterian church, eſtabliſhed by law, the Proteſtant Epiſcopalians, whoſe church had been eſtabliſhed prior to that event, and the adherents to the church of Rome. The Epiſcopalians and Papiſts were effectually excluded from every office in which they could injure the eccleſiaſtical eſtabliſhment, by the ſeveral reſtrictions under which they were laid, on account of their attachment, real or ſuppoſed, to the abdicated family of Stuart. The penal laws operated upon them more powerfully than a religious teſt. It is to be obſerved too, that in the church of Scotland, though her clergy are better provided for than any other parochial clergy perhaps in Europe (A), there is nothing of that ſplendor and temporal power which in England excite envy to clamour againſt the eſtabliſhment, under the pretence of maintaining the cauſe of religious liberty. Yet even in Scotland a religious teſt is occaſionally exacted of civil officers. In the royal boroughs of that part of the united kingdom, no man can hold the office of a magiſtrate without previouſly ſwearing the burgeſs-oath (ſee SECEDER, n° 8.); and every inſtructor of youth, whether in ſchools or colleges, may be called upon to qualify himſelf for his office, by ſubſcribing the eſtabliſhed Confeſſion of Faith. The burgeſs-oath is a more effectual teſt than that which is required of magiſtrates in England; for a man might with a ſafe conſcience receive the ſacrament of the Lord's Supper occaſionally in a church, "at which he would not ſwear to abide and defend the ſame to his *life's end*." This teſt appears to us to be neceſſary in boroughs, where faction is commonly blended with fanaticiſm; and if thoſe ſectaries which, at their firſt appearance in 1732, were inſignificant, if not contemptible, continue to multiply, and to imbibe principles much more pernicious than thoſe which were held by their fathers, it may perhaps be found expedient to extend ſome teſt over the whole country.

We do not, however, by any means, wiſh to ſee the ſacramental teſt introduced into Scotland. A teſt, ſay they, may be neceſſary to ſecure to the church all her rights and immunities; but to receive the ſacrament can give her no ſuch ſecurity, whilſt it leads inevitably to the profanation of a ſacred ordinance. A much better teſt would be, to require every man, before he be admitted to an executive office, to ſwear that in the diſcharge of it he will be careful to maintain all the rights and privileges of the church eſtabliſhed by law. Such an oath no ſenſible and peaceable diſſenter could refuſe; for it would not bind him to communicate with the eſtabliſhed church; and he cannot be ignorant that it belongs not to the executive government, but to the legiſlature, to determine what ſhall be the religion of the ſtate. On this account, we cannot help thinking that the members of the legiſlative body ſhould be ſubjected to no religious teſt whatever, that they may be at freedom to reform the corruptions of the church, or to exchange one eſtabliſhment for another, ſhould they find ſuch exchange expedient. If this reaſoning be juſt, it will be difficult to vindicate that clauſe of 25 Car. II. and of 1 Geo. I. in which it is enacted, that no member ſhall vote or ſit in either houſe of parliament till he hath, in the preſence of the houſe, ſubſcribed and repeated the declaration againſt tranſubſtantiation, the invocation of ſaints, and the ſacrifice of the maſs. The church of Rome is indeed a very corrupt ſociety; but if it be not for the purity of her doctrines and government that any church is eſtabliſhed in perference to all others, why ſhould that particular church be precluded from the poſſibility of obtaining a legal eſtabliſhment in Great Britain, even though ſhe were to become moſt acceptable to the majority of all ranks in the kingdom? The Engliſh Catholics have unqueſtionably greater reaſon to complain of this teſt, than either they or the diſſenters have to complain of the law which requires every civil and military officer to receive the Lord's Supper in the eſtabliſhed church. TESTACEA, in the Linnæan ſyſtem of natural hiſtory, the third order of vermes. This order comprehends all ſhell-fiſh arranged by Linnæus under 36 genera. Shell-fiſh are animals with a ſoft body, covered by or incloſed in a firm, hard, and as it were ſtony habitation, compoſed, according to their three ſeparate orders, 1ſt, Of many parts which are ranged under the name of *multivalves*; 2d, Of two parts which are called *bivalves*; 3d, Of one part or piece only, which we call *univalves*. Thoſe parts, pieces, or valves, are more or leſs moveable at the animal's pleaſure. The animals included in theſe hard habitations have moſt of them the characters of one or other of the genera vermium, and might be reduced under the ſame genera with the moluſca: but as theſe characters are few, and the ſhells very numerous, and different in their form and ſtructure, it will tend more to make this part of natural hiſtory eaſy, to arrange the ſubjects according to the diſtinctions of the ſhells themſelves. Barbut's Genera Vermium.

There is this farther conſideration in favour of this arrangement, viz. that the animals themſelves are rarely ſeen, and never can be preſerved in cabinets; whereas the ſhells make a figure in them, and great numbers have been met with empty of the animal.

TESTACEOUS, in natural hiſtory, an epithet ſynonymous with TESTACEA.

In medicine, all preparations of ſhells, and ſubſtances of the like kind, are called *teſtaceous*. Such are powders of crabs claws and eyes, pearl, &c. Dr Quincy and others ſuppoſe the virtue of all teſtaceous medicines to be alike; that they ſeldom or never enter the lacteals, but that the chief

(A) There are indeed many livings in the church of England, and probably in other churches, to which nothing in the church of Scotland can be compared in reſpect of emolument; but theſe rich benefices bear no proportion to the number of thoſe which, in this age of unavoidable expence, cannot afford to the incumbents the means of decent ſubſiſtence as gentlemen. In the church of Scotland many livings amount to L. 200 each annually; and we have reaſon to hope, that when the preſent plan for augmenting the ſtipends of the clergy has been extended over Scotland, very few will be below L. 100; whilſt in England the vicarages and ſmall rectories, from which we have reaſon to believe that the incumbents reap not L. 80 a-year, greatly exceed in number all the livings in Scotland: Nay we doubt if there be not upwards of a thouſand livings in England and Wales from which the rector or vicar derives not above L. 50 annually.

Teeſtamnt. chief of their action is in the firſt paſſages; in which, however, they are of great uſe in abſorbing acidities. Hence they become of uſe in fevers, and eſpecially in rectifying the many diſtempers in children, which generally owe their origin to ſuch acidities.

TESTAMENT, or LAST WILL. Teſtaments both Juſtinian and Sir Edward Coke agree to be ſo called, becauſe they are *teſtatio mentis:* an etymon which ſeems to favour too much of conceit; it being plainly a ſubſtantive derived from the verb *teſtari*, in like manner as *juramentum, incrementum*, and others, from other verbs. The definition of the old Roman lawyers is much better than their etymology; *voluntatis noſtræ juſta ſententia de eo, quod quis poſt mortem ſuam fieri velit:* which may be thus rendered into Engliſh, "the legal declaration of a man's intentions, which he wills to be performed after his death." It is called *ſententia*, to denote the circumſpection and prudence with which it is ſuppoſed to be made: it is *voluntatis noſtræ ſententia*, becauſe its efficacy depends on its declaring the teſtator's intention, whence in Engliſh it is emphatically ſtyled his *will;* it is *juſta ſententia;* that is, drawn, atteſted, and publiſhed, with all due ſolemnities and forms of law: it is *de eo, quod quis poſt mortem ſuam fieri velit*, becauſe a teſtament is of no force till after the death of the teſtator.

Blackſt. Comment. vol. ii.

Theſe teſtaments are divided into two ſorts; written, and verbal or nuncupative: of which the former is committed to writing: the latter depends merely upon oral evidence, being declared by the teſtator in *extremis*, before a ſufficient number of witneſſes, and afterwards reduced to writing.

But as nuncupative wills and CODICILS (which were formerly more in uſe than at preſent when the art of writing is become more general) are liable to great impoſitions, and may occaſion many perjuries, the ſtatute of frauds, 29 Car. II. c. 3. enacts, 1. That no written will ſhall be revoked or altered by a ſubſequent nuncupative one, except the ſame be in the lifetime of the teſtator reduced to writing, and read over to him, and approved; and unleſs the ſame be proved to have been ſo done by the oaths of three witneſſes at the leaſt, who, by ſtatute 4 & 5 Anne, c. 16. muſt be ſuch as are admiſſible upon trials at common law. 2. That no nuncupative will ſhall in anywiſe be good, where the eſtate bequeathed exceeds 30 l. unleſs proved by three ſuch witneſſes, preſent at the making thereof (the Roman law requiring ſeven), and unleſs they or ſome of them were ſpecially required to bear witneſs thereto by the teſtator himſelf; and unleſs it was made in his laſt ſickneſs, in his own habitation or dwelling-houſe, or where he had been previouſly reſident ten days at the leaſt, except he be ſurpriſed with ſickneſs on a journey, or from home, and dies without returning to his dwelling. 3. That no nuncupative will ſhall be proved by the witneſſes after ſix months from the making, unleſs it were put in writing within ſix days. Nor ſhall it be proved till fourteen days after the death of the teſtator, nor till proceſs hath firſt iſſued to call in the widow, or next of kin, to conteſt it if they think proper. Thus hath the legiſlature provided againſt any fraud in ſetting up nuncupative wills, by ſo numerous a train of requiſites, that the thing itſelf has fallen into diſuſe; and hardly ever heard of, but in the only inſtance where favour ought to be ſhown to it, when the teſtator is ſurpriſed by ſudden and violent ſickneſs. The teſtamentary words muſt be ſpoken with an intent to bequeath, not any looſe idle diſcourſe in his illneſs; for he muſt require the byſtanders to bear witneſs of ſuch his intention: the will muſt be made at home, or among his family or friends, unleſs by unavoidable accident, to prevent impoſitions from ſtrangers: it muſt be in his laſt ſickneſs; for if he recovers, he may alter his diſpoſitions, and have time to make a written will: it muſt not be proved at too long a diſtance from the teſtator's death, leſt the words ſhould eſcape the memory of the witneſſes; nor yet too haſtily and without notice, leſt the family of the teſtator ſhould be put to inconvenience or ſurpriſed. Teſtament.

As to written wills, they need not any witneſſes of their publication. We ſpeak not here of deviſes of lands, which are entirely another thing, a conveyance by ſtatute, unknown to the feodal or common law, and not under the ſame juriſdiction as perſonal teſtaments. But a teſtament of chattels written in the teſtator's own hand though it has neither his name nor ſeal to it, nor witneſſes preſent at its publication, is good; provided ſufficient proof can be had that it is his hand-writing. And though written in another man's hand, and never ſigned by the teſtator, yet if proved to be according to his inſtructions and approved by him, it hath been held a good teſtament of the perſonal eſtate. Yet it is the ſafer and more prudent way, and leaves leſs in the breaſt of the eccleſiaſtical judge, if it be ſigned or ſealed by the teſtator, and publiſhed in the preſence of witneſſes; which laſt was always required in the time of Bracton; or rather he in this reſpect has implicitly copied the rule of the civil law.

No teſtament is of any effect till after the death of the teſtator; *Nam omne teſtamentum morte conſummatum eſt, et voluntas teſtatoris eſt ambulatoria uſque ad mortem.* And therefore, if there be many teſtaments, the laſt will overthrows all the former; but the republication of a former will revoke one of a later date, and eſtabliſhes the firſt again.

Regularly, every perſon hath full power and liberty to make a will, that is not under ſome ſpecial prohibition by law or cuſtom: which prohibitions are principally upon three accounts; for want of ſufficient diſcretion; for want of ſufficient liberty and free-will; and on account of criminal conduct.

1. In the firſt ſpecies are to be reckoned infants, under the age of 14 if males, and 12 if females; which is the rule of the civil law. For though ſome of our common lawyers have held that an infant of any age (even four years old) might make a teſtament, and others have denied that under 18 he is capable; yet as the eccleſiaſtical court is the judge of every teſtator's capacity, this caſe muſt be governed by the rules of the eccleſiaſtical law. So that no objection can be admitted to the will of an infant of 14, merely for want of age; but if the teſtator was not of ſufficient diſcretion, whether, at the age 14 or 24, that will overthrow his teſtament. Madmen, or otherwiſe *non compotes*, idiots or natural fools, perſons grown childiſh by reaſon of old age or diſtemper, ſuch as have their ſenſes beſotted with drunkenneſs,—all theſe are incapable, by reaſon of mental diſability, to make any will ſo long as ſuch diſability laſts. To this claſs alſo may be referred ſuch perſons as are born deaf, blind, and dumb; who, as they have always wanted the common inlets of underſtanding, are incapable of having *animum teſtandi*, and their teſtaments are therefore void.

2. Such perſons as are inteſtable for want of liberty or freedom of will, by the civil law are of various kinds; as priſoners, captives, and the like. But the law of England does not make ſuch perſons abſolutely inteſtable; but only leaves it to the diſcretion of the court to judge upon the conſideration of their particular circumſtances of dureſs, whether or no ſuch perſons could be ſuppoſed to have *liberum animum teſtandi*. And, with regard to feme-coverts, our laws differ ſtill more materially from the civil. Among the Romans there was no diſtinction; a married woman was as capable of bequeathing as a feme-ſole. But with us a

Teſtament. married woman is not only utterly incapable of deviſing lands, being excepted out of the ſtatute of wills, 34 & 35 Hen. VIII. c. 5. but alſo ſhe is incapable of making a teſtament of chattels, without the licence of her huſband. For all her perſonal chattels are abſolutely his own; and he may diſpoſe of her chattels real, or ſhall have them to himſelf if he ſurvives her: it would be therefore extremely inconſiſtent to give her a power of defeating that proviſion of the law, by bequeathing thoſe chattels to another. The queen-conſort is an exception to this general rule, for ſhe may diſpoſe of her chattels by will, without the conſent of her lord; and any feme-covert may make her will of goods which are in her poſſeſſion *in auter droit*, as executrix or adminiſtratrix; for theſe can never be the property of the huſband: and if ſhe has any pin-money or ſeparate maintenance, it is ſaid ſhe may diſpoſe of her ſavings thereout by teſtament, without the control of her huſband. But if a feme-ſole makes her will, and afterwards marries, ſuch ſubſequent marriage is eſteemed a revocation in law, and entirely vacates the will.

3. Perſons incapable of making teſtaments on account of their criminal conduct, are in the firſt place all traitors and felons, from the time of conviction; for then their goods and chattels are no longer at their own diſpoſal, but forfeited to the king. Neither can a *felo de ſe* make a will of goods and chattels, for they are forfeited by the act and manner of his death; but he may make a deviſe of his lands, for they are not ſubject to any forfeiture. Outlaws alſo, though it be but for debt, are incapable of making a will ſo long as the outlawry ſubſiſts, for their goods and chattels are forfeited during that time. As for perſons guilty of others crimes, ſhort of felony, who are by the civil law precluded from making teſtaments (as uſurers, libellers, and others of a worſe ſtamp), at the common law their teſtaments may be good. And in general the rule is, and has been ſo at leaſt ever ſince Glanvil's time, *quod libera ſit cujuſcunque ultima voluntas*.

Teſtaments may be avoided three ways: 1. If made by a perſon labouring under any of the incapacities before-mentioned; 2. By making another teſtament of a later date; and, 3. By cancelling or revoking it. For though I make a laſt will and teſtament irrevocable in the ſtrongeſt words, yet I am at liberty to revoke it; becauſe my own act or words cannot alter the diſpoſition of law, ſo as to make that irrevocable which is in its own nature revocable. For this, ſaith lord Bacon, would be for a man to deprive himſelf of that which, of all other things, is moſt incident to human condition; and that is, alteration or repentance. It hath alſo been held, that, without an expreſs revocation, if a man, who hath made his will, afterwards marries and hath a child, this is a preſumptive or implied revocation of his former will which he made in his ſtate of celibacy. The Romans were alſo wont to lay aſide teſtaments as being *inofficioſo*, deficient in natural duty, if they diſinherited or totally paſſed by (without aſſigning a true and ſufficient reaſon) any of the children of the teſtator. But if the child had any legacy, though ever ſo ſmall, it was a proof that the teſtator had not loſt his memory or his reaſon, which otherwiſe the law preſumed; but was then ſuppoſed to have acted thus for ſome ſubſtantial cauſe: and in ſuch caſe no *querela inofficioſi teſtamenti* was allowed. Hence probably has ariſen that groundleſs vulgar error of the neceſſity of leaving the heir a ſhilling, or ſome other expreſs legacy, in order to diſinherit him effectually; whereas the law of England makes no ſuch wild ſuppoſition of forgetfulneſs or inſanity; and therefore, though the heir or next of kin be totally omitted, it admits no *inofficioſi* to ſet aſide ſuch a teſtament.

TESTAMENT, in Scots law. See LAW, n° clxxxi. 2. &c.

TESTAMENT (Old and New). See BIBLE and SCRIPTURE. Teſtament

TESTATOR, the perſon who makes his will and teſtament. Teſtudo.

TESTER, TESTON, the name of a coin ſtruck in France by Louis XII. in 1513, and in Scotland in the time of Francis II. and Mary queen of Scotland, ſo called from the head of the king, which was engraved upon it. The ſilver it contained was 11 deniers 18 grains, its weight 7 deniers 11½ grains, and its value 10 ſoles. The coinage of it was prohibited by Henry III. in 1575, when the value of it was augmented to 14 ſoles ſix deniers. The teſton or teſter in England was rated at 12d. in the reign of Henry VIII. and afterwards reduced to 6d.

TESTES, in anatomy, the teſticles. See the next article.

TESTICLE (*teſtis*,) a double part in animals of the male kind, ſerving for the office of generation.—See ANATOMY, n° 107. They are called *teſticles*, by diminution of *teſtes*, "witneſſes;" as giving teſtimony of virility. The Greeks call them *didymi*, or "twins."

In man and moſt animals, the teſticles are exterior; in ſome, as fowls, interior. Some men have only one, ordinarily they have two; ſome have naturally had three; nay, anatomiſts aſſure us they have known four.

TESTIMONY. See LOGIC, n° 29. and METAPHYSICS, n° 135—138.

TESTIMONY, in law. See EVIDENCE.

TESTUDO, the TORTOISE, in zoology; a genus belonging to the claſs of *amphibia*, and order of *reptilia*. The body has a tail, and is defended with a bony or coriaceous covering. The mouth has naked mandibles without teeth. There are 33 ſpecies, of which the *midas* or common ſea-turtle is the moſt remarkable. It is found in the iſland of Aſcenſion and other places in the South Sea. The ſhell is ſo very ſtrong that it can carry more than 600 lbs. on its back, or as many men as can ſtand on it loaded. It digs round holes in the ſand in which it lays a vaſt number of eggs yearly, to the amount of 1000, it is ſaid. It broods on them during the night. Its fleſh is of a greeniſh colour, makes excellent food, and is the favourite diſh of ſailors as well as of epicures. It lives on cuttle and ſhell-fiſh, and grows to a prodigious ſize, ſome having been found to weigh 480 lbs.

The Americans find ſo good account in catching turtle, that they have made themſelves very expert at it: they watch them from their neſts on ſhore, in moon-light nights; and, before they reach the ſea, turn them on their backs, and leave them till morning; when they are ſure to find them, ſince they are utterly unable to recover their former poſture: at other times they hunt them in boats, with a peculiar kind of ſpear, ſtriking them with it through the ſhell; and as there is a cord faſtened to the ſpear, they are taken much in the ſame manner as the whales.

Mr White, in his Natural Hiſtory of Selborne, mentions a land-tortoiſe which had been kept for 30 years at Ringmer near Lewes. It retired under ground about the middle of November, and came forth again about the middle of April. At its firſt appearance in ſpring it ſhowed little inclination for food; in the height of ſummer it became voracious; its appetite again diminiſhed toward autumn, ſo that for the laſt ſix weeks it ſcarcely ate any thing at all. It lived chiefly on milky plants, ſuch a lettuces, dandelions, and ſow-thiſtles. Nothing ſurpriſed Mr White more than the extreme timidity it always ſhowed for rain; for though it had a ſhell that would ſecure it againſt the wheel of a loaded cart, yet it diſcovered as much ſolicitude about rain as a fine lady dreſſed in her beſt attire, ſhuffling away on the firſt ſprinklings,

Teſtudo ‖ Tetragonia.

lings, and running its head up in a corner. It not only ſlept during winter, but for a great part of the ſummer; for it went to bed in the longer days at four in the evening, and often did not ſtir in the morning till it was late. There was one ſeaſon uſually about the beginning of June when its exertions were remarkable. It then roſe by five in the morning, and walked on tip toe, traverſing the garden, examining every wicket and interſtice in the fences. The motives that led it to theſe rambles ſeemed to be of the amorous kind. Mr White ſays it was an excellent weather-glaſs; for whenever it walked upright and fed with great avidity in the morning, it rained before night. It ſhowed great ſagacity in diſcerning thoſe who did it kind offices; for whenever the old lady who had fed it for 30 years came in ſight, it hobbled towards her with awkward alacrity.

TESTUDO, in antiquity, was particularly uſed among the poets, &c. for the ancient lyre; becauſe it was originally made by its inventor Mercury, of the back or hollow of the teſtudo aquatica, or ſea-tortoiſe, which he accidentally found on the banks of the river Nile. See LYRE.

TESTUDO, in the military art of the ancients, was a kind of cover or ſcreen which the ſoldiers, *e. gr.* a whole company, made themſelves of their bucklers, by holding them up over their heads, and ſtanding cloſe to each other. This expedient ſerved to ſhelter them from darts, ſtones, &c. thrown upon them, eſpecially thoſe thrown from above, when they went to the aſſault.

TESTUDO, was alſo a kind of large wooden tower which moved on ſeveral wheels, and was covered with bullock hides, ſerving to ſhelter the ſoldiers when they approached the walls to mine them, or to batter them with rams. It was called *teſtudo*, from the ſtrength of its roof, which covered the workmen as the ſhell does the tortoiſe.

TETANUS, a dreadful ſpaſmodic diſorder, in which the whole body becomes rigid and inflexible. It moſt commonly proves mortal. See MEDICINE, n° 279.

TETHYS, a genus of inſects belonging to the claſs of *vermes*, and order of *molluſca*. The body is oblong, fleſhy, and without feet; the mouth conſiſts of a cylindrical proboſcis under the duplicature of a lip: and there are two foramina at the left ſide of the neck. The ſpecies are two, both inhabitants of the ocean.

TETRACERA, in botany; a genus of plants belonging to the claſs of *polyandria*, and order of *tetragynia*, and in the natural ſyſtem ranging under the doubtful. The calyx is hexaphyllous, and the capſules four. There is only one ſpecies, the volubilis.

TETRADYNAMIA, (τεττάρες "four," and δύναμις "power"), four powers; the name of the 15th claſs in Linnæus's Sexual Syſtem, conſiſting of plants with hermaphrodite flowers, having ſix ſtamina, four of which are long, and two ſhort; it correſponds to the *ſiliquoſæ* of Ray, and *cruciformes* of Tournefort. All the ſpecies belonging to this claſs are diſtinguiſhed by cruciform flowers. It comprehends two orders, *gymnoſpermia*, thoſe plants which have naked ſeeds, being four in number, (except phryma which is monoſpermous); and *angioſpermia*, which contains thoſe plants the ſeeds of which are incloſed in a capſule. See BOTANY, p. 430.

TETRAGONIA, in botany; a genus of plants belong to the claſs of *icoſandria*, and order of *monogynia*; and in the natural ſyſtem ranging under the 13th order, *ſuculentæ*. The calyx is divided into three, four, or five parts. There is no corolla; the drupe is beneath, and the nut three or eight-celled. There are ſeven ſpecies; the puticoſa, decumbens, herbacea, echinata, expanſa, cryſtallina, and the japonica.

TETRAGRAMMATON, τετραγράμματον, a denomination given by the Greeks to the Hebrew name of God יהוה, "*Jehova*," becauſe in the Hebrew it conſiſts of four letters. Tetragrammaton ‖ Tetrao.

TETRAGYNIA, (τέτταρες, "four," and γυνὴ "a woman"); the name of an order, or ſecondary diviſion in the 4th, 5th, 6th, 8th, and 13th claſſes in the Sexual Syſtem; conſiſting of plants which, to the claſſic character, whatever it is, add the circumſtance of having four ſtyles or female organs. Herb-paris and graſs of *Parnaſſus* furniſh examples.

TETRANDRIA, (τέτταρες "four," and ἀνὴρ "a man or huſband"); the name of the fourth claſs in Linnæus's Sexual Syſtem, conſiſting of plants with hermaphrodite flowers, which have four ſtamina or male organs that are of equal length. In this laſt circumſtance conſiſts the main difference, according to Linnæus, between the plants of the claſs in queſtion and thoſe of the 14th claſs *didynamia*, in which the four ſtamina are of unequal length, two of them being long, and two ſhort.—The orders of this numerous claſs are three, founded upon the number of ſtyles or female organs. Scabious, teazel, barren wort, the ſtarry plants of Ray, and the greater number of genera in this claſs, have one ſtyle; dodder and hypecoum have two; holly and a few others have four.

TETRAO, in ornithology; a genus of birds belonging to the order of *gallinæ*, and is thus characterized by Linnæus: There is a ſpot near the eyes naked or papilloſe, or covered, though more rarely, with feathers. Gmelin has enumerated about 66 ſpecies. The genus tetrao comprehended both the grous, partridge, and quail; but Dr Latham, with great judgment and propriety, has made two genera of them, under the names of *tetrao*, comprehending the grous; and *perdix*, comprehending the partridge and quail. Dr Latham thus diſtinguiſhes the genus *tetrao*: The bill is like a crooked cone, with a naked ſcarlet ſkin above each eye, and the feet feathered to the toes. The *perdix* he characterizes by a bill convex, ſtrong, and ſhort; the noſtrils are covered above with a callous prominent rim; the orbits are papilloſe; the feet naked, and moſt of the ſpecies are furniſhed with ſpurs. He reckons 20 ſpecies under the *tetrao*, and 48 under the *perdix*. As we highly approve of this new arrangement of Dr Latham, we are diſpoſed to follow it; but as a reference has been made from PERDIX to this place, it is proper that we ſhould alſo give ſome account of that genus.

I. TETRAO. Of this genus the following ſpecies are found in Britain: 1. The *urogallus*, or wood-cock, inhabits woody and mountainous countries; in particular, foreſts of pines, birch-trees, and junipers; feeding on the tops of the former and berries of the latter; the firſt often infects the fleſh with ſuch a taſte as to render it ſcarcely eatable. In the ſpring it calls the females to its haunts with a loud and ſhrill voice; and is at that time ſo very inattentive to its ſafety, as to be very eaſily ſhot. It ſtands perched on a tree, and deſcends to the females on their firſt appearance. They lay from 8 to 16 eggs; eight at the firſt, and more as they advance in age.

This bird is common to Scandinavia, Germany, France, and ſeveral parts of the Alps.—It is found in no other part of Great Britain than the Highlands of Scotland north of Inverneſs; and is very rare even in thoſe parts. It is there known by the name of *capercalzie*, *caper-caizie*, and in the old law-books *caperkally*; the laſt ſignifying the horſe of the woods: this ſpecies being, in compariſon of others of the genus, pre-eminently large.

The length of the male is two feet nine inches: its weight ſometimes 14 pounds. The female is much leſs, the

Tetrao. the length being only 26 inches. The ſexes differ alſo greatly in colours. The bill of the male is of a pale yellow; the head, neck, and back, are elegantly marked, ſlender lines of grey and black running tranſverſely. The upper part of the breaſt is of a rich gloſſy green; the reſt of the breaſt and the belly black, mixed with ſome white feathers; the ſides are marked like the neck; the coverts of the wings croſſed with undulated lines of black and reddiſh brown; the exterior webs of the greater quill-feathers are black: the tail conſiſts of 18 feathers, the middle of which is the longeſt; theſe are black, marked on each ſide with a few white ſpots. The legs are very ſtrong, and covered with brown feathers; the edges of the toes are pectinated. —Of the female, the bill is duſky; the throat red; the head, neck, and back, are marked with tranſverſe bars of red and black: the breaſt has ſome white ſpots on it, and the lower part is of a plain orange colour: the belly is barred with pale orange and black; the tips of the feathers are white. The tail is of a deep ruſt-colour barred with black, tipped with white, and conſiſts of 16 feathers.

2. The *tetrix*, black grous, or black-cock, like the former ſpecies, is fond of woody and mountainous ſituations; feeding on bilberries and other mountain fruits, and in the winter on the tops of the heath. In the ſummer they frequently deſcend from the hills to feed on corn. They never pair: but in the ſpring the male gets upon ſome eminence, crows and claps his wings; on which ſignal all the females within hearing reſort to him. The hen lays ſeldom more than ſix or ſeven eggs. When the female is obliged, during the time of incubation, to leave her eggs in queſt of food, ſhe covers them up ſo artfully with moſs or dry leaves, that it is very difficult to diſcover them. On this occaſion ſhe is extremely tame and tranquil, however wild and timorous at other times. She often keeps to her neſt, though ſtrangers attempt to drag her away. As ſoon as the young ones are hatched, they are ſeen running with extreme agility after the mother, though ſometimes they are not entirely diſengaged from the ſhell. The hen leads them forwards for the firſt time into the woods, to ſhow them ant's eggs and the wild mountain-berries, which, while young, are their only food. As they grow older their appetites grow ſtronger, and they then feed upon the tops of heather and the cones of the pine-tree. In this manner they ſoon come to perfection: they are hardy birds, their food lies every where before them, and it would ſeem that they ſhould increaſe in great abundance. But this is not the caſe; their numbers are thinned by rapacious birds and beaſts of every kind, and ſtill more by their own ſalacious conteſts.—As ſoon as the hatching is over, which the female performs in the manner of an hen, the whole brood follows the mother for about a month or two; at the end of which the young males entirely forſake her, and keep in great harmony together till the beginning of ſpring. At this ſeaſon they begin for the firſt time to feel the amorous paſſions; and then adieu to all their former friendſhips! They begin to conſider each other as rivals; and the rage of concupiſcence quite extinguiſhes the ſpirit of ſociety. They fight each other like game-cocks; and at that time are ſo inattentive to their own ſafety, that it often happens that two or three of them are killed at a ſhot. It is probable, that in theſe conteſts the bird which comes off victorious takes poſſeſſion of the female ſeraglio, as it is certain they have no faithful attachments.

An old black cock is in length 22 inches, and weighs near four pounds. The bill is duſky; and the plumage of the whole body black, gloſſed over the neck and rump with a ſhining blue. The coverts of the wings are of a duſky brown; the inner coverts white; the thighs and legs are covered with dark brown feathers; the toes reſemble thoſe of the former ſpecies. The tail conſiſts of 16 black feathers, and is much forked; the exterior feathers bend greatly outwards, and their ends ſeem as if cut off.—The female weighs only two pounds; and its length is one foot ſix inches. The head and neck are marked with alternate bars of dull red and black; the breaſt with duſky black and white; but the laſt predominates. The back, coverts of the wings, and tail, are of the ſame colours as the neck, but the red is deeper. The tail is ſlightly forked; it conſiſts of 18 feathers variegated with red and black. The feathers under the tail are white, marked with a few bars of black and orange. This bird hatches its young late in the ſummer. It lays from ſix to eight eggs, of a dull yellowiſh white colour, marked with numbers of very ſmall ferruginous ſpecks; and towards the ſmaller end with ſome blotches of the ſame hue. Tetrao.

3. The *ſcoticus*, red game, or moor-fowl, is peculiar to the Britiſh iſlands. The male weighs about 19 ounces; and is in length 15½ inches. The bill is black; the irides hazel-coloured. The throat is red. The plumage on the head and neck is of a light tawny red; each feather is marked with ſeveral tranſverſe bars of black. The back and ſcapular feathers are of a deeper red; and on the middle of each feather is a large black ſpot; the breaſt and belly are of a dull purpliſh brown, croſſed with numerous narrow duſky lines; the quill-feathers are duſky; the tail conſiſts of 16 feathers of an equal length, all of them (except the four middlemoſt) are black, and the middle feathers are barred with red: the thighs are of a pale red, barred obſcurely with black; the legs and feet clothed to the very claws with thick ſoft white feathers. The claws are whitiſh, very broad and ſtrong. The female weighs only 15 ounces.—The colours in general are duller than thoſe of the male: the breaſt and belly are ſpotted with white; and the tips of ſome of the coverts of the wings are of the ſame colour.—Theſe birds pair in the ſpring, and lay from ſix to ten eggs. The young brood follow the hen the whole ſummer; in the winter they join in flocks of 40 or 50, and became remarkably ſhy and wild; they always keep on the tops of the hills, are ſcarce ever found on the ſides, and never deſcend into the valleys. Their food is the mountain-berries and tops of the heath.

4. The *lagopus*, white game or ptarmigan, is 15 inches in length, and weighs 19 ounces. Its plumage is of a pale brown or aſh colour, elegantly croſſed or mottled with ſmall duſky ſpots and minute bars; the head and neck with broad bars of black, ruſt colour, and white: the belly and wings are white, but the ſhafts of the greater quill feathers black. In the male, the grey colour predominates, except on the head and neck, where there is a great mixture of red, with bars of white. The females and young birds have a great deal of ruſt-colour in them. The tail conſiſts of 16 feathers; the two middle of which are aſh-coloured, mottled with black, and tipped with white; the two next black, ſlightly marked with white at their ends, the reſt wholly black: the feathers incumbent on the tail are white, and almoſt entirely cover it.

Ptarmigans are found in theſe kingdoms only on the ſummits of the higheſt hills of the Highlands of Scotland, of the Hebrides, and Orkneys; and a few ſtill inhabit the lofty hills near Keſwick in Cumberland as well as the mountains of Wales. They live amidſt the rocks, perching on the grey ſtones, the general colour of the ſtrata in thoſe exalted ſituations. They are very ſilly birds; ſo tame as to bear driving like poultry; and, if provoked to riſe, take very ſhort flights, making a great circuit like pigeons.

Like

Tetrao. Like the grous, they keep in ſmall packs; but never, like thoſe birds, take ſhelter in the heath, but beneath looſe ſtones. To the taſte they ſcarce differ from a grous.

Theſe birds are called by Pliny *lagopi*, their feet being clothed with feathers to the claws, as the hare's are with fur: the nails are long, broad, and hollow. The firſt circumſtance guards them from the rigour of the winter; the latter enables them to form a lodge under the ſnow, where they lie in heaps to protect themſelves form the cold. The feet of the grous are clothed in the ſame manner; but thoſe of the two firſt ſpecies here deſcribed, which perch upon trees, are naked, the legs only being feathered, not being in want of ſuch a protection.

II. PERDIX, comprehends both the partridge and quail.

The common partridge is ſo well known that a deſcription of it is unneceſſary, and we have not room the deſcribe the foreign ſpecies. We refer thoſe who wiſh complete information to the accurate and valuable Syſtem of Ornithology publiſhed by Dr Latham. The ſcientific ornithologiſt will find much ſatisfaction in his *Index Ornithologus*, publiſhed in 2 vols 4to; and he who wiſhes to be acquainted with the nature and diſpoſitions of birds, will read his *Synopſis* with pleaſure, publiſhed in 7 vols 4to.

The following general account of the partridge will ſuffice: "Theſe birds (ſays Willoughby) hold the principal place in the feaſts and entertainments of princes; without which their feaſts are eſteemed ignoble, vulgar, and of no account. The Frenchmen do ſo highly value, and are ſo fond of the partridge, that if they be wanting, they utterly ſlight and deſpiſe the beſt ſpread tables; as if there could be no feaſt without them." But however this might be in the times of our hiſtorian, the partridge is now too common in France to be conſidered as a delicacy; and this, as well as every other ſimple diſh, is exploded for luxuries of a more compound invention. In England, where the partridge is much ſcarcer, and a great deal dearer, it is ſtill a favourite delicacy at the tables of the rich; and the deſire of keeping it to themſelves has induced them to make laws for its preſervation, no way harmoniſing with the general ſpirit of Engliſh legiſlation.

The partridge ſeems to be a bird well known all over the world, as it is found in every country and in every climate; as well in the frozen regions about the pole, as the torrid tracks under the equator. It even ſeems to adapt itſelf to the nature of the climate where it reſides. In Greenland the partridge, which is brown in ſummer, as ſoon as the icy winter ſets in, begins to take a covering ſuited to the ſeaſon: it is then clothed with a warm down beneath; and its outward plumage aſſumes the colour of the ſnow among which it ſeeks its food. Thus it is doubly fitted for the place, by the warmth and the colour of its plumage; the one to defend it from the cold, the other to prevent its being noticed by the enemy. Thoſe of Barakonda, on the other hand, are longer legged, much ſwifter of foot, and chooſe the higheſt rocks and precipices to reſide in.—They all, however, agree in one character, of being immoderately addicted to venery; and, as ſome writers affirm, often to an unnatural degree. It is certain, the male will purſue the hen even to her neſt; and will break her eggs rather than not indulge his inclinations. Though the young ones have kept together in flocks during the winter when they begin to pair in ſpring their ſociety diſperſes; and combats, very terrible with reſpect to each other, enſue. Their manners in other circumſtances reſemble all thoſe of poultry in general; but their cunning and inſtinct ſeem ſuperior to thoſe of the larger kinds. Perhaps, as they live in the very neighbourhood of their enemies, they have more frequent occaſion to put their little arts in practice, and learn by habit the means of evaſion or ſafety. Whenever therefore a dog or other formidable animal approaches their neſt, the female uſes every means to draw him away. She keeps juſt before him, pretends to be incapable of flying, juſt hops up, and then falls down before him, but never goes off ſo far as to diſcourage her purſuer. At length, when ſhe has drawn him entirely away from her ſecret treaſure, ſhe at once takes wing, and fairly leaves him to gaze after her in deſpair. After the danger is over, and the dog withdrawn, ſhe then calls her young, who aſſemble at once at her cry, and follow where ſhe leads them. There are generally from 10 to 15 in a covey; and, if unmoleſted, they live from 15 to 17 years. There are ſeveral methods of taking them, as is well known; that by which they are taken in a net with a ſetting dog is the moſt pleaſant, as well as the moſt ſecure The dog, as every body knows, is trained to this exerciſe by a long courſe of education: by blows and careſſes he is taught to lie down at the word of command; a partridge is ſhown him and he is then ordered to lie down; he is brought into the field, and when the ſportſman perceives where the covey lies, he orders his dog to crouch: at length the dog, from habit, crouches wherever he approaches a covey; and this is the ſignal which the ſportſman receives for unfolding and covering the birds with his net. A covey thus caught is ſometimes fed in a place proper for their reception; but they can never be thoroughly tamed like our domeſtic poultry. See PARTRIDGE and SHOOTING.

2. The *coturnix*, or common quail, is not above half the ſize of the partidge. The feathers of the head are black, edged with ruſty brown; the breaſt is of a pale yellowiſh red, ſpotted with black; the feathers on the back are marked with lines of pale yellow and the legs are of a pale hue. Except in the colours thus deſcribed, and the ſize, it every way reſembles a partridge in ſhape, and, except that it is a bird of paſſage, it is like all others of the poultry kind in its habits and nature.

The quail ſeems to ſpread entirely throughout the old world, as well as the new; is ſeen from the Cape of Good Hope quite to Iceland, and is ſaid to be found in Falkland Iſles; alſo in New Zealand, throughout Ruſſia, Tartary, and China*; and in ſhort is mentioned by ſo many travellers, and in ſo many places, that we may almoſt call it an inhabitant of all. It is obſerved to ſhift quarters according to the ſeaſon, coming northward in ſpring, and departing ſouth in autumn, and in vaſt flocks, like other migrating birds. Twice in a year it comes in ſuch vaſt quantities into Capri, that the biſhop of the iſland draws the chief part of his revenue from them; hence he is called the *quail Biſhop*. But this does not ſtand alone; almoſt all the iſlands in the Archipelago, on the oppoſite coaſts, are at times covered with theſe birds, and ſome of them obtain a name from this circumſtance. On the weſt coaſt of the kingdom of Naples, within the ſpace of four or five miles, an hundred thouſand have been taken in a day, which have been ſold for eight livres *per* hundred to dealers who carry them for ſale to Rome. Great quantities alſo ſometimes alight in ſpring on the coaſts of Provence, eſpecially in the dioceſe of the biſhop of Frejus, which is near the ſea, and appear, at their firſt landing, ſo much fatigued that they are often taken by the hand. Theſe circumſtances then leave not a doubt of their being the ſame kind of birds which the divine hand of providence thought right to direct in ſuch quantities as to cover the camp of the murmuring Iſraelites.

* See Forſter's Obſ. P. 199.

Latham's Synopſis, vol. iv.

"In the autumn, great quantities are frequently imported into England from France for the table; which we have frequently ſeen (ſays Dr Latham) on their paſſage to London by the ſtage-coaches, about an hundred in a large ſquare box, divided into five or ſix partitions one above another, juſt high enough

Tetrao ‖ Tetuan.

enough to admit of the quails ſtanding upright; theſe boxes have wires on the fore part, and each partition furniſhed with a little trough for food; and I have been told, ſays our author, they may be conveyed thus to great diſtances without difficulty."

In Scotland they may be ſaid not to be plenty at any time. They breed there and the major part migrate ſouth in autumn; the reſt only ſhift their quarters, as they have been met with on the coaſts of Eſſex, and in Hampſhire, in the winter-ſeaſon, retiring thither in October.

It feeds like the partridge, and like that bird makes no neſt, except a few dry leaves or ſtalks ſcraped together may be called ſo, and ſometimes an hollow on the bare ground ſuffices. In this the female lays her eggs to the number of ſix of ſeven, of a whitiſh colour, marked with irregular ruſt-coloured ſpots: the young follow the mother as ſoon as hatched, like young partridges. They have but one brood in a year.

Quail-fighting was a favourite amuſement among the Athenians. They abſtained from the fleſh of this bird, deeming it unwholeſome, as ſuppoſing that it fed upon the white hellebore; but they reared great numbers of them for the pleaſure of ſeeing them fight; and ſtaked ſums of money, as we do with regard to cocks, upon the ſucceſs of the combat. Faſhion, however, has at preſent changed with regard to this bird: we take no pleaſure in its courage, but its fleſh is conſidered as a very great delicacy.—Quails are eaſily caught by a call: the fowler early in the morning having ſpread his net, hides himſelf under it among the corn; he then imitates the voice of the female with his quail-pipe, which the cock hearing, approaches with the utmoſt aſſiduity; when he has got under the net, the fowler then diſcovers himſelf, and terrifies the quail, who attempting to get away, entangles himſelf the more in the net, and is taken.

TETRODON, in ichthyology; a genus of fiſhes arranged by Linnæus under the claſs of *amphibia*, and order of *nantes*; but placed by Gmelin under the claſs of *piſces*, and order of *branchioſtegi*. The jaws are bony, ſtretched out, and cloven at the point; the aperture of the gills is linear; the body is muricated beneath, and there are no ventral fins. There are 13 ſpecies; of which the moſt remakable is the lineatus, called by Mr Haſſelquiſt *fahaka*, which is the Egyptian and Arabic name. It has of late been found in the Nile about Cairo, but was never known in former times. It is ſaid to grow to a prodigious ſize. When juſt caught, it pricks the ſkin if it is taken in the bare hands, and produces ſmall puſtules in the ſame manner as nettles. The fleſh is poiſonous. Mr Forſter confirms the account of the poiſonous nature of a ſpecies of tetrodon, in his account of New Caledonia.

TETRARCH, a prince who holds and governs a fourth part of a kingdom. Such originally was the import of the title *tetrarch*; but it was afterwards applied to any petty king or ſovereign; and became ſynonymous with ethnarch, as appears from the following conſiderations: 1. That Pliny makes mention of ſix tetrarchies within the city of Decapolis. 2. That Herod's kingdom was only divided into three parts, which yet were called *tetrarchies*, and the ſovereigns thereof, Luke iii. 1. *tetrarchs*. 3. Joſephus tells us, that, after the battle of Philippi, Antony, going into Syria, conſtituted Herod *tetrarch*; and on medals the ſame Herod is called *ethnarch*.

Joſephus's Antiq B. xiv. c. 23.

TETRASTYLE, in the ancient architecture, a building, and particularly a temple, with four columns in its front.

TETUAN, an ancient and pleaſant town of Africa, in the kingdom of Fez, and in the province of Habata. It is pretty well built, and the inhabitants are about 15,000 in number, who call themſelves *Andaluſians*, and almoſt all ſpeak Spaniſh; but they are great pirates. Some ſay there are 30,000 Mooriſh inhabitants, and 5000 Jews. W. Long. 5. 26. N. Lat. 35. 27.

Tenerium ‖ Teutonic.

TEUCRIUM, GERMANDER, in botany: A genus of plants belonging to the claſs of *didynamia*, and order of *gymnoſpermia*; and in the natural ſyſtem ranging under the 42d order, *Verticillatæ*. The corolla has no upper lip, is divided into two parts beyond the baſe, and is divaricated where the ſtamina iſſue out. There are 30 ſpecies; of which the ſcorodonia, ſcordium, and chamædrys, are natives of Great Britain.

1. The *ſcorodonia*, wood-ſage, or germander, is diſtinguiſhed by leaves which are heart-ſhaped ſerrated, and petiolated; by racemi, which are lateral and ranged in one row; and by an erected ſtem. The flowers are ſtraw coloured, and the filaments red. The plant has a bitter taſte, and ſmells like hops with a little mixture of garlic. It is uſed in brewing in the iſle of Jerſey inſtead of hops. 2. The *ſcordium*, or common water-germander, hath creeping perennial roots, ſending up many ſquare, procumbent, or trailing ſtalks, branching diffuſely; oblong, indented, ſerrated, cloſe-ſitting, oppoſite leaves; and ſmall reddiſh flowers, generally two together, from the ſides of the ſtalks and branches, in July and Auguſt. This plant was formerly conſidered as medicinal, but has now fallen into diſuſe. It grows naturally in marſhy places, in the iſle of Ely and other parts of England, and moſt parts of Europe; and is ſometimes admitted into gardens, in moiſt places, for variety and as a medical plant. 3. The *chamædrys*, or ſmaller creeping germander, hath fibrous, very creeping, ſpreading roots; many four-cornered, very branchy, trailing ſtalks, near a foot long; oval, cuneiform, cut, crenated leaves on ſhort footſtalks; and reddiſh flowers, growing almoſt in a verticillus, or whorls, round the ſtalk, three on each peduncle; appearing in June and July.

TEUTHIS, in ichthyology, a genus of fiſhes belonging to the order of *abdominales*. The head is ſomewhat truncated on the forepart; the branchil membrane has five rays; the teeth equal, rigid near each other, forming a regular ſeries. There are two ſpecies, the hepatus and java.

TEUTONES, or TEUTONI, (anc. geog.) a people always by hiſtorians joined with the Cimbri; both ſeated, according to Mela, beyond the Elbe, on the Sinus Codanus, or Baltic; and there, it is ſuppoſed, lay the country of the Teutones, now *Ditmarſh*; diverſity of dialects producing the different terms *Tuet*, *Tut*, *Dit*, *Tid*, and *Thod*, which in the ancient German language ſignified *people*. Of theſe Teutones, Virgil is to be underſtood in the epithet *Teutonicus*, an appellation which more lately came to the applied to the Germans in general, and later ſtill the appellation *Alemanni*.

The Teutones, in conjunction with the Cimbri and Ambrones, made war on the Romans, and marched towards Italy in the year 101 B. C. We are told, that the Teutones alone were ſo numerous, that they were ſix whole days without intermiſſion in paſſing by the Roman camp. In Tranſalpine Gaul they engaged the Roman conſul Marius; but were defeated with incredible ſlaughter; 100,000 of them, according to the loweſt calculations, being killed on the ſpot. According to others, the number of thoſe killed and taken priſoners amounted to 290,000. The inhabitants of the neighbouring country made fences for vineyards of their bones. Their king Teutobochus, ſaid to be a monſtrous giant, was taken priſoner and carried to Rome. See the article GIANT.

TEUTONIC, ſomething belonging to the Teutones.

Teutonic ‖ Text.

The Teutonic language is ſuppoſed to have been the language of the ancient Germans, and hence is reckoned amongſt the mother-tongues. See PHILOLOGY, n° 219.

TEUTONIC Order, an order of military knights, eſtabliſhed towards the cloſe of the twelfth century, on the following occaſion.—When the emperor Barbaroſſa engaged in a cruſade for the recovery of the Holy Land out of the hands of Saladin, he was followed by great numbers of German volunteers, who from various motives enliſted under his banners. After the death of Barbaroſſa, the Germans, who had ſignalized themſelves before Acre or Ptolemais, reſolved to chooſe another leader; and at laſt fixed their choice upon Frederic duke of Suabia, ſecond ſon to the emperor, and Henry duke of Brabant. Under theſe generals they behaved with ſo much bravery, that Henry king of Jeruſalem, the patriarch, and ſeveral other princes, determined to reward their valour by inſtituting an order of knighthood in their favour. This was accordingly done; and our new knights had at firſt the title of the *knights of St. George*; afterwards it was thought proper to put them under the tutelage of the Virgin Mary, to whom there was already an hoſpital dedicated on Mount Zion, for the relief of German pilgrims. From this time they were called *Equites Mariani*, or knights of St Mary. Laws, regulations, and ſtatutes, were drawn up for them by the Chriſtian kings in Syria and the patriarch; and among other obligations it was required, that every perſon admitted to the privileges of the order ſhould be of noble parentage; that the order ſhould defend the Chriſtian religion and the Holy Land; that they ſhould exerciſe hoſpitality towards the Chriſtians in general, but particularly thoſe of their own country; and that they ſhould with all their power endeavour to propagate and extend the Chriſtian faith and the religion of JESUS. In the year 1190, having become rich by donations from the ſuperſtitious, they elected their firſt grandmaſter, Henry Walpot, a German, who had diſtinguiſhed himſelf by his zeal and valour; and their choice was confirmed by the emperor. The following year, Pope Celeſtine III. confirmed their privileges already granted, giving them the title of the *Teutonic knights of the hoſpital of St Mary the Virgin*. By the conditions of this bull, they vowed perpetual continence, obedience, and poverty; obligations which it may well be imagined were not very ſtrictly kept. See POLAND, n° 59, 61, 67—69. and PRUSSIA, n° 3, 4.

TEWKESBURY, a town in Glouceſterſhire, formerly noted for its monaſtery. It is now a large handſome corporation, containing about 500 houſes, with a magnificent church. It is ſeated at the confluence of the rivers Severn and Avon, has a cotton manufactory, and ſends two members to parliament. W. Long. 2. 13. N. Lat. 52. 0.

TEXEL, a town of the United Provinces, in north Holland, ſeated at the mouth of the Zuyder-Zee, with a good harbour, and a ſtrong fort. It is ſeated in a fruitful iſland, known all over the world by the great number of ſhips that paſs this way every day from all parts; it is about ſix miles long, and five broad, lying a little northward to the continent of Holland, between which and the iſland is one of the principal paſſages out of the Zuyder-Zee into the ocean. It is defended from the ſea by ſand-hills and ſtrong banks. Moſt of the ſoil is applied to feed ſheep, of which they have great flocks; and the cheeſe made of their milk is ſaid to vie with the Parmeſan. This iſland contains ſeveral fair villages, and a town on the eaſt ſide, called *Burch*, ſtrongly fortified and garriſoned, and inhabited chiefly by fiſhermen. N. Lat. 53. 8. E. Long. 4. 51.

Nugent's Grand Tour. vol. i.

TEXT, a relative term, contradiſtinguiſhed to gloſs or commentary, and ſignifying an original diſcourſe excluſive of any note or interpretation. This word is particularly uſed for a certain paſſage of ſcripture, choſen by a preacher to be the ſubject of his ſermon.

Texture ‖ Thalia.

TEXTURE, properly denotes the arrangement and coheſion of ſeveral ſlender bodies or threads interwoven or entangled among each other, as in the webs of ſpiders, or in the cloths, ſtuffs, &c.

Texture is alſo uſed in ſpeaking of any union or conſtituent particles of a concrete body, whether by weaving, hooking, knitting, tying, chaining, indenting, intruding, compreſſing, attracting, or any other way. In which ſenſe we ſay, a cloſe compact texture, a lax porous texture, a regular or irregular texture, &c.

TEWIT, in ornithology. See TRINGA.

THABOR. See TABOR.

THALES, a celebrated Greek philoſopher, and the firſt of the ſeven wiſe men of Greece, was born at Miletus about 640 B. C. In order to improve himſelf in the knowledge of the ſciences, he travelled into Egypt, where he diſcourſed with the prieſts and other learned men. Some ſay that he married; but others obſerve, that he eluded the ſolicitations of his mother on this head, by telling her, when he was young, that it was too ſoon; and afterwards, that it was too late. Thales acquired great reputation by his wiſdom and learning: he was the firſt among the Greeks who foretold eclipſes of the ſun, and made extraordinary diſcoveries in aſtronomy. Thales was the author of the Ionian ſect of philoſophers, who were thus called from his being born at Miletus, a city of Ionia. He maintained that water was the principle of which all the bodies in the univerſe are compoſed; that the world was the work of God; and that God ſees the moſt ſecret thoughts in the heart of man. He ſaid, "That the moſt difficult thing in the world is to know ourſelves; the moſt eaſy to adviſe others; and the moſt ſweet to accompliſh our deſires. That, in order to live well, we ought to abſtain from what we find fault with in others. That the bodily felicity conſiſts in health, and that of the mind in knowledge. That the moſt ancient of beings is God, becauſe he is uncreated: that nothing is more beautiful than the world, becauſe it is the work of God; nothing more extenſive than ſpace, quicker than ſpirit, ſtronger than neceſſity, wiſer than time." It was alſo one of his ſentences, "That we ought never to ſay that to any one that may be turned to our prejudice; and that we ſhould live with our friends as with perſons that may become our enemies." He thanked God for three things; that he was born of the human, not of the brute ſpecies; a man, and not a woman; a Greek, and not a barbarian. None of the ancient philoſophers ever applied themſelves more earneſtly to the ſtudy of aſtronomy than Thales. Diogenes Laertius reports, that leaving his lodging with an old woman to contemplate the ſtars, he fell into a ditch; on which the good woman cried, "How canſt thou know what is doing in the heavens, when thou canſt not perceive what is at thy feet?" He went to ſee Cræſus, who was marching with a powerful army into Cappadocia, and enabled him to paſs the river Halys without making a bridge. Thales died ſoon after, at about 90 years of age. He compoſed ſeveral treatiſes in verſe, on meteors, the equinoxes, &c. but they are all loſt.

THALIA, in Pagan mythology, one of the nine muſes. She preſided over Comedy; and is repreſented crowned with a garland of ivy, holding a maſk in her hand, and wearing buſkins on her feet.

THALIA, in botany: A genus of plants belonging to the claſs of *monandria*, and order of *monogynia*: and in the natural ſyſtem ranging under the 8th order, *Scitamineæ*. The corolla is pentapetalous and undulated; and the drape has a bilo-

Thalictrum. Thames.

bilocular kernels. There is only one ſpecies, the geniculata.

THALICTRUM, MEADOW RUE, in botany: A genus of plants belonging to the claſs of *po'yandria*, and order of *polygynia;* and in the natural ſyſtem ranging under the 26th order, *Multiſiliqua*. There is no calyx; the petals are four or five in number, and the ſeeds are naked and without a tail. There are 15 ſpecies; three of which are indigenous, the *flavum*, *minus*, and *alpinum*.

1. The *flavum*, or common meadow-rue, has a leafy furrowed ſtalk, and a manifold erect panicle. It has commonly 24 ſtamina, and from 10 to 16 piſtils. The root and leaves of this plant dye a yellow colour, and cattle are fond of it. It grows on the banks of ſome rivers: It is found at North Queen's ferry, Fifeſhire. 2. The *minus*, or ſmall meadow-rue, has ſexpartite leaves, and bending flowers. The ſtalk is ſtriated, and about a foot high; the leaves are lax and divaricated, having rigid footſtalks; they are ſmooth and glaucous, and their lobes generally trifid; the panicle is branched and open, and the flowers nod: the petals are pale green, tinged with red; the ſtamina are from 15 to 20; the ſeeds deeply ſtriated, and from two to ſeven in number. This plant is frequent in ſandy ſoils and mountainous paſtures. 3. The *alpinum*, or alpine meadow-rue, has a very ſimple ſtalk, and almoſt naked; and a racemus ſimple and terminal. It is a pretty little plant, about a finger's-length in height; the leaves all riſe from the root, the ſtalk being naked and branched; the flowers nod, and have 4 petals, 12 ſtamina, and 8 piſtils. It is frequent on the ſides of rivulets in the highland mountains and other places.

THAMES, the fineſt river in Great Britain, which takes its riſe from a copious ſpring, called *Thames Head*, two miles ſouth-weſt of Cirenceſter in Glouceſterſhire. It has been erroneouſly ſaid, that its name is Iſis till it arrives at Dorcheſter, 15 miles below Oxford, when, being joined by the Thame or Tame, it aſſumes the name of the Thames, which, it has been obſerved, is formed from a combination of the words Thame and Iſis. What was the origin of this vulgar error, cannot now be traced. Poetical fiction, however, has perpetuated this error, and inveſted it with a kind of claſſical ſanctity. "It plainly appears (ſays Camden), that the river was always called *Thames* or *Tems*, before it came near the Thame; and in ſeveral ancient charters granted to the abbey of Malmſbury, as well as that of Enſham, and in the old deeds relating to Cricklade, it is never conſidered under any other name than that of *Thames*." He likewiſe ſays, that it occurs nowhere under the name of Iſis. All the hiſtorians who mention the incurſions of Ethelwold into Wiltſhire in the year 905, or of Canute in 1016, concur likewiſe in the ſame opinion, by declaring, that they paſſed over the Thames at Cricklade in Wiltſhire. It is not probable, moreover, that Thames Head, an appellation by which the ſource has uſually been diſtinguiſhed, ſhould give riſe to a river of the name of Iſis; which river, after having run half its courſe, ſhould reaſſume the name of Thames, the appellation of its parent ſpring. About a mile below the ſource of the river is the firſt corn-mill, which is called *Kemble Mill*. Here the river may properly be ſaid to form a conſtant current; which, though not more than nine feet wide in the ſummer, yet in the winter becomes ſuch a torrent as to overflow the meadows for many miles around. But, in the ſummer, the Thames Head is ſo dry, as to appear nothing but a large dell, interſperſed with ſtones and weeds. From Somerford the ſtream winds to Cricklade, where it unites with many other rivulets. Approaching Kemsford, it again enters its native country, dividing it from Berkſhire at Ingleſham. It widens conſiderably in its way to Lechlade; and being there joined by the Lech and Coln, at the diſtance of 138 miles from London, it becomes navigable for veſſels of 90 tons. At Enſham, in its courſe north-eaſt, to Oxford, is the firſt bridge of ſtone; a handſome one, of three arches, built by the earl of Abingdon. Paſſing by the ruins of Godſtow nunnery, where the celebrated Fair Roſamond was interred, the river reaches Oxford, in whoſe academic groves its poetical name of Iſis has been ſo often invoked. Being there joined by the Charwell, it proceeds ſouth-eaſt to Abingdon, and thence to Dorcheſter, where it receives the Tame. Continuing its courſe ſouth-eaſt by Wallingford to Reading, and forming a boundary to the counties of Berks, Bucks, Surry, Middleſex, Eſſex, and Kent, it waſhes the towns of Henley, Marlow, Maidenhead, Windſor, Eton, Egham, Staines, Laleham, Chertſey, Weybridge, Shepperton, Walton, Sunbury, Eaſt and Weſt Moulſey, Hampton, Thames Ditton, Kingſton, Teddington, Twickenham, Richmond, Iſleworth, Brentford, Kew, Mortlake, Barnes, Chiſwick, Hammerſmith, Putney, Fulham, Wandſworth, Batterſea, Chelſea, and Lambeth. Then, on the north bank of the river, are Weſtminſter and London, and, on the oppoſite ſide, Southwark; forming together one continued city, extending to Limehouſe and Deptford; and hence the river proceeds to Greenwich, Erith, Greenhithe, Gray's Thurrock, Graveſend, and Leigh, into the ocean. It receives in its courſe from Dorcheſter the rivers Kennet, Loddon, Coln, Wey, Mole, Wandle, Lea, Roding, Darent, and Medway. The juriſdiction of the lord mayor of London over the Thames extends from Coln Ditch, a little to the weſt of Staines, to Yendal or Yenleet to the eaſt, including part of the rivers Medway and Lea; and he has a deputy, named the water-bailiff, who is to ſearch for and puniſh all offenders againſt the laws for the preſervation of the river and its fiſh. Eight times a year the lord mayor and aldermen hold courts of conſervance for the four counties of Surry, Middleſex, Eſſex, and Kent. Though the Thames is ſaid to be navigable 138 miles above the bridge, yet there are ſo many flats, that in ſummer the navigation weſtward would be intirely ſtopped, when the ſprings are low, were it not for a number of locks. But theſe are attended with conſiderable expence; for a barge from Lechlade to London pays for paſſing through them 13l. 15s. 6d. and from Oxford to London 12l. 18s. This charge, however, is in ſummer only, when the water is low; and there is no lock from London Bridge to Bolter's Lock; that is, for 51½ miles above the bridge. The plan of new cuts has been adopted, in ſome places, to ſhorten and facilitate the navigation. There is one near Lechlade, which runs nearly parallel to the old river, and contiguous to St John's Bridge; and there is another a mile from Abingdon, which has rendered the old ſtream toward Culham Bridge uſeleſs. But a much more important undertaking has lately been accompliſhed; namely, the junction of this river with the Severn. A canal had been made, by virtue of an act of parliament in 1730, from the Severn to Wall Bridge, near Stroud. A new canal now aſcends by Stroud, through the vale of Chalford, to the height of 343 feet, by means of 28 locks, and thence to the entrance of a tunnel near Sapperton, a diſtance of near eight miles. The canal is 42 feet in width at top and 30 at the bottom. The tunnel (which is extended under Sapperton Hill, and under that part of earl Bathurſt's grounds called *Haley Wood*, making a diſtance of two miles and three furlongs) is near 15 feet in width, and can navigate barges of 70 tons. The canal deſcending hence 134 feet, by 14 locks, joins the Thames at Lechlade, a diſtance of above 20 miles. In the courſe of this vaſt undertaking, the canal, from the Severn at Froomlade to Ingleſham, where it joins the Thames, is a diſtance of more than 30 miles.

Brookes's Gazetteer.

Thames.

The

Thames, Thane.

The expence of it exceeded the ſum of 200,000l. of which 300ol. are ſaid to have been expended in gunpowder alone, uſed for the blowing up of the rock. This new canal was completed in 1789, in leſs than ſeven years from its commencement. A communication, not only with the Trent, but with the Merſey, has likewiſe been effected by a canal from Oxford to Coventry; and an act of parliament has paſſed to extend another canal from this, at Braunſton, to the Thames at Brentford. This is to be called *The Grand Junction Canal.* On the extenſive advantages reſulting from theſe navigable communications from the metropolis with the ports of Briſtol, Liverpool, Hull, &c. and the principal manufacturing towns in the inland parts of the kingdom, it is needleſs to expatiate. The tide flows up the Thames as high as Richmond, which, following the winding of the river, is 70 miles from the ocean; a greater diſtance than the tide is carried by any other river in Europe. The water is eſteemed extremely wholeſome, and fit for uſe in very long voyages, during which it will work itſelf perfectly fine.

THAMES is alſo the name of a river in the ſtate of Connecticut in America. See the article CONNECTICUT.

THANE, or THANUS, a name given to the nobility in Britain before the time of William the Conqueror. It ſignifies a miniſter or honourable retainer, from the verb *thenian* "to miniſter." There were ſeveral degrees of nobility among the Anglo-Saxons; but thoſe moſt commonly mentioned are the king's thanes and the alderman's thanes. The king's thanes ſeem to have been of three different degrees, according to their different degrees of wealth or favour at court. The alderman's thanes ſeem to have been of the loweſt degree of nobility, and next to them thoſe who were promoted to that dignity from their advancement in the church, from their valour, ſucceſs in agriculture or commerce: for if a ceorl or farmer applied to learning and attained to prieſts orders, if he acquitted himſelf ſo well as to obtain from a nobleman five hythes of land, or a gilt ſword, helmet, and breaſt-plate, the reward of his valour; or if by his induſtry he had acquired the property of five hythes of land; or if he applied to trade, and made three voyages beyond ſea in a ſhip of his own, and a cargo belonging to himſelf—he was denominated a *thane*.

The thanes, who were the only nobility among the Anglo-Saxons, were a very numerous body of men, comprehending all the conſiderable landholders in England, and filling up that ſpace in ſociety between the ceorls or yeomanry on the one hand, and the royal family on the other; which is now occupied both by the nobility and gentry. In times of war, they conſtituted the flower of their armies, and in times of peace they ſwelled the trains of their kings, and added greatly to the ſplendour of their courts, eſpecially at the three great feſtivals of Chriſtmas, Eaſter, and Whitſuntide. From this body all the chief officers, both civil and military, as aldermen, greeves, earls, heretogens, &c. were taken; and to obtain ſome of theſe offices was the great object of their ambition. Before they obtained an office, their lands were their only ſupport; and they lived in greater or leſs affluence, according to the extent of their eſtates. Theſe they divided into two parts; one of which they called their *inlands*, and the other their *outlands*. Their inlands they kept in their own immediate poſſeſſion, and cultivated them by the hands of their ſlaves and villains, in order to raiſe proviſions for their families; their outlands they granted to ceorls or farmers, either for one year, or for a term of years; for which they received a certain ſtipulated proportion of their produce annually. Theſe cuſtoms had long prevailed among their anceſtors in Germany, and were adhered to by their poſterity in England till the conqueſt.

Henry's Hiſtory of Great Britain. vol. ii.

Thanet || Thea.

The thanes were under no obligations on account of their lands, except the three following, which were indiſpenſably neceſſary to the defence and improvement of their country: To attend the king with their followers in military expeditions, to aſſiſt in building and defending the royal caſtles, and in keeping the bridges and highways in proper repair. To theſe obligations all proprietors of land (even the churchmen for a long time not excepted) were ſubjected; and theſe ſervices were conſidered as due to their country, rather than to the perſons of their kings; and were agreed to by all as being neceſſary to their own preſervation and conveniency.

This title of thane was aboliſhed in England at the conqueſt, upon the introduction of the feudal ſyſtem by William. The titles of earl and baron were about the ſame period introduced into Scotland by Malcom Canmore, and the title of thane fell into diſuſe.

THANET, an iſland of the county of Kent, ſurrounded by the ſea except on the north-eaſt ſide, where it is bounded by the branches of the river Stour, now inconſiderable to what they were formerly. It contains ſeveral villages, and the ſea-port towns of Margate and Ramſgate, and has the title of an earldom. It is celebrated for being the ſpot through which arts, ſciences, and divine knowledge, came into this happy iſle. The Britons called it *Richborough*, from its vicinity to the city of that name, now only a venerable ruin; but the Saxons called it *Thanet*, from fire, having ſo many beacons erected on it. It is in the north-eaſt, part of the country, lies open to the ſea on the north and eaſt, with the river Wantſum on the weſt and ſouth, is about 10 miles long from the North Foreland to Sarre-Bridge, and about 8 broad from Weſtgate to Sandwich-Ferry. The north part of it is all arable, except ſome barren land, that is ſown with faintfoin, which produces a load and ſometimes two loads of hay upon an acre; by which means, the land that otherwiſe is not worth half-a crown an acre, yields 30s. or 40s. The ſouth and weſt parts of the iſland are moſt of them marſh or paſture lands. The ſoil is generally very fertile, eſpecially in the beſt of barley, and other ſorts of grain, of which it is computed about 20,000 quarters are ſent hence to London in a year, beſides what is ſold to other places. The *alga marina*, or ſea-ore, as they call it, is their chief manure. This they dry on the ſhore, and burn, in order to make kelp, which the potters uſe in glazing their ware. But the ſmell of the rotten ore upon the ſoil, and the ſmoke of it when burning, is very noiſome. The gentlemen's families are for the moſt part gone from this part of the country, having ſold their eſtates; ſo that their manſion ſeats are converted into farm-houſes; but then, on the other hand, many of the yeomen and farmers have good eſtates, on which they live very genteelly. In this iſland are ten pariſhes, but ſeven pariſh-churches, and one chapel.

Nucomb's England's Gazetteer.

THAPSIA, the DEADLY CARROT, in botany: A genus of plants belonging to the claſs of *pentandria*, and order of *digynia*; and in the natural ſyſtem ranging under the 45th order, *umbellatæ*. The fruit is oblong and girt with a membrane. There are five ſpecies; the villoſa, fœtida, aſclepium, garganica, and trifoliata. The roots of the fœtida were formerly ordered in medicine, but are now intirely diſuſed; a ſmall doſe operating with extreme violence both upwards and downwards.

THAWING, the reſolution of ice into its former fluid ſtate by the warmth of the air. See CONGELATION and FROST.

THEA, in botany. See TEA.

Theatines, Theatre.

THEATINES, a religious order in the Romiſh church, ſo called from their principal founder John Peter Caraffa, then biſhop of Theate, or Chieti, in the kingdom of Naples, and afterwards pope, under the name of *Paul* IV. The names of the other founders were Gaetan, Boniface, and Conſiglieri. Theſe four pious men deſiring to reform the eccleſiaſtical ſtate, laid the foundation of an order of regular clerks at Rome in the year 1524. Pope Clement VII. approved the inſtitution, and permitted the brethren to make the three religious vows, to elect a ſuperior every three years, and to draw up ſtatutes for the regulation of the order. They firſt endeavoured, by their example, to revive among the clergy the poverty of the apoſtles and firſt diſciples of our Saviour, and were the firſt who aſſumed the title of *regular clerks*.

THEATRE, a place in which ſhows or dramatic repreſentations are exhibited.

For the origin of the dramatic art we always turn our eyes to Greece, the nurſery of the arts and ſciences. It may indeed have been known among more ancient nations, but no records remain ſufficient to ſupport this opinion. The different ſtates of Greece aſſerted their claim to the honour of having given it birth, but the account of the Athenians is moſt generally received. It derived its origin from the hymns which were ſung in the feſtivals of Bacchus in honour of that deity. While theſe reſounded in the ears of the multitude, choruſes of Bacchants and Fauns, ranged round certain obſcene images which they carried in triumphal proceſſion, chanted laſcivious ſongs, and ſometimes ſacrificed individuals to public ridicule.

This was the practice in the cities; but a ſtill greater licentiouſneſs reigned in the worſhip paid to the ſame divinity by the inhabitants of the country, and eſpecially at the ſeaſon when they gathered the fruits of his beneficence. Vintagers, beſmeared with wine-lees, and intoxicated with joy and the juice of the grape, rode forth in their carts and attacked each other on the road with groſs ſarcaſms, revenging themſelves on their neighbours with ridicule, and on the rich by publiſhing their injuſtice.

Anacharſis's Travels, vol. i.

Among the poets who flouriſhed at that time, ſome celebrated the great actions and adventures of gods and heroes, and others attacked with aſperity the vices and abſurdities of individuals. The former took Homer for their model, and ſupported themſelves by his example, of which they made an improper uſe. Homer, the moſt tragic of poets, the model of all who have ſucceeded him, had in the Iliad and the Odyſſey brought to perfection the heroic poem, and in his Margites had employed pleaſantry. But as the charm of his works depends in a great meaſure on the paſſions and motion with which he knew to animate them, the poets who came after him endeavoured to introduce into theirs an action which might excite emotion or mirth in the ſpectators: ſome even attempted to produce both, and ventured certain rude eſſays, which have ſince been ſtyled indifferently either tragedies or comedies, becauſe they unite the characters of thoſe two dramas. The authors of theſe ſketches have been diſtinguiſhed by no diſcovery; they only form in the hiſtory of the art a ſucceſſion of names which it would be uſeleſs to recal to light.

The neceſſity and power of theatrical intereſt was already known. The hymns in honour of Bacchus, while they deſcribed his rapid progreſs and ſplendid conqueſts, became imitative; and in the conteſts of the Pythian games, the players on the flute who entered into competition were enjoined by an expreſs law to repreſent ſucceſſively the circumſtances that had preceded, accompanied, and followed the victory of Apollo over Python. Theatre.

Some years after this regulation, Suſarion and Theſpis, both born in a ſmall borough of Attica, named *Icaria*, appeared each at the head of a company of actors, the one on a kind of ſtage, the other in a cart (A). The former attacked the vices and abſurdities of his time; and the latter treated more noble ſubjects, which he took from hiſtory.

The comedies of Suſarion were in the ſame taſte with thoſe indecent and ſatirical farces which were afterwards performed in ſome of the cities of Greece. They were long the favourite entertainment of the country people. Athens did not adopt this ſpecies of exhibition until after it was brought to perfection in Sicily.

Theſpis had more than once ſeen in the feſtivals, in which as yet hymns only were ſung, one of the ſingers, mounted on a table, form a kind of dialogue with the chorus. From this hint he conceived the idea of introducing into the tragedies an actor who, by ſimple recitals introduced at intervals, ſhould give relief to the chorus, divide the action, and render it more intereſting. This happy innovation, together with ſome other liberties in which he had allowed himſelf, gave alarm to the legiſlator of Athens who was more able than any other perſon to diſcern the value or danger of the novelty. Solon condemned a ſpecies of compoſition in which the ancient traditions were diſguiſed by fictions. "If we applaud falſehood in our public exhibitions (ſaid he to Theſpis), we ſhall ſoon find that it will inſinuate itſelf into our moſt ſacred engagements."

The exceſſive approbation and delight with which both the city and country received the pieces of Theſpis and Suſarion, at once juſtified and rendered uſeleſs the ſuſpicious foreſight of Solon. The poets, who till then had only exerciſed their genius in dithyrambics and licentious ſatire, ſtruck with the elegant forms which theſe ſpecies of compoſition began to aſſume, dedicated their talents to tragedy and comedy. Soon after a greater variety was introduced in the ſubjects of the former of theſe poems. Thoſe who judge of their pleaſures only from habit exclaimed, that theſe ſubjects were foreign to the worſhip of Bacchus; but the greater number thronged with ſtill more eagerneſs after the new pieces.

Phrynichus, the diſciple of Theſpis, made choice of that kind of verſe which is moſt ſuitable to the drama, was the author of ſome other changes, and left tragedy in its infancy.

Æſchylus received it from his hands enveloped in a rude veſtment, its viſage covered with falſe colours, or a maſk inexpreſſive of character, without either grace or dignity in its motions, inſpiring the deſire of an intereſt which it with difficulty excited, ſtill attached to the buffooneries which had amuſed its infant years, and expreſſing its conceptions ſometimes with elegance and dignity, but frequently in a feeble and low ſtyle, polluted with groſs obſcenities.

In his firſt tragedies he introduced a ſecond actor; and afterward, copying the example of Sophocles, who had juſt entered on his theatrical career, he admitted a third, and ſometimes even a fourth. By this multiplicity of perſonages, one of his actors became the hero of the piece, and attracted to himſelf the principal intereſt; and as the chorus now held only a ſubaltern ſtation, Æſchylus took care to ſhorten

(A) Suſarion repreſented his firſt pieces towards the year 580 before Chriſt. Some years after, Theſpis made his firſt attempts in tragedy, and acted his Alceſtis in 536.

Theatre. ſhorten its part, and perhaps even carried this precaution too far.

He is cenſured for having admitted mute characters into his drama. Achilles, after the death of his friend, and Niobe, after the deſtruction of her children, appear on the ſtage, and remain during ſeveral ſcenes motionleſs, with their heads covered with a veil, and without uttering a word; but if their eyes had overflown with tears, and they had poured forth the bittereſt lamentations, could they have produced an effect ſo terrible as this veil, this ſilence, and this abandonment to grief?

It was not ſufficient that the noble and elevated ſtyle of tragedy ſhould leave in the minds of the auditors a ſtrong impreſſion of grandeur; to captivate the multitude, it was requiſite that every part of the ſpectacle ſhould concur to produce the ſame effect. It was then the general opinion that nature, by beſtowing on the ancient heroes a more lofty ſtature, had impreſſed on their perſons a majeſty which procured them as much reſpect from the people as the enſigns of dignity by which they were attended. Æſchylus therefore raiſed his actors on high ſtilts or buſkins. He covered their features, which were frequently diſagreeable, with a maſk that concealed their irregularity. He clothed them in flowing and magnificent robes, the form of which was ſo decent, that the prieſts of Ceres have not bluſhed to adopt it. The inferior actors were alſo provided with maſks and dreſſes ſuited to their parts.

Inſtead of thoſe wretched ſcaffolds which were formerly erected in haſte, he obtained a theatre furniſhed with machines, and embelliſhed with decorations. Here the ſound of the trumpet was reverberated, incenſe was ſeen to burn on the altars, the ſhades of the dead to ariſe from the tomb, and the furies to ruſh from the gulphs of Tartarus. In one of his pieces theſe infernal divinities appeared, for the firſt time, with maſks of a horrid paleneſs, torches in their hands, ſerpents intertwined in their hairs, and followed by a numerous retinue of dreadful ſpectres. It is ſaid that, at the ſight of them, and the ſound of their terrific howlings, terror ſeized on the whole aſſembly, women miſcarried, and children expired with fear; and that the magiſtrates, to prevent ſimilar accidents in future, commanded that the chorus ſhould conſiſt only of fifteen actors inſtead of fifty.

The effect of ſo many new objects could not but aſtoniſh the ſpectators; nor were they leſs ſurpriſed and delighted at the intelligence diſplayed in the performance of the actors, whom Æſchylus almoſt always exerciſed himſelf. He regulated their ſteps, and taught them to give additional force to the action by new and expreſſive geſtures.

The progreſs of the art was extremely rapid. Æſchylus was born 525 years before Chriſt, 11 years after Theſpis had acted his Alceſtis. He had for competitors Chœrilus Pratenas, and Phrynichus, whoſe glory he eclipſed, and Sophocles, who rivalled his own. Sophocles was born about the year 497 B. C. about 14 years before Euripides. Theſe carried tragedy to the higheſt perfection to which it attained among the Greeks. Æſchylus painted men greater than they can be, Sophocles as they ought to be, and Euripides as they are.

Invented towards the 50th Olympiad (about 580 B. C.), and adapted to the rude manners of the ruſtics, comedy ventured not to approach the capital; and if by chance ſome companies of actors, who were unconnected with any others, found their way into the city, and performed their indecent farces, they were leſs authoriſed than tolerated by the government. It was not till after a long infancy that this ſpecies of drama began ſuddenly to make a rapid improvement in Sicily. Inſtead of a ſucceſſion of ſcenes without connection or tendency, the philoſopher Epicharmus introduced an action, all the parts of which had a dependence on each other; and conducted his ſubject, without wandering from it, through a juſt extent to a determinate end. His pieces, ſubjected to the ſame laws as tragedy, were known in Greece, where they were conſidered as models; and comedy ſoon ſhared with her rival the ſuffrages of the public, and the homage due to genius. The Athenians, eſpecially, received her with the ſame tranſports as they would have teſtified at the news of a victory: many of their poets exerciſed their genius in this novel ſpecies of compoſition; and their names adorn the numerous liſt of writers who have been diſtinguiſhed in comedy from the time of Epicharmus. Such were, among the more ancient, Magnes, Cratinus, Crates, Pherecrates, Eupolis, and Ariſtophanes. They all flouriſhed in the age of Pericles. Theatre.

If we peruſe the comic pieces which have come down to us, we ſhall be convinced that the ſole object of the authors was to pleaſe the multitude. The gods and heroes were traveſtied, groſs and obſcene language was often employed, and virulent invectives were often thrown out againſt individuals of the firſt rank for genius and virtue. Towards the end of the Peloponneſian war the licentiouſneſs of comedy was reſtrained. The chorus was laid aſide, becauſe the rich citizens were alarmed, and would no longer contribute money to ſupport it, nor provide maſks with portraits for expoſing individuals.

The poets being thus reſtrained from mentioning names of living perſons on the ſtage, invented falſe names. They ſtill expoſed real and known characters; and thus gave a more exquiſite gratification to the ſpectators, who were highly amuſed with finding out the perſons intended. The conſequence of the law was only to make that done with delicacy which was formerly done in the moſt indecent and ſcurrilous manner. Ariſtophanes, in ſome of his lateſt pieces, has given us ſome good examples of this kind of comedy, which is ſometimes called the middle comedy.

Comedy was ſtill liable to abuſe, and therefore required farther reformation. As the uſe of real names had formerly been prohibited, real ſubjects were alſo forbidden; and comedy from that time was no longer a fury armed with torches, or a firebrand ſcattering miſchief, but a pleaſing and inſtructive companion. This is called the new comedy. The moſt eminent among the Greeks in this improved ſpecies was Menander. His writings are now loſt; but we may form a good eſtimate of their merit from the comedies of Terence, which are ſaid to have been borrowed from Menander, and to have nearly reſembled the original, though inferior in that *vis comica* by which the elegant Grecian was diſtinguiſhed. The comedy of Menander is that which has been cultivated in modern times.

To give ſome idea of a Grecian theatre, we ſhall deſcribe very ſhortly the theatre of Bacchus in Athens, which was built by the famous architect Philos in the time of Pericles. The part intended for the ſpectators was of a ſemicircular form, at the diameter of which was erected the ſtage. The orcheſtra occupied the ſpace where the pit in modern theatres is ſituated, where the muſic, the chorus, and the mimi were placed. It was four feet elevated above the ground. The ſpectators were arranged in three galleries round all the ſides of the orcheſtra except that next the ſtage, each gallery containing eight rows of ſeats. At the farther end of the orcheſtra, where the ſtage is erected in modern theatres, ſtood the thymele or logeon, but projecting a little towards the audience. It was a little higher than the orcheſtra, and did not extend the whole breadth of it. In ſome theatres it was only ſix feet ſquare. Here the principal part of the chorus made their recitations, and in comical interludes the mimi performed. Behind the thymele Gentleman's Magazine for 1760.

Theatre.

mele appeared the ſtage or proſcenion, conſiderably elevated. No part of this theatre was covered except the ſtage, and a high gallery called *circys* ſet apart for the women. The Athenians, being expoſed to the weather, came uſually with great cloaks, to ſecure them from the rain or the cold; and for defence againſt the ſun, they had the *ſciadion*, a kind of paraſol, which the Romans uſed alſo in their theatres by the name of *umbellæ*; but when a ſudden ſtorm aroſe, the play was interrupted, and the ſpectators diſperſed.

A ſort of tent-work over the entire area of the edifice might have been contrived as a ſhelter from the rain and a ſhade from the ſun. Such a covering would have obviated the inconveniences of roofed theatres, which obſtruct the free communication of the air, and of unroofed theatres, which do not keep out the weather. At Athens the plays were always repreſented in the day-time, which made the unroofed theatres leſs inconvenient.

Plays were repreſented only during the three feſtivals ſolemnized in honour of Bacchus. The firſt of theſe was celebrated at the Piræus, where ſome of Euripides's pieces were firſt performed. The ſecond, which laſted only one day, was kept at the end of January or beginning of February. The third, called the greater *Dionyſia*, was celebrated a month after. It continued ſeveral days, and attracted a great multitude of ſpectators. In the feſtivals which laſted only one day, five or ſix dramatic pieces, either tragedies or comedies, were performed. But in the greater Dionyſia, which continued longer, 12 or 15, and ſometimes more, were acted. The performance began early in the morning, and ſometimes laſted the whole day.

The chorus, according as the ſubject demanded, was compoſed of men and women, old men or youths, citizens or ſlaves, prieſts, ſoldiers, &c. to the number of 15 in tragedy, and 24 in comedy. The chorus came upon the ſtage preceded by a flute-player, who regulated their ſteps; ſometimes one after the other, but in tragedy more frequently three in front and five in depth, or five in front and three in depth.

The ſame perſons performed both in tragedy and comedy; but, as among ourſelves, it was rare to meet with any who excelled in both. The pay of thoſe who had acquired great reputation was conſiderable. Polus gained a talent in two days (equal to L. 225 Sterling*). Players of eminence were ſolicited by different actors of Greece to attend their feſtivals. If, after making an engagement, they failed, they were obliged to pay a certain ſum of money; and if they were abſent during the feſtivals of their own republic, they were condemned to a heavy fine.

* Plut. in X. Rhet.

The actors had habits and ſymbols ſuited to their parts. Kings wore a diadem, leaned on a ſceptre which ſupported an eagle on its top, and were dreſſed in long robes of purple or other ſplendid colours ornamented with gold. Heroes, beſides having their ſtature frequently increaſed to ſix feet Engliſh ||, and their bulk in proportion, were frequently covered with the ſkin of a lion or a tyger, and armed with ſwords, quivers, and clubs. All who ſuffered misfortunes wore a black, brown, or dirty white garment, which frequently hung in tatters. There were various kinds of maſks for tragedy, comedy, and ſatire. Theſe certainly took away the pleaſure ariſing from the expreſſion of the countenance; but at any rate, little pleaſure could be derived from this circumſtance in a Grecian theatre, from its immenſe ſize, and the great diſtance of the audience from the ſtage.

|| Ariſt. in Ran. v. 1046. Athen. lib. v. cap. 7.

Dramatic entertainments were introduced at Rome in the year of the city 391. They were called *ludi ſcenici*, becauſe they were firſt acted in a ſhade formed by the branches and leaves of trees. They were borrowed immediately from Etruria, whence alſo they received their firſt players. Theſe Etrurians at firſt only danced to a flute, without either ſinging or acting. The Roman youth ſoon imitated them at their ſolemn feſtivals, adding raillery in rude verſes, and geſtures adapted to the ſubject. Theſe verſes were called *Feſcennia*, from Feſcennia, a city of Etruria. Livius Andronicus was the firſt poet who wrote a regular play in Latin. This happened in the year of Rome 512 or 514, about 160 years after the death of Sophocles and Euripides, and 52 after that of Menander. The Grecian model was afterwards introduced and cultivated much by ſucceeding dramatic writers. This was the model of Menander, for the old and middle comedy was unknown at Rome. As the Romans were only imitators of the Greeks in the dramatic art, as well as in moſt of the arts and ſciences, nothing more is neceſſary to be ſaid in addition to the account which we have already given of the Grecian ſtage.

Theatre.

The origin of the Engliſh ſtage is hid in obſcurity. It was not, however, copied from the Grecian or Roman; for it was evidently different in form as well as in matter, and may with more propriety be deduced from a Gothic original. It appears that there were theatrical entertainments in England almoſt as early as the conqueſt; for we are told by William Stephanides or Fitz-Stephen, a monk, who in the reign of Henry II. wrote his *Deſcriptio Nobiliſſimæ Civitatis Londoniæ*, that "London, inſtead of the common interludes of the theatre, had plays of a more holy kind; repreſentations of the miracles of confeſſors, and the ſufferings of martyrs. At this time there were alſo certain ſets of idle people, who travelled the countries and were called *Mummers*, a kind of vagrant comedians, whoſe excellence conſiſted altogether in mimickry and humour.

Gentleman's Magazine for 1761.

It is probable that, ſoon after this time, the dramatic repreſentations called *Myſteries* were exhibited: Theſe myſteries were taken from ſcripture-hiſtory: ſome repreſented the creation of the world, with the fall of Adam and Eve; ſome the ſtory of Joſeph; and others even the incarnation and ſufferings of the Son of God. Theſe pieces were exhibited in a manner ſo ridiculous as to favour libertiniſm and infidelity, as appears by a petition of the chaunters of St Paul's cathedral to Richard II. in 1378, praying, that "ſome unexpert people might be prohibited from repreſenting the hiſtory of the Old Teſtament to the prejudice of the ſaid clergy, who had been at great expence to repreſent it publicly at Chriſtmas."

Cibber's Apology for his Life.

In the year 1390, the pariſh clerks of London are ſaid to have played interludes at Skinner's-well on three ſucceſſive days in July; and, in 1409, to have acted for eight days ſucceſſively a play concerning the creation of the world, at the ſame place which thence acquired the name of *Clerkenwell*.

Theſe Myſteries were ſucceeded by Moralities, in which there were ſome rude traces of a fable and a moral; and ſome alſo of poetry, the virtues, vices, and other affections of the mind being frequently perſonified.

After theſe Moralities came what were called Interludes, which made ſome approaches to wit and humour. Many of theſe pieces were written by John Heywood, jeſter to Henry VIII.

In the time of Henry VIII. one or two pieces had been publiſhed under the claſſical names of *Comedy* and *Tragedy*, but they appear not to have been intended for popular uſe. It was not till the religious ferments had ſubſided that the public had leiſure to attend to dramatic poetry. In the reign of Elizabeth, tragedies and comedies began to appear in form, and could the poets have perſevered, the firſt models were good. *Gorboduc*, a regular tragedy, was acted in 1561; and Gaſcoigne, in 1566, exhibited *Jocaſta*, a tranſlation from Euripides, as alſo *The ſuppoſes*, a regular comedy,

Percy's Relics of Ancient Engliſh Poetry.

Theatre. comedy, from Arioſto, near thirty years before any of Shakeſpeare's were printed.

The people however ſtill retained a reliſh for their old myſteries and moralities, and the popular dramatic poets ſeem to have made them their models. The graver ſort of moralities appear to have given birth to our modern tragedy; as our comedy evidently took its riſe from the lighter interludes of that kind. And as moſt of theſe pieces contain an abſurd mixture of religion and buffoonery, an eminent critic has well deduced from thence the origin of our unnatural tragi-comedies. Even after the people had been accuſtomed to tragedies and comedies, moralities ſtill kept their ground. One of them, intitled *The New Cuſtom*, was printed ſo late as 1573. At length they aſſumed the name of *maſques*, and, with ſome claſſical improvements, became in the two following reigns the favourite entertainments of the court.

As for the old myſteries, which ceaſed to be acted after the reformation, they ſeem to have given riſe to a third ſpecies of ſtage exhibition; which, though now confounded with tragedy or comedy, were by our firſt dramatic writers conſidered as quite diſtinct from them both: theſe were hiſtorical plays, or hiſtories; a ſpecies of dramatic writing which reſembled the old myſteries in repreſenting a ſeries of hiſtorical events ſimply in the order of time in which they happened, without any regard to the three great unities. Theſe pieces ſeem to differ from tragedy juſt as much as hiſtorical poems do from epic: as the Pharſalia does from the Æneid. What might contribute to make dramatic poetry take this turn was, that ſoon after the myſteries ceaſed to be exhibited, there was publiſhed a large collection of poetical narratives, called *the Mirror for Magiſtrates*, wherein a great number of the moſt eminent characters in Engliſh hiſtory are drawn relating their own misfortunes. This book was popular and of a dramatic caſt; and therefore, as an elegant writer has well obſerved, might have its influence in producing hiſtoric plays. Theſe narratives probably furniſhed the ſubjects, and the ancient myſteries ſuggeſted the plan.

That our old writers conſidered hiſtorical plays as ſomewhat diſtinct from tragedy and comedy, appears from numberleſs paſſages of their works. "Of late days (ſays Stow in his Survey of London), inſtead of thoſe ſtage plays have been uſed comedies, tragedies, interludes, and hiſtories, both true and fained." Beaumont and Fletcher, in the prologue to the *Captain*, ſay,

"This is nor comedy, nor tragedy,
"Nor *hiſtory*."——

Polonius in *Hamlet* commends the actors as the beſt in the world, either for tragedie, comedie, hiſtorie, paſtorall, &c. And Shakeſpeare's friends, Heminge and Condell, in the firſt folio edition of his plays, in 1623, have not only intitled their book "Mr. William Shakeſpeare's Comedies, Hiſtories, and Tragedies," but, in their table of contents, have arranged them under thoſe three ſeveral heads; placing in the claſs of hiſtories, "King John, Richard II. Henry IV. 2 pts, Henry V. Henry VI. 3 pts, Richard III. and Henry VIII."

This diſtinction deſerves the attention of the critics: for if it be the firſt canon of ſound criticiſm to examine any work by thoſe rules the author preſcribed for his firſt obſervance; then we ought to try Shakeſpeare's hiſtories by the general laws of tragedy and comedy. Whether the rule itſelf be vicious or not, is another enquiry; but certainly we ought to examine a work only by thoſe principles according to which it was compoſed. This would ſave much impertinent criticiſm. Theatre.

Not fewer than 19 playhouſes had been opened before the year 1633, when Prynne publiſhed his *Hiſtriomaſtix*. From this writer we learn that tobacco, wine, and beer, were in thoſe days the uſual accommodations in the theatre, as now at Sadlers Wells. With regard to the ancient prices of admiſſion, the playhouſe called the *Hope* had five different priced ſeats, from ſixpence to half-a-crown. Some houſes had penny benches. The two-penny gallery is mentioned in the prologue to Beaumont and Fletcher's *Woman Hater*; and ſeats of threepence and a groat in the paſſage of Prynne laſt referred to. But the general price of what is now called the *Pit* ſeems to have been a ſhilling. The time of exhibition was early in the afternoon, their plays being generally acted by day light. All female parts were performed by men, no actreſs being ever ſeen on the public ſtage before the civil wars. And as for the playhouſe furniture and ornaments, they had no other ſcenes nor decorations of the ſtage, but only old tapeſtry, and the ſtage ſtrewed with ruſhes, with habits accordingly; as we are aſſured in a ſhort Diſcourſe on the Engliſh Stage, ſubjoined to Flecknoe's *Love's-Kingdom*, 1674, 12mo.

(B) For the ſtate of the theatre during the time of Shakeſpeare, ſee PLAYHOUSE; where a full account of it is given from the late valuable edition of our illuſtrious poet's works by Mr Malone. During the whole reign of James I. the theatre was in great proſperity and reputation: dramatic authors abounded, and every year produced a number of new plays; it became a faſhion for the nobility to celebrate their weddings, birth-days, and other occaſions of rejoicing, with maſques and interludes, which were exhibited with ſurpriſing expence; our great architect, Inigo Jones, being frequently employed to furniſh decorations, with all the luxuriance of his invention and magnificence of his art. The king and his lords, and the queen and her ladies, frequently performed in theſe maſques at court, and the nobility at their private houſes; nor was any public entertainment thought complete without them. This taſte for theatrical entertainments continued during great part of the reign of king Charles the firſt; but, in the year 1633, it began to be oppoſed by the Puritans from the preſs; and the troubles that ſoon after followed entirely ſuſpended them till the reſtoration of king Charles the ſecond in 1660.

The king, at his reſtoration, granted two patents, one to Henry Killigrew, Eſq. and the other to Sir William Davenant, and their heirs and aſſigns, for forming two diſtinct companies of comedians. Killigrew's were called the *King's Servants*, and Davenant's the *Duke's Company*. About ten of the company called the *King's Servants* were on the royal houſehold eſtabliſhment, having each ten yards of ſcarlet cloth, with a proper quantity of lace allowed them for liveries; and in their warrants from the lord chamberlain they were ſtyled *gentlemen of the great chamber*.

Till this time no woman had been ſeen upon the Engliſh ſtage, the characters of women having always been performed by boys, or young men of an effeminate aſpect, which probably

(B) We have been anxious to give as full an account of the ancient Engliſh drama as we could: we muſt not omit, however, to inform our readers what Mr Malone ſays of the old plays, *viz.* that not one play publiſhed before 1592 will bear a ſecond reading; and that excluſive of myſteries, moralities, and tranſlations, there are but 34 pieces extant which were publiſhed before that period.

Theatre. bably induced Shakeſpeare to make ſo few of his plays depend upon female characters, as they muſt have been performed to great diſadvantage. The principal characters of his women are innocence and ſimplicity, ſuch are Deſdemona and Ophelia; and his ſpecimen of fondneſs and virtue in Portia is very ſhort. But the power of real and beautiful women was now added to the ſtage; and all the capital plays of Shakeſpeare, Fletcher, and Ben Johnſon, were divided between the two companies, by their own alternate choice, and the approbation of the court.

The king's ſervants ſeem to have been allowed to be the beſt company; and when the variety of plays began to be exhauſted, they drew the greater audiences. Davenant, therefore, to make head againſt them, firſt added ſpectacle and muſic to action, and introduced a new ſpecies of plays, ſince called *dramatic operas;* among theſe were, *The Tempeſt*, *Pſyche*, and *Circe;* which, with many others, were ſet off with the moſt expenſive decorations of ſcenes and habits, and with the beſt voices and dancers.

In 1684 the two houſes united, and continued together for ten years. In 1690 the play began at four o'clock; and, we are told, the ladies of faſhion uſed to take the evening air in Hyde-park after the repreſentation; by which it appears that the exhibitions were in ſummer too. The principal actors were, Betterton, Montfort, Kynaſton, Sandford, Nokes, Underhill, and Leigh, commonly called *Tony Leigh;* the actreſſes were, Mrs Betterton, Barry, Leigh, Butler, Montford, and Bracegirdle; and to this company, in this year, old Cibber was admitted as a performer in the loweſt rank. It was a rule with the patentees, that no young perſon, who offered himſelf as an actor, ſhould be admitted into pay till after at leaſt half a year's probation; and Cibber waited full three quarters of a year before he was taken into a ſalary of 10s. a week.

In 1695 a new theatre was opened with Mr Congreve's comedy of Love for Love, which had ſuch extraordinary ſucceſs (ſays Cibber) that ſcarce any other play was acted there till the end of the ſeaſon; but when the ſeaſon ended, which appears to have begun in June, he does not tell us, and it is indeed difficult to gueſs; for though the company acted in ſummer, it ſeems improbable that they ſhould ſhut up the houſe in winter, as it is difficult to conceive any reaſon for ſo doing. Congreve was then in ſuch high reputation, that this company offered him a whole ſhare (but into how many ſhares the whole was divided Colley has not told us) upon condition he would give them a new play every year. This offer he accepted, and received the advantage, though he never fulfilled the condition; for it was three years before he produced the *Mourning Bride*, and three more before he gave them *the Way of the World.*

It is not neceſſary that we give in detail the remaining hiſtory of the Engliſh ſtage: thoſe who are anxious to be acquainted with it may conſult Cibber's hiſtory of the ſtage, continued by Victor, under the title of *A Hiſtory of the Theatres of London and Dublin from the year* 1730. We ſhall only mention a few facts reſpecting the ſalaries of the players about that period, and the riſe of the price of play-tickets.

A difference having ariſen in 1733 between the managers and actors, moſt of the actors ſet up for themſelves at the little theatre in the Haymarket. Upon this the managers publiſhed the following account of their ſalaries, to ſhew the public how little room they had to mutiny. To Mr Colley Cibber, from the time of letting his ſhare till he left the ſtage, 12l. 12s. *per* week. Mr The. Cibber 5l. and his wife's whole ſalary till her death, without doing the company any ſervice the greateſt part of the winter; and his own alſo, during the time of his being ill, who performed but ſeldom till after Chriſtmas. Mr Mills jun. 3l. under the ſame circumſtances with regard to his wife. Mr Mills ſen. 1l. *per* day for 200 days certain, and a benefit clear of all charges. Mr Johnſton 5l. Mr Miller 5l. paid him eight weeks before he acted, beſides a preſent of 10 guineas. Mr Harper 4l. and a preſent of 10 guineas. Mr Griffin 4l. and a preſent. Mr Shepard 3l. Mr Hallam, for himſelf and father (though the latter is of little or no ſervice) 3l. Mrs Heron 5l. raiſed from 40s. laſt winter, yet refuſed to play ſeveral parts aſſigned her, and acted but ſeldom this ſeaſon. Mrs Butler 3l. *per* week. By theſe and other ſalaries, with the incident charges (beſides clothes and ſcenes), the patentees are at the daily charge of 49l. odd money, each acting-day.

Gentleman's Magazine for 1733.

Till about the ſame time, the prices at the theatre were 4s. the boxes, 2s. 6d. the pit, 1s. 6d. the firſt gallery, and 1s. the ſecond, except upon the firſt run of a new play or pantomime, when the boxes were 5s. the pit 3s. the firſt gallery 2s. and the ſecond 1s. But Fleetwood thought fit to raiſe the prices for an old pantomime, which was revived without expence. This produced a riot for ſeveral nights, and at laſt a number deputed by the pit had an interview with the manager in the green room, where it was agreed, that the advanced prices ſhould be conſtantly paid at the doors, and that ſuch perſons as did not chooſe to ſtay the entertainment ſhould have the advanced part of their money returned. This was a very advantageous agreement for the manager; becauſe, when the audience had once paid their money, and were ſeated, very few went out at the end of the play, and demanded their advanced money; the few that did it at firſt, ſoon grew tired, and at laſt it ſettled in the quiet payment of the advanced price, as at this day.

It has been frequently a ſubject of debate, whether the ſtage be favourable to morals. We do not mean to enter into the controverſy; but we ſhall make an obſervation or two. It will be allowed by all, that the intention of the players in acting, is to procure money; and the intention of the audience in attending the theatre, is to ſeek amuſement. The players then will only act ſuch plays as they believe will anſwer their intention. And what ſort of plays are theſe? They are ſuch as correſpond with the opinions, manners, and taſte, of the audience. If the taſte of the audience be groſs, therefore the plays will be groſs; if delicate and refined, they will be the ſame. And if we go back to the time of Shakeſpeare, we ſhall find that this has been uniformly the caſe. The concluſion, then, which we draw, is this, if the taſte of the audience be pure, free from licentiouſneſs, the plays will be the ſame, and the ſtage will be favourable to virtue.

THEBAIC POWDER. See *PHARMACY-Index.*

THEBAID, a celebrated heroic poem of Statius, the ſubject whereof is the civil war of Thebes, between the two brothers Eteocles and Polynices; or Thebes taken by Theſeus.

Theatre ‖ Thebes.

THEBES, the name of a celebrated city of ancient Greece. It is ſuppoſed to have been built by Cadmus, about the year of the world 2555. This Cadmus, according to the Greeks, was the ſon of Agenor king of Sidon or of Tyre; but the Sidonians allow him to have been of no higher quality than his cook, and tell us that his wife was a muſician at court, with whom he ran away into Greece. The Greek writers tell us, that being commanded by his father to go in ſearch of his daughter Europa, whom Jupiter in the ſhape of a bull had carried off, and forbid to return without her, he built, or rebuilt, the city of Thebes, after having long ſought her in vain. He was at firſt oppoſed by the Hyantes and Aones; the former of whom he defeated in battle, and forced to retire into Locris: the

I Account of Cadmus the founder of Thebes.

the latter ſubmitted, and were incorporated among his ſubjects.

2 Suppoſed to be one of the exiled Canaanites.

Thoſe who endeavour to extract ſome truth from the multitude of fables in which the early part of the Grecian hiſtory is obſcured, are of opinion that Cadmus was one of the Canaanites expelled by Joſhua; and that he was of the family of the Cadmonites mentioned by Moſes and Joſhua. He is univerſally allowed to have introduced the Phœnician letters into Greece, ſet up the firſt ſchools, and introduced braſs; which, from him, had the name of *Cadmean* given to it. The government of Thebes continued for a long time monarchical; and the names of a number of its kings have been tranſmitted to us, with ſome account of their tranſactions; but ſo much obſcured by fable, that little or nothing can be determined concerning them. We ſhall therefore paſs over this fabulous part of their hiſtory, and only take notice of that period of it when the Thebans emerged from their obſcurity, and for a time held the ſovereignty of Greece.

3 The Thebans a degenerate ſtupid people.

Though the Thebans had been famed in the early period of their hiſtory for their martial atchievements, yet in proceſs of time they ſeem to have degenerated. At the time of the invaſion of Xerxes, they were the firſt people in Greece who were gained over to the Perſian intereſt. On account of this miſbehaviour, they were become very obnoxious to the other ſtates, eſpecially to the Athenians, whoſe power and renown increaſed every day, and threatened at laſt to ſwallow them up altogether. The Thebans being in no condition to oppoſe ſuch a formidable power, put themſelves under the protection of the Spartans, who, out of jealouſy of the Athenians, readily forgave them; and ſo grateful were the Thebans for the kindneſs ſhown them at this time, that during the whole of the Peloponneſian war Sparta had not a more faithful ally. By theſe means they not only recovered the government of Bœotia, of which they had been formerly in poſſeſſion, till deprived of it on account of their ſiding with the Perſians, but their city became one of the firſt in Greece. By this proſperity the Thebans were ſo much elated, that, when the peace of Antalcidas came to be ſigned, they refuſed to agree to it, as they were thus once more deprived of the government of Bœotia; ſo that it was not without the utmoſt difficulty that they were overawed into it by the other ſtates. Not content with forcing them to give up this point, however, the Spartans undertook to change the form of the Theban government, which at this time was a democracy, and accompliſhed it through the treachery of thoſe who had the care of the citadel.

4 Put themſelves under the protection of the Spartans.

5 The form of government changed, and the citadel ſeized by the Spartans.

6 The Thebans recover their liberty under Pelopidas.

The Thebans continued, under the power of the Spartans for four years; at the end of which term a conſpiracy being formed againſt them by ſome of the principal people in the city, among whom was a young nobleman named *Pelopidas*, the Spartans were maſſacred and driven out, and the citadel regained. During the tumult Epaminondas, afterwards the celebrated general, with a number of the beſt citizens, joined the party of Pelopidas; and the latter having called a general aſſembly of the Thebans, proclaimed liberty to them, and exhorted them in the ſtrongeſt manner to fight for their country. This ſpeech was received with the greateſt acclamations; Pelopidas was unanimouſly proclaimed the preſerver of Thebes, and was charged with the management of the war which was then to be declared againſt Sparta.

7 War with Sparta.

Theſe tranſactions ſo much exaſperated the Spartans, that they immediately ſent their king Cleombrotus againſt them, though it was then the depth of winter. The Athenians, in the mean time, who had hitherto aſſiſted the Thebans, declined any farther connection, leſt they ſhould draw upon themſelves the reſentment of the Spartans. But they were ſoon after determined to act again on the ſame ſide, by an attempt which the Spartan general, Sphadnas, had raſhly made on the Pyræum or harbour of Athens. Thus, by means of the Athenians, a powerful diverſion was made in favour of the Thebans, who gradually recovered all the towns of Bœotia, and at length began to act offenſively againſt their enemies, and made a powerful invaſion in Phocis. They had now many ſharp encounters with them; which, though they did not amount to deciſive battles, yet did not fail to raiſe their courage, and depreſs that of the Spartans. In theſe encounters Pelopidas always ſignalized himſelf; and in the battle of Tanagra, where the Lacedæmonians were entirely defeated by the Athenians and their allies, Pelopidas had a principal ſhare in the victory, and killed the Spartan general with his own hand. Soon after this, with a body of only 300 Thebans, he entirely routed and diſperſed near 1000 Spartans; which was the greateſt diſgrace the latter had ever known; for till that time, whether in war with the Greeks or Barbarians, they had never been overcome by an equal, much leſs by ſuch an inferior, number of troops.

8 The Spartans defeated by Pelopidas.

Theſe ſucceſſes of the Thebans greatly alarmed the Athenians, who continually ſought to oppoſe their growing power. In this oppoſition they were joined by the Platæans, who on this account became extremely obnoxious to the Thebans, ſo that they at laſt came to a reſolution to ſurpriſe their city. This they accompliſhed, and entirely deſtroyed it, together with Theſpia, another city extremely well affected to Athens. Soon after this, the Thebans, encouraged by their ſucceſs, began to think of enlarging their territories, and of making encroachments on their neighbours, as they ſaw other ſtates had done before them. This ſpirit of conqueſt is ſaid to have been raiſed by their general Pelopidas; in which he was ſeconded by Epaminondas, a perſon who, though like him endowed with all the neceſſary qualities to make a complete captain or patriot, had till then preferred a private life, and lived in a conſtant courſe of virtue and the ſtudy of philoſophy. He had as yet ſeldom appeared in public, except to get himſelf excuſed from thoſe ſtate-employments which were ſo eagerly courted by others. This, however, had not hindered him from contracting an intimate friendſhip with Pelopidas, which had been daily improved by the correſpondence of their tempers and principles, as well as by that zeal which both diſplayed for the good of their country; which laſt had made them, even before this time, appear together in action, and to ſuch advantage, that Epaminondas's merit could be no longer concealed, nor indeed ſuffer him to continue longer in his beloved retirement: ſo that he ſaw himſelf, at length, deſervedly placed at the head of the Theban troops; where he gave ſuch early proofs of his future proweſs and abilities, as juſtly gave him the next rank to Pelopidas. Both came now to be conſidered in the ſame light, as generals in the field, as governors at home, and as complete ſtateſmen in the council. When the general treaty for reſtoring peace to Greece came to be propoſed by the Athenians, and was upon the point of being executed by the reſt of the ſtates, the Thebans refuſed to agree to it, unleſs they were comprehended in it under the name of *Bœotians*. This demand was as ſtrenuouſly oppoſed by the other contracting powers as inſiſted on by Epaminondas, who was there as ambaſſador on the part of the Thebans. Ageſilaus, in particular, told him in plain terms, that the Thebans ought to evacuate Bœotia, and leave the cities of it free and independent. To which he was anſwered by him, that the Lacedæmonians would do well to ſet them the example, by reſtoring Meſſenia to its ancient proprietors, and Laconia to its ancient freedom; for

9 Platæa and Theſpia razed by the Thebans.

10 Account of Epaminondas.

11 His difference with Ageſilaus king of Sparta,

Thebes. that the pretenſions of the city of Thebes to Bœotia were as well founded, at leaſt, as thoſe of Sparta to thoſe two countries. After this he went on, and ſhowed how far Sparta had aggrandized herſelf at the expence of her neighbours: that peace might be indeed obtained, and upon a ſolid and laſting footing; but that this could not be otherwiſe than by bringing all to an equality. This bold, though juſt remonſtrance, in which not only Thebes, but Greece in general was concerned, failed not, however, to exaſperate the haughty Spartan monarch; and the Athenians, who had till now looked upon the Thebans as dependents either on them or on the Macedonians, were not a little offended to hear their ambaſſadors talk in ſuch high terms. The reſult of the conference was, that Ageſilaus ſtruck the name of *Thebes* out of the treaty, and declared war againſt them, about the year 371 B. C.

12 The Spartans declare war againſt Thebes.

The Thebans were in no ſmall conſternation to ſee themſelves engaged in a war with the powerful Spartans, without any ally to aſſiſt them; and the reſt of the Grecian ſtates having made peace with the latter, began to look upon the ruin of the former as unavoidable. However, they reſolved to make the beſt defence they could; and put their army under the command of Epaminondas, aſſigning him, at his own requeſt, ſix others to act as counſellors or aſſiſtants. The Theban army conſiſted at moſt but of 6000 men, whereas that of the enemy was at leaſt thrice that number; but Epaminondas truſted moſt to his horſe, wherein he had much the advantage both in quality and good management: the reſt he endeavoured to ſupply by the diſpoſition of his men, and the vigour of the attack. He even refuſed to ſuffer any to ſerve under him in the engagement, but ſuch as he knew to be fully reſolved to conquer or die. The two armies met at LEUCTRA, where the Spartans were defeated with great ſlaughter, as related under that article.

13 Are entirely defeated at Leuctra.

The victorious general, deſirous to improve this great victory, ſent an herald, crowned with garlands, to communicate it in form to the Athenians, in hopes that this would be an effectual means to reunite them to the Theban intereſt. But it proved quite otherwiſe. Athens, which now looked upon them with a jealous eye, and had then in view the ſovereignty of Greece, choſe rather, if they could not wholly obtain it, to ſhare it with Sparta, than to let the Thebans into the whole; and therefore even declined giving their herald audience. However, the Thebans took care to ſtrengthen themſelves by alliances; and beſides the Arcadians and Eleans, had got the Phocians, Locrians, Acarnanians, Eubœans, and other ſtates, under their dependence; ſo that they were now in a condition to act offenſively againſt the Spartans. Accordingly, under pretence of aſſiſting the Arcadians, they entered Peloponneſus with a gallant army, with Epaminondas and Pelopidas at their head. Here they were joined by the Arcadian and other confederate forces; ſo that the whole amounted to 40,000, ſome ſay 50,000 men beſides great numbers of thoſe who followed the camp, rather for plunder than fighting, and were computed about 20,000 more. The army was divided into four columns, and moved ſtraight towards Sellaſia, the place of their rendezvous, from which they purſued their journey with fire and ſword towards Sparta. But here they were repulſed by Ageſilaus, who was then returned to that metropolis.

14 The Athenians jealous of the Thebans.

17 The Thebans invade Peloponneſus with a formidable army, but are repulſed.

To repair, in ſome meaſure, this diſgrace, and at the ſame time to leave ſome laſting monument which ſhould redound as much to his glory as to the mortification of the Spartans, Epaminondas left not their territories till he had reſtored the poſterity of the old Meſſenians to their ancient dominions, out of which they had been baniſhed near 300 years; rebuilt their capital, and left a ſtrong garriſon for its defence. He was, however, like to have been ſtopped in his return by Iphicrates, whom the Athenians had ſent with 12,000 men to intercept him; but this laſt loitered ſo long at Corinth, that the Thebans had paſſed the defiles of Cenchreæ, the chief place where he could have obſtructed his retreat had he taken poſſeſſion of it in proper time. Epaminondas continued his march till he came in full view of the city of Corinth. He found the roads choaked up with trees, rocks, ſtones, and every thing that could render them impaſſable; and the Corinthians well fortified, and reſolute on a ſtout defence. But he came ſo furiouſly upon them, notwithſtanding all theſe difficulties, that they abandoned all their entrenchments and outworks to the Thebans, and fled into the city. Thither theſe purſued them ſword in hand, and made an horrid ſlaughter of them; inſomuch that Corinth muſt have unavoidably fallen into their hands, had their generals thought fit to purſue theſe advantages; but whether they were afraid of the Athenians falling upon them, or apprehended ſome dangerous ambuſh in a country with which they were but indifferently acquainted, or whether the army was too much weakened through ſo many fatigues, or laſtly, whether the coldneſs of the ſeaſon, it being then the depth of winter, would not permit them to proceed farther, they immediated marched towards Bœotia. This gave ſuch an handle to their enemies, that they met with a very mortifying reception at their return to Thebes, where they were both arreſted, and clapped up as ſtate-priſoners, for having preſumed to prolong their command four months longer than the time limited by law, which time took in almoſt the whole of their expedition from their firſt entrance into Peloponneſus. However, at laſt, the judges being aſhamed to proceed any farther, they were both honourably acquitted.

Thebes.

18 The Meſſenians reſtored to their ancient dominions.

19 The Corinthians defeated.

20 Epaminondas and Pelopidas diſgraced at Thebes.

This proſecution had been chiefly carried on and encouraged by Meneclides, a diſcontented Theban, and a bold and able ſpeaker, who, by his artful calumnies at the trial, had ſo far prevailed with the judges as to get Epaminondas deprived of the government of Bœotia for a whole year, though he could not gain the ſame advantage againſt Pelopidas, who was a greater favourite of the people, as being his ſenior.

By this delay the Spartans, with much difficulty, had recovered themſelves from their great defeat at Leuctra, and ſettled their affairs in as good a poſture as they could: but though they had repulſed the Thebans in Peloponneſus, yet from the exploits they had performed there, eſpecially in the diſmembering the whole kingdom of Meſſenia from them, they had ſtill cauſe to fear what their forces might do under two ſuch generals; and had accordingly taken due care to ſtrengthen themſelves againſt them, and to provide themſelves with a great number of auxiliaries from other ſtates, eſpecially from that of Athens, with whom they had renewed their old treaty, and had agreed that each ſhould have the command five days alternately. Soon after this treaty the Arcadians renewed the war, and took Pallene in Laconia by ſtorm, put the garriſon to the ſword, and were preſently aſſiſted by the Argives and Eleans, and eſpecially by the Thebans, who ſent to them 7000 foot and 500 horſe under the command of Epaminondas. This ſo alarmed the Athenians likewiſe, that they immediately ſent Gobrias with ſome forces to oppoſe his paſſage in good earneſt; and he ſo behaved himſelf againſt the Thebans, that they were forced to abandon Peloponneſus a ſecond time. This ill ſucceſs gave freſh occaſion to the enemies of Epaminondas to blame his conduct in the higheſt terms, notwithſtanding the ſingular bravery with which he and his troops had forced the paſs. Even his friends could not but ſuſpect him of

21 War renewed with Sparta.

22 The Thebans repulſed.

Thebes.

of partiality for the Spartans, in not purſuing his advantage over them, and making a greater ſlaughter of them when he had it in his power; whilſt his enemies made it amount to no leſs than treachery to his country: ſo that their brave general was once more deprived of the government of Bœotia, and reduced to the condition of a private man. He did not continue long under this diſgrace, before an occaſion offered to make his ſervices again of ſuch neceſſity to the ſtate, as to give him an opportunity to retrieve his fame, and wipe off the ſtain which his enemies had thrown upon him.

23 Epaminondas degraded.

The Theſſalians, who had groaned ſome time under the tyranny of the uſurper Alexander, ſurnamed the *Pheræan*, ſent an embaſſy to Thebes to implore their aid and protection; upon which Pelopidas was immediately ſent as ambaſſador to expoſtulate with him on their behalf. He was then in Macedon, from whence he took the young prince Philip, afterwards the celebrated monarch, in order to protect and educate him; and, upon his return, marched directly to Pharſalus in Theſſaly, in order to puniſh the treachery of ſome mercenaries, who had deſerted the Thebans in that expedition; but when he came thither, he was ſurpriſed to be met by the tyrant at the head of a numerous army before that city, whilſt his own was but as an handful of men in compariſon of it. However, whether he ſuppoſed, or would be thought to do ſo, that Alexander came thither to juſtify himſelf, and anſwer to the complaints alledged againſt him, he went, with Iſmenias his colleague, to him unarmed and unattended, not doubting but his character as ambaſſador from ſo powerful a republic, joined to his own character and authority, would protect them from inſult or violence: but he found himſelf miſtaken; for Alexander had no ſooner got them in his hands, than he cauſed them to be ſeized, and ſent priſoners to Pheræa.

24 Pelopidas ſeized by Alexander of Pheræa.

The Thebans, highly reſenting the indignity offered to their ambaſſadors, ſent immediately an army into Theſſaly: but the generals were repulſed with great loſs by the Pheræan uſurper; and it was owing to Epaminondas, who was among them only as a private centinel, that they were not totally cut off. For the Thebans finding themſelves in ſuch imminent danger, which they attributed to the incapacity of their generals, had immediately recourſe to him, whoſe valour and experience had been ſo often tried; and, partly by perſuaſions and intreaties, and partly by threats, obliged him to take the command. This ſoon gave a different turn to their affairs, and converted their flight into a ſafe and regular retreat; for he took the horſe and light-armed foot, and placed himſelf at their head in the rear, and charged the enemy with ſuch vigour and bravery, that he obliged them to deſiſt from their purſuit.

25 A Theban army ſent to reſcue him, defeated.

26 Epaminondas reſtored.

However, as the army had ſuffered ſuch loſs before as not to be able to purſue them in their turn, he was obliged to return with them to Thebes, with their puſillanimous generals; where the latter were fined 12,000 drachms each, and the former was reinſtated in the command, and ſent with a new reinforcement to repair the late diſhonour, and proſecute their revenge. The news of his being in full march on this errand, greatly alarmed the tyrant; but Epaminondas, preferring the ſafety of his impriſoned colleague to all other conſiderations, forbore puſhing hoſtilities to extremes, for fear of provoking the enemy to wreak all his fury on him: to prevent which, he contented himſelf for a while hovering about with his army, and now and then with ſuch ſlight ſkirmiſhes as ſhould intimidate the tyrant, and bring him the ſooner to make ſome ſatisfactory offers. Alexander being fully convinced of the ſuperiority of the Theban general, was glad to accept of a truce of 30 days, and to reſtore Pelopidas and Iſmenias to him; upon which he immediately withdrew his forces, and returned with them to Thebes.

27 Reſcues Pelopidas.

Thebes.

By this time, Thebes was raiſed to a ſufficient height of reputation and glory to begin to aim in earneſt at the ſovereignty of Greece. The main obſtacle to it was, that the other ſtates grew ſo jealous of her preſent greatneſs, as to enter into the ſtrongeſt alliances and confederacies to prevent its farther growth; ſo that not being able now to procure many allies at home, they made no difficulty to ſeek for them abroad; and the Lacedæmonians, by leading the van, gave them a plauſible pretence to follow their ſteps, and to procure an alliance with Perſia, which at that time they found was ready to accept of the offers on any terms; the only queſtion was, which of the three ſtates ſhould be preferred, Sparta, Athens, or Thebes. At the ſame time, the Thebans propoſed to their new confederates to ſend likewiſe proper deputies to the Perſian court, in order to ſupport their reſpective intereſts; which they readily agreed to. Theſe were the Arcadians, Eleans, and Argives; at the head of whoſe deputation Pelopidas was ſent on the behalf of the Thebans; which the Athenians being appriſed of, appointed two on their part. Theſe being all arrived at the Perſian court, began to purſue each their reſpective intereſts: but Pelopidas had by that time gained ſuch credit there, both for his ſingular addreſs and his extraordinary exploits, that he was diſtinguiſhed in a particular manner from all the other deputies, and was received by the king with the moſt manifeſt marks of honour and eſteem, who freely owned himſelf convinced that the Thebans were the people on whom he could moſt ſafely depend; and after having greatly applauded the equity of his demands, ratified and confirmed them with great readineſs, to the no ſmall mortification of the other ſtates. The ſubſtance of them was, that the liberties formerly granted to the other towns of Greece ſhould be confirmed; that Meſſenia, in particular, ſhould continue free and independent on the juriſdiction of Sparta; that the Athenians ſhould lay up their fleet; and that the Thebans ſhould be looked upon as the ancient and hereditary friends of Perſia.

28 Succeſs of Pelopidas at the Perſian court.

The Thebans took advantage of the diſſenſions which prevailed among the Greeks as a pretence for increaſing their forces; and Epaminondas thought it a proper opportunity for his countrymen to make a bold effort to obtain the dominion at ſea, as they had obtained it in a great meaſure at land. He propoſed it to them in a public aſſembly, and encouraged their hopes from the experience of the Lacedæmonians, who in Xerxes' time had, with ten ſhips only, at ſea, gained the ſuperiority over the Athenians, who had no fewer than 200; and added, that it would be a diſgrace now to Thebes, to ſuffer two ſuch republics to engroſs the empire of ſo extenſive an element, without putting in at leaſt for their ſhare of it. The people readily came into his propoſal, not without extraordinary applauſe, and immediately ordered 100 galleys to be equipped; and in the meanwhile ſent him to Rhodes, Chios, and Byzantium, to ſecure thoſe ſtates in their intereſt, and get what aſſiſtance he could from them. His negotiations had all the ſucceſs that could be wiſhed for, notwithſtanding the ſtrenuous oppoſition of the Athenians, and of their admiral Laches, who was ſent with a powerful ſquadron againſt him. But what more effectually thwarted all his meaſures, was the work that they found for him at land, and the obliging the Thebans to take part in the quarrels that then reigned among their neighbours: ſo that whatever projects they had concerted, proved abortive for the preſent; and the death of Epaminondas, which happened not long after, put an effectual ſtop to them.

29 The Thebans propoſe to build a fleet.

During the abſence of that general, and of his colleague

Thebes.

Pelopidas, the Orchomenians, being ſpirited up by ſome Theban fugitives, had formed a deſign to change the Theban government into an ariſtocracy; and 300 horſemen of the former had been actually ſent to put it in execution. Their project, however, was timely diſcovered by the vigilance of the magiſtrates, who cauſed them to be ſeized, and put immediately to death. They next ſent a ſufficient force againſt the city of Orchomenos, with orders to put all the men to death, and to ſell the women and children for ſlaves, which was punctually done; after which they razed that noble city to the ground. Pelopidas was then on his way to Theſſaly, at the head of a powerful army, whither he had been ſent to aſſiſt the Theſſalians, who ſtill groaned under the tyranny of Alexander the Pheræan, and had made ſeveral brave efforts to recover their liberty, but had been ſtill overpowered by that uſurper. Being joined by the Theſſalians, he encamped in the face of the enemy, though far ſuperior in number, and conſiſting of above 20,000 men. A fierce engagement ſoon enſued, in which both ſides fought with uncommon bravery. The place where the battle was fought was called *Cynocephala*, from ſeveral little hills on it, between which there ran a large plain. Both ſides endeavoured at firſt to poſt themſelves on theſe eminences with their foot, whilſt Pelopidas ordered his cavalry to charge that of the enemy below; which they did with ſuch ſucceſs, that they ſoon put them to the rout, and purſued them over the plain. This obliged the tyrant to gain the tops of the hills, where he greatly annoyed the Theſſalians that endeavoured to force thoſe aſcents; ſo that Pelopidas was obliged to give over his purſuit to come to their relief. This immediately inſpired the Theſſalians with freſh courage, who began again to charge the enemy at ſeveral onſets; and ſoon threw them into ſuch diſorder, that they were forced to give way. Pelopidas no ſooner perceived the advantage, than he began to look about for Alexander, with a deſign of engaging him. Having found him out as he was commanding his right wing, and endeavouring to rally his men, he moved directly to him; and being got near enough to be heard by him, challenged him to decide the battle by ſingle combat with him. Alexander, inſtead of accepting the offer, turned about, and with all the ſpeed he could ran to ſcreen himſelf among his guards. Upon this Pelopidas charged him with ſuch furious ſpeed, that he obliged him to retire farther, and ſhelter himſelf within the thickeſt ranks; the ſight of which made him attack with freſh vigour, and fight more deſperately againſt him. He tried in vain ſeveral times to break through their ranks to reach him, cutting down great numbers of thoſe that came forward to oppoſe him: his eagerneſs at length expoſed him ſo far to the darts that were ſhot at him at a diſtance, that ſome of them went quite through his armour, and gave him a deſperate wound or two, while the reſt advanced and ſtabbed him in the breaſt with their ſpears.

30 The city of Orchomenos razed.

31 Pelopidas marches againſt the Theſſalian tyrant.

32 Is killed.

It is ſcarce poſſible for words to expreſs the grief and deſpair which not only his brave Thebans, but likewiſe the Theſſalians and other allies, ſhowed at the ſight of their ſlain general: ſome of the latter, who had perceived the danger he was expoſed to, came down the hill with all poſſible ſpeed to his relief; but when they perceived that they were come too late to ſave him, both they and the reſt of the little army thought of nothing now but to revenge his death. They rallied accordingly, both horſe and foot, as quick as poſſible, and began to charge the enemy afreſh, and with ſuch deſperate fury, that they at length gained a complete victory over them, and killed above 3000 of them in their purſuit, beſides a much greater number which they had ſlain on the field of battle, though they ſtill looked upon all theſe advantages as vaſtly too ſmall to compenſate the loſs of their brave general. Thebes.

33 Alexander defeated,

The news of his death had no ſooner reached Thebes, than the whole city was ſeen in as deep a mourning as his army. However, they ſent a reinforcement to it of 7000 foot and 700 horſe, as well to revenge the death of that general, as to improve the victory he had gained over the enemy; by the help of which they fell ſo furiouſly on them, that they quickly broke and totally defeated the ſhattered remains of Alexander's army. Hereupon he was forced to ſue for peace, and to accept it on ſuch conditions as the conquerors thought fit to impoſe. He was at length diſpatched in his bed by his wife Thebe, aſſiſted by her brothers, about ſeven years after his defeat. His body was afterwards dragged along the ſtreets, trodden under foot, and left a prey to the dogs.

34 And at laſt murdered.

All this while the Thebans were watching to improve every commotion that happened, every ſucceſs they met with, to the forwarding of their then reigning and favourite project, of increaſing their power above all the reſt, and in their turn to give laws to Greece. Their late ſucceſs in Theſſaly, and the rupture between the Arcadians and Mantineans at the ſame time, about ſome conſecrated money which the former had taken out of the temple of Olympias to pay their troops employed againſt the Eleans, and which the latter called a downright ſacrilege, beſides other diſcords that reigned in the other ſtates of Greece, gave freſh encouragement to Thebes to ſet up for arbitreſs in thoſe diſputes; and ſo much the more, as thoſe who had embezzled the ſacred money, and wanted rather to embroil matters than to have them brought to light, ſent that republic word that the Arcadians were juſt upon the point of revolting to the Spartans, and adviſed them to come and put an immediate ſtop to it. At the ſame time they diſpatched ſome private directions to a Theban officer at Tegea, to apprehend ſeveral of their own people as diſturbers of the peace. This was accordingly done, and ſeveral eminent perſons were confined as priſoners of ſtate: they were ſoon after diſcharged, and loud complaints were made againſt ſuch arbitrary and unjuſt proceedings. The officer was accuſed before the Theban ſenate for having intermeddled in their affairs, and endeavoured to interrupt the good correſpondence between the two ſtates. It was even inſiſted on by ſome of the Tegeans, that he ſhould be indicted and proceeded againſt by his principals; whilſt the more moderate ſort, who foreſaw the conſequences that were likely to attend ſuch appeals, and that it would infallibly bring the Thebans upon them, loudly proteſted againſt their marching into their territories, and did all they could to prevent it. The Thebans, however, were become too powerful and ambitious to miſs ſo fair an opportunity of getting once more footing in Peloponneſus, as they had long ago premeditated; and Epaminondas was ſo far from making a ſecret of their deſign, that he told the Arcadian deputies in juſtification of it, that as it was on their account that the Thebans engaged in the war, they had acted treacherouſly with them in making peace with Athens without their conſent: however, that when he was got with his army on his march into Peloponneſus to aſſiſt his friends, he would ſoon ſee what proofs the Arcadians would give of their fidelity. This ſpeech did not fail to alarm them greatly; eſpecially as it was ſpoken in ſuch a magiſterial ſtyle and threatening tone. Even thoſe who were beſt affected to the Thebans could not forbear expreſſing their diſlike of it; and all that had the welfare of Peloponneſus at heart readily agreed with the Mantineans, that there was no time to be loſt to uſe all proper means to prevent the impending ſtorm.

35 Ambition of the Thebans.

36 Epaminondas diſpleaſes the ſtates of Greece.

Athens

Thebes.

37 A combination againſt Thebes.

Athens and Sparta were accordingly applied to, and were eaſily prevailed upon to aſſiſt the Mantineans, and to come into a ſtrict confederacy againſt the Thebans; and to prevent all diſputes about the command of the army, it was agreed that each ſtate ſhould have it in its own territories; which plainly ſhows how terrified they all were at the apprehenſion of a freſh invaſion of the Thebans; for this was a point which neither the Spartans nor Athenians would have ſo readily given up to the Arcadians, though theſe had formerly as ſtrenuouſly inſiſted upon it, even when they were almoſt reduced to the laſt extremity, and had never been able to obtain it till now. But Epaminondas was then in full march at the head of his Bœotian troops, with ſome Eubœan auxiliaries, and a body of ſtout Theſſalian horſe; and was moreover to be joined by the Meſſenians, Argives, and ſeveral other nations, as ſoon as he had entered Peloponneſus. The confederate army againſt him had ordered their rendezvous at Mantinea, the place which they naturally concluded would be firſt attacked, as being the chief ſeat of thoſe who had revolted from the Thebans. But whilſt they were ſecuring themſelves on that ſide, Epaminondas, who wiſely conſidered how far this confederacy and expedition muſt have drained the city of Sparta of its main ſtrength, broke up privately from Nemæa, where he had lain for ſome time encamped, and marched all that night with a deſign to have ſurpriſed that important capital: but his project being timely diſcovered, the vigilant king took care to diſconcert it; ſo that, though the Theban general made ſeveral vigorous aſſaults on that city, he was ſo ſtoutly repulſed, and the Spartans behaved with ſuch intrepid valour, that he was forced to retire and turn his thoughts againſt Mantinea, which he judged by this time to have been quite defenceleſs. He judged rightly indeed; for the place was not only drained of its troops, but likewiſe of its inhabitants, who took that opportunity, whilſt the ſcene of war was in Lacedæmon, to gather in their harveſt, and were ſcattered all over the country; ſo that he would not have met with any difficulty in gaining the town, had not the Athenian auxiliaries come unexpectedly to its relief, and given him a freſh repulſe.

38 Epaminondas makes an unſucceſsful attempt on Sparta,

39 And on Mantinea.

Theſe two laſt defeats greatly exaſperated the Theban general, who had never till now been uſed to them, and could not but foreſee that they would not only leſſen his reputation with his allies, but, if not timely retrieved, would ſully the glory of all his former exploits. What added to his preſent difficulties was, that the time allotted him for his expedition was almoſt expired; ſo that he had but a ſhort ſpace left to undertake ſome brave atchievement, which might recover his and his country's honour, and keep up the ſpirits of his auxiliaries and thoſe under his protection. He was moreover got very far into the enemy's country, and ſaw plainly enough how narrowly they watched all his motions, and how well prepared they were to oppoſe him whatever attempt he reſolved upon, whether to attack them or to retreat. Under all theſe difficulties, he rightly conſidered, that he muſt immediately reſolve upon a deciſive battle; in which, if his priſtine fortune followed him, he might at once retrieve his affairs, and make himſelf maſter of Peloponneſus; or, if that failed him, as it lately had done, fall honourably in the attempt. In this engagement Epaminondas made the wiſeſt diſpoſition of his troops, attacked and fought with the moſt intrepid courage and conduct, and had opened himſelf a way through the Spartan phalanxes, thrown them into the utmoſt confuſion, and made a terrible ſlaughter of them, inſomuch that the field of battle was covered with their wounded and ſlain, when, in the heat of the fight, having ventured himſelf too far in order to give them a total overthrow, the enemy rallied again, pouring with their whole fury three volleys of darts at him, ſome of which he drew out and returned to them, till at length, being covered with wounds, and weakened with the loſs of ſo much blood, he received a mortal wound from a javelin, and was with great difficulty reſcued from the enemy by his brave Thebans, and brought alive, though ſpeechleſs, into his tent. As ſoon as he had recovered himſelf, he aſked his friends that were about him what was become of his ſhield; and being told that it was ſafe, he beckoned to have it brought to him, and kiſſed it. He next inquired which ſide had gained the victory; and being anſwered, The Thebans; he replied, Then all is well: and upon obſerving ſome of his friends bewail his untimely death, and leaving no children behind him, he is ſaid to have anſwered, Yes; I have left two fair daughters, the victory of Leuctra, and this of Mantinea, to perpetuate my memory. Soon after this, upon drawing the point of the javelin out of his body, he expired.

Thebes.

41 Epaminondas killed.

40 Battle of Mantinea.

The conſequence of this great general's fall, and of this bloody fight, in which neither ſide could boaſt any great advantage over the other, but a great loſs of men on both ſides, inſomuch that Xenophon makes it a drawn battle, was, that both parties agreed on a ceſſation of arms, and parted, as it were by conſent, to take care of their wounded and ſlain. The Thebans indeed thus far gained the greater ſhare of glory, that they renewed the fight, and after a moſt deſperate conteſt, gained the victory over thoſe Spartans that oppoſed them, and reſcued the body of their dying general out of their hands. However, an effectual end was put to this bloody war, and a general peace agreed on by all but Sparta; who refuſed it only becauſe the Meſſenians were included in it. But as to the Thebans, they had no great reaſon to boaſt of this dear-bought victory, ſince their power and glory began to decline from that very time; ſo that it may be truly ſaid, that it roſe and ſet with their great general.

42 Peace concluded.

43 State of Thebes to the preſent time.

On the death of Epaminondas, the Thebans relapſed into their former ſtate of inactivity and idolence; and at laſt having ventured to oppoſe Alexander the Great, their city was taken, and the inhabitants ſlaughtered for ſeveral hours, after which the buildings were deſtroyed. It was rebuilt by Caſſander, but never afterwards made any conſiderable figure among the ſtates of Greece. About the year 146 B. C. it fell under the power of the Romans, under which it continued till the extinction of their empire by the Turks. It is now called *Thive*, and is nothing to what it was formerly; yet it is four miles in circumference, but ſo full of ruins, that there are not above 4000 Turks and Chriſtians in it. It is now famous for a fine ſort of white clay, of which they make bowls for pipes after the Turkiſh faſhion. They are never burnt, but dry naturally, and become as hard as a ſtone. There are two moſques in Thebes, and a great many Greek churches. It is ſeated between two ſmall rivers, in E. Long. 23. 40. N. Lat. 38. 17.

Thebes, in Egypt, one of the moſt renowned cities of the ancient world. It was alſo called *Dioſpolis*, or the city of Jupiter, and was built, according to ſome, by Oſiris, according to others by Buſiris. Its length, in Strabo's time, was 80 furlongs, or ten miles; but this was nothing in compariſon of its ancient extent, before it was ruined by Cambyſes, which, we are told, was no leſs than 420 ſtadia, or 52 miles and an half. The wealth of this city was ſo great, that, after it had been plundered by the Perſians, what was found, on burning the remains of the pillage, amounted to above 300 talents of gold and 2300 of ſilver.

Ancient Univerſal Hiſtory, vol. i.

Mr Bruce viſited the ruins of this celebrated city; but informs us that nothing now remains except four temples, and theſe neither ſo entire nor magnificent as ſome others at

Thebes, Theft.

a place called *Dendera*. Thebes has been celebrated by Homer for its hundred gates; but Mr Bruce informs us, that no veſtiges of theſe are now remaining, neither can we diſcover the foundation of any wall it ever had; "and as for the horſemen and chariots it is ſaid to have ſent out, all the Thebaid ſown with wheat would not have maintained one half of them. Thebes, at leaſt the ruins of the temples called *Medinet Tabu*, are built in a long ſtretch of about a mile broad, moſt parſimoniouſly choſen at the ſandy foot of the mountains. The *Horti Penſiles*, or hanging gardens, were ſurely formed upon the ſides of theſe hills, then ſupplied with water with mechanical devices. The utmoſt is done to ſpare the plain, and with great reaſon; for all the ſpace of ground this ancient city has had to maintain its myriads of horſes and men, is a plain of three quarters of a mile broad between the town and the river, upon which plain the water riſes to the height of four and five feet. All this pretended populouſneſs of ancient Thebes I therefore believe to be fabulous."

Bruce's Travels.

Mr Bruce, after examining the ground on which Thebes is ſuppoſed to have ſtood, thinks that it had no walls, and that conſequently Homer's ſtory of its having an hundred gates is miſunderſtood. The mountains of the Thebaid ſtand cloſe behind the town, not in a ridge, but ſtanding ſingle, ſo that you can go round each of them. A hundred of theſe are ſaid to be hollowed out for ſepulchres and other purpoſes. Theſe, he thinks, were the hundred gates of Homer; in proof of this they are ſtill called by the natives *Beeban el Meluke*, "the ports or gates of the kings."

All that is ſaid of Thebes by poets or hiſtorians after the days of Homer is meant of Dioſpolis, which was built by the Greeks long after Thebes was deſtroyed, as its name teſtifies; though Diodorus ſays it was built by Buſiris. It was on the eaſt ſide of the Nile, whereas ancient Thebes was on the weſt, though both are conſidered as one city; and Strabo ſays, that the river runs through the middle of Thebes, by which he means between Old Thebes and Dioſpolis.

THEFT, or SIMPLE LARCENY, is "the felonious taking and carrying away of the perſonal goods of another." This offence certainly commenced then, whenever it was that the bounds of property, or laws of *meum* and *tuum*, were eſtabliſhed. How far ſuch an offence can exiſt in a ſtate of nature, where all things are held to be common, is a queſtion that may be ſolved with very little difficulty. The diſturbance of any individual in the occupation of what he has ſeized to his preſent uſe, ſeems to be the only offence of this kind incident to ſuch a ſtate. But, unqueſtionably, in ſocial communities, when property is eſtabliſhed, any violation of that property is ſubject to be puniſhed by the laws of ſociety; though how far that puniſhment ſhould extend is matter of conſiderable doubt.

By the Jewiſh law it was only puniſhed with a pecuniary fine, and ſatisfaction to the party injured; and in the civil law, till ſome very late conſtitutions, we never find the puniſhment capital. The laws of Draco at Athens puniſhed it with death: but his laws were ſaid to be written with blood; and Solon afterwards changed the penalty to a pecuniary mulct. And ſo the Attic laws in general continued; except that once, in a time of dearth, it was made capital to break into a garden and ſteal figs: but this law, and the informers againſt the offence, grew ſo odious, that from them all malicious informers were ſtyled *ſycophants*; a name which we have much perverted from its original meaning. From theſe examples, as well as the reaſon of the thing, many learned and ſcrupulous men have queſtioned the propriety, if not lawfulneſs, of inflicting capital puniſhment for ſimple theft. And certainly the natural puniſhment for injuries to property ſeems to be the loſs of the offender's own property; which ought to be univerſally the caſe, were all mens fortunes equal. But as thoſe who have no property themſelves are generally the moſt ready to attack the property of others, it has been found neceſſary, inſtead of a pecuniary, to ſubſtitute a corporal puniſhment; yet how far this corporal puniſhment ought to extend, is what has occaſioned the doubt. Sir Thomas More and the Marquis Beccaria, at the diſtance of more than two centuries, have very ſenſibly propoſed that kind of corporal puniſhment which approaches the neareſt to a pecuniary ſatisfaction, viz. a temporary impriſonment, with an obligation to labour, firſt for the party robbed, and afterwards for the public, in works of the moſt ſlaviſh kind; in order to oblige the offender to repair, by his induſtry and diligence, the depredations he has committed upon private property and public order. But, notwithſtanding all the remonſtrances of ſpeculative politicians and moraliſts, the puniſhment of theft ſtill continues throughout the greateſt part of Europe to be capital: and Puffendorf, together with Sir Matthew Hale, are of opinion that this muſt always be referred to the prudence of the legiſlature; who are to judge, ſay they, when crimes are become ſo enormous as to require ſuch ſanguinary reſtrictions. Yet both theſe writers agree, that ſuch puniſhment ſhould be cautiouſly inflicted, and never without the utmoſt neceſſity.

Theft.

The Anglo Saxon laws nominally puniſhed theft with death, if above the value of twelvepence: but the criminal was permitted to redeem his life by a pecuniary ranſom; as, among their anceſtors the Germans, by a ſtated number of cattle. But in the 9th year of Henry I. this power of redemption was taken away, and all perſons guilty of larceny above the value of twelvepence were directed to be hanged; which law continues in force to this day. For though the inferior ſpecies of theft, or petit larceny, is only puniſhed by whipping at common law, or (by ſtat. 4 Geo. I. c. 11.) may be extended to tranſportation for ſeven years, as is alſo expreſsly directed in the caſe of the Plate-glaſs Company; yet the puniſhment of grand larceny, or the ſtealing above the value of twelvepence (which ſum was the ſtandard in the time of king Athelſtan, 800 years ago), is at common law regularly death; which, conſidering the great intermediate alteration in the price or denomination of money, is undoubtedly a very rigorous conſtitution; and made Sir Henry Spelman (above a century ſince, when money was at twice its preſent rate) complain, that while every thing elſe was riſen in its nominal value, and become dearer, the life of man had continually grown cheaper. It is true, that the mercy of juries will often make them ſtrain a point, and bring in larceny to be under the value of twelvepence, when it is really of much greater value: but this, though evidently juſtifiable and proper when it only reduces the preſent nominal value of money to the ancient ſtandard, is otherwiſe a kind of pious perjury, and does not at all excuſe our common law in this reſpect from the imputation of ſeverity, but rather ſtrongly confeſſes the charge. It is likewiſe true, that by the merciful extenſions of the benefit of clergy by our modern ſtatute law, a perſon who commits a ſimple larceny to the value of thirteen pence or thirteen hundred pounds, though guilty of a capital offence, ſhall be excuſed the pains of death; but this is only for the firſt offence. And in many caſes of ſimple larceny the benefit of clergy is taken away by ſtatute: as from horſe-ſtealing in the principals and acceſſaries both *before* and *after* the fact; theft by great and notorious thieves in Northumberland and Cumberland; taking woollen cloth from off the tenters, or linens, fuſtians, calicoes, or cotton goods, from the place of manufacture (which extends, in the laſt caſe, to aiders, aſ-

ſiſters,

Theft ‖ Theobald.

sifters, procurers, buyers, and receivers); feloniously driving away, or otherwise stealing one or more sheep or other cattle specified in the acts, or killing them with intent to steal the whole or any part of the carcase, or aiding or assisting therein; thefts on navigable rivers above the value of forty shillings, or being present, aiding and assisting thereat; plundering vessels in distress, or that have suffered shipwreck; stealing letters sent by the post; and also stealing deer, hares, and conies, under the peculiar circumstances mentioned in the Waltham black act. Which additional severity is owing to the great malice and mischief of the theft in some of these instances; and, in others, to the difficulties men would otherwise lie under to preserve those goods, which are so easily carried off. Upon which last principle the Roman law punished more severely than other thieves the *Abigei* or stealers of cattle, and the *Balnearii* or such as stole the clothes of persons who were washing in the public baths; both which constitutions seem to be borrowed from the laws of Athens. And, so too, the ancient Goths punished with unrelenting severity thefts of cattle, or of corn that was reaped and left in the field: such kind of property (which no human industry can sufficiently guard) being esteemed under the peculiar custody of heaven.

Theft-Bote (from the Saxon *theof*, i. e. *fur*, and *bote*, *compensatio*), is the receiving of a man's goods again from a thief, after stolen, or other amends not to prosecute the felon, and to the intent the thief may escape; which is an offence punishable with fine and imprisonment, &c.

THELIGONUM, in botany: A genus of plants belonging to the class of *monœcia*, and order of *polyandria*; and in the natural system ranging under the 53d order, *Scabridæ*. The male calyx is bifid; there is no corolla; the stamina are generally 12. The female calyx is also bifid; there is no corolla; only one pistil; the capsule is coriaceous, unilocular, and monospermous. There is only one species, the *Cynocrambe*, which is indigenous in the south of Europe.

THEME, denotes the subject of an exercise for young students to write or compose on.

THEMISON, a physician of Laodicea, a disciple of Asclepiades. He founded the methodic sect, with a view to the more easily teaching and practising the art of medicine. (See Medicine, n° 37). Themison gave the first account of diacodium, which was prepared of the juice and decoction of poppy-heads and honey. He invented a purging medicine called *heira*.

THEMISTIUS, an ancient Greek orator and philosopher, a native of Paphlagonia, who flourished in the 4th century. He had great interest and favour with the emperors in his time, and though a heathen, was of a very tolerating spirit. He taught for many years at Constantinople, of which city he was made præfect by Julian and Theodosius; and lived to be exceeding old. More than 30 of his orations are still extant, besides commentaries on several parts of Aristotle's works.

THEMISTOCLES, the renowned Athenian admiral, general, and patriot, who gained the battle of Salamis against the Persians. Being banished his country by his ungrateful fellow-citizens, he fled to Artaxerxes king of Persia: but, in order to avoid taking up arms against his country, he slew himself, 464 B. C. See Attica, n° 76, *et seq.*

THEOBALD (Lewis), the son of an attorney at Sittingbourn in Kent, was a well-known writer and critic in the early part of the present century. He engaged in a paper called the *Censor*, published in Mist's Journal, wherein, by delivering his opinions with too little reserve concerning some eminent wits, he exposed himself to their resentment. Upon the publication of Pope's Homer, he praised it in terms of extravagant admiration, yet afterwards thought proper to abuse it as earnestly; for which Pope at first made him the hero of his Dunciad, though he afterward laid him aside for another. Mr Theobald not only exposed himself to the lashes of Pope, but waged war with Mr Dennis, who treated him more roughly, though with less satire. He nevertheless published an edition of Shakespeare, in which he corrected, with great pains and ingenuity, many faults that had crept into that poet's writings. This edition is still in great esteem; being in general preferred to those published by Pope, Warburton, and Hanmer. He also wrote some plays, and translated others from the ancients.

Theobroma ‖ Theocritus.

THEOBROMA, in botany: A genus of plants belonging to the class of *polyadelphia*, and order of *pentandria*; and in the natural system ranging under the 37th order, *Columniferæ*. The calyx is triphyllous; the petals, which are five in number, are vaulted and two-horned; the nectarium is pentaphyllous and regular; the stamina grow from the nectarium, each having five antheræ. There are three species; the *cacao*, *guazuma*, and *angusta*.

The *cacao*, or chocolate tree, we shall describe in the words of Dr Wright: "In all the French and Spanish islands and settlements in the warmer parts of America, the chocolate tree is carefully cultivated. This was formerly the case also in Jamaica; but at present we have only a few straggling trees left as monuments of our indolence and bad policy. London Medical Journal, vol. viii.

"This tree delights in shady places and deep vallies. It is seldom above 20 feet high. The leaves are oblong, large, and pointed. The flowers spring from the trunk and large branches; they are small, and pale red. The pods are oval and pointed. The seeds or nuts are numerous, and curiously stowed in a white pithy substance.

"The cocoa nuts being gently parched in an iron pot over the fire, the external covering separates easily. The kernel is levigated on a smooth stone; a little arnotto is added, and with a few drops of water is reduced to a mass, and formed into rolls of one pound each. This simple preparation is the most natural, and the best. It is in daily use in most families in Jamaica, and seems well adapted for rearing of children." See Chocolate.

THEOCRACY, in matters of government, a state governed by the immediate direction of God alone: such was the ancient government of the Jews before the time of Saul.

THEOCRITUS, the father of pastoral poetry, was born at Syracuse in Sicily. Two of his poems ascertain his age; one addressed to Hiero king of Syracuse, who began his reign about 275 years before Christ; and the other to Ptolemy Philadelphus king of Egypt. Hiero, though a prince distinguished in arms and political wisdom, does not seem to have been a patron of learning. This is supposed to have given birth to the 16th Idyllium. From Syracuse Theocritus went to Alexandria, where he seems to have found a munificent patron in Ptolemy Philadelphus, if we may judge from the panegyric which he composed on that prince (the 17th Idyllium). It has been said that Theocritus was strangled by Hiero, but we have not found evidence of this.

The compositions of this poet are distinguished, among the ancients, by the name of *Idylliums*, in order to express the smallness and variety of their natures: they would now be called *Miscellanies*, or *Poems on several Occasions*. The first nine and the eleventh are confessed to be true pastorals, and hence Theocritus has usually passed for nothing more than a pastoral poet; yet he is manifestly robbed of a great part of his fame, if his other poems have not their proper laurels. For though the greater part of his Idylliums cannot be called the songs of shepherds, yet they have certainly their

Theodolite. Theodore.

their reſpective merits. His paſtorals ought to be conſidered as the foundation of his credit; upon this claim he will be admitted for the finiſher as well as the inventor of his art, and will be acknowledged to have excelled all his imitators as much as originals uſually do their copies.

The works of this poet were firſt publiſhed in folio by Aldus Manutius at Venice in 1495. A more elegant and correct edition was printed by Henry Stephens at Paris in 1566. An edition was publiſhed at Leipſic in 1765, with valuable notes by the learned Reiſke. But what will moſt highly gratify the admirers of paſtoral poetry, is an edition publiſhed in 1770, 2 vols 4to, by Mr Thomas Wharton. It is accompanied by the ſcholia of the beſt editors, and the different readings of 15 MSS.

THEODOLITE, a mathematical inſtrument for meaſuring heights and diſtances. See GEOMETRY, p. 679.

THEODORE, king of Corſica, baron Nieuhoff in the county of La Marc in Weſtphalia. He had his education in the French ſervice, and afterwards went to Spain, where he received ſome marks of regard from the duke of Riperda and cardinal Alberoni; but being of an unſettled diſpoſition, he quitted Spain, and travelled into Italy, England, and Holland, in ſearch of ſome new adventure. He at laſt fixed his attention on Corſica, and formed the ſcheme of rendering himſelf ſovereign of that iſland. He was a man of abilities and addreſs; and having fully informed himſelf of every thing relating to Corſica, went to Tunis, where he fell upon means to procure ſome money and arms; and then went to Leghorn, from whence he wrote a letter to the Corſican chiefs Giafferi and Paoli, offering conſiderable aſſiſtance to the nation if they would elect him as their ſovereign. This letter was conſigned to Count Domenico Rivarola, who acted as Corſican plenipotentiary in Tuſcany; and he gave for anſwer, that if Theodore brought the aſſiſtance he promiſed to the Corſicans, they would very willingly make him king.

Upon this he, without loſs of time, ſet ſail, and landed at Tavagna in the ſpring of the year 1736. He was a man of a very ſtately appearance, and the Turkiſh dreſs he wore added to the dignity of his mien. He had a few attendants with him; and his manners were ſo engaging, and his offers ſo plauſible, that he was proclaimed king of Corſica before Count Rivarola's diſpatches arrived to inform the chiefs of the terms upon which he had agreed. He brought with him about 1000 zequins of Tunis, beſide ſome arms and ammunition, and made magnificent promiſes of foreign aſſiſtance; whence the Corſicans, who were glad of any ſupport, willingly gave into his ſchemes. Theodore inſtantly aſſumed every mark of royal dignity. He had his guards and his officers of ſtate; he conferred titles of honour, and ſtruck money both of ſilver and copper. The ſilver pieces were few in number, and can now hardly be met with; the copper coins have on one ſide T. R. that is, "Theodorus Rex," with a double branch croſſed, and round it this inſcription, PRO BONO PUBLICO RE. CO. that is, "For the public good of the kingdom of Corſica:" on the other ſide is the value of the piece; *Cinque ſolidi*, or five ſous.

The Genoeſe were not a little confounded with this unexpected adventurer. They publiſhed a violent manifeſto againſt Theodore, treating him with great contempt; but at the ſame time ſhowing they were alarmed at his appearance. Theodore replied, in a manifeſto, with all the calmneſs and dignity of a monarch; but after being about eight months in Corſica, perceiving that the people began to cool in their affections towards him, he aſſembled his chiefs, and declared he would keep them no longer in a ſtate of uncertainty, being determined to ſeek in perſon the ſupport he ſo long expected. He ſettled an adminiſtration during his abſence, recommended unity in the ſtrongeſt terms, and left the iſland with reciprocal aſſurances of fidelity and affection. He went to Holland, where he was ſo ſucceſsful as to obtain credit from ſeveral rich merchants, particularly Jews, who truſted him with cannon and other warlike ſtores to a great value, under the charge of a ſupercargo. With theſe he returned to Corſica in 1739; but by this time the French, as auxiliaries to the Genoeſe, had become ſo powerful in the iſland, that though Theodore threw in his ſupply of warlike ſtores, he did not incline to venture his perſon, the Genoeſe having ſet a high price on his head. He therefore again departed; and after many unavailing attempts to recover his crown, at length choſe for retirement a country where he might enjoy the participation of that liberty which he had ſo vainly endeavoured to give his Corſicans; but his ſituation in England by degrees grew wretched, and he was reduced ſo low as to be ſeveral years before his death a priſoner for debt in the King's Bench. At length, to the honour of ſome gentlemen of rank, a charitable contribution was ſet on foot for him in the year 1753. Mr Boſwell obſerves, that Mr Horace Walpole generouſly exerted himſelf for the unhappy Theodore, and wrote a paper in *The World* with great elegance and humour, ſoliciting a contribution for the unhappy monarch in diſtreſs, to be paid to Mr Robert Dodſley bookſeller, as lord high treaſurer. This brought him a very handſome ſum, and he was ſet at liberty. That gentleman adds, that Mr Walpole has the original deed, by which Theodore made over the kingdom of Corſica in ſecurity to his creditors, and that he has alſo the great ſeal of the kingdom. Theodore died in 1756, and was buried in St Anne's churchyard, Weſtminſter; where, in 1757, a ſimple unadorned monument of marble was erected to his memory by a gentleman, with an inſcription; which, after mentioning ſome of the above particulars, concludes with the following lines:

Theodore, Theodoret.

> The grave, great teacher, to a level brings
> Heroes and beggars, galley-ſlaves and kings;
> But Theodore this moral learn'd ere dead,
> Fate pour'd its leſſon on his living head,
> Beſtow'd a kingdom and deny'd him bread.

Theodore left a ſon, who was an accompliſhed gentleman.

THEODORET, biſhop of St Cyricus in Syria, in the 4th century, and one of the moſt learned fathers of the church, was born in the year 386, and was the diſciple of Theodorus Mopſueſtia and St John Chryſoſtom. Having received holy orders, he was with difficulty perſuaded to accept of the biſhopric of St Cyricus, about the year 420. He diſcovered great frugality in the expences of his table, dreſs, and furniture, but ſpent conſiderable ſums in improving and adorning the city of Cyricus. He erected two large bridges, public baths, fountains, and aqueducts, and laboured with great zeal and ſucceſs in his dioceſe. Yet his zeal was not confined to his own church: he went to preach at Antioch and the neighbouring towns; where he became admired for his eloquence and learning, and had the happineſs to convert multitudes of people. He wrote in favour of John of Antioch and the Neſtorians, againſt Cyril's Twelve Anathemas: he afterwards attacked the opinions of Neſtorius, and was depoſed in the ſynod held by the Eutychians at Epheſus; but was again reſtored by the general council of Chalcedon, in which he was preſent, in 451. It is thought that he died ſoon after; though others ſay that he lived till the year 457. There are ſtill extant Theodoret's excellent Commentary on St Paul's Epiſtles, and on ſeveral other books of the Holy Scriptures. 2. His Eccleſiaſtical Hiſtory from the time of Arius to Theodoſius the

Theodosius Theogony.

the Younger. 3. The history of the famous Anchorites of his time. 4. Epistles. 5. Discourses on Providence. And, 6. An excellent treatise against the Pagans, intitled, *De Curandis Græcorum Affectibus;* and other works. The best edition of all which is that of Father Sirmond in Greek and Latin, in 4 vols. folio.

THEODOSIUS I. called the *Great*, was a native of Spain. The valour he had shown, and the great services he had done to the empire, made Gratian, attacked by the Goths and Germans, to admit him as a partner in the government. He received the purple in 379, aged 43. See CONSTANTINOPLE, n° 77—88.

THEOGONY, formed from Θεος *God*, and γονη *genitura*, "seed, offspring," that branch of the heathen theology which taught the genealogy of their gods. Theognis.

Hesiod gives us the ancient theogony, in a poem under that title. Among the most ancient writers, Dr Burnet observes, that theogony and cosmogony signified the same thing. In effect, the generation of the gods of the ancient Persians, fire, water, and earth, is apparently no other than that of the primary elements.

THEOGNIS, an ancient Greek poet of Megara in Achaia, flourished about the 59th Olympiad, 144 B. C. We have a moral work of his extant, containing a summary of precepts and reflections, usually to be found in the collections of the Greek minor poets.

THEOLOGY

1 Definition.

IS a Greek word (θεολογια), and signifies that science which treats of the being and attributes of God, his relations to us, the dispensations of his providence, his will with respect to our actions, and his purposes with respect to our end. The word was first used to denote the systems, or rather the heterogeneous fables, of those poets and philosophers who wrote of the genealogy and exploits of the gods of Greece. Hence Orpheus, Museus, Hesiod, Pherecydes, and Pythagoras, were called *theologians;* and the same epithet was given to Plato, on account of his sublime speculations on the same subject. It was afterwards adopted by the earliest writers of the Christian church, who styled the author of the apocalypse, by way of eminence, ὁ θεολογος, the *Divine*.

Although every pagan nation of antiquity had some tutelary deities peculiar to itself, they may yet be considered as having all had the same theology, since an intercommunity of gods was universally admitted, and the heavenly bodies were adored as the *dii majorum gentium* over the whole earth. This being the case, we are happily relieved from treating, in the same article, of the truths of Christianity and the fictions of paganism, as we have elsewhere traced idolatry from its source, and shewn by what means "the foolish hearts of men became so darkened that they changed the glory of the incorruptible God into an image made like to corruptible man, and to birds, and four-footed beasts, and creeping things." See POLYTHEISM.

The absurdities and inconsistency of the pretended revelation of the Arabian impostor have been sufficiently exposed under the words ALCORAN and MAHOMETANISM; so that

2 Christian theology,

the only theology of which we have to treat at present is *Christian* theology, which comprehends that which is commonly called *natural*, and that which is *revealed* in the scriptures of the Old and New Testaments. These taken together, and they ought never to be separated, compose a body of science so important, that in comparison with it all other sciences sink into insignificance; for without a competent knowledge of the attributes of God, of the several relations in which he stands to us, and of the ends for which we were created, it is obvious that we must wander through life like men groping in the dark, strangers to the road on which we are travelling, as well as to the fate awaiting us at the end of our journey.

3 To be studied carefully by those intended for the service of the church.

But if this knowledge be necessary to all Christians, it is doubly so to those who are appointed to feed the flock of Christ, and to teach the ignorant what they are to believe, and what to do, in order to work out their own salvation. The wisdom and piety of our ancestors have accordingly founded professorships of theology in all our universities, where the principles of our religion are taught in a systematic and scientific manner; and the church has ordained, that no man shall be admitted to the office of a preacher of the gospel who has not attended a regular course of such theological lectures.

It must not, however, be supposed, that, by merely listening to a course of lectures however able, any man will become an accomplished divine. The principles of this science are to be found only in the word and works of God; and he who would extract them pure and unsophisticated, must dig for them himself in that exhaustless mine. To fit a man for this important investigation, much previous knowledge is requisite. He must study the works of God scientifically before he can perceive the full force of that testimony which they bear to the power, the wisdom, and the goodness of their author. Hence the necessity of a general acquaintance with the physical and mathematical sciences before a man enter upon the proper study of theology, for he will not otherwise obtain just and enlarged conceptions of the God of the universe. See PHYSICS, n° 115.

4 Previous knowledge requisite for the prosecution of this study.

But an acquaintance with the physical and mathematical sciences is not alone a sufficient preparation for the study of theology. Indeed it is possible for a man to devote himself so wholly to any of these sciences, as to make it counteract the only purposes for which it can be valuable to the divine; for he who is constantly immersed in matter, is apt to suspect that there is no other substance; and he who is habituated to the routine of geometrical demonstration, becomes in time incapable of reasoning at large, and estimating the force of the various degrees of moral evidence. To avert these untoward consequences, every man, before he enters upon the study of that science which is the subject of the present article, should make himself acquainted with the principles of logic, the several powers of the human mind, and the different sources of evidence; in doing which he will find the greatest assistance from Bacon's *Novum Organum*, Locke's *Essay on the Human Understanding*, Reid's *Essays on the Intellectual and Active Powers of Man*, and Tatham's *Chart and Scale of Truth*. These works, of which the young student ought to make himself master, will teach him to think justly, and guard him against a thousand errors, which those who have not laid such a foundation are apt to embrace as the truths of God.

The man who proposes to study theology ought to have it in view, as the ultimate end of his labours, to impart to others that knowledge which he may procure for himself. "Amongst the many marks which distinguish the *Christian* philosopher from the *Pagan*, this (says a learned writer*) is one of the most striking—the *Pagan* sought knowledge in a selfish way, to secrete it for his own use; the *Christian* seeks it with the generous purpose (first in view, though last in execution)

* Warburton.

Introduction.

execution) to impart it to others. The Pagan philoſopher, therefore, having cultivated the *art of thinking*, proceeds to that of *ſpeaking*, in order to diſplay his vanity in the dexterous uſe of deceit. On the other hand, the *Chriſtian philoſopher* cultivates the *art of ſpeaking*, for the ſole purpoſe of diſſeminating the truth in his office of preacher of the goſpel."

As every man, before he enters upon the proper ſtudy of theology, receives, at leaſt in this country, the rudiments of a liberal education, it may perhaps be ſuperfluous to mention here any books as peculiarly proper to teach him the art of ſpeaking: we cannot however forbear to recommend to our ſtudent the attentive peruſal of Quintilian's *Inſtitutions*, and Dr Blair's *Lectures on Rhetoric and the Belles Lettres*. A familiar acquaintance with theſe works will enable him, if he be endowed by nature with talents fit for the office in which he propoſes to engage, to expreſs his thoughts with correctneſs and elegance; "without which, it has been well obſerved, that ſcience, eſpecially in a clergyman, is but learned lumber, a burden to the owner, and a nuiſance to every body elſe."

No man can proceed thus far in the purſuits of general ſcience without having been at leaſt initiated in the learned languages; but he who intends to make theology his profeſſion ſhould devote himſelf more particularly to the ſtudy of Greek and Hebrew, becauſe in theſe tongues the original ſcriptures are written. By this we do not mean to inſinuate that it is neceſſary for the man whoſe views aſpire no farther than to the office of paſtor of a Chriſtian congregation, to make himſelf a profound critic in either of theſe ancient languages. The time requiſite for this purpoſe is ſo long, that it would leave very little for other ſtudies of infinitely more importance to him, whoſe proper buſineſs it is to inſtruct the ignorant in thoſe plain and ſimple truths which are ſufficient to guide all men in the way to ſalvation. Still, however, it is obvious, that he who is incapable of conſulting the original ſcriptures, muſt reſt his faith, not upon the ſure foundation of the word of God, but upon the credit of fallible tranſlators; and if he be at any time called upon to vindicate revelation againſt the ſcoffs of infidelity, he will have to ſtruggle with many difficulties which are eaſily ſolved by him who is maſter of the original tongues.

5 Cautions to be obſerved in attending the lectures of a profeſſor.

The ſtudent having laid in this ſtock of preparatory knowledge, is now qualified to attend with advantage the theological lectures of a learned profeſſor; but in doing this, he ſhould be very careful neither to admit nor reject any thing upon the bare authority of his maſter. Right principles in theology are of the utmoſt importance, and can reſt upon no authority inferior to that of the word of God. On this account we have long been of opinion, that a profeſſor cannot render his pupils ſo much ſervice by a ſyſtematical courſe of lectures, as by directing their ſtudies, and pointing out the road in which they may themſelves arrive in the ſhorteſt time at the genuine ſenſe of the ſacred ſcriptures. In this opinion we have the honour to agree with the ableſt lecturer § in theology that we have ever heard. The authors of all ſyſtems are more or leſs prejudiced in behalf of ſome particular and artificial mode of faith. He, therefore, who begins with the ſtudy of them, and afterwards proceeds to the ſacred volume, ſees with a jaundiced eye every text ſupporting the particular tenets of his firſt maſter, and acts as abſurd a part as he who tries not the gold by the copel, but the copel by the gold. Before our young divine, therefore, ſit down to the ſerious peruſal of any one of thoſe *inſtitutes* or *bodies of theology* which abound in all languages, and even before he read that which the nature of our work compels us to lay before him, we beg leave, with the utmoſt deference to the ſuperior judgment of our more learned readers, to recommend to his conſideration the following

Preliminary Directions.

§ The late Dr Campbell of Aberdeen.

Preliminary Directions for the Study of Theology.

Chriſtian theology divided into two great parts.

Chriſtian theology is divided into two great parts, *natural* and *revealed*; the former comprehending that which may be known of God from the creation of the world, even his eternal power and Godhead; the latter, that which is diſcovered to man nowhere but in the ſacred volume of the Old and New Teſtaments.

7 Firſt principles of theology communicated

Concerning the extent of natural theology many opinions have been formed, whilſt ſome have contended that there is no ſuch thing. Into theſe diſputes we mean not at preſent to enter. We believe that one of them could have had no exiſtence among ſober and enlightened men, had the contending parties been at due pains to define with accuracy the terms which they uſed. Whatever be the origin of religion, which we have endeavoured to aſcertain elſewhere (ſee Religion, n° 6—17.), it is obvious, that no man can receive a written book as the word of God till he be convinced by ſome other means that God exiſts, and that he is a Being of power, wiſdom, and goodneſs, who watches over the conduct of his creature man. If the progenitor of the human race was inſtructed in the principles of religion by the Author of his being (a fact of which it is difficult to conceive how a conſiſtent theiſt can entertain a doubt), he might communicate to his children, by natural means, much of that knowledge which he himſelf could not have diſcovered had he not been ſupernaturally enlightened. Between illuſtrating or proving a truth which is already talked of, and making a diſcovery of what is wholly unknown, every one perceives that there is an immenſe difference (A).

8 To the earlieſt mortals by repeated revelations.

To beings whoſe natural knowledge originates wholly from ſenſation, and whoſe minds cannot, but by much diſcipline, advance from ſenſe to ſcience, a long ſeries of revelations might be neceſſary to give them at firſt juſt notions of God and his attributes, and to enable them to perceive the

(A) The diſcriminating powers of Ariſtotle will not be queſtioned; and in the following extract made by Cicero from ſome of his works which are now loſt, he expreſſes our ſentiments on this important ſubject with his uſual preciſion: ——"Præclare ergo Ariſtoteles, SI ESSENT, inquit, qui ſub terra ſemper habitaviſſent, bonis, et illuſtribus domiciliis, quæ eſſent ornata ſignis atque picturis, inſtructaque rebus iis omnibus, quibus abundant ii, qui beati putantur, nec tamen exiſſent unquam ſupra terram: ACCEPISSENT AUTEM FAMA ET AUDITIONE, ESSE QUODDAM NUMEN, ET VIM DEORUM; deinde aliquo tempore, patefactis terræ faucibus, ex illis abditis ſedibus evadere in hæc loca, quæ nos incolimus, atque exire potuiſſent: cum repente terram, et maria, cœlumque vidiſſent: nubium magnitudinem, ventorumque vim cognoviſſent, adſpexiſſentque ſolem, ejuſque tum magnitudinem, pulchritudinemque, tum etiam efficientiam cognoviſſent, quod is diem efficeret, toto cœlo luce diffuſa: cum autem terras nox opacaſſet, tum cœlum totum cernerent aſtris diſtinctum et ornatum, lunæque luminum varietatem tum creſcentis, tum ſeneſcentis, eorumque omnium ortus et occaſus, atque in omni æternitate ratos, immutabileſque curſus: hæc cum viderent, PROFECTO ET ESSE DEOS, et HÆC TANTA OPERA DEORUM ESSE arbitrarentur." *De Nat. Deorum*, lib. ii. § 37.

From

Preliminary Directions.

the relation between the effect and its cauſe, ſo as to infer by the powers of their own reaſon the exiſtence of the Creator from the preſence of his creatures. Such revelations, however, could be ſatisfactory only to thoſe who immediately received them. Whenever the Deity has been pleaſed by ſupernatural means to communicate any information to man, we may be ſure that he has taken effectual care to ſatisfy the perſon ſo highly favoured that his underſtanding was not under the influence of any illuſion; but ſuch a perſon could not communicate to another the knowledge which he had thus received by any other means than an addreſs to his rational faculties. No man can be required to believe, no man indeed can believe, without proof, that another, who has no more faculties either of ſenſation or intellect than himſelf, has obtained information from a ſource to which he has no poſſible acceſs. An appeal to miracles would in this caſe ſerve no purpoſe; for we muſt believe in the exiſtence, power, wiſdom, and juſtice, of God, before a miracle can be admitted as evidence of any thing but the power of him by whom it is performed. See MIRACLE.

9 And yet may be properly termed natural principles.

It is therefore undeniable that there are ſome principles of theology which may be called *natural*; for though it is in the higheſt degree probable that the parents of mankind received all their theological knowledge by *ſupernatural* means, it is yet obvious that ſome parts of that knowledge muſt have been capable of a proof purely rational, otherwiſe not a ſingle religious truth could have been conveyed through the ſucceeding generations of the human race but by the immediate inſpiration of each individual. We indeed admit many propoſitions as certainly true, upon the ſole authority of the Jewiſh and Chriſtian ſcriptures, and we receive theſe ſcriptures with gratitude as the lively oracles of God; but it is ſelf-evident that we could not do either the one or the other, were we not convinced by natural means that God exiſts, that he is a Being of goodneſs, juſtice, and power, and that he inſpired with divine wiſdom the penmen of theſe ſacred volumes. Now, though it is very poſſible that no man or body of men, left to themſelves from infancy in a deſert world, would ever have made a theological diſcovery; yet whatever propoſitions relating to the being and attributes of the firſt cauſe and the duty of man, can be demonſtrated by human reaſon, independent of written revelation, may be called *natural theology*, and are of the utmoſt importance, as being to us the firſt principles of all religion. Natural theology, in this ſenſe of the word, is the foundation of the Chriſtian revelation; for without a previous knowledge of it, we could have no evidence that the ſcriptures of the Old and New Teſtaments are indeed the word of God.

10 Natural theology to be ſtudied before the doctrines of revelation.

Our young divine, therefore, in the regular order of his ſtudies, ought to make himſelf maſter of *natural theology* before he enter upon the important taſk of ſearching the ſcriptures. On this ſubject many books have been publiſhed in our own and other languages; but perhaps there is none more worthy of attention than the Religion of Nature delineated by Mr. Wollaſton (B). It is a work of great merit, and bears ample teſtimony to its author's learning and acuteneſs: yet we think it ought to be read with caution. Mr. Wollaſton's theory of moral obligation is fanciful and groundleſs; and whilſt we readily acknowledge that he demonſtrates many truths with elegance and perſpicuity, we cannot deny that he attempts a proof of others, for which we believe no other evidence can be brought than the declarations of Chriſt and his apoſtles in the holy ſcriptures. To ſupply the defects of his theory of morals, we would recommend to the ſtudent an attentive peruſal of Cumberland on the Law of Nature, and Paley's Elements of Moral Philoſophy. A learned author * affirms of Cumberland, that "he excels all men in fixing the true grounds of moral obligation, out of which natural law and natural religion both ariſe;" and we have ourſelves never read a work in which the various duties which a man owes to his Maker, himſelf, and his fellow-creatures, are more accurately ſtated or placed on a ſurer baſis than in the moral treatiſe of the archdeacon of Carliſle.

Preliminary Directions.

11 Books recommended.

* Warburton.

As Wollaſton demonſtrates with great perſpicuity, and to the abſolute conviction of every man capable of feeling the force of argument, the being and many of the attributes of God, it may perhaps appear ſuperfluous to recommend any other book on that ſubject. The preſent age, however, having among other wonderful phenomena, witneſſed a revival of the monſter *Atheiſm*, we would adviſe our ſtudent to read with much attention Cudworth's Intellectual Syſtem, and to read it rather in Moſheim's Latin tranſlation than in the author's original Engliſh. In the original, though many authors are quoted that are now but little known, there are very few references to the book, or chapter, or ſection, from which the quotations are taken. Theſe omiſſions are ſupplied by the tranſlator, who has likewiſe enriched his edition with many valuable and learned notes. It is well known that Cudworth wrote his incomparable work in confutation of Hobbes's philoſophy; but inſtead of confining himſelf to the whimſies of his antagoniſt, which were in a little time to ſink into oblivion, he took a much wider range, and traced atheiſm through all the mazes of antiquity, expoſing the weakneſs of every argument by which ſuch an abſurdity had ever been maintained. In exhauſting the metaphyſical queſtions agitated among the Greeks concerning the being and perfections of God, he has not only given us a complete hiſtory of ancient learning, as far as it relates to theſe inquiries, but has in fact anticipated moſt of the ſophiſms of our modern atheiſts, who are by

From this paſſage it is evident, that the Stagyrite, though he conſidered the motions of the heavenly bodies, the ebbing and flowing of the ſea, and the other phenomena of nature, as affording a complete *proof* of the being and providence of God, did not however ſuppoſe that from theſe phenomena an untaught barbarian would *diſcover* this fundamental principle of religion. On the contrary, he expreſsly affirms, that before a man can feel the force of the evidence which they give of this important truth, he muſt have HEARD of the exiſtence and power of God.

(B) It may not be improper to inform the reader, that Mr Wollaſton, the author of the Religion of Nature, was a different man from Mr Woolſton, who blaſphemed the miracles of our Saviour. The former was a clergyman of great piety, and of ſuch moderate ambition as to refuſe one of the higheſt preferments in the church of England when it was offered to him; the latter was a layman remarkable for nothing but gloomy infidelity, and a perverſe deſire to deprive the wretched of every ſource of comfort. In the mind of the former, philoſophy and devotion were happily united; in the mind of the latter, there was neither devotion nor ſcience. Yet theſe writers have been frequently confounded; ſometimes through inadvertence from the ſimilarity of their names; and ſometimes, we are afraid, deſignedly, from a weak and bigotted abhorrence of every ſyſtem of religion that pretends to have its foundation in reaſon and in the nature of things.

Preliminary Directions.

no means ſuch diſcoverers as they are ſuppoſed to be by their illiterate admirers.

The ſtudent having made himſelf maſter of natural theology, and carefully endeavoured to aſcertain its limits, is now prepared to enter upon the important taſk of ſearching the ſcriptures. In doing this, he ought to diveſt himſelf as much as poſſible of the prejudices of education in behalf of a particular ſyſtem of faith, and ſit down to the ſtudy of the ſacred volume as of a work to which he is an entire ſtranger. He ought firſt to read it as a moral hiſtory of facts and doctrines, beginning with the books of Moſes, and proceeding through the reſt, not in the order in which they are commonly publiſhed, but in that in which there is reaſon to believe they were written (ſee SCRIPTURES). If he be maſter of the Hebrew and Greek languages, he will doubtleſs prefer the original text to any verſion; and in this peruſal we would adviſe him to conſult no commentator, becauſe his object at preſent is not to ſtudy the doctrines contained in the bible, but merely to diſcover what are the ſubjects of which it treats. Many hiſtories of the bible have been written; and were we acquainted with a good one, we ſhould recommend it as a clue to direct the young divine's progreſs through the various books which compoſe the ſacred volume. Stackhouſe's hiſtory has been much applauded by ſome, and as much cenſured by others. It is not a work of which we can expreſs any high degree of approbation; but if read with attention, it may no doubt be uſeful as a guide to the ſeries of facts recorded in the ſcriptures. Between the Old and New Teſtaments there is a great chaſm in the hiſtory of the Jewiſh nation; but it is ſupplied in a very able and ſatisfactory manner by Dr Prideaux, whoſe *Old and New Teſtament* connected is one of the moſt valuable hiſtorical works in our own or any other language. Shuckford's *Sacred and Profane Hiſtory of the World connected* is likewiſe a work of merit, and may be read with advantage as throwing light upon many paſſages of the Old Teſtament: but this author is not entitled to the ſame confidence with Prideaux, as his learning was not ſo great, and his partialities ſeem to have been greater.

12 How the ſcriptures are to be ſtudied.

In thus making himſelf maſter of the hiſtory of the Old and New Teſtaments, the ſtudent will unavoidably acquire ſome general notion of the various doctrines which they contain. Theſe it will now be his buſineſs to ſtudy more particularly, to aſcertain the preciſe meaning of each, and to diſtinguiſh ſuch as relate to the whole human race, from thoſe in which Abraham and his poſterity were alone intereſted. He muſt therefore travel over the ſacred volume a ſecond time; and ſtill we would adviſe him to travel without a guide. From Walton's *Polyglote bible*, and the large collection called *Critici ſacri*, he may indeed derive much aſſiſtance in his endeavours to aſcertain the ſenſe of a difficult text; but we think he will do well to make little uſe of commentators and expoſitors, and ſtill leſs of ſyſtem-builders, till he has formed ſome opinions of his own reſpecting the leading doctrines of the Jewiſh and Chriſtian religions.

"Impreſſed (ſays an able writer) with an awful ſenſe of the importance of the ſacred volume, the philoſophical divine will ſhake off the bias of prejudices however formed, of opinions however ſanctioned, and of paſſions however conſtitutional, and bring to the ſtudy of it the advantage of a pure and impartial mind. Inſtead of waſting all his labour upon a number of minute and leſs ſignificant particulars, and of refining away plain and obvious ſenſe by the ſubtleties of a narrow and corroſive mind, his firſt object will be to inſtitute a theological inquiry into the general deſign of the written word; and from principles fully contained and fairly underſtood, to illuſtrate the true *nature* and *genius of the religious diſpenſation* in all its parts. He will mark the difference between the firſt and ſecond covenants, and obſerve the connection that ſubſiſts between them. He will trace the temporary economy of the *Old Teſtament*, and weigh the nature and intent of the *partial covenant* with the Jews; obſerving with aſtoniſhment how it was made introductory of better things to come: and he will follow it through the *law* and the *prophets* in its wonderful evolutions, till he ſee this vaſt and preparatory machine of providence crowned and completed in the eternal goſpel. This *New Teſtament*, the laſt and beſt part of the religious diſpenſation, he will purſue through the ſacred pages of that goſpel with redoubled attention; contemplating the divine foundation on which it claims to be built, the ſupernatural *means* by which it was executed, and the immortal end which it has in view.*"

Preliminary Directions.

* Tatham's Chart and Scale of Truth.

In the courſe of this inquiry into the import of the ſacred volume, the ſtudent will pay particular attention to the circumſtances of the age and country in which its various writers reſpectively lived, and to the nature of the different *ſtyles*, *analogical* and *parabolical*, in which it is written. He will likewiſe keep in mind that God, whom it claims for its author, is the parent of truth, and that all his actions and diſpenſations muſt be conſiſtent with one another. He will therefore compare the different paſſages of the Old and New Teſtaments which relate to the ſame doctrine, or to the ſame event, reaſonably concluding that the bible muſt be the beſt interpreter of itſelf; and though the opinions which he thus forms may often be erroneous, they will ſeldom be dangerous errors, and may eaſily be corrected by mature reflection, or by conſulting approved authors who have treated before him of the various points which have been the ſubject of his ſtudies. Of this mode of proceeding one good conſequence will be, that, having from the ſacred ſcriptures formed a ſyſtem of theology for himſelf, he will afterwards ſtudy the ſyſtems of other men without any violent prejudices for or againſt them; he will be ſo much attached to his own opinions as not to relinquiſh them in obedience to mere human authority, at the ſame time that he will be ready to give them up when convinced that they are not well founded; and if he have read the ſcriptures to any good purpoſe, he will have acquired ſuch a love of truth as to embrace her wherever ſhe may be found, whether among Papiſts or Proteſtants, in the ſchool of Arminius or in that of Calvin.

As we have ſuppoſed that every man, after having formed a theological ſyſtem of his own, will conſult the ſyſtems of others, it may perhaps be expected that we ſhould here recommend thoſe which, in our opinion, are moſt worthy of his attention. To do this, however, would, we apprehend, be a very ungracious interference with the rights of private judgment. It would be to arrogate to ourſelves a kind of authority to which, when aſſumed by others, we have cautioned our readers not to ſubmit. But leſt we ſhould be ſuſpected of wiſhing to bias the mind of the young ſtudent toward the ſhort ſyſtem which we are obliged to give, we ſhall juſt obſerve, that by the divines of what is called the *Arminian ſchool*, Epiſcopius's *Theologiæ Inſtitutiones* (c), Limborch's *Theologia Chriſtiana*, and Locke's *Reaſonableneſs*

13 Approved ſyſtems of divinity.

(c) There is, however, one chapter of this work which the majority of Arminians loudly condemn. Epiſcopius acknowledges

Preliminary Directions.

ſonableneſs of Chriſtianity, have long been held in the higheſt eſteem; whilſt the followers of Calvin have preferred the *Inſtitutiones* of their maſter, Turretine's *Inſtitutio Theologiæ Elenctica*, and Gill's *Body of Divinity*. This laſt work, which was publiſhed in two vols 4to in 1769, has many merits and many defects. Its ſtyle is coarſe, impure, and tedious; and the author, who was a zealous antipædo baptiſt, and ſeems to have poſſeſſed very little ſcience, embraces every opportunity of introducing the diſcriminating tenets of his ſect: but his book is fraught with profound learning, breathes the ſpirit of piety, and may be read with advantage by every divine who has previouſly formed the outlines of a ſyſtem for himſelf.

14 Books recommended on the Moſaic diſpenſation.

As the Jewiſh and Chriſtian diſpenſations are cloſely linked together, being in truth but parts of one great whole, it is impoſſible to have an adequate notion of the latter without underſtanding the deſign of the former. Now, though the Moſaic religion is nowhere to be learned but in the Old Teſtament, it may be convenient for our ſtudent, after he has formed his own opinions of it from that ſacred ſource, to know what has been written on the ſubject by others. For illuſtrating the ritual law, a learned prelate warmly recommends the *Ductor Dubitantium* of Maimonides, and Spencer's book entitled *De Legibus Hebræorum Ritualibus*. Both works have undoubtedly great merit; but our young divine will do well to read along with them *Hermanni Witſii Ægyptiaca*, and Dr Woodward's Diſcourſe on the Worſhip of the Ancient Egyptians, communicated to the London Society of Antiquaries in 1775, where ſome of Spencer's notions are ſhortly and ably refuted. On the other parts of this diſpenſation, ſuch as the nature of its civil government; the rewards and puniſhments peculiar to it (D); its extraordinary adminiſtration by appointed agents, endowed with ſupernatural powers, and with the gifts of miracles and prophecy; the *double ſenſe* in which the latter is ſometimes involved; and the language conſequent to its nature and uſe—the reader will find much erudition and ingenuity diſplayed in the ſecond part of Warburton's *Divine Legation of Moſes demonſtrated*. His Lordſhip indeed is ſuppoſed by many, and perhaps juſtly, to have advanced, together with a great deal of good ſenſe, many paradoxes in his favourite work; but ſtill that work is entitled to a ſerious peruſal, for it diſplays great learning and genius, and, we believe, the heavieſt cenſures have fallen upon it from thoſe by whom it was never read.

15 Inquiry to be made into the reality of revelation.

Having proceeded thus far in the courſe, the ſtudent's next buſineſs ſhould be to inquire ſeriouſly what evidence there is that the doctrines which he has ſo carefully ſtudied were indeed revealed in times paſt by God. He muſt already have perceived, in the nature and tendency of the doctrines themſelves, ſtrong marks of their origin being more than human; but he muſt likewiſe have met with many difficulties, and he muſt prepare himſelf to repel the attacks of unbelievers. Here he will find opportunities of exerting the utmoſt powers of his reaſoning faculties, and of employing in the ſervice of religion all the ſtores he may have amaſſed of human learning. The ſcriptures pretend to have been written by ſeveral men who lived in different ages of the world; but the lateſt of them in an age very remote from the preſent. His firſt buſineſs therefore muſt be to prove the authenticity of theſe books, by tracing them up by hiſtorical evidence to the ſeveral writers whoſe names they bear. But it is not enough to prove them authentic. They profeſs to have been written by men divinely aſſiſted and inſpired, and of courſe infallible in what they wrote. He muſt therefore inquire into the truth of this inſpiration. "The Bible contains a number of truths doctrinal and moral, which are called *myſteries*, and aſſerted to be the immediate dictates of God himſelf. To evince this great point to man, a number of ſupernatural *teſts* and *evidences* are inſeparably connected with thoſe myſteries; ſo that if the former be true, the latter muſt likewiſe be ſo. He muſt therefore examine theſe teſts and evidences, to eſtabliſh the divinity of the Holy Scriptures;" and in this part of his courſe he will find much aſſiſtance from many writers whoſe defences of the truth and divinity of the Chriſtian religion do honour to human nature.

Preliminary Directions.

16 Books recommended on that ſubject.

The firſt ſtep towards the embracing of any truth is, to get fairly rid of the objections which are made to it; and the general objections made by deiſtical writers to the Chriſtian revelation are by no writer more completely removed than by Biſhop Butler, in his celebrated work entitled *The Analogy of Religion natural and revealed to the Conſtitution and Courſe of Nature*. This book therefore the ſtudent ſhould read with attention, and meditate upon with patience; but as it does not furniſh a *poſitive proof* of the divinity of our religion, he ſhould paſs from it to *Grotius de Veritate Religionis Chriſtianæ*, and Stillingfleet's *Origines Sacræ*. Both theſe works are excellent; and the latter, which may be conſidered as an improvement of the former, is perhaps the fulleſt and ableſt defence of revelation in general that is to be found in any language. In this part of the united kingdom it is now indeed hardly mentioned, or mentioned with indifference; but half a century ago the Engliſh divines thought it a ſubject of triumph, and ſtyled its author their *incomparable Stillingfleet*. Other works, however, may be read with great advantage, and none with greater than Paley's *Evidences of the Chriſtian Religion*, and Leſlie's *Short Method with the Deiſts*; which laſt work, in the compaſs of a very few pages, contains proofs of the divinity of the Jewiſh and Chriſtian revelations, to which the celebrated Dr Mid-

---

ledges (lib. iv. ſect. 2. cap. 33.) that it may be proved from ſcripture, that the perſon who was afterwards Jeſus Chriſt was from eternity the only begotten of his Father, by whom all things were made, and that therefore he is really and truly God. He mentions five ſenſes in which our Saviour is called the ſon of God; and ſhews that in this fifth and laſt ſenſe the filiation is peculiar to him alone. Yet in cap. 34. he ſtates the following queſtion: "An quintus iſte modus filiationis Jeſu Chriſti ad ſalutem ſcitu ac creditu neceſſarius ſit, uſque, qui illum negant, anathema dicendum ſit?" and gravely anſwers it in the negative. It is not to be wondered at that moſt Arminians differ from this celebrated remonſtrant in their anſwers to this queſtion; for nothing can be more abſurd than to hold religious communion with thoſe who deny the *divinity* of that perſon, whoſe divinity, it is *acknowledged*, may be clearly proved. Againſt this extravagant poſition many Arminian pens were drawn; but none to better purpoſe than that of biſhop Bull, whoſe *Judicium Eccleſiæ Catholicæ trium primorum ſeculorum, &c. aſſertum contra M. Simonem Epiſcopium alioſque*, obtained for its author the thanks of the whole clergy of France aſſembled (1710) at *St. Germaine en Laye* in a national ſynod.

(D) On this ſubject the reader will find many excellent obſervations in Biſhop Bull's *Harmonia Apoſtolica*, with its ſeveral defences, and in a ſmall book of Dr Wells's, entitled An Help for the right underſtanding of the ſeveral Divine Laws and Covenants, whereby man has been obliged through the ſeveral ages of the world to guide himſelf in order to ſalvation.

Preliminary Directions.

Middleton confeſſed (E), that for 20 years he had laboured in vain to fabricate a ſpecious anſwer (F).

17 Jewiſh controverſy to be ſtudied,

Having ſatisfied himſelf of the truth of revelation in general, it may be worth the young divine's while to provide a defence of the Chriſtian religion againſt the objections of modern Judaiſm. In this part of his ſtudies he will need no other inſtruction than what he may reap from Limborch's work entitled, *De Veritate Religionis Chriſtianæ amica collatio cum erudito Judæo.* "In that diſputation which was held with Orobio, he will find all that the ſtretch of human parts on the one hand, or ſcience on the other, can produce to varniſh error or unravel ſophiſtry. All the papers of Orobio in defence of Judaiſm, as oppoſed to Chriſtianity, are printed at large, with Limborch's anſwers, ſection by ſection; and the ſubtileſt ſophiſms of a very ſuperior genius are ably and ſatisfactorily detected and expoſed by the ſtrong, profound, and clear reaſoning, of this renowned remonſtrant.†" See OROBIO and LIMBORCH.

† Warburton's Directions for the Study of Theology.

The various controverſies ſubſiſting between the ſeveral denominations of Chriſtians, about points which ſeparate them into different churches, ought next to be ſtudied in the order of the courſe; for nothing is unimportant which divides the followers of that Maſter whoſe favourite precept was *love*. It has indeed been long faſhionable to decry polemical divinity as an uſeleſs, if not a pernicious, ſtudy; but it is not impoſſible that this faſhion, like many others, has had its origin in ignorance, and that it tends to perpetuate thoſe ſchiſms which it profeſſes to lament. We are, however, far, very far, from recommending to the young divine a peruſal of the works of the ſeveral combatants on each ſide of a diſputed queſtion, till he has fitted himſelf for judging between them by a long courſe of preparatory ſtudy; and the only preparation which can fit him for this purpoſe is an impartial and comprehenſive ſtudy of eccleſiaſtical hiſtory. He who has with accuracy traced the progreſs of our holy religion from the days of the apoſtles to the preſent time, and marked the introduction of new doctrines, and the riſe of the various ſects into which the Chriſtian world is unhappily divided, is furniſhed with a criterion within himſelf by which to judge of the importance and truth of the many conteſted doctrines; whilſt he who, without this preparation, ſhall read a multitude of books on any one religious controverſy, will be in danger of becoming a convert to his laſt author, if that author poſſeſs any tolerable ſhare of art and ingenuity. This we know was the caſe with Pope, who declares, that in ſtudying the controverſy between the churches of England and Rome, he found himſelf a Papiſt and Proteſtant by turns, according to the laſt book he read.

18 And the various controverſies among Chriſtians themſelves.

19 Importance of eccleſiaſtical hiſtory, and books recommended.

There are many hiſtories of the Chriſtian church which poſſeſs great merit, but we are acquainted with none which appears to us wholly impartial. Moſheim's is perhaps the moſt perfect compend (G); and one of its greateſt excellencies is, that on every ſubject the beſt writers are referred to for fuller information. Theſe indeed ſhould often be conſulted, not only to ſupply the defects neceſſarily reſulting from the narrowneſs of the limits which the author, with great propriety, preſcribed to himſelf; but alſo to correct his partial obliquities; for with all his merits, and they were many and great, he is certainly not free from the influence of prejudice. Indeed there is no coming at the true hiſtory of the primitive church, but by ſtudying the works of the primitive writers; and the principal works of the four firſt centuries will amply reward the labour of peruſing them (H). The riſe and progreſs of the reformation in general, the moſt important period of church-hiſtory, may be beſt learned from Sleidan's book *De ſtatu Religionis et Reipublicæ Carolo V. Cæſare Commentarii;* the Hiſtory of the Reformation of the Church of Scotland from Knox and Spotiſwood: and that of the Church of England from the much applauded work of Biſhop Burnet.

Preliminary Directions.

After this courſe of eccleſiaſtical hiſtory, the young divine may read with advantage the moſt important controverſies which have agitated the Chriſtian world; for he will now read them without danger of giving up his faith to the mere authority of great names. To enumerate theſe controverſies, and to point out the ableſt authors who have written on each, would be a very tedious, and perhaps not a very profitable, taſk. On one controverſy, however, we are induced to recommend a very maſterly work, becauſe it is ſufficient of itſelf to fix the principles of Proteſtants with reſpect to the church of Rome, and to put to ſhame the faſhionable cenſurers of *polemical divinity*. The work to which we allude is Chillingworth's book againſt Knott, entitled *The Religion of Proteſtants a ſafe way to Salvation;* in which the ſchool jargon of that ſubtile Jeſuit is incomparably expoſed, and the long diſpute between the Popiſh and Reformed churches placed on its proper ground, the Holy Scriptures.

20 Toleration.

One of the ſtrongeſt and moſt plauſible objections to the ſtudy of polemical divinity, is its tendency to give a rigid turn to the ſentiments of thoſe long engaged in it; whilſt we know, from higher authority than that of the ableſt diſputant, "that the end of the commandment is charity." But for preſerving charity in the minds of Chriſtians, there are better means than abſolute ignorance or indifference to truth. Charity is violated only when a church unreaſonably reſtrains the inquiries of its own members, or exerciſes intolerance towards thoſe who have renounced its juriſdiction. The injuſtice of the firſt ſpecies of eccleſiaſtical tyranny is expoſed in a very maſterly manner by Jeremy Taylor in his *Liberty of Prophecying*, and by Stillingfleet in his *Irenicum;* the injuſtice of the ſecond by Locke in his celebrated Letters on Toleration. The man who ſhall peruſe

(E) This piece of information we had from the late Dr Berkely, prebendary of Canterbury, who had it from Archbiſhop Secker, to whom the confeſſion was made.

(F) To theſe defences of revelation we might have added the collection of ſermons preached at Boyle's lecture from 1691 to 1732, publiſhed in three volumes folio, 1739; the works of Leland; Biſhop Newton's Diſſertations on Prophecy; and above all, Lardner's Credibility of the Goſpel Hiſtory, with the Supplement to it. But there would be no end of recommending eminent writers on this ſubject. We have mentioned ſuch as we moſt approve among thoſe with whom we are beſt acquainted; but we muſt, once for all, caution the reader againſt ſuppoſing that we approve of *every* thing to be found in any work except the ſacred ſcriptures.

(G) The Biſhop of Landaff, in the catalogue of books publiſhed at the end of his Theological Tracts, recommends ſeveral other eccleſiaſtical hiſtories as works of great merit; ſuch as, Dupin's, Echard's, Gregory's, and Formey's, together with *Pauli Erneſti Jablonſki Inſtitutiones Hiſtoriæ Chriſtianæ*, publiſhed at Frankfort in three volumes, 1754-67.

(H) For a proof of this poſition, and for a juſt eſtimate of the value of the *Fathers*, as they are called, ſee the introduction to Warburton's Julian, and Kett's Sermons at Bampton's Lectures.

Preliminary Directions.

use these three works, and impartially weigh the force of their arguments, will be in no danger, unless his pride be very great, or his temper uncommonly irritable, of thinking uncharitably of those from whose principles the love of truth may compel him to dissent.

In these directions for the study of theology, we might have enumerated many more books on each branch of the subject well deserving of the most attentive perusal; but he who shall have gone through the course here recommended, will have laid a foundation on which, if he continue his diligence, he may raise such a superstructure as will entitle him to the character of an accomplished divine. His diligence must indeed be continued through life; for when a man ceases to make acquisitions in any department of learning, he soon begins to lose those which he has already made; and a more contemptible character is nowhere to be found than that of a clergyman unacquainted with the learning of his profession. This learning, however, is not to be acquired, and indeed is hardly to be preserved, by studying *bodies or institutes of theology*; and though we have mentioned a few generally approved by two rival sects of Christians, and must in conformity with the plan of our work, give another ourselves, we do not hesitate to declare, that the man who has carefully gone through the course of study which we have recommended, though it be little more than the outlines on which he is to work, may, with no great loss to himself, neglect ours and all other systems. For as an excellent writer,* whom we have often quoted, well observes, "to judge of the *fact* whether such a revelation containing such a principle, with its mysteries and credentials, was actually sent from God and received by man, by examining the *evidences* and *circumstances* which accompanied it —the *time* when, the *place* where, the *manner* how, it was delivered—the *form* in which it descends to us—and in what it is *contained*—together with the particular *substance* and *burden* of it—and how every part is to be rightly *understood*: these are the various and extensive subjects which constitute the sublime office of THEOLOGIC REASONING and the PROPER STUDY OF DIVINITY." On this account we shall pass over slightly, and sometimes perhaps without any notice, many things which every clergyman ought thoroughly to understand, and confine ourselves, in the short compend which we are to give, to the prime articles of Christian theology. In doing this, we shall endeavour as much as possible to divest ourselves of party prejudices; but as we are far from thinking that this endeavour will be completely successful (for we believe there is no man totally free from prejudice), we cannot conclude this part of the article more properly than with the following solemn CHARGE with which a very learned divine‡ always prefaced his Theological Lectures.

* Tatham.

Preliminary Directions.

‡ Dr Taylor of Norwich.

21 A charge to students of theology.

I. "I do solemnly charge you, in the name of the God of Truth, and of our Lord Jesus Christ, who is the Way, the Truth, and the Life, and before whose judgment seat you must in no long time appear, that in all your studies and inquiries of a religious nature, present or future, you do constantly, carefully, impartially, and conscientiously, attend to evidence, as it lies in the Holy Scriptures, or in the nature of things, and the dictates of reason; cautiously guarding against the sallies of imagination, and the fallacy of ill-grounded conjecture.

II. "That you admit, embrace, or assent, to no principle or sentiment by me taught or advanced, but only so far as it shall appear to you to be supported and justified by proper evidence from revelation or the reason of things.

III. "That if, at any time hereafter, any principle or sentiment by me taught or advanced, or by you admitted or embraced, shall, upon impartial and faithful examination, appear to you to be dubious or false, you either suspect or totally reject such principle or sentiment.

IV. "That you keep your mind always open to evidence: That you labour to banish from your breast all prejudice, prepossessions, and party zeal: That you study to live in peace and love with all your fellow Christians; and that you steadily assert for yourself, and freely allow to others, the unalienable rights of judgment and conscience."

PART I. OF NATURAL THEOLOGY.

SECT. I. *Of the Being and Attributes of* GOD.

* St. Paul.

HE who cometh to God, says an ancient divine*, deeply read in the philosophy of his age, must believe that he is, and that he is a rewarder of them who diligently seek him. This is a truth as undeniable as that a man cannot concern himself about a nonentity. The existence of God is indeed the foundation of all religion, and the first principle of the science which is the subject of this article. It is likewise a principle which must command the assent of every man who has any notion of the relation between effects and their causes, and whose curiosity has ever been excited by the phenomena of nature. This great and important truth we have elsewhere endeavoured to demonstrate (see METAPHYSICS, Part III. Chap. vi.): but it may be proved by arguments less abstracted from common apprehension than the nature of that article required us to use. Of these we shall give one or two, which we hope will be level to every ordinary capacity; whilst, at the same time, we earnestly recommend to the young divine a diligent study of those books on the subject which we have mentioned in the preceding directions.

22 The being of a God proved from

23 Propagation of animals

We see that the human race, and every other species of animals, is at present propagated by the co-operation of two parents; but has this process continued from eternity? A moment's reflection will convince us that it has not. Let us take any one man alive, and, to avoid perplexity, let us suppose his father and mother dead, and himself the only person at present existing: how came he into the world? It will be said he was produced mechanically or chemically by the conjunction of his parents, and that his parents were produced in the same manner by theirs. Let this then be supposed; it must surely be granted, that when this man was born, an addition was made to the series of the human race. But a series that can be enlarged may likewise be diminished; and by tracing it backwards, we must at some period, however remote, reach its beginning. There must therefore have been a first pair of the human race, who were not propagated by the conjunction of parents. How did these come into the world?

Anaximander tells us*, that the first men and all animals were bred in a warm moisture, inclosed in crustaceous skins like crab-fish and lobsters; and that when they arrived at a proper age, their shelly prisons growing dry, broke, and made way for their liberty. Empedocles informs us, that mother earth at first brought forth vast numbers of legs, and arms, and heads, &c. which approaching each other, arranging themselves properly, and being cemented together, started up at once full grown men. Another of these philosophers relates, that there first grew up a sort of wombs, which

* See Bentley's Boyle's Lectures.

Being and attributes of God.

which having their roots in the earth, attracted thence a kind of milk for the nourishment of the fœtus, which in process of time broke through the membranes and shifted for itself; whilst the Egyptian fathers § of this hopeful school content themselves with simply affirming, that animals like vegetables sprung at first from the bosom of the earth.

§ Diodorus Siculus apud Euseb. Prep. Evangel.

Surely those sages, or their followers, should have been able to tell us why the earth has not in any climate this power of putting forth vegetable men or the parts of men at present. If this universal parent be eternal and self-existent, it must be incapable of decay or the smallest change in any of its qualities; if it be not eternal, we shall be obliged to find a cause for its existence, or at least for its form and all its powers. But such a cause may have produced the first human pair, and undoubtedly did produce them, without making them spring as plants from the soil. Indeed the growth of plants themselves clearly evinces a cause superior to any vegetative power which can be supposed inherent in the earth. No plant, from the sturdy oak to the creeping ivy, can be propagated but from seed or slips from the parent stock; but when one contemplates the regular process of vegetation, the existence of every plant implies the prior existence of a parent seed, and the existence of every seed the prior existence of a parent plant. Which then of these, the oak or the acorn, was the first, and whence was its existence derived? Not from the earth; for we have the evidence of universal experience that the earth never produces a tree but from seed, nor seed but from a tree. There must therefore be some superior power which formed the first seed or the first tree, planted it in the earth, and gave to it those powers of vegetation by which the species has been propagated to this day.

24 And vegetables,

Thus clearly do the processes of generation and vegetation indicate a power superior to those which are usually called *the powers of nature*. The same thing appears no less evident from the laws of attraction and repulsion, which plainly prevail through the whole system of matter, and hold together the stupendous structure. Experiment shows that very few particles of the most solid body are in actual contact with each other (see OPTICS, n° 63—68, PHYSICS, n° 23,); and that there are considerable interstices between the particles of every elastic fluid, is obvious to the smallest reflection. Yet the particles of solid bodies strongly cohere, whilst those of elastic fluids repel each other. How are these phenomena accounted for? To say that the former is the effect of attraction and the latter of repulsion, is only to say that two individual phenomena are subject to those laws which prevail through the whole of the classes under which they are respectively arranged; whilst the question at issue is concerning the ORIGIN OF THE LAWS THEMSELVES, the *power* which makes the particles of gold cohere, and those of air repel each other. Power without substance is inconceivable; and by a law of human thought, no man can believe a being to operate but where it is in some manner or other actually present; but the particles of gold adhere, and the particles of air keep at a distance from each other, by powers exerted where no matter is present. There must therefore be some substance endowed with power which is not material.

25 And from the laws of attraction and repulsion, &c.

Of this substance or being the power is evidently immense. The earth and other planets are carried round the sun with a velocity which human imagination can hardly conceive. That this motion is not produced by the agency of these vast bodies on one another, or by the interposition of any material fluid, has been shown elsewhere (see METAPHYSICS, n° 196–200. and OPTICS, n° 67.); and since it is a law of our best philosophy, *that we are not to multiply substances without necessity*, we must infer that the same Being which formed the first animals and vegetables, endowing them with powers to propagate their respective kinds, is likewise the cause of all the phenomena of nature, such as *cohesion*, *repulsion*, *elasticity*, and *motion*, even the motions of the heavenly bodies themselves.

Being and attributes of God.

If this powerful Being, who is the parent of vegetable and animal life, and the source of all corporeal motions, be self-existent, intelligent, and independent in his actions and volitions, he is an original or first cause, and that Being whom we denominate God. If he be not self-existent and independent, there must be a cause in the order of nature prior and superior to Him, which is either itself the first cause, or a link in that series of causes and effects, which, however vast we suppose it, must be traced ultimately to some one Being, who is self-existent, and has in himself the power of beginning motion, independent of every thing but his own intelligence and volition. In vain have the atheists alleged, that the series may ascend infinitely, and for that reason have no first mover or cause. An infinite series of successive beings involves an absurdity and contradiction (see METAPHYSICS, n° 288.): but not to insist upon this at present, we shall only beg leave to consider such a series as a whole, and see what consequences will flow from the supposition. That we may with logical propriety consider it in this light, is incontrovertible; for the birth of every individual of the human race shows that it is made up of parts; but parts imply a whole as necessarily as an attribute implies its substance. As in this supposed series there is no cause which is not likewise an effect, nor any body moving another which was not itself moved by a third, the whole is undeniably equivalent to an infinite effect, or an infinite body moved: but if a finite effect must necessarily have proceeded from a cause, and a finite body in motion must have been put into that state by a mover, is there a human mind which can conceive an infinite effect to have proceeded from *no* cause, or an infinite body in motion to have been moved by *nothing?* No, surely! An infinite effect, were such a thing possible, would compel us to admit an infinite cause, and an infinite body in motion a mover of infinite power.

26 Absurdity of an infinite series of effects.

This great cause is GOD, whose wisdom, power, and goodness, all nature loudly proclaims. That the phenomena which we daily see evince the existence of *one* such Being, has just been shown; and that we have no reason to infer the existence of *more* than one, a very few reflections will make abundantly evident. For, not to lay more stress than it will bear upon that rule of Newton's which forbids us to multiply substances without necessity, such a harmony prevails through the whole visible universe, as plainly shows it to be under the government of one intelligence. That on this globe the several elements serve for nourishment to plants, plants to the inferior animals, and animals to man; that the other planets of our system are probably inhabited, and their inhabitants nourished in the same or a similar manner; that the sun is so placed as to give light and heat to all, and by the law of gravitation to bind the whole planets into one system with itself—are truths so obvious and so universally acknowledged, as to supersede the necessity of establishing them by proof. The fair inference therefore is, that the solar system and all its parts are under the government of *one intelligence*, which directs all its motions and all the changes which take place among its parts for some wise purposes. To suppose it under the government of two or more intelligences would be highly unreasonable; for if these intelligences had equal power, equal wisdom, and the same designs, one of them would evidently be superfluous; and if they had equal power and contrary designs, they could not be the parents of that harmony which we clearly perceive to prevail in the system.

27 There is only one original cause.

But

Being and attributes of God.

But the Being capable of regulating the movements of so vast a machine, may well be supposed to possess infinite power, and to be capable of superintending the motions of the universe. That the widely extended system of nature is but one system, of which the several parts are united by many bonds of mutual connection, has been shown elsewhere (see PHYSICS), and appears daily more and more evident from our progress in physical discoveries; and therefore it is in the highest degree unreasonable to suppose that it has more than one author, or one supreme governor.

28 Of infinite power, wisdom, and

As the unity of design apparent in the works of creation plainly prove the unity of their Author, so do the immensity of the whole, and the admirable adjustment of the several parts to one another, demonstrate His power and His wisdom. On this subject the following beautiful reflections by Mr Wollaston are deserving of the most serious attention.

‖ Religion of Nature, sec. v. prop. 14.

"In order (says that able writer ‖) to prove to any one the grandness of this fabric of the world, one needs only to bid him consider the *sun*, with that insupportable glory and lustre that surrounds it; to demonstrate its vast distance, magnitude, and heat; to represent to him the chorus of planets moving periodically, by uniform laws, in their several orbits about it; guarded some of them by secondary planets, and as it were emulating the state of the sun, and probably all possessed by proper inhabitants; to remind him of those surprising visits which the *comets* make to us, and the large trains of uncommon splendour which attend them, the far country from which they come, and the curiosity and horror which they excite not only among us, but in the inhabitants of other planets, who may also be up to see the entry and progress of these ministers of fate: to direct his eye and contemplation through those azure fields and vast regions above him up to the *fixed stars*, that radiant numberless host of heaven; and to make him understand how unlikely a thing it is that they should be placed there only to adorn and bespangle a canopy over our heads; to convince him that they are rather so many *other suns*, with their several systems of planets about them; to show him by the help of glasses still more and more of these fixed lights, and to beget in him an apprehension of their inconceivable numbers, and those immense spaces that lie beyond our reach and even our imagination: One needs but to do this (continues our author), and explain to him such things as are now known almost to every body; and by it to show, that if the world be not infinite, it is *infinitæ similis*, and undoubtedly the work of an INFINITE ARCHITECT.

"But if we would take a view of all the *particulars* contained within that astonishing compass which we have thus hastily run over, how would wonders multiply upon us? Every corner, every part of the world, is as it were, made up of *other* worlds. If we look upon this our earth, what scope does it furnish for admiration! The great variety of mountains, hills, valleys, plains, rivers, seas, trees, and plants! The many tribes of different animals with which it is stocked; the multifarious inventions and works of one of these, *i. e.* of us men; with the wonderful instincts of others, guiding them uniformly to what is best for themselves, in situations where neither sense nor reason could direct them. And yet when all these (heaven and earth) are surveyed as nicely as they can be by the help of our unassisted senses and of telescopes, we may discover by the assistance of good microscopes, in very small parts of matter, as many *new* wonders as those already discovered, new kingdoms of animals, with new and curious architecture. So that as our senses and even conception fainted before in the vast journeys we took in considering the expanse of the universe, they here again fail us in our researches into the principles and minute parts of which it is composed. Both the *beginnings* and the *ends* of things, the *least* and the *greatest*, all conspire to baffle us; and which way soever we prosecute our inquiries, we still meet with fresh subjects of amazement, and fresh reasons to believe that there are indefinitely more and more behind, that will forever escape our eagerest pursuits and deepest penetration.

Being and attributes of God.

"In this vast assemblage, and amidst all the multifarious motions by which the several processes of generation and corruption, and the other phenomena of nature, are carried on, we cannot but observe that there are stated methods, as so many forms of proceeding, to which things punctually and religiously adhere. The same *causes* circumstanced in the same manner produce always the same *effects*; all the *species* of animals among us are made according to one general *idea*; and so are those of *plants* also, and even of *minerals*. No new species are brought forth or have arisen anywhere; and the old are preserved and continued by the *old ways*.

"It appears, lastly, beyond dispute, that in the parts and model of the world there is a contrivance for accomplishing certain ends. The sun is placed near the centre of our system, for the more convenient dispensing of his benign influences to the planets moving about him; the place of the earth's *equator* intersects that of her *orbit*, and makes a proper angle with it, in order to diversify the *year*, and create an useful variety of *seasons*; and many other things of this kind will be always observed, and though a thousand times repeated, be meditated upon with pleasure by good men and true philosophers. Who can observe the vapours to ascend, especially from the sea, meet above in clouds, and fall again, after condensation, without being convinced that this is a kind of *distillation*, in order to clear the water of its grosser salts, and then by rains and dews to supply the fountains and rivers with fresh and wholesome liquor; to nourish the vegetables below by showers, which descend in drops as from a *watering-pot* upon a garden? Who can view the *structure* of a plant or animal, the indefinite number of its fibres and fine vessels, the formation of larger vessels, and the several members out of them, with the apt disposition of all these; the means contrived for the reception and distribution of *nutriment*; the *effect* this nutriment has in extending the vessels, bringing the vegetable or animal to its full growth and expansion, continuing the *motion* of the several fluids, repairing the decays of the body and preserving *life*? Who can take notice of the several *faculties* of animals, their arts of saving and providing for themselves, or the ways in which they are provided for; the uses of plants to animals, and of some animals to others, particularly to mankind; the care taken that the several species should be propagated, without confusion, from their proper seeds; the strong inclination planted in animals for that purpose, their love of their young and the like.—Who (says our author) can observe all this, and not see a *design* in such *regular* pieces, so nicely wrought and so admirably preserved? If there were but one animal in existence, and it could not be doubted but that his eyes were formed that he might see with them, his ears that he might hear with them, and his feet to be instruments by which he might remove himself from place to place; if *design* and *contrivance* can be much less doubted, when the same things are repeated in the individuals of all the tribes of animals; if the like observations may be made with respect to vegetables and other things; and if all these *classes* of things, and much more the *individuals* comprehended under them, be inconceivably numerous, as most unquestionably they are—one cannot but be convinced, from what so plainly runs through the nobler parts of the visible world, that not only *they*, but other things, even those that seem to be *less noble*, have their ends likewise, though not always

Being and attributes of God.

perceived by capacities limited like ours. And ſince we cannot, with the Epicureans of old, ſuppoſe the parts of matter to have *contrived* among themſelves this wonderful form of a world, to have taken by agreement each its reſpective *poſt*, and then to have purſued in conjunction conſtant *ends* by certain methods and meaſures *concerted*, there muſt be ſome other Being, whoſe wiſdom and power are equal to ſuch a mighty work as is the *ſtructure* and *preſervation* of the world. There muſt be ſome Almighty MIND who modelled and preſerves it; lays the cauſes of things ſo deep; preſcribes them ſuch uniform and ſteady laws; deſtines and adapts them to certain purpoſes; and makes one thing to fit and anſwer another ſo as to produce one harmonious whole. Yes,

> Theſe are thy glorious works, Parent of good!
> Almighty, thine this univerſal frame,
> Thus wondrous fair; THYSELF how wondrous then!
> How wondrous in wiſdom and in power!"

29 Goodneſs.

But the GOODNESS of God is not leſs conſpicuous in his works than His power or His wiſdom. Contrivance proves deſign, and the predominant tendency of the contrivances indicates the diſpoſition of the deſigner. "The world (ſays an elegant and judicious writer†) abounds with contrivances, and all the contrivances in it with which we are acquainted are directed to beneficial purpoſes. Evil no doubt exiſts; but it is never that we can perceive the object of contrivance. Teeth are contrived to eat, not to ache; their aching now and then is incidental to the contrivance, perhaps inſeparable from it; but it is not its object. This is a diſtinction which well deſerves to be attended to. In deſcribing implements of huſbandry, one would hardly ſay of a ſickle that it is made to cut the reaper's fingers, though from the conſtruction of the inſtrument, and the manner of uſing it, this miſchief often happens. But if he had occaſion to deſcribe inſtruments of torture or execution, this, he would ſay, is to extend the ſinews; this to diſlocate the joints; this to break the bones; this to ſcorch the ſoles of the feet. Here pain and miſery are the very objects of the contrivance. Now nothing of this ſort is to be found in the works of nature. We never diſcover a train of contrivance to bring about an evil purpoſe. No anatomiſt ever diſcovered a ſyſtem of organization calculated to produce pain and diſeaſe; or, in explaining the parts of the human body, ever ſaid, this is to irritate, this to inflame, this duct is to convey the gravel to the kidneys, this gland to ſecrete the humour which forms the gout. If by chance he come to a part of which he knows not the uſe, the moſt that he can ſay is, that to him it appears to be uſeleſs: no one ever ſuſpects that it is put there to incommode, to annoy, or to torment. If God had wiſhed our miſery, he might have made ſure of his purpoſe, by forming our ſenſes to be as many ſores and pains to us as they now are inſtruments of gratification and enjoyment; or, by placing us among objects ſo ill ſuited to our perceptions, as to have continually offended us, inſtead of miniſtering to our refreſhment and delight. He might have made, for inſtance, every thing we taſted bitter, every thing we ſaw loathſome, every thing we touched a ſting, every ſmell a ſtench, and every ſound a diſcord."

† Dr Paley.

Inſtead of this, all our ſenſations, except ſuch as are excited by what is dangerous to our health, are pleaſures to us: The view of a landſcape is pleaſant; the taſte of nouriſhing food is pleaſant; ſounds not too loud are agreeable, while muſical ſounds are exquiſite; and hardly any ſmells, except ſuch are excited by effluvia obviouſly pernicious to the brain, are diſagreeable; whilſt ſome of them, if not too long indulged, are delightful. Our lives are preſerved and the ſpecies is continued by obeying the impulſe of appetites; of which the gratification is exquiſite when not repeated too frequently to anſwer the purpoſes of the Author of our being. Since, then, God has called forth his conſummate wiſdom to contrive and provide for our happineſs, and has made thoſe things which are neceſſary to our exiſtence and the continuance of the race ſources of our greateſt ſenſual pleaſures, who can doubt but that benevolence is one of his attributes; and that, if it were not impious to draw a compariſon between them, it is the attribute in which he himſelf moſt delighteth?

Being and attributes of God.

But it is not from ſenſation only that we may infer the benevolence of the Deity: He has formed us with minds capable of intellectual improvement, and he has implanted in the breaſt of every man a very ſtrong deſire of adding to his knowledge. This addition to be ſure cannot be made without labour; and at firſt the requiſite labour is to moſt people irkſome: but a very ſhort progreſs in any ſtudy converts what was irkſome into a pleaſure of the moſt exalted kind; and he who by ſtudy, however intenſe, enlarges his ideas, and is conſcious that he is daily riſing in the ſcale of intelligence, experiences a complacency, which, though not ſo poignant perhaps as the pleaſures of the ſenſualiſt, is ſuch as endears him to himſelf, and is what he would not exchange for any thing elſe which this world has to beſtow, except the ſtill ſweeter complacency ariſing from the conſciouſneſs of having diſcharged his duty.

That the practice of virtue is attended with a peculiar pleaſure of the pureſt kind, is a fact which no man has ever queſtioned, though the immediate ſource of that pleaſure has been the ſubject of many diſputes. He who attributes it to a moral ſenſe, which inſtinctively points out to every man his duty, and upon the performance of it rewards him with a ſentiment of ſelf-approbation, muſt of neceſſity acknowledge benevolence to be one of the attributes of that Being who has ſo conſtituted the human mind. That to protect the innocent, relieve the diſtreſſed, and do to others as we would in like circumſtances wiſh to be done by, fills the breaſt, previous to all reflection, with a holy joy, as the commiſſion of any crime tears it with remorſe, cannot indeed be controverted. Many, however, contend, that this joy and this remorſe ſpring not from any moral inſtinct implanted in the mind, but are the conſequence of early and deep-rooted aſſociations of the practice of virtue with the hope of future happineſs, and of vice with the dread of future miſery. On the reſpective merits of theſe two theories we ſhall not now decide. We have ſaid enough on the ſubject in other articles (ſee INSTINCT, MORAL PHILOSOPHY, and PASSION); and ſhall here only obſerve, that they both lead with equal certainty to the benevolence of the Deity, who made us capable of forming aſſociations, and ſubjected thoſe aſſociations to fixed laws. This being the caſe, the moral ſenſe, with all its inſtantaneous effects, affords not a clearer or more convincing proof of his goodneſs, than that principle in our nature by which remote circumſtances become ſo linked together, that, after the connecting ideas have eſcaped from the mind, the one circumſtance never occurs without bringing the other alſo into view. It is thus that the pleaſing complacency, which was perhaps firſt excited by the hopes of future happineſs, comes in time to be ſo aſſociated with the conſciouſneſs of virtuous conduct, the only thing entitled to reward, that a man never performs a meritorious action without experiencing the moſt exquiſite joy diffuſed over his mind, though his attention at that inſtant may not be directed either to heaven or futurity. Were we obliged, before we could experience this joy, to eſtimate by reaſon the merit of every individual action, and trace its connection to heaven and future happineſs through a long train of intermediate argumentation,

Being and attributes of God.

mentation, we ſhould be in a great meaſure deprived of the preſent reward of virtue; and therefore this aſſociating principle contributes much to our happineſs. But the benevolence of a Being, who ſeems as it were thus anxious to furniſh us with both ſenſual and intellectual enjoyments, and who has made our duty our greateſt pleaſure, cannot be queſtioned; and therefore we muſt infer, that the Author of Nature wiſhes the happineſs of the whole ſenſible and intelligent creation.

30 Objections,

To ſuch reaſoning as this in ſupport of the Divine Benevolence many objections have been made. Some of them appear at firſt ſight plauſible, and are apt to ſtagger the faith of him who has beſtowed no time on the ſtudy of that branch of general ſcience which is called *phyſics* (ſee PHYSICS). To omit theſe altogether in ſuch an article as this might be conſtrued into neglect; whilſt it is certain that there is in them nothing worthy of the attention of that man who is qualified either to eſtimate their force, or to underſtand the arguments by which they have often been repelled.

It has been aſked, Why, if the Author of Nature be a benevolent Being, are we neceſſarily ſubject to pain, diſeaſes, and death? The ſcientific phyſiologiſt replies, Becauſe from theſe evils Omnipotence itſelf could not in our preſent ſtate

31 Anſwered.

exempt us, but by a conſtant ſeries of miracles. He who admits miracles, knows likewiſe that mankind were originally in a ſtate in which they were not ſubject to death; and that they fell under its dominion through the fault of their common progenitors. But the fall and reſtoration of man is the great ſubject of revealed religion; and at preſent we are diſcuſſing the queſtion like philoſophers who have no other data on which to proceed than the phenomena of nature. Now we know, that as all matter is diviſible, every ſyſtem compoſed of it muſt neceſſarily be liable to decay and diſſolution; and our material ſyſtem would decay and be diſſolved long before it could ſerve the purpoſes of nature, were there not methods contrived with admirable wiſdom for repairing the waſte occaſioned by perpetual friction. The body is furniſhed with different fluids, which continually circulate through it in proper channels, and leave in their way what is neceſſary to repair the ſolids. Theſe again are ſupplied by food *ab extra*; and to the whole proceſſes of digeſtion, circulation, and nutrition, the air we breathe is abſolutely neceſſary. (See PHYSIOLOGY, Sect. 1, 2, 3, 4, 5). But as the air is a very heterogeneous fluid, and ſubject to violent and ſudden changes, it is obvious that theſe changes muſt affect the blood, and by conſequence the whole frame of the human body. We ſee the air indeed in proceſs of time conſume even marble itſelf; and therefore cannot wonder, that as it is in one ſtate the parent of health, it ſhould in another be the ſource of diſeaſe to ſuch creatures as man and other terreſtrial animals. Nor could theſe conſequences be avoided without introducing others much more deplorable. The world is governed by general laws, without which there could be among men neither arts nor ſciences; and tho' laws different from thoſe by which the ſyſtem is at preſent governed might perhaps have been eſtabliſhed, there is not the ſmalleſt reaſon to imagine that they could on the whole have been better, or attended with fewer inconveniencies. As long as we have material and ſolid bodies capable of motion, liable to reſiſtance from other ſolid bodies, ſupported by food, ſubject to the agency of the air, and diviſible, they muſt neceſſarily be liable to pain, diſeaſe, corruption, and death, and that too by the very influence of thoſe laws which preſerve the order and harmony of the univerſe. Thus gravitation is a general law ſo good and ſo neceſſary, that were it for a moment ſuſpended, the world would inſtantly fall to pieces; and yet by means of this law the man muſt inevitably be cruſhed to death upon whom a tower ſhall chance to tumble. Again, the attraction of coheſion is a general law, without which it does not appear that any corporeal ſyſtem could poſſibly exiſt: it is by this law too, or a modification of it, that the glands and lacteals of the human body extract from the blood ſuch particles as are neceſſary to nouriſh the ſolids; and yet it is by means of the very ſame modification of the very ſame law that a man is liable to be poiſoned. How are theſe effects to be prevented?

Being and attributes of God

> Shall burning Ætna, if a ſage requires,
> Forget to thunder, and recal her fires?
> On air or ſea new motions be impreſt,
> Oh blameleſs Bethel! to relieve thy breaſt:
> When the looſe mountain trembles from on high,
> Shall gravitation ceaſe if you go by?
> Or ſome old temple nodding to its fall,
> For Charters' head reſerve the hanging wall;

Such a perpetual miracle, ſuch a frequent ſuſpending of the laws of nature in particular inſtances, we cannot doubt to be within the compaſs of Almighty power: but were this ſuſpenſion really to take place, mankind would be involved in ignorance greater than that of childhood; for not one of them could know, or have any means of diſcovering this moment, what was to happen the next; and the conſequence would be, that, uncertain but the ſingle motion of a ſingle joint might bring on them ſudden deſtruction, they would all periſh in a ſtate of abſolute inactivity.

32 Sickneſs, pain, and the dread of death ſerve good purpoſes.

But though the human body could not have been preſerved from dangers and diſſolution but by introducing evils greater on the whole than thoſe to which it is now liable, why, it has ſometimes been aſked, is every diſorder to which it is ſubject attended with ſickneſs or with pain? and why is ſuch a horror of death implanted in our breaſts, ſeeing, that by the laws of nature death is inevitable? We anſwer That ſickneſs, pain, and the dread of death, ſerve the very beſt purpoſes. Could a man be put to death, or have his limbs broken without feeling pain, the human race had long ago been extinct. Felt we no uneaſineſs in a fever, we ſhould be inſenſible of the diſeaſe, and die before we ſuſpected our health to be impaired. The horror which generally accompanies our reflections on death tends to make us more careful of life, and prevents us from quitting this world raſhly when our affairs proſper not according to our fond wiſhes. It is likewiſe an indication that our exiſtence does not terminate in this world; for our dread is ſeldom excited by the proſpect of the pain which we may ſuffer when dying, but by our anxiety concerning what we may be doomed to ſuffer or enjoy in the next ſtage of our exiſtence; and this anxiety tends more perhaps than any thing elſe to make us live while we are here in ſuch a manner as to enſure our happineſs hereafter.

Thus from every view that we can take of the works and laws of God, and even from conſidering the objections which have ſometimes been made to them, we are compelled to acknowledge the benevolence of their Author. We muſt not, however, ſuppoſe the Divine benevolence to be a fond and weak affection like that which is called benevolence among men. All human affections and paſſions originate in our dependence and wants; and it has been doubted whether any of them be at firſt diſintereſted (ſee PASSION): but he to whom exiſtence is eſſential cannot be dependent; he who is the Author of every thing can feel no want. The divine benevolence therefore muſt be wholly diſintereſted, and of courſe free from thoſe partialities originating in ſelf-love, which are alloys in the moſt ſublime of human virtues. The moſt benevolent man on earth, though he wiſhes the happineſs of

Being and attributes of God.

every fellow-creature, has ſtill, from the ties of blood, the endearments of friendſhip, or, perhaps from a regard to his own intereſt, ſome particular favourites whom, on a competition with others, he would certainly prefer. But the equal Lord of all can have no particular favourites. His benevolence is therefore coincident with juſtice; or, to ſpeak more properly, that which is called *divine juſtice*, is only benevolence exerting itſelf in a particular manner for the propagation of general felicity. When God preſcribes laws for regulating the conduct of his intelligent creatures, it is not becauſe he can reap any benefit from their obedience to thoſe laws, but becauſe ſuch obedience is neceſſary to their own happineſs; and when he puniſhes the tranſgreſſor, it is not becauſe in his nature there is any diſpoſition to which the proſpect of ſuch puniſhment can afford gratification, but becauſe in the government of free agents puniſhment is neceſſary to reform the criminal, and to intimidate others from committing the like crimes. But on this ſubject we need not dwell. It has been ſhewn elſewhere (METAPHYSICS, n° 312.), that all the moral attributes of God, his HOLINESS, JUSTICE, MERCY, and TRUTH, ſhould be conceived as the ſame divine BENEVOLENCE, acting in different ways according to different exigencies, but always for the ſame ſublime end—the propagation of the utmoſt poſſible happineſs.

33 The divine benevolence coincident with juſtice.

34 God incomprehenſible,

The ſubſtance or eſſence of this ſelf-exiſtent, all-powerful, infinitely wiſe, and perfectly good being, is to us wholly incomprehenſible. That it is not matter, is ſhewn by the proceſs of argumentation by which we have proved it to exiſt; but what it is we know not, and it would be impious preſumption to inquire. It is ſufficient for all the purpoſes of religion to know that God is ſome how or other preſent to every part of his works; that exiſtence and every poſſible perfection is eſſential to him; and that he wiſhes the happineſs of all his creatures. From theſe truths we might proceed to prove and illuſtrate the perpetual ſuperintendance of his providence, both general and particular, over every the minuteſt part of the univerſe: but that ſubject has been diſcuſſed in a ſeparate article; to which, therefore, we refer the reader. (See PROVIDENCE). We ſhall only obſerve at preſent, that the manner in which animals are propagated affords as complete a proof of the conſtant ſuperintendance of divine power and wiſdom, as it does of the immediate exertion of theſe faculties in the formation of the parent pair of each ſpecies. For were this buſineſs of propagation carried on by *neceſſary* and mechanical laws, it is obvious, that in every age there would be generated, in each ſpecies of animals, the very ſame proportion of males to females that there was in the age preceding. On the other hand, did generation depend upon *fortuitous* mechaniſm, it is not conceivable but that, ſince the beginning of the world, or, according to this hypotheſis, during the courſe of eternity, ſeveral ſpecies of animals ſhould in *ſome* age have generated nothing but *males*, and others nothing but *females*; and that of courſe many ſpecies would have been long ſince extinct. As neither of theſe caſes has ever happened, the preſervation of the various ſpecies of animals, by keeping up conſtantly in the world a due, though not always the ſame, proportion between the ſexes of male and female, is a complete proof of the ſuperintendance of divine providence, and of that ſaying of the apoſtle, that it is "in God we live, move, and have our being."

35 But conſtantly preſent to his works.

SECT. II. *Of the Duties and Sanctions of Natural Religion.*

FROM the ſhort and very inadequate view that we have taken of the divine perfections, it is evidently our duty to reverence in our minds the ſelf-exiſtent Being to whom they belong. This is indeed not only a duty, but a duty of which no man who contemplates theſe perfections, and believes them to be real, can poſſibly avoid the performance. He who thinks irreverently of the Author of nature, can never have conſidered ſeriouſly the power, the wiſdom, and the goodneſs, diſplayed in his works; for whoever has a tolerable notion of theſe muſt be convinced, that he who performed them has no imperfection; that his power can accompliſh every thing, which involves not a contradiction; that his knowledge is intuitive, and free from the poſſibility of error; and that his goodneſs extends to all without partiality and without any alloy of ſelfiſh deſign. This conviction muſt make every man on whoſe mind it is impreſſed ready to proſtrate himſelf in the duſt before the Author of his being; who, though infinitely exalted above him, is the ſource of all his enjoyments, conſtantly watches over him with paternal care, and protects him from numberleſs dangers. The ſenſe of ſo many benefits muſt excite in his mind a ſentiment of the livelieſt gratitude to him from whom they are received, and an ardent wiſh for their continuance.

Duties and ſanctions of natural religion.

36 Reverence and gratitude due to God.

37 Of whom no poſitive idea ſhould be formed.

Whilſt ſilent gratitude and devotion thus glow in the breaſt of the contemplative man, he will be careful not to form even a mental image of that all-perfect Being to whom they are directed. He knows that God is not material; that he exiſts in a manner altogether incomprehenſible; that to frame an image of him would be to aſſign limits to what is infinite; and that to attempt to form a poſitive conception of him would be impiouſly to compare himſelf with his Maker.

38 How he ought to be ſpoken of; and

The man who has any tolerable notion of the perfections of the Supreme Being will never ſpeak lightly of him, or make uſe of his name at all but on great and ſolemn occaſions. He knows that the terms of all languages are inadequate and improper, when applied directly to him who has no equal, and to whom nothing can be compared; and therefore he will employ theſe terms with caution. When he ſpeaks of his mercy and compaſſion, he will not conſider them as feelings wringing the heart like the mercy and compaſſion experienced by man, but as rays of pure and diſintereſted benevolence. When he thinks of the ſtupendous ſyſtem of nature, and hears it, perhaps, ſaid that God formed it for his own glory, he will reflect that God is ſo infinitely exalted above all his creatures, and ſo perfect in himſelf, that he can neither take pleaſure in their applauſe, as great men do in the applauſes of their fellow-creatures, nor receive any acceſſion of any kind from the exiſtence of ten thouſand worlds. The immenſe fabric of nature therefore only diſplays the glory or perfections of its Author to *us* and to other *creatures* who have not faculties to comprehend him in himſelf.

When the contemplative man talks of *ſerving* God, he does not dream that his ſervices can increaſe the divine felicity; but means only that it is his duty to obey the divine laws. Even the pronoun *He*, when it refers to God, cannot be of the ſame import as when it refers to man; and by the philoſophical divine it will ſeldom be uſed but with a mental alluſion to this obvious diſtinction.

39 What is meant by ſerving him.

As the man who duly venerates the Author of his being will not ſpeak of him on trivial occaſions, ſo will he be ſtill further from calling upon him to witneſs impertinences and falſehood, (ſee OATH). He will never mention his name but with a *pauſe*, that he may have time to reflect in ſilence on his numberleſs perfections, and on the immenſe diſtance between himſelf and the Being of whom he is ſpeaking. The ſlighteſt reflection will convince him that the world with all that it contains depends every moment upon

Duties and sanctions of natural religion.

upon that God who formed it; and this conviction will compel him to wish for the divine protection of himself and his friends from all dangers and misfortunes. Such a wish is in effect a prayer, and will always be accompanied with adoration, confession, and thanksgiving (see PRAYER). But adoration, confession, supplication, and thanksgiving, constitute what is called *worship*, and therefore the worship of God is a natural duty. It is the addressing of ourselves as his dependants to him as the supreme cause and governor of the world, with acknowledgments of what we enjoy, and petitions for what we really want, or he knows to be convenient for us. As if, *ex. gr.* I should in some humble and composed manner (says Mr Wollaston) pray to that "Almighty Being, upon whom depends the existence of the world, and by whose providence I have been preserved to this moment, and enjoyed many undeserved advantages, that he would graciously accept my grateful sense and acknowledgments of all his beneficence towards me; that he would deliver me from the evil consequences of all my transgressions and follies; that he would endue me with such dispositions and powers as may carry me innocently and safely through all future trials, and may enable me on all occasions to behave myself conformably to the laws of reason piously and wisely; that He would suffer no being to injure me, no misfortunes to befal me, nor me to hurt myself by any error or misconduct of my own; that he would vouchsafe me clear and distinct perceptions of things; with so much health and prosperity as may be good for me; that I may at least pass my time in peace, with contentment and tranquillity of mind; and that having faithfully discharged my duty to my family and friends, and endeavoured to improve myself in virtuous habits and useful knowledge, I may at last make a decent and happy exit, and find myself in some better state."

40 Divine worship a natural duty.

That an untaught savage would be prompted by *instinct* to address the Supreme Being in such terms as this, we are so far from thinking, that to us it appears not probable that such a savage, in a state of solitude, would be led by instinct to suppose the existence of that Being. But as soon as the being and attributes of God were, by whatever means, made known unto man, every sentiment expressed in this prayer must necessarily have been generated in his mind; for not to be sensible that we derive our existence and all our enjoyments from God, is in effect to deny his being or his providence; and not to feel a wish that he would give us what we want, is to deny either his goodness or his power.

The worship of God therefore is a natural duty resulting from the contemplation of his attributes and a sense of our own dependence. But the reasoning which has led us to this conclusion respects only *private* devotion; for it is a question of much greater difficulty, and far enough from being yet determined, whether *public* worship be a duty of that religion which can with any propriety be termed *natural*. Mr Wollaston indeed positively affirms that it is, and endeavours to prove his position by the following arguments.

41 Whether or not is public worship a duty of natural religion?

42 Arguments for it,

"A man (says he) may be considered as a member of some society: and as *such* he ought to worship God if he has the opportunity of doing it, if there be proper prayers used publicly which he may resort to, and if his health, &c. permit. Or the society may be considered as *one body*, that has common interests and concerns, and *as such* is obliged to worship the Deity, and offer one prayer. Besides, there are many who know not of themselves how to pray; perhaps cannot so much as read. These must be taken *as they are*; and consequently some time and place *appointed* where they may have suitable prayers read to them, and be guided in their devotions. And further, towards the keeping mankind in order, it is *necessary* there should be some religion professed, and even established, which cannot be without public worship. And were it not for that sense of virtue which is *principally* preserved (so far as it is preserved) by national *forms* and *habits* of religion, men would soon lose it *all*, run wild, prey upon one another, and do what else the worst of savages do."

Duties and sanctions of natural religion.

These are in themselves just observations, and would come with great force and propriety from the tongue or pen of a Christian preacher, who is taught by revelation that the Master whom he serves has commanded his followers "not to forsake the assembling of themselves together," and has promised, "that if two of them shall agree on earth as touching any thing that they shall ask, it shall be done for them of his Father who is in heaven." As urged by such a man and on such grounds, they would serve to show the fitness of the divine command, and to point out the benefits which a religious obedience to it might give us reason to expect. But the author is here professing to treat of *natural* religion, and to state the duties which result from the mere relation which subsists between man as a creature and God as his creator and constant preserver. Now, though we readily admit the benefits of public worship as experienced under the Christian dispensation, we do not perceive any thing in this reasoning which could lead a pious theist to expect the same benefit previous to all experience. When the author thought of *national forms* and *establishments of religion*, he certainly lost sight of his proper subject, and, as such writers are too apt to do, comprehended under the religion of nature what belongs only to that which is revealed. Natural religion, in the proper sense of the words, admits of no particular *forms*, and of no *legal establishment*. Private devotion is obviously one of its duties, because sentiments of adoration, confession, supplication, and thanksgiving, necessarily spring up in the breast of every man who has just notions of God and of himself: but it is not so obvious that such notions would induce any body of men to meet at *stated times* for the purpose of expressing their devotional sentiments in public. Mankind are indeed social beings, and naturally communicate their sentiments to each other; but we cannot conceive what should at first have led them to think that public worship at stated times would be acceptable to the self-existent Author of the universe. In case of a famine, or any other calamity in which the whole tribe was equally involved, they might speak of it to each other, inquire into its cause, and in the extremity of their distress join perhaps in one fervent petition, that God would remove it. In the same manner they might be prompted to pour forth occasional ejaculations of public gratitude for public mercies; but it does not follow from these incidental occurrences that they would be led to institute times and places and forms of national worship, as if they believed the omniscient Deity more ready to hear them in public than in private. That the appointment of such times and forms and places is beneficial to society, experience teaches us; and therefore it is the duty, and has been the practice, of the supreme magistrate in every age and in every civilized country to provide for the maintenance of the national worship. But this practice has taken its rise, not from the deductions of reason, but either from direct revelation, as among the Jews and Christians; or from tradition, which had its origin in some early revelation, as among the more enlightened Pagans of ancient and modern times.

43 Borrow'd from revelation.

We hope that none of our readers will be so unjust as to suppose that by this disquisition we mean, in any degree, to call

Duties and sanctions of natural religion.

call in queſtion the fitneſs or the duty of public worſhip. This is ſo far from our intention, that we firmly believe with Mr. Wollaſton, that what piety remains among us is to be attributed in a great meaſure to the practice of frequenting the church on Sundays; and that it is the neglect of this particular duty which has rendered the preſent generation of men leſs pious, leſs humble, and more prone to faction than their fathers were, who made it a point every Lord's day to unite with ſome congregation of Chriſtians in the public worſhip of their Creator and Redeemer. But whilſt we are convinced of the importance and neceſſity of this too much neglected duty, and could wiſh to impreſs our conviction upon the minds of all our readers, we do not apprehend that we leſſen its dignity, or detract from the weight of almoſt univerſal practice, by endeavouring to derive that practice from its true ſource, which appears to us to be not human reaſon, but divine revelation.

44 Its great uſefulneſs

45 The practice of virtue a duty of natural religion.

But whatever doubts may be entertained with reſpect to the origin of public worſhip, there can be none as to the foundation of moral virtue. Reaſon clearly perceives it to be the will of our Maker, that every individual of the human race ſhould treat every other individual as, in ſimilar circumſtances, he could juſtly expect to be treated himſelf. It is thus only that the greateſt ſum of human happineſs can be produced (ſee MORAL PHILOSOPHY, n° 17. and 135.); for were all men temperate, ſober, juſt in their dealings, faithful to their promiſes, and charitable to the poor, &c. it is obvious that no miſeries would be felt upon earth, but the few which, by the laws of corporeal nature, unavoidably reſult from the union of our minds with ſyſtems of matter. But it has been already ſhown, that the deſign of God in forming ſentient beings was to communicate to them ſome portion, or rather ſome reſemblance, of that felicity which is eſſential to himſelf; and therefore every action which in its natural tendency co-operates with this deſign muſt be agreeable to him, as every action of a contrary tendency muſt be diſagreeable.

From this reaſoning it follows undeniably, that we are obliged not only to be juſt and beneficent to one another, but alſo to abſtain from all unneceſſary cruelty to inferior animals. That we have a right to tame cattle, and employ them for the purpoſes of agriculture and other arts where ſtrength is required, is a poſition which we believe has never been controverted. But if it is the intention of God to communicate, in different degrees according to their different ranks, a portion of happineſs to all his creatures endowed with ſenſe, it is obvious that we ſin againſt him when we ſubject even the horſe or the aſs to greater labour than he is able to perform; and this ſin is aggravated when from avarice we give not the animal a ſufficient quantity of food to ſupport him under the exertions which we compel him to make. That it is our duty to defend ourſelves and our property from the ravages of beaſts of prey, and that we may even exterminate ſuch beaſts from the country in which we live, are truths which cannot be queſtioned; but it has been the opinion of men, eminent for wiſdom and learning, that we have no right to kill an ox or a ſheep for *food*, but in conſequence of the divine permiſſion to Noah recorded in the ninth chapter of the book of Geneſis. Whether this opinion be well or ill founded we ſhall not poſitively determine, though the arguments upon which it is made to reſt are of ſuch a nature as the faſhionable reaſoners of the preſent day would perhaps find it no eaſy taſk to anſwer; but it cannot admit of a doubt, that, in killing ſuch animals, we are, in duty to *their* Creator and *ours*, bound to put them to the leaſt poſſible pain. If this be granted, and we do not ſee how it can be denied by any man convinced of the benevolence of the Deity, it is ſtill more evident that we act contrary to the divine will when, for our mere amuſement, we torture and put to death ſuch animals as are confeſſedly not injurious to ourſelves, or to any thing upon which the comforts of life are known to depend. We are indeed far from being convinced with the poet, that inſects and reptiles "in mortal ſufferance feel as when a giant dies," (ſee PLEASURE and PHYSIOLOGY, Sect. viii.); but their feelings on that occaſion are certainly ſuch, as that, when we wantonly inflict them, we thwart, as far as in our power, the benevolent purpoſe of the Creator in giving them life and ſenſe. Let it be obſerved too, that the man who practiſes needleſs cruelty to the brute creation is training up his mind for exerciſing cruelty towards his fellow creatures, to his ſlaves if he have any, and to his ſervants; and by a very quick progreſs to all who may be placed beneath him in the ſcale of ſociety.

46 Cruelty to the inferior animals a ſin.

Such are the plain duties of natural religion; and if they were univerſally practiſed, it is ſelf-evident that they would be productive of the greateſt happineſs which mankind could enjoy in this world, and that piety and virtue would be their own reward. They are however far from being univerſally practiſed; and the conſequence is, that men are frequently raiſed to affluence and power by vice, and ſometimes ſunk into poverty by a rigid adherence to the rules of virtue.

This being the caſe, there can be no queſtion of greater importance, while there are few more difficult to be anſwered, than "What are the ſanctions by which natural religion enforces obedience to her own laws?" It is not to be ſuppoſed that the great body of mankind ſhould, without the proſpect of an ample reward, practiſe virtue in thoſe inſtances in which ſuch practice would be obviouſly attended with injury to themſelves; nor does it appear reaſonable in any man to forego preſent enjoyment, without the well-grounded hope of thereby ſecuring to himſelf a greater or more permanent enjoyment in reverſion. Natural religion therefore, as a ſyſtem of doctrines influencing the conduct, is exceedingly defective, unleſs it affords ſufficient evidence, intelligible to every ordinary capacity, of the immortality of the ſoul, or at leaſt of a future ſtate of rewards and puniſhments. That it *does* afford this evidence, is ſtrenuouſly maintained by ſome deiſts, and by many philoſophers of a different deſcription, who, though they profeſs Chriſtianity, ſeem to have ſome unaccountable dread of being deceived by their bibles in every doctrine which cannot be propped by the additional buttreſs of philoſophical reaſoning.

47 Natural religion defective in its evidence of a future ſtate.

One great argument made uſe of to prove that the immortality of the ſoul is among the doctrines of natural religion, is the univerſal belief of all ages and nations that men continue to live in ſome other ſtate after death has ſeparated their ſouls from their bodies. "Quod ſi *omnium conſenſus naturæ vox eſt:* omneſque, qui ubiqui ſunt, conſentiunt eſſe aliquid, quod ad eos pertineat, qui vita ceſſerint: nobis quoque idem exiſtimandum eſt: et ſi, quorum aut ingenio, aut virtute animus excellit, eos arbitramur, quia natura optima ſunt, cernere naturæ vim maxime: veriſimile eſt, *cum optimus quiſque maxime poſteritati ſerviat*, eſſe aliquid, cujus is poſt mortem ſenſum ſit, habiturus. Sed ut deos eſſe natura opinamur, qualeſque ſint, ratione cognoſcimus, ſic permanere animos arbitramur *conſenſu nationum omnium* *."

48 The general expectation of a future ſtate.

* Cicer. Tuſc. Queſt. lib. i. § 15, 16.

That this is a good argument for the truth of the doctrine, through whatever channel men may have received it, we readily acknowledge; but it appears not to us to be any proof of that doctrine's being the deduction of human reaſoning. The popular belief of Paganiſm, both ancient and modern, is ſo fantaſtic and abſurd, that it could never have been

49 Not the offſpring of nature.

Duties and sanctions of natural religion.

been rationally inferred from what nature teaches of God and the soul. In the Elysium of the Greek and Roman poets, departed spirits were visible to mortal eyes; and must therefore have been clothed with some material vehicle of sufficient density to reflect the rays of light, though not to resist the human touch. In the mythology of the northern nations, as deceased heroes are represented as eating and drinking, they could not be considered as entirely divested of matter; and in every popular creed of idolatry, future rewards were supposed to be conferred, not for private virtue, but for public violence, upon heroes and conquerors and the destroyers of nations. Surely no admirer of what is now called natural religion will pretend that these are part of its doctrines; they are evidently the remains of some primeval tradition obscured and corrupted in its long progress through ages and nations.

50 Opinions of the philosophers respecting a future state.

The philosophers of Greece and Rome, despising the popular mythology of their respective countries, employed much time and great talents in disquisitions concerning the human soul and the probability of a future state; and if the genuine conclusions of natural religion on this subject are anywhere to be found, one would naturally look for them in the writings of those men whose genius and virtues did honour to human nature. Yet it is a fact which cannot be controverted, that the philosophers held such notions concerning the substance of the soul and its state after death as could afford no rational support to suffering virtue, (see METAPHYSICS, Part III. chap. 4). Socrates is indeed an exception. Confining himself to the study of ethics, and despising those metaphysical subtilties with which so many others had bewildered themselves, that excellent person inferred by the common moral arguments (see MORAL PHILOSOPHY, n° 232—246), that the reality of a future state of rewards and punishments is in the highest degree probable. He was not, however, at all times absolutely *convinced* of this important truth; for a little before his death he said to some who were about him, "I am now about to leave this world, and ye are still to continue in it; which of us have the better part allotted us, God only knows*." And again, at the end of his most admired discourse concerning the immortality of the soul, delivered at a time when he must have been serious, he said to his friends who came to pay their last visit, "I would have you to know that I have great hopes that I am now going into the company of good men; yet I would not be too peremptory and confident concerning it §."

* Plato in Apolog. Soc.

§ Plato in Phæd.

Next to Socrates, Cicero was perhaps the most respectable of all the philosophers of antiquity; and he seems to have studied this great question with uncommon care: yet what were his conclusions? After retailing the opinions of various sages of Greece, and showing that some held the soul to be the *heart*; others, the *blood* in the heart; some, the *brain*; others, the *breath*; one, that it was *harmony*; another, that it was *number*; one, that it was *nothing* at all; and another, that it was a certain *quinteſſence* without a name, but which might properly be called εντελεχια—he gravely adds, "Harum sententiarum quæ vera sit, Deus aliquis viderit: quæ verisimillima, magna quæstio est §." He then proceeds to give his own opinion; which, as we have shown elsewhere, was, that the soul is part of God.

§ Tusc. Quest. lib. i § 9, 10, 11.

To us who know by other evidence that the soul is immortal, and that there will be a future state in which all the obliquities of the present shall be made straight, the argument drawn from the moral attributes of God, and the unequal distribution of the good things of this life, appears to have the force of demonstration. Yet none of us will surely pretend to say that his powers of reasoning are greater than were those of Socrates and Cicero: and therefore the probability is, that had we been like them destitute of the light of revelation, we should have been disturbed by the same doubts, and have said with the latter, upon reading the arguments of the former as detailed by Plato, "Nescio quomodo, dum lego, assentior: cum posui librum, et mecum ipse de immortalitate animorum cœpi cogitare, assensio illa elabitur ‡."

Duties and sanctions of natural religion.

51 Without the light of revelation we should have doubted like them.

‡ Ibid.

No one, we hope, will suspect us of an impious attempt to weaken the evidence of a future state, God forbid! The expectation of that state is the only support of virtue and religion; and we think the arguments which we have stated elsewhere, and referred to on the present occasion, make the reality of it so highly probable, that, though there were no other evidence, he would act a very foolish part who should confine his attention wholly to the present life. But we do not apprehend that we can injure the cause either of virtue or of religion, by confessing, that those arguments which left doubts in the minds of Socrates and Cicero appear not to us to have the force of *complete demonstration* of that life and immortality which our Saviour brought to light through the gospel.

52 Natural religion has no means of certainly reconciling the Deity to sinners.

Were the case, however, otherwise; were the arguments which the light of nature affords for the immortality of the human soul as absolutely convincing as any geometrical demonstration—natural religion would still be defective; because it points out no method by which such as have offended God may be certainly restored to his favour, and to the hopes of happiness, which by their sin they had lost. That he who knows whereof we are made would show himself placable to sinners, and that he would find some way to be reconciled, might perhaps be reasonably inferred from the consideration of his benevolence displayed in his works. But when we come to inquire more particularly *how* we are to be reconciled, and whether a *propitiation* will be required, *nature* stops short, and expects with impatience the aid of some particular revelation. That God will receive returning sinners, and accept of repentance instead of perfect obedience, cannot be certainly known by those to whom he has not *declared* that he will. For though repentance be the most probable, and indeed the only means of reconciliation which nature suggests; yet whether he, who is of purer eyes than to behold iniquity, will not require something further before he restore sinners to the privileges which they have forfeited, mere human reason has no way of discovering. From nature therefore arises no sufficient comfort to sinners, but anxious and endless solicitude about the means of appeasing the Deity. Hence those divers ways of sacrificing, and those numberless superstitions which overspread the heathen world, but which were so little satisfactory to the wiser part of mankind, that, even in those days of darkness, the philosophers frequently declared that, in their opinion, those rites and oblations could avail nothing towards appeasing the wrath of an offended God, or making their prayers acceptable to him. Hence Socrates and one of his disciples are represented by Plato† as expecting a person divinely commissioned to inform them whether sacrifices be acceptable to the Deity, and as resolving to offer no more till that person's arrival, which they piously hoped might be at no great distance.

† In Alcibiades.

53 These doubts removed by the Scriptures.

This darkness of the pagan world, which the best of men who lived under it so pathetically deplored, is to us who live under the sunshine of the gospel happily removed by the various revelations contained in the scriptures of the Old and New Testaments. These taken together, and in the order in which they were given, exhibit such a display of providence, such a system of doctrines, and such precepts of practical

Duties and sanctions of natural religion.

practical wiſdom, as the ingenuity of man could never have diſcovered. The Chriſtian, with the ſcriptures in his hands, can regulate his conduct by an infallible guide, and reſt his hopes on the ſureſt foundation. Theſe ſcriptures it is now our buſineſs to examine.

Duties and sanctions of natural religion.

Part II. Of REVEALED THEOLOGY.

54 Many pretences to revelation,

IN every civilized country the popular ſyſtem of theology has claimed its origin from divine revelation. The Pagans of antiquity had their augurs and oracles; the Chineſe have their inſpired teachers Confucius and Fohi; the Hindoos have their ſacred books derived from Brahama; the followers of Mahomet have their koran dictated by an angel; and the Jews and Chriſtians have the ſcriptures of the Old and New Teſtaments, which they believe to have been written by holy men of old, who ſpake and wrote as they were moved by the Holy Ghoſt.

That the claims of ancient Paganiſm to a theology derived from heaven, as well as the ſimilar claims of the Chineſe, Hindoos, and Mahometans, are ill founded, has been ſhown in various articles of this work, (ſee China, Hindostan, Mahometanism, Mythology, and Polytheism); whilſt, under the words Religion, Revelation, and Scripture, we have ſufficiently proved the divine inſpiration of the Jewiſh and Chriſtian ſcriptures, and of courſe the divine origin of Jewiſh and Chriſtian theology. Theſe indeed are not two ſyſtems of theology, but parts of one ſyſtem which was gradually revealed as men were able to receive it; and therefore both ſcriptures muſt be ſtudied by the Chriſtian divine.

55 Though the Jewiſh and Chriſtian revelations are alone true.

There is nothing in the ſacred volume which it is not of importance that he ſhould underſtand whoſe office it is to be a teacher of religion; for the whole proceeds from the fountain of truth: but ſome of its doctrines are much more important than others, as relating immediately to man's everlaſting happineſs; and theſe it has been cuſtomary to arrange and digeſt into regular ſyſtems, called *bodies* or *inſtitutes* of *Chriſtian theology*. Could theſe artificial ſyſtems be formed with perfect impartiality, they would undoubtedly be uſeful, for the bible contains many hiſtorical details, but remotely related to human ſalvation; and even of its moſt important truths, it requires more time and attention than the majority of Chriſtians have to beſtow, to diſcover the mutual connection and dependence.

56 Common diviſions of revealed theology,

Artificial ſyſtems of theology are commonly divided into two great parts, the *theoretic* and the *practical*; and theſe again are ſubdivided into many inferior branches. Under the theoretic part are ſometimes claſſed,

1. *Dogmatic* theology; which comprehends an entire ſyſtem of all the dogmas or tenets which a Chriſtian is bound to believe and profeſs. The truth of theſe the divine muſt clearly perceive, and be able to enforce upon his audience: and hence the neceſſity of ſtudying what is called,

2. The *exegeſis*, or the art of attaining the true ſenſe of the holy ſcriptures; and,

3. *Hermeneutic* theology, or the art of interpreting and explaining the ſcriptures to others; an art of which no man can be ignorant who knows how to attain the true ſenſe of them himſelf.

4. *Polemical* theology, or controverſy; and,

5. *Moral* theology, which is diſtinguiſhed from moral philoſophy, or the ſimple doctrine of ethics, by teaching a much higher degree of moral perfection than the mere light of reaſon could ever have diſcovered, and adding new motives to the practice of virtue.

The practical ſciences of the divine are,

1. *Homiletic*, or *paſtoral* theology; which teaches him to adapt his diſcourſes from the pulpit to the capacity of his hearers, and to purſue the beſt methods of guiding them by his doctrine and example in the way of ſalvation.

2. *Catechetic* theology, or the art of teaching youth and ignorant perſons the principal points of evangelical doctrine, as well with regard to belief as to practice.

3. *Caſuiſtic* theology, or the ſcience which decides on doubtful caſes of moral theology, and that calms the ſcruples of conſcience which ariſe in the Chriſtian's ſoul during his journey through the preſent world.

We have mentioned theſe diviſions and ſubdiviſions of the ſcience of theology, not becauſe we think them important, but merely that our readers may be at no loſs to underſtand the terms when they meet with them in other works. Of ſuch terms we ſhall ourſelves make no uſe, for the greater part of them indicate diſtinctions where there is no difference, and tend only to perplex the ſtudent. As the truths of Chriſtianity are all contained in the ſcriptures of the Old and New Teſtaments, it is obvious that dogmatic theology muſt comprehend the ſpeculative part of that which is called moral, as well as every doctrine about which controverſy can be of importance. But no man can extract a ſingle dogma from the bible but by the practice of what is here called the *exegeſis*; ſo that all the ſubdiviſions of this arrangement of theoretical theology muſt be ſtudied together as they neceſſarily coaleſce into one. The ſame thing is true of the three branches into which practical theology is here divided. He who has acquired the art of adapting his homilies to the various capacities of a mixed audience, will need no new ſtudy to fit him for inſtructing children, and the moſt ignorant perſons who are capable of inſtruction; and the complete maſter of moral theology will find it no very difficult taſk to reſolve all the caſes of conſcience which he can have reaſon to ſuppoſe will ever be ſubmitted to his judgment. For theſe reaſons we ſhall not, in the ſhort ſummary which our limits permit us to give, trouble either ourſelves or our readers with the various diviſions and ſubdiviſions of theology. Our preliminary directions will ſhow them how we think the ſcience ſhould be ſtudied; and all that we have to do as ſyſtem-*builders*, a title of which we are far from being ambitious, is to lay before them the view which the ſcriptures preſent to us of the being and perfections of God, his various diſpenſations to man, and the duties thence incumbent upon Chriſtians. In doing this, we ſhall follow the order of the divine diſpenſations as we find them recorded in the Old and New Teſtaments, dwelling longeſt upon thoſe which appear to us of moſt general importance. But as we take it for granted that every reader of this article will have previouſly read the whole ſacred volume, we ſhall not ſcruple to illuſtrate dogmas contained in the Old Teſtament by texts taken from the New, or to confirm doctrines peculiar to the Chriſtian religion by the teſtimony of Jewiſh prophets.

57 Uſeleſs.

Sect. I. *Of God and his Attributes.*

58 The firſt revelation ſuppoſes the Being of God to be a known truth.

IN every ſyſtem of theology the firſt truths to be believed are thoſe which relate to the being and attributes of God. The Jewiſh lawgiver, therefore, who records the earlieſt revelations that were made to man, begins his hiſtory with a diſplay of the power and wiſdom of God in the creation of the world. He does not inform his country-

men,

God and his attributes.

men, and expect them to believe, upon the authority of his divine commiſſion, that God *exiſts*; for he well knew that the being of God muſt be admitted, and tolerably juſt notions entertained of his attributes, before man can be required to pay any regard to miracles which afford the only evidence of a primary revelation. "In the beginning (ſays he) God created the heavens and the earth." Here the being of God is aſſumed as a truth univerſally received; but the ſentence, ſhort as it is, reveals another which, as we ſhall afterwards ſhew, human reaſon could never have diſcovered.

It will however be proper, before we conſider the creation of the world, and compare what the ſcriptures ſay of it with the opinions of the moſt enlightened ancients on the ſame ſubject, to attend to the appellation which is here given to God; and inquire what light is thrown upon it by ſubſequent revelations. The paſſage in the original is בראשית ברא אלהים, where it is remarkable that the Creator is denominated by a noun in the plural number, ſignifying literally "perſons under the obligation of an oath to perform certain conditions." This is certainly a very extraordinary denomination for the one ſupreme and ſelf-exiſtent Being; and what adds to the ſtrangeneſs of the phraſeology is, that the verb with which this plural noun is made to agree is put in the ſingular number. What now could be the ſacred hiſtorian's motive for expreſſing himſelf in this manner? His ſtyle is in general remarkable for its plainneſs and grammatical accuracy; and we believe it would be difficult to find in all his five books a ſingle phraſe not relating to the Supreme Being in which there appears ſuch a violation of concord.

59 Extraordinary denomination of the Supreme Being in the book of Geneſis

In anſwer to this queſtion, it has been ſaid, that Moſes uſes the plural noun to expreſs in a magnificent way the majeſty of God, juſt as it is cuſtomary for kings and earthly potentates, when publiſhing edicts and laws, to call themſelves *we* and *us*. But there is no evidence on record that ſuch a mode of ſpeaking was introduced among kings at a period ſo early as the era of Moſes. Pharaoh was probably as mighty a potentate as any who then reigned upon the earth; but though he is often mentioned by the ſame ſacred hiſtorian as iſſuing edicts with regal authority, he is nowhere repreſented as ſpeaking of himſelf in the plural number. Let it be obſerved, too, that whenever this phraſeology was introduced among men, the plural noun was in every grammatical tongue joined to a plural verb; whereas Moſes not only puts the noun and the verb in different numbers in the verſe under conſideration, but afterwards repreſents the אלהים as ſaying, "let *us* make man in *our* image;" and, "behold the man is become as *one of us*." Such phraſes as theſe laſt were never uſed by a ſingle man, and therefore cannot have been borrowed from human idioms.

Do they then denote a plurality of gods? No; there is nothing which the ſcriptures more frequently or more earneſtly inculcate than the unity of the divine nature. The texts aſſerting this great and fundamental truth are almoſt numberleſs. "Unto thee (ſays Moſes to his countrymen†) it was ſhewed, that thou mighteſt know that the Lord is God; there is *none elſe beſides him*. Know therefore that the Lord *he is God* in *heaven above* and upon the *earth beneath: there is none elſe*." And again, "Hear, O Iſrael, the Lord our God is *one Lord*," or, as it is expreſſed in the original, "Jehovah our God is one Jehovah," one Being to whom exiſtence is eſſential, who could not have a beginning and cannot have an end. In the prophecies of Iſaiah, God is introduced as repeatedly declaring‡, "I am Jehovah, and there is *none elſe*; there is *no God beſides me*; that they may know from the riſing of the ſun and from the weſt, that there is *none beſides me*: I am *Jehovah*, and there is *none elſe*: Is there a God beſides me? Yea there is *no God*; I know not any." In perfect harmony with theſe declarations of Moſes and the prophets, our Saviour, addreſſing himſelf to his Father, ſays§, "This is life eternal, that they might know *Thee, the only true God*, and Jeſus Chriſt whom Thou haſt ſent;" and St Paul, who derived his doctrine from his divine Maſter, affirms‖, that an idol is nothing in the world; and that there is *none other God but one*."

† Deut. iv. 35. and 39. vi. 4.

‡ Iſaiah xiv. 5, 6, 18, 21. xliv. 8.

§ John xvii.

‖ 1 Cor. viii. 4.

The unity of the divine nature, which, from the order and harmony of the world, appears probable to human reaſon, theſe texts of revelation put beyond a doubt. Hence the firſt precept of the Jewiſh law, and, according to their own writers, the foundation of their whole religion, was, "Thou ſhalt have none other gods before Me." Hence, too, the reaſon of that ſtrict command to Jews and Chriſtians to give divine worſhip to none but God: "Thou ſhalt worſhip the Lord thy God, and him only ſhalt thou ſerve;" becauſe he is *God alone*. Him only muſt we fear, becauſe he alone hath infinite power; in him alone muſt we truſt, becauſe "he only is our rock and our ſalvation;" and to him alone muſt we direct our devotions, becauſe "he only knoweth the hearts of the children of men."

60 Denotes a plurality of perſons in the Godhead.

It is paſt diſpute, then, that the word אלהים does not indicate a plurality of gods. In the opinion, however, of many eminent divines, it denotes, by its junction with the ſingular verb, a plurality of perſons in the one Godhead; and ſome few have contended, that by means of this peculiar conſtruction, the Chriſtian doctrine of the Trinity may be proved from the firſt chapter of the book of Geneſis. To this latter opinion we can by no means give our aſſent. That there are three diſtinct perſons in the one divine nature may be inferred with ſufficient evidence from a multitude of paſſages in the Old and New Teſtaments diligently compared together; but it would perhaps be raſh to reſt the proof of ſo ſublime a myſtery upon any ſingle text of holy ſcripture, and would certainly be ſo to reſt it upon the text in queſtion. That Moſes was acquainted with this doctrine, we, to whom it has been explicitly revealed, may reaſonably conclude from his ſo frequently making a plural name of God to agree with a verb in the ſingular number, but had we not poſſeſſed the brighter light of the New Teſtament to guide us, we ſhould never have thought of drawing ſuch an inference. For ſuppoſing the word אלהים to denote clearly a plurality of perſons, and that it cannot poſſibly ſignify any thing elſe, how could we have known that the number is neither more nor leſs than three, had it not been aſcertained to us by ſubſequent revelations?

There are indeed various paſſages in the Old Teſtament of the phraſeology of which no rational account can be given, but that they indicate more than one perſon in the Godhead. Such are thoſe texts already noticed, "and the Lord God ſaid, let US make man in OUR image, after OUR likeneſs;" and "the Lord God ſaid, behold the man is become like ONE of US." To theſe may be added the following, which are to us perfectly unintelligible upon any other ſuppoſition; "and the Lord God, ſaid, let US go down and there confound their language†." "If I be a *Maſter* (in the Hebrew *adonim*, MASTERS), where is my fear ‡?" "The fear of the Lord (JEHOVAH) is the beginning of wiſdom, and the knowledge of the Holy (in the Hebrew HOLY ONES) is underſtanding‖." "Remember thy Creator (Hebrew, thy CREATORS) in the days of thy youth*." "And now the LORD GOD and his SPIRIT hath ſent me§." "Seek ye out of the book of the LORD and read; for MY mouth it hath commanded, and his SPIRIT it hath gathered them¶."

† Gen. xi. 6, 7.

‡ Mal. i. 6.

‖ Prov. ix. 10.

* Eccl. xii. 1.

§ Iſaiah xlviii. 16.

¶ Iſaiah xxxiv. 16.

That theſe texts imply a plurality of divine perſons, ſeems to us incontrovertible. It has been already obſerved, that when Moſes repreſents God as ſaying, let us

God and his attributes.

make man, the majesty of the plural number had not been adopted by earthly sovereigns; and it is obvious that the Supreme being could not, as has been absurdly supposed, call upon angels to make man; for in different places of scripture* creation is attributed to God alone. Hence it is that Solomon speaks of Creators in the *plural number*, though he means only the one Supreme Being, and exhorts men to remember them in the days of their youth. In the passage first quoted from Isaiah, there is a distinction made between the *Lord God* and his *Spirit;* and in the other, three divine persons are introduced, *viz.* the *Speaker*, the *Lord* and the *Spirit* of the Lord. It does not, however, appear evident from these passages, or from any other that we recollect in the Old Testament, that the persons in Deity are three and no more: but no sober Christian will harbour a doubt but that the precise number was by some means or other made known to the ancient Hebrews; for inquiries leading to it would be naturally suggested by the form in which the high-priest was commanded to bless the people. "The LORD bless thee and keep thee. The LORD make his face to shine upon thee, and be gracious unto thee. The Lord lift up his countenance upon thee, and give thee peace†."

* Job ix. 8. xlv. passim.

†Numb. vi. 24, 25, 26

Of this benediction it has been well observed, that if its three articles be attentively considered, they will be found to agree respectively to the three persons taken in the usual order of the FATHER, the SON, and the HOLY GHOST. The Father is the author of *blessing* and *preservation*. *Grace* and *illumination* are from the Son, by whom we have "the light of the knowledge of the glory of God, in the face of Jesus Christ." *Peace* is the gift of the Spirit, whose name is the *Comforter*, and whose first and best fruit is the work of *peace* (1).

61 A Trinity in unity the doctrine of scripture.

Similar to this benediction, but much more explicit, is the form of Christian baptism; which, to us who live under the sunshine of the gospel, establishes the truth of the doctrine of the Trinity beyond all reasonable ground of dispute. "Go (says our blessed Saviour) and teach all nations, baptizing them in the name of the Father, and of the Son, and of the Holy Ghost." What was it the apostles, in obedience to this command, were to teach all nations? Was it not to turn from their vanities to the living God; to renounce their idols and false gods, and so to be baptized in the name of the Father, and of the Son, and of the Holy Ghost? What now must occur to the Gentile nations upon this occasion, but that, instead of all their deities, to whom they had before bowed down, they were in future to serve, worship, and adore, Father, Son, and Holy Ghost, as the only true and living God? To suppose that GOD and TWO CREATURES are here joined together in the solemn rite by which men were to be admitted into a new religion, which directly condemns all *creature-worship*, would be so extravagantly unreasonable, that we are persuaded such a supposition never was made by any converted Polytheist of antiquity. The nations were to be baptized in the name of three persons, in the *same manner*, and therefore, doubtless, in the *same sense*. It is not said in the name of GOD and his two faithful *servants;* nor in the name of GOD, and CHRIST, and the HOLY GHOST, which might have suggested a thought that *one* only of the three is God; but in the name of the FATHER, and of the SON, and of the HOLY GHOST. Whatever honour, reverence, or regard, is paid to the first person in this solemn rite, the same we cannot but suppose paid to all three. Is he acknowledged as the object of worship? So are the other two likewise. Is he God and Lord over us? So are they. Are we enrolled as subjects, servants, and soldiers, under him? So are we equally under all. Are we hereby regenerated and made the temple of the Father? So are we likewise of the Son and Holy Ghost. "We will come (says our Saviour‡) and make our abode with him."

God and his attributes.

‡ John xiv. 23.

If those who believe the inspiration of the scriptures could require any further proof that the Godhead comprehends a Trinity of persons in one nature, we might urge upon them the apostolical form of benediction; "The grace of our LORD JESUS CHRIST, and the love of GOD, and the communion of the HOLY GHOST, be with you all*." Would St Paul, or any other man of common sense, have in the same sentence, and in the most solemn manner, recommended his Corinthian converts to the love of God, and to the grace and communion of two creatures? We should think it very absurd to recommend a man at once to the favour of a king and a beggar; but how infinitely small is the distance between the greatest earthly potentate and the meanest beggar when compared with that which must for ever subsist between the Almighty Creator of heaven and earth and the most elevated creature?

* 2 Cor. xiii. 14.

62 Difficulties in this doctrine.

But how, it will be asked, can three divine persons be but one and the same God? This is a question which has been often put, but which, we believe, no created being can fully answer. The divine nature and its manner of existence is, to us, wholly incomprehensible; and we might with greater reason attempt to weigh the mountains in a pair of scales, than by our limited faculties to fathom the depths of infinity. The Supreme Being is present in power to every portion of space, and yet it is demonstrable, that in his essence he is not extended (see METAPHYSICS, n° 309, 310). Both these truths, his inextension and omnipresence, are fundamental principles in what is called *natural religion*; and when taken together they form, in the opinion of most people, a mystery as incomprehensible as that of the Trinity in unity. Indeed there is nothing of which it is more difficult for us to form a distinct notion than *unity* simple, and absolutely indivisible; and we are persuaded that such of our readers as have been accustomed to turn their thoughts inwards, and reflect upon the operations of their own minds, will acknowledge the difficulty is not much less to them. Though the Trinity in unity, therefore, were no Christian doctrine, mysteries must still be believed; for they are as inseparable from the religion of nature as from that of revelation; and atheism involves the most incomprehensible of all mysteries, even the beginning of existence without a cause. We must indeed form the best notions that we can of this and of all other mysteries; for if we have no notions whatever of a Trinity in unity, we can neither believe nor

(1) Petrus Alphonsi, an eminent Jew, converted in the beginning of the 12th century, and presented to the font by Alphonsus a king of Spain, wrote a learned treatise against the Jews, wherein he presses them with this scripture, as a plain argument that there are three persons to whom the great and incommunicable name of *Jehovah* is applied. And even the unconverted Jews, according to Bechai, one of their Rabbies, have a tradition, that when the high-priest pronounced this blessing over the people—*elevatione manuum sic digitos composuit, ut* Triada *exprimerent*, "he lifted up his hands, and disposed his fingers into such a form as to express a *Trinity*." All the foundation there is for this in the scripture, is Lev. ix. 22. As for the rest, be it a matter of fact or not, yet if we consider whence it comes, there is something very remarkable in it. See *Observ. Jos. de voiss.* in *Pug. Fid.* p. 400, 556, 557.

God and his attributes

nor disbelieve that doctrine. It is however to be remembered, that all our notions of God are more or less analogical; that they must be expressed in words which, literally interpreted, are applicable only to man; and that propositions understood in this literal sense may involve an apparent contradiction, from which the truth meant to be expressed by them would be seen to be free, had we direct and adequate conceptions of the divine nature. On this account it is to be wished that men treating of the mystery of the holy Trinity, had always expressed themselves in scripture language, and never aimed at being wise beyond what is written; but since they have acted otherwise, we must, in justice to our readers, animadvert upon one or two statements of this doctrine, which we have reason to believe are earnestly contended for by some who consider themselves as the only orthodox.

In the scriptures, the three persons are denominated by the terms FATHER, SON, and HOLY GHOST, or by GOD, the WORD, who is also declared to be God, and the SPIRIT OF GOD. If each be truly God, it is obvious that they must all have the same divine nature, just as every man has the same human nature with every other man; and if there be but ONE GOD, it is equally obvious that they must be of the same individual substance or essence, which no three men can possibly be. In this there is a difficulty; but, as will be seen by and by, there is no contradiction. The very terms FATHER and SON imply such a relation between the two persons so denominated, as that though they are of the same substance, possessed of the same attributes, and equally God, just as a human father and his son are equally men, yet the second must be personally subordinate to the first. In like manner, the HOLY GHOST, who is called the Spirit of God, and is said to *proceed from* the *Father*, and to be *sent* by the *Son*, must be conceived as subordinate to both, much in the same way as a son is subordinate to his parents, tho' possessed of equal or even of superior powers. That this is the true doctrine, appears to us undeniable from the words of our Saviour himself, who, in a prayer addressed to his Father, styles‖ him by way of pre-eminence, "the only true God," as being the fountain or origin of the Godhead from which the Son and the Holy Ghost derive their true divinity. In like manner, St Paul, when opposing the polytheism of the Greeks, says expressly ‡, that "to us there is but one God, THE FATHER, OF whom are all things, and we in, or for, him; and one LORD JESUS CHRIST, BY whom are all things, and we by him."

63 Subordination of the second and third persons.

‖ John xvii. 3.

‡ 1 Cor. viii. 6

That the primitive fathers of the Christian church maintained this subordination of the second and third persons of the blessed Trinity to the first, has been evinced with such complete evidence by bishop Bull, that we do not perceive how any man can read his works and entertain a doubt on the subject. We shall transcribe two quotations from him, and refer the reader for fuller satisfaction to *sect.* 4. of his *Defensio fidei Nicenæ*. The first shall be a passage cited from *Novatian*, or whoever is the author of the book on the Trinity published among the works of Tertullian, in which the learned prelate assures us the sense of all the ancients is expressed. "Quia quid est Filius, non ex se est, quia nec innatus est; sed ex patre est, quia genitus est: sive dum verbum est, sive dum virtue est, sive dum sapientia est, sive dum lux est, sive dum Filius est, et quicquid horum est, non aliunde est quam ex Patre, Patri suo originem suam debens." The next is from Athanasius, who has never been accused of holding low opinions respecting the second person of the holy Trinity. This father, in his fifth discourse against the Arians, says, κατα γαρ τον Ιωαννην εν ταυτη τη αρχη ην ο λογος και ο λογος ην προς τον θεον. Θεος γαρ εστιν η αρχη, και επειδαν εξ αυτης εστι, δια τουτο και θεος ην ο λογος; *according to John, the word was in this first principle, and the word was God. For God is the principle; and because the word is from the principle, therefore the word is God.* Agreeably to this doctrine, the Nicene fathers, in the creed which they published for the use of the universal church, style the only begotten Son, GOD OF GOD θεος εκ θεου.

God and his attributes.

64 Denied by some modern divines, but

Regardless however of antiquity, and as we think, of the plain sense of scripture, some modern divines of great learning contend, that the three persons in Deity are all *consubstantial*, *co-eternal*, *co-ordinate*, without *derivation*, *subordination*, or *dependence*, of *any sort*, as to nature or essence; whilst others affirm, that the second and third persons derive from the first their personality, but not their nature. We shall consider these opinions as different, though, from the obscurity of the language in which we have always seen them expressed, we cannot be certain but they may be one and the same. The maintainers of the former opinion hold, that the three persons called *Elohim* in the Old Testament, naturally independent on each other, entered into an agreement before the creation of the world, that one of them should in the fulness of time assume human nature, for the purpose of redeeming mankind from that misery into which it was foreseen that they would fall. This antemundane agreement, they add, constitutes the whole of that paternal and filial relation which subsists between the first and second persons whom we denominate Father and Son; and they hold, that the Son is said to be begotten before all worlds, to indicate that *He* who was before all worlds was *begotten*, or to *be* begotten, into the office of redeemer; or, more decisively, to signify that he undertook that office before the creation, and *assumed* to himself some appearance or figure of the reality in which he was to execute it; and he is called μονογενης or the only begotten, because he *alone* was begotten into the office of redeemer*.

*See Ridgeley's Body of divinity,

65 The express doctrine of scripture.

† John iv 9.

To many of our readers we doubt not but this will appear a very extraordinary doctrine, and not easy to be reconciled with the unity of God. It is however sufficiently overturned by two sentences of holy scripture, about the meaning of which there can be no dispute. "In this (says St John †) was manifested the love of God towards us, because that God sent his only begotten Son into the world, that we might live through him." Taking the word *son* in its usual acceptation, this was certainly a wonderful degree of love in the Father of mercies to send into the world on our account a person so nearly related to him as an only son; but if we substitute this novel interpretation of the words *only begotten son* in their stead, the apostle's reasoning will lose all its force. St John will then be made to say, "In this was manifested the love of God toward us, because that God sent a divine person equal to himself, and no way related to him, but who had before the creation covenanted to come into the world, that we might live through him." Is this a proof of the love of the person here called God? Again, the inspired author of the epistle to the Hebrews, treating of our Saviour's priesthood, says, among other things expressive of his humiliation, that "though he was a son, yet learned he obedience (or, as others would render the words εμαθεν υπακοην, he taught obedience) by the things which he suffered ‡." If the word *son* be here understood in its proper sense, this verse displays in a very striking manner the condescension of our divine Redeemer, who, though he was no less a person than the proper Son of God by nature, yet vouchsafed to learn or teach us obedience by the things which he suffered; but if we substitute this metaphorical sonship in place of the natural, the reasoning of the author (for that he is reasoning cannot be denied) will be very extraordinary. "Though this divine personage agreed before all words to suffer death for the redemption of man, yet learned he obedience, or yet taught

‡ Heb. v. 8.

God and his attributes.

he us obedience, by the things which he ſuffered." What ſenſe is there in this argument? Is it a proof of condeſcenſion to fulfil one's engagement? Surely, if the meaning of the word *ſon*, when applied to the ſecond perſon of the bleſſed Trinity, were what is here ſuppoſed, the inſpired writer's argument would have been more to the purpoſe for which it is brought had it run thus; "Though he was *not* a ſon, *i. e.* though he had made no previous agreement, yet condeſcended he to learn or teach," &c.

The other opinion, which ſuppoſes the Son and the Holy Ghoſt to derive from the Father their perſonality, but not their nature, is to us wholly unintelligible; for perſonality cannot exiſt, or be conceived in a ſtate of ſeparation from all natures, any more than a quality can exiſt in a ſtate of ſeparation from all ſubſtances. The former of theſe opinions we are unable to reconcile with the unity of God; the latter is clothed in words that have no meaning. Both, as far as we can underſtand them, are palpable polytheiſm; more palpable indeed than that of the Grecian philoſophers, who though they worſhipped gods many, and lords many, yet all held one God ſupreme over the reſt. See POLYTHEISM, n° 32.

66 The ſecond and third perſons not poſterior to the firſt.

But if the Son and the Holy Ghoſt derive their nature as well as their perſonality from the Father, will it not follow that they muſt be poſterior to him in time, ſince every effect is poſterior to its cauſe? No; this conſequence ſeems to follow only by reaſoning too cloſely from one nature to another, when there is between the two but a very diſtant analogy. It is indeed true, that among men, every father muſt be prior in time as well as in the order of nature to his ſon; but were it eſſential to a man to be a father, ſo as that he could not exiſt otherwiſe than in that relation, it is obvious that his ſon would be coeval with himſelf, though ſtill as proceeding from him, he would be poſterior in the order of nature. This is the caſe with all neceſſary cauſes and effects. The viſible ſun is the immediate and neceſſary cauſe of light and heat, either as emitting the rays from his own ſubſtance, or as exciting the agency of a fluid diffuſed for that purpoſe through the whole ſyſtem. Light and heat therefore muſt be as old as the ſun; and had he exiſted from all eternity, they would have exiſted from eternity with him, though ſtill, as his effects, they would have been behind him in the order of nature. Hence it is, that as we muſt ſpeak analogically of the Divine nature, and when treating of mind, even the Supreme mind, make uſe of words literally applicable only to the modifications of matter, the Nicene fathers illuſtrate the eternal generation of the ſecond perſon of the bleſſed Trinity by this proceſſion of light from the corporeal ſun, calling him *God of God, light of light.*

Another compariſon has been made uſe of to enable us to form ſome notion, however inadequate, how three Divine perſons can ſubſiſt in the ſame ſubſtance, and thereby conſtitute but one God. Moſes informs us, that man was made after the image of God. That this relates to the ſoul more than to the body of man, has been granted by all but a few groſs anthropomorphites; but it has been well obſerved §, that the ſoul, though in itſelf one indiviſible and unextended ſubſtance, is conceived as conſiſting of three principal faculties, the *underſtanding*, the *memory*, and the *will*. Of theſe, though they are all coeval in time, and equally eſſential to a rational ſoul, the underſtanding is in the order of nature obviouſly the firſt, and the memory the ſecond; for things muſt be perceived before they can be remembered; and they muſt be remembered and compared together before they can excite volitions, from being, ſome agreeable, and others diſagreeable. The memory therefore may be ſaid to ſpring from the underſtanding, and the will from both; and as theſe three faculties are conceived to conſtitute one ſoul, ſo may three Divine perſons partaking of the ſame individual nature or eſſence conſtitute one God.

§ Leſlie's Socinian Controverſy.

God and his attributes.

67 No contradiction in the Catholic doctrine of the Trinity.

Theſe parallels or analogies are by no means brought forward as proofs of the Trinity, of which the evidence is to be gathered wholly from the word of God; but they ſerve perhaps to help our labouring minds to form the juſteſt notions of that adorable myſtery which it is poſſible for us to form in the preſent ſtate of our exiſtence; and they ſeem to reſcue the doctrine ſufficiently from the charge of contradiction, which has been ſo often urged againſt it by Unitarian writers. To the laſt analogy we are aware it has often been objected, that the ſoul may as well be ſaid to conſiſt of ten or twenty faculties as of three, ſince the paſſions are equally eſſential to it with the underſtanding, the memory, and the will, and are as different from one another as theſe three faculties are. This, however, is probably a miſtake; for the beſt philoſophy ſeems to teach us, that the paſſions are not innate; that a man might exiſt through a long life a ſtranger to many of them; and that there are probably no two minds in which are generated *all* the paſſions (ſee PASSION); but underſtanding, memory, and will, are abſolutely and equally neceſſary to every rational being. But whatever be in this, if the human mind can be *conceived* to be one indiviſible ſubſtance, conſiſting of different faculties, whether many or few, why ſhould it be thought an impoſſibility for the infinite, and eternal nature of God to be communicated to three perſons acting different parts in the creation and government of the world, and in the great ſcheme of man's redemption.

68 Objections.

To the doctrine of the Trinity many objections have been made, as it implies the divinity of the Son and the Holy Ghoſt; of whom the former aſſumed our nature, and in it died for the redemption of man. Theſe we ſhall notice when we come to examine the revelations more peculiarly Chriſtian; but there is one objection which, as it reſpects the doctrine in general, may be properly noticed here. It is ſaid that the firſt Chriſtians borrowed the notion of a Tri-une God from the later Platoniſts; and that we hear not of a Trinity in the church till converts were made from the ſchool of Alexandria. But if this be the caſe, we may properly aſk, whence had thoſe Platoniſts the doctrine themſelves? It is not ſurely ſo ſimple or ſo obvious as to be likely to have occurred to the reaſoning mind of a Pagan philoſopher; or if it be, why do Unitarians ſuppoſe it to involve a contradiction? Plato indeed taught a doctrine in ſome reſpects ſimilar to that of the Chriſtian Trinity, and ſo did Pythagoras, with many other philoſophers of Greece and the Eaſt (ſee PLATONISM, POLYTHEISM, and PYTHAGORAS); but tho' theſe ſages appear to have been on ſome occaſions extremely credulous, and on others to have indulged themſelves in the moſt myſterious ſpeculations, there is no room to ſuppoſe that they were *naturally weaker men* than ourſelves, or that they were capable of inculcating as truths what they *perceived* to involve a *contradiction*. The Platonic and Pythagorean Trinities never could have occurred to the mind of him who merely from the works of creation endeavoured the diſcover the being and attributes of the Creator; and therefore as thoſe philoſophers travelled into Egypt and the Eaſt in queſt of knowledge, it appears to us in the higheſt degree probable, that they picked up this myſterious and ſublime doctrine in thoſe regions where it had been handed down as a dogma from the remoteſt ages, and where we know that ſcience was not taught ſyſtematically, but detailed in collections of ſententious maxims and traditionary opinions. If this be ſo, we cannot doubt but that the Pagan Trinities had their origin in ſome primœval

96 Anſwered.

reve-

God and his attributes.

revelation. Nothing elſe indeed can account for the general prevalence of a doctrine ſo remote from human imagination, and of which we find veſtiges in the ſacred books of almoſt every civilized people of antiquity. The corrupt ſtate in which it is viewed in the writings of Plato and others, is the natural conſequence of its deſcent through a long courſe of oral tradition; and then falling into the hands of men who bent every opinion as much as poſſible to a conformity with their own ſpeculations. The Trinity of Platoniſm therefore, inſtead of being an objection, lends, in our opinion, no feeble ſupport to the Chriſtian doctrine, ſince it affords almoſt a complete proof of that doctrine's having made part of the firſt revelations communicated to man.

Having thus diſcovered that the one God, to whom Moſes gives the plural name *Elohim*, comprehends three perſons; let us now inquire what power this Tri-une God exerted, when, as the ſame ſacred writer informs us, he created the heaven and the earth. That by the heaven and the earth is here meant the whole univerſe, viſible and inviſible, is known to every perſon acquainted with the phraſeology of Scripture; and we need inform no man converſant with Engliſh writers, that by *creation*, in its proper ſenſe, is meant bringing into *being*, or making that to *exiſt* which exiſted not *before*. It muſt, however, be acknowledged, that the Hebrew word ברא does not always imply the production of ſubſtance, but very often the forming of particular organized bodies out of pre-exiſting matter. Thus when it is ſaid * that God *created* great whales, and every living creature that moveth, which the waters brought forth abundantly after their kind," and again, that "he *created* man male and female;" though the word ברא is uſed on both occaſions, we are not to conceive that the bodies of the firſt human pair, and of theſe animals, were brought into being from nonentity, but only that they were formed by a proper organization being given to pre-exiſtent matter. But when Moſes ſays, "In the beginning God *created* the heaven and the earth," he cannot be ſuppoſed to mean that "in the beginning God only gave form to matter already exiſting of itſelf;" for in the very next verſe we are aſſured that after this act of creation was over, "the earth was ſtill *without form* and void," or, in other words, in a chaotic ſtate.

* Gen. i. 21, 27.

70 Creation taught by Moſes.

That the Jews, before the coming of our Saviour, underſtood their lawgiver to teach a proper creation, is plain from that paſſage in the ſecond book of the Maccabees, in which a mother, to perſuade her ſon to ſuffer the cruelleſt tortures rather than forſake the law of his God, uſes the following argument: "I beſeech thee, my ſon, look upon the heaven and the earth, and all that is therein, and conſider that God made them of things that were not." To the ſame purpoſe the inſpired author of the epiſtle to the Hebrews, when magnifying the excellence of faith, ſays, "Through faith we underſtand that the worlds were framed by the word of God, ſo that things which are ſeen were not made of things which do appear?" where, as biſhop Pearſon has ably proved ‖, the phraſe μη εκφαινόμενω is equivalent to ουκ εξ οντων, in the quotation from the Maccabees.

‖ Expoſition of the creed.

The very firſt verſe therefore of the book of Geneſis informs us of a moſt important truth, which all the uninſpired wiſdom of antiquity could not diſcover. It aſſures us, that as nothing exiſts by chance, ſo nothing is neceſſarily exiſting but the three divine perſons in the one Godhead. Every thing elſe, whether material or immaterial, derives its ſubſtance, as well as its form or qualities, from the fiat of that ſelf-exiſtent Being, "who was, and is, and is to come."

It does not, however, follow from this verſe, or from any other paſſage in the ſacred Scriptures, that the whole univerſe was called into exiſtence at the ſame inſtant; neither is it by any means evident that the chaos of our world was brought into being on the firſt of thoſe ſix days during which it was gradually reduced into form. From a paſſage ‡ in the book of Job, in which we are told by God himſelf, that when the "foundation of the earth was laid the morning ſtars ſang together, and all the ſons of God ſhouted for joy," it appears extremely probable that worlds had been created, formed, and inhabited, long before our earth had any exiſtence. Nor is this opinion at all contrary to what Moſes ſays of the creation of the ſtars; for though they are mentioned in the ſame verſe with the ſun and moon, yet the manner in which, according to the original, they are introduced, by no means indicates that all the ſtars were formed at the ſame time with the luminaries of our ſyſtem. Moſt of them may have been created long before, and ſome of them ſince, our world was brought into being; for that clauſe (verſe 16.) "he made the ſtars alſo," is in the Hebrew no more than "and the ſtars;" the words *he made* being inſerted by the tranſlators. The whole verſe therefore ought to be rendered thus, "and God made two great lights; the greater light to rule the day, and the leſſer light with the ſtars to rule the night;" where nothing is intimated with reſpect to the *time* when the ſtars were formed, any more than in that verſe of the Pſalms ‖, which exhorts us to give thanks to God who made the moon and ſtars to rule by night; for his mercy endureth "for ever." The firſt verſe of the book of Geneſis informs us, that all things ſpiritual and corporeal derive their exiſtence from God; but it is nowhere ſaid that all matter was created at the ſame time; and the generations of men afford ſufficient evidence of a ſucceſſive and continual creation of ſpirits.

God and his attributes.

71 The whole univerſe not created at once.

‡ xxxviii. 7.

‖ Pſalms cxxxvi. 9

That the whole corporeal univerſe *may have been* created at once muſt be granted; but if ſo, we have reaſon to believe that this earth, with the ſun and all the planets of the ſyſtem, were ſuffered to remain for ages in a ſtate of chaos, "without form and void;" becauſe it appears from other ſcriptures, that worlds of intelligent creatures exiſted, and even that ſome angels had fallen from a ſtate of happineſs prior to the era of the Moſaic coſmogony. That the ſun and the other planets revolving round him were formed at the ſame time with the earth, cannot indeed be queſtioned; for it is not only extremely probable in itſelf from the known laws of nature, but is expreſsly affirmed by the ſacred hiſtorian, who relates the formation of the ſun and moon in the order in which it took place. Into the particulars of his narrative we have no occaſion to enter, as it is ſufficiently explained and vindicated in other articles of this work (ſee CREATION and EARTH); but there is one difficulty which, though we have given the common ſolutions of it elſewhere, we may again notice in this place, becauſe it has furniſhed infidel ignorance with ſomething like an objection to the divine legation of the Hebrew lawgiver.

72 The ſolar ſyſtem created at once.

Moſes informs us, that on the *firſt day* after the production of the chaos, the *element of light* was created; and yet within a few ſentences he declares, that the ſun, the fountain of light, was not made till the *fourth day*. How are theſe two paſſages to be reconciled? We anſwer, That they may be reconciled many ways. Moſes wrote for the uſe of a whole people, and not for the amuſement or inſtruction of a few aſtronomers; and in this view his language is ſufficiently proper, even though we ſuppoſe the formation of the ſun and the other planets to have been carried on at the ſame time, and in the ſame progreſſive manner, with the formation of this earth. The voice which called light into exiſtence would ſeparate the fiery and luminous particles of the

73 A difficulty ſolved.

God and his attributes.

the chaos from thoſe which were opake, and, on this hypotheſis, conſolidate them in one globe, diffuſing an obſcure light through the planetary ſyſtem; but if the earth's atmoſphere continued till the fourth day loaded with vapours, as from the narrative of Moſes it appears to have done, the ſun could not till *that day* have been *ſeen* from the earth, and may therefore, in popular language, be ſaid with ſufficient propriety to have been *formed* on the fourth day, as it was then firſt made to *appear*. (See CREATION, n° 13. and EARTH, n° 108, 174, 175). But though this ſolution of the difficulty ſerves to remove the infidel objection, and to ſecure the credit of the ſacred hiſtorian, candour compels us to confeſs that it appears not to be the true ſolution.

The difficulty itſelf ariſes entirely from ſuppoſing the ſun to be the ſole fountain of light; but the truth of this opinion is not ſelf-evident, nor has it ever been eſtabliſhed by ſatisfactory proof. It is indeed to a mind diveſted of undue deference to great names, and conſidering the matter with impartiality, an opinion extremely improbable. The light of a candle placed upon an eminence may in a dark night be ſeen in every direction at the diſtance of at leaſt three miles. But if this ſmall body be rendered viſible by means of rays emitted from itſelf, the flame of a candle, which cannot be ſuppoſed more than an inch in diameter, muſt, during every inſtant that it continues to burn, throw from its own ſubſtance luminous matter ſufficient to fill a ſpherical ſpace of ſix miles in diameter. This phenomenon, if real, is certainly ſurpriſing; but if we purſue the reflection a little farther, our wonder will be greatly increaſed. The matter which, when converted into flame, is an inch in diameter, is not, when of the conſiſtence of cotton and tallow, of the dimenſions of the 20th part of an inch; and therefore, upon the common hypotheſis, the 20th part of an inch of tallow may be ſo rareſied as to fill a ſpace of 113,0976 cubic miles! a rarefaction which to us appears altogether incredible. We have indeed heard much of the diviſibility of matter *ad infinitum*, and think we underſtand what are uſually called *demonſtrations* of the truth of that propoſition; but theſe demonſtrations prove not the actual diviſibility of real ſolid ſubſtances, but only that upon trial we ſhall find no end of the ideal proceſs of dividing and ſubdividing imaginary extenſion.

Upon the whole, therefore, we are much more inclined to believe that the matter of light is an extremely ſubtile fluid, diffuſed through the corporeal univerſe, and only excited to agency by the ſun and other fiery bodies, than that it conſiſts of ſtreams continually iſſuing from the ſubſtance of theſe bodies. It is indeed an opinion pretty generally received, and certainly not improbable in itſelf, that light and electricity are one and the ſame ſubſtance (ſee *ELECTRICITY Index*); but we know that the electrical fluid, though pervading the whole of corporeal nature, and, as experiments ſhow, capable of acting with great violence, yet lies dormant and unperceived till its agency be excited by ſome foreign cauſe. Juſt ſo it may be with the matter of light. That ſubſtance may be "diffuſed from one end of the creation § to the other, it may traverſe the whole univerſe, form a communication between the moſt remote ſpheres, penetrate into the inmoſt receſſes of the earth, and only wait to be put in a proper motion to communicate viſible ſenſations to the eye. Light is to the organ of ſight what the air is to the organ of hearing. Air is the medium which, vibrating on the ear, cauſes the ſenſation of ſound; but it equally exiſts round us at all times, though there be no ſonorous body to put it in motion. In like manner, light may be equally extended at all times, by night as well as by day, from the moſt diſtant fixed ſtars to this earth, tho' it then only ſtrikes our eyes ſo as to excite viſible ſenſations when impelled by the ſun or ſome other maſs of fire." Nor let any one imagine that this hypotheſis interferes with any of the known laws of optics; for if the rays of light be impelled in ſtraight lines, and in the ſame direction in which they are ſuppoſed to be emitted, the phenomena of viſion muſt neceſſarily be the ſame.

§ Nature diſplayed.

God and his attributes.

74 Moſes a found philoſopher.

Moſes therefore was probably a more accurate philoſopher than he is ſometimes ſuppoſed to be. The element of light was doubtleſs created, as he informs us, on the firſt day; but whether it was then put in that ſtate in which it is the medium of viſion, we cannot know, and we need not inquire, ſince there was neither man nor inferior animal with organs fitted to receive its impreſſions. For the firſt three days it may have been uſed only as a powerful inſtrument to reduce into order the jarring chaos. Or if it was from the beginning capable of communicating viſible ſenſations, and dividing the day from the night, its agency muſt have been immediately excited by the Divine power till the fourth day, when the ſun was formed, and endowed with proper qualities for inſtrumentally diſcharging that office. This was indeed miraculous, as being contrary to the preſent laws of nature: but the whole creation was miraculous: and we ſurely need not heſitate to admit a leſs miracle where we are under the neceſſity of admitting a greater. The power which called light and all other things into exiſtence, could give them their proper motions by ten thouſand different means; and to attempt to ſolve the difficulties of creation by philoſophic theories reſpecting the laws of nature, is to trifle with the common ſenſe as well as the piety of mankind: it is to conſider as ſubſervient to a law that very power by whoſe continued exertion the law is eſtabliſhed.

Having thus proved that the univerſe derives its being, as well as the form and adjuſtment of its ſeveral parts, from the one ſupreme and ſelf-exiſtent God, let us here pauſe, and reflect on the ſublime conceptions which ſuch aſtoniſhing works are fitted to give us of the Divine perfections.

75 Infinite power of the Creator.

And, in the firſt place, how ſtrongly do the works of creation impreſs upon our minds a conviction of the infinite power of their Author? He ſpoke, and the univerſe ſtarted into being; he commanded, and it ſtood faſt. How mighty is the arm which "ſtretched out the heavens and laid the foundations of the earth; which removeth the mountains, and they know it not; which overturneth them in his anger; which ſhaketh the earth out of her place, and the pillars thereof tremble! How powerful the word which commandeth the ſun, and it riſeth not; and which ſealeth up the ſtars;" which ſuſtaineth numberleſs worlds of amazing bulk ſuſpended in the regions of empty ſpace, and directs their various and inconceivably rapid motions with the utmoſt regularity! "Lift up your eyes on high, and behold, who hath created all theſe things? By the word of the Lord were the heavens made, and all the hoſt of them by the breath of his mouth. Hell is naked before him, and deſtruction hath no covering. He ſtretcheth out the North over the empty place, and hangeth the earth upon nothing. He has meaſured the waters in the hollow of his hand, and meted out the heavens with a ſpan; and comprehended the duſt of the earth in a meaſure; and weighed the mountains in ſcales, and the hills in a balance. Behold! the nations are as a drop of the bucket, and are counted as the ſmall duſt of the balance; behold, he taketh up the iſles as a very little thing. All nations before him are as nothing, and they are counted to him leſs than nothing, and vanity. To whom then will ye liken God, or what likeneſs will ye compare unto him ‖?"

‖ Pſ. xxxiii. 6, 9.; Job ix. 4, &c. xxvi 6. Iſa. xi. 12.

As the works of creation are the effects of God's power, they likewiſe in the moſt eminent manner diſplay his wiſdom. This was ſo apparent to Cicero, even from the partial

76 His wiſdom.

God and his attributes.

§ De Nat. Deorum, lib. II.

partial and very imperfect knowledge in aſtronomy which his time afforded, that he declared § thoſe who could aſſert the contrary void of all underſtanding. But if that great maſter of reaſon had been acquainted with the modern diſcoveries in aſtronomy, which exhibit numberleſs worlds ſcattered through ſpace, and each of immenſe magnitude; had he known that the ſun is placed in the centre of our ſyſtem, and that to diverſify the ſeaſons the planets move round him with exquiſite regularity; could he have conceived that the diſtinction between light and darkneſs is produced by the diurnal rotation of the earth on its own axis, inſtead of that diſproportionate whirling of the whole heavens which the ancient aſtronomers were forced to ſuppoſe; had he known of the wonderful motions of the comets, and conſidered how ſuch excentric bodies have been preſerved from falling upon ſome of the planets in the ſame ſyſtem, and the ſeveral ſyſtems from falling upon each other; had he taken into the account that there are yet greater things than theſe, and "that we have ſeen but a few of God's works;"—that virtuous Pagan would have been ready to exclaim in the words of the Pſalmiſt, "O Lord, how manifold are thy works! In wiſdom haſt thou made them all; the earth is full of thy riches."

77 And goodneſs.

That creation is the offſpring of unmixed goodneſs, has been already ſhown with ſufficient evidence (ſee METAPHYSICS, n° 312, and n° 29, of this article); and from the vaſt number of creatures on our earth endowed with life and ſenſe, and a capability of happineſs, and the infinitely greater number which probably inhabit the planets of this and other ſyſtems, we may infer that the goodneſs of God is as boundleſs as his power, and that "as is his majeſty, ſo is his mercy." Out of his own fulneſs hath he brought into being numberleſs worlds repleniſhed with myriads of myriads of creatures, furniſhed with various powers and organs, capacities and inſtincts; and out of his own fulneſs he continually and plentifully ſupplies them all with every thing neceſſary to make their exiſtence comfortable. "The eyes of all wait upon him, and he giveth them their meat in due ſeaſon. He openeth his hand and ſatisfies the deſires of every living thing: he loveth righteouſneſs and judgment; the earth is full of the goodneſs of the Lord. He watereth the ridges thereof abundantly; he ſettleth the furrows thereof; he maketh it ſoft with ſhowers, and bleſſeth the ſpringing thereof. He crowneth the year with his goodneſs; and his paths drop fatneſs. They drop upon the paſtures of the wilderneſs; and the little hills rejoice on every ſide. The paſtures are clothed with flocks; the valleys alſo are covered with corn; they ſhout with joy, they alſo ſing."* Survey the whole of what may be ſeen on and about this terraqueous globe, and ſay if our Maker hath a ſparing and a niggardly hand. Surely the Author of ſo much happineſs muſt be eſſential goodneſs; and we muſt conclude with St John, that "God is love."

* Pſal. cxlv. 15, 16. xxiii. 5. lv. 10, &c.

78 The ſecond perſon in the Trinity the immediate Creator.

Theſe attributes of power, wiſdom, and goodneſs, ſo conſpicuouſly diſplayed in the works of creation, belong in the ſame ſupreme degree to each perſon in the bleſſed Trinity; for Moſes declares that the heaven and the earth were created, not by *one* perſon, but by the *Elohim*. The λογος indeed, or ſecond perſon, appears to have been the *immediate* Creator; for St John aſſures us,‖ that "all things were made by him, and that without him was not any thing made that was made." Some Arian writers of great learning (and we believe the late Dr Price was of the number) have aſſerted, that a being who was created himſelf may be endowed by the Omnipotent God with the power of creating other beings; and as they hold the λογος or *word* to be a creature, they contend that he was employed by the Supreme Deity to create, not the whole univerſe, but only this earth, or at the utmoſt the ſolar ſyſtem. "The old argument (ſays one of them), that no being inferior to the great Omnipotent can create a world, is ſo childiſh as to deſerve no anſwer. Why may not God communicate the power of making worlds to any being whom he may chooſe to honour with ſo glorious a prerogative? I have no doubt but ſuch a power may be communicated to many good men during the progreſs of their exiſtence; and to ſay that it may *not*, is not only to limit the power of God, but to contradict acknowledged analogies."

‖ Ch. i. 3.

God and his attributes.

79 Creation peculiar to God.

We are far from being inclined to limit the power of God. He can certainly do whatever involves not a direct contradiction; and therefore, though we know nothing *analogous* to the power of *creating worlds*, yet as we perceive not any contradiction implied in the notion of that power being communicated, we ſhall admit that ſuch a communication may be *poſſible*, though we think it in the higheſt degree *improbable*. But ſurely no man will contend that the *whole univerſe* was brought into exiſtence by *any creature;* becauſe that creature himſelf, however highly exalted, is neceſſarily comprehended in the notion of the univerſe. Now St Paul expreſsly affirms,§ that, by the ſecond perſon in the bleſſed Trinity, "were ALL *things* created that are in heaven, and that are in earth, *viſible* and *inviſible*, whether they be THRONES, or DOMINIONS, or PRINCIPALITIES, or POWERS; all things were created by him and for him; and he is before all things, and by him all things conſiſt." Indeed the Hebrew Scriptures in more places than one† expreſsly declare that this earth and of courſe the whole ſolar ſyſtem, was *formed* as well as *created*, not by any inferior being, but by the *true* God, even *Jehovah* alone; and in the New Teſtament*, the Gentiles are ſaid to be without excuſe for not glorifying him as God, "becauſe his eternal power and Godhead are clearly ſeen from the creation of the world." But if it were natural to ſuppoſe that the power of creating worlds has been, or ever will be, communicated to beings inferior to the great Omnipotent, this reaſoning of the apoſtle's would be founded on falſe principles, and the ſentence which he paſſed on the Heathen would be contrary to juſtice.

§ Coloſ. iv. 17.

† Iſai. xl. 12. xliv. 24. Jerem. x. 10—13.

* Rom. i. 18—22.

But though it be thus evident that the λογος was the immediate Creator of the univerſe, we are not to ſuppoſe that it was without the concurrence of the other two perſons. The Father, who may be ſaid to be the fountain of the Divinity itſelf, was certainly concerned in the creation of the world, and is therefore in the apoſtle's creed denominated the "Father Almighty, Maker of heaven and earth;" and that the Holy Ghoſt or third perſon is likewiſe a Creator, we have the expreſs teſtimony of two inſpired writers: "By the word of the Lord (ſays the Pſalmiſt) were the heavens made, and all the hoſt of them by the breath (Hebrew SPIRIT) of his mouth." And Job declares that the "SPIRIT of God made him, and that the breath of the Almighty gave him life." Indeed theſe three divine perſons are ſo intimately united, that what is done by one muſt be done by all, as they have but one and the ſame will. This is the reaſon aſſigned by Origen* for our paying divine worſhip to each; θρησκευομεν ουν τον πατερα της αληθειας και τον υιον την αληθειαν, οντα δυο τη υποστασει πραγματα, εν δε τη ομονοια, και τη συμφωνια και τη ταυτοτητι της βουλησεως, "we worſhip the Father of truth, and the Son the truth itſelf, being two things as to Hypoſtaſis, but one in agreement, conſent, and ſameneſs of will." Nor is their union a mere agreement in will only; it is a phyſical or eſſential union: ſo that what is done by one muſt neceſſarily be done by the others alſo, according to that of our Saviour, "I am in the Father and the Father in me: The Father who dwelleth in me, he doth the works."

* Contr. Celſ. p. 386.

Thus

Original state of man.

Thus we ſee, that to the ſeveral perſons in the ever bleſſed Trinity is equal praiſe due for the creation of the world. Their all-powerful word commanded into being every thing that exiſts, and by the ſame Divine power is every thing continued in exiſtence. Well therefore might the Pſalmiſt call upon the heavens and the earth to praiſe the name of the Lord; "for he commanded, and they were created. He hath alſo eſtabliſhed them for ever and ever; he hath made a decree which ſhall not paſs. Let all things praiſe the name of the Lord; for his name יהוה אלהים, Father, Son, and Holy Ghoſt, alone is excellent, and his glory above the earth and heaven."

SECT. II. *Of the Original State of Man, and the firſt Covenant of Eternal Life which God vouchſafed to make with him.*

80 Peculiarity of the expreſſion in which God is ſaid to make man

IN the Moſaic account of the creation, every attentive reader muſt be ſtruck with the manner in which the ſupreme Being is repreſented as making man: "and God ſaid, let us make man in our image, after our likeneſs; and let *them* have dominion over the fiſh of the ſea, and over the fowl of the air, and over the cattle, and over all the earth, and over every creeping thing that creepeth upon the earth. So God created man in his own image; in the image of God created he him; male and female created he THEM. And God bleſſed them; and God ſaid unto them, be fruitful, and multiply, and repleniſh the earth, and ſubdue it; and have dominion over the fiſh of the ſea, and over the fowl of the air, and over every living thing that moveth upon the earth. And God ſaid, behold, I have given you every herb bearing ſeed, which is upon the face of all the earth; and every tree in the which is the fruit of a tree yielding ſeed: to you it ſhall be for meat. And God ſaw every thing that he had made, and, behold, it was very good. And the evening and the morning were the ſixth day. Thus the heavens and the earth were finiſhed, and all the hoſt of them. And on the ſeventh day God ended his work which he had made; and he reſted on the ſeventh day from all his works which he had made. And God bleſſed the ſeventh day, and ſanctified it: becauſe that in it he had reſted from all his work which God created and made‡".

‡ Gen. i. 26, &c. ii. 1, 2, 3.

This is a very remarkable paſſage, and contains much important information. It indicates a plurality of perſons in the Godhead, deſcribes the nature of man as he came at firſt from the hands of his Creator, and furniſhes data from which we may infer what were the duties required of him in that primeval ſtate, and what were the rewards to which obedience would entitle him.

81 In his own image.

Of the plurality of Divine perſons, and their eſſential union, we have treated in the preceding ſection, and proceed now to inquire into the ſpecific nature of the firſt man. This muſt be implied in the *image of God*, in which he is ſaid to have been created; for it is by that phraſe alone that he is characterized, and his pre-eminence marked over the other animals. Now this image or likeneſs muſt have been found either in his body alone, his ſoul alone, or in both united. That it could not be in his body alone, is obvious; for the infinite and omnipotent God is allowed by all men to be without body, parts, or paſſions, and therefore to be ſuch as nothing corporeal can poſſibly reſemble.

82 Different opinions reſpecting the image of God.

If the likeneſs is to be found in the human ſoul, it comes to be a queſtion in what faculty or power of the ſoul it conſiſts. Some have contended, that man is the only creature on this earth who is animated by a principle eſſentially different from matter; and hence they have inferred, that he is ſaid to have been formed in the Divine image, on account of the immateriality of that vital principle which was infuſed into his body when the "Lord God breathed into his noſtrils the breath of life, and man became a living ſoul§." That this account of the animation of the body of man indicates a ſuperiority of the human ſoul to the vital principle of all other animals, cannot, we think, be queſtioned; but it does not therefore follow, that the human ſoul is the only immaterial principle of life which animates any terreſtrial creature. It has been ſhown elſewhere (ſee METAPHYSICS, n° 235), that the power of ſenſation, attended with individual conſciouſneſs, as it appears to be in all the higher ſpecies of animals, cannot reſult from any organical ſtructure, or be the quality of a compound extended being. The vital principle in ſuch animals therefore muſt be immaterial as well as the human ſoul; but as the word *immaterial* denotes only a negative notion, the ſouls of men and brutes, though both immaterial, may yet be ſubſtances eſſentially different. This being the caſe, it is plain that the Divine image in which man was formed, and by which he is diſtinguiſhed from the brute creation, cannot conſiſt in the mere circumſtance of his mind being a ſubſtance different from matter, but in ſome poſitive quality which diſtinguiſhes him from every other creature on this globe.

Original state of man.

§ Gen. ii. 7.

83 Calviniſtic opinions,

About this characteriſtic quality very various opinions have been formed. Some have ſuppoſed‖ "that the image of God in Adam appeared in that rectitude, righteouſneſs, and holineſs, in which he was made; for God made man upright (Eccleſ. vii. 2.) a holy and righteous creature; which holineſs and righteouſneſs were in their kind perfect; his underſtanding was free from all error and miſtakes; his will biaſſed to that which is good; his affections flowed in a right channel towards their proper objects; there were no ſinful motions and evil thoughts in his heart, nor any propenſity or inclination to that which is evil; and the whole of his conduct and behaviour was according to the will of God. And this righteouſneſs (ſay they) was *natural*, and not perſonal and acquired. It was not obtained by the exerciſe of his free-will, but was created with him, and belonged to his mind, as a natural faculty or inſtinct." They therefore call it *original righteouſneſs*, and ſuppoſe that it was loſt in the fall.

‖ Gill's Body of Divinity, b. iii. ch. 3.

84 Objected to.

To this doctrine many objections have been made. It has been ſaid that righteouſneſs conſiſting in right actions proceeding from proper principles, could not be created with Adam and make a part of his nature; becauſe nothing which is produced in a man without his knowledge and conſent can be in him either virtue or vice. Adam, it is added, was unqueſtionably placed in a ſtate of trial, which proves that he had righteous habits to *acquire*; whereas the doctrine under conſideration, affirming his original righteouſneſs to have been perfect, and therefore incapable of improvement, is inconſiſtent with a ſtate of trial. That his underſtanding was free from all errors and miſtakes, has been thought a blaſphemous poſition, as it attributes to man one of the incommunicable perfections of the Deity. It is likewiſe believed to be contrary to fact; for either his underſtanding was bewildered in error, or his affections flowed towards an improper object, when he ſuffered himſelf at the perſuaſion of his wife to tranſgreſs the expreſs law of his Creator. The objector expreſſes his wonder at its having ever been ſuppoſed that the *whole* of Adam's conduct and behaviour was according to the will of God, when it is ſo notorious that he yielded to the firſt temptation with which, as far as we know, he was aſſailed in paradiſe.

Convinced by theſe and other arguments, that the image of God in which man was created could not conſiſt in original righteouſneſs, for in exemption from all poſſibility of error, many learned men, and Biſhop Bull* among others, have

* See his Engliſh Works, vol. iii.

Original state of man.

have ſuppoſed, that by the image of God is to be underſtood certain gifts and powers ſupernaturally infuſed by the Holy Spirit into the minds of our firſt parents, to guide them in the ways of piety and virtue. This opinion they reſt chiefly upon the authority of Tatian, Irenæus, Tertullian, Cyprian, Athanaſius, and other fathers of the primitive church; but they think, at the ſame time, that it is countenanced by ſeveral paſſages in the New Teſtament. Thus when St Paul ſays §, "and ſo it is written, The firſt man Adam was made a living ſoul, the laſt Adam was made a quickening Spirit; they underſtand the whole paſſage as relating to the creation of man, and not as drawing a compariſon between Adam and Chriſt, to ſhow the great ſuperiority of the latter over the former. In ſupport of this interpretation they obſerve, that the apoſtle immediately adds, "howbeit, that was not firſt which is ſpiritual, but that which is natural, and afterwards that which is ſpiritual;" an addition which they think was altogether needleſs, if by the quickening Spirit he had referred to the incarnation of Chriſt, which had happened in the very age in which he was writing. They are therefore of opinion, that the body of Adam, after being formed of the duſt of the ground, was firſt animated by a vital principle endowed with the faculties of reaſon and ſenſation, which entitled the whole man to the appellation of a living ſoul. After this they ſuppoſe certain graces of the Holy Spirit to have been infuſed into him, by which he was made a quickening ſpirit, or formed in the image of God; and that it was in conſequence of this ſucceſſion of powers communicated to the ſame perſon, that the apoſtle ſaid, "Howbeit, that was not firſt which is ſpiritual, but that which is natural."

85 Opinion of Biſhop Bull and ſome of the ancient fathers

§ 1 Cor. xv. 45, 46.

We need hardly obſerve, that with reſpect to a queſtion of this kind the authority of *Tatian* and the other fathers quoted is nothing. Thoſe men had no better means of diſcovering the true ſenſe of the ſcriptures of the Old Teſtament than we have; and their ignorance of the language in which theſe ſcriptures are written, added to ſome metaphyſical notions reſpecting the ſoul, which too many of them had derived from the ſchool of Plato, rendered them very ill qualified to interpret the writings of Moſes. Were authority to be admitted, we ſhould conſider that of biſhop Bull and his modern followers as of greater weight than the authority of all the ancients to whom they appeal. But authority cannot be admitted; and the reaſoning of this learned and excellent man from the text of St Paul is ſurely very inconcluſive. It makes two perſons of Adam; a firſt, when he was a natural man compoſed of a body and reaſonable ſoul; a ſecond, when he was endowed with the gifts of the Holy Spirit, and by them formed in the image of God! In the verſe following too, the apoſtle expreſsly calls the ſecond man, of whom he had been ſpeaking, "the Lord from heaven;" but this appellation we apprehend to be too high for Adam in the ſtate of greateſt perfection in which he ever exiſted. That our firſt parents were endowed with the gifts of the Holy Ghoſt, we are ſtrongly inclined to believe for reaſons which ſhall be given by and by; but as theſe gifts were adventitious to their nature, they could not be that image in which God *made* man.

86 Ill founded.

87 Other opinions.

Since man was *made* in the image of God, that phraſe, whatever be its preciſe import, muſt denote ſomething *peculiar* and at the ſame time eſſential to human nature; but the only two qualities at once natural and peculiar to man are his ſhape and his reaſon. As none but an anthropomorphite will ſay that it was Adam's ſhape which reflected this image of his Creator, it has been concluded that it was the faculty of reaſon which made the reſemblance. To give ſtrength to this argument it is obſerved ‡, that when God ſays, "let us make man in our image," he immediately adds, "and let them have dominion over the fiſh of the ſea, and over the fowl of the air, and over the cattle, and over all the earth;" but as many of the cattle have much greater bodily ſtrength than man, this dominion could not be maintained but by the faculty of reaſon beſtowed upon him and withheld from them.

‡ Warburton's Divine Leg. book iv.

Original ſtate of man.

If the image of God was impreſſed only on the mind of man, this reaſoning ſeems to be concluſive; but it has been well obſerved ‡ that it was the whole man, and not the *ſoul alone*, or the *body* alone, that is ſaid to have been formed in the divine image; even as the whole man ſoul and body, is the ſeat of the new and ſpiritual image of God in regeneration and ſanctification. "The very God of peace (ſays the apoſtle) ſanctify you wholly; and may your whole *ſpirit, ſoul* and *body*, be preſerved blameleſs to the coming of our Lord Jeſus Chriſt." It is worthy of notice too, that the reaſon aſſigned for the prohibition of murder to Noah and his ſons after the deluge, is, that man was made in the image of God. "Whoſo ſheddeth man's blood, by man ſhall his blood be ſhed; for in the image of God made he man." Theſe texts ſeem to indicate, that whatever be meant by the image of God, it was ſtamped equally on the ſoul and on the body. In vain is it ſaid that man cannot reſemble God in ſhape. This is true, but it is little to the purpoſe; for man does not reſemble God in his reaſoning faculty more than in his form. It would be idolatry to ſuppoſe the ſupreme majeſty of heaven and earth to have a body or a ſhape; and it would be little ſhort of idolatry to imagine that he is obliged to compare ideas and notions together; to advance from particular truths to general propoſitions; and to acquire knowledge, as we do, by the tedious proceſſes of inductive and ſyllogiſtic reaſoning. There can therefore be no direct image of God either in the ſoul or in the body of man; and the phraſe really ſeems to import nothing more than thoſe powers or qualities by which man was fitted to exerciſe dominion over the inferior creation; as if it had been ſaid, "Let us make man in our image, after our likeneſs, that *they may have* dominion, &c." But the erect form of man contributes in ſome degree, as well as his rational powers, to enable him to maintain his authority over the brute creation; for it has been obſerved by travellers, that the fierceſt beaſt of prey, unleſs ready to periſh by hunger, ſhrinks back from a ſteady look of the human face divine.

‡ Gill's Body of Divinity, book iii. chap. 3.

88 True import of the phraſe.

By ſome *, however, who have admitted the probability of this interpretation, another, and in their opinion a ſtill better reaſon, has been deviſed for its being ſaid that man was formed in the image of God. All the members of Chriſt's body, ſay they, were written and delineated in the book of God's purpoſes and decrees, and had an ideal exiſtence from eternity in the divine mind; and therefore the body of Adam might be ſaid to be formed after the image of God, becauſe it was made according to that idea. But to this reaſoning objections may be urged, which we know not how to anſwer. All things that ever were or ever ſhall be, the bodies of us who live at preſent as well as the bodies of thoſe who lived 5000 years ago, have from all eternity had an ideal exiſtence in the Divine mind; nor in this ſenſe can one be ſaid to be prior to another. It could not therefore be after the idea of the identical body of Chriſt that the body of Adam was formed; for in the Divine mind ideas of both bodies were preſent together from all eternity, and each body was undoubtedly formed after the ideal archetype of itſelf. It may be added likewiſe, that the body of Chriſt was not God, nor the idea of that body the idea of God. Adam therefore could not with propriety, or even with truth, be ſaid to have been formed in the image of God, if by that phraſe nothing more were intended than the reſemblance between his body and the body of Chriſt.

* Gill, &c.

Original state of man.

These objections to this interpretation appear to us unanswerable; but we mean not to dictate to our readers. Every man will adopt that opinion which he thinks supported by the best arguments; but it is obvious, that whatever more may be meant by the image of God in which man was made, the phrase undoubtedly comprehends all those powers and qualities by which he is enabled to maintain his authority over the inferior creation. Among these the faculty of reason is confessedly the most important; for it is by it that man is capable of being made acquainted with the Author of his being, the relation which subsists between them, and the duties implied in that relation from the creature to the Creator.

89 Religious instruction communicated to Adam.

That the first man, however, was not left to discover these things by the mere efforts of his own unassisted reason, we have endeavoured to show in another place; (see RELIGION, n° 5—10.); and the conclusion to which we were there led is confirmed by the portion of revelation before us, The inspired historian says, "that God blessed the seventh day and *sanctified* it, because that in it he had rested from all his works, which he created and made; but Adam could not have understood what was meant by the *sanctification* of a particular day, or of any thing else, unless he had previously received some religious instruction. There cannot therefore be a doubt, but that as soon as man was made, his Creator communicated to him the truths of what is called natural religion, which we have endeavoured to explain and establish in Part I. of this article; and to these were added the precept to keep holy the Sabbath day, and set it apart for the purposes of contemplation and worship.

90 Institution of the Sabbath.

This was a very wise institution, as all the divine institutions must be. "The great end for which we are brought into life, is to attain the knowledge and be confirmed in the love of God. This includes obedience to his will in thought, word, and deed, or that course of conduct which can alone make us happy here, and fit us for everlasting glory hereafter. But of these things we cannot retain a proper sense without close and repeated application of thought; and the unavoidable cares and concerns of the present life occupying much of our attention, it is, in the nature of things, necessary that some certain portion of time should be appropriated to the purposes of religious instruction and the public adoration of our Creator, in whom we all live, and move, and have our being." Hence a very learned divine † has inferred, that though the particular time is a matter of positive appointment, the observation of a sabbath in general is a duty of natural religion, as having its foundation in the reason of things. See SABBATH.

† Dr Taylor of Norwich.

91 Duties of man in his original state,

Man therefore in his *natural* and original state was a rational and religious being, bound to do "justice, to love mercy, to walk humbly with his God, and to keep holy the Sabbath-day." These seem to be all the duties which in that state were required of him; for as soon as he was introduced into the terrestrial paradise and admitted into covenant with his Maker, he was placed in a *supernatural* state, when other duties were of course enjoined.

‖ Gen. i. 27. v. 2.

That our first parents were both made on the sixth day, Moses expressly affirms when he says ‖, that "God created them male and female, and blessed them, and called *their* name *Adam* (K), in the day when they were created:" but that they were introduced into the garden of Eden on that day, is an opinion which, however generally it may be received, seems not to be reconcileable with the plain narrative of the sacred penman. After telling us that on the sixth day God finished all his works, which he saw to be very good, and rested on the seventh day, he briefly recapitulates the history of the generations of the heavens and of the earth, gives us a more particular account of the formation of the first man, informing us that the "Lord God formed him out of the dust of the ground, and breathed into his nostrils the breath of life, when man became a living soul;" and then proceeds to say ‡, that the "Lord God planted a garden eastward in Eden, where he put the man whom he HAD *formed*." From this short history of the first pair it appears beyond dispute evident, that neither the man nor the woman was formed *in* the garden: and that from their creation some time elapsed before the garden was prepared for their reception, is likewise evident from a comparison of Gen. i. 29. with Gen. ii. 16, 17. In the first of these passages God gives to man, immediately after his creation, "every herb bearing seed which was upon the face of all the earth, and *every tree*, without exception, in which was the fruit of a tree bearing seed: to him he said it should be for meat." In the second, "he commanded the man, saying, of every tree of the garden thou mayest freely eat; but of the tree of knowledge of good and evil, thou shalt not eat of it; for in the day thou eatest thereof thou shalt surely die." When the first grant of food was given, Adam and his wife must have been where no tree of knowledge grew, and they must have been intended to live at least so long in that state as that they should have occasion for food, otherwise the formal grant of it would have been not only superfluous, but apt to mislead them with respect to the subsequent restriction.

‡ Gen. ii. 7, 8, and 15.

92 Before he was placed in the garden of Eden,

Original state of man.

In this original state man was under the discipline of what we have called *natural religion*, entitled to happiness while he should perform the duties required of him, and liable to punishment when he should neglect those duties, or transgress the law of his nature as a rational and moral agent. This being the case, it is a matter of some importance, and what will enable us to perceive more clearly the prerogatives of Christianity, to ascertain, if we can, what the rewards and punishments are which natural religion holds out to her votaries.

That under every dispensation of religion the pious and virtuous man shall, during the whole of his existence, enjoy more happiness than misery; and that the incorrigibly wicked, if there be any such, shall have a greater portion of misery than happiness, are truths which cannot be controverted by any one who admits, that the Almighty governor of the universe is a Being of wisdom, goodness, and justice. But respecting the rewards of virtue and the punishment of vice, more than these general truths seems not to be taught by natural religion. Many divines, however, of great learning and worth, have thought otherwise, and have contended, that from the nature of things the rewards bestowed by an infinite God upon piety and virtue must be eternal like their author. These men indeed appear willing enough to allow that the punishments with which natural religion is armed against vice must be only of a temporary duration, because reason, say they, is ready to revolt at the thought of *everlasting* punishment.

93 Did not, when performed, entitle him to eternal life.

This opinion, which confounds natural with revealed religion, giving to the former an important truth which belongs exclusively

(K) The woman was some time afterwards distinguished by the name of Eve חוה, because she was to be the mother of all living, and particularly of that blessed seed which was to bruise the head of the serpent. See *Parkhurst's Lexicon* on the word.

Original state of man.

exclusively to the latter, has been so ably confuted by a learned writer, who was never averse from allowing to human reason all the discoveries which it can justly claim, that we shall submit his arguments to our readers in preference to any thing which we can give ourselves.

"If reason doth, on the one hand, seem to revolt at *everlasting punishment*, we must confess that FANCY, on the other, (even when full plumed by *vanity*), hath scarce force enough to rise to the idea of *infinite rewards*. How the heart of man came to consider this as no more than an adequate retribution for his right conduct during the short trial of his virtue here, would be hard to tell, did we not know what monsters PRIDE begot of old upon *Pagan philosophy;* and how much greater still these latter ages have disclosed, *by the long* incubation of *school-divinity* upon *folly*. What hath been urged from natural reason, in support of this extravagant presumption, is so very slender, that it recoils as you enforce it. First, you say, 'that the soul, the subject of these eternal rewards, being *immaterial*, and so therefore unaffected by the causes which bring material things to an end, is, by its nature, fitted for eternal rewards.—This is an argument *ad ignorantiam*, and holds no farther. Because an *immaterial* being is not subject to that mode of dissolution which affects *material* substances, you conclude it to be eternal. This is going too fast. There may be, and probably are, many natural causes (unknown indeed to us), whereby immaterial beings come to an end. But if the nature of things cannot yet God certainly can, put a final period to such a being when it hath served the purpose of its creation. Doth ANNIHILATION impeach that wisdom and goodness which was displayed when God brought it *out of nothing?* Other immaterial beings there are, *viz.* the souls of brutes, which have the same natural security with man for their existence, of whose *eternity* we never dream. But pride, as the poet observes, *calls God unjust.*

94 Arguments to prove that they did inconclusive.

> If man alone engross not heaven's high care;
> Alone made *perfect* here, IMMORTAL there.

However, let us (for argument's sake) allow the human soul to be unperishable by nature, and secured in its existence by the unchangeable will of God, and see what will follow from thence—An *infinite* reward for virtue, during one moment of its existence, because reason discovers that, by the law of nature, *some* reward is due? By no means. When God hath amply repaid us for the performance of our duty, will he be at a loss how to dispose of us for the long remainder of *eternity?* May he not find new and endless employment for reasonable creatures, to which, when properly discharged, new rewards and in endless succession will be assigned? Modest reason seems to dictate this to the followers of the *law of nature*. The flattering expedient of ETERNAL REWARDS for virtue here was invented in the simplicity, of early speculation, after it had fairly brought men to conclude that the soul is immaterial.

"Another argument urged for the eternity of the rewards held out by natural religion to the practice of piety and virtue is partly physical and partly moral. The merit of service (say the admirers of that religion) increases in proportion to the excellence of that Being to whom our service is directed and becomes acceptable. An infinite being, therefore, can dispense no rewards but what are infinite. And thus the virtuous man becomes intitled to immortality.

"The misfortune is, that this reasoning holds equally on the side of the unmerciful doctors, as they are called, who doom the wicked to EVERLASTING PUNISHMENT. Indeed were this the only discredit under which it labours, the mercileſs doctors would hold themselves little concerned. But the truth is, that the argument from *infinity* proves just nothing. To make it of any force, both the parties should be *infinite*. This inferior emanation of God's *image*, MAN, should either be supremely good or supremely bad, a kind of deity or a kind of devil. But these reasoners, in their attention to the *divinity*, overlook the *humanity* which makes the decrease keep pace with the accumulation, till the rule of logic, that the *conclusion follows the weaker* part, comes in to end the dispute ‡.

Original state of man.

These arguments seem to prove unanswerably that immortality is not essential to any part of the compound being man, and that it cannot be claimed as a reward due to his virtue. It is not indeed essential to any created being, for what has not existence of itself, cannot of itself have perpetuity of existence (see METAPHYSICS, n° 272, &c.); and as neither man nor angel can be profitable to God, they cannot claim from him any thing as a debt. Both, indeed, as moral agents have duties prescribed them; and while they faithfully perform these duties, they have all the security which can arise from the perfect benevolence of him who brought them into existence, that they shall enjoy a sufficient portion of happiness to make that existence preferable to non-existence; but reason and philosophy furnish no data from which it can be inferred that they shall exist for ever. Man is composed in part of perishable materials. However perfect Adam may be thought to have been when he came first from the hands of his Creator, his body, as formed of the dust of the ground, must have been naturally liable to decay and dissolution. His soul, indeed, was of a more durable substance; but as it was formed to animate his body, and had no prior conscious existence, it is not easy to conceive what should have led him, under an equal providence, where rewards and punishments were exactly distributed, to suppose that one part of him should survive the other. In his natural and original state, before the covenant made with him in paradise, he was unquestionably a mortal creature. How long he continued in that state, it seems not possible to form a plausible conjecture. Bishop Warburton supposes him to have lived several years under no other dispensation than that of natural religion; during which he was as liable to death as his fallen posterity are at present.

‡ Warburton's Divine Legation, book ix.

95 Adam before his introduction into paradise liable to death.

"We must needs conclude (says this learned writer*), that God having tried Adam in *the state of nature*, and approved of the good use he made of his free-will under the direction of that light, advanced him to a superior station in *Paradise*. How long, before this remove, man had continued subject to *natural religion* alone, we can only guess; but of this we may be assured, that it was some considerable time before the garden of Eden could naturally be made fit for his reception. Since Moses, when he had concluded his history of the creation, and of God's *rest* on, and *sanctification* of, the seventh day, proceeds to speak of the condition of this new world in the following terms: "*And God made every plant of the field before it was in the earth, and every herb of the field before it grew; for the Lord God had not caused it to rain upon the earth* ‡.' Which seems plainly to intimate, that when the seeds of vegetables had been created on the third day, they were left to nature, in its ordinary operations, to mature by sun and showers. So that when in course of time Paradise was become capable of accommodating its inhabitants, they were transplanted thither."

* Divine Legation, b. ix. ch. i.

96 How long he continued in that state.

‡ Gen. ii. 4, 5.

This reasoning is not without a portion of that ingenuity which was apparent in every thing that fell from the pen of Warburton; but it was completely confuted almost as soon as it was given to the public, and shown to be deduced from premises which could be employed against the author's system. If only the *seeds* of vegetables were created on the third day, and then left to nature, in its ordinary operations,

Original state of man.

to mature by sun and showers, the first pair must have perished before a single vegetable could be fit to furnish them with food; and we may suppose that it was to prevent this disaster that the garden of Eden was miraculously stored at once with full grown trees and fruit in perfect maturity, whilst the rest of the earth was left under the ordinary laws of vegetation. There is, however, no evidence that they were only the *seeds* of vegetables that God created. On the contrary, Moses says expressly †, that "God made the earth on the third day bring forth the herb *yielding* seed after his kind, and the tree *yielding fruit* whose *seed* was in itself after his kind;" and when he recapitulates the history of the creation, he says, that God made, not every seed, but every *plant* of the field *before* it was in the earth, and every *herb* of the field *before* it grew. From the process of vegetation, therefore, nothing can be inferred with respect to the time of Adam's introduction into Paradise, or to ascertain the duration of his original state of nature. If angels were created during the six days of which the Hebrew lawgiver writes the history, an hypothesis very generally received (see ANGEL), though in the opinion of the present writer not very probable, there can be no doubt but our first parents lived a considerable time under the law of nature before they were raised to a superior station in the garden of Eden; for it seems very evident that the period of their continuance *in* that station was not long. Of this, however, nothing can be said with certainty. They may have lived for years or only a few days in their original state; but it is very necessary to distinguish between that state in which they were under no other dispensation than what is commonly called *natural religion*, entitled, upon their obedience, to the indefinite rewards of piety and virtue, and their state in Paradise when they were put under a new law, and by the free grace of God promised, if they should be obedient, a supernatural and eternal reward. Into that state we must now attend them, and ascertain, if we can, the precise terms of the first covenant.

† Gen. i. 12

97 Impossible to be known.

Moses, who in this investigation is our only guide, tells us, that the Lord God, after he had formed the first pair, "planted a garden eastward in Eden, and took the man and put him into the garden to dress it and to keep it. And the Lord God (continues he) commanded the man, saying, of every tree of the garden thou mayest freely eat; but of the tree of the knowledge of good and evil thou shalt not eat of it; for in the day that thou eatest thereof, thou shalt surely die‡." Here is no mention made of the laws of piety and moral virtue resulting from the relation in which the various individuals of the human race stand to each other, and in which all as creatures stand to God their Almighty and beneficent Creator. With these laws Adam was already well acquainted; and he must have been sensible, that as they were founded in his nature no subsequent law could dispense with their obligation. They have been equally binding upon all men in every state and under every dispensation; and they will continue to be so as long as the general practice of justice, mercy, and piety, shall contribute to the sum of human happiness. The new law peculiar to his paradisaical state was the command not to eat of the fruit of the tree of the knowledge of good and evil. This was a positive precept, not founded in the nature of man, but very proper to be the test of his obedience to the will of his Creator. The laws of piety and virtue are sanctioned by nature, or by that general system of rules according to which God governs the physical and moral worlds, and by which he has secured, in some state or other, happiness to the pious and virtuous man, and misery to such as shall prove incorrigibly wicked. The law respecting the forbidden fruit was sanctioned by the penalty of *death* denounced against disobedience; and by the subjects of that law the nature of this penalty must have been perfectly understood: but Christian divines, as we shall afterwards see, have differed widely in opinion respecting the full import of the Hebrew words which our translators have rendered by the phrase *thou shalt surely die*. All, however, agree that they threatened death, in the common acceptation of the word, or the separation of the soul and body as one part of the punishment to be incurred by eating the forbidden fruit; and hence we must infer, that had the forbidden fruit not been eaten, our first parents would never have died, because the penalty of death was denounced against no other transgression. What therefore is said respecting the fruit of the tree of knowledge, implies not only a law but also a covenant (L), promising to man, upon the observance of one positive precept, immortality or eternal life; which is not essential to the nature of any created being, and cannot be claimed as the merited reward of the greatest virtue or the most fervent piety.

Original state of man.

98 The covenant of eternal life made with Adam in paradise,

This obvious truth will enable us to dispose of the objections which have been sometimes brought by free-thinking divines against the wisdom and justice of punishing so severely as by death the breach of a mere positive precept; which, considered in itself, or as connected with the general principles of moral obligation, appears to be a precept of very little importance. We have only to reply, that as an exemption from death is not due either to the nature or to the virtue of man, it was wise and just to make it depend upon the observance of a positive precept, to impress upon the minds of our first parents a constant conviction that they were to be preserved immortal, not in the ordinary course of divine providence, but by the special grace and favour of God. The same consideration will show us the folly of those men who, because the terms of the first covenant, as stated in some systems of theology, agree not with certain philosophical maxims which they have adopted, are for turning all that is said of the trees of knowledge and of life into figure and allegory. But the other trees which Adam and Eve were permitted to eat were certainly real trees, or they must have perished for want of food. And what rules of interpretation will authorise us to interpret *eating* and *trees* literally in one part of the sentence and figuratively in the other? A garden in

‡ Gen. ii. 8, 15, 16, 17.

(L) It does not appear that any transaction between God and mankind in general was denominated by a word equivalent to the English word *covenant* till the end of the fourth century, when such phraseology was introduced into the church by the celebrated Augustine, bishop of Hippo. That the phraseology is strictly proper, no man can suppose who reflects on the infinite distance between the contracting parties, and the absolute dominion of the one over the other. To be capable of entering into a *covenant*, in the proper sense of the word, both parties must have a right either to agree to the terms proposed or to reject them; but surely Adam had no right to bargain with his Maker, or to refuse the gift of immortality on the terms on which it was offered to him. The word *dispensation* would more accurately denote what is here meant by the word *covenant*; but as this last is in general use, we have retained it as sufficient, when thus explained, to distinguish what man received from God upon certain positive conditions, from what he had a claim to by the constitution of his nature.

Original state of man.

in a delightful climate is the very habitation, and the fruits produced in that garden the very food, which we ſhould naturally ſuppoſe to have been prepared for the progenitors of the human race; and though in the garden actually fitted up for this purpoſe two trees were remarkably diſtinguiſhed from the reſt, perhaps in ſituation and appearance as well as in uſe, the diſtinction was calculated to ſerve the beſt of purpoſes. The one called the *tree of life*, of which, while they continued innocent, they were permitted to eat, ſerved as a ſacramental pledge or aſſurance on the part of God, that as long as they ſhould obſerve the terms of the covenant their life ſhould be preſerved; the other, of which it was death to taſte, was admirably adapted to impreſs upon their minds the neceſſity of implicit obedience to the Divine will, in whatever manner it might be made known to them.

A queſtion has been ſtated, and it is of ſome importance, What would have finally become of men if the firſt covenant had not been violated? That they would have been all immortal is certain; but it is by no means certain that they would have lived for ever upon this earth. On the contrary, it has been an article of very general belief in all ages of the church *, that the garden of Eden was an emblem or type of heaven, and therefore called *Paradiſe* (ſee PARADISE;) and that under the firſt covenant, mankind, after a ſufficient probation here, were to be tranſlated into heaven without taſting death. This doctrine is not indeed explicitly taught in ſcripture; but many things conſpire to make it highly probable. The frequent communications between God and man before the fall (M), ſeem to indicate that Adam was training up for ſome higher ſtate than the terreſtrial paradiſe. Had he been intended for nothing but to cultivate the ground and propagate his ſpecies, he might have been left like other animals to the guidance of his own reaſon and inſtincts; which, after the rudiments of knowledge were communicated to him, muſt ſurely have been ſufficient to direct him to every thing neceſſary to the comforts of a life merely ſenſual and rational, otherwiſe he would have been an imperfect animal. It is obvious too, that this earth, however fertile it may have originally been, could not have afforded the means of ſubſiſtence to a race of immortal beings multiplying to infinity. For theſe reaſons, and others which will readily occur to the reader, it ſeems incontrovertible, that, under the firſt covenant, either mankind would have been ſucceſſively tranſlated to ſome ſuperior ſtate, or would have ceaſed to propagate their kind as ſoon as the earth ſhould have been repleniſhed with inhabitants. He who reflects on the promiſe, that, after the general reſurrection, there is to be a new heaven and a new earth, will probably embrace the latter part of the alternative; but that part in its conſequences differs not from the former. In the new earth promiſed in the Chriſtian revelation, nothing is to dwell but righteouſneſs. It will therefore be preciſely the ſame with what we conceive to be expreſſed by the word heaven; and if under the firſt covenant this earth was to be converted into a ſimilar place, where, after a certain period, men ſhould neither marry nor be given in marriage, but enjoy what divines have called the *beatific viſion*, we may confidently affirm, that, had the firſt covenant been faithfully obſerved, Adam and his poſterity, after a ſufficient probation, would all have been tranſlated to ſome ſuperior ſtate or heaven.

* Bull's ſtate of Man before the fall.

99 Had it not been violated, entitled him to heaven,

100 And the gifts of divine grace.

To fit them for that ſtate, the gifts of divine grace ſeem to have been abſolutely neceſſary. To them it was a ſtate certainly ſupernatural, otherwiſe a God of infinite wiſdom and perfect goodneſs would not, for a moment, have placed them in an inferior ſtate. But to enable any creature, eſpecially ſuch a creature as man, whom an ancient philoſopher has juſtly ſtyled ζωον μιμητικον, to riſe above its *nature*, foreign and divine aid is unqueſtionably requiſite: and therefore, though we cannot perſuade ourſelves that the gifts of the Holy Ghoſt conſtituted that image of God in which man was originally made, we agree with biſhop Bull, that theſe gifts were beſtowed upon our firſt parents to enable them to fulfil the terms of the covenant under which they were placed.

Original ſtate of man.

Upon the whole, we think it apparent from the portions of ſcripture which we have examined, that Adam and Eve were endued with ſuch powers of body and mind as fitted them to exerciſe dominion over the other animals; that thoſe powers conſtituted that image of God in which they are ſaid to have been formed; that they received by immediate revelation the firſt principles of all uſeful knowledge, and eſpecially of that ſyſtem which is uſually called *natural religion*; that they lived for ſome time with no other religion, entitled to the natural rewards of piety and virtue, but all the while liable to death; that they were afterwards tranſlated into paradiſe, where they were placed under a new law, with the penalty of death threatened to the breach of it, and the promiſe of endleſs life if they ſhould faithfully obſerve it; and that they were endued with the gifts of the Holy Ghoſt, to enable them, if not wanting to themſelves, to fulfil the terms of that covenant, which has been improperly termed the *covenant of works*, ſince it flowed from the mere grace of God, and conferred privileges on man to which the moſt perfect human virtue could lay no juſt claim.

101 It is therefore improperly called the Covenant of Works,

SECT. III. *Of the Fall of Adam, and its Conſequences.*

FROM the preceding account of the primeval ſtate of man, it is evident that his continuance in the terreſtrial paradiſe, together with all the privileges which he there enjoyed, were made to depend upon his obſervance of one poſitive precept. Every other duty incumbent on him, whether as reſulting from what is called the law of his nature, or from the expreſs command of his God, was as much his duty before as after he was introduced into the garden of Eden; and though the tranſgreſſion of any law would undoubtedly have been puniſhed, or have been forgiven only in conſequence of ſincere repentance and amendment, it does not appear that a breach of the *moral* law, or of the commandment reſpecting the ſanctification of the *Sabbath-day*, would have been puniſhed with death, whatever may be the import of that word in the place where it is firſt threatened. The puniſhment was denounced only againſt eating the fruit of the tree of the knowledge of good and evil: For "the Lord God commanded the man, ſaying, of every tree of the garden thou mayeſt freely eat, but of the tree of the knowledge of good and evil thou ſhalt not eat of it; for in the day that thou eateſt thereof thou ſhalt ſurely die." To the word *death* in this paſſage, divines have affixed many and different meanings. By ſome it is ſuppoſed to import a ſeparation of the ſoul and body, while the former was to continue in a ſtate of conſcious exiſtence; by others, it is taken to imply annihilation or a ſtate without conſciouſneſs; by ſome, it is imagined to ſignify eternal life in torments; and by others a ſpiritual and moral death, or a ſtate neceſſarily ſubject to ſin.

102 As it could be violated only by diſobedience to one poſitive command.

In

(M) That there were ſuch frequent communications, has been ſhown to be in the higheſt degree probable by the late Dr Law biſhop of Carliſle. See his *Diſcourſe on the ſeveral Diſpenſations of revealed Religion.*

Fall of Adam, and its conſequences.

In any one of theſe acceptations it denoted ſomething new to Adam, which he could not underſtand without an explanation of the term; and therefore, as it was threatened as the puniſhment of only one tranſgreſſion, it could not be the divine intention to inflict it upon any other.

103 It was violated,

The abſtaining from a particular fruit in the midſt of a garden abounding with fruits of all kinds, was a precept which at firſt view appears of eaſy obſervation; and the penalty threatened againſt the breach of it was, in every ſenſe, awful. The precept, however, was broken notwithſtanding that penalty; and though we may thence infer that our firſt parents were not beings of ſuch abſolute perfection as by ſyſtem building divines they have ſometimes been repreſented, we ſhall yet find, upon due conſideration, that the temptation by which they were ſeduced, when taken with all its circumſtances, was ſuch as no wiſe and modeſt man will think himſelf able to have reſiſted. The ſhort hiſtory of this important tranſaction, as we have it in the third chapter of the book of Geneſis, is as follows:

"Now the ſerpent was more ſubtile than any beaſt of the field which the Lord God had made: and he ſaid unto the woman, Yea, hath God ſaid, ye ſhall not eat of every tree of the garden? And the woman ſaid unto the ſerpent, We may eat of the fruit of the trees of the garden; but of the fruit of the tree which is in the midſt of the garden, God hath ſaid ye ſhall not eat of it, neither ſhall ye touch it, leſt ye die. And the ſerpent ſaid unto the woman, ye ſhall not ſurely die: For God doth know, that on the day ye eat thereof, then your eyes ſhall be opened, and ye ſhall be as gods, knowing good and evil. And when the woman *ſaw* that the tree was good for food, and that it was pleaſant to the eyes, and a tree to be deſired to make one wiſe, ſhe took of the fruit thereof, and did eat, and gave alſo unto her huſband with her, and he did eat."

104 In conſequence of a moſt artful temptation,

To the leſs attentive reader this converſation between the ſerpent and the woman muſt appear to begin abruptly; and indeed it is not poſſible to reconcile it with the natural order of a dialogue, or even with the common rules of grammar, but by ſuppoſing the tempter's queſtion. "Yea, hath God ſaid, ye ſhall not eat of every tree in the garden?" to have been ſuggeſted by ſomething immediately preceding either in words or in ſignificant ſigns. Eve had undoubtedly by ſome means or other informed the ſerpent that ſhe was forbidden to eat of the fruit upon which he was probably feaſting; and that information, whether given in words or in actions, muſt have produced the queſtion with which the ſacred hiſtorian begins his relation of this fatal dialogue. We are told that the woman *ſaw* that the tree was *good for food*; that it was pleaſant to the eyes, and a tree to be *deſired to make one wiſe*; but all this ſhe could not have *ſeen*, had not the ſerpent eaten of its fruit in her preſence. In her walks through the garden, it might have often appeared pleaſant to her eyes; but previous to experience ſhe could not know but that its fruit was the moſt deadly poiſon, far leſs could ſhe conceive it capable of conferring wiſdom. But if the ſerpent eat of it before her, and then extolled its virtues in rapturous and intelligible language, ſhe would at once ſee that it was not deſtructive of animal life, and naturally infer that it had very ſingular qualities. At the moment ſhe was drawing this inference, it is probable that he invited her to partake of the delicious fruit, and that her refuſal produced the conference before us. That ſhe yielded to his temptation need excite no wonder; for ſhe knew that the ſerpent was by nature a mute animal, and if he attributed his ſpeech to the virtues of the tree, ſhe might infer, with ſome plauſibility, that what had power to raiſe the brute mind to human, might raiſe the human to divine, and make her and her huſband, according to the promiſe of the tempter, become as gods, knowing good and evil. Milton, who was an eminent divine as well as the prince of poets, makes her reaſon thus with herſelf.

Fall of Adam, and its conſequences.

Great are thy virtues, doubtleſs, beſt of fruits,
Tho' kept from man, and worthy to be admir'd;
Whoſe taſte, too long forborne, at firſt eſſay
Gave elocution to the mute, and taught
The tongue not made for ſpeech to ſpeak thy praiſe.
* * * * *
——— For us alone
Was death invented? or to us denied
This intellectual food, for beaſts reſerved?
For beaſts it ſeems: yet that one beaſt which firſt
Hath taſted, envies not, but brings with joy
The good befallen him, author unſuſpect,
Friendly to man, far from deceit or guile.
What fear I then, rather what know to fear
Under this ignorance of good and evil,
Of God or death, of law or penalty?
Here grows the cure of all, this fruit divine,
Fair to the eye, inviting to the taſte,
Of virtue to make wiſe: what hinders then
To reach, and feed at once both body and mind?

Paradiſe Loſt, book ix.

Full of theſe hopes of raiſing herſelf to divinity, and not, as has ſometimes been ſuppoſed, led headlong by a ſenſual appetite, ſhe took of the fruit and did eat, and gave to her huſband with her, and he did eat. The great poet makes Adam delude himſelf with the ſame ſophiſtry that had deluded Eve, and infer, that as the ſerpent had attained the language and reaſoning powers of man, they ſhould attain

Proportional aſcent, which could not be
But to be gods, or angels, demi-gods.

105 And Adam and Eve turned out of paradiſe.

Thus was the covenant, which, on the introduction of our firſt parents into paradiſe, their Creator was graciouſly pleaſed to make with them, broken by their violation of the condition on which they were advanced to that ſupernatural ſtate; and therefore the hiſtorian tells us, that "leſt they ſhould put forth their hand and take alſo of the tree of life and eat, and live for ever, the Lord God ſent them forth from the garden of Eden to till the ground from whence they were taken (N)." Had they been ſo ſent forth without any farther intimation reſpecting their preſent condition or their future proſpects, and if the death under which they had fallen was only a loſs of conſciouſneſs, they would have been in preciſely the ſame ſtate in which they lived before they were placed in the garden of Eden; only their minds muſt now have been burdened with the inward ſenſe of guilt, and they muſt have *known* themſelves to be ſubject to death; of which, though not exempted from it by nature, they had probably no *apprehenſion* till it was revealed to them in the covenant of life which they had ſo wantonly broken.

God, however, did not ſend them forth thus hopeleſs and forlorn from the paradiſe of delights which they had ſo recently

(N) The ideas which this language conveys are indeed *allegorical*; but they inform us of this, and nothing but this, that *immortal life was a thing extraneous to our nature*, and not put into our paſte or compoſition when firſt faſhioned by the forming hand of the Creator." *Warburton's Divine Legation*, Book ix. Chap. 1.

Fall of Adam, and its consequences.

cently forfeited. He determined to punish them for their transgression, and at the same time to give them an opportunity of recovering more than their lost inheritance. Calling therefore the various offenders before him, and inquiring into their different degrees of guilt, he began with pronouncing judgment on the serpent in terms which implied that there was mercy for man. "And the Lord God said unto the serpent, Because thou hast done this, thou art cursed above all cattle, and above every beast of the field: upon thy belly shalt thou go, and dust shalt thou eat all the days of thy life; and I will put enmity between thee and the woman, and between thy seed and her seed: it shall bruise thy head, and thou shalt bruise his heel."

106 The tempter punished.

That this sentence has been fully inflicted on the serpent, no reasoning can be necessary to evince. Every species of that reptile is more hateful to man than any other terrestrial creature; and there is literally a perpetual war between them and the human race. It is remarkable too that the *head* of this animal is the only part which it is safe to bruise. His tail may be bruised, or even cut off, and he will turn with fury and death on his adversary: but the slightest stroke on the head infallibly kills him. That the serpent, or at least the greater part of serpents, go on their belly, every one knows; though it is said*, that in some parts of the east serpents have been seen with wings, and others with feet, and that these species are highly beautiful. If there be any truth in this story, we may suppose that these walking and flying serpents have been suffered to retain their original elegance, that mankind might see what the whole genus was before the curse was denounced on the tempter of Eve: but it is certain that most of the species have neither wings nor feet, and that many of the most poisonous of them live in burning deserts, where they have nothing to eat but the dust among which they crawl ‖,

* Delanay's Rev. examined with candour.

‖ See Bochart and Pliny on Serpents, with Bruce's Travels.

To this degradation of the serpent, infidels have objected, that it implies the punishment of an animal which was incapable of guilt; but this objection is founded in thoughtlessness and ignorance. The elegant form of any species of inferior animals adds nothing to the happiness of the animals themselves: the ass is probably as happy as the horse, and the serpent that crawls as he that flies. Fine proportions attract indeed the notice of man, and tend to impress upon his mind just notions of the wisdom and goodness of the Creator; but surely the symmetry of the horse or the beauty of the peacock is more properly displayed for this purpose than the elegance of the instrument employed by the enemy of mankind. The degradation of the serpent in the presence of our first parents must have served the best of purposes. If they had so little reflection as not yet to have discovered that he was only the instrument with which a more powerful Being had wrought their ruin, they would be convinced, by the execution of this sentence, that the forbidden fruit had no power in itself to improve the nature either of man or of beast. But it is impossible that they could be so stupid as this objection supposes them. They doubtless knew by this time that some great and wicked spirit had actuated the organs of the serpent; and that when enmity was promised to be put between its seed and the seed of the woman, that promise was not meant to be fulfilled by serpents occasionally biting the heels of men, and by men in return bruising the heads of serpents! If such enmity, though it has literally taken place, was all that was meant by this prediction, why was not Adam directed to bruise the head of the identical serpent which had seduced his wife? If he could derive any consolation from the exercise of revenge, surely it would be greater from his revenging himself on his own enemy, than from the knowledge that there should be a perpetual warfare between his descendants and the breed of serpents through all generations.

Fall of Adam, and its consequences.

We are told, that when the foundations of the earth were laid, the morning stars sang together, and all the sons of God shouted for joy; and it is at least probable that there would be similar rejoicing when the six days work of creation was finished. If so, Adam and Eve, who were but a little lower than the angels, might be admitted into the chorus, and thus be made acquainted with the existence of good and evil spirits. At all events, we cannot doubt but their gracious and merciful Creator would inform them that they had a powerful enemy; that he was a rebellious angel capable of deceiving them in many ways; and that they ought therefore to be constantly on their guard against his wiles. They must have known too that they were themselves animated by something different from matter; and when they found they were deceived by the serpent, they might surely, without any remarkable stretch of sagacity, infer that their malignant enemy had actuated the organs of that creature in a manner somewhat similar to that in which their own souls actuated their own bodies. If this be admitted, the degradation of the serpent would convince them of the weakness of the tempter when compared with their Creator; and confirm their hopes, that since he was not able to preserve unhurt his own instrument of mischief, he should not be able finally to prevail against them; but that though he had bruised their heels, the promised seed of the woman should at last bruise his head, and recover the inheritance which they had lost. See PROPHECY, n° 9, 10.

107 Sentence passed on Adam and Eve.

Having thus punished the original instigator to evil, the Almighty Judge turned to the fallen pair, and said to the woman, "I will greatly multiply thy sorrow and thy conception: in sorrow shalt thou bring forth children; and thy desire shall be to thy husband, and he shall rule over thee. And unto Adam he said, Because thou hast hearkened unto the voice of thy wife, and hast eaten of the tree of which I commanded thee, saying, Thou shalt not eat of it; cursed is the ground for thy sake; in sorrow shalt thou eat of it all the days of thy life. Thorns also and thistles shall it bring forth unto thee, and thou shalt eat the herb of the field. In the sweat of thy face shalt thou eat bread till thou return unto the ground; for out of it wast thou taken: for dust thou art, and unto dust shalt thou return."

Here is a terrible denunciation of toil and misery and death upon two creatures; who, being inured to nothing, and formed for nothing but happiness, must have felt infinitely more horror from such a sentence, than we, who are familiar with death, intimate with misery, and "born to sorrow as the sparks fly upward," can form any adequate conception of. The hardship of it, too, seems to be aggravated by its being severer than what was originally threatened against the breach of the covenant of life. It was indeed said, "In the day thou eatest thereof, thou shalt surely die:" but no mention was made of the woman's incurring sorrow in conception, and in the bringing forth of children; of the curse to be inflicted on the ground; of its bringing forth thorns and thistles instead of food for the use of man; and of Adam's eating bread in sorrow and the sweat of his face till he should return to the dust from which he was taken.

108 An obscure intimation given them of deliverance from it.

These seeming aggravations, however, are in reality instances of divine benevolence. Adam and Eve were now subjected to death; but in the sentence passed on the serpent, an obscure intimation had been given them that they were not to remain for ever under its power. It was therefore their interest, as well as their duty, to reconcile themselves as much as possible to their fate; to wean their affections from this world, in which they were to live only for a time;

Fall of Adam, and its conſequences.

time; and to hope, with humble confidence, in the promiſe of their God, that, upon their departure from it, they ſhould be received into ſome better ſtate. To enable them to wean their affections from earth, nothing could more contribute than to combine ſenſual enjoyment with ſorrow, and lay them under the neceſſity of procuring their means of ſubſiſtence by labour, hard and often fruitleſs. This would daily and hourly impreſs upon their minds a full conviction that the preſent world is not a place fit to be an everlaſting habitation; and they would look forward, with pious reſignation, to death, as putting a period to all their woes. Had they indeed been furniſhed with no ground of hope beyond the grave, we cannot believe that the Righteous Judge of all the earth would have added to the penalty originally threatened. That penalty they would doubtleſs have incurred the very day on which they fell; but as they were promiſed a deliverance from the conſequences of their fall, it was proper to train them up by ſevere diſcipline for the happineſs reſerved for them in a future ſtate.

After the paſſing of their ſentence, the man and woman were turned out into the world, where they had formerly lived before they were placed in the garden of Eden; and all future acceſs to the garden was for ever denied them. They were not, however, in the ſame ſtate in which they were originally before their introduction into Paradiſe: They were now conſcious of guilt; doomed to ſevere labour; liable to ſorrow and ſickneſs, diſeaſe and death: and all theſe miſeries they had brought, not only upon themſelves, but alſo, as we learn from different paſſages of the New Teſtament, upon their unborn poſterity to the end of time. It may ſeem indeed to militate againſt the moral attributes of God, to inflict miſery upon children for the ſins of their parents; but before any thing can be pronounced concerning the Divine goodneſs and juſtice in the preſent caſe, we muſt know preciſely how much we ſuffer in conſequence of Adam's tranſgreſſion, and whether we have ourſelves any ſhare in that guilt which is the cauſe of our ſufferings.

109 Doubtful whether men would have been exempted from pain under the firſt covenant,

That women would have had leſs ſorrow in conception and in the bringing forth of children; that we ſhould have been ſubjected to leſs toil and exempted from death, had our firſt parents not fallen from their paradiſaical ſtate—are truths incontrovertible by him who believes the inſpiration of the Holy Scriptures; but that mankind would in that ſtate have been wholly free from pain and every bodily diſtreſs, is a propoſition which is not to be found in the Bible, and which therefore no man is bound to believe. The bodies of Adam and Eve conſiſted of fleſh, blood, and bones, as ours do; they were ſurrounded by material objects as we are; and their limbs were unqueſtionably capable of being fractured. That their ſouls ſhould never be ſeparated from their bodies while they abſtained from the forbidden fruit, they knew from the infallible promiſe of him who formed them, and breathed into their noſtrils the breath of life; but that not a bone of themſelves or of their numerous poſterity ſhould ever be broken by the fall of a ſtone or of a tree, they were not told, and had no reaſon to expect. Of ſuch fractures, pain would ſurely have been the conſequence; though we have reaſon to believe that it would have been quickly removed by ſome infallible remedy, probably by the fruit of the tree of life.

Perhaps it may be ſaid, that if we ſuppoſe our firſt parents or their children to have been liable to accidents of this kind in the garden of Eden, it will be difficult to conceive how they could have been preſerved from death, as a ſtone might have fallen on their heads as well as on their feet, and have at once deſtroyed the principle of vitality. But this can be ſaid only by him who knows little of the phyſical world, and ſtill leſs of the power of God. There are many animals which are ſuſceptible of pain, and yet not eaſily killed; and man in Paradiſe might have reſembled theſe. At any rate, we are ſure that the Omnipotent Creator could and would have preſerved him from death; but we have no reaſon to believe that, by a conſtant miracle, he would have preſerved him from every kind of pain. Indeed, if, under the firſt covenant, mankind were in a ſtate of probation, it is certainly conceivable that ſome one individual of the numerous race might have fallen into ſin, without actually breaking the covenant by eating the fruit of the tree of knowledge; and ſuch a ſinner would undoubtedly have been puniſhed by that God who is of purer eyes than to behold iniquity: but how puniſhment could have been inflicted on a being exempted from all poſſibility of pain as well as of death, we confeſs ourſelves unable to imagine. Remorſe, which is the inſeparable conſequence of guilt, and conſtitutes in our preſent ſtate great part of its puniſhment, flows from the fearful looking for of judgment, which the ſinner knows ſhall, in a future ſtate, devour the adverſaries of the goſpel of Chriſt; but he, who could neither ſuffer pain nor death, had no cauſe to be afraid of future judgment, and was therefore not liable to the tortures of remorſe. We conclude, therefore, that it is a miſtake to ſuppoſe pain to have been introduced into the world by the fall of our firſt parents, or at leaſt that the opinion contrary to ours has no foundation in the word of God.

Fall of Adam, and its conſequences.

110 Though they would from death.

Death, however, was certainly introduced by their fall; for the inſpired apoſtle aſſures us, that in *Adam all die** ; and again, that *through the offence of* ONE *many are dead* †. But concerning the full import of the word *death* in this place, and in the ſentence pronounced upon our firſt parents, divines hold opinions extremely different. Many contend, that it includes death *corporal, ſpiritual*, or *moral* and *eternal*; and that all mankind are ſubjected to theſe three kinds of death, on account of their ſhare in the guilt of the original tranſgreſſion, which is uſually denominated *original ſin*, and conſidered as the ſource of all moral evil.

* 1 Cor. xv. 22.
† Rom. v. 15.

That all men are ſubjected to death corporal in conſequence of Adam's tranſgreſſion, is univerſally admitted; but that they are in any ſenſe partakers of his guilt, and on that account ſubjected to death ſpiritual and eternal, has been very ſtrenuouſly denied. To diſcover the truth is of great importance; for it is intimately connected with the Chriſtian doctrine of redemption. We ſhall therefore ſtate, with as much impartiality as we can, the arguments commonly urged on each ſide of this much agitated queſtion: but ſhould the reader perceive, as very probably he may, that we lean more to the one ſide than to the other, he will do well to ſhut our book, and, diſregarding all artificial ſyſtems, ſtudy, with an unbiaſſed mind, the writings only of the prophets and apoſtles.

111 Doctrine of original ſin ſtated.

Thoſe who maintain that all men ſinned in Adam, generally ſtate their doctrine thus: "The covenant being made with Adam, as a public perſon, not for himſelf only but for his poſterity, all mankind deſcending from him by ordinary generation *ſinned* in him and fell with him in that firſt tranſgreſſion; whereby they are deprived of that original righteouſneſs in which he was created, and are utterly indiſpoſed, diſabled, and made oppoſite to all that is ſpiritually good, and wholly inclined to all evil, and that continually; which is commonly called *original ſin*, and from which do proceed all actual tranſgreſſions, ſo as we are by nature children of wrath, bond-ſlaves to Satan, and juſtly liable to all puniſhments in this world and in that which is to come, even to everlaſting ſeparation from the comfortable preſence of God, and to moſt grievous torments in ſoul and body, without intermiſſion, in hell fire for ever."

That which in this paſſage we are firſt to examine, is the

ſentence

Fall of Adam and its conſequences.

ſentence which affirms all mankind deſcending from Adam by ordinary generation to have *ſinned* in him and fallen with him in his firſt tranſgreſſion; the truth of which is attempted to be proved by various texts of Holy Scripture. Thus St Paul ſays expreſsly, that "by one man ſin entered into the world and death by ſin; and ſo death paſſed upon all men, for that *all have ſinned*. But not as the offence, ſo alſo is the free gift. For if, through the *offence* of *one*, *many* be *dead*; much more the grace of God, and the gift by grace, which is by one man, Jeſus Chriſt, hath abounded unto many; and not as it was by one that ſinned, ſo is the gift (for the *judgment* was by *one* unto *condemnation*); but the free gift is of many offences unto juſtification. For if by one man's offence, death reigned by one; much more they, who receive the abundance of grace and of the gift of righteouſneſs, ſhall reign in life by one, Jeſus Chriſt. Therefore as, by the *offence of one*, *judgment* came upon *all men* to *condemnation*; even ſo, by the righteouſneſs of One, the free gift came upon all men unto juſtification of life. For as by one man's diſobedience *many were made ſinners*; ſo by the obedience of one ſhall many be made righteous‡." In this paſſage the apoſtle aſſures us, that all upon whom death hath paſſed have *ſinned*; but death hath paſſed upon infants, who could not commit actual ſin. Infants therefore muſt have ſinned in Adam, ſince death hath paſſed upon them; for death "is the wages only of ſin." He tells us likewiſe, that by the offence of one, judgment came upon all men to condemnation; and therefore, ſince the Righteous Judge of heaven and earth never condemns the innocent with the wicked, we muſt conclude, that all men partake of the guilt of that offence for which judgment came upon them to condemnation. Theſe concluſions are confirmed by his ſaying expreſsly, that "by one man's diſobedience many (*i. e.* all mankind) were *made ſinners*;" and elſewhere*, that "there is none righteous, no *not one*;" and that his Epheſian converts "were dead in treſpaſſes and ſins, and were by *nature* children of wrath even as *others*." The ſame doctrine, it is ſaid, we are taught by the inſpired writers of the Old Teſtament. Thus Job, expoſtulating with God for bringing into judgment with him ſuch a creature as man, ſays, "Who can bring a clean thing out of an unclean? Not one." And Eliphaz, reproving the patient patriarch for what he deemed preſumption, aſks‡, "What is man that he ſhould be clean, or he who is born of a woman that he ſhould be righteous?" From theſe two paſſages it is plain, that Job and his unfeeling friend, though they agreed in little elſe, admitted as a truth unqueſtionable, that man inherits from his parents a ſinful nature, and that it is impoſſible for any thing born of a woman by ordinary generation to be righteous. The Pſalmiſt talks the very ſame language; when acknowledging his tranſgreſſions, he ſays§, "Behold I was ſhapen in iniquity, and in ſin did my mother conceive me."

112 Arguments for it.

‡Job xiv. 4. and xv, 14.

§ Pſalm li. 5.

113 Adam's guilt imputed to his poſterity.

Having thus proved the fact, that all men are made ſinners by Adam's diſobedience, the divines, who embrace this ſide of the queſtion, proceed to inquire how they can be partakers in guilt which was incurred ſo many ages before they were born. It cannot be by imitation; for infants, according to them, are involved in this guilt before they be capable of imitating any thing. Neither do they admit that ſin is by the apoſtle put for the conſequences of ſin, and many ſaid to be made ſinners by one man's diſobedience, becauſe by that diſobedience they were ſubjected to death, which is the wages of ſin. This, which they call the doctrine of the Arminians, they affirm to be contrary to the whole ſcope and deſign of the context; as it confounds together ſin and death, which are there repreſented, the one as the cauſe, and the other as the effect. It likewiſe exhibits the apoſtle reaſoning in ſuch a manner as would, in their opinion, diſgrace any man of common ſenſe, and much more an inſpired writer; for then the ſenſe of theſe words, "Death hath paſſed upon all men, for that all have ſinned," muſt be, death hath paſſed upon all men, becauſe it hath paſſed upon all men; or, all men are obnoxious to death, becauſe they are obnoxious to it. The only way therefore, continue they, in which Adam's poſterity can be made ſinners through his diſobedience, is by the IMPUTATION of his diſobedience to them; and this imputation is not to be conſidered in a *moral* ſenſe, as the action of a man committed by himſelf, whether good or bad, is reckoned unto him as his own; but in a *forenſic* ſenſe, as when one man's debts are in a legal way placed to the account of another. Of this we have an inſtance in the apoſtle Paul, who ſaid to Philemon concerning Oneſimus, "If he hath wronged thee, or oweth thee any thing (ελλογει) let it be imputed to me," or placed to and put on my account. And thus the poſterity of Adam are made ſinners by his diſobedience; that being imputed to them and put to their account, as if it had been committed by them perſonally, though it was not.

Fall of Adam, and its conſequences.

Some few divines of this ſchool are indeed of opinion, that the phraſe, "By one man's diſobedience many were made ſinners," means nothing more than that the poſterity of Adam, through his ſin, derive from him a corrupt nature. But though this be admitted as an undoubted truth, the more zealous abettors of the ſyſtem contend, that it is not the whole truth. "It is true (ſay they) that all men are made of one man's blood, and that blood tainted with ſin; and ſo a clean thing cannot be brought out of an unclean. What is born of the fleſh is fleſh, carnal and corrupt: every man is conceived in ſin and ſhapen in iniquity: but then there is a difference between being *made ſinners* and *becoming* ſinful. The one reſpects the *guilt*, the other the *pollution* of nature; the one is previous to the other, and the foundation of it. Men receive a corrupt nature from their immediate parents; but they are made ſinners, not by any act of their diſobedience, but only by the imputation of the ſin of Adam."

To confirm and illuſtrate this doctrine of imputed ſin, they obſerve, that the word κατεσταθησαν, uſed by the apoſtle, ſignifies *conſtituted* in a judicial way, ordered and appointed in the diſpenſation of things that ſo it ſhould be; juſt as Chriſt was made ſin or a ſinner by imputation, or by that conſtitution of God which laid upon him the ſins of all his people, and dealt with him as if he had been the guilty perſon. That this is the ſenſe of the paſſage, they argue further from the puniſhment inflicted on men for the ſin of Adam. The puniſhment threatened to that ſin was death; which includes death corporal, moral, and eternal. Corporal death, ſay they, is allowed by all to be ſuffered on account of the ſin of Adam; and if ſo, there muſt be guilt, and that guilt made over to the ſufferer, which can be done only by *imputation*. A moral death is no other than the loſs of the image of God in man, which conſiſted in righteouſneſs and holineſs; and particularly it is the loſs of original righteouſneſs, to which ſucceeded unrighteouſneſs and unholineſs. It is both a ſin and a puniſhment for ſin; and ſince it comes upon all men as a puniſhment, it muſt ſuppoſe preceding ſin, which can be nothing but Adam's diſobedience; the guilt of which is made over to his poſterity by *imputation*. This appears ſtill more evident from the poſterity of Adam being made liable to eternal death in conſequence of his tranſgreſſion; for the wages of ſin, we are aſſured, is death, even death eternal, which never can be inflicted on guiltleſs perſons. But from the paſſage before us we learn, that "by the offence of *one* judgment came upon

114 The puniſhment of imputed guilt.

Fall of Adam and its consequences.

all men to condemnation;" and therefore the guilt of that offence muſt be reckoned to all men, or they could not be juſtly condemned for it. That Adam's ſin is imputed to his poſterity, appears not only from the words, "by one man's diſobedience many were made ſinners;" but likewiſe from the oppoſite clauſe, "ſo by the obedience of One ſhall many be made righteous;" for the many ordained to eternal life, for whom Chriſt died, are made righteous, or juſtified, only through the imputation of his righteouſneſs to them; and therefore it follows, that all men are made ſinners only through the imputation of Adam's diſobedience.

To this doctrine it is ſaid to be no objection that Adam's poſterity were not in being when his ſin was committed: for though they had not then actual being, they had yet a virtual and repreſentative one. They were in him both *ſeminally* and *federally*, and ſinned in him * ; juſt as Levi was in the loins of Abraham, and paid in him tithes to Melchizedeck †. From Adam, as their common parent, they derive a corrupt nature; but it is only from him, as their federal head, that they derive a ſhare of his guilt, and are ſubjected to his puniſhment. That he was a federal head to all his poſterity, the divines of this ſchool think evident from his being called a figure of Chriſt ‡; and the firſt Adam deſcribed as natural and earthly, in contradiſtinction to Chriſt the ſecond Adam deſcribed as ſpiritual and the Lord from heaven; and from the puniſhment threatened againſt his ſin being inflicted not on himſelf only, but on all his ſucceeding offſpring. He could not be a figure of Chriſt, ſay they, merely as a man; for all the ſons of Adam have been men as well as he, and in that ſenſe were as much figures of Chriſt as he; yet Adam and Chriſt are conſtantly contraſted, as though they had been the only two men that ever exiſted, becauſe they were the only two heads of their reſpective offſpring. He could not be a figure of Chriſt on account of his extraordinary production; for though both were produced in ways uncommon, yet each was brought into the world in a way peculiar to himſelf. The firſt Adam was formed of the duſt of the ground; the ſecond, though not begotten by a man, was born of a woman. They did not therefore reſemble each other in the manner of their formation, but in their office as covenant-heads; and in that alone the compariſon between them is exact.

* Rom. v. 12.

† Heb. vii. 9, 10.

115 Adam a federal head to his poſterity.

‡ Rom. v. 14.

116 No cauſe of complaint in this conſtitution of things.

Nor have any of the poſterity of Adam, it is ſaid, reaſon to complain of ſuch a procedure. Had he ſtood in his integrity, they would have been, by his ſtanding partakers of all his happineſs; and therefore ſhould not murmur at receiving evil through his fall. If this do not ſatisfy, let it be conſidered, that ſince God, in his infinite wiſdom, thought proper that men ſhould have a head and repreſentative, in whoſe hands their good and happineſs ſhould be placed, none could be ſo fit for this high ſtation as the common parent, made after the image of God, ſo wiſe, ſo holy, juſt, and good. Laſtly, to ſilence all objections, let it be remembered, that what God gave to Adam as a federal head, relating to himſelf and his poſterity, he gave as the Sovereign of the univerſe, to whom no created being has a right to aſk, "What doſt thou *?

* See Gill's Body of Divinity.

117 St Auguſtine the author of this doctrine.

Such are the conſequences of Adam's fall, and ſuch the doctrine of original ſin, as maintained by the more rigid followers of Calvin. That great reformer, however, was not the author of this doctrine. It had been taught, ſo early as in the beginning of the fifth century, by St Auguſtine, the celebrated biſhop of Hippo (ſee AUGUSTINE); and the authority of that father had made it more or leſs prevalent in both the Greek and Roman churches long before the Reformation. Calvin was indeed the moſt eminent modern divine by whom it has been held in all its rigour; and it conſtitutes one great part of that theological ſyſtem, which, from being taught by him, is now known by the name of *Calviniſm*. Thoſe by whom it is embraced maintain it with zeal, as, in their opinion, forming together with the other tenets of their maſter, the only pure ſyſtem of evangelical truths; but it hath met with much oppoſition in ſome of the Lutheran churches, as well as from private divines in the church of England, and from the great body of Dutch remonſtrants (ſee CALVINISM, ARMINIANS, and SYNOD OF DORT); and of their objections it is now our duty to give a candid view, as well as of the doctrine which they ſubſtitute in its ſtead.

Fall of Adam and its conſequences.

18 Objections to it,

They begin then with alleging, that if it was as ſovereign of the univerſe that God gave to Adam what he received in paradiſe relating to himſelf and his poſterity, Adam could in no ſenſe of the words be a federal head; becauſe, upon this ſuppoſition, there was no covenant. The Sovereign of the Univerſe may unqueſtionably diſpenſe his benefits, or withhold them, as ſeems expedient to his infinite wiſdom; and none of his ſubjects or creatures can have a right to ſay to him, What doſt thou? But the diſpenſing or withholding of benefits is a tranſaction very different from the entering into covenants; and a judgment is to be formed of it upon very different principles. Every thing around us proclaims that the Sovereign of the Univerſe is a being of perfect benevolence; but, ſay the diſciples of the ſchool now under conſideration, the diſpenſation given to Adam in paradiſe was ſo far from being the offſpring of benevolence, that, as it is underſtood by the followers of Calvin, it cannot poſſibly be reconciled with the eternal laws of equity. The ſelf-exiſtent and all-ſufficient God might or might not have created ſuch a being as man; and in either caſe there would have been no reaſon for the queſtion "What doſt thou?" But as ſoon as he determined to create him capable of happineſs or miſery, he would not have been either benevolent or juſt, if he had not placed him in a ſtate where, by his own exertions, he might, if he choſe, have a greater ſhare of happineſs than of miſery, and find his exiſtence, upon the whole, a bleſſing. They readily acknowledge, that the exiſtence of any created being may be of longer or ſhorter duration, according to the good pleaſure of the Creator; and therefore they have no objection to the apoſtolic doctrine, that "in Adam all die:" for immortality being not a debt, but a *free gift*, may be beſtowed upon any terms whatever, and with perfect juſtice withdrawn when theſe terms are not complied with. Between death, however, as it implies a loſs of conſciouſneſs, and the extreme miſery of eternal life in torments, there is an immenſe difference. To death all mankind might juſtly be ſubjected through the offence of one; becauſe they had originally no claim of right to be exempted from it, though that one and they too had remained for ever innocent: but eternal life in torments is a puniſhment which a God of juſtice and benevolence can never inflict but upon perſonal guilt of the deepeſt die. That we can perſonally have incurred guilt from a crime committed ſome thouſands of years before we were born, is impoſſible. It is indeed a notion, if ſuch a notion can be formed, as contrary to Scripture as to reaſon and common ſenſe: for the apoſtle expreſsly informs us *, "that ſin is the tranſgreſſion of ſome law; and the ſin of Adam was the tranſgreſſion of a law which it was never in our power either to obſerve or to break. Another apoſtle † aſſures us, that "where no law is, there is no tranſgreſſion;" but there is now no law, nor has been any theſe 5000 years, forbidding mankind to eat of a particular fruit; for, according to the Calviniſts themſelves ‡, Adam had no ſooner committed his firſt ſin, by which the covenant with him was broken, than he ceaſed to be a covenant-head. The law given

119 As inconſiſtent with the juſtice of God.

* 1 John iii. 4.

† Rom. iv. 15.

‡ Gill's Body of Divinity, book iii. ch. 10.

Fall of Adam, and its conſequences.

given him was no more; the promiſe of life by it ceaſed; and its ſanction, death, took place. But if this be ſo, how is it poſſible that his unborn poſterity ſhould be under a law which had no exiſtence, or that they ſhould be in a worſe ſtate in conſequence of the covenant being broken, and its promiſe having ceaſed, than he himſelf was before the covenant was firſt made? He was originally a mortal being, and was promiſed the ſupernatural gift of immortality on the ſingle condition of his abſtaining from the fruit of the tree of knowledge of good and evil. From that fruit he did not abſtain; but by eating it fell back into his natural ſtate of mortality. Thus far it is admitted that his poſterity fell with him; for they have no claim to a ſupernatural gift which he had forfeited by his tranſgreſſion. But we cannot admit, ſay the divines of this ſchool, that they fell into his guilt; for to render it poſſible for a man to incur guilt by the tranſgreſſion of a law, it is neceſſary not only that he have it in his power to keep the law, but alſo that he be capable of tranſgreſſing it by a *voluntary* deed. But ſurely no man could be capable of voluntarily eating the forbidden fruit 5000 years before he himſelf or his volitions exiſted. The followers of Calvin think it a ſufficient objection to the doctrine of tranſubſtantiation, that the ſame numerical body cannot be in different places at the ſame inſtant of time. But this ubiquity of body, ſay the remonſtrants, is not more palpably abſurd, than the ſuppoſition that a man could exert volitions before he or his will had any exiſtence. If indeed there be any difference between the two caſes, it is in favour of the Catholic doctrine of the real preſence; for we are by no means ſo intimately acquainted with the internal ſubſtance of body, and what can be predicated of it, as we are with the nature of guilt and the exerciſe of volition. Theſe we know thoroughly as they really are in themſelves; the former only relatively as it is ſeen in its qualities.

120 The ſcripture, and the nature of things.

121 The word IMPUTATION removes no difficulties.

Nor will the introduction of the word *imputation* into this important queſtion remove a ſingle difficulty. For what is it that we mean by ſaying that the ſin of Adam is imputed to his poſterity? Is the guilt of that ſin transferred from him to them? So ſurely thought Dr. Gill, when he ſaid that it *is made over to them*. But this is the ſame abſurdity as the making over of the ſenſible qualities of bread and wine to the internal ſubſtance of our Saviour's body and blood! This imputation either found the poſterity of Adam guilty of his ſin, or it made them ſo. It could not find them guilty for the reaſon already aſſigned; as well as becauſe the apoſtle ſays expreſsly, that for the offence of *one* judgment came upon *all* men, which would not be true had *all* offended. It could not make them guilty; for this reaſon, that if there be in phyſics or metaphyſics a ſingle truth ſelf-evident, it is, that the numerical powers, actions, or qualities, of one being cannot poſſibly be transferred to another, and be made its powers, actions, or qualities. Different beings may in diſtant ages have qualities of the ſame kind; but as eaſily may 4 and 3 be made equal to 9, as two beings be made to have the ſame identical quality. In Scripture we nowhere read of the actions of one man being imputed to another. "Abraham (we are told) believed in God, and it was counted to him for righteouſneſs;" but it was his *own* faith, and not the faith of another man, that was ſo counted. "To him that worketh not, but believeth, his faith (not another's) is imputed for righteouſneſs." And of our faith in him that raiſed Chriſt from the dead, it is ſaid, that "it ſhall be imputed, not to our fathers or our children, but to us for righteouſneſs."

122 Meaning of that word in ſcripture.

When this phraſe is uſed with a negative, not only is the man's own perſonal ſin ſpoken of, but the non-imputation of that ſin means nothing more but that it brings not upon the ſinner condign puniſhment. Thus when Shemei "ſaid unto David, Let not my lord *impute* iniquity unto me;" it could not be his meaning that the king ſhould not think that he had offended; for with the ſame breath he added, "Neither do thou remember that which thy ſervant *did perverſely*, the day that my lord the king went out of Jeruſalem, that the king ſhould take it to his *heart*. For thy ſervant doth *know* that *I have ſinned*." Here he plainly confeſſes his ſin, and declares, that by intreating the king not to *impute it to him*, he wiſhed only that it ſhould not be ſo remembered as that the king ſhould take it to heart, and puniſh him as his perverſeneſs deſerved. When therefore it is ſaid*, that "God was in Chriſt reconciling the world to himſelf, not imputing to them their iniquities, the meaning is only that for Chriſt's ſake he was pleaſed to exempt them from the puniſhment due to their ſins. In like manner, when the prophet, foretelling the ſufferings of the Meſſiah, ſays, that "the Lord laid on him the iniquity of us all," his meaning cannot be, that the Lord by *imputation* made his immaculate Son guilty of all the ſins that men have ever committed; for in that caſe it would not be true that the "juſt ſuffered for the unjuſt," as the apoſtle expreſsly teaches §: but the ſenſe of the verſe muſt be as Biſhop Coverdale tranſlated it, "through him the Lord pardoneth all our ſins." This interpretation is countenanced by the ancient verſion of the Seventy, και Κυριος παρεδωκεν αυτον τας αμαρτιας ημων; words which expreſs a notion very different from that of imputed guilt. The Meſſiah was, without a breach of juſtice, delivered for ſins of which he had voluntarily offered to pay the penalty; and St Paul might have been juſtly charged by Philemon with the debts of Oneſimus, which he had deſired might be placed to his account. Had the apoſtle, however, expreſſed no ſuch deſire, ſurely Philemon could by no deed of his have made him liable for debts contracted by another; far leſs could he by *imputation*, whatever that word may mean, have made him virtually concur in the contracting of thoſe debts. Juſt ſo it ſeems to be with reſpect to the ſufferings of Chriſt for the ſins of men: He could not have been juſtly ſubjected to ſuffering without his own conſent; and he could not poſſibly have been made guilty of the ſins of thoſe for whom he ſuffered.

* 2 Cor. v. 19.

§ 1 Peter iii. 18.

The doctrine of imputed guilt therefore, as underſtood by the Calviniſts, is, in the opinion of their opponents, without foundation in Scripture, and contrary to the nature of things. It is an impious abſurdity (ſay they), to which the mind can never be reconciled by the hypotheſis, that all men were in Adam both ſeminally and federally, and ſinned in him, as Levi paid tithes to Melchizedeck in the loins of Abraham. The apoſtle, when he employs that argument to leſſen in the minds of his countrymen the pride of birth and the lofty opinions entertained of their prieſthood, plainly intimates, that he was uſing a bold figure, and that Levi's paying tithes is not to be underſtood in a ſtrict and literal ſenſe. "Now conſider (ſays he) how great this man was, unto whom even the patriarch Abraham gave the tenth of his ſpoils. And, *as I may ſo ſay*, Levi alſo, who receiveth tithes, paid tithes in Abraham: for he was yet in the loins of his father when Melchizedeck met him." This is a very good argument to prove that the Levitical prieſthood was inferior in dignity to that of Melchizedeck; and by the apoſtle it is employed for no other purpoſe. Levi could not be greater than Abraham, and yet Abraham was inferior to Melchizedeck. This is the whole of St Paul's reaſoning, which lends no ſupport to the doctrine of original ſin, unleſs it can be ſhown that Levi and all his deſcendants contracted from this circumſtance ſuch a ſtrong propenſity to the *paying* of tithes, as made it a matter of extreme difficulty for them, in every ſubſequent generation,

123 Moral guilt cannot be tranſmitted from father to ſon.

Fall of Adam, and its conſequences.

to comply with that part of the divine law which conſtituted them *receivers* of tythes. That all men were ſeminally in Adam, is granted; and it is likewiſe granted that they may have derived from him, by ordinary generation, diſeaſed and enfeebled bodies: but it is as impoſſible to believe that moral guilt can be tranſmitted from father to ſon by the phyſical act of generation, as to conceive a ſcarlet colour to be a cube of marble, or the ſound of a trumpet a cannon ball. That Adam was as fit a perſon as any other to be entruſted with the good and happineſs of his poſterity, may be true; but there is no fitneſs whatever, according to the Arminians, in making the everlaſting happineſs or miſery of a whole race depend upon the conduct of any fallible individual. "That any man ſhould ſo repreſent me (ſays Dr Taylor*), that when he is guilty, I am to be reputed guilty; when he tranſgreſſes, I ſhall be accountable and puniſhable for his tranſgreſſion; and this before I am born, and conſequently before I am in any capacity of knowing, helping, or hindering, what he doth: all this every one who uſeth his underſtanding muſt clearly ſee to be falſe, unreaſonable, and altogether inconſiſtent with the truth and goodneſs of God." And that no ſuch appointment ever had place, he endeavours to prove, by ſhowing that the texts of Scripture upon which is built the doctrine of the Calviniſts reſpecting original ſin, will each admit of a very different interpretation.

* Doctrine of Original Sin, part iii.

124 The ſeveral texts on which this doctrine is built capable of a different interpretation.

One of the ſtrongeſt of theſe texts is Romans v. 19. which we have already quoted, and which our author thus explains. He obſerves, that the apoſtle was a Jew, familiarly acquainted with the Hebrew tongue; that he wrote his epiſtle as well for the uſe of his own countrymen reſiding in Rome, as for the benefit of the Gentile converts; and that though he made uſe of the Greek language, as moſt generally underſtood, he frequently employed Hebrew idioms. Now it is certain that the Hebrew words חטאה and עון, "ſin and iniquity," are frequently uſed in the Old Teſtament to ſignify *ſuffering*, by a figure of ſpeech which puts the effect for the cauſe; and it is ſurely more probable, that in the verſe under conſideration, the apoſtle uſed the correſponding Greek word ἁμαρτωλοι in the ſame Hebrew ſenſe, than that he meant to contradict what he had ſaid in the former verſe, by teaching that all men were made guilty of an act of diſobedience committed thouſands of years before the majority of them had any being. In the preceding verſe he ſays, "that by the offence of one, judgment came upon all men to condemnation." But this cannot be true, if by that offence all men were made ſinners; for then judgment muſt have come upon each for his own ſhare in the original diſobedience. "Any one may ſee (ſays our author) that there is a vaſt difference between a man's making *himſelf* a ſinner by his *own* wicked act, and his being made a ſinner by the wicked act of *another*. In the latter caſe, he can be a ſinner in no other ſenſe but as he is a ſufferer; juſt as Lot would have been made a ſinner with the Sodomites, had he been conſumed in the iniquity of the city § ; and as the ſubjects of Abimelech would have been made ſinners, had he, in the integrity of his heart, committed Adultery with Abraham's wife*. That the people of Gerar could have contracted any real guilt from the adultery of their ſovereign, or that he, by lying with a woman whom he had reaſon to believe to be not the wife but the ſiſter of another man, would have incurred all the moral turpitude of that crime, are poſitions which cannot be maintained. Yet he ſays, that Abraham had brought upon him and on his kingdom a *great ſin*; though it appears, from comparing the 6th verſe with the 17th and 18th, that he had not been brought under ſin in any other ſenſe than as he was made to ſuffer for taking Sarah into his houſe. In this ſenſe, "Chriſt, though we are ſure that he knew no ſin, was made ſin for us, and numbered with the tranſgreſſors," becauſe he ſuffered death for us on the croſs; and in this ſenſe it is true, that by the diſobedience of Adam all mankind were made ſinners, becauſe, in conſequence of his offence, they were by the judgment of God made ſubject to death.

§ Gen. xix. 15.

* Gen. xx.

Fall of Adam, and its conſequences.

But it may be thought that this interpretation of the words *ſin* and *ſinners*, though it might perhaps be admitted in the 19th verſe, cannot be ſuppoſed to give the apoſtle's real meaning, as it would make him employ in the 12th verſe an abſurd argument, which has been already noticed. But it may perhaps be poſſible to get quit of the abſurdity, by examining the original text inſtead of our tranſlation. The words are, και ουτως εις παντας ανθρωπους ο θανατος διηλθεν εφ ω παντες ημαρτον. In order to aſcertain the real ſenſe of theſe words, the firſt thing to be done is to diſcover the antecedent to the relative ω. Our tranſlators ſeem to conſider it as uſed abſolutely without any antecedent; but this is inaccurate, as it may be queſtioned whether the relative was ever uſed in any language without an antecedent either expreſſed or underſtood. Accordingly, the Calviniſt critics, and even many Remonſtrants, conſider ενος ανθρωπου in the beginning of the verſe as the antecedent to ω in the end of it, and tranſlate the clauſe under conſideration thus: "And ſo death hath paſſed upon all men, in whom (*viz.* Adam) all have ſinned." θανατος, however, ſtands much nearer to ω than ανθρωπου; and being of the ſame gender, ought, we think, to be conſidered as its real antecedent; but if ſo, the clauſe under conſideration ſhould be thus tranſlated: "and ſo death hath paſſed upon all men, unto which (o) all have ſinned, or, as the Arminians explain it, have ſuffered. If this criticiſm be admitted as juſt, εφ' ω muſt be conſidered as ſtanding here under a particular emphaſis, denoting the utmoſt length of the conſequences of Adam's ſin (p); as if the apoſtle had ſaid, "ſo far have the conſequences of Adam's ſin extended, and ſpread their influence among mankind, introducing not only a curſe upon the earth, and ſorrow and toil upon its inhabitants, but even DEATH, UNIVERSAL DEATH, in every part, and in all ages of the world." His words (ſay the Remonſtrants) will unqueſtionably bear this ſenſe; and it is ſurely much more probable that it is their true ſenſe, than that an inſpired writer ſhould have taught a doctrine ſubverſive of all our notions of right and wrong, and which, if really embraced, muſt make us incapable of judging when we are innocent and when guilty.

When the apoſtle ſays that there is none righteous, no not one, he gives us plainly to underſtand that he is quoting from the 14th Pſalm; and the queſtion to be firſt anſwered is, In what ſenſe were theſe words uſed by the Pſalmiſt?

(o) That επι, when conſtrued with a dative caſe, often ſignifies *to* or *unto*, is known to every Greek ſcholar. Thus επ' ευδοξια ὁδος, *the way to fame*, (Lucian.) Κακουργος επι τω θανατω, *a criminal unto death*, (Demoſth.) Επι θανατω συλλαβειν, *to carry to death or execution*, (Iſoc.) Υμεις επ ελευθερια εκληθητε, *ye have been called to liberty*, (Gal. 5. 13.) Κτισθεντες εν Χριστω Ιησου επι εργοις αγαθοις, *created in Chriſt Jeſus unto good works*, (Epheſ. ii. 10.) See alſo 1 Theſ. iv. 7.; 2 Tim. ii. 14.; and many other places of the New Teſtament.

(p) Εφ' ω has likewiſe this import, denoting the *terminus ad quem* in Phil. iii. 12. and iv. 10.

Fall of Adam, and its consequences.

miſt? That they were not meant to include all the men and women then living, far leſs that have ever lived, is plain from the fifth verſe of the ſame Pſalm, where we are told that thoſe wicked perſons "were in great fear becauſe God was in the congregation of the *righteous*." There was then, it ſeems, a congregation of righteous perſons, in oppoſition to thoſe called the *children of men*, of whom alone it is ſaid that there was none that did good, no not one. The truth is, that the perſons of whom David generally complains in the book of Pſalms, conſtituted a ſtrong party diſaffected to his perſon and government. That faction he deſcribes as proud and oppreſſive, as deviſing miſchief againſt him, as violent men continually getting together for war. He ſtyles them his *enemies*; and ſometimes characterizes them by the appellation which was given to the apoſtate deſcendants of Cain before the deluge. Thus in the 57th Pſalm, which was compoſed when he fled from Saul to the cave in which he ſpared that tyrant's life, he complains, "I lie among them that are ſet on fire, even the SONS OF MEN, whoſe teeth are ſpears," &c.; and again in the 58th Pſalm, he ſays, "Do ye indeed ſpeak righteouſneſs, O congregation? Do ye judge uprightly, O ye ſons of men?" By comparing theſe texts with 1 Sam. xxvi. 19. it will appear evident beyond diſpute, that by the SONS OF MEN mentioned in them, he meant to characterize thoſe enemies who exaſperated Saul againſt him. Now it is well known, that there was a party adhering to the intereſts of the houſe of Saul which continued its enmity to David during the 40 years of his reign, and joined with Abſalom in rebellion againſt him only eight years before his death. But it is the opinion of the moſt judicious commentators§, that the 14th Pſalm was compoſed during the rebellion of Abſalom; and therefore it is ſurely much more probable, that by *the children of men*, of whom it is ſaid "there is none that doth good, no not one," the inſpired poet meant to characterize the rebels, than that he ſhould have directly contradicted himſelf in the compaſs of two ſentences ſucceeding each other. Had he indeed known that all the children of men, as deſcending from Adam, "are utterly indiſpoſed, diſabled, and made oppoſite to all that is ſpiritually good, and wholly and continually inclined to all evil," he could not with the leaſt degree of conſiſtency, have repreſented the Lord as looking down from heaven upon them, to ſee if there were any that did underſtand and ſeek after God;" but if by the children of men was meant only the rebel faction, this ſcenical repreſentation is perfectly conſiſtent, as it was natural to ſuppoſe that there might be in that faction ſome men of good principles miſled by the arts of the rebel chiefs.

§ Hammond, &c.

Having thus aſcertained the ſenſe of the words as originally uſed by the Pſalmiſt, the Arminian proceeds to inquire for what purpoſe they were quoted by the apoſtle; and in this inquiry he ſeems to find nothing difficult. The averſion of the Jews from the admiſſion of the Gentiles to the privileges of the goſpel, the high opinion which they entertained of their own worth and ſuperiority to all other nations, and the ſtrong perſuaſion which they had that a ſtrict obedience to their own law was ſufficient to juſtify them before God, are facts univerſally known; but it was the purpoſe of the apoſtle to prove that all men ſtood in need of a Redeemer, that Jews as well as Gentiles had been under the dominion of ſin, and that the one could not in that reſpect claim any ſuperiority over the other. He begins his epiſtle, therefore, with ſhewing the extreme depravity of the Heathen world; and having made good that point, he proceeds to prove by quotations from the book of Pſalms, Proverbs, and Iſaiah, that the Jews were in nowiſe better than they, that every mouth might be ſtopped, and all the world become guilty, or inſufficient for their own juſtification before God.

Fall of Adam, and its conſequences.

The next proof brought by the Calviniſts in ſupport of their opinion, that all men derive guilt from Adam by ordinary generation, is that text in which St Paul ſays that the Epheſians were by *nature* children of wrath even as others." To this their opponents reply, that the doctrine of original ſin is in this verſe, as in the laſt quoted, countenanced only by our tranſlation, and not by the original Greek as underſtood by the ancient fathers of the Chriſtian church, who were greater maſters of that language than we. The words are και ημεν τεκνα φυσει οργης; in which it is obvious, that τεκνα, though in its original ſenſe it ſignifies the genuine children of parents by natural generation, cannot be ſo underſtood here; becauſe no man was ever begotten by, or born of, the abſtract notion *wrath*. It muſt therefore be uſed figuratively; and in other places of Scripture it often denotes a cloſe relation to any perſon or thing. Thus we read of the children of *God*, of the *kingdom*, the *reſurrection*, *wiſdom*, *light*, *obedience*, and *peace*; whence it is concluded, that by the children of wrath are meant thoſe who are liable to puniſhment or rejection. And becauſe there were in thoſe days ſome children, in a lower and leſs proper ſenſe, by *adoption*, and others, in a higher and more proper ſenſe, by *natural generation*, of whom the relation of the latter to their parents was much cloſer than that of the former; the apoſtle tells the Epheſians, that they were by *nature* children of wrath, to convince them that they were *really* liable to it by the ſtricteſt and cloſeſt relation poſſible. That the word φυσει here is of the ſame import with *really* or *truly*, and that it does not ſignify what we mean by *nature* in the proper ſenſe of that word, the ancient fathers are generally agreed*; and that the modern Greeks, who ſtill ſpeak a dialect of the noble language of their anceſtors, underſtand the word in the ſame ſenſe, is apparent from their verſion of the text before us. In the moſt correct and elegant edition of the New Teſtament in their vernacular tongue, the words under conſideration are thus rendered; και φυσικα ημασθαν τεκνα οργης ωσαν και οι λοιποι, where it is impoſſible that φυσικα can ſignify *natural*, otherwiſe the apoſtle will be made to ſay, not that we are by the nature derived from Adam liable to wrath, but that we were *naturally begotten* by *wrath* in the abſtract! For taking the word φυσει in the ſenſe of *really* or *truly*, both the ancient and modern Greeks appear indeed to have the authority of St Paul himſelf; who, writing to Timothy, calls him γνησιον τεκνον "his true or genuine ſon;" not to ſignify that he was the child of the apoſtle by natural generation, but that he was cloſely related to him in the faith to which St Paul had converted him. That the words τεκνα φυσει οργης can ſignify nothing but *truly* or *really relations to wrath*, is ſtill farther evident from the ground aſſigned of that relation. It is not the ſin of Adam, or the impurity of natural generation, "but the treſpaſſes and ſins in which the Epheſians in time paſt *walked*, according to the courſe of the world, according to the prince of the power of the air," the ſpirit that at the time of the apoſtle's writing "worked in the children of diſobedience." Surely no man can ſuppoſe that the Epheſians at any paſt time *walked* in Adam's treſpaſs and ſin, or that the prince of the power of the air tempted *them* to eat the forbidden fruit.

* See Hammond and Whitby on the Text, and Suidas on the word φυσις

Having thus commented on the principal texts which are cited from the New Teſtament to prove the doctrine of original ſin, the Arminians treat thoſe which are quoted from the Old Teſtament, in ſupport of the ſame doctrine, with much leſs ceremony. Thus, when Job ſays, "who

can

Fall of Adam and its consequences.

can bring a clean thing out of an unclean? Not one," he is ſpeaking, ſay they, not of the pravity of our nature, but of its frailty and weakneſs, of the ſhortneſs and miſery of human life. The ſentence is proverbial; and as it is uſed only to ſignify, that nothing can be more perfect than its original, it muſt, whenever it occurs, be underſtood according to the ſubject to which it is applied. That in the place under conſideration it refers to our mortality, they think plain from the context; and Dr Taylor adds*, with ſome plauſibility, that if the words refer to the guilt which we are ſuppoſed to derive from Adam, they will prove too much to ſerve the common ſcheme of original ſin. They will prove that our natural and inherent pravity, ſo far from rendering us fit ſubjects of wrath, may be urged as a reaſon why God ſhould not even bring us into judgment; for the patriarch's whole expoſtulation runs thus, "Doſt thou open thine eyes upon ſuch a one, and bringeſt me into judgment with thee? Who can bring a clean thing out of an unclean?"

* Scripture Doctrine, part ii.

The other text quoted from the ſame book, they think ſtill leſs to the purpoſe; for Eliphaz is evidently contraſting the creature with the Creator; in compariſon with whom, he might well ſay, without alluding to original guilt, "what is man that he ſhould be clean? and he who is born of a woman that he ſhould be righteous? Behold he putteth no truſt in his ſaints; yea the *heavens* are not clean in his ſight. How much more abominable and filthy is man, who drinketh iniquity like water?" He does not ſay, who derives by birth an iniquitous nature; for he knew well, that as we are born, we are the pure workmanſhip of God, "whoſe hands have faſhioned and formed every one of us;" but "who *drinketh* iniquity like water," who maketh himſelf iniquitous by running headlong into every vicious practice.

Of the text quoted from the fifty-firſt Pſalm in ſupport of the doctrine of original ſin, Dr Taylor labours†, by a long and ingenious criticiſm, to prove that our tranſlators have miſtaken the ſenſe. The word which they have rendered *ſhapen*, he ſhews to be uſed once by Iſaiah, and twice in the book of Proverbs, to ſignify *brought forth*; and that which is rendered *conceived me*, is never, he ſays, employed in ſcripture, to denote human conception. In this laſt remark, however, he is contradicted by a great authority, no leſs indeed than that of Mr Parkhurſt‡, who ſays, that the LXX conſtantly render it by κισσαω or εγκισσαω, and the Vulgate generally by *concipio*. Without taking upon us to decide between theſe two eminent Hebrew ſcholars, we ſhall only obſerve, that upon one occaſion ‖ it certainly denotes ideas much groſſer than thoſe which the Pſalmiſt muſt have had of his mother's conception; and that there, at leaſt, Dr Taylor properly tranſlates it *incaleſcebant*, adding, "de hoc vero incaleſcendi genere loqui Davidem nemo ſanus exiſtimare poteſt. Matrem enim incaluiſſe, aut ipſum calefeciſce eo modo quo incaleſcerent Jacobi pecudes Regem dicere, prorſus indecorum et abſurdum." He contends, however, that the original force of the word is *to be hot*, and that it is applied to *conception*, to *reſentment*, to *warmth* by which the body is nouriſhed, to *idolaters* in love with idols, and to the heat of metals. The heat of idolaters, of reſentment, and of metals, are evidently foreign to the Pſalmiſt's purpoſe; and the idea conveyed by the word *incaleſcere* being ſet aſide for the reaſons already aſſigned, there remains only the warmth by which the body is nouriſhed, and of that warmth our author is confident that David ſpoke.

† Ubi Supra.

‡ See his Lexicon on the word יחם

‖ Gen. xxx. 38, 39, 40, compared with xxxi. 10.

If this criticiſm be admitted, the whole verſe will then run thus: "Behold I was born in iniquity, and in ſin did my mother nurſe me;" which hath no reference to the original formation of his conſtitution, but is a periphraſis of his being a *ſinner from the womb*, and means nothing more than that he was a *great ſinner*, or had contracted *early habits* of ſin. He no more deſigned to ſignify in this verſe, that by ordinary generation he had a nature conveyed to him which was "utterly indiſpoſed, diſabled, and oppoſite to all that is ſpiritually good, and wholly and continually inclined to evil," than he meant in another ‡ to ſignify ſtrictly and properly that the wicked are eſtranged from the womb, and TELL LIES as ſoon as they are born;" or than Job meant to ſignify ‖, that from the moment he came from his mother's womb he had been a guide to the widow and a ſuccour to the fatherleſs. All theſe are hyperbolical forms of expreſſion; which, though they appear ſtrained, and perhaps extravagant, to the phlegmatic inhabitants of Europe, are perfectly ſuited to the warm imaginations of the orientals, and to the genius of eaſtern languages. They mean not that Job was *born* with *habits* of *virtue*, that the wicked actually *walked*, and *ſpoke*, and *ſpoke lies* from the inſtant of their *birth*, or that the Pſalmiſt was really *ſhapen* in *ſin*, and *conceived in iniquity*. This laſt ſentence, if interpreted literally, would indeed be groſsly impious: it would make the inſpired penman throw the whole load of his iniquity and ſin from off himſelf upon *him* who ſhaped and upon *her* who conceived him; even upon that God "whoſe hands had made him and faſhioned him, and whom he declares that he will praiſe for having made him fearfully and wonderfully," and upon that parent who conceived him with ſorrow, and brought him forth with pain, and to whom the divine law commanded him to render honour and gratitude. "But if, after all (ſays Dr Taylor*), you will adhere to the literal ſenſe of the text for the common doctrine of *original ſin*, ſhew me any good reaſon why you ought not to admit the literal ſenſe of the text, *this is my body* for *tranſubſtantiation?* If you ſay, it is abſurd to ſuppoſe that Chriſt ſpeaks of his real natural body; I ſay, it is likewiſe abſurd to ſuppoſe that the Pſalmiſt ſpeaks of his being really and properly ſhapen in iniquity, and conceived in ſin. If you ſay, that the ſenſe of the words *this is my body* may be clearly explained by other texts of ſcripture where the like forms of ſpeech are uſed; I ſay, and have ſhewn, that the Pſalmiſt's ſenſe may as clearly and evidently be made out by parallel texts, where you have the like kind of expreſſion. If you ſay that tranſubſtantiation is attended with conſequences hurtful to piety, I ſay that the common doctrine of original ſin is attended with conſequences equally hurtful; for it is a principle apparently leading to all manner of iniquity to believe that ſin is natural to us, that it is interwoven and ingrafted into our very conſtitution from our conception and formation in the womb."

‡ Pſ. lviii. 3.

‖ Job xxxi. 18.

* Scripture Doctrine, part ii.

125 Conſequences of eating the forbidden fruit, according to the Arminians.

The Arminians having thus, as they think, proved that the poſterity of Adam are not in any ſenſe rendered guilty by his ſin, contend, that the death threatened againſt his eating of the forbidden fruit, and which, in conſequence of his tranſgreſſion, came upon all men, can mean nothing more than the loſs of that vital principle which he received when God breathed into his noſtrils the breath of life, and he became a living ſoul. Every thing beyond this is pure conjecture, which has no foundation in the ſcriptures of truth, and is directly contrary to all the notions of right and wrong which we have been able to acquire from the ſtudy of thoſe very ſcriptures. It is not conceivable from any thing in the hiſtory, that Adam could underſtand it of the loſs of any other life than that which he had lately received, for no other life is ſpoken of to which the threatened death can be oppoſed; and in ſuch circumſtances it was

ſtrange

Fall of Adam, and its conſequences.

ſtrange indeed, if by the word *death* he underſtood either eternal life in miſery, or a neceſſity of continuing in ſin. The ſenſe therefore of the threatening, ſay they, is this; "I have formed thee of the duſt of the ground, and breathed into thy noſtrils the breath of life; and thus thou art become a living ſoul. But if thou eateſt of the fruit of the tree of knowledge of good and evil, thou ſhalt ceaſe to be a living ſoul; for I will take from thee the breath of life, and thou ſhalt return to the duſt of which thou waſt formed."

126 Some of them admit the depravity of human nature.

Thus far the Arminians of the preſent day (q) are agreed in oppoſing the doctrine of the rigid Calviniſts, and in ſtating their own notions of the conſequences of Adam's fall; but from that event their adverſaries deduce one conſequence, which ſome of them admit and others deny. It is ſaid, that though we cannot poſſibly be partakers in Adam's guilt, we yet derive from him a moral taint and infection, by which we have a natural propenſity to ſin; that having loſt the image of God, in which he was created, Adam begat ſons in his own image; and in one word, that the ſenſual appetites of human nature were inflamed, and its moral and intellectual powers greatly weakened by the eating of the forbidden fruit. The heathens themſelves acknowledged and lamented this depravity, though they were ignorant of the ſource from which it ſprung. The ſcriptures aſſert it, affirming that no man can be born pure and clean; that whatever is born of the fleſh, or comes into the world by ordinary generation, is fleſh, carnal and corrupt; that the imagination of the thoughts of man's heart is only evil continually; that the heart is deceitful above all things and deſperately wicked; and that out of it proceeds all that is vile and ſinful ‖.

‖ Job xiv. 4. John iii. 6. Rom. iii. 9. Gen. vi. 5. Jer. xvii 9. Mat. xv. 19

127 And illuſtrate it upon principles of natural knowledge.

This depravity of human nature, thus clearly deducible from ſcripture, and confirmed by the teſtimony of ages, an ingenious writer of the moderate Arminian ſchool undertakes to illuſtrate upon the principles of natural knowledge. "We know (ſays he †), that there are ſeveral fruits in ſeveral parts of the world of ſo noxious a nature as to deſtroy the beſt human conſtitution upon earth. We alſo know that there are ſome fruits in the world which inflame the blood into fevers and frenzies; and we are told that the Indians are acquainted with a certain juice, which immediately turns the perſon who drinks it into an idiot, leaving him at the ſame time in the enjoyment of his health and all the powers of this body. Now I aſk, Whether it is not poſſible, nay whether it is not rational, to believe, that the ſame fruit, which, in the preſent infirmity of nature, would utterly deſtroy the human conſtitution, might, in its higheſt perfection, at leaſt diſturb, impair, and diſeaſe it? and whether the ſame fruit, which would now inflame any man living into a fever or a frenzy, might not inflame Adam into a turbulence and irregularity of paſſion and appetite? and whether the ſame fluids, which inflame the blood into irregularity of paſſion and appetite, may not naturally produce infection and impair the conſtitution? That the forbidden fruit had the effect to produce irregularity of appetite, appears as from other proofs, ſo I think fully and clearly from the covering which Adam and Eve made uſe of ſoon after their offence; for there is no imaginable reaſon for that covering but one, and that one ſufficiently demonſtrates, that irregularity and violence of appetite, independent of the dominion of reaſon, was the effect of their offence. But the fruit which inflamed the ſenſual appetite might likewiſe debaſe their rational powers; for I aſk, whether the ſame juice, which now affects the brain of an ordinary man ſo as to make him an idiot, might not affect the brain of Adam ſo as to bring his underſtanding down to the preſent ſtandard of ordinary men? And if this be poſſible, and not abſurd to be ſuppoſed, it is evident that the ſubſequent ignorance and corruption of human nature may be clearly accounted for upon theſe ſuppoſitions; nay, I had almoſt ſaid upon any one of them. For it is univerſally known, that the infections and infirmities of the father affect the children yet in his loins; and if the mother be equally infected, muſt, unleſs removed by proper remedies, affect their poſterity to the end of the world, or at leaſt till the race become extinct. Therefore why all mankind might not by their firſt father's ſin be reduced to the ſame condition of infirmity and corruption with himſelf, eſpecially when the mother was equally infirm and infected, I believe no man any way ſkilled in the knowledge of nature will ſo much as pretend to ſay."

† Delany's Revelation examined with candour, Diſſert. 1. and 7.

This account of the corruption of human nature ſeems to be generally adopted by moderate divines, as well among the Calviniſts as among the Arminians; but by the high-fliers in both ſchools it is rejected, upon different principles indeed, with great indignation. The zealous Calviniſt contends, that this hereditary corruption is not to be accounted for or attempted to be explained by any principle of phyſical ſcience, ſince it is part of that puniſhment which was inflicted on the race for their original ſin. If we were not partakers of Adam's guilt, ſay they, we ſhould not have been partakers of his corruption. The one is previous to the other, and the foundation of it. The depravity of human nature is a puniſhment for ſin; and ſo it was threatened to Adam, and came upon him as ſuch, and ſo to all his poſterity, by the *ordination* and *appointment of God*; for which there can be no other foundation but the imputation of Adam's diſobedience to them, nor can any thing elſe vindicate the righteouſneſs of God. For if the law of nature

Fall of Adam, and its conſequences.

(q) We ſay the Arminians of the *preſent day*; becauſe in the beginning of this century many of them having imbibed the ſcholaſtic notion of the *natural* and *eſſential* immortality of the ſoul, ſeem to have been at a loſs to conceive how it was to have been diſpoſed of, had there been no redemption from Adam's curſe. They were perſuaded, that for his ſin the ſouls of his poſterity did not deſerve eternal puniſhment; and as eternal *life* is every where in the New Teſtament repreſented as the gift of God through Jeſus Chriſt, they thus expreſſed themſelves concerning the death incurred by the fall of Adam. "It is well to be obſerved, that the *death* wherewith God threatened man as his puniſhment if he broke the covenant, is not in reaſon to be underſtood of *eternal death*, any farther than as by eternal death may be ſignified only the *eternal ſeparation* of the *ſoul from the body*, and alſo the *eternal excluſion* of the *ſoul from God*, or *heavenly bliſs*." That the death threatened implied the annihilation of the ſoul, ſeems never to have occurred to them, though the apoſtle expreſsly ſays, that if there be no reſurrection, "then they who are fallen aſleep in Chriſt are periſhed, απωλοντο "are loſt." They ſuppoſed that the ſin of Adam would have ſeparated the ſoul from the body, and excluded the former both from heaven and from hell; but what would have become of it in that ſtate of excluſion, both from future happineſs and future miſery, we do not remember at preſent that any one of them has hazarded a conjecture. See *Dr Well's Help for the Right Underſtanding of the Several Divine Laws and Covenants*; and biſhop Bull's *Harmonica Apoſtolica*, with its ſeveral defences.

Fall of Adam, and its consequences.

ture was sufficient, why should this *original* taint infect men rather than the sins of their immediate parents †?"

† Gill's Body of Divinity, book iii. ch. 10, 11. and 13.

The more violent Arminians, on the other hand, deny that we inherit any moral taint whatever from Adam, or that the rational powers of our minds are naturally weaker than his were. Of that wonderful degree of perfection which is usually attributed to the first pair, they find no evidence in scripture. All that we learn of them, say they, is, that they fell from a state of exquisite happiness by yielding to a temptation less powerful by far than some others which many of their degenerate sons have successfully resisted. " I leave you to judge (says Dr Taylor ‡), whether Joseph, when he resisted the solicitations of his mistress, and Moses when he refused to be called the son of Pharaoh's daughter, choosing rather to suffer affliction with the people of God than to enjoy the pleasures of sin for a season, esteeming the reproach of true religion greater riches than the treasures of Egypt, did not exhibit proofs of regularity of passions and appetites equal at least to what Adam displayed in the garden of Eden. When the three young men mentioned in the book of Daniel submitted to be burnt alive in a fiery furnace rather than worship Nebuchadnezzar's golden image; when Daniel himself resolved, rather than conceal the worship of God for one month only for his life, to be torn in pieces by hungry lions; and, to come nearer to our own times, when numbers of men and women, during the reign of Mary Queen of England, chose rather to be burnt at a stake than renounce the reformed religion and embrace the errors of popery—surely all these persons exhibited a virtue, a faith in God, and a steady adherence to what they believed to be the truth, far superior to what Adam displayed, when his wife gave him of the forbidden fruit, and he did eat." If it be said that these persons were supported under their trials by the grace of God strengthening them, the same will be said of Adam. He was undoubtedly supplied with every aid from the spirit of grace which was necessary to enable him to fulfil his duty; for being designed for more than mere animal life, even for the refined enjoyments of heaven, there is every reason to believe, as we have already observed, that he was put under the guidance of the Holy Ghost, to train him for that supernatural state of felicity. These communications of the spirit would of course be withdrawn when he forfeited his right to those privileges, on account of which they were originally vouchsafed to him; but that any positive malignity or taint was infused into his nature, that his mere rational powers were weakened, or his appetites inflamed by the forbidden fruit, there is no evidence to be found in scripture, or in the known constitution of things. The attributing of this supposed hereditary taint to the noxious qualities of the forbidden fruit, is a whimsical hypothesis, which receives no countenance from any well authenticated fact in natural history. After the numberless falsehoods that have been told of the poison tree of Java (see *Poison Tree*), something more would be requisite than the common evidence of a lying voyager to give credit to the qualities of the Indian tree, of which the fruit instantly turns the wisest man into an idiot: and yet for this singular story our ingenious author vouchsafes not even that evidence, slight as it generally is. The inference drawn from the covering used by our first parents is contradicted by every thing that we know of human nature; for surely no man, inflamed to the utmost with the fire of animal love, ever turned his eyes from a naked beauty ready and eager to receive him to her embrace. Yet this, it seems, was the behaviour of Adam and Eve in such a state! According to our author, the juice of the forbidden fruit had rendered their carnal appetites violent and independent of reason; according to the scripture, they were both naked; and as they were husband and wife, there was no law prohibiting them from gratifying these inflamed appetites. In such circumstances, how did they conduct themselves? One would naturally imagine that they immediately retired to some shady grove, and pleased themselves in all the soft dalliancies of wedded love. Their conduct, however, was very different. We are told, that " they sewed fig-leaves together, and made themselves aprons to cover their nakedness:" And this transaction is brought as a proof of the impetuosity of their carnal appetites (R). The truth is, that the carnal appetite appears not to be naturally more violent than is necessary to answer the end for which it was implanted in the human constitution. Among savages the desires of animal love are generally very moderate; and even in society they have not often, unless inflamed by the luxurious arts of civil life, greater strength than is requisite to make mankind attend to the continuation of their species. In the decline of empires highly polished, where the difference of rank and opulence is great, and where every man is ambitious of emulating the expence of his immediate superiors, early marriages are prevented by the inability of most people to provide for a family in a way suitable to what each is pleased to consider as his proper station; and in that state of things the violence of animal love will indeed frequently produce great irregularities. But for that state of things, as it was not intended by the Author of nature, it is perhaps unreasonable to suppose that provision should be made; and yet we believe it will be found, upon due consideration, that if the desires of animal love were less violent than they are, the general consequences would be more pernicious to society than all the irregularities and vices which these desires now accidentally produce; for there would then be no intercourse between the sexes whatever except in the very highest stations of life. That our constitution is attended with many sensual appetites and passions, which, if suffered to grow excessive or irregular, become sinful, is true; and that there is great danger of their becoming excessive and irregular in a world so full of temptation as ours is, is also true; but there is no evidence that all this is the consequence of Adam's fall, and far less that it amounts to a *natural propensity* to sin. " For I presume (says Dr Taylor, that by a natural propensity is meant a necessary inclination to sin, or that we are necessarily sinful from the original bent and bias of our natural powers. But this must be false; for then we should not be

‡ Scripture Doctrine, &c.

128 Whilst others reject the doctrine

129 And deem the physical illustration of it whimsical.

Fall of Adam, and its consequences.

130 Maintaining that we have no natural propensity to sin.

(R) We have never met with a satisfactory reason for the expedient of these fig-leave-coverings. To us the following has sometimes occurred as an account of the matter, at least more plausible than that which has been assigned by Dr Delany. Persons under the agonies of remorse, or with the prospect of immediate death before them, have no relish for the pleasures of love; and as our first parents, upon eating the forbidden fruit, must have been in the one or other of these situations, they might think of sewing fig-leaves together, and making themselves aprons, as a mean of subduing an appetite, of which, at that instant, they must have abhorred the gratification. If they had any hope of a reprieve from death, and yet knew all the consequences of their sin, their most ardent wish would be to have no children; and not being acquainted as we are with the effects of dress, they would naturally imagine that their proposed coverings would diminish the force of the sexual appetite.

Fall of Adam, and its conſequences.

be ſinful at all, becauſe that which is neceſſary, or which we cannot help, is not ſin. That we are weak and liable to temptation, is the will of God holy and good, and for glorious purpoſes to ourſelves; but if we are wicked, it muſt be through our own fault, and cannot proceed from any conſtraint, or neceſſity, or taint in our conſtitution."

Thus have we given as full and comprehenſive a view as our limits will permit of the different opinions of the Calviniſts and Arminians reſpecting the conſequences of Adam's fall. If we have dwelt longer upon the ſcheme of the latter than of the former, it is becauſe every Arminian argument is built upon criticiſm, and appeals to the original text; whilſt the Calviniſts reſt their faith upon the plain words of ſcripture as read in our tranſlation. If we might hazard our own opinion, we ſhould ſay that the truth lies between them, and that it has been found by the moderate men of both parties, who, while they make uſe of different language, ſeem to us to have the ſame ſentiments. That all mankind really ſinned in Adam, and are on that account liable to moſt grievous torments in ſoul and body, without intermiſſion, in hell fire for ever, is a doctrine which cannot be reconciled to our natural notions of God. On the other hand, if human nature was not ſomehow debaſed by the fall of our firſt parents, it is not eaſy to account for the numberleſs phraſes in ſcripture which certainly ſeem to ſpeak that language, or for the very general opinion of the Pagan philoſophers and poets reſpecting the golden age and the degeneracy of man. Cicero, in a quotation preſerved by St Auguſtine from a work that is now loſt, has theſe remarkable words, "Homo non ut a matre ſed ut a noverca natura editus eſt in vitam corpore nudo, et fragili, et infirmo: animo autem anxio ad moleſtias, humili ad timores, molli ad labores, prono ad libidines; in *quo tamen ineſt tanquam obrutus quidam divinus ignis ingenii et mentis* †." Nor do we readily perceive what ſhould induce the more zealous Arminians to oppoſe ſo vehemently this general opinion of the corruption of human nature. Their deſire to vindicate the juſtice and goodneſs of God does them honour; but the doctrine of inherent corruption militates not againſt theſe attributes; for what we have loſt in the firſt Adam has been amply ſupplied to us in the ſecond; and we know from the higheſt authority that the duties required of us are in proportion to our ability, ſince we are told, that "unto whomſoever much is given, of him ſhall much be required."

131 The opinions of moderate men among the Calviniſts and Arminians the ſame, and countenanced by general tradition.

Sect. IV. *View of Theology from the fall of Adam to the coming of Chriſt.*

We have dwelt long on the original ſtate of man, his introduction into the terreſtrial paradiſe, the privileges to which he was there admitted, his forfeiture of thoſe privileges, and the ſtate to which he was reduced by tranſgreſſing the law of his Maker; but the importance of theſe events renders them worthy of all the attention that we have paid to them. They paved the way for the coming of Chriſt and the preaching of the goſpel; and unleſs we thoroughly underſtand the origin of the goſpel, we cannot have an adequate conception of its deſign. By contraſting the firſt with the ſecond Adam, St. Paul gives us clearly to underſtand, that one purpoſe for which Chriſt came into the world and ſuffered death upon the croſs, was to reſtore to mankind that life which they had loſt by the fall of their original progenitor. The preaching of the goſpel therefore commenced with the firſt hint of ſuch a reſtoration; and the promiſe given to Adam and Eve, that "the ſeed of the woman ſhould bruiſe the head of the ſerpent, was as truly evangelical as theſe words of the apoſtle, by which we are taught, that "this is a faithful ſaying and worthy of all acceptation, that Chriſt Jeſus came into the world to ſave ſinners *." The former text taken by itſelf is indeed obſcure, and the latter is explicit; but both belong to the ſame ſyſtem, for the ſcriptures contain but two covenants or diſpenſations of God to man, in which the whole race is included.

Theology from the fall of Adam to the coming of Chriſt.

* 1 Tim. i. 15.

Chriſtianity therefore is indeed very near as old as the creation; but its principles were at firſt obſcurely revealed and afterwards gradually developed under different forms as mankind became able to receive them, (ſee Prophecy, n° 5, &c.). All that appears to have been at firſt revealed to Adam and Eve was, that by ſome means or other one of their poſterity ſhould in time redeem the whole race from the curſe of the fall; or if they had a diſtinct view of the means by which that redemption was to be wrought, it was probably communicated to them at the inſtitution of ſacrifices, (ſee Sacrifice). This promiſe of a future deliverer ſerved to comfort them under their heavy ſentence; and the inſtitution of ſacrifices, whilſt it impreſſed upon their minds lively ideas of the puniſhment due to their tranſgreſſion, was admirably calculated to prepare both them and their poſterity for the great atonement which, in due time, was to take away the ſins of the world.

132 Chriſtianity may be ſaid to have commenced with the fall.

Our firſt parents, after their fall, were ſo far from being left to fabricate a mode of worſhip for themſelves by thoſe innate powers of the human mind of which we daily hear ſo much and feel ſo little, that God was graciouſly pleaſed to manifeſt himſelf to their *ſenſes*, and viſibly to conduct them by the angel of his preſence in all the rites and duties of religion. This is evident from the different diſcourſes which he held with Cain, as well as from the complaint of that murderer of being hid from his face, and from its being ſaid, that "he went out from the preſence of the Lord and dwelt on the eaſt of Eden." Nor does it appear that God wholly withdrew his viſible preſence, and left mankind to their own inventions, till their wickedneſs became ſo very great that his ſpirit could no longer ſtrive with them. The infant ſtate of the world ſtood in conſtant need of his ſupernatural guidance and protection. The early inhabitants of this globe cannot be ſuppoſed to have been able, with Moſes *, to look up to him who is *inviſible*, and perform a worſhip purely rational and ſpiritual. They were all tillers of the ground, or keepers of cattle; employed in cultivating and repleniſhing this new world; and, through the curſe brought upon it by their forefather, forced, with him, to eat their bread "in the ſweat of their brow." Man in ſuch circumſtances could have little leiſure for ſpeculation; nor has mere ſpeculation, unleſs furniſhed with principles from another ſource, ever generated in the human mind adequate notions of God's nature or providence, or of the means by which he can be acceptably worſhipped. Frequent manifeſtations, therefore, of his preſence would be neceſſary to keep up a tolerable ſenſe of religion among them, and ſecure obedience to the divine inſtitutions; and that the Almighty did not exhibit ſuch manifeſtations, cannot be inferred from the ſilence of that very ſhort hiſtory which we have of thoſe early ages. Adam himſelf continued 930 years a living monument of the juſtice and mercy of God; of his extreme hatred and abhorrence of ſin, as well as of his love and long-ſuffering towards the ſinner. He was very ſenſible how ſin had entered into the world, and he could not but appriſe his children of its author. He would at the ſame time inform them of the unity of God, and his dominion over the evil one; of the means by which he had appointed himſelf to be worſhipped; and of his promiſe of future deliverance from the curſe of the fall. Such information would produce a tolerable idea of the Divine Be-

133 Revelation frequent in the early ages of the world,

* Heb. xi. 23.

Theology from the fall of Adam to the coming of Chriſt.

ing, and afford ſufficient motives to obey his will. The effects of it accordingly were apparent in the righteous family of Seth, who ſoon diſtinguiſhed themſelves from the poſterity of Cain, and for their eminent piety were honoured with the appellation of *the ſons of God*. Of this family ſprang a perſon ſo remarkable for virtue and devotion, as to be exempted from Adam's ſentence and the common lot of his ſons; for after he had walked with God 300 years, and prophecied to his brethren, he was tranſlated that he ſhould not ſee death. Of this miraculous event there can be no doubt but that his contemporaries had ſome viſible demonſtration; and as the fate of Abel was an argument to their reaſon, ſo the tranſlation of Enoch was a proof to their ſenſes of another ſtate of life after the preſent. To Adam himſelf, if he was then alive (s), it muſt have been a lively and affecting inſtance of what he might have enjoyed, had he kept his innocence; it muſt have been a comfortable earneſt of the promiſed victory over the evil one; and have confirmed his hope, that when the head of the ſerpent ſhould be completely bruiſed, he and his poſterity would be reſtored to the favour of their Maker, and behold his preſence in bliſs and immortality.

134 Yet vice, and probably idolatry ſoon became prevalent.

Notwithſtanding this watchful care of God over his fallen creature man, vice, and probably idolatry, ſpread through the world with a rapid pace. The family of Seth married into that of Cain, and adopted the manners of their new relations. Rapine and violence, unbounded luſt and impurity of every kind, prevailed univerſally; and when thoſe giants in wickedneſs had filled the earth with tyranny, injuſtice, and oppreſſion; when the whole race was become entirely carnal—God, after raiſing up another prophet to give them frequent warnings of their fate for the ſpace of 120 years, was at length obliged, in mercy to themſelves as well as to the ſucceeding generations of men, to cut them off by a general deluge. See DELUGE.

135 Pure religion for ſome time after the flood;

Thus did God, by the ſpirit of prophecy, which is by ſome ſuppoſed to have been hereditary in the heads of families; by frequent manifeſtations of his own preſence; and by uninterrupted tradition—make ample proviſion for the inſtruction and improvement of the world for the firſt 1600 years. After the deluge he was pleaſed to converſe again with Noah, and make in his perſon a new and extenſive covenant with mankind, (ſee PROPHECY, n° 11.). Of his power, juſtice, and goodneſs; of his ſupreme dominion over the earth and the heavens; of his abhorrence of ſin, and his determination not to let it go unpuniſhed—that patriarch and his family had been moſt awfully convinced; nor could they or their children, for ſome time, want any other argument to enforce obedience, fear, and worſhip. The ſons of Noah were an 100 years old when the deluge overwhelmed the earth. They had long converſed with their anceſtors of the old world, had frequented the religious aſſemblies, obſerved every Sabbath day, and been inſtructed by thoſe who had ſeen Adam. It is therefore impoſſible that they could be ignorant of the creation of the world, of the fall of man, or of the promiſe of future deliverance from the conſequences of that fall; or that they could offer their ſacrifices, and perform the other rites of the inſtituted worſhip, without looking forward with the eye of faith to that deliverance ſeen, perhaps obſcurely, through their typical oblations.

In this ſtate of things, with the awful remembrance of the deluge continually preſent to their minds, religion might for ſome time be ſafely propagated by tradition. But when by degrees mankind corrupted that tradition in its moſt eſſential parts; when, inſtead of the one Supreme God, they ſet up ſeveral orders of inferior deities, and worſhipped all the hoſt of heaven; when, at the ſame time they were uniting under one head, and forming a univerſal empire under the patronage of the Sun their chief divinity (ſee BABEL)—God ſaw it neceſſary to diſperſe them into diſtinct colonies, by cauſing ſuch diſcord among them as rendered it impoſſible for any one ſpecies of idolatry to be at once univerſally eſtabliſhed.

Theology from the fall of Adam to the coming of Chriſt.

136 Idolatry, however, the cauſe of the diſperſion from Babel.

After this diſperſion, there is reaſon to believe that particular revelations were vouchſafed wherever men were diſpoſed to regard them. Peleg had his name prophetically given him from the diſperſion which was to happen in his days; and not only his father Eber, but all the heads of families mentioned from Noah to Abraham, are with much plauſibility ſuppoſed to have had the ſpirit of prophecy on many occaſions. Noah was undoubtedly both prieſt and prophet; and living till within two years of the birth of Abraham, or, according to others, till that patriarch was near 60 years old, he would ſurely be able to keep up a tolerable ſenſe of true religion among ſuch of his deſcendants as ſojourned within the influence of his doctrine and example. His religious ſon Shem, who lived till after the birth of Iſaac, could not but preſerve in tolerable purity the faith and worſhip of the true God among ſuch of his own deſcendants as lived in his neighbourhood.

But though the remains of true religion were thus preſerved among a few righteous men, idolatry, with its inſeparable attendants, unnatural luſts and cruel ſuperſtition (t), had in a ſhort time prevailed ſo far among the ſons of Noah, that God, in his infinite wiſdom, ſaw it expedient not only to ſhorten the lives of men, but alſo to withdraw his preſence from the generality, who had thus rendered themſelves unworthy of ſuch communications; and to ſelect a particular family in which his worſhip might be preſerved pure amidſt the various corruptions that were overſpreading the world. With this view Abraham was called; and after many remarkable trials of his faith and conſtancy, admitted to a particular intimacy and friendſhip with his Maker. God entered into a peculiar covenant with him, engaging to be his preſent guide, protector, and defender; to beſtow all temporal bleſſings upon him and his ſeed; and to make ſome of thoſe ſeed the inſtruments of conveying bleſſings of a higher kind to all the nations of the earth.

137 The call of Abraham was

138 To prevent the univerſal ſpreading of idolatry,

It was doubtleſs for his ſingular piety that Abraham was fixed upon to be the parent of that people, who ſhould preſerve the knowledge of the unity of God in the midſt of an idolatrous and polytheiſtic world; but we are not to imagine that it was for his ſake only that all this was done, or that his leſs worthy deſcendants were by the equal Lord of all, treated with partial fondneſs for the virtues of their anceſtor; it was for the benefit of mankind in general that he was called from his country, and from his father's houſe, that he might preſerve the doctrine of the Divine unity in his own family, and be an inſtrument in the hand of Providence (and a fit one he was) to convey the ſame faith to the nations around him. Accordingly, we find him diſtinguiſhed among the neighbouring princes, and kings reproved for his ſake; who being made acquainted with his prophetic character, deſire his interceſſion with God. Hiſtory tells us of his converſing on the ſubject of religion with the moſt learned

(s) According to the Samaritan chronology, he was alive; according to the Hebrew, he had been dead 57 years.
(t) See the effects of idolatry well deſcribed in the Apocryphal book of Wiſdom, chap. xiv.

Theology from the fall of Adam to the coming of Christ.

ed Egyptians, who appear to have derived from him or ſome of his deſcendants the rite of circumciſion, and to have been for a while ſtopt in their progreſs towards the laſt ſtage of that degrading idolatry which afterwards rendered their national worſhip the opprobrium of the whole earth, (ſee POLYTHEISM, n° 28). We are informed that his name was had in the greateſt veneration all over the Eaſt; that the Magians, Sabians, Perſians, and Indians, all glory in him as the great reformer of their reſpective religions: and to us it appears extremely probable, that not only the Brachmans, but likewiſe the Hindoo god Brahma*, derive their names from the father of the faithful. As he was let into the various counſels of the Almighty, and taught to reaſon and reflect upon them; as he was fully appriſed of the overthrow of Sodom and Gomorrah, with the particular circumſtances of that miraculous event; and as he had frequent revelations of the promiſed Redeemer, whoſe day he longed earneſtly to ſee, and ſeeing it was glad—there can be no doubt but that he and his family took care to propagate theſe important doctrines in every nation which they viſited; for the only reaſon which we can conceive for his being made to wander from place to place was, that different people might be induced to inquire after his profeſſion, his religion, and his hopes.

*See Aſiatic Reſearches and Newt. Chron.

But though the Supreme Being was pleaſed to manifeſt himſelf in a more frequent and familiar manner to Abraham, he by no means left the reſt of the world without ſufficient light. Lot profeſſed the true religion in the midſt of Sodom. In Canaan we meet with Melchizedeck, king and prieſt of the moſt high God, who bleſſed Abraham, and to whom that patriarch himſelf did homage. Abimelech king of Gerar receiving an admonition from the Lord, immediately paid a due regard to it; and the ſame ſenſe of religion and virtue deſcended to his ſon. Laban and Bethuel acknowledged the Lord, and the former of them was even favoured with a viſion. In Arabia, we find Job and his three friends, all men of high rank, entering into the deepeſt diſquiſitions in theology; agreeing about the unity, omnipotence, and ſpirituality of God; the juſtice of his providence, with other fundamental articles of true religion; and mentioning divine inſpiration or revelation as a thing not uncommon in their age and country* (u). Balaam appears to have been a true prophet; and as he was unqueſtionably a man of bad morals, the natural inference is, that the gift of prophecy was then, as afterwards, beſtowed on individuals, not for their own ſakes, but for the ſake of the public; and that, as in "every nation, he who feareth God and worketh righteouſneſs is accepted of him;" ſo in thoſe early ages of the world, when mankind were but children in religious knowledge, they were bleſſed with the light of divine revelation wherever they were diſpoſed to make a proper uſe of it.

139 Occaſional revelations given to other pious men.

* Job iv. 12, 15, 16, 17. vi. 10. xxiii. 12.

140 A ſecond purpoſe for which Abraham was called.

Very few, however, appear to have had this diſpoſition; and therefore God was pleaſed to adopt Abraham and part of his poſterity as the race from which the great Redeemer was to ſpring, to train them up by degrees in ſuitable notions of their Creator, and gradually to open up to them, as they were able to receive it, the nature of that diſpenſation under which "all the nations of the earth were to be bleſſed in the patriarch's ſeed, (ſee PROPHECY, n° 13). For this purpoſe, he held frequent correſpondence with them; and to ſtrengthen and confirm their faith, to fix and preſerve their dependence on the one God of heaven and earth, he daily gave them new promiſes, each more magnificent than that which preceded it. He bleſſed Iſaac, miraculouſly increaſed his ſubſtance, and ſoon made him the envy of the neighbouring princes. He foretold the condition of his two ſons, renewed the promiſe made to Abraham, and bleſſed the adopted ſon Jacob, with whom he condeſcended to converſe as he had converſed with Abraham and Iſaac; renewing to him the great promiſe; beſtowing upon him all kinds of riches; and impreſſing ſuch terror upon all the cities which were round about him as prevented them from hurting either him or his family.

Theology from the fall of Adam to the coming of Chriſt.

All this was indeed little enough to keep alive even in the mind of Jacob a tolerable ſenſe of duty and dependence on his Creator. After the firſt viſion he is ſurpriſed, and heſitates, ſeeming inclined to make a kind of ſtipulation with his Maker. "If (ſays he) God will be with me, and will keep me in this way that I go, and will give me bread to eat, and raiment to put on, ſo that I come again to my father's houſe in peace, *then* ſhall the Lord be my God‖." It appears not to have been till after many ſuch revelations, bleſſings, and deliverances, and being reminded of the vow which on this occaſion he had vowed, that he ſet himſelf in good earneſt to reform the religion of his own family, and to drive out from it all ſtrange gods*. So little able, in that age, were the boaſted powers of the human mind to preſerve in the world juſt notions of the unity of the Godhead, that we ſee there was a neceſſity for very frequent revelations, to prevent even the beſt men from running headlong into polytheiſm and idolatry.

‖ Gen. xxviii. 20, 21.

* Gen. xxxv. 2.

Thus was God obliged to treat even with the patriarchs themſelves, by way of poſitive covenant and expreſs compact; to promiſe to be their God if they would be his people; to give them a portion of temporal bleſſings as introductory to future and ſpiritual ones; and to engage them in his ſervice by immediate rewards, till they could be led on to higher views, and prepared by the bringing in of a better hope to worſhip him in ſpirit and in truth. With regard to what may be called the *theory* of religion, mankind were yet ſcarcely got out of their childhood. Some extraordinary perſons indeed occaſionally appeared in different countries, ſuch as Enoch, Noah, Abraham, and Job, with many others, who had a more enlarged proſpect of things, and entertained more worthy ſentiments of the divine diſpenſations and of the ultimate end of man; but theſe were far ſuperior to the times in which they lived, and appear to have been providentially raiſed up to prevent the ſavage ſtate and ſavage idolatry from becoming univerſal among men. See SAVAGE.

141 The patriarchal worſhip of thoſe early ages performed in faith.

The worſhip which was practiſed by thoſe holy men appears to have conſiſted principally of the three kinds of ſacrifice mentioned elſewhere (ſee SACRIFICE); to which were doubtleſs added prayers and praiſes, with the more valuable oblation of pure hands and devout hearts. Such of them as looked forward to a future redemption, and had any tolerable notion of the means by which it was to be effected, as Abraham certainly had, muſt have been ſenſible that the blood of bulls and of goats could never take away ſin, and that their ſacrifices were therefore valuable only when they were offered in faith of that great promiſe, "which they,

(u) There are great diſputes among the learned reſpecting the antiquity and the author of the *book* of Job, and whether it be a hiſtory of events, or a poem which has its foundation in hiſtory. All ſober men, however, are agreed, that there really was ſuch a *perſon* as Job, eminent for patience under uncommon ſufferings; and that he was of very remote antiquity. The LXX. give us the names of his father and mother, and ſay that he was the fifth from Abraham.

Theology from the fall of Adam to the coming of Chriſt.

having ſeen it afar off, were perſuaded of, and embraced; and confeſſed that they were ſtrangers and pilgrims upon earth."

That ſuch perſons looked for "a better country, even a heavenly one," in a future ſtate, cannot be queſtioned; for they knew well how ſin and death had entered into the world, and they muſt have underſtood the promiſe made to their original progenitor, and repeatedly renewed to themſelves, to include in it a deliverance at ſome period from every conſequence of the firſt tranſgreſſion. They were to all intents and purpoſes Chriſtians as well as we. They indeed placed their confidence in a Redeemer, who in the fulneſs of time was to appear upon earth, while we place ours in a redeemer that has been already manifeſted; they expreſſed that confidence by one mode of worſhip, we expreſs it by another; but the patriarchal worſhip had the ſame end in view with the Chriſtian—the attainment of everlaſting life in heaven.

142 Of a future Redeemer;

143 Such faith, however, not general

The generality of men, however, appear not, in the early age of which we now write, to have extended their views beyond the preſent life. From the confuſed remains of ancient tradition, they acknowledged indeed ſome ſuperior power or powers, to whom they frequently applied for direction in their affairs; but in all probability it was only for direction in temporal affairs, ſuch as the cultivation of the ground, or their tranſactions with each other. In the then ſtate of things, when no part of the world was overſtocked with inhabitants, and when luxury with its conſequences were every where unknown, virtue and vice muſt have produced their natural effects; and the good man being happy here, and the wicked man miſerable, reaſon had no data from which to infer the reality of a future ſtate of rewards and puniſhments. Thoſe who were bleſſed with the light of revelation undoubtedly looked forward to that ſtate with a holy joy; but the reſt worſhipped ſuperior powers from worldly motives. How many of thoſe powers there might be, or how far their influence might reach, they knew not. Uncertain whether there be one Supreme Governor of the whole world, or many co-ordinate powers preſiding each over a particular country, climate, or place—gods of the hills and of the valleys, as they were afterwards diſtinguiſhed—they thought that the more of theſe they could engage in their intereſt the better. Like the Samaritans therefore, in after times, they ſought, wherever they came, the "manners of the god of the land," and ſerved him, together with their own gods.

144 The purpoſe for which the Iſraelites were made to ſojourn in Egypt.

Thus was the world ready to loſe all knowledge of the true God and his worſhip, had not he been graciouſly pleaſed to interpoſe, and take effectual care to preſerve that knowledge in one nation, from which it might be conveyed to the reſt of mankind at different times, and in greater or leſs degrees, as they ſhould be capable of receiving it. To this purpoſe he made way for the removal of Jacob and his family to one of the moſt improved and poliſhed countries of the world; and introduced them into it in a manner ſo advantageous, as to give them an opportunity of imparting much religious knowledge to the natives. The natives, however, were groſs idolaters; and that his choſen people might be as far as poſſible from the contagion of their example, he placed them upon the borders of Egypt, where, though they multiplied exceedingly, they were by their very occupation † ſtill kept a ſeparate people, and muſt have been rendered, by a long and ſevere oppreſſion, in a great degree averſe from the manners and religion of their neighbours. This averſion, however, ſeems to have gradually become leſs and leſs; and before they were miraculouſly redeemed from their houſe of bondage, they had certainly loſt all correct notions of the unity of God, and the nature of his worſhip, and had adopted the greater part of the ſuperſtitions of their taſk-maſters. Of this we need no other proof than what is implied in the words of Moſes *, when he ſaid unto God, "Behold, when I come unto the children of Iſrael, and ſay unto them, the God of your fathers hath ſent me unto you; and they ſhall ſay unto me, WHAT IS HIS NAME? what ſhall I ſay unto them?" Had not the deſtined lawgiver of the Hebrews been aware that his countrymen had adopted a plurality of gods, this difficulty could not have occurred to him; for *names* are never thought of but to diſtinguiſh from each other beings of the ſame kind; and he muſt have remembered, that in Egypt, where the multitude of gods was marſhalled into various claſſes, the knowledge of their names was deemed of great importance. This we learn likewiſe from Herodotus, who informs us * that the Pelaſgi, after ſettling in Greece, thought it neceſſary to conſult the oracle of Dodona, whether it would be proper to give to their own gods the names of the Egyptian divinities? and that the oracle, as might have been ſuppoſed, aſſured them that it would. Indeed the Hebrews during their reſidence in Egypt had acquired ſuch an attachment to the idolatrous worſhip of the country, that it appears never to have left them entirely till many ages afterwards, when they were carried captive into Babylon, and ſeverely puniſhed for their repeated apoſtacies; and ſo completely were they infatuated by theſe ſuperſtitions at the era of their exodus, that, as the prophet Ezekiel informs us*, they rebelled againſt God, and would not caſt away their abominations, or forſake the idols of Egypt, even in the *very day* that the hand of Omnipotence was lifted up to bring them forth of that land in which they had been ſo long and ſo cruelly oppreſſed. In ſuch a ſtate of things, to have ſuffered them to remain longer in Egypt, could have ſerved no good purpoſe: and therefore to fulfil the promiſe which he had given to Abraham, God determined to deliver them out of the hand of the Egyptians by means which ſhould convince both them and their offſpring of his own ſupremacy over heaven and earth.

* Ch. xx.

146 Moſes appointed to bring them out of Egypt.

As Moſes was the perſon appointed to deliver God's meſſage to Pharaoh, and to demand of him leave for the Iſraelites to go three days journey into the wilderneſs to ſerve the God of their fathers, it was neceſſary that he ſhould be endowed with the power of working miracles to evince the reality of his divine miſſion. Without a conviction that his claims were well-founded, neither Pharaoh nor his own countrymen could reaſonably have been expected to liſten to the propoſals of a man who, though bleſſed in his youth with a princely education, had come directly on his embaſſy from the humble employment of a ſhepherd, which he had for many years exerciſed in the country of Midian. To prove that he was really ſent by God, any viſible and undoubted controul of the laws of nature would have been abundantly ſufficient; but he was to prove not only this truth, but alſo the unity of the Divine nature; and the miracles which he was directed to work were executions of judgments againſt the very gods of Egypt*.

* Exod. xii. 12.

When Pharaoh firſt turned a deaf ear to his requeſt, tho' enforced by the converſion of a rod into a ſerpent, at the command of Jehovah he ſmote with the ſame rod upon the waters in the river, which were inſtantly converted into blood, and occaſioned the death of all the fiſhes that ſwam in them. To any people this miracle would have been a proof of Divine agency: but it was in a particular manner calculated to open the eyes of the blind and infatuated Egyptians, who conſidered the Nile as one of their greateſt gods, and all the fiſhes that it contained as ſubordinate divinities. They called that noble river ſometimes *Sirius*, ſometimes *Oſiris*, ſometimes *Canobus* (ſee CANOBUS), and not

147 The propriety of the miracles which he wrought

† Gen. xlvi. 33, 34.

Theology from the fall of Adam to the coming of Chriſt.

not unfrequently Ωκεανος (x); and adored it as the parent of all their deities. What then muſt the people have thought when they found their moſt revered god, at the command of a ſervant of Jehovah, converted into blood, and all his ſacred offſpring into ſtinking carcaſes? To conceive their conſternation, if it can be conceived, the reader muſt remember, that the Egyptian prieſts held blood in the utmoſt abhorrence, as a thing of which the very touch would deeply pollute them, and require immediate and ſolemn expiation. The ſame ſacred river was a ſecond time polluted, when it ſent forth frogs, which covered all the land of Egypt, and died in the houſes, in the villages, and in the fields; thus rendering it impoſſible for the people to avoid the touch of dead bodies, though from every ſuch contact they believed themſelves to contract an impurity, which, in the caſe before us, muſt have been the more grievous, that in the whole country there was not left a pool of uninfected water to waſh away the ſtain.

148 To evince the vanity of idol worſhip.

The third plague inflicted upon the Egyptians was, the converting of the duſt of the land into lice, upon man and upon beaſt, throughout the whole kingdom. To ſee the propriety of this miracle as a judgment upon their idolatry, we muſt recollect their utter abhorrence of all kinds of vermin, and their extreme attention to external purity above every other people perhaps that has hitherto exiſted on the face of the earth. Upon this head they were more particularly ſolicitous when about to enter the temples of their gods; for Herodotus informs us, that their prieſts wore linen raiment only, and ſhaved off every hair from their heads and bodies, that there might be no *louſe* or other deteſtable object upon them when performing their duty to the gods. This plague therefore, while it laſted, made it impoſſible for them to perform their idolatrous worſhip, without giving ſuch offence to their deities as they imagined could never be forgiven. Hence we find, that on the production of the lice, the prieſts and magicians perceived immediately from what hand the miracle had come, and exclaimed, "This is the finger of God!" The fourth plague ſeems to have been likewiſe acknowledged to be the finger of God, if not by the magicians, at leaſt by Pharaoh; for in a fit of terror he agreed that the Iſraelites ſhould go and ſerve the Lord. That he was terrified at the ſwarms of flies which infeſted the whole country, except the land of Goſhen, will excite no wonder, when it is known that the worſhip of the fly originated in Egypt; whence it was carried by the Caphtorim to Paleſtine; by the Phœnicians to Sidon, Tyre, and Babylon; and from theſe regions to other parts of the world. The denunciation of this plague was delivered to Pharaoh early in the morning, when he was on the banks of the Nile, probably paying his accuſtomed devotion to his greateſt god; and when he found himſelf and his people tormented by a ſwarm of ſubordinate divinities, who executed the judgment of Jehovah in defiance of the power of the ſupreme *numen* of Egypt, he muſt have been convinced, had any candour remained in his mind, that the whole ſyſtem of his ſuperſtition was a maſs of abſurdities, and that his gods were only humble inſtruments at the diſpoſal of a Superior Power. He was not, however, convinced; he was only alarmed, and quickly relapſed into his wonted obſtinacy. The fifth plague therefore, the murrain among the cattle, brought death and deſtruction upon his moſt revered gods themſelves. Neither Oſiris, nor Iſis, nor Ammon, nor Pan, had power to ſave his brute repreſentatives. The ſacred bull, and heifer, and ram, and goat, were carried off by the ſame malady which ſwept away all the other herds of deities, theſe *dii ſtercorei*, who lived on graſs and hay. The impreſſion of this puniſhment muſt have been awful upon the minds of the Egyptians, but perhaps not equal to that which ſucceeded it.

Theology from the fall of Adam to the coming of Chriſt.

In Egypt there were ſeveral altars on which human ſacrifices were offered; and from the deſcription of the perſons qualified to be victims, it appears that thoſe unhappy beings muſt have been foreigners, as they were required to have bright hair and a particular complexion. The hair of the Iſraelites was much brighter than that of the Egyptians, and their complexions fairer; and therefore there can be little doubt but that, during their reſidence in Egypt, they were made to furniſh the victims demanded by the bloody gods. Theſe victims being burnt alive on a high altar, and thus ſacrificed for the good of the nation, their aſhes were gathered together by the prieſts, and ſcattered upwards in the air, that a bleſſing might be entailed on every place to which an atom of this duſt ſhould be wafted. Moſes too, by the direction of the true God, took aſhes of the furnace, probably of one of thoſe very furnaces in which ſome of his countrymen had been burnt, and ſprinkling them towards heaven in the ſight of Pharaoh, brought boils and blains upon all the people, of ſo malignant a nature, that the magicians and the other miniſters of the medical gods, with which Egypt abounded beyond all other countries, could not themſelves eſcape the infection.

The powers of darkneſs were thus foiled; but the heart of the monarch was ſtill hardened. Deſtruction was therefore next brought upon him and his country by the elements, which were among the earlieſt idol deities not only of the Egyptians, but of every other polytheiſtic nation. "The Lord rained hail upon the land of Egypt; ſo that there was hail, and fire mingled with the hail, ſuch as there was none like it in all the land of Egypt ſince it became a nation. And the hail ſmote throughout all the land of Egypt all that was in the field, both man and beaſt; and the hail ſmote every herb of the field, and broke every tree of the field." This was a dreadful calamity in itſelf; and the horror which it excited in the minds of the people muſt have been greatly aggravated by the well-known fact, that Egypt is bleſſed with a ſky uncommonly ſerene; that in the greateſt part of it rain has never been ſeen at any other time ſince the creation of the world; and that a ſlight and tranſient ſhower is the utmoſt that in the ordinary courſe of nature falls anywhere throughout the country. The ſmall quantity of vegetables which was left undeſtroyed by the fire and the hail was afterwards devoured by locuſts, which by a ſtrong eaſt wind were brought in ſuch numbers from Arabia, where they abound at all times, that they covered the whole face of the earth, and did eat every herb of the land, and all the fruit of the trees, ſo that there remained not any green thing in the trees or in the herbs of the field through all the land of Egypt.

The ninth plague which the obſtinacy of Pharaoh brought upon his country, whilſt it ſeverely puniſhed the Egyptians for their cruelty to the Hebrews, ſtruck at the very foundation of all idolatry. We have elſewhere ſhown, that the firſt objects of idolatrous worſhip were the contending powers of light and darkneſs (ſee POLYTHEISM); and that the benevolent principle, or the power of light, was everywhere believed to maintain a conſtant ſuperiority over the power of darkneſs. Such was the faith of the ancient Perſians; and ſuch, as a very learned writer has lately proved, was likewiſe

(x) Whence came the Greek word ωκεανος, *the ocean*.

Theology from the fall of Adam to the coming of Chriſt.

wiſe the faith of the earlier Egyptians. It was therefore with wiſdom truly divine, that God, to ſhow the vanity of their imaginations, brought upon thoſe votaries of light, who fancied themſelves the offſpring of the ſun, a preternatural darkneſs, which, for three days, all the powers of their ſupreme deity and his ſubordinate agents could not diſpel.

The tenth and laſt plague brought upon this idolatrous people was more univerſally and ſeverely felt than any which had preceded it. It was likewiſe, in ſome ſenſe, an inſtance of the *lex talionis*, which requires an eye for an eye, and a tooth for a tooth, &c. Moſes was commanded, at his firſt interview with Pharaoh, to ſay, "Thus ſaith the Lord, Iſrael is my ſon, even my firſt-born. Let my ſon go that he may ſerve me: and if thou refuſe to let him go, behold, I will ſlay thy ſon, even thy firſt-born." Before this threat was put in execution, every attempt was made to ſoften the hardened heart of the obſtinate tyrant. The waters of his ſacred river were turned into blood, and all the fiſhes that it contained ſlain; frogs were brought over all the land to pollute the people; the miniſters of religion were rendered ſo impure by vermin, that they could not diſcharge their wonted offices; the animals moſt revered as gods, or emblems of gods, were cut off by a murrain; the elements, that were everywhere worſhipped as divinities, carried through the land a devaſtation, which was completed by ſwarms of locuſts; the aſhes from the ſacred furnace, which were thought to convey bleſſings whitherſoever they were wafted, were made to communicate incurable diſeaſes; a thick and preternatural darkneſs was ſpread over the kingdom, in defiance of the power of the great Oſiris; and when the hearts of the people and their ſovereign continued ſtill obdurate, the eldeſt ſon in each family was ſlain, becauſe they refuſed to let go Iſrael, God's firſt-born. From this univerſal peſtilence the Iſraelites were preſerved by ſprinkling the doorpoſts of their houſes with the blood of one of the animals adored in Egypt; a fact which, as it could not be unknown to Pharaoh or his ſubjects, ought to have convinced that people of the extreme abſurdity of their impious ſuperſtitions. This effect it ſeems not to have had; but the death of the firſt-born produced the deliverance of the Hebrews; for when it was found that there was not a houſe where there was not one dead, "Pharaoh called for Moſes and Aaron by night, and ſaid, Riſe up, and get you forth from among my people, both you and the children of Iſrael; and bleſs me alſo. And the Egyptians were urgent upon the people, that they might ſend them out of the land in haſte; for they ſaid, We be all dead men (y)." The wonted obſtinacy of the monarch indeed very ſoon returned; and his ſubjects, forgetting the loſs of their children, joined with him in a vain attempt to bring back to bondage the very people whom they had been thus urgent to ſend out of the land; but their attempt was defeated by Jehovah, and all who engaged in it drowned in the Red Sea.

The God of Iſrael having thus magnified himſelf over the Egyptians and their gods, and reſcued his people from bondage by ſuch means as muſt not only have ſtruck terror and aſtoniſhment into the whole land, but alſo have ſpread his name through all the countries which had any communication with that far-famed nation, proceeded to inſtruct and exerciſe the Hebrews for many years in the wilderneſs. He inculcated upon them the unity of the Godhead; gave them ſtatutes and judgments more righteous than thoſe of any other nation; and by every method conſiſtent with the freedom of moral agency guarded them againſt the contagion of idolatry and polytheiſm. He ſent his angel before them to keep them in the way, took upon himſelf the office of their ſupreme civil governor, and by his preſence directed them in all their undertakings. He led them with repeated ſigns and wonders through the neighbouring nations, continued to try and diſcipline them till they were tolerably attached to his government and eſtabliſhed in his worſhip, and introduced them into the Promiſed Land when its inhabitants were ripe for deſtruction. At their entrance into it, he gave them a ſummary repetition of their former laws, with more ſuch ordinances, both of a ceremonial and moral kind, as were both ſuited to their temper and circumſtances, as well as to prefigure, and by degrees to prepare them for, a more perfect diſpenſation under the Meſſiah.

Theology from the fall of Adam to the coming of Chriſt.

149 Reaſon of detaining the Iſraelites ſo long in the wilderneſs.

150 Great objects of the Jewiſh law.

The Jewiſh law had two great objects in view; of which the firſt was to preſerve among them the knowledge of the true God, a rational worſhip ſpringing from that knowledge, and the regular practice of moral virtue; and the ſecond was to fit them for receiving the accompliſhment of the great promiſe made to their anceſtors, by means analogous to thoſe which a ſchoolmaſter employs to fit his pupils for diſcharging the duties of maturer years. Every thing in that law peculiar to itſelf, its various ceremonies, modes of ſacrificing, the ſanctions by which it was enforced, and the theocratic government by which it was adminiſtered, had a direct tendency to promote one or other of theſe ends; and keeping theſe ends in view, even the minuteſt laws, at which impious ignorance has affected to make itſelf merry, will be diſcovered by thoſe who ſhall ſtudy the whole ſyſtem, and are at the ſame time acquainted with the genius of ancient polytheiſm, to have been enacted with the moſt conſummate wiſdom.

It is not eaſy for us, who have been long bleſſed with the light of revelation, and who have cultivated our minds by the ſtudy of the ſciences, to conceive the propenſity of all nations, in that early age of the world, to the worſhip of falſe gods, of which they were daily adding to the number. It is indeed probable, from many paſſages of Scripture, as well as from profane authors of the greateſt antiquity, that one ſupreme *numen* was everywhere acknowledged; but he was conſidered as an extramundane being, too highly exalted to concern himſelf with the affairs of this world, the government of which, it was believed, he had delegated to various orders of ſubordinate deities. Of thoſe deities, ſome were ſuppoſed to have the charge of one nation and ſome of another. Hence it is, that we read of the gods of Egypt, the gods of the Amorites, and the gods of the different nations round about Paleſtine. None of thoſe nations denied the exiſtence of their neighbour's gods; but all agreed, that while the Egyptians were the peculiar care of Oſiris and Iſis, the Amorites might be the favourites of Moloch, the Phœnicians of Cronus, and the Philiſtines of Dagon; and they

(y) For this account of the plagues of Egypt, we are indebted to the very valuable *Obſervations* on the ſubject lately publiſhed by *Mr. Bryant*. We have not quoted the authorities by which the learned and pious author ſupports his opinions; becauſe it is to be hoped, that for a fuller account of theſe important tranſactions the reader will have recourſe to his work, of which we have given only a very brief abſtract. For much of the preceding parts of this ſection, we acknowledge our obligations to the late Biſhop Law's admirable diſcourſe on the *Several Diſpenſations of Revealed Religion*.

Theology from the fall of Adam to the coming of Christ.

they had no objection occaſionally to join with each other in the worſhip of their reſpective tutelary deities. Nay, it was thought impiety in foreigners, while they ſojourned in a ſtrange country, not to ſacrifice to the gods of the place. Thus Sophocles makes Antigone ſay to her father, that a ſtranger ſhould both venerate and abhor thoſe things which are venerated and abhorred in the city where he reſides; and another author*, who, though comparatively late, drew much of his information from ancient writings, which are now loſt, aſſures us, that this complaiſance proceeded from the belief that the "ſeveral parts of the world were from the beginning diſtributed to ſeveral powers, of which each had his peculiar allotment and reſidence."

* Celſus apud Aug.

From this notion of local divinities, whoſe power or partial fondneſs was confined to one people, the Iſraelites, at their exodus from Egypt, appear not to have been free (z). Hence it is, that when the true God firſt tells them, by their leader Moſes*, that if they would obey his voice indeed and keep his covenant, then they ſhould be a PECULIAR TREASURE to him above all people: to prevent them from ſuppoſing that he ſhared the earth with the idols of the heathen, and had from partial fondneſs choſen them for his *portion*, he immediately adds, for ALL THE EARTH IS MINE. By this addition he gave them plainly to underſtand that they were choſen to be his peculiar treaſure for ſome purpoſe of general importance; and the very firſt article of the covenant which they were to keep was, that they ſhould have no other gods but him. So inveterate, however, was the principle which led to an intercommunity of the objects of worſhip, that they could not have kept this article of the covenant but in a ſtate of ſeparation from the reſt of mankind†; and that ſeparation could neither have been effected nor continued without the viſible providence of the Almighty watching over them as his peculiar treaſure. This we learn from Moſes himſelf, who, when interceding for the people after their idolatrous worſhip of the golden calf, and intreating that the preſence of God would ſtill accompany them, adds theſe words §: "For wherein ſhall it be known here that I and thy people have found grace in thy ſight? Is it not in that THOU GOEST WITH US? So ſhall we be SEPARATED, I and thy people, from all the people that are upon the face of the earth." Upon this ſeparation every thing depended; and therefore to render it the more ſecure, Jehovah, who in compliance with their prejudices had already aſſumed the appellation of their tutelary God, was graciouſly pleaſed to become likewiſe their ſupreme Magiſtrate, making them a "kingdom of prieſts and a holy nation," and delivering to them a digeſt as well of their civil as of their religious laws.

* Exod. xix. 5.

151 Purpoſe of their ſeparation from other people.

† 1 Sam. xxvi. 19.

§ Exod. xxxiii. 16.

152 Of their theocratic government.

The Almighty thus becoming their King, the government of the Iſraelites was properly a THEOCRACY, in which the two ſocieties, civil and religious, were of courſe incorporated. They had indeed after their ſettlement in the Promiſed Land, at firſt, temporary *judges* occaſionally raiſed up; and afterwards permanent magiſtrates called *kings*, to lead their armies in war, and to give vigour to the adminiſtration of juſtice in peace: but neither thoſe judges nor thoſe kings could abrogate a ſingle law of the original code, or make the ſmalleſt addition to it but by the ſpirit of prophecy. They cannot therefore be conſidered as ſupreme magiſtrates, by whatever title they may have been known; for they were to go out and come in at the word of the prieſts, who were to aſk counſel for them of the Lord, and with whom they were even aſſociated in all judicial proceedings, as well of a civil as of a ſpiritual nature*. Under any other than a theocratic government the Hebrews could not have been kept ſeparate from the nations around them; or if they could, that ſeparation would not have anſwered the great purpoſe for which it was eſtabliſhed. "The people, on their leaving Egypt, were ſunk into the loweſt practices of idolatry. To recover them by the diſcipline of a ſeparation, it was neceſſary that the idea of God and his attributes ſhould be impreſſed upon them in the moſt *ſenſible* manner. But this could not be commodiouſly done under his character of God of the univerſe: under his character of King of Iſrael, it well might. Hence it is, that we find him in the Old Teſtament ſo frequently repreſented with affections analogous to human paſſions. The civil relation in which he ſtood to the Iſraelites made ſuch a repreſentation natural; the groſſneſs of their conceptions made the repreſentation neceſſary; and the guarded manner in which it was always qualified prevented it from being miſchievous*." Hence too it is, that under the Moſaic diſpenſation, idolatry was a crime of ſtate, puniſhable by the civil magiſtrate. It was indeed high treaſon, againſt which laws were enacted upon the juſteſt principles, and carried into effect without danger of error. Nothing leſs indeed than penal laws of the ſevereſt kind could have reſtrained the violent propenſity of that headſtrong people to worſhip, together with their own God, the gods of the Heathen. But penal laws enacted by human authority for errors in religion are manifeſtly unjuſt; and therefore a theocratic government ſeems to have been abſolutely neceſſary to obtain the end for which the Iſraelites were ſeparated from the ſurrounding nations.

Theology from the fall of Adam to the coming of Chriſt.

* Num. xxvii. 21 and Deut. xvii. 8, 13.

* Warburton's Div. Leg. b. v. ſec. 2.

153 And of the ritual law.

It was for the ſame purpoſe of guarding them againſt idolatry, and preventing all undue communications with their Heathen neighbours, that the ritual law was given, after their preſumptuous rebellions in the wilderneſs. Before the buſineſs of the golden calf, and their frequent attempts to return into Egypt, it ſeems not to have been the Divine intention to lay upon them a yoke of ordinances; but to make his covenant depend entirely upon their duly practiſing the rite of circumciſion: obſerving the feſtivals inſtituted in commemoration of their deliverance from bondage, and other ſignal ſervices vouchſafed them; and keeping inviolate all the precepts of the decalogue (a), which, if they had done, they ſhould have even lived in them*. But, after their repeated apoſtacies, and impious wiſhes to mix with the ſurrounding nations, it was neceſſary to ſubject them

* Divine Leg. b. iv. ſec. 6.

(z) It is not indeed evident that they had got entirely quit of this abſurd opinion at a much later period. Jephtha, one of their judges, who, though half paganized (as Warburton obſerves) by a bad education, had probably as correct notions of religion as an ordinary Iſraelite, certainly talked to the king of Ammon as if he had believed the different nations of the earth to be under the immediate protection of different deities: "Wilt not thou (ſays he) poſſeſs that which Chemoſh THY GOD giveth thee to poſſeſs? So whomſoever the Lord OUR GOD ſhall drive out from before us, them will we poſſeſs." Judges xi. 24.

(a) Of theſe precepts we think it not neceſſary, in an abſtract ſo ſhort as this, to waſte the reader's time with a formal and laboured defence. To the decalogue no objection can be made by any man who admits the obligations of natural religion; for, except the obſervation of the Sabbath-day, it enjoins not a ſingle duty which does not by the confeſſion of all men reſult from our relations to God, ourſelves, and our fellow-creatures.

Theology from the fall of Adam to the coming of Chriſt.

them to a multifarious ritual, of which the ceremonial parts were ſolemn and ſplendid, fitted to engage and fix the attention of a people whoſe hearts were groſs; to inſpire them with awful reverence, and to withdraw their affections from the pomp and pageantry of thoſe idle ſuperſtitions which they had ſo long witneſſed in the land of Egypt. To keep them warmly attached to their public worſhip, that worſhip was loaded with operoſe and magnificent rites, and ſo completely incorporated with their civil polity as to make the ſame things at once duties of religion and acts of ſtate. The ſervice of God was indeed ſo ordered as to be the conſtant buſineſs as well as entertainment of their lives, ſupplying the place of all other entertainments; and the ſacrifices which they were commanded to offer on the moſt ſolemn occaſions, were of ſuch animals as the Egyptians and other Heathens deemed ſacred.

154 Inſtanced in their ſacrifices.

Thus a heifer without blemiſh was in Egypt held ſacred to the goddeſs Iſis, and actually worſhipped as the repreſentative of that divinity; but the ſame kind of heifer was by the ritual law of the Hebrews commanded to be burnt without the camp, as the vileſt animal, and the water of ſeparation to be prepared from her aſhes†. The goat was by the Egyptians held in great veneration as emblematical of their ancient god Pan, and ſacrifices of the moſt abominable kind were offered to the impure animal (ſee PAN); but God, by his ſervant Moſes, enjoined the Iſraelites to offer goats themſelves as ſacrifices for ſin, and on one occaſion to diſmiſs the live animal loaded with maledictions into the wilderneſs*. The Egyptians, with ſingular zeal, worſhipped a calf without blemiſh as the ſymbol of Apis, or the god of fertility; and it appears from the book of Exodus, that the Iſraelites themſelves had been infected with that ſuperſtition. They were, however, ſo far from being permitted by their Divine lawgiver to conſider that animal as in any reſpect ſacred, that their prieſts were commanded to offer for themſelves a young calf as a ſin offering ‖. No animal was in Egypt held in greater veneration than the ram, the ſymbol of their god Ammon, one of the heavenly conſtellations. It was therefore with wiſdom truly divine, that Jehovah, at the inſtitution of the paſſover, ordered his people to kill and eat a young ram on the very day that the Egyptians began their annual ſolemnities § in honour of that animal as one of their greateſt gods; and that he enjoined the blood of this divinity to be ſprinkled as a ſign upon the two ſide-poſts and upper door-poſt of the houſe in which he was eaten. Surely it is not in the power of imagination to conceive a ritual better calculated to cure the Iſraelites of their propenſity to idol worſhip, or to keep them ſeparate from the people who had firſt given them that propenſity, than one which enjoined them to offer in ſacrifice the very creatures which their ſuperſtitious maſters had worſhipped as gods. "Shall we (ſaid Moſes) ſacrifice the abominations of the Egyptians before their eyes, and will they not ſtone us?"

† Num. xix.

* Levit. xvi.

‖ Lev. ix.

§ Spencer de Legibus Heb. Rit. lib. ii. cap. 4.

But it was not againſt Egyptian idolatry only that the ritual law was framed: the nations of Syria, in the midſt of whom the Iſraelites were to dwell, were addicted to many cruel and abſurd ſuperſtitions, againſt which it was as neceſſary to guard the people of God as againſt the brute-worſhip of Egypt. We need not inform any reader of the books of Moſes that thoſe nations worſhipped the ſun and moon and all the hoſt of heaven; or that it was part of their religion to propitiate their offended gods by occaſionally ſacrificing their ſons and their daughters. From ſuch worſhip and ſuch ſacrifices the Iſraelites were prohibited under the ſevereſt penalties; but we cannot conſider that prohibition as making part of the *ritual* law, ſince it relates to practices impious and immoral in themſelves, and therefore declared to be abominations to the Lord. The Phœnicians, however, and the Canaanites, entertained an opinion that every child came into the world with a *polluted nature*, and that this pollution could be removed only by a *luſtral fire*. Hence they took their new born infants, and with particular ceremonies made them paſs through the flame of a pile ſacred to Baal or Moloch, the ſymbols of their great god the ſun. Sometimes this purgation was delayed till the children had arrived at their tenth or twelfth year, when they were made either to leap through the flame, or run ſeveral times backwards and forwards between two contiguous ſacred fires; and this luſtration was ſuppoſed to free them from every natural pollution, and to make them through life the peculiar care of the deity in whoſe honour it was performed*. The true God, however, who would have no fellowſhip with idols, forbade all ſuch purgations among his people, whether done by fires conſecrated to himſelf or to the bloody deities of the Syrian nations. "There ſhall not be found (ſays he) among you any one that maketh his ſon or his daughter to paſs through the fire †."

155 And in the laws reſpecting eating, and drinking, and agriculture.

* Spencer, lib. ii. cap. 13.

† Deut. xvii. 10. xii. 26, and Levit. xx. 2, &c.

There are, in the Jewiſh law, few precepts more frequently repeated than that which prohibits the ſeething of a kid in its mother's milk‖; and there being no moral fitneſs in this precept when conſidered abſolutely and without regard to the circumſtances under which it was given, infidel ignorance has frequently thought fit to make it the ſubject of profane ridicule. But the ridicule will be forborne by thoſe who know that, among the nations round Judea, the feaſting upon a kid boiled in its mother's milk was an eſſential part of the impious and magical ceremonies celebrated in honour of one of their gods, who was ſuppoſed to have been ſuckled by a ſhe-goat. Hence, in the Samaritan Pentateuch, the text runs thus; "Thou ſhalt not ſeeth a kid in its mother's milk; for whoever does ſo, is as one who ſacrifices an abominable thing, which offends the God of Jacob §." Another precept, apparently of very little importance, is given in theſe words: "Ye ſhall not round the corners of your heads, neither ſhalt thou mar the corners of thy beard*." But its wiſdom is ſeen at once, when we know that at funerals it was the practice of many of the heathens, in that early period, to round the corners of their heads, and mar their beards, that by throwing the hairs they had cut off upon the dead body, or the funeral pile, they might propitiate the ſhade of the departed hero; and that in other nations, particularly in Phœnicia, it was cuſtomary to cut off all the hair of their heads except what grew upon the crown, which, with great ſolemnity, was conſecrated either to the ſun or to Saturn†. The unlearned Chriſtian, if he be a man of reflection, muſt read with ſome degree of wonder ſuch laws as theſe. "Thou ſhalt not ſow thy vineyard with divers ſeeds, leſt the fruit of thy ſeed which thou haſt ſown, and the fruits of thy vineyard be defiled. Thou ſhalt not plow with an ox and an aſs together. Thou ſhalt not wear a garment of divers ſorts, or of woollen and linen together‡." But his wonder will ceaſe when he knows that all theſe were practices from which the Sabian idolaters of the eaſt expected the greateſt advantages. Their belief in magic and judicial aſtrology led them to imagine, that by ſowing different kinds of corn among their vines they ſhould propitiate the gods which were afterwards known in Rome by the names of Bacchus and Ceres; that, by yoking animals ſo heterogeneous as the ox and the aſs in the ſame plough, they ſhould by a charm ſecure the favour of the deities who preſided over the affairs of huſbandry; and that a garment compoſed of linen and woollen worn under certain conjunctions of the ſtars, would protect its owner, his flocks, his herds, and his field, from all malign influences, and render him in the higheſt degree

Theology from the fall of Adam to the coming of Christ.

degree prosperous through the whole course of his life §. But magical ceremonies, of which the very essence seems to have consisted in uniting in one group or jumble things never brought together by nature, were always performed in order to render propitious good or evil demons (see MAGIC); and therefore such ceremonies, however unimportant in themselves, were in that age most wisely prohibited in the Mosaic law, as they naturally led those who were addicted to them to the worship of idols and impure spirits.

§ Spenser, lib. ii. cap. 30, 31, 33.

If the whole ritual of the Jewish economy be examined in this manner, every precept in it will be found to be directed against some idolatrous practice of the age in which it was given. It was therefore admirably calculated to keep the Israelites a separate people, and to prevent too close an intercourse between them and their Gentile neighbours. And their civil institutes, even those which appear the most trifling, were all contrived with the most consummate wisdom to promote the same end. The distinction made by their law between clean and unclean animals (see SLAVERY, n° 33.) rendered it impossible for them, without a breach of that law, to eat and drink with their idolatrous neighbours; their sacred and civil ceremonies being directly levelled against the Egyptian, Zabian, and Canaanitish superstitions, had a tendency to generate in their minds a keen contempt of those superstitions; and that contempt must have been greatly increased by their yearly, monthly, and daily sacrifices, of the very animals which their Egyptian masters had worshipped as gods.

156 The Mosaic laws enforced by temporal sanctions.

That these laws might have the fuller effect upon minds gross and carnal, they were all enforced by temporal sanctions. This was indeed the natural and even necessary consequence of the theocratic government established in Israel; for when God condescended to become their supreme civil magistrate, he of course engaged to execute, either immediately by himself, or by the medium of his vicegerents the judges and the kings, all the offices included in such magistracy. Hence it is that Moses assured them, that if they would hearken to God's judgments, and keep them, and do them, they should be blessed above all people; threatening them at the same time with utter destruction if they should at all walk after other gods, and serve them, and worship them‡. Nor were these temporal rewards and punishments held out only to the nation as a collective body; they were promised and threatened to every individual in his private capacity as the certain consequences of his obedience or disobedience. Every particular Hebrew was commanded to honour his father and mother, that it might go well with him, and that his days might be prolonged; whilst he who cursed his father or his mother was surely to be put to death. Against every idolater, and even against the wilful transgressor of the ceremonial law, God repeatedly declared that he would set his face, and would cut off that man from among his people: and that individuals, as well as the nation, were in this life actually rewarded and punished according to their deserts, has been proved by bishop Warburton with a force of evidence § which must carry conviction to every mind which his lordship's rude railings at some favourite system have not filled with prejudices against all his works. Indeed the Mosaic law, taken in its literal sense holds out no other prospects to the Israelites than temporal happiness; such as, health, long life, peace, plenty, and dominion, if they should keep the covenant; and temporal misery, *viz.* diseases, immature death, war, famine, want, subjection, and captivity, if they should break it. "See (says Moses), I have set before thee this day life and good, death and evil; in that I command thee this day to love the Lord thy God, to walk in his ways, and to keep his commandments, and his statutes, and his judgments, that thou mayest live and multiply; and the Lord thy God shall bless thee in the land whither thou goest to possess it. But if thine heart turn away, so that thou wilt not hear, but shalt be drawn away, and worship other gods, and serve them; I denounce unto you this day, that ye shall surely perish, and that ye shall not prolong your days upon the land whither thou passest over Jordan to possess it." And elsewhere, having informed them that, upon their apostacy, their land should be rendered like Sodom and Gomorrah, he adds, that all men should know the reason of such barrenness being brought upon it, and should say, "Because they have forsaken the covenant of the Lord God of their fathers, which he made with them when he brought them forth out of the land of Egypt, the anger of the Lord was kindled against this land, to bring upon it all the curses that are written in this book ‡."

‡ Deut. passim

§ Div. Leg. book v. sect. 4.

Theology from the fall of Adam to the coming of Christ.

‡ Deut. xxx. 15—19. xxix. 25.

From this notorious fact, which hardly any man of letters will now dare to deny, some divines have concluded, we think rashly, that the ancient Israelites had no hope whatever beyond the grave; and that in the whole Old Testament there is not a single intimation of a future state. That many of the lowest vulgar, who could neither read nor write, were in this state of darkness, may be true; but it is impossible that such of them as understood the book of Genesis could be ignorant that death came into the world by the transgression of their first parents, and that God had repeatedly promised to redeem mankind from every consequence of that transgression. They must likewise have known that, before the deluge, Enoch was translated into heaven without tasting death; that afterwards Elijah had the same exemption from the common lot of humanity; and that, as God is no respecter of persons, every one who served him with the zeal and fidelity of these two prophets would, by some means or other, be made capable of enjoying the same rewards. The God of Abraham, Isaac, and Jacob, was not the God of the dead but of the living.

157 Whence it has been rashly inferred that the ancient Hebrews had no hope beyond the grave.

In the earliest periods of their commonwealth, the Israelites could, indeed, only *infer*, from different passages of their sacred books, that there would be a general resurrection of the dead, and a future state of rewards and punishments; but from the writings of the prophets it appears, that before the Babylonish captivity that doctrine must have been very generally received. We shall not, in support of our opinion, quote the famous passage in the book of Job §, because it is not determined at what period that beautiful and sublime poem was admitted into the Jewish canon; but in the Psalms, and in the prophecies of Isaiah, Daniel, and Ezekiel, there are several texts which seem to us to prove, incontrovertibly, that, at the time when these inspired books were written, every Israelite who could read the scriptures must have had some hopes of a resurrection from the dead. We shall consider two of these texts, because they have been quoted by a very learned and valuable writer in support of an opinion the reverse of ours.

§ Chap. xix. verse 25, &c.

158 This opinion confuted.

In a sublime song, composed with a view to incite the people to confidence in God, the prophet Isaiah has these remarkable words; "Thy dead men shall live; together with my dead body shall they arise. Awake and sing, ye that dwell in the dust; for thy dew is as the dew of herbs, and the earth shall cast out the dead‡." We agree with bishop Warburton that these words are figurative, and that they were uttered to give the Israelites consolation in very disastrous times. The purpose of the prophet was to assure them, that though their community should, in Babylon, be as completely dissolved as a dead body reduced to dust, yet God would restore them to their own land, and raise that community again to life. This was indeed a prophecy only of a temporal deliverance; but as it is expressed in terms

‡ Chap. xxvi. 19.

Theology from the fall of Adam to the coming of Chriſt.

relating to the death and reſurrection of man, the doctrine of a reſurrection muſt then have been well known, and generally received, or ſuch language would have been altogether unintelligible. No (ſays the biſhop); that the language might be intelligible, it was only neceſſary that the Iſraelites ſhould have diſtinct *ideas* of a reſurrection from the dead, without knowing that the natural body is indeed to riſe again; and as he thinks that ſuch metaphorical expreſſions as this would have the greateſt force where the doctrine of the reſurrection was unknown, he concludes that it muſt have been unknown among the Iſraelites in the days of Iſaiah*.

* Div. Leg. book vi. ſect. 2.

Had there been no ſacred books among the Iſraelites before this prophecy was uttered, his lordſhip's reaſoning would have been at leaſt plauſible, if not concluſive; but that a people who knew how death had entered into the world, who believed that they were by ſome means or other to be freed from its ſting, who, it is natural to ſuppoſe, often meditated upon the bruiſing of the ſerpent's head, and the nature of the bleſſing which all nations were to derive from the ſeed of Abraham, ſhould form diſtinct *ideas* of a reſurrection, and read this prophecy without believing that the natural body is *indeed to riſe again*, we cannot poſſibly conceive. The very ſuppoſition is one of his lordſhip's moſt irreconcileable paradoxes; and it is a paradox which his ſyſtem did not require him to ſupport.

The prophet Ezekiel, when the ſtate of things was moſt deſperate, is carried by the Spirit into a valley full of dry bones, and aſked this queſtion; "Son of man, can theſe bones live?" To which he anſwers; "O Lord God, thou knoweſt†;" an anſwer which the ſame learned prelate thinks the prophet could not have made, had he been brought up in the knowledge and belief of a reſurrection from the dead. Our opinion is directly the reverſe of that of his lordſhip, who ſeems to have miſtaken the nature of this ſcenical repreſentation. The prophet was not aſked if *all* the dead would riſe at the laſt day; but only if the particular bones *then* preſented to him could live at *that time*, and while other bones were mouldering in corruption: and to ſuch a queſtion we cannot conceive any anſwer that a man brought up in the belief of a general reſurrection could have given, but—"O Lord God, thou knoweſt." Had Ezekiel been a ſtranger to the doctrine of a general reſurrection, or had he not believed that doctrine, he would doubtleſs have anſwered the queſtion that was put to him in the negative; but convinced that *all* men are at *ſome* period to riſe from the dead, "that every one may receive the things done in his body, according to that he hath done, whether it be good or bad," he very naturally ſaid, that God alone knew whether the bones then exhibited to him in the valley would riſe before the general reſurrection.

† Chap. xxxvii. 3.

But though the more intelligent and righteous Iſraelites certainly "all died in faith, and not having received the promiſes, but having ſeen them afar off, were perſuaded of them and embraced them, confeſſing that they were ſtrangers and pilgrims on earth, who deſired a better country, that is, a heavenly one †," we are not to ſuppoſe that this heavenly deſire aroſe from any thing taught in the law of Moſes. That law, when taken by itſelf, as unconnected with prior and ſubſequent revelations, makes no mention whatever of a heavenly inheritance, which St Paul aſſures us ‡ was given 430 years before to Abraham by a promiſe which may be traced back to the firſt ray of comfort vouchſafed to fallen man in the ſentence paſſed on the original deceiver. "Wherefore then ſerved the law? It was added (ſays the apoſtle), becauſe of tranſgreſſions, till the ſeed ſhould come to whom the promiſe was made." The tranſgreſſions here alluded to were polytheiſm and idolatry, which, with their never-failing train of cruel and deteſtable vices, had overſpread the whole world; and the primary intention of the law was to ſtem the torrent of theſe corruptions, for which we have ſeen it was admirably calculated; and, like a ſchoolmaſter, to inſtruct the Iſraelites in the unity and worſhip of Jehovah, and thus by degrees bring them to Chriſt.

Theology from the fall of Adam to the coming of Chriſt.

159 The hope of the Hebrews, however, not from their own law.

† Heb. xi. 13, &c.

‡ Gal. iii. 16—19.

But though it is apparent that a future ſtate of rewards and puniſhments made no part of the Moſaic diſpenſation, yet the law had certainly a ſpiritual meaning to be underſtood when the fulneſs of time ſhould come. Every Chriſtian ſees a ſtriking reſemblance between the ſacrifice of the paſchal lamb, which delivered the Iſraelites from the deſtroying angel in Egypt, and the ſacrifice of the lamb of God, which taketh away the ſin of the world. Indeed the whole ritual of ſacrifice muſt have led the more intelligent of them to faith in a future ſacrifice; by which, while the heel of the ſeed of the woman ſhould be bruiſed, the head of the ſerpent ſhould be completely cruſhed (ſee SACRIFICE); and as prophets were raiſed up from time to time, to prepare them for the coming of the Meſſiah, and to foretel the nature of his kingdom, there can be no doubt but that thoſe inſpired teachers would lay open to them, as far as was expedient, the temporary duration of the Moſaic law, and convince them that it was only the ſhadow of better things to come. From the nature of their ritual, and the different prophecies vouchſafed them, which became more and more explicit as the time approached for their accompliſhment, they muſt ſurely have been led to expect redemption from the curſe of the fall by the ſufferings of their Meſſiah; but that any one of them knew preciſely the *manner* in which they were to be redeemed, and the nature of that religion which was to ſuperſede their own, is wholly incredible (B). Such knowledge would have

160 Why the law was typical.

(B) This doctrine is ſtated in ſo clear a light by biſhop Bull, whom, as a divine, we think the glory of the church of England, and who has had few ſuperiors in any church, that the learned reader will be pleaſed to have his opinions in his own words. "An igitur, inquies, fuerunt ſub lege, qui vitam æternam ſperarent? Reſp. Qui meliores erant et perſpicaciores in populo Judaico, veroſimile eſt eos ſeu generalium promiſſionum vi, ſeu temporalium bonorum levi æſtimatione, ſeu divinæ bonitatis intuitu, ſeu animæ ſuæ, melioris quam caduci boni appetentis, conſideratione, ſeu Enochi exemplo (cui ſequiori ævo acceſſit Eliæ raptus) ſeu Patriarcharum traditione, (quibus Deus multis indiciis ſpem futurorum bonorum fecerat, in quorum indiciorum genere non minimum erat et illud, quod multi eximie boni terreſtris felicitatis expertes vixerint, quod argumentum late exequitur Scriptor ad Hebræos cap. 11.) ſeu aliis rationibus adductos credidiſſe, Deum, præter ſpecialia iſta bona ad hanc vitam pertinentia, et legibus Moſaicis comprehenſa, etiam alia poſt mortem cultoribus ſuis fidis largiri velle. Imo ſtatuendum illud omnino eſt, ne viros ſanctos eximioſque in populo Dei ſuum inſtar tum vixiſſe, tum devixiſſe credatur. Nec refert, quod hujus fidei vix ac ne vix quidem ulla in Canonicis V. T. Scripturis mentio fiat. Nam certum eſt, Abrahamum filium promiſſionis, mactare juſſum non recuſaſſe, hac ratiocinatione ſuſtentatum, Deum potentia tanta præditum eſſe, ut filium jam mortuum in vitam revocare, eumque ei redivivum reſtituere poſſet. Certum, inquam, illud eſt, quia divinus Autor Epiſtolæ ad Hebræos id diſerte teſtatur, cap.

Theology from the fall of Adam to the coming of Christ.

have made them impatient under the yoke of ordinances to which they were subjected; for after the Christian faith came into full splendour, mankind could be no longer under the tuition of such a schoolmaster as the law, which "had only a *shadow* of good things; and so far from their reality, not even the very *image* of them †." Through these shadows, however, the Jews, aided by the clearer light of prophecy, though it too shone in a dark place, might have seen enough of God's plan of redemption to make them acknowledge Jesus of Nazareth, when he came among them working miracles of mercy, for the Messiah so long promised to their forefathers, and in whom it was repeatedly said, that all the nations of the earth should be blessed.

† Heb. x. 1.

161 Means used to prepare the world for the coming of Christ.

While such care was taken to prepare the descendants of Abraham for the coming of the Prince of Peace, we must not suppose that God was a respecter of persons, and that the rest of the world was totally neglected. The dispersion of the ten tribes certainly contributed to spread the knowledge of the true God among the eastern nations. The subsequent captivity of the tribes of Judah and Benjamin must have confirmed that knowledge in the great empires of Babylon and Persia; and that particular providence of God which afterwards led Ptolemy Philadelphus to have the Jewish scriptures translated into the Greek language, laid the divine oracles open to the study of every accomplished scholar. At last, when the arms of Rome had conquered the civilized world, and rendered Judea a province of the empire; when Augustus had given peace to that empire, and men were at leisure to cultivate the arts and sciences; when the different sects of philosophers had by their disputations whetted each others understandings so that none of them was disposed to submit to an imposture; and when the police of the Roman government was such that intelligence of every thing important was quickly transmitted from the most distant provinces to the capital of the empire; "when that fulness of time was come, God sent forth his Son made of a woman, made under the law, to redeem them that were under the law, that we might receive the adoption of sons," and be restored to that inheritance of which the forfeiture introduced the several dispensations of revealed religion into the world.

SECT. V. *View of Theology, more peculiarly Christian.*

MANKIND being trained by various dispensations of providence for the reception of that seed of Abraham, in whom all the nations of the earth were to be blessed, and the time fixed by the Jewish prophets for his coming being arrived, "a messenger was sent before his face to prepare his way before him by preaching the baptism of repentance for the remission of sins." This messenger was John the Baptist, a very extraordinary man, and the greatest of all the prophets. His birth was miraculous, the scene of his ministry the wilderness, his manners austere, and his preaching upright, without respect of persons. He frankly told his audience that he was not the Messiah, that the Messiah would soon appear among them, that "he was mightier than himself, and that he would baptise them with the Holy Ghost and with fire."

Theology more peculiarly Christian.

162 Christ the divine word incarnate.

Mightier indeed he was; for though born of a woman the Messiah was not the son of a human father; and though living for the first thirty years of his life in obscurity and poverty, he was the lineal descendant of David, and heir to the throne of Israel. But the dignity of his human descent, great as it was, vanishes from consideration when compared with the glory which he had with his father before the world was. The Jewish dispensation was given by the ministry of Moses, and illustrated by subsequent revelations vouchsafed to the prophets; the immediate author of the Christian religion is the λογος or second person of the blessed Trinity, of whom St John declares, that "he was in the beginning with God, and was God; that all things were made by him; and that without him was not any thing made that was made." We have already proved that in the one Godhead there is a Trinity of persons; and that the λογος is one of the three, is apparent from these words of the apostle, and from many other passages of sacred scripture. Thus he is called *the Lord of hosts himself; the first and the last, besides whom there is no God; the most high God; God blessed for ever; the mighty God, the everlasting Father, Jehovah our righteousness;* and *the only wise God our Saviour* (c). This great Being, as the same apostle assures us, was made flesh, and dwelt among men; not that the divine nature was or could be changed into humanity, for God is immutable, the same Almighty and incomprehensible Spirit yesterday, to-day, and forever; but the word or second person in the godhead, assuming a human soul and body into a personal union with himself, dwelt upon earth as a man, veiling his divinity under mortal flesh. Hence he is said elsewhere to have been "manifested in the flesh," and "to have taken upon him the nature of man;" phrases of the same import with that which asserts "the WORD to have been made flesh."

163 Objections to the incarnation of the word

This incarnation of the Son of God is perhaps the greatest mystery of the Christian faith, and that to which ancient and modern heretics have urged the most plausible objections. The doctrine of the Trinity is indeed equally incomprehensible; but the nature of God and the mode of his subsistence, as revealed in scripture, no man, who thinks, can be surprised that he does not comprehend; for a revelation which should teach nothing mysterious on such a subject would be as incredible and as useless as another which

cap. 11. 19. Hujus tamen vere admirandæ fidei, atque Evangelicæ supparis, in historia Abrahami nec volam, nec vestigium reperias. Præterea floruerunt singulis sæculis in populo Judaico Viri Dei ac Prophetæ cælitus edocti, quos, inter tot arcana ipsis patefacta, mysticum hunc legis sensum penitus ignorasse, nihilque de futura vita intellexisse, nemo prudens suspicabitur. Cum autem nefas sit vel cogitasse, Viros optimos sapientiam, qua ipsi pollebant, aliis invidisse, credendum omnino est, eos, *sicubi idoneos invenerint Auditores*, evolvisse iis obtecta in lege mysteria, singulisque tantum aperuisse, quantum captus ipsorum et utilitatis ratio ferebat. In publicis autem concionibus Prophetæ ac Sapientes ita loquebantur, ut nec in contemptum adducerent arcana sanctioris disciplinæ, et tamen Auditorem attentum ad investigandi sollicitudinem excitarent. Atque hinc natum arbitratur maximus Grotius discrimen antiquitus inter Judæos celebratum, scriptæ legis, et legis oralis, quam et קבלה i. e. παράδοσιν seu *Traditionem* vocant; utramque dicentes a Mose profectam: non quod res aliæ fuerint in traditione quam in lege scripta; sed quod ea quæ in lege scripta occultius continebantur, studiosis indagatoribus enodaret accuratior interpretatio. *Harmonia Apostolica*, Dissert. post. cap. 10.

Theology more peculiarly Christian.

contained nothing but *myſtery*. The difficulty reſpecting the incarnation, which forces itſelf upon the mind, is not how two natures ſo different as the divine and human can be ſo intimately united as to become one perſon; for this union in itſelf is not more inconceivable than that of the ſoul and body in one man: but that which at firſt is apt to ſtagger the faith of the reflecting Chriſtian is the infinite diſtance between the two natures in Chriſt, and the comparatively ſmall importance of the object, for the attainment of which the eternal Son of God is ſaid to have taken upon him our nature.

164 Obviated.

Upon mature reflection, however, much of this difficulty will vaniſh to him who conſiders the ways of Providence, and attends to the meaning of the words in which this myſtery is taught. The importance of the object for which the WORD condeſcended to be made fleſh, we cannot adequately know. The oracles of truth indeed inform us, that Chriſt Jeſus came into the world to ſave ſinners; but there are paſſages ſcattered through the New Teſtament * which indicate, not obſcurely that the influence of his ſufferings extends to other worlds beſides this: and if ſo, who can take upon him to ſay, that the quantity of good which they may have produced was not of ſufficient importance to move even to this condeſcenſion a Being who is emphatically ſtyled LOVE?

* Eph. i. 10. Col. i. 19, 20

But let us ſuppoſe that every thing which he did and taught and ſuffered was intended only for the benefit of man, we ſhall, in the daily adminiſtration of providence, find other inſtances of the divine condeſcenſion; which, though they cannot be compared with the incarnation of the ſecond perſon in the bleſſed Trinity, are yet ſufficient to reconcile our underſtandings to that myſtery when revealed to us by the Spirit of God. That in Chriſt there ſhould have dwelt on earth "all the fulneſs of the Godhead bodily ‖," is indeed a truth by which the devout mind is overwhelmed with aſtoniſhment; but it is little leſs aſtoniſhing that the omnipotent Creator ſhould be intimately preſent at every inſtant of time to the meaneſt of his creatures, "upholding all things, the vileſt reptile as well as the moſt glorious angel, by the word of his power‡." Yet it is a truth ſelf-evident, that without this conſtant preſence of the Creator, nothing which had a beginning could continue one moment in being; that the viſible univerſe would not only crumble into chaos, but vaniſh into nothing; and that the ſouls of men, and even the moſt exalted ſpirits of creation, would inſtantly loſe that exiſtence, which, as it was not of itſelf, and is not neceſſary, muſt depend wholly on the will of him from whom it was originally derived. See METAPHYSICS, n° 272—276, and PROVIDENCE, n° 3.

‖ Col. ii.

‡ Heb. i. 3.

In what particular way God is preſent to his works, we cannot know. He is not diffuſed through the univerſe like the *anima mundi* of the ancient Platoniſts, or that modern idol termed the *ſubſtratum of ſpace* (METAPHYSICS, n° 309, 310.); but that he is in power as intimately preſent now to every atom of matter as when he firſt brought it into exiſtence, is equally the dictate of ſound philoſophy and of divine revelation; for "in him we live and move and have our being;" and power without ſubſtance is inconceivable. If then the divine nature be not debaſed, if it cannot be debaſed by being conſtantly preſent with the vileſt reptile on which we tread, why ſhould our minds recoil from the idea of a ſtill cloſer union between the ſecond perſon of the ever bleſſed trinity and the body and ſoul of Jeſus Chriſt? The one union is indeed different from the other, but we are in truth equally ignorant of the nature of both. Reaſon and revelation aſſure us that God muſt be preſent to his works to preſerve them in exiſtence; and revelation informs us farther, that one of the perſons in the Godhead aſſumed human nature into a perſonal union with himſelf, to redeem myriads of rational creatures from the miſerable conſequences of their own folly and wickedneſs. The importance of this object is ſuch, that, for the attainment of it, we may eaſily conceive that he who condeſcends to be potentially preſent with the worms of the earth and the graſs of the field, would condeſcend ſtill farther to be perſonally preſent with the ſpotleſs ſoul and body of a man. Jeſus Chriſt lived indeed a life of poverty and ſuffering upon earth, but his divine nature was not affected by his ſufferings. At the very time when, as a man he had not a place where to lay his head; as God, he was in heaven as well as upon earth*, dwelling in light inacceſſible; and while, as a man, he was increaſing in wiſdom and ſtature, his divinity was the fulneſs of him who filleth all in all, and from whom nothing can be hid.

Theology more peculiarly Christian.

* John iii. 13.

Perhaps the very improper appellation of *mother of God*, which at an early period of the church was given to the Virgin Mary, may have been one cauſe of the reluctance with which the incarnation has been admitted; for as we have elſewhere obſerved (ſee NESTORIUS), ſuch language, in the proper ſenſe of the words, implies what thoſe, by whom it is uſed, cannot poſſibly believe to be true; but it is not the language of ſcripture. We are there taught, that "Chriſt being in the form of God, thought it no robbery to be equal with God; but made himſelf of no reputation, and took upon him the form of a ſervant, and was made in the likeneſs of man†;" that "God ſent forth his Son made of a woman, made under the law, to redeem them that were under the law, that we might receive the adoption of ſons‖;" and that "the WORD who was in the beginning with God, and was God, by whom all things were made, was made fleſh, and dwelt among men (who beheld his glory, the glory as of the only begotten of the father), full of grace and truth‡:" but we are nowhere taught that as God, he had a mother! It was indeed the doctrine of the primitive church‖, that the very principle of perſonality and individual exiſtence in Mary's ſon, was union with the uncreated WORD; and this doctrine is thought to imply the miraculous conception, which is recorded in the plaineſt terms by two of the evangeliſts; for he was conceived by the Holy Ghoſt and born of a virgin§; but, as God, he had been begotten from all eternity of the Father, and in order of nature was prior to the Holy Ghoſt. This is evident from the appellation of ὁ λογος given to him by St John; for the term being uſed in that age, both by the Jewiſh Rabbies and the heathen philoſophers, to denote the ſecond divine ſubſiſtence, which they conſidered as an eternal and neceſſary emanation from the firſt, ſometimes called τ' αγαθον and ſometimes το ἑν; and the apoſtle giving no intimation of his uſing the word in any uncommon ſenſe, we muſt neceſſarily conclude, that he meant to inform us that the divinity of Chriſt is of eternal generation. That the term λογος was uſed in this ſenſe by the later Platoniſts, and in all probability by Plato himſelf, we have ſufficiently ſhewn in another place (ſee PLATONISM); and that a ſimilar mode of expreſſion prevailed among the Jews in the time of St John, is apparent from the Chaldee paraphraſe; which, in the 110th Pſalm, inſtead of the words "the Lord ſaid unto my Lord," has, "the Lord ſaid unto his WORD." Again, where we are told in the Hebrew that Jehovah ſaid to Abraham§, "I am thy ſhield and thy exceeding great reward," we read in the Chaldee, "my WORD is thy ſhield, and thy exceeding great reward." Where it is ſaid, "your new moons and your appointed feaſts my ſoul hateth*." the paraphraſt hath it, "my WORD hateth;" and where it is ſaid, that "Iſrael ſhall be ſaved in the Lord with an everlaſting ſalvation†," in the ſame paraphraſe it is, "Iſraël

rael ſhall be ſaved by the WORD of the Lord with everlaſting ſalvation." But there is a paſſage in the Jeruſalem Targum which puts it beyond a doubt, that by the λογος the Jews underſtood a divine perſon begotten of his Father before all worlds; for commenting on Geneſis iii. 22. the authors of that work thus expreſs themſelves: "The WORD of the Lord ſaid, behold Adam, whom I created, is the only begotten upon earth, as I AM THE ONLY BEGOTTEN IN HEAVEN;" in conformity with which, Philo introduces ‡ the Logos ſpeaking thus of himſelf; και γαρ ουτε αγεννητος ως θεος ων, ουτε γεννητος ως ημεις, *I am neither unbegotten, as God, nor begotten after the ſame manner as you are.*

‡ De Agricult. lib. ii.

166 Orthodoxy of the Nicene creed.

From theſe quotations we may juſtly conclude, that the Nicene fathers expreſſed themſelves properly when they declared that the only begotten Son of God was begotten of his Father before all worlds, and is God of God; for if St John had believed the λογος or WORD to be unbegotten, contrary to the belief of all who made uſe of the phraſe at the time when he wrote, he would ſurely have expreſſed his diſſent from the generally received opinion. This however, he is ſo far from doing, that he gives the ampleſt confirmation of that opinion, by declaring, that "he beheld the glory of the WORD incarnate as the glory of the only begotten of the Father;" for this declaration is true only of the divinity of Chriſt, his human nature not being begotten of the Father, but conceived by the Holy Ghoſt of the Virgin Mary. Hence our bleſſed Lord aſſures us, that "as the Father HATH life in HIMSELF, ſo hath he GIVEN the Son to have life in himſelf;" that "the Son can do nothing of *himſelf*, but what he ſeeth the Father do ‖;" and that "he knew the Father becauſe he was from him and ſent by him †." We muſt therefore agree with biſhop Pearſon (D), that "though the Father and Son are both truly God, and therefore equal in reſpect of nature, yet the one is greater than the other, as being the fountain of the Godhead. The Father is God, but *not of God*; Light, but *not of Light*. Chriſt is God, but *of* God; Light, but *of* Light. There is no difference or inequality in the nature or eſſence, becauſe the ſame in both; but the Father of our Lord Jeſus Chriſt hath that eſſence of himſelf, from none; Chriſt hath the ſame eſſence, not of himſelf, but from him."

‖ St John v. 26. 19. † John vii. 29.

167 Purpoſe for which Chriſt was ſent into the world.

The great purpoſe for which this divine perſon was ſent into the world, and born of a woman, was to bruiſe the head of the ſerpent, and reſtore mankind to the inheritance which had been forfeited by Adam's tranſgreſſion. Every diſpenſation of Providence from the fall had been preparatory to this reſtoration. Prophets had been raiſed from time to time to preſerve in the early ages of the world the knowledge and worſhip of the true God: the children of Abraham, as we have ſeen, had been ſeparated from the ſurrounding nations for the ſame purpoſe; and by the diſperſion of the ten tribes, the captivity of the other two in Babylon, and the tranſlation of the Hebrew ſcriptures into the Greek language, much of the knowledge which had been revealed to the Iſraelites was gradually diffuſed over the eaſtern world.

Theology, more peculiar y Chriſtian.

But while the Jews were thus rendered the inſtruments of enlightening the heathen nations of antiquity, their intercourſe with thoſe nations made them almoſt unavoidably acquainted with the philoſophy which was cultivated among the Chaldeans, the Perſians, and the Egyptian Greeks; and ingrafting many of the opinions derived from thoſe ſchools upon the doctrines of Moſes and the prophets, they corrupted their own religion while they improved that of their neighbours. Hence, by the time that Chriſt came among them, they had made the word of God of none effect through a number of idle fancies which they inculcated on the people as the traditions of the elders; and as they had attached themſelves to different maſters in philoſophy, their unauthoriſed opinions were of courſe different according to the different ſources whence they were drawn. The peculiar tenets of the ESSENES ſeem to have been a ſpecies of myſtic Platoniſm. The PHARISEES are thought to have derived their origin from a Jewiſh philoſopher of the Peripatetic ſchool; and the reſemblance between the doctrines of the SADDUCEES and the philoſophy of Epicurus has eſcaped no man's obſervation.

168 Corruption of the Jews at the time of his coming.

Though theſe ſects maintained mutual communion in public worſhip, they abhorred each other's diſtinguiſhing tenets; and their eternal wranglings had well nigh baniſhed from them every ſentiment of true religion. They agreed, however, in the general expectation of the Meſſiah promiſed to their fathers; but, unhappily for themſelves, expected him as a great and temporal prince. To this miſtake ſeveral circumſtances contributed: ſome of their prophets had foretold his coming in lofty terms, borrowed from the ritual law, and the ſplendour of earthly monarchs. The neceſſity of caſting this veil over thoſe living oracles we have ſhewn in another place (ſee PROPHECY, n° 17.). At the time when the predictions were made, the Moſaic ſyſtem had not run out half its courſe, and was therefore not to be expoſed to popular contempt by an information that it was only the harſh rudiment of one more eaſy and perfect. To prevent, however, all miſtakes in the candid and impartial, when the Meſſiah ſhould arrive with the credentials of miraculous powers, other prophets had deſcribed him in the cleareſt terms as having no form nor comelineſs, as a ſheep dumb before his ſhearers, and as a lamb brought to the ſlaughter; but the Jews had ſuffered ſo much from the Chaldeans, the Greeks, and other nations by whom they had been conquered, and were then ſuffering ſo much from their maſters the Romans, that their carnal minds could think of no deliverance greater than that which ſhould reſcue their nation from every foreign yoke.

What men earneſtly wiſh to be true, they very readily believe.

(D) We beg leave to recommend to our readers this author's excellent expoſition of the apoſtle's creed, as a work which will render them great aſſiſtance in acquiring juſt notions of the fundamental articles of the Chriſtian faith. They will find it, we think, a complete antidote againſt the poiſon of modern Unitarians and modern Tritheiſts; of whom the former teach that Jeſus Chriſt was a mere man, the ſon of Joſeph as well as of Mary; while the latter, running to the other extreme, maintain, that, with reſpect to his divinity, he is in no ſenſe ſubordinate to the Father, but might have been the Father, the Son, or the Holy Ghoſt, according to the good pleaſure of the eternal three. We have been at ſome pains to prove his divinity, and likewiſe his eternal generation; but in ſuch a ſhort compend as we muſt give, it ſeems not to be worth while to prove his miraculous conception. That miracle is plainly aſſerted in the New Teſtament in words void of all ambiguity; and as it is ſurely as eaſy for God to make a man of the ſubſtance of a woman as of the duſt of the earth, we cannot conceive what ſhould have induced any perſon profeſſing Chriſtianity to call it in queſtion. The natural generation of Chriſt is a groundleſs fancy, which can ſerve no purpoſe whatever, even to the Unitarians.

Theology, more peculiarly Christian.

believe. Hence that people, losing sight of the yoke under which they and the whole human race were brought by the fall of Adam, mistaking the sense of the blessing promised to all nations through the seed of Abraham, and devoting their whole attention to the most magnificent descriptions of the Messiah's kingdom, expected in him a prince who should conquer the Romans, and establish on earth a universal monarchy, of which Jerusalem was to be the metropolis.

169 The objects of his preaching.

As our Saviour came for a very different purpose, the first object of his mission was to rectify the notions of his erring countrymen, in order to fit them for the deliverance which they were to obtain through him. Accordingly, when he entered upon his office as a preacher of righteousness, he embraced every opportunity of inveighing with becoming firmness against the false doctrines taught as traditions of the elders; and by his knowledge of the secrets of all hearts, he exposed the vile hypocrisy of those who made a gain of godliness. The Jews had been led, by their separation from the rest of the world, to consider themselves as the peculiar favourites of Jehovah; and the consequence was, that, contrary to the spirit of their own law, and the explicit doctrines of some of their prophets, they looked upon all other nations with abhorrence, as upon people physically impure. These prejudices the blessed Jesus laboured to eradicate. Having desired a lawyer, by whom he was tempted, to read that part of the law of Moses which commanded the Israelites to love their neighbours as themselves, he compelled him, by means of a parabolical account of a compassionate Samaritan, to acknowledge, that under the denomination of neighbour the divine lawgiver had comprehended all mankind as the objects of love ‖. The importance in which Moses held the ritual law, and to which, as the means of preserving its votaries from the contagion of idolatry, it was justly intitled, had led the Jews to consider every ceremony of it as of intrinsic value and perpetual obligation: but Jesus brought to their recollection God's declared preference of mercy to sacrifice; shewed them that the weightier matters of the law, judgment, mercy, and faith, claimed their regard in the first place, and its ceremonial observances only in the second; and taught them, in conformity with the predictions of their own prophets †, that the hour was about to come when the worship of God should not be confined to Jerusalem, but that "true worshippers should every where worship the Father in spirit and in truth. ‡"

‖ St Luke x. 25—38.

† Jeremiah xxxi. 31, &c.

‡ John iv. 25—27.

It being the design of Christ's coming into the world to break down the middle wall of partition between the Jews and Gentiles, and to introduce a new dispensation of religion which should unite all mankind as brethren in the worship of the true God, and fit them for the enjoyment of heaven; he did not content himself with merely restoring the moral part of the Mosaic law to its primitive purity, disencumbered of the corrupt glosses of the Scribes and Pharisees, but added to it many refined and spiritual precepts, which, till they were taught by him, had never occurred either to Jew or Gentile. The Hebrew lawgiver had prohibited murder under the penalty of death; but Christ extended the prohibition to causeless anger, and to contemptuous treatment of our brethren, commanding his followers, as they valued their everlasting salvation, to forgive their enemies, and to love all mankind. Adultery was forbidden by the law of Moses as a crime of the deepest dye; but Jesus said to his disciples, "that whosoever looketh on a woman to lust after her, hath committed adultery with her already in his heart," and is of course liable to the divine vengeance. The *lex talionis* was in force among the Jews, so that the man who had deprived his neighbour of an eye or a tooth, was to suffer the loss of an eye or a tooth himself; but this mode of punishment, which inflicted *blemish* for *blemish*, though suited to the hardness of Jewish hearts, being inconsistent with the mild spirit of Christianity, was abolished by our blessed Lord, who severely prohibited the indulgence of revenge, and commanded his followers to love even their enemies. Perjury has in every civilized nation been justly considered as a crime of the highest atrocity, and the Mosaic law doomed the false witness to bear the punishment, whatever it might be, which he intended by swearing falsely to bring upon his brother; but the Author of the Christian religion forbade not only false swearing, but swearing at all, except on solemn occasions, and when an oath should be required by legal authority. See OATH.

Theology, more peculiarly Christian.

170 In which he executed the office of a prophet.

By thus restoring the law to its original purity, and in many cases extending its sense, the blessed Jesus executed the office of a PROPHET to the lost sheep of the house of Israel; but had he not been more than an ordinary prophet, he could not have abrogated the most trivial ceremony of it, nor even extended the sense of any of its moral precepts; for their great lawgiver had told them, that "the Lord their God would raise up unto them but one Prophet, like unto him, to whom they should hearken ‡." That Prophet was by themselves understood to be the Messiah, whom they expected to tell them all things. It was necessary therefore that Jesus, as he taught some new doctrines, and plainly indicated that greater changes would soon be introduced, should vindicate his claim to that exalted character which alone could authorise him to propose innovations. This he did in the amplest manner, by fulfilling prophecies and working miracles (see MIRACLE and PROPHECY); so that the unprejudiced part of the people readily acknowledged him to be of a truth "that prophet which should come into the world—the Son of God, and the King of Israel. "He did not, however, make any change in the national worship, or assume to himself the smallest civil authority. He had submitted to the rite of circumcision, and strictly performed every duty, ceremonial as well as moral, which that covenant made incumbent upon other Jews; thus fulfilling all righteousness. Though the religion which he came to propagate was in many respects contrary to the ritual law, it could not be established, or that law abrogated, but in consequence of his death, which the system of sacrifices was appointed to prefigure; and as his kingdom, which was not of this world, could not commence till after his resurrection, he yielded during the whole course of his life a cheerful obedience to the civil magistrate, and wrought a miracle to obtain money to pay the tribute that was exacted of him. Being thus circumstanced, he chose from the lowest and least corrupted of the people certain followers, whom he treated with the most endearing familiarity for three years, and commissioned at his departure to promulgate such doctrines as, consistently with the order of the divine dispensations, he could not personally preach himself. With these men, during the course of his ministry on earth, he went about continually doing good, healing the sick, casting out devils, raising the dead, reproving vice, preaching righteousness, and instructing his countrymen, by the most perfect example which was ever exhibited in the world, of whatsoever things are true, or honest, or just, or pure, or lovely, or of good report. The Scribes and Pharisees, however, finding him not that conqueror whom they vainly expected, becoming envious of his reputation among the people, and being filled with rancour against him for detecting their hypocritical arts, delivered him up to the Roman governor, who, though convinced of his innocence, yielded to the popular clamour, and crucified him between two thieves, as an enemy to Cæsar.

171 His strict obedience to the law.

Just

Theology, more peculiarly Christian.

Juſt before he expired, he ſaid, It is finiſhed, intimating that the purpoſe was now fulfilled for which he had come into the world, and which, as he had formerly told his diſciples, "was not to be miniſtered unto but to miniſter, and to give his life a ranſom for many ‖." For his blood, as he aſſured them at the inſtitution of the Euchariſt, "was to be ſhed for the remiſſion of ſins." That Chriſt died voluntarily for us, the juſt for the unjuſt, and that "there is none other name under heaven given among men whereby we muſt be ſaved;" is the uniform doctrine of the prophets who foretold his coming, of John the Baptiſt who was his immediate harbinger, and of the apoſtles and evangeliſts who preached the goſpel after his aſcenſion into heaven. Thus Iſaiah ſays of the Meſſiah †, that "he was wounded for our tranſgreſſions, and bruiſed for our iniquities; that the chaſtiſement of our peace was upon him, and that with his ſtripes we are healed; that we had all like ſheep gone aſtray, turning every one to his own way, and that the Lord laid on him the iniquity of us all; that he was cut off out of the land of the living, and ſtricken for the tranſgreſſion of God's people; that his ſoul or life was made an offering for ſin; and that he bore the ſin of many, and made interceſſion for the tranſgreſſors." The Baptiſt, "when he ſaw Jeſus coming unto him, ſaid to the people, Behold the Lamb of God, which taketh away the ſin of the world;" plainly intimating that his death was to be a ſacrifice, ſince it was only as a ſacrifice that the Jews could form any conception of a lamb taking away ſin. The epiſtles of St Paul are ſo full of the doctrine of Chriſt's ſatisfaction, that it is needleſs from his writings to quote particular texts in proof of it. He tells the Romans, that Jeſus Chriſt was ſet forth to be a propitiation through faith in his blood; that he was delivered for our offences, and "raiſed again for our juſtification; that he died for the ungodly; and that God commendeth his love towards us, in that while we were yet ſinners Chriſt died for us." He aſſures the Corinthians that Chriſt died for all; that they who live ſhould not henceforth live unto themſelves, but to him who died for them and roſe again; and that God made him to be ſin for us who knew no ſin, that we might be made the righteouſneſs of God in him." He informs the Galatians, that Chriſt "gave himſelf for our ſins, that he might deliver us from this preſent evil world, according to the will of God and our Father; and that he redeemed us from the curſe of the law, being made a curſe for us." St Peter and St John talk the very ſame language; the former teaching us, that "Chriſt ſuffered for us, and bare our ſins in his own body on the tree †; the latter, that the blood of Jeſus Chriſt cleanſeth us from all ſin, and that he is the propitiation for our ſins; and not for our's only, but alſo for the ſins of the whole world ‡." That he came into the world for the purpoſe of ſuffering, appears from his own words: for "no man (ſaid he §) taketh my life from me, but I lay it down of myſelf: I have power to lay it down, and I have power to take it again. This commandment have I received from my Father." And that he voluntarily laid it down for mankind, is evident from his calling himſelf the Good Shepherd, and adding, that "the Good Shepherd giveth his life for the ſheep*."

‖ St Matth. xx. 28.

172 He voluntarily died for us.

† Chap. liii.

† 1 Peter ii. 21. and 24.

‡ 1 John i 7 ii. 2.

§ St John x. 18.

* Ibid. ver. 11.

173 Different opinions reſpecting the nature and extent of the benefit reaped from his death.

That Chriſt died for the benefit of the human race, is a truth ſo apparent from theſe texts, and from many others which might be quoted, that no man profeſſing Chriſtianity has hitherto called it in queſtion. Very different opinions have been formed indeed concerning the nature and extent of that benefit, and the means by which it is applied; but that the paſſion and death of the bleſſed Jeſus were eſſential parts of his miniſtry on earth, has never been controverted, unleſs perhaps by thoſe modern Unitarians who have corrected the errors of the apoſtles and evangeliſts, and with whoſe writings we acknowledge ourſelves to be very little acquainted. That on the croſs he made ſatisfaction to his Father for the ſins of the world, is the general belief of Chriſtians; but preſumptuous men, aiming at being wiſe beyond what is written, have ſtarted a thouſand idle queſtions concerning the neceſſity of ſuch ſatisfaction, and the manner in which it was made. Some limiting the power and mercy of the Omnipotent, have dared to affirm that God *could not* have pardoned man without receiving full ſatisfaction for his offences; that nothing but the ſhedding of the blood of Chriſt could make that ſatisfaction; that his death was indeed ſufficient to atone for a thouſand worlds; that, however, he did not die for all mankind, but only for a choſen few, ordained to eternal life by a ſecret decree before the foundation of the world; and that the reſt of the race are paſſed by, and doomed to eternal perdition, for the glory of God's juſtice. Others, convinced by every thing around them that the Creator and Governor of the univerſe is a being of infinite benevolence, whoſe only end in giving life muſt have been to communicate happineſs, have contended, that no atonement whatever could be neceſſary to obtain from him the forgiveneſs of ſin upon ſincere repentance; that it is contrary to all our notions of juſtice to puniſh the innocent for the guilty; and that therefore the death of Chriſt, though an eſſential part of his miniſtry, could not be neceſſary, but at the moſt expedient.

Theology, more peculiarly Christian.

We enter not into theſe impious debates. The Scriptures have nowhere ſaid what God could or could not do; and on this ſubject we can know nothing but what they have taught us. That "we are reconciled to God by the death of his Son," is the principal doctrine of the New Teſtament; and without preſuming to limit the power, the mercy, or the wiſdom, of him who created and ſuſtains the univerſe, we ſhall endeavour to ſhow that it is a doctrine worthy of all acceptation. In doing this, we ſhall ſtate impartially the opinions which men really pious have held reſpecting the form or manner in which Chriſt by his death made ſatisfaction to God for the ſins of the world; and we hope that our readers, diſregarding what may be prejudices in us, will embrace that opinion which ſhall appear to them moſt conſonant to the general ſenſe of ſacred Scripture.

174 Opinions of the Calviniſts.

The ſtricteſt adherents to the theological ſyſtem of Calvin, interpreting literally ſuch texts of Scripture as ſpeak of his being *made ſin* for us, of his *bearing our ſins in his own body on the tree*, and of the Lord's *laying on him the iniquity of us all*, contend, that the ſins of the elect were lifted off from them and laid upon Chriſt by *imputation*, much in the ſame way as they think the ſin of Adam is imputed to his poſterity. "By bearing the ſins of his people (ſays Dr Gill*), he took them off from them, and took them upon himſelf, bearing or carrying them as a man bears or carries a burden on his ſhoulders. There was no ſin *in* him inherently, for if there had, he would not have been a fit perſon to make ſatisfaction for it; but ſin was *put* upon him by his Divine Father, as the ſins of the Iſraelites were put upon the ſcape-goat by Aaron. No creature (continues he) could have done this; but the LORD hath laid on him, or made to meet on him, the iniquity of us all, not a ſingle iniquity, but a whole maſs and lump of ſins collected together, and laid as a common burden upon him; even the ſins of all the elect of God. This phraſe of laying ſin on Chriſt is expreſſive of the *imputation* of it to him; for it was the will of God not to impute the tranſgreſſions of his elect to themſelves, but to Chriſt, which was done by an act of his own; for he hath made him to be ſin for us; that is, by *imputation*, in which way we are made the righteouſneſs of God in him; that

* Body of Divinity, vol. ii book iii. chap. v. § 4.

Theology, more peculiarly Christian.

that being imputed to us by him as our sins were to Christ. The sense (says our author) is, a charge of sin was brought against him as the surety of his people. He was numbered with the transgressors; for bearing the sins of many, he was reckoned as if he had been a sinner himself, sin being *imputed* to him; and was dealt with as such. Sin being found upon him by *imputation*, a demand of satisfaction for sin was made, and he answered it to the full. All this was with his own consent. He *agreed* to have sin laid upon him, and *imputed* to him, and a charge of it brought against him, to which he engaged to be responsible; yea, he himself took the sins of his people upon him; so the evangelist Matthew has it. 'Himself took our infirmities, and bore our sicknesses †.' As he took the nature of men, so he took their sins, which made his flesh to have *the likeness of sinful flesh*, though it really was not sinful. What Christ bore being laid upon him, and imputed to him, were *sins* of all sorts, original and actual; sins of every kind, open and secret, of heart, lip, and life; all acts of sin committed by his people, for he has redeemed them from all their iniquities; and God, for Christ's sake, forgives all trespasses, his blood cleanses from all sin, and his righteousness justifies from all; all being imputed to him as that is to them. Bearing sin supposes it to be a burden; and indeed it is a burden too heavy to bear by a sensible sinner (E). When sin is charged home upon the conscience, and a saint groans, being burdened with it, what must that burden be, and how heavy the load which Christ bore, consisting of all the sins of all the elect from the beginning of the world to the end of it? and yet he sunk not, but stood up under it; failed not, nor was he discouraged, being the mighty God, and the Man of God's right-hand, made strong for himself."

† Chap. viii. 17.

175 Objected to

To the Arminians or Remonstrants, this doctrine of the imputation of the sins of men to the Son of God appears as absurd as the similar doctrine of the imputation of the sin of Adam to his unborn posterity; and it is certainly attended with consequences which have alarmed serious Christians of other denominations.

Were it possible in the nature of things, says the Arminian, to transfer the guilt of one person to another, and to lay it upon him as a burden, it could not be done without violating those laws of equity which are established in the scripture and engraven on the human heart. But this is not possible. To talk of lifting lumps of sin or transferring them like burdens from the guilty to the innocent, is to utter jargon, says he, which has no meaning; and we might with as much propriety speak of lifting a scarlet colour from a piece of cloth and laying it on the sound of a trumpet, as of literally lifting the sins of the elect from them and laying them on Christ. Guilt is seated in the mind; and no man can become a sinner but by an act of volition. If Christ therefore *really* took upon him the sins of his people, he must have deliberately formed a wish to have actually *committed* all those sins; but such a wish, though it would have made him inherently guilty, and therefore incapable of satisfying for sin, could not have cancelled deeds that were done before he was born, or have made those innocent who had really been sinners. A deed once done cannot be undone; a volition which has been formed cannot be annihilated. By sincere repentance, the habitual dispositions are indeed changed, and those who have been sinners become objects of mercy; but no power can recal the hours that are past, or make those actions which have been performed to have been not performed. To remove guilt from the sinner and lay it upon the innocent may therefore be safely pronounced impossible even for Omnipotence itself, for it implies that a thing may be and not be at the same instant of time; and the doctrine which teaches that this removal was made from the elect to Christ, is an imagination of yesterday, which has no countenance from scripture, and is contrary to the established constitution of things. Those who imagine that guilt may be propagated from father to son, have something like an argument to urge for the imputation of Adam's sin to his numberless posterity; for all the men and women who have by ordinary generation been introduced into the world, have undoubtedly derived their nature from the primeval pair. But Christ did not derive his nature from the *elect*, that their sins should be communicated to him; nor, as he was miraculously conceived by the Holy Ghost, can we attribute to him any degree of that *taint* which is supposed to have been conveyed from Adam to all the other generations of men.

Theology, more peculiarly Christian.

176 Texts on which they are built explained.

Nothing more, therefore, can be meant by "Christ's being made sin for us," and "bearing our sins in his own body on the tree," or by God's "laying upon him the iniquity of us all," than that by his sufferings we are freed from the punishment of our sins; it being in scripture a common figure of speech, as even Dr Gill has somewhere acknowledged, to denote by the word *sin* the *consequences* of sin. That this figure is used in those texts from which he infers that Christ took the sins of the elect upon himself, is evident from the verse which he quotes from the gospel of St Matthew; in which it is said, that "himself took our infirmities and bore our sicknesses." The sicknesses and infirmities there alluded to are the leprosy, the palsy, the fever, and demoniacal possessions: but when our blessed Lord cured these diseases, surely he did not by his omnipotent word lift them off from the patients and take them on himself, so as actually to become a leper, a paralytic, and a dæmoniac, or even to be reckoned as such either by the multitude, or by the priests whose duty it was to take cognizance of every legal uncleanness*. And if his inveterate enemies did not *impute* to him the leprosy when he removed that plague from others, why should it be supposed that his own Father, to whom he was at all times well-pleasing, *imputed* to him those sins of which, by his sufferings, he removed the punishment from those who were guilty? To impute to a person any action, whether virtuous or vicious, which he did not perform, can proceed only from ignorance, or malice, or partiality; but God is no respecter of persons, and from ignorance and malice he is removed to an infinite distance. It is indeed an undoubted truth, that "the Lord Jesus, by his perfect obedience and sacrifice of himself, which he through the eternal spirit once offered up unto God, hath fully satisfied the justice of his Father; and purchased not only reconciliation, but an everlasting inheritance in the kingdom of heaven for all those whom the Father hath given him †;" but that he actually took upon himself the sins of mankind, or that those sins were imputed to him by God, who punished him as a person whom he considered as guilty, is a doctrine equally injurious to the justice of the Father and to the immaculate purity of the Son.

* Levit. xiii.

† Confession of Faith, chap. viii. § 5.

177 They have probably contributed to make Socinius deny the doctrine of redemption.

The earnestness with which this doctrine was inculcated by some of the earliest reformers, and the impossibility of admitting it, which every reflecting and unprejudiced mind must feel, was probably one of the causes which drove Socinius

(E) By the phrase *a sensible sinner*, the learned author means a sinner who is not past feeling, but has a conscience alive to the sense of remorse.

Theology more peculiarly Christian.

cinus and his followers to the other extreme of denying Christ's satisfaction altogether, and considering his death as nothing more than that of an ordinary martyr, permitted for the purpose of attesting the truth of his doctrine, and paving the way for his resurrection, to confirm the great promise of immortality. According to these men, forgiveness is freely dispensed to those who repent, by the essential goodness of God, without regard to the merit or sufferings of any other being; and the gospel is said to save from sin, because it is the most perfect lesson of righteousness. The great objection of *Crellius* to the doctrine of the satisfaction is, that it is a hindrance to piety; for if Christ has payed the whole debt, he thinks that we must have nothing to do, as nothing more can be required of us. And if it were indeed true that our sins are imputed to Christ, and his righteousness imputed to us, this objection would be insurmountable; for God could not justly exact a double punishment for the same sin, or inflict misery upon those to whom he imputes perfect righteousness. But as to this imaginary transferring of virtues and vices from one person to another, the Christian scriptures give no countenance; so they nowhere call the death of Christ a *satisfaction* for the sins of men. The term has indeed been long in use among divines, and when properly explained it may be retained without any danger; but in treating of this subject, it would perhaps be more prudent to restrict ourselves to the use of scripture language, as the word *satisfaction* carries in it the ideas of a debt paid and accepted; whereas it is said by St Paul, that "eternal life is the *gift* of God through Jesus Christ our Lord; and that we are justified *freely by his grace* through the redemption that is in Jesus Christ, whom God hath set forth to be a propitiation through faith in his blood."

178 The death of Christ restored to mankind what they had lost in Adam.

To clear up this matter, and attain adequate notions of redemption and justification, it will be necessary to look back to the fall of our first parents; for the great purpose for which Christ was promised, and for which he came into the world, was by bruising the head of the serpent, to restore mankind to the inheritance which they had lost through the transgression of Adam. This is apparent not only from the original promise made to the woman, but also from different passages in the epistles of St Paul, who expressly calls Christ the second Adam, and says, that, "as by the offence of one, judgment came upon all men to condemnation; even so by the righteousness of one, the free-gift came upon all men unto justification of life;" that "as by one man's disobedience many were made sinners, so by the obedience of one shall many be made righteous;" and that, "as in Adam all die, even so in Christ shall all be made alive." Hence it was that John the Baptist, when he saw Jesus coming to him, said to his disciples†, "Behold the Lamb of God which taketh away, not the *sins*, but the *sin* of the world," evidently alluding to Adam's sin and its consequences, since no other sin was ever committed of which the consequences extend to the whole world.

† Ch. i. ver. 29.

This being the case, it is undeniable, that whatever we lost in the first Adam is restored to us by the second; and therefore they who believe that the punishment denounced against eating the forbidden fruit was death *corporal*, *spiritual*, and *eternal*, must believe that we are redeemed from all these by Christ: who having "appeared once in the end of the world to put away sin by the sacrifice of himself, died for us, that whether we wake or sleep we should live together with him*." If the image of God in which man was created was lost by the breach of the first covenant, it is more than restored to us "by the Mediator of a better covenant, which is established upon better promises;" if by the sin of Adam we were utterly indisposed, disabled, and made opposite to all that is spiritually good, and wholly inclined to all evil, and that continually, we are freed from that dreadful curse by "our saviour Jesus Christ, who gave himself for us, that he might redeem us from all iniquity, and purify to himself a peculiar people zealous of good works†;" and if for our share in the first transgression we be justly liable to all punishments in this world and in that which is to come, the apostle assures us, that "when we were enemies we were reconciled to God by the death of his Son, because that God was in Christ reconciling the world to himself, not imputing their trespasses unto them‡." As Jesus is "the Lamb slain in the divine decree from the foundation of the world," these beneficial consequences of his death have been extended by a retrospective view to all in every age whose names are written in the book of life, though it is absurd to suppose that he literally took their sins upon him, and impious to imagine that he suffered under the imputation of sin.

179 Moderate Calvinists and Remonstrants of the same opinion.

Such is the general doctrine of redemption, as it is taught by the more moderate Calvinists and more moderate Remonstrants; for moderate Christians of all denominations, though they express themselves differently, have nearly the same views of the fundamental articles of their common faith. It must not, however, be concealed, that many divines of great learning and piety, though removed to an infinite distance from the school of Socinus, contend strenuously against the doctrine of vicarious atonement for actual transgressions of the moral law. These are the more zealous Arminians, who deny that we inherit any moral taint or intellectual weakness from our first parents, whom they believe never to have been in a state of greater perfection than many of their posterity who are called *degenerate*. According to them, we lost nothing by the fall of Adam but our title to eternal life or perpetual existence, together with those graces of the Holy Spirit which were bestowed under the first covenant to train mankind for the society of heaven; and as eternal life and supernatural grace constituted one free-gift, not due to the nature of man, or indeed of any created being, they might, when forfeited, be restored by any means or upon any condition which should seem expedient to the all-wise Donor. These means, and that condition, human reason cannot indeed discover; but it seems very fit that they should be different from the means by which moral agents under the law of nature can secure to themselves the favour of their Creator, or recover it when occasionally lost. The former depends on arbitrary will and pleasure, or at least upon no other principles discoverable by us; while the latter ariseth out of the established and well-known constitution of things. Thus moral virtue, comprehending piety, was the condition of that favour and protection which the creature man, in his original state, could claim from his Maker; but obedience to a positive command was the condition of the free gift of immortality conferred upon Adam on his introduction into paradise. The claim arising from the relation between the creature and the Creator is indissoluble, because that relation cannot be dissolved; so that the man who, by a transgression of the moral law, or of any part of that system which is called the *religion of nature*, has forfeited the favour of God, may reasonably hope to recover it by sincere repentance and a return to his duty: and nothing but such repentance and reformation can recover it; because, in a moral agent, nothing can be agreeable to God but moral dispositions, which cannot be transferred from one person to another, and for the want of which nothing can atone. Our virtues are not required nor our vices prohibited, as if the one could profit and the other injure him who created us; "for *is it any pleasure* to the Almighty that we are righteous? Or is it

180 Doctrine of the more zealous Arminians.

Theology more peculiarly Christian.

gain to him that we make our ways perfect? Will he reprove us for *fear* of us?" No! He commands us to be virtuous, and forbids us to be vicious, only becauſe virtue is neceſſary to our own happineſs, and vice productive of everlaſting miſery.

Were an immoral man to be introduced into the ſociety of angels and juſt men made perfect, he would not experience in that ſociety what we are taught to expect from the joys of heaven; becauſe to ſuch joys his acquired diſpoſitions would be wholly repugnant. Nor could the ſufferings of any perſon whatever, or the *imputation* of any extrinſic righteouſneſs, make that mind which had long been immerſed in the groſſeſt ſenſuality reliſh the intellectual and refined enjoyments of heaven; or the man who had been the habitual ſlave of envy, malice, and duplicity, a fit inhabitant of that place where all are actuated by mutual love. On the other hand, ſay the divines whoſe doctrine we are now detailing, it is impoſſible that the Father of mercies, who knows whereof we are made, ſhould have doomed to eternal miſery any moral agent who had laboured through life to ſerve him in ſincerity and in truth; or that any atonement could be neceſſary to redeem from the pains of hell the man whoſe pious and virtuous diſpoſitions have through penitence and prayer become ſuited to the ſociety of heaven. Unſinning perfection never was nor ever could be expected in man. He is brought into the world free indeed from vice, but equally deſtitute of virtue; and the great buſineſs of his life is to guard his mind from being polluted by the former, and to acquire diſpoſitions habitually leading to the practice of the latter. Till theſe habits be fairly formed, it ſeems impoſſible that he ſhould not ſometimes deviate from the paths of rectitude, and thereby incur a temporary forfeiture of the divine favour; but the very conſtitution of his mind, and the purpoſe for which he is placed in a ſtate of probation, ſhow that the divine favour thus forfeited can be recovered only by repentance and reformation.

Widely different, however, is the caſe with reſpect to the forfeiture and recovery of a free gift, to which man has no natural claim. When the condition is broken on which ſuch a gift was beſtowed, repentance can be of no avail; it muſt be either irrecoverably loſt, or reſtored by the mere good pleaſure of the giver. Immortality or perpetual exiſtence is a gift which upon certain terms was freely beſtowed upon the human race, and forfeited by the tranſgreſſion of their firſt parent violating thoſe terms. It was reſtored by the free grace of God, who was pleaſed to ordain, that "ſince by man came death, by man ſhould alſo come the reſurrection of the dead; for as in Adam all die, even ſo in Chriſt ſhall all be made alive." "Hence the apoſtle, writing to the Romans of the benefits of being the children of God, and joint-heirs with Chriſt, ſummeth up thoſe benefits with the reſurrection from the dead." For the creature, *i. e.* mankind, was made ſubject (ſays he*) to vanity or death, not willingly, but by reaſon of him who has ſubjected the ſame in hope; becauſe the creature itſelf alſo ſhall be delivered from the bondage of corruption into the glorious liberty of the children of God. For we know that the whole creation groaneth, and travaileth in pain together until now: and not only *they* but *ourſelves* alſo, who have the firſt fruits of the ſpirit, even we ourſelves, groan within ourſelves, waiting for the adoption, viz. *the redemption of our body* (F). That this redemption of our body is the conſequence of the ſacrifice of Chriſt, is taught in the moſt explicit terms in the epiſtle to the Hebrews; of which the inſpired author informs us, that foraſmuch as the children are partakers of fleſh and blood, he alſo himſelf likewiſe took part of the ſame; that through *death* he might deſtroy him that had the power of death, that is the devil; and deliver them, who through fear of death were all their life-time ſubject to bondage‡." A vicarious atonement made with this view, the divines, whoſe theory we are now conſidering, acknowledge to be perfectly rational and conſiſtent with the ſtricteſt juſtice. "The law of nature (ſay they§) allows not of vicarious atonements; but ordains that the man who tranſgreſſeth ſhall himſelf bear the puniſhment of his iniquity; a puniſhment which no man deſerves for the faults of another, unleſs he be partaker of the guilt by joining in the tranſgreſſion." And in proof of this their opinion, they appeal to the words of God himſelf, declaring to Moſes, —"Whoſoever hath ſinned againſt me, him will I blot out of my book*." But when the free gift of immortality was loſt, it was with great wiſdom, ſay they, that God reſtored it through a Mediator who ſhould make atonement by his blood for the breach of the firſt covenant; ſince ſuch a mediation implies that the gift reſtored is merely of grace, to the attainment of which man could no further co-operate than by his hopes and wiſhes.

§ Warburton's Div. Leg. b. ix. and Law's Conſiderations on the Theory of Religion, part iii.

* Exod. xxxii. 31—34.

182 An objection.

To this view of redemption, and indeed to every view of it which we yet have taken, an objection forces itſelf upon the mind. Throughout the New Teſtament LIFE AND IMMORTALITY are conſidered as a FREE *gift*, and called ſo in expreſs words by St Paul*. To the ſcheme under conſideration it is eſſential to conſider them as ſuch; and yet we know that a large price was paid for them, as St Paul likewiſe acknowledges, when he twice tells the Corinthians that they were bought with a price§.

* Rom. v. 15.

§ 1 Cor. vi. 20. vii. 23.

183 Obviated.

"To clear up this matter (ſays biſhop Warburton), and to reconcile the apoſtle to himſelf who certainly was not defective either in natural ſenſe or artificial logic, let us once again remind the reader, that life and immortality beſtowed on Adam in paradiſe was a FREE *gift*, as appears from the hiſtory of his creation. As a *free gift*, it was taken back by the Donor when Adam fell; to which reſumption our original natural rights are not ſubject, ſince natural religion teacheth, that ſincere repentance alone will reinſtate us in the poſſeſſion of thoſe rights which our crimes had ſuſpended. So that when this free gift, forfeited by the *firſt* Adam, was recovered by the *ſecond*, its nature continuing the ſame, it muſt ſtill remain a *free gift*—a gift to which man, by and at his creation, had no claim; a gift which natural religion did not beſtow. But if miſled by meaſuring this *revealed myſtery* of human redemption by the ſcant idea of human tranſactions, where a *free gift* and *purchaſed benefit* are commonly oppoſed to one another, yet even here we may be able to ſet ourſelves right, ſince, with regard to man, the character of a *free gift* remains to *immortality reſtored*. For the price paid for forfeited man was not paid by him, but by a Redeemer of divine extraction, who was pleaſed, by participating

181 That Chriſt died to redeem us from the power of the grave.

* Rom. viii. 20—24.

(F) That by the words *creature* and *creation* the apoſtle here means all mankind, and by *vanity* and *corruption*, death, the reader will find proved by Dr Whitby, in his note on the place, with a ſtrength of argument which cannot be ſhaken; and that the whole creation, the Gentiles as well as the Jews, groaned and travailed in pain together under the apprehenſion of death, is apparent from the writings of Cicero, who always ſeems doubtful whether death be a good or an evil; and from the lamentation of Hezekiah, when deſired by the prophet to ſet his houſe in order becauſe he ſhould die and not live.

Theology, more peculiarly Christian.

ticipating of man's nature, to ſtand in his ſtead. Hence the ſacred writers ſeeing, in this caſe, the perfect agreement betwen a *FREE GIFT* and a *PURCHASED POSSESSION*, call it ſometimes by the one and ſometimes by the other name*."

* Div. Leg. book 9. ch. 2.

A reſtoration to life and immortality from that ſtate of unconſciouſneſs or extinction as living agents, to which all mankind were doomed in conſequence of the fall of Adam, is that great ſalvation which we have obtained through the blood of our Redeemer; and according to the theologians whoſe theory we are now conſidering, it was the only thing in the divine intention when the promiſe was given to the firſt mother that the ſeed of the woman ſhould bruiſe the head of the ſerpent. But though they contend thus earneſtly that the death of Chriſt does not operate *directly* as an atonement for the *actual* ſins of men, they admit that it does ſo *indirectly* and by neceſſary conſequence, ſince it gives opportunities for repentance and newneſs of life, which under the firſt covenant they did not enjoy. Had a man under that covenant tranſgreſſed any moral precept, he would of courſe have forfeited the favour of his God, and either been ſubjected to puniſhment or to a long courſe of repentance; but ſuppoſing the efficacy of repentance under the law of nature to be what they ſuppoſe it to be, he might before it was perfected have loſt his exiſtence by the eating of the forbidden-fruit; and thus his penitence or puniſhment have ended in everlaſting death. This can never be the iſſue of things under the new covenant, which, by the death of Chriſt, ſecures immortality to man, and gives to him opportunities, as long as he ſhall be in a ſtate of probation, of recovering the divine favour when forfeited, whether by a moral tranſgreſſion or a temporary violation of the peculiar condition of the covenant. Hence they admit the truth of the apoſtle's doctrine, that we are gainers by the fall of Adam and the redemption wrought by Chriſt; which will appear when we come to conſider their notions of Chriſtian juſtification. In the mean time it may be proper to obſerve, that they conſider it as no ſmall confirmation of their opinion, that it tends to put an end to the long agitated diſputes concerning the *extent* of redemption, and to reconcile paſſages of ſcripture which, on the commonly received theories both of Calviniſts and Arminians, ſeem to be at variance with each other.

184 The death of Chriſt an atonement only indirectly for actual ſin.

185 According to the Calviniſts Chriſt died only for the elect.

It is well known to be one of the fundamental doctrines of the Calviniſtic ſchool, that "none are *redeemed* by Chriſt, effectually called, juſtified, adopted, ſanctified, and ſaved, but the elect only †; and if the notions of redemption, which, in the end of the laſt century, were very generally embraced, be admitted as juſt, it will not be eaſy to overturn the arguments by which that doctrine is ſupported. Such of them as are connected with the great queſtion of election and reprobation, and enter into the deciſion of it, we have ſtated in another place (ſee PREDESTINATION, n° 14); but it is farther argued ‡, that the doctrine of *univerſal* redemption reflects on the wiſdom, the juſtice, and the power of God, and robs him of his glory.

† Confeſſion of Faith of the Church of Scotland, ch. iii. § 6.

‡ Gill's Body of Divinity, vol. ii book 3. ch. 3.

The ſcriptures aſſure us that all men ſhall not be ſaved; but how can this be, if Chriſt died for all, and the ſcheme of ſalvation by his death was formed by infinite wiſdom? The Arminians indeed ſay, that thoſe who fail of ſalvation, fail through their own fault in not performing the conditions required of them; but God either *knew* or knew *not* that ſuch men would not perform thoſe conditions. If he knew it not, his knowledge is limited; if he did know it, where was his wiſdom in providing a ſcheme of redemption for men to whom he was aware that it would be of no benefit? "God, we are told, is righteous in all his ways and holy in all his works;" but there is no righteouſneſs in making Chriſt bear the ſins of *all* men, and ſuffer the puniſhment due to them, if any one of thoſe men ſhall be afterwards puniſhed everlaſtingly. If Chriſt has already paid the debts of the whole world, it cannot be juſt to caſt a ſingle inhabitant of the world into the priſon of hell, there to be detained till he ſhall again have paid the uttermoſt farthing. "The Lord's hand is not ſhortened that it cannot ſave;" for he is and always will be the ſame Almighty power that he was from eternity; but if by the divine decree Chriſt died for all men, and yet all men ſhall not be ſaved, it would appear that man is mightier than his Maker! The ultimate end of God in the redemption of man is admitted to have been his own glory; but if any individual of the human race, who was redeemed by Chriſt, ſhall not be ſaved, God will ſo far loſe his end, and be deprived of his glory. For, if this were the caſe, where would be the glory of God the Father in forming a ſcheme which, with reſpect to multitudes, does not ſucceed? and where would be the glory of the Son of God, the Redeemer, in working out the redemption of men who are yet not to be ſaved by him? and where would be the glory of the ſpirit of God, if redemption were not by him effectually applied to every individual for whom it was wrought? By ſuch arguments as theſe do the Calviniſts oppoſe the ſcheme of univerſal redemption, and contend that Chriſt died only for the *elect*, or ſuch as ſhall be placed on his right hand at the day of judgment. This notion of a limited redemption, as they think it more worthy of the ſovereignty of God, they believe to be taught by our Saviour himſelf, when he ſaith *, "All that the Father *giveth* me ſhall come to me; and him that cometh to me, I will in nowiſe caſt out. For I came down from heaven, not to do mine own will, but the will of him that ſent me. And this is the Father's will who hath ſent me, that of all which he hath *given* me I ſhould loſe nothing, but ſhould raiſe it up again at the laſt day."

* John vi. 37—40.

186 According to the Arminians he died for all men.

The Arminians, on the other hand, contend, that it is impious to limit the effects of Chriſt's death to a choſen few, ſince it appears from ſcripture, that by the decree and intention of his Father he taſted death for every man, that all, without exception, might through him obtain remiſſion of their ſins. Thus our Lord himſelf told Nicodemus †, that "as Moſes lifted up the ſerpent in the wilderneſs, even ſo muſt the Son of Man be lifted up; that *whoſoever* believeth in him, ſhould not periſh, but have everlaſting life. For God ſo loved the *world*, that he gave his only begotten Son, that whoſoever believeth in him ſhould not periſh, but have everlaſting life. For God ſent not his Son into the world to condemn the world, but that the *world* through him might be ſaved." In perfect conformity with the doctrine of his divine Maſter, St Paul teaches ‡, that "Chriſt died for *all*; that God was in Chriſt reconciling the *world* to himſelf, not imputing their treſpaſſes unto them;" that "he will have *all* men to be ſaved, and to come unto the knowledge of the truth;" that "Chriſt gave himſelf a ranſom for *all*;" and that "Jeſus was made a little lower than the angels, that by the grace of God he ſhould taſte death for *every man*." The very ſame thing is taught by St Peter and St John, when the former ſays §, that "the Lord is not willing that *any* ſhould periſh, but that *all* ſhould come to repentance;" and the latter ‖, that "Jeſus Chriſt the righteous is the propitiation for our ſins; and not for our's only, but for *the whole world*."

† John iii. 14—18.

‡ 2 Cor. v 14—20 1 Tim. ii. 4—7. Heb. ii. 9.

§ 2 Peter iii. 9.

‖ 1 John ii. 2.

Upon theſe texts, without any commentary, the Arminians are willing to reſt their doctrine of univerſal redemption; though they think that a very ſtrong additional argument for its truth ariſes from the numberleſs abſurdities which flow from the contrary opinion. Thus, ſay they *, the apoſtles were commanded by our Saviour † to "go into *all* the world and preach the goſpel to *every creature*,"

* Limborch's Theologia Chriſtiana, Eng. Tranſ. book 4. ch. 3.

† St Mark xvi. 15, 16.

Theology, more peculiarly Chriſtian.

and all who hear it preached are required to believe it: but no man, as the Calviniſts themſelves confeſs, can believe the goſpel as a Chriſtian, without believing that Chriſt *died for him;* and therefore, if it be true that Chriſt died only for the *elect*, a great part of mankind are required to believe a lie, and a falſity is made the object of divine faith! Again, if Chriſt did not die for *all*, then no man can be ſure that he is bound to believe in Chriſt when preached to him; nor can any man be juſtly condemned for infidelity: which is not only abſurd in itſelf, but directly contrary to what we are taught by our bleſſed Lord, who aſſures us*, that unbelief is the cauſe of condemnation. Laſtly, if Chriſt died not for *all*, then is it certain that he cannot claim dominion *over all* in *conſequence* of his *death* and *reſurrection;* but St Paul ſays expreſsly †, that "to *this end* Chriſt both *died*, and *roſe*, and *revived*, that he might be the Lord both of the *dead* and *living*." The Arminians acknowledge, that though Chriſt died for all, there are many who will not be ſaved; for, ſay they ‡, the death of Chriſt did not literally pay the debts incurred by ſinners, but only obtained for them the gracious covenant of the goſpel, by which all who believe in him, and ſincerely endeavour to work out their own ſalvation with fear and trembling, are entitled to forgiveneſs of ſins and eternal life.

* St John iii. 18, 19, and 36.

† Rom. xiv. 9.

‡ Wells's Div. Laws and Covenants, part 2. ch. 3.

187 Difficulties removed by the modern Arminians.

Such is the ſtate of this controverſy as it was agitated between the Calviniſts and Arminians of the laſt century; but the preſent leaders of this latter ſchool are of opinion, that it never could have been ſtarted, had not both parties miſtaken the purpoſe for which Chriſt died. It is not conceivable, ſay they, that any thing for which the eternal Son of God took upon him human nature, and in that nature ſuffered a cruel and ignominious death, ſhall not be fully accompliſhed; and therefore, if in the divine intention he died to make atonement for the ſins of man actual as well as original, we muſt of neceſſity conclude that thoſe for whom he died ſhall certainly be ſaved. Yet we learn from ſcripture that many ſhall go away into everlaſting puniſhment, though the ſame ſcripture repeatedly aſſures us that Chriſt gave his life a ranſom for *all*, and that he is the propitiation for *the whole world*. To reconcile theſe different paſſages of ſcripture is impoſſible, if we ſuppoſe that he laid down his life to atone for the *actual* tranſgreſſions of men; but if the direct purpoſe of the Godhead in forming this ſtupendous plan of redemption was, that the death of Chriſt ſhould be the ranſom of all from the grave or utter extinction, every difficulty is removed; for we know that all, the wicked as well as the righteous, ſhall through him be raiſed to life at the laſt day. That this was the purpoſe for which he died, they think apparent from the very words quoted by the Calviniſts to prove that redemption was not univerſal; for he declares that it was his Father's will, "that of all which had been given him he ſhould loſe nothing," *not* that he ſhould ſave it all from *future puniſhment*, but only that he "ſhould raiſe it up at the laſt day." When St John calls him a propitiation for our ſins, which, as we have ſeen, the divines whoſe doctrine we are now ſtating hold him to be indirectly, he does not add, as in our tranſlation, for the *ſins* of the whole world, but περι ὁλου του κοσμου, for the whole world, which, by his death, he redeemed from that vanity and corruption under which, according to St Paul, it had groaned from the fall till the preaching of the goſpel. Hence it is that our bleſſed Lord calls himſelf "the reſurrection and the life," and always promiſes to thoſe who ſhould believe in him that though they were dead, yet ſhould they live, and that he would raiſe them up at the laſt day.

Theology, more peculiarly Chriſtian.

Among theſe various opinions reſpecting the deſtination of the death of Chriſt, it belongs not to us to decide. The ſerious reader, diveſting himſelf of prejudice in favour of the ſyſtem in which he has been educated, will ſearch the ſcriptures, and adopt the theory which he ſhall find moſt explicitly taught in that ſacred volume; but as in every ſyſtem it is admitted, that *one purpoſe* for which Chriſt died was to redeem mankind from the everlaſting power of the grave, and bring to light life and immortality, it is of the utmoſt importance to know whether that purpoſe has been fully attained. Death we ſee ſtill triumphing over all the generations of men; and as the ſcriptures give us no hopes of being reſcued from its dominion but through the medium of a reſurrection, ſome ſenſible evidence ſeems neceſſary to evince that a general reſurrection ſhall actually take place. This we are promiſed as one great benefit purchaſed for us by the ſufferings of Chriſt ſacrificed on the croſs. And ſince the price has been *paid*, and paid thus *viſibly*, the nature of the covenant requires that the benefit ſhould be as *viſibly enjoyed* by the perſon whoſe ſufferings obtained it for his brethren. "If the Redeemer himſelf had not been ſeen to enjoy the fruits of the redemption procured, what hopes could have remained for the reſt of mankind? Would not the natural concluſion have been, that the expedient of *redemption*, by the death and ſacrifice of Jeſus, had proved ineffectual?" This is the concluſion which St Paul himſelf draws: "If Chriſt be not riſen (ſays he*), then is our preaching vain, and your faith is alſo vain; ye are yet in your ſins. Then they alſo, who are fallen aſleep in Chriſt, are periſhed—απωλοντο—are loſt, as if they had never exiſted. But now (adds he) is Chriſt riſen from the dead, and become the firſt fruits of them that *ſlept*. For ſince by man came *death*, by man came alſo the *reſurrection* of the dead: For as in Adam *all die*, even ſo in Chriſt ſhall *all be made alive*."—So neceſſarily connected, in the opinion of the apoſtle, is the reſurrection of Chriſt with the very eſſence of Chriſtianity †.

188 One purpoſe for which Chriſt died was to bring to light life and immortality.

* 1 Cor. xv. 15—23.

† Warburton's Sermon on the Reſurrection.

Though we have in another place (ſee RESURRECTION, n° 50.) ſtated ſuch arguments for the truth of this fundamental article of our common faith, as muſt carry conviction to every mind capable of eſtimating the force of evidence; yet as attempts are daily made, ſometimes openly and ſometimes with the moſt inſidious art, to propagate in this nation the French doctrine concerning the eternal ſleep of death (G), we truſt that we ſhall not treſpaſs on the ſerious reader's patience if we here reſume the ſubject, and endeavour to ſhow that it was abſolutely impoſſible for the apoſtles to perſuade the world, or to think of perſuading the world, that their Maſter roſe from the dead, if his reſurrection was not real.

In the article MIRACLE*, we have ſaid, that "the very *reſolution* of the apoſtles to propagate the belief of falſe miracles in ſupport of ſuch a religion as that which is taught in

* Vol. XII. p. 173.

(G) Once we intended (ſee Vol. XVI. page 140. note A) to notice in this place ſome of the moſt recent of thoſe attempts, and to expoſe them to that indignation with which, we truſt, the good ſenſe of our countrymen ſhall alway treat ſuch ſophiſtical reaſonings as have no other object than to diminiſh the ſum of human happineſs. On maturer reflection, however, it ſeems more expedient to ſtate one deciſive argument for the reſurrection of Chriſt, which may be ſafely oppoſed to any new ſophiſms of our minute philoſophers, when thoſe which are at preſent in faſhion ſhall have ſunk through their own weakneſs into oblivion, or quietly retired with their authors to that place "Where Tindal dictates and Silenus ſnores." *Dunciad.*

Theology, more peculiarly Chriſtian.

in the New Teſtament, is itſelf as great a miracle as human imagination can eaſily conceive." We ſhall illuſtrate this poſition by the reſurrection of Jeſus, which we are to ſuppoſe the apoſtles reſolving to publiſh as an unqueſtionable fact, whilſt they were conſcious that they themſelves ſtole the body from the ſepulchre, and ſaw it in their cuſtody under the dominion of death. On ſuch an enterpriſe they could not enter without much deliberation; and we may conceive him, to whom the thought of propagating this fable firſt occurred, addreſſing his companions in ſome ſuch terms as the following:—

189 The truth of his reſurrection demonſtrated.

"The Maſter whom we ſerved is now no more, and the magnificent hopes which we had formed with reſpect to him and to ourſelves are blaſted by his death. The time which he fixed for his reſurrection is paſſed; and it is folly to cheriſh any expectation of that event, as we ſee his body which we ſtole a prey to corruption. We muſt therefore either ſeparate and return to our former profeſſions, the obſcurity of which will ſcreen us from the diſgrace of having been deceived; or, remaining united, take the generous reſolution of ſupporting our glory, by ſaying to every body that our Maſter is riſen from the dead, and is the true Meſſiah expected by our nation, and foretold by the prophets. To return to our profeſſions would be cowardly and mean; to propagate the ſtory of the reſurrection will be attended with infinite difficulty and danger; but to deſpiſe danger and to conquer difficulties, is worthy of great ſouls ſuch as ours; and therefore I take it for granted that this is the part which you have all reſolved to act.

"To ſucceed in our glorious enterpriſe, it will be abſolutely neceſſary to admit into our moſt ſecret counſels, not only the ſeventy diſciples whom our Lord ſent before him, in pairs, into every city and place which he viſited *, but alſo that crowd of women ‡ who followed him from Galilee, were preſent at his crucifixion, and viſited his ſepulchre; for all theſe perſons are ſo intimately acquainted with every circumſtance of his life and death, that they have it in their power completely to defeat our project in ſpite of our utmoſt art; and that power, it cannot be doubted, they will exert, unleſs admitted to ſhare with us the glory of deceiving the world. The taſk which they and we have to perform is no ordinary one; for we muſt all ſpeak the ſame things, and things which each of us knows to be falſe. Yet we muſt advance them with an air ſo intrepid as to remove ſuſpicion, and be able to bury in profound ſecrecy the reſolutions which in concert we take to-day.

* St Luke x. 1—18.
‡ St Matth. xxvii. 55, 56. St Luke xxiii. 55, 56. xxiv. 1—12.

"No truth can be ſo deeply impreſſed upon our minds as that our Maſter continues under the dominion of death; and we all know that truth ſtands ſo ready at the door of the lips, that the greateſt liar among us has hitherto uttered a thouſand truths for one falſehood (H); but henceforth, on this moſt intereſting ſubject, we muſt never let a ſingle truth eſcape us either in our moſt unguarded moments or when put to the torture; for all will be loſt, if any one perſon in whom we may place confidence ſhall reveal to our enemies what ſhould be known to ourſelves alone. It is therefore neceſſary to foreſee all that is capable of extorting ſecrets from ſuch perſons as are not like us proof againſt every thing. We ſhall be expoſed to much bad treatment, to priſons, to ſevere examinations, to death itſelf, and even to the moſt cruel and lingering kinds of death, ſufficient to ſhake any but the moſt invincible reſolutions. All this ſhould be foreſeen, and muſt be deſpiſed by every perſon among us, man and woman!

Theology, more peculiarly Chriſtian.

"But I muſt forewarn you, that under the greateſt tortures we are not to hope for the ſmalleſt ſupport from the teſtimony of a good conſcience and the proſpect of a future reward; for the very cruelleſt of our ſufferings will ariſe from the remorſe of conſcience, unleſs we fortify ourſelves againſt it by the moſt determined reſolution. Others have indeed been wonderfully ſupported under violent and tedious ſufferings, by the internal perſuaſion that they ſuffered for truth and righteouſneſs ſake; but as we are called upon to give new proofs of courage by ſuffering for what we know to be an impious falſehood, every reflection which tended to ſupport them will torment us, and tempt us, in the moſt forcible manner, to betray our cauſe. From him, for whom we are to ſuffer and be ſacrificed, we have nothing to expect; for ſince he could neither reſcue himſelf from the violence of his enemies, nor fulfil his promiſe of riſing from the dead, it would be madneſs to ſuppoſe that he will deliver us from our perſecutors, or afford us the ſmalleſt conſolation when ſinking under the cruelleſt tortures which malicious ingenuity can invent. He was a deceiver, and has deceived us. He promiſed, a few hours before he was taken, that he would riſe from the dead and go before us into Galilee; but God has ordered things otherwiſe; and as he is ſupreme Lord, we are not to ſound his judgments, or even to *think* too much of them.

"You ſeem aſtoniſhed at this counſel! It is new indeed, but neceſſary; and neceſſary to ſuch a degree, that all our deſigns will prove abortive if we ſuffer the fear of God to get poſſeſſion of our minds, and make us timid and puſillanimous in the teſtimony which we are determined to give againſt him, by maintaining that he raiſed from the dead a man whom he has without doubt condemned as an uſurper of the glory which was not his due. Such aſſertions in favour of falſehood will no doubt coſt us ſomething in the beginning; but we muſt endeavour to make ourſelves as eaſy as we can, by imprinting ſtrongly on our minds how glorious and diſintereſted it will be to ſuffer without hope either from God or man, and even with the certainty of being puniſhed both by God and man, not only in this life, but eternally in the next, if there be another. For let me not attempt to conceal from you, that preſent and future miſery muſt be our inevitable portion; and that we muſt therefore become inacceſſible to fear, even to ſuch fear as religion itſelf ought to inſpire, or return ignobly to our nets and boats; there is abſolutely no other alternative. He whom we lament has not only aſſumed openly the character of the Meſſiah, but has dared even to call himſelf the Son of God; and though we have ſeen him ready to be ſtoned for theſe pretenſions, and cannot doubt but that God was highly provoked at them, we muſt, in defiance of the divine vengeance, undertake to make them good, or at leaſt cauſe him to be worſhipped as the Son of God; whom to our own knowledge God has expreſsly diſavowed. This might frighten timid and vulgar ſouls; but we muſt have none ſuch among us. All the men and women of our company muſt be capable of braving Omnipotence, and of deriving new vigour and reſolution from the proſpect of uninterrupted miſery.

"Let us now conſider how this great deſign is to be carried into execution; for it would be the exceſs of folly to enter upon

(H) To the moſt illiterate fiſherman of Galilee this muſt have been known as a *fact*; for no man can ſpeak an intelligible ſentence without uttering a truth or a falſehood, and ſurely every man ſpeaks a thouſand ſentences for one in which he either utters or intends to utter a falſehood. How he muſt neceſſarily do ſo, we have ſhown in another place. See METAPHYSICS, n° 135, &c.

Theology, more peculiarly Christian.

upon it without preparing the means of ſucceſs. Firſt of all, we will draw up together a hiſtory of the pretended apparitions of our common Maſter. Thoſe who have the beſt inventions ſhall be employed in it; the reſt of us ſhall reviſe and correct the work; and all muſt ſtrongly imprint on their memories the pretended facts and diſcoveries which ſhall be agreed upon; becauſe we muſt never think of retracting, and the leaſt contradiction in our evidence would be of fatal conſequence (1). To this labour we muſt join another, which requires more knowledge of the Scriptures than we poſſeſs; but we will ſupply our deficiencies by ſtudy. Our rulers, and indeed our countrymen in general, expect that the Meſſiah ſhall be a great and invincible hero; that he ſhall deliver his country from the dominion of the Romans; that he ſhall conquer all nations, and eſtabliſh on earth an univerſal monarchy, of which Jeruſalem is to be the capital. As ſuch (they ſay) he is foretold by the prophets; but the perſon whom we mean to impoſe on them as the Meſſiah, expreſsly diſclaimed all wordly greatneſs, and made the ſufferings of himſelf and his followers one teſt of the truth of his pretenſions to the character which he aſſumed. Some of the moſt ſubtile among us therefore muſt carefully examine the books of Moſes, the Pſalms, and the Prophets, and wreſt all the prophecies of the true Meſſiah in favour of him whom we know to be an impoſtor. The enterpriſe, as it is directly oppoſed, not only by truth, but alſo by all the prejudices and hopes of the nation, is indeed bold: but what is the whole of our deſign but the exceſs of boldneſs?

Theology, more peculiarly Christian.

"We have hitherto believed that the religion of our forefathers is true, and was given by God to Moſes. It is certainly the moſt ancient, the moſt authorized, the pureſt religion in the world; and the only one founded on divine revelation, or that boaſts of ſuch a foundation. But if we are to preach to the whole world, that our Maſter, whom we know to be an impoſtor, is the true and only Meſſiah; and if we are to apply to him prophecies which have another object, we muſt neceſſarily deſpiſe this moſt ancient religion, which our fathers and we have hitherto deemed divine and incontrovertible; and this is the ultimate point to which it has been my aim to bring you. I deſire not that you ſhould conſent immediately, for to abandon one's religion is a thing which ſhould not be done without maturely weighing the conſequences; but what I deſire is, that you will diligently compare all the parts of the plan which I have ſuggeſted to you, examine their ſtrict and neceſſary union, and ſatisfy yourſelves completely, that we muſt *adopt* the whole or *reject* the whole; for it is obvious that modifications and exceptions are here abſolutely impoſſible.

"I hope you will not deliberate long on my propoſal; for we ſhall have much to do after your reſolution is formed, and the time in which I propoſe to concert and finiſh the whole ſcheme is very ſhort. We have but the interval betwixt the preſent moment and the feaſt of Pentecoſt in which to prepare the order of falſe apparitions, and fix it in the memories of our numerous coadjutors, male and female; to ſtudy in the Scripture all that relates to the Meſſiah; to form the plan and adjuſt the parts of a new religion;

---

(1) Deiſtical writers have laboured ſtrenuouſly, though in vain, to find ſuch contradictions in the different accounts of the circumſtances attending the reſurrection as may diſcredit the evidence of the evangeliſts to the principal fact.—This gave occaſion to Mr Weſt's admirable *Obſervations on the Reſurrection*; and were there any candour or modeſty among our minute philoſophers, the appearance of that book would have ſilenced them for ever. This, however, it has not done. The old cavils have, without the leaſt notice of Mr Weſt, been again brought forward by Thomas Paine, and again obviated by the Biſhop of Landaff in his maſterly *Apology for the Bible*. "If the writers of the Goſpels (ſays Paine) had gone into any court of juſtice to prove an *alibi* (for it is of the nature of an alibi that is here attempted to be proved, namely, the abſence of a dead body by ſupernatural means), and had given their evidence in the ſame contradictory manner as it is here given, they would have been in danger of having their ears cropt for perjury, and would have juſtly deſerved it." In reply to this impious ſarcaſm, the right reverend apologiſt thus addreſſes its author: "As we cannot have this *viva voce* examination of all the witneſſes, let us call up and queſtion the evangeliſts as witneſſes to a ſupernatural alibi.—Did you find the ſepulchre of Jeſus empty? One of us actually ſaw it empty, and the reſt heard from eye witneſſes that it was empty.—Did you, or any of the followers of Jeſus, take away the dead body from the ſepulchre? All anſwer, No.—Did the ſoldiers, or the Jews, take away the body? No.—How are you certain of that? Becauſe we ſaw the body when it was dead, and we ſaw it afterwards when it was alive.—How do you know that what you ſaw was the body of Jeſus? We had been long and intimately acquainted with Jeſus, and knew his perſon perfectly.—Were you not affrighted, and miſtook a ſpirit for a body? No; the body had fleſh and bones; we are ſure that it was the very body which hung upon the croſs, for we ſaw the wound in the ſide, and the print of the nails in the hands and feet.—And all this you are ready to ſwear? We are; and we are ready to die alſo, ſooner than we will deny any part of it.—This is the teſtimony which all the evangeliſts would give, in whatever court of juſtice they were examined; and this, I apprehend, would ſufficiently eſtabliſh the alibi of the dead body from the ſepulchre by ſupernatural means."

"The book of Matthew (ſays Paine) continues its account, that at the end of the Sabbath, as it began to *dawn*, towards the firſt day of the week, came *Mary Magdalene* and the other *Mary* to ſee the ſepulchre. Mark ſays it was ſun-riſing, and John ſays it was dark. Luke ſays it was Mary Magdalene, and Joanna, and *Mary the mother of James*, and *other women*, that came to the ſepulchre. And John ſays that Mary Magdalene came alone. So well do they agree about their firſt evidence! they all appear, however, to have known moſt about Mary Magdalene; ſhe was a woman of a large acquaintance; and it was not an ill conjecture that ſhe might be upon the ſtroll."

"This (replies the Biſhop) is a long paragraph, and I will anſwer it diſtinctly: Firſt, There is no diſagreement of evidence with reſpect to the time when the women went to the ſepulchre; all the evangeliſts agree as to the day on which they went; and as to the time of the day, it was early in the morning: what court of juſtice in the world would ſet aſide this evidence as inſufficient to ſubſtantiate the fact of the women's having gone to the ſepulchre, becauſe the witneſſes differed as to the degree of twilight which lighted them on their way? Secondly, There is no diſagreement of evidence with reſpect to the perſons who went to the ſepulchre. John ſtates that Mary Magdalene went to the ſepulchre; but he does not ſtate, *as you make him ſtate*, that Mary Magdalene went alone; ſhe might, for any thing you have proved or can prove to the contrary, have been accompanied by all the women mentioned by Luke. Is it an unuſual thing to diſtinguiſh by name a principal perſon going on a viſit or an embaſſy, without mentioning his ſubordinate attendants?

Theology more peculiarly Christian.

gion; to efface in our mind all traces and ideas of the ancient one; and to fortify ourſelves againſt our prejudices, our fears, and our worldly intereſts: for we muſt get quit of all theſe, ſince we are going moſt generouſly to renounce all the goods of this life, and all the hopes of the next.—What makes me chooſe the feaſt of Pentecoſt for our firſt public appearance in our new capacity, is the great concourſe of people from all nations which will be then at Jeruſalem; for it will be a favourable opportunity to preach to them the reſurrection of him whom our rulers have crucified, and by their means to ſpread the news quickly over the whole world. We are ignorant indeed of foreign tongues, and we are without interpreters; but our preſence will ſuffice. Some will comprehend by ſigns what we would ſay to them, and others, who hear and underſtand our language, will aſſiſt them. We cannot, it is true, work a miracle; but was there ever ſuch a miracle thought of as our daring to reſiſt all that is mighty and reſpectable in our nation? There would perhaps be more prudence in not appearing all together; and as we have nothing extraordinary or divine to command reſpect, nor any protection to hope from God or man, in not expoſing ourſelves in a *body* on the firſt day of our enterprize; but in a deſign like ours, ſingular in its whole nature, and contrary to common rules, of what uſe would prudence be? I am ſure that with our Galilean pronunciation, and with the goodly appearance that we ſhall make in our fiſhermens garments, we ſhall perſuade a multitude of people. Nay, ſo confident am I of our ſucceſs, that I include in my deſign not only Judea but all the nations upon earth. Nor ſhall I be diſcouraged by the diverſity of religions, manners, and tongues, which prevail in the world; be affrighted by the hoſtile power of all mankind; or have my zeal in the leaſt abated for him who hath deceived us, by the improbability of being able to make the Gentiles who know nothing of the Scriptures or the Meſſiah, adore as the Son of God the man whom the Jews have crucified as an impoſtor.

"In the mean time, it will be proper to accuſtom ourſelves to the moſt inhuman ſpectacles, in order to arrive by degrees at ſuch a hardneſs of heart as nothing can be ſuppoſed to move. You may depend upon it, that we ſhall ſee multitudes of people, ſeduced by our diſcourſes, proſcribed, baniſhed, thrown into dark priſons, torn in pieces by engines of torture, condemned to wild beaſts, to the fire, and to the moſt ſhameful and inſupportable puniſhments, for preaching with us the reſurrection of Jeſus. Now, as we are all by nature inclined to compaſſion, we might be tempted to relieve them from ſuch exquiſite miſery, ſince we could effectually do it by a ſingle word; but this word, which would diſcover the whole myſtery, muſt never ſlip from our mouths. There muſt not be ſo much as one ſigh or one groan to betray us. Inſtead of unſeaſonably reproaching ourſelves with our impoſture by which we deceived them, we muſt applaud ourſelves for their ſeduction; we muſt place our own joy in their wretchedneſs; and we muſt not be afraid to honour and cauſe them to be honoured, as illuſtrious witneſſes of the truth, though we know them to be only martyrs to our hypocriſy, and to their own facility in believing falſehood*."

Theology, more peculiarly Christian.

This is a faithful view of the outlines of that plan which *muſt have been formed* by the apoſtles, if they intended to deceive the world with reſpect to the reſurrection of their Maſter. It is of no conſequence to the argument whether it grew gradually out of the joint deliberations of the whole body, or was completely digeſted, as we have ſuppoſed, by one of the number, and implicitly adopted by the reſt: it is enough that every circumſtance which we have mentioned muſt have occurred to them, and that every reſolution muſt have been unanimouſly adopted which we have made to flow from the mouth of this daring orator. But ſurely the bare recital of ſuch an oration is ſufficient to ſhow the impoſſibility of carrying into effect ſo abſurd, ſo horrible, and ſo impious a meaſure—a meaſure diametrically oppoſite to all the principles and motives of human actions.

* See the Principles of the Chriſtian Religion tranſlated by Mr Lally.

Archbiſhop King has ſuppoſed*, that the human will is a faculty diſtinct from the underſtanding and the appetites; that activity is eſſential to it; and that previous to an election formed, it is equally indifferent to all objects. He thence infers that a man may chooſe, and even take delight in, what is not naturally agreeable to any of his appetites; becauſe

---

dants? Thirdly, In oppoſition to your inſinuation, that Mary Magdalene was a common woman, I wiſh it to be conſidered whether there is any ſcriptural authority for that imputation; and whether there be or not, I muſt contend, that a repentant and reformed woman ought not to be eſteemed an improper witneſs of a fact. The conjecture which you adopt concerning her is nothing leſs than an illiberal, indecent, unfounded calumny, not excuſable in the mouth of a libertine, and intolerable in yours.

"The book of Matthew (continues Paine) goes on to ſay: 'And behold there was an earthquake, for the angel of the Lord deſcended from heaven, and came and rolled back the ſtone from the door, and *ſat upon it*;—but the other books ſay nothing about any earthquake.'—What then? does their ſilence prove that there was none?—'Nor about the angel rolling back the ſtone and ſitting upon it.'—What then? does their ſilence prove that the ſtone was not rolled back by an angel, and that he did not ſit upon it?—'And according to their accounts there was no angel ſitting there.'—This concluſion (ſays his Lordſhip) I muſt deny; their accounts do not ſay there was no angel ſitting there at the time that Matthew ſays he ſat upon the ſtone. They do not deny the fact, they ſimply omit the mention of it; and they all take notice that the women, when they arrived at the ſepulchre, found the ſtone rolled away: hence it is evident that the ſtone was rolled away *before* the women arrived at the ſepulchre; and the other evangeliſts, giving an account of what happened to the women *when* they reached the ſepulchre, have merely omitted giving an account of a tranſaction previous to their arrival. Where is the contradiction? What ſpace of time intervened between the rolling away the ſtone and the arrival of the women at the ſepulchre, is nowhere mentioned; but it certainly was long enough for the angel to have changed his poſition; from ſitting on the outſide he might have entered into the ſepulchre; and another angel might have made his appearance, or from the firſt, there might have been two, one on the outſide rolling away the ſtone, and the other within. Luke, you tell us, 'ſays there were two, and they were both ſtanding; and John ſays there were two, and both ſitting.'—It is impoſſible, I grant, even for an angel to be ſitting and ſtanding at the ſame inſtant of time: but Luke and John do not ſpeak of the ſame inſtant, nor of the ſame appearance.—Luke ſpeaks of the appearance to all the women; and John of the appearance to Mary Magdalene alone, who tarried weeping at the ſepulchre after Peter and John had left it. But I forbear making any more minute remarks on ſtill minuter objections, all of which are grounded on this miſtake—that the angels were ſeen at one particular time, in one particular place, and by the ſame individuals."

Theology, more peculiarly Chriſtian.

cauſe when the choice is made, a relation is formed between the will and the object of choice, which, from being originally indifferent, now becomes a favourite object. But neither his Grace, nor any other aſſerter of human liberty, has ever affirmed or ſuppoſed, that any man or body of men could deliberately chooſe *evil* for its *own ſake*, or enter zealouſly upon a tedious and difficult enterpriſe, from which *no good* could *poſſibly ariſe*, and from which *unmixed miſery* was *clearly foreſeen* as the *neceſſary reſult of every ſtep of the progreſs*. Such however, muſt have been the choice and the conduct of the apoſtles, when they reſolved to preach a new religion founded on the reſurrection of Jeſus, if they did not certainly know that Jeſus had riſen from the dead. And this conduct muſt have been adopted, and in oppoſition to every motive which can influence the human mind; have been perſevered in by a great number of men and women, without the ſmalleſt contradiction having ever appeared in the various teſtimonies, which at different times, and under the cruelleſt tortures, they all gave to a variety of circumſtances, of which not one had its foundation in truth. He who can admit this ſuppoſition, will not ſurely object to the incredibility of miracles. The reſurrection of a man from the dead is an event ſo different indeed from the common courſe of things, that nothing but the moſt complete evidence can make it an object of rational belief; but as the reſurrection of Jeſus has always been ſaid to have had God for its Author, it is an effect which does not exceed the power of the cauſe aſſigned, and is therefore an event poſſible in itſelf and capable of proof. It is a deviation from the laws of nature, but it is not contradictory to any one of thoſe laws.

That a great number of men and women ſhould deliberately form a plan of ruin and miſery to themſelves, without a proſpect of the ſmalleſt advantage either in this world or in the next, is as different from the common courſe of things as the reſurrection from the dead: and therefore in itſelf at leaſt as great a miracle: but that they ſhould perſiſt in proſecuting this plan in the midſt of torments; that they ſhould ſpread themſelves over the whole world, and everywhere publiſh a number of falſehoods, without any one of them contradicting the reſt; that truth ſhould never eſcape them either in an unguarded moment, or when lingering on the rack, and yet that all their lies ſhould be in perfect agreement with each other; that they ſhould every one of them court ſufferings for a perſon whom they knew to be an impoſtor; that not one of the number—not even a ſingle woman—ſhould have ſo much compaſſion for a fellow-creature, as to reſcue him from the flames by confeſſing a truth which could injure nobody—not even the ſuffering deceivers themſelves—all this is not only different from the common courſe of things, but directly contrary to the moſt known laws of nature, and is therefore not miraculous, but may be pronounced impoſſible. Yet this impoſſibility we muſt admit, or acknowledge, that as "Chriſt died for our ſins, according to the Scriptures, and was buried; ſo he roſe again the third day according to the Scriptures; that he was ſeen of Cephas, then of the twelve; after that of above five hundred brethren at once; after that of James; then of all the apoſtles; and that he was laſt of all ſeen of St Paul*," who was converted by the viſion to preach the faith which till then he had perſecuted.

* 1 Cor. xv. 3—9.

190 Hence we are aſſured of our own reſurrection.

Thus are we aſſured, that thoſe who have fallen aſleep in Chriſt are not loſt, ſince he is riſen from the dead, and become the firſt fruits of them that ſlept. For ſince by man came death, by man came alſo the reſurrection of the dead. For as in Adam all die, even ſo in Chriſt ſhall all be made alive. But every man in his own order: Chriſt the firſt-fruits, afterwards they that are Chriſt's at his coming; for all that are in the graves ſhall hear his voice, and ſhall come forth; they that have done good unto the reſurrection of life, and they that have done evil to the reſurrection of damnation*."

Theology, more peculiarly Chriſtian.

Our bleſſed Lord having converſed familiarly with the eleven apoſtles for forty days after his reſurrection, inſtructing them in the things pertaining to the kingdom of God; having extended their authority as his miniſters, by giving them a commiſſion to teach all nations, and make them his diſciples, by baptizing them in the name of the Father, and of the Son, and of the Holy Ghoſt; and having promiſed them power from on high to enable them to diſcharge the duties of ſo laborious an office—led them out as far as Bethany, that they might be witneſſes of his aſcenſion into heaven. "When they therefore were come together, they aſked of him, ſaying, Lord, wilt thou at this time reſtore again the kingdom to Iſrael? And he ſaid, it is not for you to know the times and the ſeaſons, which the Father hath put in his own power. But ye ſhall receive power after that the Holy Ghoſt is come upon you; and ye ſhall be witneſſes unto me, both in Jeruſalem, and in all Judea, and in Samaria, and unto the uttermoſt parts of the earth. But tarry ye in the city of Jeruſalem, until ye be endued with power from on high; and he lift up his hands and bleſſed them; and it came to paſs, while he bleſſed them, he was parted from them, and a cloud received him out of their ſight. And while they looked ſtedfaſtly towards heaven, as he went up, behold, two men ſtood by them in white apparel; who alſo ſaid, ye men of Galilee, why ſtand ye gazing up into heaven? This ſame Jeſus, who is taken up from you into heaven, ſhall ſo come, in like manner as ye have ſeen him go into heaven. And they worſhipped him, and returned to Jeruſalem with great joy‡."

* 1 Cor. xv. 20—24. and St John v. 28. 29.

§ St Luke xxiv. 49—53. and Acts i. 6—12.

181 Proofs of Chriſt's aſcenſion.

That our bleſſed Lord aſcended into heaven, will hardly be denied in the preſent age by any one who admits that he roſe from the dead. The aſcenſion was indeed the natural conſequence of the reſurrection; for we cannot ſuppoſe that a man would be called back from the grave to live for ever in a world where all other men fall in ſucceſſion a prey to death. The purpoſe for which he died was to recover for the deſcendants of Adam every privilege which they had forfeited through his tranſgreſſion; and if, as has been generally believed, mankind were by the terms of the firſt covenant to enjoy eternal life in heaven, ſome proof was neceſſary that Chriſt by his death and reſurrection had opened the kingdom of heaven to all faithful obſervers of the terms of the ſecond. Hence it was propheſied § of the Meſſiah, in whom all the nations of the earth were to be bleſſed, that "he ſhould aſcend on high, lead captivity captive, and ſit on the right hand of God until his enemies ſhould be made his footſtool." It was therefore of the greateſt importance to the apoſtles to have ſufficient proof of their Maſter's exaltation to the right hand of the Majeſty on high; for otherwiſe they could neither have looked for an entrance into heaven themſelves, by a new and living way, as the author of the epiſtle to the Hebrews expreſſes it, nor have preached Jeſus as the Meſſiah promiſed to their fathers, ſince they could not have known that in him theſe prophecies were fulfilled. But the proof vouchſafed them was the moſt complete that the nature of the thing would bear. The ſpectators of the aſcenſion were many; for according to the hiſtory of St Luke*, thoſe who returned from the Mount of Olives to Jeruſalem, and prepared themſelves for the coming of the Holy Ghoſt, were in number about ſix ſcore; and to ſuch a cloud of witneſſes the evangeliſt would not have appealed, had not the fact he was recording been very generally known. Yet theſe were perhaps but part of the witneſſes; for ſince Chriſt had told to his diſciples that he was to aſcend

§ Pſ. lxviii. 12. cx. 1. Micah iv. 13.

* Acts i. 12—16.

Theology, more peculiarly Chriſtian.

cend to his Father and their Father, to his God and their God, and that he was going to prepare a place for them, that where he is there they might be likewiſe; we can hardly doubt but that all who believed in him as the Redeemer of the world would take care to be preſent, not only to view their Maſter's triumph over all his enemies, but alſo to have a ſight of that glory which awaited themſelves. It was on this occaſion probably that he was ſeen after his reſurrection by above five hundred brethren at once, of whom the greater part were alive at the writing of St Paul's firſt epiſtle to the Corinthians.

But though ſuch multitudes of people ſaw Jeſus lifted up from the mount, and gradually vaniſh out of their ſight, ſome other evidence ſeemed neceſſary to certify them of the place to which he had gone. Two angels therefore appear, and atteſt what human eyes could not ſee, but what was indeed the conſequence of what they had ſeen. They atteſt that Chriſt had aſcended to heaven, not to deſcend again till the laſt day; and ſurely, with reſpect to this point, the citizens of heaven were the moſt unexceptionable witneſſes. We muſt therefore acknowledge and confeſs, againſt all the wild hereſies of old (K), that Jeſus Chriſt the Son of God, who died and roſe again, did with the ſame body and ſoul with which he had lived upon earth aſcend up "into heaven, there to appear in the preſence of God for us*." Having in the outward tabernacle of this world once offered up himſelf a pure and perfect ſacrifice for the expiation of our ſins, he entered within the veil into the moſt holy place, there to preſent his blood before God himſelf, in order to obtain mercy for us, and reſtore us to the Divine favour. So that, "if any man ſin, we have an advocate with the Father, Jeſus Chriſt the righteous, who is the propitiation for our ſins, and not for ours only, but alſo for the ſins of the whole world; and he is able to ſave to the uttermoſt thoſe that come to God by him, ſeeing he ever liveth to make interceſſion for us." "Seeing then that we have a great high-prieſt, who is paſſed into the heavens, Jeſus the Son of God, we may through him come boldly unto the throne of grace, that we may obtain mercy, and find grace to help in time of need."

192 In heaven our Saviour executes the office of a prieſt

* Heb. ix 24.

But it is not the office of a prieſt only that our Lord diſcharges in heaven; he is repreſented as ſitting on the right hand of God, to denote that regal authority with which he is now veſted; "angels, and authorities, and powers, being made ſubject to him ‡." Hence it is, that after his reſurrection, he ſaid of himſelf †, "all power is given unto me in heaven and in earth;" for, as St Paul informs us ‡, "becauſe he humbled himſelf and became obedient unto death, even the death of the croſs, therefore God hath highly exalted him, and given him a name which is above every name; that at the name of Jeſus every knee ſhould bow, of things in heaven, and things in earth, and things under the earth." And this ſubmiſſion is due to him, becauſe "God raiſed him from the dead, and ſet him at his own right hand in the heavenly places, far above all principalities and powers, and might, and dominion, and every name that is named, not only in this world, but alſo in that which is to come; and hath put all things under his feet, and gave him to be head over all things to the church*." As God, Chriſt poſſeſſed a kingdom, which, as it had not a beginning, can never have an end: but the dominion, of which the apoſtle is here treating, was conferred upon him as the mediator of the new covenant, and will no longer continue than till his enemies ſhall be ſubdued; for we are told, that "he muſt reign till he hath put all enemies under his feet; and that the laſt enemy which ſhall be deſtroyed is death." "He will ranſom his ſubjects from the power of the grave; he will redeem them from death. O death, he will be thy plague; O grave, he will be thy deſtruction ‡." The trumpet ſhall ſound, the graves ſhall be opened, all the ſons and daughters of Adam ſhall return to life, and death ſhall be ſwallowed up in victory. "Then cometh the end, when the office of mediator ceaſing, he ſhall have delivered up the kingdom to God, even the Father, when he ſhall have put down all rule and all authority and power. For when all things ſhall be ſubdued unto him, then ſhall the Son alſo himſelf be ſubject unto him that put all things under him, that God may be all in all ‖."

Theology, more peculiarly Chriſtian.

* Eph. i. 20, &c.

‡ Hoſea xiii. 14.

‖ 1 Cor. xv. 24—28.

The firſt conſpicuous proof which our bleſſed Lord gave of being veſted with ſupreme power, and made head over all things to the church, was on the day of Pentecoſt. He had told the apoſtles that he would pray the Father to give them another comforter, who ſhould abide with them for ever, even the Spirit of truth, which ſhould teach them all things, and bring all things to their remembrance which he had ſaid unto them. He had aſſured them, that it was expedient for them that he himſelf ſhould go away; "for if I go not away (ſaid he ‡), the Comforter will not come unto you; but if I depart, I will ſend him unto you." At his laſt interview with them, juſt before his aſcenſion, he had deſired them to tarry at Jeruſalem till they ſhould be endued with power from on high, before they entered upon their great work of converting the nations. Theſe promiſes were amply fulfilled; for "when the day of Pentecoſt was fully come, they were all with one accord in one place. And ſuddenly there came a ſound from heaven as of a ruſhing mighty wind, and it filled all the houſe where they were ſitting. And there appeared unto them cloven tongues, like as of fire, and it ſat upon each of them. And they were all filled with the Holy Ghoſt, and began to ſpeak with other tongues, as the Spirit gave them utterance. And there were dwelling at Jeruſalem Jews, devout men, out of every nation under heaven. Now when this was noiſed abroad, the multitude came together, and were confounded, becauſe that every man heard them ſpeak in his own language. And they were all amazed, and marvelled, ſaying one to another, Behold, are not all theſe who ſpeak Galileans? And how hear we every man in our own tongue, wherein we are born? Parthians, and Medes, and Elanites, and the dwellers in Meſopotamia, and in Judea, and Cappadocia, in Pontus and Aſia, Phrygia and Pamphylia, in Egypt and in the parts of Libya about Cyrene, and ſtrangers of Rome, Jews and proſelytes, Cretes and Arabians—we do hear them ſpeak in our tongues the wonderful works of God. And they were all amazed, and were in doubt, ſaying one to another, What meaneth this*?"

194 Deſcent of the Holy Ghoſt on the apoſtles.

‡ John xvi. 7.

* Acts ii. 1—13.

That thoſe who heard the apoſtles ſpeak ſo many different

(K) There was one Apelles in the primitive church, who was condemned as a heretic for teaching that Chriſt's body was diſſolved in the air, and that he aſcended to heaven without it. The opinions of this man and his followers are ſtated at large and confuted by Tertullian, Gregory Nazianzen, and Epiphanius; and the reader who thinks ſuch ridiculous notions worthy of his notice, will find enough ſaid of them in the Notes to the ſixth article of Pearſon's Expoſition of the Creed. Perhaps it may be from a hint communicated in theſe Notes, that our great modern corrector of the evangeliſts has diſcovered, if it be indeed true that he pretends to have diſcovered, that Jeſus Chriſt is ſtill upon earth.

Theology, more peculiarly Christian.

ferent languages were amazed, is what we ſhould naturally ſuppoſe; but that a ſingle individual among them remained unconvinced, is aſtoniſhing: for the gift of tongues on the day of Pentecoſt is one of the moſt palpable miracles that was ever wrought. It is likewiſe one of the beſt authenticated miracles; for the book entitled *the Acts of the Apoſtles* was written not more than 30 years after the event took place (ſee SCRIPTURE, n° 168.); and it is not conceivable that, within ſo ſhort a period, St Luke, or any man of common ſenſe, would have appealed for the truth of what he recorded to ſo many inveterate enemies of the Chriſtian name, had he not been aware that the miraculous gift of tongues was a fact incontrovertible. We all know how deſirous the Jewiſh rulers were to ſtop the progreſs of the faith, by whatever means, whether of fraud or force; but if this miracle was not really performed, they had now an opportunity of doing it effectually by means to which truth and honour would give their approbation. Thouſands muſt have been alive in the city of Jeruſalem who were men and women at the time when the apoſtles were ſaid to have been thus ſuddenly inſpired with the tongues of the Parthians, Medes, and Elamites, &c.; and as theſe foreigners were themſelves either Jews by deſcent, or at leaſt proſelytes to the Jewiſh religion, ſurely the chief-prieſt would have found multitudes ready, both at home and abroad, to contradict this confident appeal of St Luke's, if contradiction had been poſſible. We read however of no objection whatever being made to this miracle. Some of the audience, indeed, when the apoſtles addreſſed people of ſo many nations in all their reſpective languages, not underſtanding what was ſaid, and taking it for jargon which had no meaning, concluded, not unnaturally, that the ſpeakers were full of new wine, and mocked them for being drunk ſo early in the day; but this is a circumſtance which, ſo far from rendering the miracle doubtful, adds much to the credit of the hiſtorian, as it would hardly have occurred to the writer of a narrative wholly falſe, and would certainly not have been mentioned, had he known that the apoſtles really attempted to impoſe upon the multitude unmeaning ſounds for foreign languages.

195 Certainty of that miracle.

196 The gift of tongues permanent with the apoſtles.

As it is thus certain that the apoſtles were miraculouſly furniſhed with the gift of tongues, ſo the elegance and propriety of that miracle to atteſt the real deſcent of the Spirit of truth, who was to teach them all things, and endue them with power from on high to convert the nations; can never be enough admired by the pious Chriſtian; for words being the vehicle of knowledge, an ability to ſpeak the different languages of the earth was abſolutely neceſſary to enable thoſe who had been originally fiſhermen to go into all the world and preach the goſpel to every creature. Yet there have been writers‡, who, though unable to call in queſtion the reality of the gift of tongues on the day of Pentecoſt, have contended, that it was a gift "not laſting, but inſtantaneous and tranſitory; not beſtowed upon them for the conſtant work of the miniſtry, but as an occaſional ſign only, that the perſon endowed with it was a choſen miniſter of the goſpel; which ſign, according to them, ceaſed and totally vaniſhed as ſoon as it had ſerved that particular purpoſe." The chief argument upon which this opinion is attempted to be built, is drawn from the ſcripture Greek, which is ſaid to be "utterly rude and barbarous, and abounding with every fault which can poſſibly deform a language; whereas we ſhould naturally expect to find an inſpired language pure, clear, noble, and affecting, even beyond the force of common ſpeech, ſince nothing can come from God but what is perfect in its kind. In ſhort, we ſhould expect, ſays the objector, the purity of Plato and the eloquence of Cicero*."

† Dr Middleton and Lord Shafteſbury.

197 Objections * Middleton's Eſſay on the Gift of Tongues

In reply to this objection, it has been well obſerved†, that it ſuppoſes what is called the purity, elegance, and ſublimity, of language, to be ſomething natural and eſſential to human ſpeech, and inherent in the conſtitution of things. "But the matter is far otherwiſe. Theſe qualities are accidental and arbitrary, and depend on cuſtom and faſhion; modes of humanity as various as the differing climes of the earth; and as inconſtant as the tempers, genius, and circumſtances, of its inhabitants. For what is *purity*, but the uſe of ſuch terms and their combinations as the caprice of a writer or ſpeaker of authority hath preferred to their equals? what is *elegance*, but ſuch a turn of idiom as a faſhionable fancy hath brought into credit? and what is *ſublimity*, but the application of ſuch images as arbitrary and caſual connections, rather than their own native grandeur, have dignified and ennobled? The conſequence of this is, that the mode of compoſition which is a model of perfection to one nation or people, has always appeared either extravagant or mean to another. Aſiatic and Indian eloquence was eſteemed hyperbolical and unnatural by the Greeks and Romans, and is ſo eſteemed by us; whilſt the Greek and Roman eloquence in its turn appeared cold and inſipid to the warm inhabitants of the eaſt; and ours would appear perhaps ſtill colder. But the New Teſtament was deſigned for the rule of life to all mankind. Such a rule required inſpiration; and inſpiration, ſay the objecters, implies the moſt perfect eloquence. What human model then was the Holy Ghoſt to follow? for a human model it muſt have been becauſe there was no other; and if there had, no other would have anſwered the purpoſe, which was to make a due impreſſion on the mind and affections. Should the eaſtern eloquence have been employed? But it would have been too ſwelling and animated for the weſt. Should the weſtern? This would have been too ſtill and inactive for the eaſt. Or ſuppoſe us only ſolicitous for what we beſt underſtand; which ſpecies of this latter genus ſhould the ſacred writers have preferred? The diſſolute ſoftneſs of the Aſiatic Greeks, or the dry conciſeneſs of the Spartans? The flowing exuberances of Attic eloquence, or the grave ſeverity of the Roman?

Theology, more peculiarly Christian.

† Warburton's Doctrine of Grace.

198 Anſwered.

"But are there not ſome general principles of eloquence in common to all the ſpecies? There are. Why then ſhould not theſe have been employed to credit the apoſtolic inſpiration? Becauſe the end even of theſe (replies our author) is to miſlead reaſon, and inflame the paſſions; which being abhorrent to the truth and purity of our holy religion, were very fitly rejected by the inſpired penman. Beſides, it might eaſily be known to have been the purpoſe of Providence, though ſuch purpoſe had not been expreſsly declared, that the goſpel ſhould bear all poſſible marks of its divine original, as well in the courſe of its progreſs as in the circumſtances of its promulgation. To this end, the human inſtruments of its conveyance were mean and illiterate, and choſen from among the loweſt of the people, that when the world ſaw itſelf converted by the *fooliſhneſs of preaching*, as the only learned apoſtle thinks fit to call it, unbelievers might have no pretence to aſcribe its ſucceſs to the parts, or ſtations, or authority, of the preachers. Now had the language inſpired into theſe illiterate men been the eloquence of Plato or Tully, Providence would have appeared to counteract its own meaſures, and to defeat the purpoſe beſt calculated to advance its glory. But God is wiſe, though man is a fool. The courſe of Providence was uniform and conſtant: It not only choſe the weakeſt inſtruments, but carefully kept out of their hands that powerful weapon, of WORDS which their adverſaries might ſo eaſily have wreſted to the diſhonour of the goſpel. Common ſenſe tells us, that the ſtyle of an univerſal law ſhould retain

Theology, more peculiarly Christian.

tain what is common to all languages, and neglect what is peculiar to each. It should retain nothing but CLEARNESS and PRECISION, by which the mind and sentiments of the writer are intelligibly conveyed to the reader. This quality is essential, invariably the same, and independent of custom and fashion. It is the consequence of syntax, the very thing in language which is least positive, as being formed on the principles of philosophy and logic: whereas all besides, from the very power of the elements and signification of the terms to the tropes and figures in composition, are arbitrary; and, as deviating from these principles, frequently vicious. But this quality of clearness and precision eminently distinguishes the writings of the New Testament; insomuch that it may be easily shown, that whatever difficulties occur in the sacred books do not arise from any imperfect information caused by this local or nominal barbarity of style; but either from the sublime or obscure nature of the things treated of, or from the intentional conciseness of the writers; who, in the casual mention of any thing not essential to the dispensation, always observe a studied brevity."

After much ingenious and sound reasoning on the nature of language in general, our author concludes, that the STYLE of the New Testament, even on the supposition of the truth of what has been said to its discredit, is so far from proving the language not to be divinely inspired, that it bears one certain mark of that original. "Every language consists of two distinct parts, the single terms, and the phrases and idioms. Suppose now a foreign language to be instantaneously introduced into the minds of illiterate men like the apostles; the impression must be made either by fixing in the memory the terms and single words only with their signification, as, for instance, Greek words corresponding to such or such Syriac or Hebrew words; or else, together with that simple impression, by enriching the mind with all the phrases and idioms of the language so inspired. But to enrich the mind with the peculiar phrases and idioms of a foreign language, would require a previous impression to be made of the manners, notions, fashions, and opinions, of the people to whom that language is native; because the idioms and phrases arise from and are dependent on these manners. But this would be a waste of miracles without sufficient cause or occasion; for the Syriac or Hebrew idiom, to which the Jews were of themselves enabled to adapt the Greek or any other words, abundantly served the useful purposes of the gift of tongues, which all centered in those tongues, being so spoken and written as to be CLEARLY UNDERSTOOD. Hence it follows, that if the style of the New Testament were indeed derived from that language which was miraculously impressed upon the apostles on the day of Pentecost, it must be just such a one as in reality we find it to be; that is, it must consist of Greek words in the Syriac or Hebrew idiom."

199 Divinity of the Holy Ghost.

The immediate author of this gift, so necessary to the propagation of the gospel, was the Spirit of truth, or the Comforter, who is the Holy Ghost and the third person in the blessed Trinity. That there are three persons in the one Godhead, has been shewn at large in a former section of this article; and that the Holy Ghost is one of these three, might be safely concluded from the form of baptism instituted by Christ himself. But as more plausible objections have been urged against his divinity than any that we have met with against the divinity of Christ, it may not be improper to consider these before we proceed to give an account of the graces which he imparted to the infant church, and of the apostles preaching under his influence. By the Arians the Holy Ghost is considered as a creature; by the Socinians and modern Unitarians, as they call themselves, the words *Holy Ghost* are supposed to express, not a person or spiritual substance, but merely an energy or operation, a quality or power, of the Father, whom alone they acknowledge to be God. If this doctrine can be confuted, the Arian hypothesis will fall to the ground of itself; for it is not conceivable that any inspired teacher should command his followers to be baptized in the name of the self-existent God and two creatures.

Theology, more peculiarly Christian.

200 Objections.

It is admitted by the Socinians themselves, that in the scriptures many things are spoken of the Holy Ghost which can be properly predicated only of a person; but the inference drawn from this concession they endeavour to invalidate by observing, that in scripture there are likewise expressions in which things are predicated of abstract virtues, which can be literally true only of such persons as practise these virtues. Thus when St Paul says*, that "charity suffereth long and is kind, charity envieth not, charity vaunteth not itself, is not puffed up, &c." we cannot suppose his meaning to be, that these actions are performed by charity in the abstract, but that every charitable person, in consequence of that one Christian grace, suffereth long and is kind, envieth not, vaunteth not himself, and is not puffed up, &c. In like manner, say they, personal actions are attributed to the Holy Ghost, which itself is no person, but only the virtue, power, or efficacy, of God the Father; because God the Father, who is a person, performs such actions by that power, virtue, or efficacy, in himself, which is denominated the Holy Ghost. Thus when we read ‡ that "the Spirit said unto Peter, Behold three men seek thee; arise therefore and get thee down, and go with them, doubting nothing, for I have sent them;" we must understand that God the Father was the person who spoke these words and sent the three men; but because he did so by that virtue in him which is called the *Spirit*, therefore the *Spirit* is said to have spoken the words and sent the men. Again, when "the Holy Ghost said || to those at Antioch, Separate me Barnabas and Saul for the work whereunto I have called them;" we are to conceive that it was God the Father who commanded the two apostles to be separated for the work to which he had called them; but because he had done all this by that power within him which is called the Holy Ghost, therefore his words and actions are attributed to the Holy Ghost, just as long-suffering in men is attributed to charity.

* 1 Cor. xiii. 4—8.

‡ Acts x. 19, 20.

|| Acts xiii. 2.

201 Answered.

This reasoning has a plausible appearance, and would be of much force, were *all* the actions which in scripture are attributed to the Holy Ghost of such a nature as that they could be supposed to have proceeded from the person of God the Father, in consequence of any particular power or virtue in him; but this is far from being the case. Thus "the Spirit is said † to make intercession for us;" but with whom can we suppose God the Father, the fountain of divinity, to intercede? Our Saviour assured ‡ his disciples, that the Father would, in his name, send to them the Holy Ghost, who is the Comforter; that he would himself send the Comforter unto them from the Father; that the Comforter should not speak of himself, but speak only what he should hear; and that he should receive of Christ's, and shew it unto them. But we cannot, without blasphemy and absurdity, suppose that the Father would, in the name of Christ, send himself; that the Son would send the Father from the Father; that the Father would not speak of himself, but speak only what he heard; or that either the Father in person, or a quality of the Father, should receive any thing of Christ to shew unto the apostles.

† Rom. viii. 26, 27.

‡ St John xiv. 26. xv. 26. xvi. 13, 14, 15.

The sagacity of Socinus perceived the force of such objections as these to his notion of the Holy Ghost, being nothing more than the power of the Father personified; and therefore he invented another *prosopopeia* to serve his

Theology, more peculiarly Christian.

purpose in the interpretation of those texts to which this one cannot be applied. "The Spirit of God (says he §) may be considered either as a property or power in God, or as the things on which that power is working. When taken in the former sense, the Spirit, where any personal attribute is given to it, means God the Father; when taken in the latter sense, it means the man on whom the power of the Father is working; who, as long as he is affected by that power, is therefore called the Spirit of God;" and he quotes, we think most absurdly, the tenth verse of the second chapter of the first epistle to the Corinthians, as a text in which by the Spirit is meant an inspired man who could search all things, yea, even THE DEEP THINGS OF GOD.

§ Faust. Socinus in Resp. ad Wickham, cap. 10.

How his modern followers, who deny the plenary inspiration even of Christ, will relish such a degree of inspiration as this, which raises mere man to a temporary equality with God, we know not; but leaving them to settle the dispute with their master as they best can, we shall produce one or two passages in which personal attributes are given to the Spirit of God, when it is impossible to conceive that Spirit either as a power inherent in the Divine Father, or as the person on whom that power is operating. We need not bring new texts into view, as some of those already quoted will serve our purpose. When our Saviour promises that the *Holy Ghost*, *the Comforter*, *the Spirit of truth*, should be sent by the Father and the Son to the apostles, we have seen, that by this Spirit he could not mean the Father or a property of the Father; neither could he possibly mean the apostles themselves, unless we are to suppose that the Father and the Son sent St Peter to St Peter, and that St Peter, so sent, came to St Peter! Again, when Christ saith of the Holy Ghost, "he shall receive of mine, and shall shew it unto you," he could not, for the reason already assigned, mean by the Holy Ghost the Father or the power of the Father; and surely his meaning was not, that the apostles, under the influence of the power of the Father, should receive something and shew it each to himself! The Holy Ghost therefore is unquestionably a person; for tho' there are many passages of scripture in which the *gifts* of the Holy Ghost are called the *Holy Ghost*, they are so called by a very common figure of speech, in which the effect receives the name of its cause: and since this person is joined with the Father and the Son in the formula of Christian baptism; since they who lied to the Holy Ghost are said † to have lied unto God; since blasphemy against him is a more heinous offence than the same sin against even the Father or the Son ‡; and since it was by the operation of the Holy Ghost that Jesus Christ was conceived of the Virgin Mary, and even on that account † called the Son of God—it follows undeniably, that the Holy Ghost is God, of the same substance with the Father and Son.

† Acts v. 4.

‡ Mark iii. 28, 29.

† Luke i. 35.

202 The apostles miraculously instructed in the principles of religion.

It was this divine Spirit which, on the day of Pentecost, inspired the apostles with the knowledge of different languages; and as these were given only to enable them to preach the gospel to every creature, it can admit of no doubt but that he, who so amply provided the means of preaching, would take care that the gospel should be preached in purity. Our Saviour had told his apostles that the Comforter would guide them into all the truth (εις πασαν την αληθειαν), and bring all things to their remembrance, whatsoever he had said unto them; but if they had not comprehended the meaning of what he said, the bare remembrance of his sayings would have been of little importance. That before this miraculous shedding abroad of the Spirit they had but a very imperfect knowledge of his doctrines, and of the purpose for which he had come into the world, is apparent from that unseasonable question which they put to him when assembled to witness his glorious ascension; "Lord, wilt thou at this time restore again the kingdom to Israel?"

Theology, more peculiarly Christian.

203 Their great need of such instruction.

Their minds still cherished with fondness the vain prospect of temporal power; but after the day of Pentecost they were directed to nobler objects. From the same Spirit they received diversities of gifts besides that of language; for we are assured by St Paul*, when speaking of the early converts to Christianity in general, that "to one was given by the Spirit the word of WISDOM; to another the word of KNOWLEDGE by the same Spirit; to another FAITH by the same Spirit; to another the gifts of HEALING by the same Spirit; to another the working of MIRACLES; to another PROPHECY; to another DISCERNING OF SPIRITS; to another DIVERS KINDS OF TONGUES; to another the INTERPRETATION of tongues:" and these gifts, which were severally divided either among private Christians or among the inferior orders of ministers in the church, we have reason to believe were all bestowed in a greater or less degree upon each of the apostles.

* 1 Cor. xii. 8—12.

Men thus endowed were well qualified to declare unto the world all the council of God. By the word of *wisdom* they communicated to the Gentile nations a pure system of what is called *natural religion*; turning them from the vanity of idols to the worship of the living God: by the word of *knowledge*, they preached the great doctrines of revelation both to Jews and Gentiles, shewing them that there is none other name under heaven given unto men whereby they may be saved than the name of Jesus Christ (L); and by their gifts of *healing* and of *miracles*, &c. they were enabled to prove unanswerably that their doctrines were divine. They taught everywhere the unity of God, the creation of the world, the fall of man, the necessity of redemption, the divinity of the Redeemer, his sacrifice on the cross to restore mankind to their forfeited immortality, and the terms of the new covenant into which they had through him been graciously admitted by God.

Such a view as our limits would admit of we have given of all these doctrines, except that which respects the terms of the gospel covenant; but these being explicitly stated only by St Paul and St James, we could not till now investigate them, without violating the historical order into which, for the sake of perspicuity, we have digested the several parts of this short system. Our Saviour himself has indeed taught with great plainness the necessity of faith and baptism

(L) It is not perhaps easy to determine what is here meant by the word of WISDOM and the word of KNOWLEDGE, as distinguished from each other. By the former (λογος σοφιας), bishop Warburton understands all the great principles of natural religion. "The ancients (says he) used the word σοφια in this peculiar sense; it is used in the same sense by St. Paul in Col. iv. 5; and we can hardly give it any other in the place before us, where we see the word of wisdom distinguished from the word of knowledge (λογος γνωσεως), which evidently means all the great principles of revelation; the term γνωσις being as peculiarly applied by Christian writers to revealed religion as σοφια is by the Gentiles to the natural. St Paul uses the word in this sense in 2 Cor. xi. 6. where he says, Ει δε και ιδιωτης τω λογω αλλ ου τη γνωσει; and St Peter in his first epistle, chap. iii. verse 7. Hence those early heretics, who so much deformed the simplicity and purity of the Christian faith by visionary pretences to superior knowledge of revelation, took from this word the name of Gnostics." See *Warburton's Sermon on the Office and Operation of the Holy Ghost.*

Theology, more peculiarly Christian.

baptiſm to the ſalvation of thoſe who have an opportunity of hearing the goſpel preached with power (ſee BAPTISM); and in his ſermon on the mount, which is ſuch a lecture of ethics founded on religion as the Son of God only could have delivered, we learn, that "unleſs our righteouſneſs ſhall exceed the righteouſneſs of the Scribes and Phariſees, we ſhall in no caſe enter into the kingdom of heaven; that not every one who ſaith unto Chriſt, Lord, Lord, ſhall enter into the kingdom of heaven, but he who doth the will of his Father who is in heaven; and that many will ſay to him at the day of judgment, Lord, Lord, have we not propheſied in thy name? and in thy name done many wonderful works?" which could not be done without faith; "to whom he will, notwithſtanding, ſay, Depart from me, ye that work iniquity ‡." St Paul, however, ſeems to attribute our juſtification to the bare act of believing; for he repeatedly aſſures us, "that a man is juſtified by faith without the deeds of the law;" while St James, on the other hand, affirms, "that by works a man is juſtified, and not by faith only."

‡ St Matth. v. 20. vii. 21, —24.

This apparent difference in the language of the two apoſtles, for we hope to ſhow that it is only apparent, has produced among divines opinions really different reſpecting the juſtification of Chriſtians; and the principal of theſe opinions it is our duty to ſtate. But previous to this, it will be neceſſary to aſcertain the meaning of the word *juſtification*; for we are ſorry to ſay, that for want of accurate definitions, many theological controverſies are nothing better than empty logomachies; and perhaps againſt no controverſy can this charge be brought with greater truth than againſt that which, in the end of the laſt century and in the beginning of the preſent, was ſo violently agitated concerning the *cauſes*, the *inſtruments*, and the *conditions*, of juſtification.

204 Meaning of juſtification.

Between *pardon* of ſin and *juſtification* there is ſo cloſe a connection, that many writers ſeem to conſider the terms as ſynonymous, and to infer, that he who is pardoned is *ipſo facto* juſtified. That every Chriſtian, who ſhall be pardoned at the judgment of the great day, will likewiſe be juſtified, is indeed true; but in propriety of ſpeech, *juſtification* is a word of very different import from *pardon*, and will entitle the Chriſtian to what mere pardon could not lead him to expect. An innocent perſon, when falſely accuſed and acquitted, is *juſtified* but not *pardoned*; and a criminal may be *pardoned*, though he cannot be *juſtified* or declared innocent. A man whoſe ſins are pardoned is free from puniſhment; but the juſtified Chriſtian is entitled to everlaſting life, happineſs, and glory. If we were only pardoned through Chriſt, we ſhould indeed eſcape the pains of hell, but could have no claim to the enjoyments of heaven; for theſe, being more than the moſt perfect human virtue can merit, muſt be, what in the Scriptures they are always ſaid to be, "the gift of God through Jeſus Chriſt our Lord." Hence it is that St Paul, diſtinguiſhing, as we have done upon his authority, between mere remiſſion of ſins and juſtification of life, declares ‡, that "Jeſus our Lord was *delivered* for our *offences*, and *raiſed* again for our *juſtification*."

‡ Romans iv. 25.

The word juſtification, as uſed both by St Paul and St James, has been very generally conſidered as a forenſic term expreſſing the ſentence of a judge. The moſt eminent reformed divines of all denominations*, and even many of the Romaniſts themſelves, have ſtrenuouſly contended, that this is its genuine ſenſe, when it is diſtinguiſhed from mere remiſſion of ſins, regeneration, and ſanctification; and if ſo, it will ſignify God's pronouncing a perſon *juſt*, either as being perfectly blameleſs, or as having fulfilled certain conditions required of him in the Chriſtian covenant. But that "there is not a juſt man upon earth, who doth good and ſinneth not," is made known to us by the moſt complete evidence poſſible, the joint dictates of our own conſciences and of divine revelation; and therefore whoſoever is pronounced juſt by the Judge of all the earth, muſt be ſo, either becauſe, though not abſolutely blameleſs, he has performed the conditions required of him in the covenant of grace, or becauſe Chriſt has fulfilled all righteouſneſs in his ſtead.

* Limborch, Bull, Waterland Warburton Beveridge, Vitringa, Gill, &c.

Theology, more peculiarly Christian.

105 It is a forenſic term.

If this be the Scripture notion of juſtification, it muſt be wholly the act of God, and cannot be the effect either of our faith or of our virtue. Accordingly, we are ſaid by the apoſtle to be juſtified freely by his grace through the redemption that is in Jeſus Chriſt; whom *God hath ſet forth* to be a propitiation through faith in his blood †. The act of juſtification therefore proceeds from the divine philanthropy, and cannot be performed by the inſtrumentality of faith; for it is not God, but man, who believes; and man is not the juſtifier of himſelf. To talk of any kind of *inſtrument* of juſtification beſides the propitiation ſet forth by God, is indeed to make uſe of very improper language: "Omnis cauſa inſtrumentalis (ſays Biſhop Bull ‡), ſuo modo in effectum influit, eique effecti productio propriè attribui poteſt. Jam vero, cum juſtificatio nihil aliud ſit quam gratioſus Dei actus, quo peccata noſtra nobis condonet, ac nos ad ſalutem acceptet, valde abſurdum eſſet dicere, vel fidem, vel opera noſtra, vel quidvis aliud noſtri aut remittere peccata noſtra, aut perſonas noſtras acceptare: quod tamen, ſi inſtrumentalis cauſa juſtificationis fides ſit, plane dicendum eſſet."

† Rom iii. 24, 25.

‡ Harmonia Apoſtolica, cap. ii. § 9.

In this ſentiment of the illuſtrious Biſhop of St David's, ſome of the moſt eminent divines both among the Calviniſts and Arminians agree; and indeed it is not eaſy to be conceived how any man can entertain a different ſentiment, when conſidering juſtification in its proper ſenſe. Many, however, have choſen to treat of juſtification not only in the active ſenſe, as it is the act of God, for all admit that it is he who juſtifies; but likewiſe in a paſſive ſenſe, as it means our *privilege* or *poſſeſſion* holden of him, when we are ſaid to be juſtified by his grace. In this view of the ſubject they may talk, with ſufficient propriety, of an inſtrument of juſtification, not as the mean by which it is conveyed, but as the medium through which it is received by the true Chriſtian. And hence it follows, that the Doctors Waterland and Warburton, of whom the former was not a thorough Calviniſt, and the latter was a profeſſed Arminian, ſtrenuouſly maintain the doctrine of the Weſtminſter Confeſſion, that "faith receiving and reſting on Chriſt is the alone inſtrument of juſtification; though it cannot be alone in the perſon juſtified, but muſt ever be accompanied with all other ſaving graces, and be a faith which worketh by love."

But notwithſtanding this agreement between the leaders of the rival ſects, they have found abundant matter of controverſy reſpecting faith and works, in deciding the great queſtion, "Whether, when God juſtifies man, he conſiders him as abſolutely righteous on account of Chriſt's righteouſneſs performed in his ſtead; or only as juſt, becauſe he has fulfilled the conditions of the covenant of grace, which does not require of him perfect righteouſneſs?" The former is the doctrine of the more rigid Calviniſts, the latter that of the Arminians or Remonſtrants.

"A notion (ſays Dr Gill ‡) obtained ſome years ago, that a relaxation of the law and the ſeverities of it has been obtained by Chriſt; and a new law, a remedial law, a law of milder terms, been introduced by him, which is the goſpel; the terms of which are, faith, repentance, and new obedience; and though theſe be imperfect, yet, being ſincere, they are accepted by God in the room of a perfect righteouſneſs. But every article of this ſcheme (continues he) is wrong;

‡ Body of Divinity, vol. ii. book iii. chap. 8. § 5.

for

Theology, more peculiarly Christian.

for the law is not relaxed, nor any of its severities abated; Christ came not to destroy, but to fulfil it; and therefore it requires the same holy, just, and good things, as ever. Nor is the gospel a new law. There is nothing in it (he says) which looks like a law; for it has no commands in it, but all promises, being a pure declaration of grace and salvation by Christ; nor are faith, repentance, and new obedience, required by it as conditions of man's acceptance with God. Faith and repentance are gospel doctrines, and parts of the gospel ministry; they are graces, and not terms required to be performed by men of themselves. Faith is the gift of God, and repentance is a grant from him. It is not true (continues our author) that God will accept of an imperfect righteousness in the room of a perfect one; nor can any thing more highly reflect upon the justice and truth of God, who is the judge of all the earth, than to suppose that he can ever account that as a righteousness which is not one."

206 Doctrine of the Calvinists respecting it.

Having thus proved by arguments which were almost in the same words stated long before by Bishop Beveridge ‖, that the gospel is no relaxation of the law, he proceeds to lay down his own notions of justification, of which (he says) "the sole matter, or that for the sake of which a sinner is justified before God, is the righteousness of Christ—that which he did and suffered on earth, in our nature, in our stead, and as our representative. This is commonly called his active and passive obedience; and when the purity and holiness of his own nature was added to it, the whole made up the δικαιωμα του νομου, *the righteousness of the law*, which was fulfilled by him as the head and representative of his people *; for whatever the law required is necessary to a sinner's justification before God, and it required of sinners more than it did of man in innocence. Man was created with a pure and holy nature, conformable to the pure and holy law of God; and it was incumbent on him to continue so, and to yield in it perfect and sinless obedience; in the failure whereof he was threatened with death. Man did fail; by which his nature was vitiated and corrupted, and his obedience became faulty and imperfect. He therefore became liable to the penalty of the law, and still perfect obedience was required of him. To the justification of a sinner therefore is required the most complete obedience, active and passive; or, in other words, purity of nature, perfect obedience, and the sufferings of death; all which meet in Christ, the representative of his people, in whom they are justified. There are indeed some divines (continues our author) who exclude the active obedience of Christ from being any part of the righteousness by which men are justified. They allow it to have been a condition requisite in him as a Mediator, qualifying him for his office; but deny that it is the matter of justification, or reckoned for righteousness to man. But without the active obedience of Christ the law would not be satisfied; the language of which is, *Do and live;* and unless its precepts be obeyed, as well as its penalty endured, it cannot be satisfied; and unless it be satisfied, there can be no justification. If therefore men are justified by the righteousness of Christ, it must be by his active obedience imputed and made over to them, so as to become their's, *even as David describeth the blessedness of the man unto whom God imputeth righteousness without works* *. That this is really the way in which men are justified, our author thinks evident, because they must be justified either by an inherent or by an imputed righteousness; but they cannot be justified by their own inherent righteousness, for that is imperfect, and therefore not justifying. Hence the apostle 'counts all things but dung, that he may win Christ and be found in him; not having his own righteousness, which is of the law, but that which is *through the faith of Christ*, the righteousness which is of *God by Faith* §.' But by such a righteousness as this a man cannot be justified in any other way than by an imputation of it to him. Whence it follows, that "*as by one man's disobedience many were made sinners* by imputation, so *by the obedience of one shall many be made* righteous, by having that obedience placed to their account."

‖ See his Private Thoughts of religion.

* Rom. viii, 4.

* Rom. iv. 6.

Theology, more peculiarly Christian.

§ Philip. iii. 8, 9.

As this author properly considers justification as the act of God, he does not approve of the language in which faith is called the instrument either of conferring or receiving it. "Faith (says he *) is merely the evidence of justification to the person justified; for 'faith is the evidence of things not seen.' The righteousness of God, of the God man and Mediator Jesus Christ, is revealed from faith to faith in the everlasting gospel ‡; and therefore must be before it is revealed, and before the faith to which it is revealed. Faith is that grace whereby a soul, having seen its guilt and its want of righteousness, beholds in the light of the Divine Spirit, a complete righteousness in Christ, renounces its own, lays hold on that, puts it on as a garment, rejoices in it, and glories of it; the Spirit of God witnessing to his spirit that he is a justified person: and so he is evidently and declaratively 'justified in the name of the Lord Jesus, and by the Spirit of our God †'. Faith adds nothing to the *esse*, only to the *bene esse* of justification; which is a complete act in the eternal mind of God, without the being or consideration of faith, or any foresight of it. In the account of God, a man is as much justified before his faith as after it; and after he does believe, his justification depends not on his acts of faith, for though *we believe not, yet God abides faithful* to his covenant-engagements with his Son, by whose suretyship-righteousness the elect are justified; but by faith men have a comfortable sense, perception, and apprehension, of their justification, and enjoy that peace of soul which results from it. It is by that only, under the testimony of the Divine Spirit, that they know their interest in it, and can claim it, and so have the comfort of it."

* Body of Divinity, vol. i. book ii. § 5.

‡ Rom. i. 17.

† 1 Cor. vi. 11.

Though this language differs from that of the Westminster Confession, the author seems not to teach a different doctrine; for if faith be that grace by which a soul renounces its own righteousness, and lays hold of Christ's, which it puts on as a garment, it must be that very thing which the compilers of the Confession meant by their definition of faith receiving and resting on Christ and his righteousness, when they called it "the alone instrument of justification." Accordingly our author elsewhere * teaches, that "true faith in sensible sinners assents to Christ and embraces him, not merely as a Saviour of man in general, but as a special suitable Saviour for them in particular. It proceeds upon Christ's being revealed *in* them as well as *to* them, by the spirit of wisdom and revelation, in the knowledge of him as a Saviour that becomes them. It comes not merely through external teachings by the hearing of the word from men; for no man, saith our blessed Lord, can come to me except the Father draw him; but such souls as are thus drawn, having heard and learned of the Father, believe not only in the *doctrine* of Christ, but also in *himself*, trusting in him alone for everlasting life and salvation."

* Body of Practical Divinity, book i. chap. 6.

207 And of the more moderate Arminians.

Were it not that this author, in every thing that he writes, has an eye to the doctrine of election and reprobation, which he screws up to a greater height than almost any other divine with whose works we are acquainted, he would differ little in his notions of justification from the more moderate Arminians. "Justification (says Limborch) is the merciful and gracious act of God, whereby he fully absolves from all guilt the truly penitent and believing soul, through and for the sake of Christ apprehended by a true faith: or gratuitously remits sins upon the account of faith

in

Theology, more peculiarly Christian.

in Jesus Christ, and graciously imputes that faith for righteousness." Here indeed the imputation of Christ's righteousness is expressly denied; but our countryman Dr Waterland, who can hardly be considered as a Calvinist, seems to contend for the imputation of that righteousness to the sinner, as well as for faith being the instrument by which it is received.

* Summary View of Justification.

"It cannot be for nothing (says that able writer *) that St Paul so often and so emphatically speaks of man's being justified by faith, or through faith in Christ's blood; and that he particularly notes it of Abraham, that he *believed*, and that his faith was counted to him for justification, when he might as easily have said that Abraham, to whom the gospel was preached, was justified by gospel faith and obedience, had he thought faith and obedience equally instruments of justification. Besides, it is on all hands allowed, that though St Paul did not directly oppose faith to *evangelical works*, yet he comprehended the works of the *moral law* under those which he excluded from the office of *justifying*, in his sense of the word justification. He even used such arguments as extended to all kinds of works; for Abraham's works were excluded, though they were undoubtedly evangelical. To prove that he interprets the apostle's doctrine fairly, our author quotes, from the genuine epistle of Clemens of Rome, a passage, in which it appears beyond a doubt that this fellow-labourer of St Paul so understood the doctrine of justifying faith as to oppose it even to evangelical works, however exalted. It is true (continues our author), Clemens elsewhere, and St Paul almost everywhere, insists upon true holiness of heart and obedience of life as indispensable conditions of salvation or justification; and of that, one would think, there could be no question among men of any judgment or probity. But the question about conditions is very distinct from the other question about instruments; and therefore both parts may be true, viz. that faith and obedience are equally conditions, and equally indispensable where opportunities permit; and yet faith over and above is emphatically the instrument both of receiving and holding justification, or a title to salvation.

208 Faith the instrument of it.

"To explain this matter more distinctly, let it be remembered, that God may be considered either as a party contracting with man on very gracious terms, or as a Judge to pronounce sentence on him. Man can enter into the covenant, supposing him adult, only by assenting to it, and accepting it, to have and to hold it on such kind of tenure as God proposes: that is to say upon a self-denying tenure, considering himself as a guilty man standing in need of pardon, and of borrowed merits, and at length resting upon mercy. So here, the previous question is, Whether a person shall consent to hold a privilege upon this submissive kind of tenure or not? Such assent or consent, if he comes into it, is the very thing which St Paul and St Clemens call *faith*. And this previous and general question is the question which both of them determine against any proud claimants who would hold by a more self-admiring tenure.

"Or if we next consider God as sitting in judgment, and man before the tribunal going to plead his cause; here the question is, What kind of plea shall a man resolve to trust his salvation upon? Shall he stand upon his innocence, and rest upon strict law? or shall he plead guilty, and rest in an act of grace? If he chooses the former, he is proud, and sure to be cast: if he chooses the latter, he is safe so far in throwing himself upon an act of grace. Now this question also, which St Paul has decided, is previous to the question, What conditions even the act of grace itself finally insists upon? A question which St James in particular, and the general tenure of the whole Scripture, has abundantly satisfied; and which could never have been made a question by any considerate or impartial Christian. None of our works are good enough to stand by themselves before him who is of purer eyes than to behold iniquity. Christ only is pure enough for it at first hand, and they that are Christ's at second hand in and through him. Now because it is by faith that we thus interpose, as it were, Christ between God and us, in order to gain acceptance by him; therefore faith is emphatically the instrument whereby we receive the grant of justification. Obedience is equally a condition or qualification, but not an instrument, not being that act of the mind whereby we look up to God and Christ, and whereby we embrace the promises."

Theology, more peculiarly Christian.

209 Faith and obedience its conditions.

But though our author contends that faith is the instrument of justification, he does not, like the Antinomians, teach that it will save men without works. "The covenant of grace, says he, has conditions annexed to it of great importance, for without them no instruments can avail. These are faith and obedience, as St James hath particularly maintained. St Paul had before determined the general and previous question respecting the plea by which we ought to abide; and when some libertines, as is probable, had perverted his doctrine of faith and grace, St James showed that the very faith which rests in a covenant of grace implies a cordial submission to the conditions of that covenant, otherwise it would be nothing but an empty ceremony. The perfect agreement between St Paul and St James in the article of *justification*, appears very clear and certain. St Paul declares, that in order to come at justification, it is necessary to stand upon grace, not upon merit; which St James does not deny, but rather confirms, in what he says of the perfect law of liberty (James i. 25. ii. 12). St Paul makes faith the instrument of receiving that grace; which St James does not dispute, but approves by what he says of Abraham (ii. 23.); only he maintains also, that, in the conditionate sense, justification depends equally upon faith and good works; which St Paul also teaches and inculcates in effect, or, in other words, through all his writings. If St Paul had had precisely the same question before him which St James happened to have, he would have decided just as St James did; and if St James had had precisely the same question before him which St Paul had, he would have determined just as St Paul did. Their principles were exactly the same, but the questions were diverse; and they had different adversaries to deal with, and opposite extremes to encounter, which is a common case.

"It may be noted, that that faith which is here called a *condition*, is of much wider compass than that particular kind of faith which is precisely the instrument of justification. For faith as a condition means the whole complex of Christian belief, as expressed in the creeds; while faith as an instrument means only the laying hold on grace, and resting in Christ's merits in opposition to our own deservings: though this also, if it is a vital and operative principle (and if it is not, it is nothing worth), must of course draw after it an hearty submission to, and observance of, all the necessary conditions of that covenant of grace wherein we repose our whole trust and confidence. So that St Paul might well say, "Do we then make void the law (the moral law) through faith? God forbid: Yea, we establish the law *." We exempt no man from religious duties; which are duties still, though they do not merit nor are practicable to such a degree as to be above the need of pardon: they are necessary conditions in their measure of justification, though not sufficient in themselves to justify, nor perfect enough to stand before God or to abide trial: therefore Christ's merits must be taken in to supply their defects: and so our resting in Christ's atonement by an humble self-denying faith is our last resort, our anchor of salvation both sure and stedfast,

* Rom. iii. 31.

Theology, more peculiarly Christian.

fast, after we have otherwise done our utmost towards the fulfilling of God's sacred laws, towards the performing of all the conditions required.

"That good works, internal and external, are according as opportunities offer and circumstances permit, *conditions* properly so called, is clear from the whole tenor of Scripture, as hath been often and abundantly proved by our own divines (M), and is admitted by the most judicious among the foreign Reformed (N). Yet some have been very scrupulous as to this innocent name, even while they allow the absolute necessity of good works as indispensable qualifications for future blessedness. Why not conditions therefore as well as qualifications? Perhaps because that name might appear to strike at absolute predestination, or unconditional election; and there may lie the scruple: otherwise the difference appears to lie rather in words than in things.

"Some will have them called not conditions, but *fruits* or *consequents* of justification. If they mean by justification the same as the grace of the Holy Spirit, and the first grace of faith springing from it, they say true; and then there is nothing more in it than an improper use of the word *justification*, except that from abuse of words very frequently arises some corruption of doctrine. If they mean only, that outward acts of righteousness are fruits of inward habits or dispositions; that also is undoubtedly true: but that is no reason why internal acts, virtues, graces (good works of the mind), should not be called conditions of justification; or why the outward acts should not be justly thought conditions of preserving it. But if they mean that justification is ordinarily given to adults, without any preparative or previous conditions of faith and repentance, that indeed is very new doctrine and dangerous, and opens a wide door to carnal security and to all ungodliness."

Such is the doctrine of Christian justification as it has been taught by the followers of Calvin, and by some of the most eminent Arminians who flourished in the end of the last and beginning of the present century. They appear not, from this view of their opinions, to differ so widely as some of them have wished the world to believe. It is evident that Dr Waterland, though he rejects some of the distinguishing tenets of Calvinism, lays greater stress upon faith in his scheme of justification than Dr Gill himself; and that they both consider it as the *instrument* by which the adult Christian must receive the imputed righteousness of Christ. The greater part of modern Arminians, however, exclaim against the imputation of Christ's righteousness, as a doctrine false in itself, and fraught with the most pernicious consequences; and they would be ready to tell Dr Gill, in his own words, that of his scheme every article is wrong. It is not true (say they) that God exacts of man, or ever did exact of him, an obedience absolutely perfect; for under every dispensation man was in a state of discipline, and had habits of virtue and piety to acquire; and it is probable that his progress in piety, virtue, and wisdom, will continue for ever, as none but God is perfect and stationary, and incapable of deviating from the line of rectitude. Most of them, after Bishop Bull, dislike the use of such unscriptural phrases as the *instrument of justification*, applied either to faith or to works; and think, that by considering God as the sole justifier of man, upon certain conditions, they can more precisely ascertain the distinct provinces of faith and obedience in the scheme of justification, than either their brethren of the old school of Arminius, or their rivals of the school of Calvin.

210 Objections of the more zealous Arminians to this statement of the doctrine.

By the very constitution of man, piety and virtue are duties which, if he do not sincerely perform, he must of course forfeit the favour of his Maker; but the most perfect performance of his natural duties would not entitle him to a supernatural and eternal reward. Eternal life is the *gift* of God through Jesus Christ; and it is surely reasonable that we should acknowledge it to be so, and not claim it as a debt due to our merits. The pious and virtuous man has a natural claim to more happiness than misery during the period of his existence, a claim founded on the attributes of that God who called him into being; but he has no natural claim to a future life, and still less to a perpetuity of existence. This is a truth not more clearly taught in the holy scripture than consonant to the soundest philosophy: and yet, by not attending to it, have St Paul and St James been set at variance, and the most opposite doctrines taught respecting the justification of Christians.

211 Their own statement of it.

Because faith in Christ cannot entitle a wicked man to eternal *happiness*, one class of divines seem to infer that such faith is not necessary to Christian *justification*, and that "his faith cannot be wrong whose life is in the right." They proceed upon the supposition that man is naturally immortal; that piety and virtue are entitled to reward; and that therefore the pious and virtuous man whatever be his belief, must undoubtedly inherit an eternal reward. But this is very fallacious reasoning. That piety and virtue are through the divine justice and benevolence entitled to reward, is indeed a truth incontrovertible; but that man who is of yesterday is naturally immortal; that a being who began to exist by the mere good will of his Maker, has in himself a principle of perpetual existence independent of that will—is a direct contradiction. Whatever began to be, can be continued in being only by the power, and according to the pleasure, of the infinite Creator; but it pleased the Creator of his free grace at first to promise mankind eternal life, on the single condition of their first father's observing one positive precept. That precept was violated, and the free gift lost: but the covenant was renewed in Christ, who "by his death hath abolished death, and by his resurrection hath brought to light life and immortality." The condition annexed to the gift thus restored was faith; for "being justified by faith §, we have peace with God through our Lord Jesus Christ; by whom also we have access by faith into his grace wherein we stand, and rejoice in the hope of the GLORY OF GOD." Faith therefore in the Son of God and Saviour of the world, is not only a condition, but the *sole* condition, of that justification which is peculiarly Christian; for since Christ, without any co-operation of ours, hath purchased for us the free gift of eternal life, we shall be guilty of the grossest ingratitude to our Divine Benefactor, and impiously claim an independence on God, if we look upon that gift either as a right inherent in our nature, or as a debt due to our meritorious deeds.

212 Faith the sole condition of the justification peculiarly Christian; § Rom. v. 1, 2.

But though faith be the condition of Christian justification, as that implies the inheritance of *eternal life*, there are other conditions to be performed before a man can be put in possession of *eternal felicity*. By a law long prior to the promulgation of the gospel—a law interwoven with our very being—no man can enjoy the favour of his Maker, who does not make it his constant endeavour "to do justly, to love mercy, and to walk humbly with his God." This law was in force before man fell; it continues to be in force now that he is redeemed; and it will not be abrogated even at that

213 But not of obtaining eternal happiness.

Theology, more peculiarly Christian.

that period when faith shall give place to vision, and hope to enjoyment. By the grace of the Christian covenant, all mankind are rendered immortal in consequence of the death and resurrection of Christ, who is the Lamb slain, in the divine decree, from the foundation of the world; but to obtain immortal *happiness*, they must observe the conditions both of natural and of revealed religion, which are repentance from dead works, and faith in Christ the Redeemer. The former is that condition upon which alone we can retain the Divine favour, and of course enjoy either present or future happiness; the latter is a most equitable acknowledgement required of us, that perpetual conscious existence is neither a right inherent in our nature, nor a debt due to our virtuous obedience, but merely the gift of God through Jesus Christ our Lord.

214 The different conditions of divine favour and of eternal life.

"To make the distinct provinces of faith and works in the business of justification clear, let us suppose (says bishop Warburton †), that, at the publication of the gospel, all to whom the glad tidings of immortality were offered on the condition of *faith in Jesus* had been moral or virtuous men, and on that account entitled (as natural religion teacheth) to the favour of God and an abundant reward; is it not self-evident, that FAITH ALONE, exclusive of the condition of good works, would, in that case, have been the very thing which *justified* or entitled them to life *everlasting*? But are *good works*, therefore, of no use in the Christian system? So far from it, that those only who serve God in sincerity and in truth are capable of the justification which faith alone embraces; for, to illustrate this matter by a familiar instance, suppose a British monarch to bestow, in *free gift*, a certain portion of his own *domains*, to which immortality may well be compared, upon such of his subjects as should perform a certain service to which they were not obliged by the laws of the kingdom; it is evident that the performance of this last service ONLY would be the thing which entitled them to the *free gift*. Yet it is obvious that obedience to the laws, which gave them a claim to protection as subjects, in the enjoyment OF THEIR OWN PROPERTY (to which the reward offered by natural religion may be compared), would be a previous and necessary qualification to their enjoyment of their new possession; since it is absurd to suppose that such a *gift* could be intended for rebels and traitors, or indeed for any but good and faithful servants of their king and country." Well therefore might the apostle reprove the ignorance or licentiousness of certain of his converts at Rome, in his question—"Do we then make void the LAW through FAITH? God forbid! yea, we ESTABLISH THE LAW;" obedience to it being the previous qualification of all who are entitled to the fruits of justifying faith—LIFE AND IMMORTALITY.

† Div. Leg. book ix. chap. 3.

215 Illustrated by a familiar example.

Had proper attention been paid to this distinction, which St Paul everywhere makes between such duties as are common to all religions that are true, and those which are peculiar to the Christian revelation, many useless controversies might have been avoided respecting the instrument of justification and the conditions of the Christian covenant. By not attending to it, the divines of one school, who perceive that the mere belief of any truth whatever cannot entitle a man to eternal felicity, have almost dropt faith from their system of Christianity, and taught moral duties like Pagan philosophers; whilst another party, who err almost as far in their interpretations of scripture, finding eternal life represented as the *gift of God*, and faith in Christ as the instrument or means by which that gift must be accepted, have expunged from their system the necessity of good works, forgetting surely that wicked believers, like believing devils, may be doomed to an eternity of torments. But the sum of Christianity, as we are taught by the beloved disciple, is

216 Sum of Christianity.

comprehended in this one commandment of God, "that we should believe on the name of his Son Jesus Christ, and love one another as he gave us commandment." In perfect harmony with him, the great apostle of the Gentiles, from whose mistaken words much empty noise has been raised about this question, assures us §, that "in Christ Jesus nothing can avail to our eternal happiness but faith which WORKETH BY LOVE;" and he informs Titus ‖, that it "is a true saying, and what he wills to be constantly affirmed, that they who have believed in God be careful to maintain good works."

Theology, more peculiarly Christian.

§ Gal. v. 6.

‖ iii. 8.

Indeed no man can have complete faith in Christ, who believes not the promises of the gospel; but all those promises, except the single one of a resurrection from the dead to perpetual conscious existence, are made to us upon the express condition that we obey the law of the gospel; "for God will render to every man according, to his deeds: to them that are contentious and do not obey the truth, but obey unrighteousness, indignation and wrath; tribulation and anguish upon every soul of man that doth evil, of the Jew first and also of the Gentile; but glory, honour, and peace to every man that worketh good, to the Jew first and also to the Gentile *."

* Rom. ii. 8, 9.

Such are the notions of justification entertained by those who in the present age have been considered as the leaders† of the sect of Arminians. How far they are just, the reader must decide for himself, as our business is little more than to collect into one point of view the scattered opinions of others; but under every view of this doctrine which we have taken, the Christian covenant appears much more gracious than that into which Adam was admitted in paradise; since it affords room for repentance, even to that man, who may be so unhappy as to be withdrawn for a time into apostacy from the terms of the covenant. Whether the death of Christ therefore was a *direct* atonement for the actual sins of men, or only operated as such *indirectly* by procuring for them repeated opportunities of repentance, it is an undoubted truth, that "if through the offence of one many be dead, much more the grace of God, and the gift by grace, which is by one man, Jesus Christ, hath abounded unto many. And not as it was by one that sinned, so is the gift: for the judgment was of one offence to *condemnation*, but the free gift is of many offences to *justification* ‖."

† Warburton and Law, &c.

217 The Christian covenant more gracious than the paradisaical

‖ Rom. v. 16, 17

Thus graciously has the divine goodness displayed itself in the restoration of our lost inheritance. But it stopt not here. The same bountiful Lord of life, for its further security, imparts to every true believer the strength and light of his holy spirit to support faith in working out our own salvation. Our blessed Saviour, "who gave himself for us, that he might redeem us not only from death, but likewise from all iniquity, and purify to himself a peculiar people zealous of good works §," promised, before he left this world, to send to his followers the Holy Ghost or Comforter to abide with them for ever, to guide them into all truth, to bring all things to their remembrance whatsoever he had said unto them, and as we learn from other passages of scripture, to "work in them both to will and to do of his good pleasure." How amply this promise was fulfilled to the apostles, we have already seen; but we are not to suppose that it was restricted to them. As man is designed for a supernatural state in heaven, he stands in need of supernatural direction to guide him to that state. "No man (says our Saviour) can come to me except the Father draw him; for as no man knoweth the things of a man save the spirit of a man which is in him, even so none knoweth the things of God but the Spirit of God." This omniscient Spirit indeed "searcheth all things, yea even the deep things of God," and revealeth them to the sons of men, to enlighten

218 Christians sanctified by the Holy Ghost, who

Theology, more peculiarly Chriſtian.

their underſtandings and purify their hearts. The grace which he ſheds abroad is either external and general, or internal and particular. The former has been extended to the whole church of God under the patriarchal, Moſaic, and Chriſtian diſpenſations, in ſuch a revelation of the divine will as was ſufficient to inſtruct men unto eternal life, whether they had a clear view or not of that ſtupendous plan of redemption, by which the kingdom of heaven was opened to them after the forfeiture of the terreſtrial paradiſe; for there have been "holy prophets ever ſince the world began; and prophecy came not at any time by the will of man, but holy men of God ſpake as they were moved by the Holy Ghoſt*." Hence it is that all ſcripture was given by inſpiration of God to teach us every thing which it is neceſſary for us to know and believe; and the ſcripture is that work of the ſpirit which is extended to the univerſal church.

* Luke i. 70. and 2 Peter i. 21.

But the ſame ſpirit which thus generally reveals the object of faith to the church, does likewiſe particularly illuminate the minds of individual believers, working in them an aſſent to that which is taught them from the written word. It was thus that "the Lord opened the heart of Lydia †, that ſhe attended to the things which were ſpoken of Paul;" it is thus that "the word preached doth not profit if it be not mixed with faith in them who hear it ‡;" and it is thus that "God deals to every man the meaſure of faith;‖" for "by grace are we ſaved through faith, which is not of ourſelves; it is the gift of God §." This illumination of the Spirit was conveyed to the apoſtles "in a ſound from heaven as of a ruſhing mighty wind," becauſe it was meant to teſtify to the world that they were choſen miniſters of the goſpel; but the ordinary Chriſtian receives it "in the ſtill ſmall voice," becauſe it is conveyed to him only to "open his underſtanding that he may underſtand the ſcriptures."

† Acts xvi. 14.

‡ Heb. iv. 2.

‖ Rom. xii. 3.

§ Eph. ii. 8.

219 Regenerates them,

Another operation of the Spirit on the minds of believers is that which in ſcripture is called REGENERATION; for "according to his mercy God ſaveth us by the waſhing of regeneration and renewing of the Holy Ghoſt*, which he ſheds on us abundantly through Jeſus Chriſt our Lord." To thoſe who believe that we derive from Adam a corrupted nature, this particular grace muſt appear ſo abſolutely neceſſary, that without it we could have no reliſh for heaven or heavenly things. "The natural man (we are told) receiveth not the things of the ſpirit of God; for they are fooliſhneſs to him; neither can he know them, becauſe they are ſpiritually diſcerned." Indeed whatever be the powers of our moral faculties, when compared with thoſe of our firſt father, it is ſo long before they be completely developed, that we ſhould infallibly be loſt, if we were not bleſſed by a ſupernatural guide, when reaſon is incapable of directing our conduct. Our paſſions and appetites are in their full ſtrength before experience has furniſhed the mind with materials, by means of which motives may be weighed; and therefore it would be impoſſible during the giddy period of youth, to keep them in due ſubjection, or to prevent vicious habits from being formed, were we not influenced by divine grace. So true is it, that "except a man be born again of water and of the Holy Ghoſt, he cannot enter into the kingdom of God." This change in our diſpoſitions, from an immoderate attachment to earth to a reliſh for the things of heaven, is in ſcripture called "a renewing of our minds, a new creation, a new man;" in oppoſition to our natural diſpoſition, which is called "the old man, corrupted according to the deceitful luſts." The ancient fathers of the church, as well as ſome very eminent modern divines †, generally ſpeak of baptiſm as the inſtrument in God's hand of man's regeneration; and for the truth of their opinion they appeal to John iii. 3, 5, Epheſ. v. 25, 26. and 1 Cor. vi. 11. in which great ſtreſs is certainly laid upon the waſhing of water, as well as upon ſanctification by the word.

* Titus i. 5, 6.

† Clarke and Waterland.

Theology, more peculiarly Chriſtian.

A third office of the Holy Spirit is to lead, direct, and govern us through all the periods of our lives. Without ſuch a leader and guide, the temptations with which we are ſurrounded would certainly overcome us, and we ſhould faint long before we arrive at the end of our journey. By the very conſtitution of our nature we are ſubjected in ſome degree to the influence of ſenſe, of which the objects are preſent, whilſt the enjoyments of heaven are future, and ſeen, as at a diſtance, only by the eye of faith; but "the law of the Spirit of life, in Chriſt Jeſus, hath made us free from the law of ſin and death; for God worketh in us both to will and to do of his good pleaſure; and as many as are thus led by the ſpirit of God, they are the ſons of God; and while they walk in the Spirit, they do not fulfil the luſts of the fleſh." Without the aid of the ſame Spirit, we could not even make our prayers acceptable; for ſince "our confidence in God is, that he heareth us only when we aſk any thing according to his will; and ſince we know not what we ſhould pray for as we ought, the Spirit itſelf maketh the interceſſion for us with groanings which cannot be uttered *."

220 Guides them through life,

* Rom. viii. 26.

A fourth operation of the Holy Ghoſt, as he is the ſanctifier of Chriſtians, is to join them to Chriſt, and make them members of that one body of which he is the head. "For by one Spirit are we all baptized into one body †; and as the body is one and hath many members, and all the members of that one body being many are one body, ſo alſo is Chriſt." "Hereby we know that God abideth in us, by the Spirit which he hath given us;" and as, in the ordinary courſe of his dealings with Chriſtians, this Spirit is firſt given in baptiſm, ſo is it continued to the faithful by the inſtrumentality of the Lord's ſupper. That ordinance we have elſewhere (ſee *SUPPER of the Lord*) proved to be a federal rite; and ſurely no time can be ſuppoſed ſo highly ſanctified for the reception of the graces of the Holy Spirit, as that in which we renew our federal union with our Lord and Maſter in the communion of his body and blood.

† 1 Cor. xii. 12, 13.

221 Unites them to Chriſt,

It is likewiſe the office of the Holy Ghoſt to give us an earneſt of our everlaſting inheritance, to create in us a ſenſe of the paternal love of God, and thereby to aſſure us of the adoption of ſons. "As many as are led by the Spirit of God, they are the SONS of God; and becauſe we are ſons, God hath ſent forth the ſpirit of his Son into our hearts. For we have not received the ſpirit of bondage again to fear; but we have received the Spirit of adoption, whereby we cry Abba Father; the Spirit itſelf bearing witneſs with our ſpirit, that we are the children of God ‡."

‡ Gal. iv. 6. Rom. viii. 15, 16.

As the gifts of grace are generally annexed to means, to the proper uſe of the word and ſacraments, it is a ſixth office of the ſame Spirit to ſanctify ſuch perſons as are regularly ſet apart for the work of the miniſtry, and ordained to offer up the public prayers of the people; to bleſs them in the name of God; to teach the doctrines of the goſpel; to adminiſter the ſacraments inſtituted by Chriſt; and to perform all things neceſſary "for the perfecting of the ſaints, for the work of the miniſtry, for the edifying of the body of Chriſt*." The ſame Spirit which illuminated the apoſtles, and endowed them with power from above to perform perſonally their apoſtolic functions, fitted them alſo for ſending others, as they were ſent by their Divine Maſter; and for eſtabliſhing ſuch a conſtitution of the church as was beſt adapted for preſerving Chriſtians in the unity of the Spirit and bond of peace. They committed a ſtanding power to a ſucceſſive miniſtry to be conveyed down to the end of the world; and thoſe who are veſted with that power are obliged to "take heed unto themſelves, and

222 And ſanctifies the adminiſtrations of the miniſters of the goſpel.

* Eph. iv. 12.

to

Theology more peculiarly Christian.

to all the flock over which the HOLY GHOST hath made them overſeers, to feed the church of God, and to contend earneſtly for the faith which was once delivered unto the ſaints†." See EPISCOPACY, INDEPENDENTS, PRESBYTERIANS, POPE, and QUAKERS.

† Acts xx. 18. and Jude ver. 3.

By theſe, and the like means, doth the Spirit of God ſanctify the ſons of men; and in conſequence of this ſanctification proceeding immediately from his office, he is called the HOLY Spirit and the COMFORTER. This is ſuch a proviſion "for renewing us in the ſpirit of our minds, and enabling us to put on the new man, which, after God, is created in righteouſneſs and true holineſs," as, when made known by revelation appears to have been expedient, may be conceived to have been even neceſſary, and, though reaſon could hardly have hoped for it, is contradicted by none of our natural notions either of God or of man. Many, however, are the controverſies to which it has given riſe in the church of God; ſome contending that it is given only unto the elect, upon whom it operates with reſiſtleſs efficacy; others affirming that it is offered to all, but in ſuch a manner as that, by the abuſe of their free will, it may be "reſiſted, grieved, and quenched;" and ſome few, ſtill intoxicated with the pride of PELAGIUS, think it is not neceſſary, and of courſe is not beſtowed.

223 Controverſies occaſioned by this doctrine.

The queſtions concerning *election*, the *efficacy of grace*, and the final *perſeverance of the ſaints*, we have ſtated elſewhere, and given a ſummary view of the arguments by which the contending parties maintain their reſpective opinions (ſee PREDESTINATION); and the texts of Scripture which we have juſt quoted, under the different heads of ſanctification, ſhow ſufficiently that the opinion of Pelagius is directly contrary to the doctrine of the apoſtles. It may not be improper to inquire whether it be as agreeable to reaſon and experience as its proud patrons ſeem to imagine.

224 Diſcuſſed elſewhere.

If it be unreaſonable to expect any aſſiſtance from the Spirit of God in carrying on the work of our own ſalvation, how came ſo many of the wiſeſt and beſt of men in all ages to believe, that he who ſincerely endeavours to diſcharge his duty is ſupported in that endeavour by aſſiſtance from heaven? That ſuch was the popular belief of the early Greeks, is evident from the poems of Homer; in which we everywhere find ſome god calming the paſſions of the heroes, altering their determinations when improper, and inſpiring them with wiſdom. Nor was this the ſentiment of the poets only. Socrates, it is well known, profeſſed to believe that his own conduct was under the direction of a ſuperior ſpirit, which he called a *demon*; and Plutarch, as we find him quoted by Wollaſton, ſpeaks of the gods aſſiſting men, by "exciting the powers or faculties of the ſoul; by ſuggeſting ſecret principles, imaginations, or thoughts; or, on the contrary, by diverting or ſtopping them." Of the ſame opinion muſt Cicero have been, when he ſaid, "ſtabit illud quidem, quod locum hunc continet, de quo agimus, eſſe Deos, et eorum providentia mundum adminiſtrari, eoſdemque conſulere rebus humanis, nec ſolum *univerſis*, verum etiam SINGULIS*;" for it is not conceivable that a particular providence can be adminiſtered without the influence of the Deity on the minds of men. That the poets and philoſophers of the heathen world derived theſe notions from primeval tradition, cannot, we think, be queſtioned; but if they were abſurd in themſelves, or apparently contradictory to the laws of nature, they would not ſurely have been ſo univerſally embraced; for it will hardly be denied, that Socrates and Cicero were men of as great natural ſagacity as Pelagius or any of his followers. It is indeed ſo far from being incredible that the Father of ſpirits occaſionally directs the thoughts and actions of men, that we believe there are very few who have made obſervations upon themſelves and their own affairs, who have not found, upon reflection, many inſtances in which their uſual judgment and ſenſe of things were *over-ruled*, they know not *how* or *why*; and that the actions which they performed in thoſe circumſtances have had conſequences very remarkable in their general hiſtory. See PROVIDENCE, n° 18, 19.

225 Opinions of the heathens concerning it.

* De Div. lib. 1. ſect. 51.

Theology more peculiarly Chriſtian.

This being the caſe, why ſhould the pride of Chriſtians make them heſitate to admit, upon the authority of divine revelation, what Socrates, and Plutarch, and Cicero, and all the virtuous and wiſe men of antiquity, admitted in effect, upon no better evidence than that of oral tradition, ſupported by their own meditations on their own thoughts, and the principles of their own conduct? Is it that they ſee not ſuch beneficial effects of Chriſtianity as to induce them to believe the profeſſors of that religion to be indeed "choſen to ſalvation through the ſanctification of the Spirit‖?" Let them ſtudy the practical precepts of the goſpel, conſider the conſequences which they have had on the peace and happineſs of ſociety, and compare the general conduct of Chriſtians with that of the Jews, Pagans, and Mahometans (ſee RELIGION), and they will doubtleſs find reaſon to alter their opinion; and let thoſe who embrace the truth, remember, that as they are the temple of God, if the Spirit of God dwell in them, "it is their indiſpenſable duty to cleanſe themſelves from all filthineſs of the fleſh and ſpirit; to follow peace with all men, and holineſs, without which no man ſhall ſee the Lord; and to work out their own ſalvation with fear and trembling, ſince it is God who worketh in them both to will and to do of his good pleaſure."

‖ Theſſ. iv. 3.

226 The goſpel the laſt revelation.

From this ſhort view of the ſeveral diſpenſations of revealed religion, it is evident that the goſpel is not only the beſt but the laſt gift of the kind which man has to expect from his Maker; that the ſcheme of revelation is completed; and that the pretences of Mahomet and of more modern enthuſiaſts to divine inſpiration are not only falſe, but fraught with contradictions. All theſe men admit the divine origin of the Moſaic and Chriſtian religions; but it appears from the ſcriptures, in which thoſe religions are taught, that the ſyſtem of revealed truths which conſtitute the Patriarchal, Moſaic, and Chriſtian revelations, commenced with the fall of man, and that it muſt therefore neceſſarily end with his reſtoration to life and immortality by the ſacrifice of Chriſt upon the croſs. A new revelation therefore like that of Mahomet cannot be admitted without rejecting the whole Bible, though the impoſtor himſelf everywhere acknowledges the inſpiration of Abraham, of Moſes, and of Chriſt. Nor is greater regard due to the claims of Chriſtian enthuſiaſts. Such of theſe men as pretend to have been in heaven†, and thence to have brought ſpiritual diſcoveries to the earth, have either forgotten or never underſtood, that in the ſcriptures of the Old and New Teſtaments the great ſcene of providence appears to be cloſed in the full completion of its one regular, entire, and eternal purpoſe; that St Paul has pronounced ‡ a curſe upon any man or angel from heaven who ſhall preach another goſpel than what has been already preached by the apoſtles and evangeliſts; that in their writings we are taught every thing which it is our duty to believe or to practiſe in order to our own ſalvation; and that we have the promiſe of our bleſſed Lord himſelf, that the Spirit of truth ſhall remain with us to guide us into all neceſſary truth, till that great day when he ſhall come again to judge the world in righteouſneſs, and render to every man according to his works.

† Boehman, Swedenbourgh, and others.

‡ Gal. i. 8.

Theophraſta ‖ Theoſophiſts.

THEOPHRASTA, in botany; a genus of plants belonging to the claſs of *pentandria* and order of *monogynia*. The corolla is campanulated, with diviſions and ſegments obtuſe; the capſule unilocular, globular, very large, and many-ſeeded. There is only one ſpecies, the *americana*.

THEOPHRASTUS, the philoſopher, was born about 371 years before Chriſt, and was ſucceſſively the diſciple of Plato and of Ariſtotle. He ſucceeded Ariſtotle in the Peripatetic ſchool, and conducted the charge with ſuch high reputation that he had about 2000 ſcholars. He is highly celebrated for his induſtry, learning, and eloquence; and for his generoſity and public ſpirit. He is ſaid to have twice freed his country from the oppreſſion of tyrants. He contributed liberally towards defraying the expence attending the public meetings of philoſophers; which were held, not for the ſake of ſhew, but for learned and ingenious converſation. In the public ſchools he commonly appeared, as Ariſtotle had done, in an elegant dreſs, and was very attentive to the graces of elocution. He lived to the advanced age of 85: Some ſay of 107. Towards the cloſe of his life, he grew exceedingly infirm, and was carried to the ſchool on a couch. He expreſſed great regret on account of the ſhortneſs of life; and complained that nature had given long life to ſtags and crows, to whom it is of ſo little value, and had denied it to man, who, in a longer duration, might have been able to attain the ſummit of ſcience; but now, as ſoon as he arrives within ſight of it, is taken away. His laſt advice to his diſciples was, that, ſince it is the lot of man to die as ſoon as he begins to live, they would take more pains to enjoy life as it paſſes, than to acquire poſthumous fame. His funeral was attended by a large body of Athenians. He wrote many valuable works, of which all that remain are, ſeveral treatiſes on the Natural Hiſtory of Plants and Foſſils; Of Winds, Of Fire, &c. a rhetorical work intitled "Characters," and a few Metaphyſical Fragments.

Enfield's Hiſtory of Philoſophy.

To Theophraſtus we are indebted for preſerving the works of Ariſtotle. See ARISTOTLE.

THEOPOMPUS, a celebrated Greek orator and hiſtorian, was born in the iſland of Chios, and flouriſhed in the reign of Alexander the Great. He was one of the moſt famous of all the diſciples of Iſocrates, and won the prize from all the panegyriſts whom Artemiſia invited to praiſe Mauſolus. He wrote ſeveral works, which are loſt.

THEOREM, a propoſition which terminates in theory, and which conſiders the properties of things already made or done; or it is a ſpeculative propoſition deduced from comparing together ſeveral definitions. A theorem is ſomething to be proved, and a problem ſomething to be done.

THEORETIC, ſomething relating to theory, or that terminates in ſpeculation.

THEORY, in general, denotes any doctrine which terminates in ſpeculation, without conſidering the practical uſes or application thereof.

THEOSOPHISTS, a ſect of men who pretend to derive all their knowledge from divine illumination. They boaſt that, by means of this celeſtial light, they are not only admitted to the intimate knowledge of God, and of all divine truth, but have acceſs to the moſt ſublime ſecrets of nature. They aſcribe it to the ſingular manifeſtation of divine benevolence, that they are able to make ſuch a uſe of the element of fire, in the chemical art, as enables them to diſcover the eſſential principles of bodies, and to diſcloſe ſtupendous myſteries in the phyſical world. They even pretend to an acquaintance with thoſe celeſtial beings which form the medium of intercourſe between God and man, and to a power of obtaining from them, by the aid of magic, aſtrology, and other ſimilar arts, various kinds of information and aſſiſtance.

Ibid.

To this claſs belonged Paracelſus, Robert Fludd, Jacob Boehmen, Van Helmont, Peter Poiret, and the Roſicrucians. They are alſo called *FIRE-Philoſophers*, which ſee.

Therapeutæ ‖ Thermometer.

THERAPEUTÆ, a term applied to thoſe that are wholly in the ſervice of religion. This general term has been applied to particular ſects of men, concerning whom there have been great diſputes among the learned.

THERAPEUTICS, that part of medicine which acquaints us with the rules that are to be obſerved, and the medicines to be employed, in the cure of diſeaſes.

THERIACA ANDROMACHI, a compound medicine made in the form of an electuary. See PHARMACY, n° 605.

THERMÆ, hot baths or bagnios. Luxury and extravagance were in nothing carried to ſuch heights as in the thermæ of the Roman emperors. Ammian complains, that they were built to ſuch an extent as to equal whole provinces; from which Valeſius would abate, by reading *piſcinæ* inſtead of *provinciæ*. And yet after all, the remains of ſome ſtill ſtanding are ſufficient teſtimonies for Ammian's cenſure; and the accounts tranſmitted of their ornaments and furniture, ſuch as being laid with precious ſtones (Seneca), ſet round with ſeats of ſolid ſilver (Pliny), with pipes and ciſterns of the ſame metal (Statius), add to, rather than take from, the cenſure. The moſt remarkable bagnios were thoſe of Diocleſian and Caracalla at Rome, great part of which remains at this day; the lofty arches, ſtately pillars, variety of foreign marble, curious vaulting of the roofs, great number of ſpacious apartments, all attract the curioſity of the traveller. They had alſo their ſummer and winter baths.

THERMOMETER, an inſtrument for meaſuring the degree of heat or cold in any body.

1 Invention of the thermometer.

The thermometer was invented about the beginning of the 17th century; but, like many other uſeful inventions, it has been found impoſſible to aſcertain to whom the honour of it belongs. Boerhaave * aſcribes it to Cornelius Drebbel of Alcmar, his own countryman. Fulgenzio † attributes it to his maſter Paul Sarpi, the great oracle of the Venetian republic; and Viviani gives the honour of it to Galilæo §. But all theſe are poſthumous claims. Sanctorio ‡ claims this honour to himſelf; and his aſſertion is corroborated by Borelli § and Malpighi * of the Florentine academy, whoſe partiality is not to be ſuſpected in favour of a member of the Patavinian ſchool.

Martine's Eſſays.
* Chem. I. p. 152, 156,
† Life F. Paul p. 158.
§ Vit. Galil. p. 67.
‡ Corn. in Galen. p. 736—842.
§ De Mot. Animal. II. prop. 175.
* Opera Poſth. p. 30.

Perhaps the beſt way to reconcile theſe different claims would be, to ſuppoſe that the thermometer was really invented by different perſons about the ſame time. We know that there are certain periods in the progreſs of the arts when the ſtream of human genius runs in the ſame direction, and moves towards the ſame object. That part of the current which reaches the object firſt may poſſeſs the title; but the other parts follow ſo rapidly and arrive ſo ſoon after, that it is impoſſible for a ſpectator to decide which is firſt in point of time.

2 The air thermometer deſcribed.

The firſt form of this inſtrument for meaſuring the degrees of heat and cold, was the air thermometer. It is a well known fact that air expands with heat ſo as to occupy more ſpace than it does when cold, and that it is condenſed by cold ſo as to occupy leſs ſpace than when warmed, and that this expanſion and condenſation is greater or leſs according to the degree of heat or cold applied. The principle then on which the air-thermometer was conſtructed is very ſimple. The air was confined in a tube by means of ſome coloured liquor; the liquor roſe or fell according as the air became expanded or condenſed. What the firſt form of the tube was, cannot now perhaps be well known; but the following deſcription of the air-thermometer will fully explain its nature.

The air thermometer conſiſts of a glaſs tube BE, connected Plate DVI. fig. 1.

Thermometer.

nected at one end with a large glaſs ball A, and at the other end immerſed in an open veſſel, or terminating in a ball DE, with a narrow orifice at D; which veſſel, or ball, contains any coloured liquor that will not eaſily freeze. Aquafortis tinged of a fine blue colour with a ſolution of vitriol or copper, or ſpirit of wine tinged with cochineal, will anſwer this purpoſe. But the ball A muſt be firſt moderately warmed, ſo that a part of the air contained in it may be expelled through the orifice D; and then the liquor preſſed by the weight of the atmoſphere will enter the ball DE, and riſe, for example, to the middle of the tube at C, at a mean temperature of the weather; and in this ſtate the liquor by its weight, and the air included in the ball A, &c. by its elaſticity, will counterbalance the weight of the atmoſphere. As the ſurrounding air becomes warmer, the air in the ball and upper part of the tube, expanding by heat, will drive the liquor into the lower ball, and conſequently its ſurface will deſcend; on the contrary, as the ambient air becomes colder, that in the ball is condenſed, and the liquor preſſed by the weight of the atmoſphere will aſcend: ſo that the liquor in the tube will aſcend or deſcend more or leſs according to the ſtate of the air contiguous to the inſtrument. To the tube is affixed a ſcale of the ſame length divided upwards and downwards from the middle C into 100 equal parts, by means of which the aſcent and deſcent of the liquor in the tube, and conſequently the variations in the cold or heat of the atmoſphere, may be obſerved.

3 Its defects.

This inſtrument was extremely defective; for the air in the tube was not only affected by the heat and cold of the atmoſphere, but alſo by its weight.

4 The ſpirit of wine thermometer

The air being found improper for meaſuring with accuracy the variations of heat and cold according to the form of the thermometer which was firſt adopted, another fluid was propoſed about the middle of the 17th century by the Florentine academy. This fluid was ſpirit of wine, or alcohol, as it is now generally named. The alcohol being coloured, was incloſed in a very fine cylindrical glaſs tube previouſly exhauſted of its air, having a hollow ball at one end A, and hermetically ſealed at the other end D. The ball and tube are filled with rectified ſpirit of wine to a convenient height, as to C, when the weather is of a mean temperature, which may be done by inverting the tube into a veſſel of ſtagnant coloured ſpirit, under a receiver of the air pump, or in any other way. When the thermometer is properly filled, the end D is heated red hot by a lamp, and then hermetically ſealed, leaving the included air about $\frac{1}{3}$ of its natural denſity, to prevent the air which is in the ſpirit from dividing it in its expanſion. To the tube is applied a ſcale, divided from the middle, into 100 equal parts, upwards and downwards.

As ſpirit of wine is capable of a very conſiderable degree of rarefaction and condenſation by heat and cold, when the heat of the atmoſphere increaſes the ſpirit dilates, and conſequently riſes in the tube; and when the heat decreaſes, the ſpirit deſcends, and the degree or quantity of the motion is ſhown by a ſcale.

5 Its defects.

The ſpirit of wine thermometer was not ſubject to ſome of the inconveniences which attended the air thermometer. In particular, it was not affected by variations in the weight of the atmoſphere: accordingly it ſoon came into general uſe among philoſophers. It was, at an early period, introduced into Britain by Mr Boyle. To this inſtrument, as then uſed, there are, however, many objections. The liquor was of different degrees of ſtrength, and therefore different tubes filled with it, when expoſed to the ſame degree of heat, would not correſpond. There was alſo another defect: The ſcale which was adjuſted to the thermometer did not commence at any fixed point. The higheſt term was adjuſted to the great ſunſhine heats of Florence, which are too variable and undetermined; and frequently the workman formed the ſcale according to his own fancy. While the thermometer laboured under ſuch diſadvantages it could not be of general uſe.

Martine's Eſſays.

Thermometer.

6 Different fixed points propoſed by philoſophers.

To obtain ſome fixed unalterable point by which a determined ſcale might be diſcovered, to which all thermometers might be accurately adjuſted, was the ſubject which next drew the attention of philoſophers. Mr Boyle, who ſeems at an early period to have ſtudied this ſubject with much anxiety, propoſed the freezing of the eſſential oil of anniſeeds as a convenient point for graduating thermometers; but this opinion he ſoon laid aſide. Dr Halley next propoſed that thermometers ſhould be graduated in a deep pit under ground, where the temperature both in winter and ſummer is pretty uniform; and that the point to which the ſpirit of wine ſhould riſe in ſuch a ſubterraneous place ſhould be the point from which the ſcale ſhould commence. But this propoſal was evidently attended with ſuch inconveniences that it was ſoon abandoned. He made experiments on the boiling point of water, of mercury, and of ſpirit of wine; and he ſeems rather to give a preference to the ſpirit of wine*. He objected to the freezing of water as a fixed point, becauſe he thought that it admitted conſiderable latitude.

* Phil. Tranſ. Abr. II. 34.

7 Sir Iſaac Newton's oil thermometer.

It ſeems to have been reſerved to the all conquering genius of Sir Iſaac Newton to determine this important point, on which the accuracy and value of the thermometer depends. He choſe, as fixed, thoſe points at which water freezes and boils; the very points which the experiments of ſucceeding philoſophers have determined to be the moſt fixed and convenient. Senſible of the diſadvantages of ſpirit of wine, he tried another liquor which was homogeneous enough, capable of a conſiderable rarefaction, about 15 times greater than ſpirit of wine. This was linſeed oil. It has not been obſerved to freeze even in very great colds, and it bears a heat about four times that of water before it boils. With theſe advantages it was made uſe of by Sir Iſaac Newton, who diſcovered by it the comparative degree of heat for boiling water, melting wax, boiling ſpirit of wine, and melting tin; beyond which it does not appear that this thermometer was applied. The method he uſed for adjuſting the ſcale of this oil thermometer was as follows: Suppoſing the bulb, when immerged in thawing ſnow, to contain 10,000 parts, he found the oil expand by the heat of the human body ſo as to take up $\frac{1}{39}$th more ſpace, or 10,256 ſuch parts; and by the heat of water boiling ſtrongly 10,725, and by the heat of melting tin 11,516. So that reckoning the freezing point as a common limit between heat and cold, he began his ſcale there, marking it 0, and the heat of the human body he made 12°; and conſequently, the degrees of heat being proportional to the degrees of rarefaction, or 256: 725 :: 12 : 34, this number 34 will expreſs the heat of boiling water; and by the ſame rule, 72 that of melting tin‡. This thermometer was conſtructed in 1701.

‡ Phil. Tranſ. No. 270. or Abr. vol. iv. part 2.

To the application of oil as a meaſure of heat and cold, there are inſuperable objections. It is ſo viſcid, that it adheres too ſtrongly to the ſides of the tube. On this account it aſcends and deſcends too ſlowly in caſe of a ſudden heat or cold. In a ſudden cold, ſo great a portion remains adhering to the ſides of the tube after the reſt has ſubſided, that the ſurface appears lower than the correſponding temperature of the air requires. An oil thermometer is therefore not a proper meaſure of heat and cold.

8 Its imperfections.

All the thermometers hitherto propoſed were liable to many inconveniences, and could not be conſidered as exact ſtandards for pointing out the various degrees of temperature. This led Reaumur to attempt a new one, an account of which was publiſhed in the year 1730 in the Memoirs

9 Reaumur's ſpirit of wine thermometer.

Thermometer.

moirs of the Academy of Sciences. This thermometer was made with ſpirit of wine. He took a large ball and tube, the dimenſions and capacities of which were known; he then graduated the tube, ſo that the ſpace from one diviſion to another might contain 1000th part of the liquor; the liquor containing 1000 parts when it ſtood at the freezing point. He adjuſted the thermometer to the freezing point by an artificial congelation of water: then putting the ball of his thermometer and part of the tube into boiling water, he obſerved whether it roſe 80 diviſions: if it exceeded theſe, he changed his liquor, and by adding water lowered it, till upon trial it ſhould juſt riſe 80 diviſions; or if the liquor, being too low, fell ſhort of 80 diviſions, he raiſed it by adding rectified ſpirit to it. The liquor thus prepared ſuited his purpoſe, and ſerved for making a thermometer of any ſize, whoſe ſcale would agree with his ſtandard.

Martine's Eſſays on the Conſtruction of Thermometers.

10 Its defects.

This thermometer was far from being perfect. As the bulbs were three or four inches in diameter, the ſurrounding ice would be melted before its temperature could be propagated to the whole ſpirits in the bulb, and conſequently the freezing point would be marked higher than it ſhould be. Dr Martine accordingly found, that inſtead of coinciding with the 32d degree of Fahrenheit, it correſponded with the 34th, or a point a little above it. Reaumur committed a miſtake alſo reſpecting the boiling point; for he thought that the ſpirit of wine, whether weak or ſtrong, when immerged in boiling water, received the ſame degree of heat with the boiling water. But it is well known that highly rectified ſpirit of wine cannot be heated much beyond the 175th degree of Fahrenheit, while boiling water raiſes the quickſilver 37 degrees higher. There is another thermometer that goes by the name of *Reaumur's*, which ſhall be afterwards deſcribed.

11 Mercurial thermometers.

At length a different fluid was propoſed, by which thermometers could be made free from moſt of the defects hitherto mentioned. This fluid was mercury, and ſeems firſt to have occurred to Dr. Halley in the laſt century; but was not adopted by him on account of its having a ſmaller degree of expanſibility than the other fluids uſed at that time*. Boerhaave ſays that the mercurial thermometer was firſt conſtructed by Olaus Roemer; but the honour of this invention is generally given to Fahrenheit of Amſterdam, who preſented an account of it to the Royal Society of London in 1724.

* Phil. Tranſ. vol. xvii. or Abr. vol. ii.

That we may judge the more accurately of the propriety of employing mercury, we will compare its qualities with thoſe of the fluids already mentioned, air, alcohol, and oil. Thermometer.

12 Properties of air, alcohol, and oil.

Air is the moſt expanſible fluid, but it does not receive nor part with its heat ſo quickly as mercury. Alcohol does not expand much by heat. In its ordinary ſtate it does not bear a much greater heat than 175° of Fahrenheit; but when highly rectified it can bear a greater degree of cold than any other liquor hitherto employed as a meaſure of temperature. At Hudſon's Bay, Mr Macnab, by a mixture of vitriolic acid and ſnow, made it to deſcend to 69 below 0 of Fahrenheit. There is an inconvenience, however, attending the uſe of this liquor; it is not poſſible to get it always of the ſame degree of ſtrength. As to oil, its expanſion is about 15 times greater than that of Alcohol; it ſuſtains a heat of 600°, and its freezing point is ſo low that it has not been determined; but its viſcoſity renders it uſeleſs.

13 Thermometrical properties of mercury.

Mercury is far ſuperior to alcohol and oil, and is much more manageable than air. 1. As far as the experiments already made can determine, it is of all the fluids hitherto employed in the conſtruction of thermometers, that which meaſures moſt exactly equal differences of heat by equal differences of its bulk: its dilations are in fact very nearly proportional to the augmentations of heat applied to it (A). 2. Of all liquids it is the moſt eaſily freed from air. 3. It is fitted to meaſure high degrees of heat and cold. It ſuſtains a heat of 600° of Fahrenheit's ſcale, and does not congeal till it fall 39 or 40 degrees below 0. 4. It is the moſt ſenſible of any fluid to heat and cold, even air not excepted. † Sir Benjamin Thompſon, now Count Rumford, found that mercury was heated from the freezing to the boiling point in 58 ſeconds, while water took two minutes 13 ſeconds, and common air 10 minutes and 17 ſeconds. 5. Mercury is a homogeneous fluid, and every portion of it is equally dilated or contracted by equal variations of heat. Any one thermometer made of pure mercury is, *cæteris paribus*, poſſeſſed of the ſame properties with every other thermometer made of pure mercury. Its power of expanſion is indeed about ſix times leſs than that of ſpirit of wine, but it is great enough to anſwer moſt of the purpoſes for which a thermometer is wanted.

Recherches ſur les Mod. de l'Atmoſphere.

† Phil. Tranſ. for 1786.

14 Fixed points.

The fixed points which are now univerſally choſen for adjuſting

---

(A) We have affirmed that the expanſions of the bulk of quickſilver by heat are nearly (for they are not ſtrictly ſo) in a regular arithmetical progreſſion, according to the quantity of heat it is expoſed to; and ſuch ſeems to be the caſe according to the Table publiſhed by Mr de Luc, at page 309 of his firſt volume on the Modifications of the Atmoſphere. The following extract of this table ſhows theſe variations: and the firſt and ſecond differences are added, in order to render theſe irregularities more ſenſible. They are ſuch as can hardly be conceived from the nature of any ſubſtance, without the influence of extraneous and accidental cauſes, which may have eſcaped the attention of the obſerver; neither have they been found exactly true by Dr Crawford. Mr de Luc ſuppoſes the whole heat from melting ice to that of boiling water to be divided into 80 parts; by the fractional ſubdiviſions of which he expreſſes the abſolute quantities of heat, anſwering to each 5, or 10 degrees of Reaumur's thermometer (=22,5 of Fahrenheit's ſcale); ſo that the whole ſum of theſe fractions amounts exactly to the aſſumed number 80. They are as follow:

Cronſtedt's Mineralogy, vol. ii.

	Reaumur's Thermometer.	Fahrenheit's Thermometer.	Quantities of heat.	Firſt differences.	Second differences.

Thermometer.

adjuſting thermometers to a ſcale, and to one another, are the boiling and freezing water points. The boiling water point, it is well known, is not an invariable point, but varies ſome degrees according to the weight and temperature of the atmoſphere. In an exhauſted receiver, water will boil with a heat of 98° or 100°; whereas in Papin's digeſter it will acquire a heat of 412. Hence it appears that water will boil at a lower point, according to its height in the atmoſphere, or to the weight of the column of air which preſſes upon it. In order to enſure uniformity therefore in the conſtruction of thermometers, it is now agreed that the bulb of the tube be plunged in the water when it boils violently, the barometer ſtanding at 30 Engliſh inches (which is its mean height round London), and the temperature of the atmoſphere 55°. A thermometer made in this way, with its boiling point at 212°, is called by Dr. Horſley *Bird's Fahrenheit*, becauſe Mr Bird was the firſt perſon who attended to the ſtate of the barometer in conſtructing thermometers.

15 Rule for adjuſting thermometers to theſe.

As artiſts may be often obliged to adjuſt thermometers under very different preſſures of the atmoſphere, philoſophers have been at pains to diſcover a general rule which might be applied on all occaſions. M. de Luc, in his *Recherches ſur les Mod. de l'Atmoſphere* from a ſeries of experiments, has given an equation for the allowance on account of this difference, in Paris meaſure, which has been verified by Sir George Schuckburgh ‡; alſo Dr Horſley, Dr Maſkelyne, and Sir George Schuckburgh, have adapted the equation and rules to Engliſh meaſures, and have reduced the allowances into tables for the uſe of the artiſt. Dr Horſley's rule, deduced from De Luc's, is this:

‡ Phil. Tranſ. for 1775 and 1778.

$$\frac{99}{8990000}\log. z - 92{\cdot}804 = h.$$

where h denotes the height of a thermometer plunged in boiling water, above the point of melting ice, in degrees of Bird's Fahrenheit, and z the height of the barometer in 10ths of an inch. From this rule he has computed the following table, for finding the heights, to which a good Bird's Fahrenheit will riſe when plunged in boiling water, in all ſtates of the barometer, from 27 to 31 Engliſh inches; which will ſerve, among other uſes, to direct inſtrument-makers in making a true allowance for the effect of the variation of the barometer, if they ſhould be obliged to finiſh a thermometer at a time when the barometer is above or below 30 inches; though it is beſt to fix the boiling point when the barometer is at that height.

16 Table formed from the rule.

Equation of the Boiling Point.

The numbers in the firſt column of this table expreſs heights of the quickſilver in the barometer in Engliſh inches and decimal parts: the ſecond column ſhows the equation to be applied, according to the ſign prefixed, to 212° of Bird's Fahrenheit, to find the true boiling point for every ſuch ſtate of the barometer. The boiling point for all intermediate ſtates of the barometer may be had with ſufficient accuracy, by taking proportional parts, by means of the third column of differences of the equations. See *Phil. Tranſ.* lxiv. art. 30; alſo Dr Maſkelyne's *Paper*, vol. lxiv. art. 20.

Thermometer.

17 Sir George Schuckburgh's obſervations compared with De Luc's rules.

In the following table we have the reſult of 15 different obſervations made by Sir George Schuckburgh compared with the reſult of M. de Luc's rules.

Height of the Barometer reduced to the ſame temperature of 50°	Mean boiling Point by Obſervation.	Boiling Point by De Luc's Rules.	Height of Barometer.	Boiling Point by Obſervation.	Boiling Point by De Luc's Rules.

18 Obſervations made by a committee of the Royal Society for adjuſting the fixed points.

The Royal Society, fully apprized of the importance of adjuſting the fixed points of thermometers, appointed a committee of ſeven gentlemen to conſider of the beſt method for this purpoſe; and their report is publiſhed in the Phil. Tranſ. vol. lxvii. part ii. art. 37.

They obſerved, that though the boiling point be placed ſo much higher on ſome of the thermometers now made than on others, yet this does not produce any conſiderable error in the obſervations of the weather, at leaſt in this climate; for an error of 10°½ in the poſition of the boiling point, will make an error only of half a degree in the poſition of 92°, and of not more than a quarter of a degree in the point of 62°. It is only in nice experiments, or in trying the heat of hot liquors, that this error in the boiling point can be of much importance.

In adjuſting the freezing as well as the boiling point, the quickſilver in the tube ought to be kept of the ſame heat as that in the ball. When the freezing point is placed at a conſiderable diſtance from the ball, the pounded ice ſhould be piled to ſuch a height above the ball, that the error which can ariſe from the quickſilver in the remaining part of the tube not being heated equally with that in the ball, ſhall be very ſmall, or the obſerved point muſt be corrected on that account according to the following table:

Heat

Thermometer.

19 Table for correcting the freezing point.

Heat of the Air.	Correction.
42°	,00087
52	,00174
62	,00261
72	,00348
82	,00435

The correction in this table is expreſſed in 1000th parts of the diſtance between the freezing point and the ſurface of the ice: *e.g.* if the freezing point ſtands ſeven inches above the ſurface of the ice, and the heat of the room is 62, the point of 32° ſhould be placed 7 × 00261, or ,018 of an inch lower than the obſerved point. A diagonal ſcale will facilitate this correction.

20 The quickſilver in the tube ought to be heated to the ſame degree as that in the ball.

The committee obſerve, that in trying the heat of liquors, care ſhould be taken that the quickſilver in the tube of the thermometer be heated to the ſame degree as that in the ball; or if this cannot be done conveniently, the obſerved heat ſhould be corrected on that account; for the manner of doing which, and a table calculated for this purpoſe, we muſt refer to their excellent report in the Phil. Tranſ. vol. lxvii. part ii. art. 37.

21 The tubes ought to be cylindrical and capillary.

With regard to the choice of tubes, they ought to be exactly cylindrical. But though the diameter ſhould vary a little, it is eaſy to manage that matter in the manner propoſed by the Abbé Nollet ‖, by making a ſmall portion of the quickſilver, *e. g.* as much as fills up an inch or half an inch, ſlide backward and forward in the tube; and thus to find the proportions of all its inequalities, and from thence to adjuſt the diviſions to a ſcale of the moſt perfect equality. The capillary tubes are preferable to others, becauſe they require ſmaller bulbs, and they are alſo more ſenſible, and leſs brittle. The moſt convenient ſize for common experiments has the internal diameter about the 40th or 50th of an inch, about 9 inches long, and made of thin glaſs, that the riſe and fall of the mercury may be better ſeen.

‖ Lecons de Phyſ. Exp. tom. iv. p. 376.

22 The number of degrees into which the ſcale ought to be divided.

The next thing to be conſidered, is of what number of degrees or diviſions the ſcale ought to conſiſt, and from what point it ought to commence. As the number of the diviſions of the ſcale is an arbitrary matter, the ſcales which have been employed differ much from one another in this circumſtance. Fahrenheit has made 180 degrees between the freezing and boiling water point. Amonton's made 73, and Sir Iſaac Newton only 34. There is, however, one general maxim, which ought to be obſerved: *That ſuch an arithmetical number ſhould be choſen as can eaſily be divided and ſubdivided, and that the number of diviſions ſhould be ſo great that there ſhall ſeldom be occaſion for fractions.* The number 80 choſen by Reaumur anſwers extremely well in this reſpect, becauſe it can be divided by ſeveral figures without leaving a remainder; but it is too ſmall a number: the conſequence of which is, that the degrees are placed at too great a diſtance from one another, and fractions muſt therefore be often employed. We think, therefore, that 160 would have been a more convenient number. Fahrenheit's number 180 is large enough, but when divided its quotient ſoon becomes an odd number.

23 At what point the ſcale ought to commence.

As to the point at which the ſcale ought to commence, various opinions have been entertained. If we knew the beginning or loweſt degree of heat, all philoſophers would agree, that the loweſt point of the thermometer ought to be fixed there; but we know neither the loweſt nor the higheſt degrees of heat; we obſerve only the intermediate parts. All that we can do, then, is to begin it at ſome invariable point, to which thermometers made in different places may eaſily be adjuſted. If poſſible too, it ought to be a point at which a natural well-known body receives ſome remarkable change from the effects of heat or cold. Fahrenheit began his ſcale at the point at which ſnow and ſalt congeal. Kirwan propoſes the freezing point of mercury. Sir Iſaac Newton, Hales, and Reaumur, adopted the freezing point of water. The objection to Fahrenheit's loweſt point is, that it commences at an artificial cold never known in nature, and to which we cannot refer our feelings, for it is what few can ever experience. There would be ſeveral great advantages gained, we allow, by adopting the freezing point of mercury. It is the loweſt degree of cold to which mercury can be applied as a meaſure; and it would render unneceſſary the uſe of the ſigns plus and minus, and the extenſion of the ſcale below 0. But we object to it, that it is not a point well known; for few, comparatively ſpeaking, who uſe thermometers, can have an opportunity of ſeeing mercury congealed. As to the other advantage to be gained by adopting the freezing point of mercury, namely, the abolition of negative numbers, we do not think it would counterbalance the advantage to be enjoyed by uſing a well-known point. Beſides, it may be aſked, Is there not a propriety in uſing negative numbers to expreſs the degree of cold, which is a negative thing? Heat and cold we can only judge of by our feelings: the point then at which the ſcale ſhould commence, ought to be a point which can form to us a ſtandard of heat and cold; a point familiar to us from being one of the moſt remarkable that occurs in nature, and therefore a point to which we can with moſt clearneſs and preciſion refer to in our minds on all occaſions. This is the freezing point of water choſen by Sir Iſaac Newton, which of all the general changes produced in nature by cold is the moſt remarkable. It is therefore the moſt convenient point for the thermometers to be uſed in the temperate and frigid zones; we may ſay over the globe, for even in the hotteſt countries of the torrid zone many of the mountains are perpetually covered with ſnow.

Thermometer.

24 Only four thermometers generally uſed.

Having now explained the principles of the thermometer as fully as appears neceſſary, in order to make it properly underſtood, we will now ſubjoin an account of thoſe thermometers which are at preſent in moſt general uſe. Theſe are Fahrenheit's, De l'Iſle's, Reaumur's, and Celſius's. Fahrenheit's is uſed in Britain, De l'Iſle's in Ruſſia, Reaumur's in France, and Celſius's in Sweden. They are all mercurial thermometers.

25 Fahrenheit's deſcribed.

Fahrenheit's thermometer conſiſts of a ſlender cylindrical tube and a ſmall longitudinal bulb. To the ſide of the tube is annexed a ſcale which Fahrenheit divided into 600 parts, beginning with that of the ſevere cold which he had obſerved in Iceland in 1709, or that produced by ſurrounding the bulb of the thermometer with a mixture of ſnow or beaten ice and ſal ammoniac or ſea ſalt. This he apprehended to be the greateſt degree of cold, and accordingly he marked it, as the beginning of his ſcale, with 0; the point at which mercury begins to boil, he conceived to ſhow the greateſt degree of heat, and this he made the limit of his ſcale. The diſtance between theſe two points he divided into 600 equal parts or degrees; and by trials, he found that the mercury ſtood at 32 of theſe diviſions, when water juſt begins to freeze, or ſnow or ice juſt begins to thaw; it was therefore called the degree of the freezing point. When the tube was immerſed in boiling water, the mercury roſe to 212, which therefore is the boiling point, and is juſt 180 degrees above the former or freezing point. But the preſent method of making the ſcale of theſe thermometers, which is the ſort in moſt common uſe, is firſt to immerge the bulb of the thermometer in ice or

ſnow

Thermometer.

ſnow juſt beginning to thaw, and mark the place where the mercury ſtands with a 32; then immerge it in boiling water, and again mark the place where the mercury ſtands in the tube, which mark with the num. 212, exceeding the former by 180; dividing therefore the intermediate ſpace into 180 equal parts, will give the ſcale of the thermometer, and which may afterwards be continued upwards and downwards at pleaſure.

Other thermometers of a ſimilar conſtruction have been accommodated to common uſe, having but a portion of the above ſcale. They have been made of a ſmall ſize and portable form, and adapted with appendages to particular purpoſes; and the tube with its annexed ſcale has often been encloſed in another thicker glaſs tube, alſo hermetically ſealed, to preſerve the thermometer from injury. And all theſe are called *Fahrenheit's thermometers*.

26 De l'Iſle's thermometer. Plate DVII.

In 1733, M. De l'Iſle of Peterſburgh conſtructed a mercurial thermometer on the principles of Reaumur's ſpirit thermometer. In his thermometer, the whole bulk of quickſilver, when immerged in boiling water, is conceived to be divided into 100,000 parts; and from this one fixed point the various degrees of heat, either above or below it, are marked in theſe parts on the tube or ſcale, by the various expanſion or contraction of the quickſilver, in all imaginable varieties of heat. Dr Martine apprehends it would have been better if De l'Iſle had made the integer 100,000 parts, or fixed point, at freezing water, and from thence computed the dilatations or condenſations of the quickſilver in thoſe parts; as all the common obſervations of the weather, &c. would have been expreſſed by numbers increaſing as the heat increaſed, inſtead of decreaſing, or counting the contrary way. However, in practice it will not be very eaſy to determine exactly all the diviſions from the alteration of the bulk of the contained fluid. And beſides, as glaſs itſelf is dilated by heat, though in a leſs proportion than quickſilver, it is only the exceſs of the dilatation of the contained fluid above that of the glaſs that is obſerved; and therefore if different kinds of glaſs be differently affected by a given degree of heat, this will make a ſeeming difference in the dilatations of the quickſilver in the thermometers conſtructed in the Newtonian method, either by Reaumur's rules or De l'Iſle's. Accordingly it has been found, that the quickſilver in De l'Iſle's thermometers has ſtood at different degrees of the ſcale when immerged in thawing ſnow: having ſtood in ſome at 154°, while in others it has been at 156° or even 158°.

27 Reaumur's, or rather De Luc's thermometer.

The thermometer preſently uſed in France is called *Reaumur's*; but it is very different from the one originally invented by Reaumur in 1730, and deſcribed in the Memoirs of the Academy of Sciences. The one invented by Reaumur was filled with ſpirit of wine; and tho' its ſcale was divided by the author into 80 parts, of which 0 was the freezing point and 80 the boiling water point, yet in fact 80 was only the boiling point of the ſpirit of wine that he employed, which, as Dr Martine computes, correſponded with 180 of Fahrenheit. But the thermometer now in uſe in France is filled with mercury; and the boiling water point which is at 80, correſponds with the 212th degree of Fahrenheit. The ſcale indeed commences at the freezing point, as the old one did. The new thermometer ought more properly to be called *De Luc's thermometer*, for it was firſt made by De Luc; and is in fact as different from Reaumur's as it is from Sir Iſaac Newton's. When De Luc had fixed the ſcale, and finiſhed an account of it, he ſhowed the manuſcript to M. De la Condamine. Condamine adviſed him to change the number 80; remarking, that ſuch was the inattention of phyſicians, that they would probably confound it with Reaumur's. De Luc's modeſty, as well as a predeliction for the number 80, founded as he thought, on philoſophical reaſons, made him decline following this advice. But he found by experience that the prediction of Condamine was too well founded.

Thermometer.

28 Celſius's thermometer.

The thermometer of Celſius, which is uſed in Sweden, has a ſcale of 100 degrees from the freezing to the boiling water point.

29 How to compare theſe together.

Theſe are the principal thermometers now uſed in Europe; and the temperatures indicated by any of them may be reduced into the correſponding degrees on any of the others by means of the following ſimple canons; in which R ſignifies the degrees on the ſcale of Reaumur, F thoſe of Fahrenheit, and S thoſe of the Swediſh thermometer.

1. To convert the degrees of Reaumur into thoſe of Fahrenheit; $\frac{R \times 9}{4} + 32 = F$.

2. To convert the degrees of Fahrenheit into thoſe of Reaumur; $\frac{F - 32 \times 4}{9} = R$.

3. To convert the Swediſh degrees into thoſe of Fahrenheit; $\frac{S \times 9}{5} + 32 = F$.

Lavoiſier's Elements of Chemiſtry.

4. To convert Fahrenheit's into Swediſh; $\frac{F - 32 \times 5}{9} = S$.

5. To convert Swediſh degrees into thoſe of Reaumur; $\frac{S \times 4}{5} = R$.

6. To convert Reaumur's degrees into Swediſh; $\frac{R \times 5}{4} = S$.

To ſuch readers as are unacquainted with the algebraic expreſſion of arithmetical formulæ, it will be ſufficient to expreſs one or two of theſe in words to explain their uſe.—1. Multiply the degree of Reaumur by 9, divide the product by 4, and to the quotient add 32, the ſum expreſſes the degree on the ſcale of Fahrenheit.—2. From the degree of Fahrenheit ſubtract 32, multiply the remainder by 4, and divide the product by 9, the quotient is the degree according to the ſcale of Reaumur, &c.

As many other thermometers have been uſed beſides theſe, and conſequently obſervations taken by them, it is of importance to have them placed in ſuch a point of view that they may be eaſily compared with any of theſe four now in general uſe. We therefore give them in Plate DVII. in the ſame order as they were arranged by Dr Martine in his valuable Eſſay on the Conſtruction and Graduation of Thermometers, and at the ſame time adding thoſe of Celſius and De Luc. We call it by the name of De Luc for the ſake of diſtinguiſhing it from Reaumur's ſpirit of wine thermometer, which may be ſeen in the ſame Plate.

It is unneceſſary to deſcribe any of theſe more minutely, as they are no longer uſed. Thoſe who wiſh to read a more particular account of them may conſult Dr Martine's Eſſays.

30 Account of ſelf-regiſtering thermometers.

As in meteorological obſervations it is neceſſary to attend to the greateſt riſe and fall of the thermometer, attempts have been made to conſtruct a thermometer which might regiſter the greateſt degree of heat, or greateſt degree of cold, which took place during the abſence of the obſerver. In 1757 Lord Charles Cavendiſh preſented to the Royal Society of London a thermometer in two different forms; the one contrived to mark the greateſt degree of heat, and the other the greateſt degree of cold.

31 Lord Charles Cavendiſh's thermometer. Plate DVI. Fig. 3.

The firſt conſiſts of a glaſs tube A B, with a cylindrical bulb B at the lower end, and capillary at the top, over which there is fixed a glaſs ball C. The bulb and part of the tube are filled with mercury, the top of which ſhows the

Thermometer.

degrees of heat as uſual. The upper part of the tube above the mercury is filled with ſpirit of wine; the ball C is alſo filled with the ſame liquor almoſt to the top of the capillary tube. When the mercury riſes the ſpirit of wine is alſo raiſed, and falls into the ball C, which is ſo made that the liquor cannot return into the tube when the mercury ſinks; conſequently the height of the ſpirit of wine in the ball, added to that in the tube, will give the greateſt degree of heat to which the thermometer has pointed ſince laſt obſervation. When a new obſervation is to be made, the inſtrument muſt be inclined till the liquor in the ball cover the end of the capillary tube.

In this thermometer it is evident that the mercury muſt be affected by the weight and elaſticity of the ſpirit of wine, and therefore it will not correſpond to any of the common mercurial thermometers.

The thermometer for ſhowing the greateſt degree of cold is repreſented in fig. 4. by the crooked tube ABCD. This inſtrument is filled with ſpirit of wine, with the addition of as much mercury as is ſufficient to fill both legs of the ſyphon, and about a fourth or fifth part of the hollow ball C. We are not told what the proportion of mercury was to that of ſpirit of wine. The degrees of heat are ſhown by the riſe or fall of the mercury in the leg AB. The thermometer marks the greateſt fall by means of the hollow ball C. When the mercury in the longer leg ſinks by cold, that in the ſhorter will riſe and run over into the ball C, from which it cannot return when the mercury ſubſides in the ſhorter and riſes in the longer leg. The upper part of the ſhorter leg will therefore be filled with a column of ſpirits of a length proportional to the increaſe of heat; the bottom or lower ſurface of which, by means of a proper ſcale, will ſhow how much the mercury has been lower than it is; which being ſubtracted from the preſent height will give the loweſt point to which the mercury has fallen. That the thermometer may be fitted for a new obſervation, the mercury muſt be made to run back from the ball into the ſhorter leg, by inclining the tube and heating the ball.

32 Mr Six's thermometer. Fig. 5.

In 1782 Mr Six propoſed another ſelf-regiſtering thermometer. It is properly a ſpirit of wine thermometer, though mercury is alſo employed for ſupporting an index. *a b* is a thin tube of glaſs 16 inches long, and $\frac{5}{10}$ths of an inch caliber: *c d e* and *f g h* are ſmaller tubes about $\frac{1}{10}$th of an inch caliber. Theſe three tubes are filled with highly rectified ſpirit of wine, except the ſpace between *d* and *g*, which is filled with mercury. As the ſpirit of wine contracts or expands in the middle tube, the mercury falls or riſes in the outſide tubes. An index, ſuch as that repreſented in fig. 6. is placed on the ſurface, within each of theſe tubes, ſo light as to float upon it. *k* is a ſmall glaſs tube $\frac{1}{4}$ths of an inch long, hermetically ſealed at each end, and incloſing a piece of ſteel wire nearly of its own length. At each end *l*, *m*, of this ſmall tube, a ſhort tube of black glaſs is fixed, of ſuch a diameter as to paſs freely up and down within either of the outſide tubes of the thermometer *c e* or *f h*. From the upper end of the index is drawn a ſpring of glaſs to the fineneſs of a hair, and about $\frac{4}{5}$ths of an inch long; which being placed a little oblique, preſſes lightly againſt the inner ſurface of the tube, and prevents the index from deſcending when the mercury deſcends. Theſe indexes being inſerted one into each of the outſide tubes, it is eaſy to underſtand how they point out the greateſt heat or cold that has happened in the obſerver's abſence. When the ſpirit of wine in the middle tube expands, it preſſes down the mercury in the tube *h f*, and conſequently raiſes it in the tube *e c*; conſequently the index on the left hand tube is left behind and marks the greateſt cold, and the index in the right hand tube riſes and marks the greateſt heat.

Thermometer.

33 Rutherford's thermometer.

In 1790 a paper was given into the Royal Society of Edinburgh, deſcribing two thermometers, newly invented, by Dr John Rutherford of Middle Bailiſh; the one for regiſtering the higheſt and the other for regiſtering the loweſt degree of heat to which the thermometer has riſen or fallen during the abſence of the obſerver. An account of them may be found in the third volume of the Tranſactions of the Society.

34 Mr Keith's thermometer.

A new ſelf-regiſtering thermometer has more lately been invented by Mr Keith of Ravelſtone, which we conſider as the moſt ingenious, ſimple, and perfect, of any which has hitherto appeared. Its ſimplicity is ſo great, that it requires only a very ſhort deſcription to make it intelligible.

Fig. 7.

A B is a thin glaſs tube about 14 inches long and $\frac{3}{4}$ths of an inch caliber, cloſe or hermetically ſealed at top. To the lower end, which is open, there is joined the crooked glaſs tube BE, ſeven inches long, and $\frac{4}{10}$ths of an inch caliber, and open at top. The tube A B is filled with the ſtrongeſt ſpirit of wine, and the tube B E with mercury. This is properly a ſpirit of wine thermometer, and the mercury is uſed merely to ſupport a piece of ivory or glaſs, to which is affixed a wire for raiſing one index or depreſſing another, according as the mercury riſes or falls. E is a ſmall conical piece of ivory or glaſs, of ſuch a weight as to float on the ſurface of the mercury. To the float is joined a wire called the *float-wire*, which reaches upwards to H, where it terminates in a knee bent at right angles. The float-wire, by means of an eye at *a*, moves eaſily along the ſmall harpſichord wire G K. LL are two indexes made of thin black oiled ſilk, which ſlide upwards or downwards with a force not more than two grains. The one placed above the knee points out the greateſt riſe, and the one placed below it points out the greateſt fall, of the thermometer.

When the inſtrument is to be prepared for an obſervation, both indexes are to be brought cloſe to the knee H. It is evident, that when the mercury riſes, the float and float wire, which can be moved with the ſmalleſt force, will be puſhed upwards till the mercury become ſtationary. As the knee of the float-wire moves upwards it will carry along with it the upper index L. When the mercury again ſubſides, it leaves the index at the higheſt point to which it was raiſed, for it will not deſcend by its own weight: As the mercury falls the float-wire does the ſame; it therefore brings along with it the lower index L, and continues to depreſs it till it again become ſtationary or aſcend in the tube; in which caſe it leaves the lower index behind it as it had formerly left the upper. The ſcale to which the indexes point is placed parallel to the ſlender harpſichord wire. It may be ſeen more diſtinctly in fig. 8. That the ſcale and indexes may not be injured by the wind and rain, a cylindrical glaſs cover, cloſe at top, and made ſo as to exactly fit the part F G, is placed over it.

The ingenious inventor has another improvement in contemplation, which, if upon trial it be found to anſwer, will make this thermometer as perfect as can be deſired, provided there do not ariſe ſome errors from the variable preſſure of the atmoſphere. He propoſes to adapt clock-work to this thermometer, in ſuch a way as to regiſter with the utmoſt preciſion the degrees of heat and cold for every month, day, and minute in the year. The principles on which this clock-work is to be formed we ſhall forbear to deſcribe, hoping that the author himſelf, after his experiment has met with the ſucceſs which we ardently wiſh, will favour the world with his own account of it.

Thermometer.

The ſame ingenious gentleman has invented a ſelf-regiſtering barometer, upon the ſame principles with his ſelf-regiſtering thermometer. We have had the pleaſure of ſeeing both; and are convinced that they will fully gratify the wiſhes of all who are engaged in meteorological ſtudies. He is alſo in expectation of being ſoon able to produce an air-thermometer free from the defects of thoſe which were formerly made, as he has found out a way of preventing it from being affected by the preſſure of the atmoſphere.

35 M. De Luc's ſuppoſed improvements.

M. De Luc has deſcribed the beſt method of conſtructing a thermometer, fit for determining the temperature of the air, in the menſuration of heights by the barometer. He has alſo ſhown how to divide the ſcale of a thermometer, ſo as to adapt it for aſtronomical purpoſes in the obſervation of refractions.

36 Mr Cavallo has propoſed a thermometrical barometer.

Mr Cavallo, in 1781, propoſed the conſtruction of a thermometrical barometer, which by means of boiling water, might indicate the various gravity of the atmoſphere, or the height of the barometer. But as he does not ſay that the inſtrument has been tried with the deſired ſucceſs, we forbear to deſcribe it. Thoſe who wiſh to know his ideas reſpecting it may conſult the Philoſophical Tranſactions vol. lxxi. page 524.

37 The thermometers deſcribed above too limited.

The thermometers hitherto deſcribed are very limited in their extent; they indeed point out to us the loweſt degrees of heat which are commonly obſerved even in cold climates, but they by no means reach to thoſe degrees of heat which are very familiar to us. The mercurial thermometer extends no farther than to 600 of Fahrenheit's ſcale, the heat of boiling mercury; but we are ſure that the heat of ſolid bodies, when heated to ignition, or till they emit light, far exceeds the heat of boiling mercury.

38 Sir Iſaac Newton's method of extending the ſcale of the thermometer.

In order to remedy this defect, Sir Iſaac Newton, whoſe genius overcame thoſe obſtacles which ordinary minds could not approach, attempted by an ingenious experiment to extend the ſcale to any degree required. Having heated a maſs of iron red-hot, and expoſed it to the cold air, he obſerved the time which elapſed till it became cold, or of the ſame temperature with the air; and when the heat ſo far decreaſed that he could apply ſome known meaſure (as a thermometer) to it, he obſerved the degrees of heat loſt in given times; and thence drew the general concluſion, that the quantities of heat loſt in given ſmall ſpaces are always proportional to the heat remaining in the body, reckoning the heat to be the exceſs by which it is warmer than the ambient air. So that taking the number of minutes which it took to cool after it came to a determined point in an arithmetical progreſſion, the decrements of the heat of the iron would be continually proportional. Having by this proportion found out the decrements of heat in a given time after it came to a known point, it was eaſy, by carrying upwards the ſame proportion to the beginning of its cooling, to determine the greateſt heat which the body had acquired. This proportion of Sir Iſaac's was found by Dr Martine to be ſomewhat inaccurate. The heat of a cooling body does not decreaſe exactly in proportion to that which the body retains. As the reſult of many obſervations, he found that two kinds of proportion took place, an arithmetical as well as the geometrical proportion which Sir Iſaac Newton had adopted; namely, that the decrements of heat were partly proportional to the times (that is, that quantities of heat are loſt in equal times), as well as partly in proportion to the remaining heat; and that if theſe two are added together the rule will be ſufficiently accurate. By the geometrical proportion which Sir Iſaac Newton adopted he diſcovered the heat of metals red-hot or in fuſion.

Martine's Eſſays.

This method, ſo ſucceſsfully purſued by Sir Iſaac, was ſufficient to form a ſcale of high degrees of heat, but was not convenient for practical purpoſes. Accordingly the ingenious Mr Joſiah Wedgwood, who is well known for his great improvement in the art of pottery, applied himſelf in order to diſcover a thermometer which might be eaſily managed. After many experiments recorded in the Philoſophical Tranſactions, but which it is unneceſſary to detail in this place, he has invented a thermometer which marks with much preciſion the different degrees of ignition from a dull red heat viſible in the dark to the heat of an air-furnace. This thermometer is extremely ſimple. It conſiſts of two rulers fixed upon a ſmooth flat plate, a little farther aſunder at the one end than at the other, leaving an open longitudinal ſpace between them. Small pieces of alum and clay mixed together are made of ſuch a ſize as juſt to enter at the wide end; they are then heated in the fire along with the body whoſe heat we wiſh to determine. The fire, according to the degree of heat it contains, diminiſhes or contracts the earthy body, ſo that when applied to the wide end of the gage, it will ſlide on towards the narrow end, leſs or more according to the degree of heat to which it has been expoſed.

Thermometer.

39 Mr Wedgwood's thermometer for meaſuring high degrees of heat.

40 Deſcribed.

That this inſtrument may be perfectly underſtood, we have given a repreſentation of it in Plate DVI. fig. 9. ABCD is a ſmooth flat plate; and EF and GH two rulers or flat pieces, a quarter of an inch thick, fixed flat upon the plate, with the ſides that are towards one another made perfectly true, a little farther aſunder at one end EG than at the other end FH: thus they include between them a long converging canal, which is divided on one ſide into a number of ſmall equal parts, and which may be conſidered as performing the offices both of the tube and ſcale of the common thermometer. It is obvious, that if a body, ſo adjuſted as to fit exactly at the wider end of this canal, be afterwards diminiſhed in its bulk by fire, as the thermometer pieces are, it will then paſs further in the canal, and more and more ſo according as the diminution is greater; and converſely, that if a body, ſo adjuſted as to paſs on to the narrow end, be afterwards expanded by fire, as is the caſe with metals, and applied in that expanded ſtate to the ſcale, it will not paſs ſo far; and that the diviſions on the ſide will be the meaſures of the expanſions of the one, as of the contractions of the other, reckoning in both caſes from that point to which the body was adjuſted at firſt.

Philoſophical tranſactions, vol. lxxiv.

I is the body whoſe alteration of bulk is thus to be meaſured. This is to be gently puſhed or ſlid along towards the end FH, till it is ſtopped by the converging ſides of the canal.

41 Thermometer pieces of what compoſed.

Mr Wedgwood at firſt uſed clay for his thermometer pieces; but he ſoon found it impoſſible to procure freſh ſupplies of the ſame quality. He therefore had recourſe to an artificial preparation. As the earth of alum is the pure argillaceous earth to which all clays owe their property of diminiſhing in the fire, he mixed ſome of this earth with the clay, and found it to anſwer his wiſhes completely, both in procuring the neceſſary degree of diminution and of increaſing its unvitreſcibility. The only way of aſcertaining the proportion of alum earth to be added is by repeated trials. Mr Wedgwood found that 10 hundred weight of the porcelain clay of Cornwall required all the earth that was afforded by five hundred weight of alum. But as the clay or alum differs in quality, the proportion will alſo differ. There can now, however, be no difficulty in making thermometers of this kind, as common clay anſwers the purpoſe very well, and alum-earth can eaſily be procured. Thoſe who wiſh to ſee a more particular account of this ſubject may peruſe Mr Wedgwood's

Thermometer.

papers in the Philoſophical Tranſactions for 1782, 1784, and 1786.

As Mr Wedgwood's thermometer begins at the loweſt degree of ignition, and Fahrenheit's goes no higher than the boiling point of mercury, Mr Wedgwood continued to fill up the interval of the ſcale by uſing a piece of ſilver inſtead of his common thermometer pieces; and in this way he has found out that 130 degrees of Fahrenheit are equal to one of his. He has accordingly, by obſerving this proportion, continued Fahrenheit's ſcale to the top of his own. We are now therefore enabled to give a ſcale of heat from the higheſt degree of heat produced by an air-furnace to the greateſt degree of cold hitherto known, which was produced at Hudſon's Bay in December 1784 by a mixture of vitriolic acid and ſnow. Of the remarkable degrees between theſe extreme points we ſhall now lay before our readers a ſcale.

42 Scale of heat.

	Fahrenheit's ſcale.	Wedgwood's ſcale.
Extremity of Wedgwood's ſcale	32277°	240°
Greateſt heat of his ſmall air-furnace	21877	160

Thermopylæ Theſeus.

THERMOPYLÆ, (anc. geog.); a narrow paſs or defile, between the waſh of the Sinus Maliacus; on the eaſt, and ſteep mountains, reaching to Oeta, made dreadful by unpaſſable woods; on the weſt, leading from Theſſaly to Locris and Bœotia. Theſe mountains divide Greece in the middle, in the ſame manner as the Appennine does Italy; forming one continued ridge from Leucate on the weſt to the ſea on the eaſt, with thickets and rocks interſperſed; that perſons even prepared for travelling, much leſs an army encumbered with baggage, cannot eaſily find a commodious paſſage. In the valley verging towards the Sinus Maliacus, the road is only ſixty paces broad; the only military way for an army to paſs, if not obſtructed by an enemy; and therefore the place is called *Pylæ*, and by others, on account of its hot water, *Thermopylæ*. Ennobled by the brave ſtand made by Leonidas and three hundred Spartans againſt the whole army of Perſia; and by the bold reſolution of blind Euthycus, chooſing rather to fall there in fight, than return to Sparta and eſcape the common danger. Famous alſo for the Amphyctiones, the common council or ſtates general of Greece, aſſembling there twice a year, ſpring and autumn. For an account of the battle of Thermopylæ at which Leonidas with a handful of men engaged the Perſian army, ſee SPARTA.

THESEA, in antiquity, feaſts celebrated by the Athenians in honour of Theſeus, conſiſting of ſports and games, with mirth and banquets; ſuch as were poor and unable to contribute to them were entertained at the public expenſe.

THESEUS, a famous hero of antiquity, ranked among the demi-gods, whoſe hiſtory is fabulous. He was the reputed ſon of Ægeus king of Athens. He threw Sciron, a cruel robber, down a precipice; faſtened Procruſtes tyrant of Attica to a bending pine, which being let looſe tore him aſunder; killed the Minotaur kept in the Labyrinth by king Minos, in Crete; and by the aſſiſtance of that prince's daughter, Ariadne, who gave him a clue, eſcaped out of that labyrinth, and ſailed with his deliverer to the iſle of Naxos, where he had the ingratitude to leave her.

Theſeus afterwards overcame the Centaurs, ſubdued the Thebans, and defeated the Amazons. He aſſiſted his friend Pirithous in his expedition to the infernal regions to carry off Proſerpine; but was impriſoned by Pluto, till he was releaſed by Hercules. He is alſo ſaid to have eſtabliſhed the Iſthmean games, in honour of Neptune; to have united the twelve cities of Attica; and to have founded a republic there, 1236 B. C. Some time after, taking a voyage into Epirus, he was ſeized by Aidonius king of the Moloſſians; meanwhile Meneſtheus rendered himſelf maſter of Athens. But at length Theſeus being releaſed from priſon, retired to Scyros, where king Lycomedes cauſed him to be thrown from the top of a rock. Theſeus had ſeveral wives; the firſt of whom was Helena the daughter of Tyndarus; the ſecond Hypolita queen of the Amazons; and the laſt, Phedra ſiſter to Ariadne, who puniſhed him for

Theſis ‖ Thetis.

for his infidelity to her ſiſter, by her inceſtuous paſſion for his ſon Hippolitus.

THESIS, a general poſition which a perſon advances, and offers to maintain. In taking degrees in univerſities, the candidates are generally obliged to write a theſis, which they muſt afterwards defend.

THESIUM, BASE FLUELLIN, in botany; a genus of plants belonging to the claſs of *pentandria*, and order of *monogynia*. The calyx is monophyllous, with the ſtamina inſerted into it: there is only one ſeed, which is inferior. There are 17 ſpecies; one of which is a Britiſh plant, the *linophyllum* or baſtard toad-flax. It has a foliaceous panicle with linear leaves, and flowers in June and July.

THESPIS, a famous Greek tragic poet, and the firſt repreſenter of tragedy at Athens. He carried his troop from village to village in a waggon, from which they performed their pieces. Alceſtis was the firſt tragedy they performed at Athens, 536 B. C. See THEATRE.

THESSALIAN Chair, ſo called from Theſſaly, where chairs of this figure were moſt in uſe; it is recommended by Hippocrates * in place of a machine for reducing a recent luxation of the ſhoulder bone. The back of this chair is perpendicular to the ſeat, as Galen tells us; by which conſtruction it is diſtinguiſhed and accommodated to the operation.

* Lib. de Art.

THESSALY, a country of Greece, whoſe boundaries have been different at different periods. Properly ſpeaking, Theſſaly was bounded on the ſouth by the ſouthern parts of Greece or Græcia Propria; eaſt by the Ægean; north, by Macedonia and Mygdonia; and weſt, by Illyricum and Epirus. It was generally divided into four ſeparate provinces, Theſſaliotis, Pelaſgiotis, Iſtiæotis, and Phthiotis, to which ſome add Magneſia. It has been ſeverally called *Æmonia*, *Pelaſgicum*, *Argos*, *Hellas*, *Argeia*, *Dryopis*, *Pelaſgia*, *Pyrrhæa*, &c. The name of Theſſaly is derived from Theſſalus, one of its monarchs. Theſſaly is famous for a deluge which happened there in the age of Deucalion. Its mountains and cities are alſo celebrated, ſuch as Olympus, Pelion, Oſſa, Lariſſa, &c. The Argonauts were partly natives of Theſſaly. The inhabitants of the country paſſed for a treacherous nation, ſo that falſe money was called *Theſſalian coin*, and a perfidious action a *Theſſalian deceit*. Theſſaly was originally governed by kings, till it became ſubject to the Macedonian monarchs. The cavalry was univerſally eſteemed, and the people were ſuperſtitious and addicted to the ſtudy of magic and incantations. See *Lucan.* 6. v. 438, &c.; *Dionyſ.* 219; *Curt.* 3. c. 2; *Ælian*, *V. H.* 2. c. 1.; *Pauſ.* 4. c. 36. l. 10. c. 1; *Mela.* 2. c. 3; *Juſtin* 7. c. 6; *Diod.* 4.

Lempriere's Dictionary.

Theſſaly is now called *Janna*, a province of European Turkey, bounded by Macedonia on the north, by the Archipelago on the eaſt, by Achaia or Livadia on the ſouth, and by Epirus on the weſt.

THETIS, in Pagan mythology, the wife of Oceanus, and the mother of Nereus and Doris, who were married to each other; and from this marriage ſprung the nymphs of the earth and ſea. Among the ſea nymphs there was one named *Thetis the Younger*, who excelled all the reſt in beauty, and for whom Jupiter conceived ſuch a paſſion, that he reſolved to eſpouſe her; but being informed by the Deſtinies that ſhe would bring forth a ſon who would riſe above his father, he married her to Peleus. To their nuptials all the gods and goddeſſes were invited except Diſcord, who, to be revenged for this contempt threw a golden apple into the aſſembly, on which was engraven, *For the Faireſt*. Juno, Pallas, and Venus, diſputed for this apple; but Paris being choſen to decide the difference, adjudged it to Venus. From this marriage of Thetis and Peleus ſprung Achilles.

Theurgy. ‖ Thiſtle.

THEURGY, Θεουργία, a name which the ancients gave to that ſacred part of magic which we ſometimes call *white magic*, or the *white art*.

The word is formed from Θεος, "God," and ἐργον "work;" *q. d.* the art of doing divine things, or things which God alone can do; or the power of working extraordinary and ſupernatural things, by invoking the names of God, ſaints, angels, &c. Accordingly thoſe who have written of magic in general, divide it into three parts: the firſt whereof is called *theurgy*, as operating by divine or celeſtial means; the ſecond, *natural magic*, performed by the powers of nature; and the third, comprehending *necromancy*, *ſorcery*, and *witchcraft* or *magic*, performed by the aſſiſtance of demons or departed men. See MAGIC.

THIBET. See TIBET.

THIGH, in anatomy. See ANATOMY, n° 58.

THINKING, a general name for any act or operation of the mind. See METAPHYSICS.

THIRLAGE. See LAW, n° clxx. 12—18.

THIRST, an uneaſy ſenſation ariſing from a deficiency of the ſaliva to moiſten the inward parts of the mouth. Hence ariſes a ſtrong deſire for drink; and thirſt is a ſymptom generally attending fevers of all kinds. Thirſt is beſt allayed by acids; water kept a while in the mouth, then ſpit out, and repeated as required; a bit of bread chewed with a little water, which latter may be gradually ſwallowed; if the perſon is very hot, brandy is the beſt for holding in the mouth, but ſhould be ſpit out again: except in fevers, large draughts of cold water are hurtful.

Preſervation againſt Hunger and THIRST. See HUNGER.

THISTLE, a well known weed in corn-fields. In Britain there are eight ſpecies of thiſtles according to the vulgar arrangement; the carduus lanceolatus or ſpear-thiſtle, the nutans or muſk-thiſtle, the paluſtris or marſh-thiſtle, the marianus or milk-thiſtle, acanthoides or welted-thiſtle, criſpus or curled-thiſtle, onopordum acanthium or cotton thiſtle, ſerratula arvenſis or corn-thiſtle. All theſe, except the laſt, are annual or biennial, and therefore may be eaſily deſtroyed by cutting them down before their ſeed ripens; but the ſerratula arvenſis is perennial, continues in the earth increaſing and throwing up new ſhoots every year. Mr Curtis aſcertained the annual increaſe of its root, by planting in a garden a piece of the root two inches long and about the thickneſs of a gooſe's quill, and a ſmall head of leaves. By the 2d of November the root had extended itſelf eight feet, and when dug and waſhed it weighed four pounds.

As to the uſes of the thiſtle, they are not well known. The corn-thiſtle is eaten by the aſs, and formerly was pulled with great care by the farmers in ſome parts of Scotland as food for their horſes. For a botanical deſcription of the different kinds of thiſtle, ſee CARDUUS, CACTUS, DIPSAUS, ONOPORDUM, SERRATULA, SONCHUS.

Order of the THISTLE, or *of St Andrew*, a military order of knighthood in Scotland, the riſe and inſtitution of which is variouſly related by different authors. Leſley, biſhop of Roſs reports, that the night before the battle between Athelſtan king of Northumberland, and Hungus king of the Picts, a bright croſs, in form of that whereon St Andrew (the tutelar ſaint of Scotland) ſuffered martyrdom, appeared to Hungus; who having gained the victory, ever after bore the figure of that croſs on his banners. Others aſſert, that Achaius king of Scotland firſt inſtituted this order, after having made the famous league offenſive and defenſive with Charlemagne king of France. But although the thiſtle had been acknowledged as the ſymbol of the kingdom of Scotland from the reign of Achaius, yet

ſome

Thlapſi || Thomas.

ſome refer the beginning of this order to Charles VII. of France. Others place the foundation of it as low as the year 1500.

The chief and principal enſign is a gold collar compoſed of thiſtles and ſprigs of rue interlinked with amulets of gold, having pendent thereto the image of St Andrew with his croſs, and the motto, NEMO ME IMPUNE LACESSET. "No body ſhall provoke me with impunity."

The ordinary or common enſign worn by the knights is a ſtar of four ſilver points, and over them a green circle, bordered and lettered with gold, containing the ſaid motto, and in the centre is a thiſtle; all which is embroidered on their left breaſt, and worn with the collar, with a green riband over the left ſhoulder, and brought under the right arm; pendent thereto is the image of St Andrew, with his croſs, in a purple robe, within an oval of gold enamelled vert, with the former motto; but ſometimes they wear, encircled in the ſame manner, a thiſtle crowned.

About the time of the Reformation, this order was dropped, till James II. of Great Britain reſumed it, by creating eight knights. The Revolution unſettled it again; and it lay neglected, till queen Anne, in 1703, reſtored it to the primitive deſign, of twelve knights of St Andrew.

THLAPSI, BASTARD-CRESS, or *mithridate-muſtard*, in botany: A genus of plants belonging to the claſs of *tetradynamia*, and order of *ſiliculoſa*; and in the natural ſyſtem ranging under the 39th order, *Siliquoſa*. The pod is emarginated, obcordate, and polyſpermous; the valves are boat-ſhaped and marginato-carinated. There are 12 ſpecies; of which ſix only are natives of Britain, the *arvenſe*, *hirtum*, *campeſtre*, *montanum*, *perfoliatum*, and *burſa paſtoris*.

1. The *arvenſe*, treacle-muſtard or penny-creſs, has orbiculate pods, and leaves oblong, ſmooth, and ſcalloped. It ſmells like garlic, and has a white flower. 2. The *hirtum*, or perennial mithridate muſtard, has roundiſh hairy pods; the cauline leaves are ſagittate and villous. 3. The *campeſtre*, or mithridate-muſtard, has roundiſh pods, ſagittate leaves, dentated and hairy. 4. *Montanum*, or mountain mithridate muſtard, has obcordate pods, ſmooth leaves; the radical leaves ſomewhat fleſhy, obovate and entire; the cauline embracing the ſtalk, and the corolla being larger than the calyx. 5. The *perfoliatum*, or perfoliate treacle-muſtard, has obcordate pods; the cauline leaves are ſmooth and ſubdentate; the petals of the length of the calyx, and the ſtalk branchy. 6. The *burſa paſtoris*, or ſhepherd's purſe, has obcordate pods; the radical leaves are pinnatifid.

The ſeeds of ſome of theſe ſpecies have an acrid biting taſte, approaching to that of the common muſtard; with which they agree nearly in their pharmaceutic properties. They are rarely made uſe of any otherwiſe than as ingredients in the compoſitions whoſe names they bear; though ſome recommend them in different diſorders, preferably to the common muſtard.

THOMÆANS, THOMISTS. See *CHRISTIANS of St Thomas*.

THOMAS AQUINAS. See AQUINAS.

St THOMAS's Day, a feſtival of the Chriſtian church, obſerved on December 21. in commemoration of St Thomas the apoſtle.

St THOMAS of Canterbury's Day, a feſtival of the Romiſh church, obſerved on December 29. in memory of Thomas Becket archbiſhop of Canterbury, who was murdered, or, as the Romaniſts ſay, martyred, in the reign of king Henry II.

Thomas, Thomiſm.

THOMAS the Reymour, called alſo *Thomas Lermout*, and *Thomas of Erceldon*, was born at Erceldon, a village near Melroſe in Tweedale, in what year is uncertain; but he was an old man when Edward I. was carrying on war in Scotland.

The character of Lermont as a prophet, and which was common to him with Linus, Orpheus, and other early poets in many countries, aroſe, if we may believe Mackenyie in his Lives of Scottiſh Writers, from his having conferences with Eliza, a nun and propheteſs at Haddington. Lermont put her predictions into verſe, and thus came in for his ſhare of the prophetic ſpirit. None of theſe ancient prophecies now remain; but the following, which pretends to be one of them, is given from a manuſcript of the time of Edward I. or II. The counteſs of Dunbar is the lady famous for the defence of her caſtle againſt the Engliſh. Her proper title was *Counteſs of March*; but it was common in theſe times to ſtyle a nobleman from his chief reſidence. Thus Gilbert Strongbow, earl of Pembroke, is called *Earl of Striguil*, from his reſidence at Striguil caſtle, near Chepſtow, Monmouthſhire, &c.

Pinkerton's Account of Scottiſh Poets.

La Counteſſe de Donbar demande a Thomas de Eſſedouné, quant la guere d'Eſcoce prendreit fyn. E yl l'a repoundy, et dyt.

When man as mad a kyng of a capped mon.
When mon is levere other mons thyng than his owen.
When londe thouys foreſt, and foreſt ys felde.
When hares kendles othe herſton.
When Wyt and Wille werres togedere.
When mon makes ſtables of kyrkes; and ſteles caſtles with ſtyes.
When Rokeſbourh nys no burgh; ant market is at Forwyleye.
When the alde is gan, and the newe is come that doue noht.
When Bambourne ys donged with dede men.
When men ledes men in ropes to buyen ant to ſellen.
When a quarter of whaty whete is chaunged for a colt of ten markes.
When prude prikes, ant pees is leyd in priſoun.
When a Scot ne may hym hude aſe hare in forme, that the Engliſh ne ſhal hym fynde.
When ryht ant wrong aſtente the togedere.
When laddes weddeth lovedies.
When Scottes flen ſo faſte, that for ſaute of ſhip, hy drouneth hemſelve.
When ſhal this be?
Nouther in thine tyme, ne in myne.
Ah comen, ant gone,
Withinne twenty wynter ant on.

In fact, the prophecies of Lermont appear to have been merely traditional; nay, it ſeems doubtful if he ever pretended to ſuch folly, notwithſtanding Mackenyie's ſtory of Eliza. The reverence of the people for a learned and reſpectable character ſeems to have been the ſole foundation of Thomas's claim to prophecy. But, in the 16th century, prophecies were made, and aſcribed to him, as well as others given to Bede, Merlin, &c. (A). They were printed at Edinburgh, 1615, reprinted 1680, and 1742.

THOMISM. See AQUINAS.

THOMSON

(A) Sibilla and Baniſter Anglicus are mentioned in the time of Edward IV. (MSS Cot. Dom. A. IX.) A long Latin prophecy of Bridlington is there given. Waldhave and Eltraine ſeem alſo Engliſh prophets. In the whole collection, therefore, Thomas is the only Scottiſh one.

Thomſon. THOMSON (James), an excellent Britiſh poet, the ſon of a Scotch divine, was born in the ſhire of Roxburgh in 1700, and was educated in the univerſity of Edinburgh with a view to the miniſtry. But his genius inclining him to the ſtudy of poetry, which he ſoon found would be incompatible with that of theology, or at leaſt might prevent his being provided for in that way in his own country, he relinquiſhed his views of engaging in the ſacred function, and repaired to London in conſequence of ſome encouragement which he had received from a lady of quality there, a friend of his mother.

The reception he met with wherever he was introduced, emboldened him to riſk the publication of his excellent poem on Winter.—This piece was publiſhed in 1726; and from the univerſal applauſe it met with, Mr Thomſon's acquaintance was courted by people of the firſt taſte and faſhion. But the chief advantage which it procured him was the acquaintance of Dr Rundle, afterwards biſhop of Derry, who introduced him to the late lord Chancellor Talbot; and ſome years after, when the eldeſt ſon of that nobleman was to make his tour on the continent, Mr Thomſon was choſen as a proper companion for him. The expectations which his Winter had raiſed, were fully ſatisfied by the ſucceſſive publications of the other ſeaſons; of Summer, in the year 1727; of Spring, in the following year; and of Autumn, in a quarto edition of his works, in 1730. Beſide the Seaſons, and his tragedy of Sophoniſba, written and acted with applauſe in the year 1729, he had, in 1727, publiſhed his poem to the memory of Sir Iſaac Newton, with an account of his chief diſcoveries; in which he was aſſiſted by his friend Mr Gray, a gentleman well verſed in the Newtonian philoſophy. That ſame year the reſentment of our merchants, for the interruption of their trade by the Spaniards in America, running very high, Mr Thomſon zealouſly took part in it, and wrote his Britannia, to rouſe the nation to revenge.

With the Honourable Charles Talbot, our author viſited moſt of the courts in Europe, and returned with his views greatly enlarged; not only of exterior nature and the works of art, but of human life and manners, and of the conſtitution and policy of the ſeveral ſtates, their connections, and their religious inſtitutions. How particular and judicious his obſervations were, we ſee in his poem on Liberty, begun ſoon after his return to England. We ſee at the ſame time to what a high pitch his care of his country was raiſed, by the compariſons he had all along been making of our happy government with thoſe of other nations. To inſpire his fellow-ſubjects with the like ſentiments, and ſhow them by what means the precious freedom we enjoy may be preſerved, and how it may be abuſed or loſt, he employed two years in compoſing that noble work, upon which he valued himſelf more than upon all his other writings. On his return to England with Mr Talbot (who ſoon after died), the chancellor made him his ſecretary of briefs; a place of little attendance, ſuiting his retired indolent way of life, and equal to all his wants. From this office he was removed, when death, not long after, deprived him of his noble patron. He then found himſelf reduced to a ſtate of precarious dependence. In this ſituation, having created ſome few debts, and his creditors finding that he had no longer any certain ſupport, became inexorable; and imagined by confinement to force that from his friends, which his modeſty would not permit him to aſk. One of theſe occaſions furniſhed Quin, the celebrated actor, with an opportunity of diſplaying the natural goodneſs of his heart, and the diſintereſtedneſs of his friendſhip. Hearing that Thomſon was confined in a ſpunging houſe for a debt of about 70l. he repaired to the place; and, having inquired for him, was introduced to the bard. Thomſon was a good deal diſconcerted at ſeeing Quin, as he had always taken pains to conceal his wants; and the more ſo, as Quin told him he was come to ſup with him. His anxiety upon this head was however removed, upon Quin's informing him, that, as he ſuppoſed it would have been inconvenient to have had the ſupper dreſſed in the place they were in, he had ordered it from an adjacent tavern; and, as a prelude, half a dozen of claret was introduced. Supper being over, and the bottle circulating pretty briſkly, Quin ſaid, "It is time now we ſhould balance accounts." This aſtoniſhed Thomſon, who imagined he had ſome demand upon him; but Quin perceiving it, continued, "Mr. Thomſon, the pleaſure I have had in peruſing your works I cannot eſtimate at leſs than a hundred pounds, and I inſiſt upon now acquitting the debt." On ſaying this, he put down a note of that value, and took his leave, without waiting for a reply. Thomſon.

The profits ariſing from his works were not inconſiderable; his tragedy of Agamemnon, acted in 1738, yielded a good ſum. But his chief dependence was upon the prince of Wales, who ſettled on him a handſome allowance, and honoured him with many marks of particular favour. Notwithſtanding this, however, he was refuſed a licence for his tragedy of Edward and Eleanora, which he had prepared for the ſtage in the year 1736, for ſome political reaſons. Mr Thomſon's next performance was the Maſque of Alfred, written in the year 1740 jointly with Mr Mallet, by the command of the prince of Wales, for the entertainment of his royal highneſs's court at Cliſden, his ſummer reſidence.

Mr Thomſon's poem, entitled the Caſtle of Indolence, was his laſt work publiſhed by himſelf; his tragedy of Coriolanus being only prepared for the theatre, when a fatal accident robbed the world of one of the beſt of men and beſt of poets. He would commonly walk the diſtance between London and Richmond (where he lived) with any acquaintance that offered, with whom he might chat and reſt himſelf, or perhaps dine by the way. One ſummer evening being alone in his walk from town to Hammerſmith, he had over-heated himſelf, and in that condition imprudently took a boat to carry him to Kew; apprehending no bad conſequence from the chill air on the river, which his walk to his houſe, towards the upper end of Kew-lane, had always hitherto prevented. But now the cold had ſo ſeized him, that the next day he was in a high fever. This, however, by the uſe of proper medicines, was removed, ſo that he was thought out of danger; till the fine weather having tempted him to expoſe himſelf once more to the evening dews, his fever returned with violence, and with ſuch ſymptoms as left no hopes of a cure. His death happened on the 27th of Auguſt 1748.

Mr Thomſon had improved his taſte upon the fineſt originals, ancient and modern. The autumn was his favourite ſeaſon for poetical compoſition, and the deep ſilence of the night he commonly choſe for his ſtudies. The amuſement of his leiſure hours were civil and natural hiſtory, voyages, and the beſt relations of travellers. Though he performed on no inſtrument, he was paſſionately fond of muſic, and would ſometimes liſten a full hour at his window to the nightingales in Richmond gardens; nor was his taſte leſs exquiſite in the arts of painting, ſculpture, and architecture. As for the more diſtinguiſhing qualities of his mind and heart, they beſt appear in his writings. There his devotion to the Supreme Being, his love of mankind, of his country, and friends, ſhine out in every page; his tenderneſs of heart was ſo unbounded, that it took in even the brute creation. It is not known, that through his whole life he ever gave any perſon a moment's pain, either by his writings

Thomſon ‖ Thornhill.

writings or otherwiſe. He took no part in the political ſquabbles of his time, and was therefore reſpected and left undiſturbed by both ſides. Theſe amiable virtues did not fail of their due reward; the applauſe of the public attended all his productions, and his friends loved him with an enthuſiaſtic ardour.

"As a writer (ſays Dr Johnſon), he is intitled to one praiſe of the higheſt kind; his mode of thinking, and of expreſſing his thoughts, is original. His blank verſe is no more the blank verſe of Milton, or of any other poet, than the rhymes of Pryor are the rhymes of Cowley. His numbers, his pauſes, his diction, are of his own growth, without tranſcription, without imitation. He thinks in a peculiar train, and he thinks always as a man of genius; he looks round on Nature and on life with the eye which Nature beſtows only on a poet; the eye that diſtinguiſhes, in every thing repreſented to its view, whatever there is on which imagination can delight to be detained, and with a mind that at once comprehends the vaſt, and attends to the minute. The reader of the Seaſons wonders that he never ſaw before what Thomſon ſhews him, and that he never yet has felt what Thomſon impreſſes."

Johnſon's Lives of the Poets.

His teſtamentary executors were the lord Lyttleton, whoſe care of our poet's fortune and fame ceaſed not with his life; and Mr Mitchell, a gentleman equally noted for the truth and conſtancy of his private friendſhip, and for his addreſs and ſpirit as a public miniſter. By their united intereſts, the orphan play of Coriolanus was brought on the ſtage to the beſt advantage; from the profits of which, and the ſale of manuſcripts and other effects, a handſome ſum was remitted to his ſiſters. His remains were depoſited in the church of Richmond, under a plain ſtone, without any inſcription. A handſome monument was erected to him in Weſtminſter abbey in the year 1762, the charge of which was defrayed by the profits ariſing from a ſplendid edition of all his works in 4to; Mr Millar the bookſeller, who had purchaſed all Mr Thomſon's copies, giving up his property on this grateful occaſion. A monument has alſo been erected to him at the place of his birth.

THOR, the eldeſt and braveſt of the ſons of Odin and Frea, was, after his parents, the greateſt god of the Saxons and Danes while they continued heathens. They believed, that Thor reigned over all the aerial regions, which compoſed his immenſe palace, conſiſting of 540 halls; that he launched the thunder, pointed the lightning, and directed the meteors, winds, and ſtorms. To him they addreſſed their prayers for favourable winds, refreſhing rains, and fruitful ſeaſons; and to him the fifth day of the week, which ſtill bears his name, was conſecrated.

WHITE or *Haw* THORN. See CRATÆGUS.

THORN, a town of Poland, in Regal Pruſſia, and in the palatinate of Culm. It was formerly a Hanſeatic town, and ſtill enjoys great privileges; is large and well fortified; but part of the fortifications, and a great number of houſes, were ruined by the Swedes in 1703. It is ſeated on the Viſtula, and contains 10,000 inhabitants. E. Long. 18. 42. N. Lat. 53. 6.

THORNBACK, in ichthyology. See RAIA.

THORNHILL (Sir James), an eminent Engliſh painter, was born in Dorſetſhire in 1676, of an ancient family; but was conſtrained to apply to ſome profeſſion by the diſtreſſes of his father, who had been reduced to the neceſſity of ſelling his family eſtate. His inclination directed him to the art of painting; and on his arrival at London he applied to his uncle, the famous Dr Sydenham, who enabled him to proceed in the ſtudy of the art under the direction of a painter who was not very eminent. However, the genius of Thornhill made ample amends for the inſufficiency of his inſtructor, and by an happy application of his talents he made ſo great a progreſs, that he gradually roſe to the higheſt reputation.

Dictionary of Painters.

Thorough ‖ Thrace.

His genius was well adapted to hiſtorical and allegorical compoſitions; he poſſeſſed a fertile and fine invention; and he ſketched his thoughts with great eaſe, freedom, and ſpirit. He excelled alſo equally in portrait, perſpective, and architecture; ſhewed an excellent taſte for deſign, and had a free and firm pencil. Had he been ſo fortunate as to have ſtudied at Rome and Venice, to acquire greater correctneſs at the one, and a more exact knowledge of the perfection of colouring at the other, no artiſt among the moderns might perhaps have been his ſuperior. Nevertheleſs, he was ſo eminent in many parts of his profeſſion, that he muſt for ever be ranked among the beſt painters of his time; and his performances in the dome of St Paul's church at London, in the hoſpital at Greenwich, and at Hampton court, are ſuch public proofs of his merit as will convey his name to poſterity with great honour.

This painter lived in general eſteem; he enriched himſelf by the excellence of his works; was appointed ſtate-painter to Queen Anne, from whom he received the honour of knighthood; had the ſingular ſatisfaction to repurchaſe his family eſtate; and was ſo much diſtinguiſhed as to be elected one of the members of parliament. He died in 1732.

THOROUGH-WAX, in botany. See BUPLEURUM.

THOTH, or THEUT, (called by the Phœnicians *Taaut*, by the Greeks *Hermes*, and by the Romans *Mercury*), was a Phœnician of very ſuperior talents, and one of the civilizers of mankind. He was prime miniſter to Oſiris, whom, after his death, he deified; and he was himſelf deified by his countrymen the Egyptians, for the benefits that he had rendered to the human race. See MERCURY, MYTHOLOGY, n° 34, and POLYTHEISM, n° 18.

THOUGHT, a general name for all the ideas conſequent on the operations of the mind, and even on the operations themſelves. See METAPHYSICS.

THOUGHT, in compoſition. See ORATORY, Part I. and II.

THOUINIA, in botany; a genus of plants belonging to the claſs of *diandria*, and order of *monogynia*. The corolla is quadripetalous; the calyx quadripartite, and the antheræ ſeſſile. There is only one ſpecies diſcovered, the *nutans*.

THRACE, a country very frequently mentioned by the Greek and Latin writers, deriving its name, according to Joſephus, from Tiras one of the ſons of Japhet. It was bounded on the north by mount Hæmus; on the ſouth, by the Ægean Sea; on the weſt, by Macedon and the river Strymon; and on the eaſt, by the Euxine Sea, the Helleſpont, and the Propontis.—The Thracian Cherſoneſus is a peninſula incloſed on the ſouth by the Ægean Sea, on the weſt by the gulf of Melas, and on the eaſt by the Helleſpont; being joined on the north to the continent by a neck of land about 37 furlongs broad. The inland parts of Thrace are very cold and barren, the ſnow lying on the mountains the greateſt part of the year; but the maritime provinces are productive of all ſorts of grain and neceſſaries for life; and withal ſo pleaſant that Mela compares them to the moſt fruitful and agreeable countries of Aſia.

The ancient Thracians were deemed a brave and warlike nation, but of a cruel and ſavage temper; being, according to the Greek writers, ſtrangers to all humanity and good nature. It was to the Thracians, however, that the Greeks were chiefly indebted for the polite arts that flouriſhed among them; for Orphæus, Linus, Muſæus, Thamyris, and Eumolpus, all Thracians, were the firſt, as Euſtathius informs us, who charmed the inhabitants of Greece with their

eloquence

Thraſhing. eloquence and melody, and perſuaded them to exchange their fierceneſs for a ſociable life and peaceful manners; nay, great part of Greece was anciently peopled by Thracians. Tereus, a Thracian, governed at Daulis in Phocis, where the tragical ſtory of Philomela and Progne was acted. From thence a body of Thracians paſſed over to Eubœa, and poſſeſſed themſelves of that iſland. Of the ſame nation were the Aones, Tembices, and Hyanthians, who made themſelves maſters of Bœotia; and great part of Attica itſelf was inhabited by Thracians, under the command of the celebrated Eumolpus. It is not therefore without the utmoſt ingratitude and injuſtice that the Greeks ſtyle them *Barbarians*, ſince to them chiefly they were indebted both for the peopling and poliſhing of their country.

Thrace was anciently divided into a number of petty ſtates, which were firſt ſubdued by Philip of Macedon. On the decline of the Macedonian empire, the country fell under the power of the Romans. It continued under ſubjection to them till the irruption of the Turks, in whoſe hands it ſtill remains.

THRASHING, in agriculture, the operation by which corn is ſeparated from the ſtraw. This operation is performed in a variety of ways, ſometimes by the feet of animals, ſometimes by a flail, and ſometimes by a machine.

The moſt ancient method of ſeparating the corn from the ſtraw was by the hoofs of cattle or horſes. This was practiſed by the Iſraelites, as we find from the books of Moſes; it was alſo common among the Greeks and Romans*. Flails and thraſhing machines were alſo not uncommon among theſe nations †. The flail which was uſed by the Romans, called *baculus*, *fuſtis*, or *pertica*, was probably nothing more than a cudgel or pole. The thraſhing machine, which was called *tribula* or *tribulum*, and ſometimes *traha*, was a kind of ſledge made of boards joined together, and loaded with ſtone or iron. Horſes were yoked to this machine, and a man was ſeated upon it to drive them over the ſheaves of corn.

* Pliny, xviii. 30. Virgil, Georg. iii. 132. Col ii. 21. Tibull. i. 5. 21.
† Iſaiah xviii. 27. Homer, Il. xx. 495.

Different methods are employed in different countries for ſeparating the corn from the ſtalk. In the greateſt part of France the flail is uſed; but in the ſouthern diſtricts it is generally performed by the feet of animals: animals are alſo uſed for the ſame purpoſe in Spain, in Italy, in the Morea, in the Canaries, in China, and in the vicinity of Canton, where the flail is alſo ſometimes uſed. It appears that in hot climates the grains do not adhere ſo firmly to the ſtalk as in cold countries, and therefore may be more eaſily ſeparated. This will explain the reaſon why animals are ſo frequently employed in hot countries for treading out the corn; whereas in cold climates we know they are ſeldom tried, and have no reaſon to ſuppoſe that they would anſwer the purpoſe. In the Iſle of France in Africa, rice and wheat are thraſhed with poles, and maize with ſticks; for it has not been poſſible to teach the negroes the uſe of the flail.

The animals uſed for treading out corn are, oxen, cows, horſes, mules, and even aſſes when the quantity is not great. The operation is performed in this manner: The ſheaves, after being opened, are ſpread in ſuch a manner that the ears of the corn are laid as much uppermoſt as poſſible, and a man ſtanding in the centre, holds the halters of the cattle, which are made to trot round as in a manege; whilſt other men with forks ſhake the ſtraw up from time to time, and the cattle are trotted over it again and again till they have beaten out all the grain. This method is expeditious enough; but beſides bruiſing a conſiderable quantity of corn, it requires a great many cattle, and injures the legs of the horſes and mules, which are preferred before cows and oxen for this work.

The flail is undoubtedly a much better inſtrument for thraſhing corn than the feet of animals, for it ſeparates the Thraſhing. grain from the ſtraw and huſks both more effectually and more expeditiouſly; yet it is liable to many objections. It is a very laborious employment, too ſevere indeed even for a ſtrong man; and as it is uſually the intereſt of the thraſher rather to thraſh much than to thraſh clean, a good deal of corn will generally be left upon the ſtraw. It is therefore an object of great importance in huſbandry to procure a proper machine for ſeparating the corn from the ſtraw.

The firſt thraſhing machine attempted in modern times, of which we have received any account, was invented in Edinburgh by Mr Michael Menzies about the year 1732. It conſiſted of a number of inſtruments like flails, fixed in a moveable beam, and inclined to it at an angle of ten degrees. On each ſide of the beam in which the flails were fixed, floors or benches were placed for ſpreading the ſheaves on. The flails were moved backwards and forwards upon the benches by means of a crank fixed on the end of an axle, which made about 30 revolutions in a minute.

The ſecond thraſhing machine was invented by Mr Michael Stirling, a farmer in the pariſh of Dunblane, Perthſhire. Of this diſcovery we have received a very accurate and authentic account from his ſon, the Reverend Mr Robert Stirling, miniſter of Crieff.

It is an old proverb, that neceſſity is the mother of invention. This was verified on the preſent occaſion. Beſides his ordinary domeſtic ſervants, Mr M. Stirling had occaſion ſometimes to hire an additional number to thraſh out his grain, and frequently found it difficult to procure ſo many as he needed. This naturally led him to reflect whether the operation of thraſhing could not eaſily be performed by machinery. Accordingly, ſo early as the year 1753, under the pretence of joining in the amuſements of his children, he formed in miniature a water mill, in which two iron ſprings, made to riſe and fall alternately, repreſented the motion of two flails, by which a few ſtalks of corn put under them might be ſpeedily thraſhed. This plan he executed on a ſcale ſufficiently large within two years after, making the ſprings about ten feet long, each of which had one end firmly ſcrewed into a ſolid plank, and the other terminated in a round batoon of ſolid iron, two feet long and above an inch in diameter. Under theſe the ſheaves were conveyed gradually forward in a narrow channel or trough, by paſſing between two indented horizontal cylinders, ſimilar to thoſe now uſed in moſt of the thraſhing mills in that part of the country, and called *feeders*. In this manner the thraſhing was executed completely, and with conſiderable rapidity; but as the operation was performed on a low floor, and no method contrived for carrying off the ſtraw, the accumulation of it produced ſuch confuſion, and the removal of it was attended with ſuch danger, that this ſcheme was very ſoon entirely abandoned. The mortification ariſing from diſappointment, and eſpecially the ſcoffs of his neighbours, for what was univerſally accounted an abſurd and ridiculous attempt, ſerved only to ſtimulate the exertions of the inventor to accompliſh his deſigns on another plan.

Laying aſide therefore the iron ſprings with the feeders, and all the apparatus adapted to them, he retained only an outer or water wheel, with an inner or cog wheel moving on the ſame axle; to this inner wheel, which had 48 teeth or cogs, he applied a vertical trundle or pinion, with ſeven notches, the axle of which paſſed through a floor above the wheel, and having its upper pivot ſecured in a beam ſix feet above that floor. At the diſtance of three feet three inches above the floor two ſtraight pieces of ſquared wood, each four feet long, paſſed through the axle of the trundle at right angles, forming four arms, to be moved round horizontally. To the extremities of theſe arms were fixed

Thraſhing. four iron plates, each 20 inches long, and eight broad at the end next the arms, but tapering towards a point at the other end. This large horizontal fly, conſtituting four thraſhers, was incloſed within a wooden cylindrical box three and an half feet high and eight in diameter. On the top of the box was an opening or port (two or three ports were made at firſt, but one was found ſufficient) eight inches wide, and extending from the circumference a foot and an half towards its centre, through which the corn ſheaves deſcended, being firſt opened and laid one by one on a board with two ledges gently declining towards the port; on which board they were moderately preſſed down with a boy's hand, to prevent them from being too haſtily drawn in by the repeated ſtrokes of the thraſhers. Within the box was an inclined plane, along which the ſtraw and grain fell down into a wide wire riddle two feet ſquare, placed immediately under a hole of nearly the ſame ſize. The riddle received a jerk at every revolution of the ſpindle from a knob placed on the ſide of it, and was inſtantly thruſt backward by a ſmall ſpring preſſing it in the oppoſite direction. The ſhort ſtraw, with the grain and chaff which paſſed through the wide riddle, fell immediately into an oblong ſtrait riddle, which hung with one end raiſed and the other depreſſed, and was moved by a contrivance equally ſimple as the other; and having no ledge at the lower end, the long chaff which could not paſs through the riddle dropped from thence to the ground; while the grain and moſt of the chaff falling through the riddle into a pair of common barn-fanners that ſtood under it on the ground floor, the ſtrong grain, the weak, and the chaff, were all ſeparated with great exactneſs. The fanners were moved by a rope or band running circuitouſly in a ſhallow niche cut on the circumference of the cog-wheel. The ſtraw collected gradually in the bottom of the box over the wide riddle, and through an opening two and an half feet wide, and as much in height, left in that ſide of the box neareſt the brink of the upper floor, was drawn down to the ground with a rake by the perſon or perſons employed to form it into ſheaves or rolls.

Such was the thraſhing mill invented by Mr Michael Stirling, which, after various alterations and improvements, he completed in the form now deſcribed, A. D. 1758. By experiment it was found that four bolls of oats, Linlithgow meaſure, could be thraſhed by it in 25 minutes. From that period he never uſed a common flail in thraſhing, except for humbling or bearding barley. In every other kind of grain he performed the whole operation of thraſhing with the mill; and continued always to uſe it till 1772, when he retired from buſineſs, and his thraſhing mill became the property of his ſecond ſon, who continues to uſe it with equal advantage and ſatisfaction. Several machines were conſtructed on the ſame plan, particularly one near Stirling, under Mr Stirling's direction, for Mr Moir of Leckie, in 1765, which, we underſtand has been uſed ever ſince, and gives complete ſatisfaction to the proprietor. There was another erected in 1778 by Mr Thomas Keir (in the pariſh of Muthil and county of Perth), who has contrived a method of bearding barley with it: and by the addition of a ſmall ſpindle with ſhort arms contiguous to the front of the box, and moved by a band common to it and the great ſpindle to which it is parallel, the ſtraw is ſhaken and whirled out of the box to the ground. That this machine did not come immediately into general uſe, was owing partly to the ſmallneſs of the farms in that part of the country, whoſe crops could eaſily be thraſhed by the few hands neceſſarily retained on them for other purpoſes; and chiefly to an apprehenſion that the machine could only be moved by water; an apprehenſion which experience proves to be entirely groundleſs. The machine however, was ingenious, and did great credit to the worthy inventor, and certainly deſerved a better fate than it was deſtined to undergo. Thraſhing

A third threſhing mill was invented in 1772, by two perſons nearly about the ſame time, and upon the ſame principles. The inventors were, Mr Alderton who lived near Alnwick, and Mr Smart at Wark in Northumberland. The operation was performed by rubbing. The ſheaves were carried round between an indented drum of about ſix feet diameter, and a number of indented rollers arranged round the circumference of the drum, and attached to it by means of ſprings; ſo that while the drum revolved, the fluted rollers rubbed the corn off from the ſtraw by rubbing againſt the flutings of the drum. But as a conſiderable quantity of the grain was bruiſed in paſſing between the rollers, the machine was ſoon laid aſide.

In 1776 an attempt was made by Mr Andrew Meikle, an ingenious millwright in the pariſh of Tyningham, Eaſt Lothian, to conſtruct a new machine upon the principles which had been adopted by Mr. Menzies already mentioned. This conſiſted in making joints in the flails, which Mr Menzies had formed without any. But this machine, after much labour and expence, was ſoon laid aſide, on account of the difficulty of keeping it in repair, and the ſmall quantity of work performed, which did not exceed one boll or ſix Wincheſter buſhels of barley *per* hour.

Some time after this, Mr Francis Kinloch, then junior of Gilmerton, having viſited the machine invented in Northumberland, attempted an improvement upon it. He incloſed the drum in a fluted cover; and inſtead of making the drum itſelf fluted, he fixed upon the outſide of it four fluted pieces of wood, which by means of ſprings could be raiſed a little above the circumference of the drum, ſo as to preſs againſt the fluted covering, and thus rub off the ears of corn as the ſheaves paſſed round between the drum and the fluted covering. But not finding this machine to anſwer his expectation (for it bruiſed the grain in the ſame manner as the Northumberland machine did), he ſent it to Mr Meikle, that he might, if poſſible, rectify its errors.

Mr. Meikle, who had long directed his thoughts to this ſubject, applied himſelf with much ardour and perſeverance to the improvement and correction of this machine; and after ſpending a good deal of time upon it, found it was conſtructed upon principles ſo erroneous, that to improve it was impracticable.

At length, however, Mr Meikle's own genius invented a model, different in principle from the machines which had already been conſtructed. This model was made in the year 1785; and in the following year the firſt thraſhing machine on the ſame principles was erected in the neighbourhood of Alloa, in the county of Stirling, by Mr George Meikle the ſon of the inventor. This machine anſwered completely the wiſhes of Mr Stein, the gentleman for whom it was erected, who gave the moſt ample teſtimony of his ſatisfaction both to the inventor and to the public. The fame of this diſcovery ſoon ſpread over the whole country, and a great many farmers immediately applied to Mr Meikle, deſiring to have thraſhing mills erected on their farms. The diſcovery, it appeared, would be profitable, and it was reaſonable that the inventor ſhould enjoy the profits of his invention. He accordingly applied for a patent; which, after conſiderable expence, ariſing from the oppoſition of ſome perſons, who claimed a ſhare in the diſcovery, was granted. Theſe machines are now becoming very common in many parts of Scotland, and are increaſing very conſiderably in number every year over all the united kingdom.

We will now endeavour to deſcribe this machine in its moſt improved ſtate; which is ſo ſimple, that with the aſſiſt-

ance

Thraſhing. Plate DVIII.

ance of a plate, exhibiting the plan of elevation, n° 1. the ground plan, n° 2. and the 3d ſhowing its eſſential parts in a diſtinct manner, we hope it will be eaſily underſtood by all our readers who have not had an opportunity of ſeeing it. The power employed for turning that part of the machine which ſeparates the corn from the ſtraw is produced by four wheels (when moved by horſes), the teeth of which move in one another and turn the drum, on which four ſcutchers are fixed. The ſheaves are introduced between two fluted rollers, which hold them firm, and draw them in gradually, while the ſcutchers ſtrike off the grain from the ſtraw as it paſſes through. This will ſuffice for a general idea of this machine. We will now be more particular.

The large ſpur-wheel A, n° 1. and 2. which has 276 cogs, is horizontal, and moves the pinion B, which has 14 teeth. The pinion B moves the crown-wheel C, which has 84 teeth; the wheel C moves a ſecond pinion D, which has 16 teeth; and the pinion D moves the drum HIKL. The drum is a hollow cylinder three feet and an half diameter, and placed horizontally; on the outſide of which the ſcutchers are fixed by ſtrong ſcrew bolts. The ſcutchers conſiſt of four pieces of wood, faced on one ſide with a thin plate of iron, placed at an equal diſtance from each other, and at right angles to the axis of the drum.

The ſheaves are ſpread on an inclined board F, n° 3. from which they are introduced between two fluted rollers GG made of caſt iron, about three inches and an half in diameter, and making about 35 revolutions in a minute. As theſe rollers are only about three quarters of an inch diſtant from the ſcutchers or leaves of the drum HIKL, they ſerve to hold the ſheaves faſt, while the ſcutchers *a*, *b*, *c*, *d*, moving with prodigious velocity, ſeparate the grain completely from the ſtraw, and at the ſame time throw out both grain and ſtraw upon the concave rack M, lying horizontally with ſlender parallel ribs, ſo that the corn paſſes through them into a hopper N placed below. From the hopper it paſſes through a harp or riddle O into a pair of fanners P, from which, in the moſt improved machines, it comes out clean and fit for the market. The ſtraw, after being thrown by the ſcutchers *a*, *b*, *c*, *d*, into the rack, is removed from it by a rake QRST into a place contiguous V. The rake conſiſts of four thin pieces of wood or leaves; on the end of each of theſe leaves is ranged a row of teeth *e*, *f*, *g*, *h*, five inches long. The rake moves in a circular manner in the concave rack, while the teeth catch hold of the ſtraw, and throw it out of the rack. Theſe are all the eſſential parts of the machine; the reſt may be eaſily underſtood by the references to the Plate. W is the horſe-courſe, n° 1, which is 27 feet diameter. X is the pillar for ſupporting the beams on which the axle of the ſpur-wheel is fixed. YYY are three ſpindles for moving the two fluted rollers, the rake, and fanners. To the deſcription now given we have only to add, that the drum has a covering of wood Z at a ſmall diſtance above it, for the purpoſe of keeping the ſheaves cloſe to the ſcutchers.

The advantages of this machine are many. As the drum makes 300 revolutions in a minute, the four ſcutchers together make 1200 ſtrokes in the ſame ſpace of time. From ſuch power and velocity, it is evident that much work muſt be performed. When the horſes go at the rate of two and one-third miles *per* hour, from three to ſix bolls will be thraſhed; but as the quantity thraſhed will be leſs when the ſtraw is long than when it is ſhort, we ſhall take the average at four bolls. One gentleman, whoſe veracity and accuracy we can depend on, aſſures us, that his mill thraſhed 63 bolls in a day; by which, we ſuppoſe, he meant 10 hours. To prove the ſuperior advantage of this machine to the common method of thraſhing with flails, a gentleman ordered two equal quantities of oats to be thraſhed by the mill and by flails. When the corn was cleaned and meaſured, he obtained $\frac{1}{16}$ more from the ſheaves thraſhed by the mill than from thoſe thraſhed by the flail. We are alſo informed by another gentleman who has ſtudied this machine with much attention, and calculated its advantages with care, that, independently of having the corn much cleaner ſeparated from the ſtraw than is uſually done by flails, there is a ſaving of 30 or 40 *per cent.* in the expence of thraſhing.

Thraſhing ‖ Thread.

The number of perſons requiſite for attending the mill when working is ſix: One perſon drives the horſes; a ſecond hands the ſheaves to a third, who unties them, while a fourth ſpreads them on the inclined boards and preſſes them gently between the rollers; a fifth perſon is neceſſary to riddle the corn as it falls from the fanners, and a ſixth to remove the ſtraw (A).

This machine can be moved equally well by water, wind, or horſes. Mr Meikle has made ſuch improvements on the wind-mill as to render it much more manageable and convenient than formerly; and we are informed many wind-mills are now erecting in different parts of the country. As to the comparative expence of theſe different machines, the erection of the horſe machine is leaſt; but then the expence of employing horſes muſt be taken into conſideration. One of this kind may be erected for L.70. A water-mill will coſt L.10 more on account of the expence of the water-wheel. A wind-mill will coſt from L.200 to L.300 Sterling.

THRAVE *of Corn*, an expreſſion denoting 24 ſheaves, or four ſhocks of ſix ſheaves to the ſhock; though in ſome countries they only reckon 12 ſheaves to the thrave.

THRASYBULUS, a renowned Athenian general and patriot, the deliverer of his country from the yoke of the 30 tyrants, lived about 294 B. C*.

* See Attica, n° 199—174.

THRASYMENUS LACUS (anc. geog.), a lake of Etruria, near Peruſia, and not far from the Tiber, fatal to the Romans in the Punic war. Now *Il Lago de Perugia* on the Eccleſiaſtical State.

THREAD, a ſmall line made up of a number of fine fibres of any vegetable or animal ſubſtance, ſuch as flax, cotton, or ſilk; from which it takes its name of linen, cotton, or ſilk thread.

Dyeing Thread Black. Linen and cotton thread may be dyed of a durable and deep black by ſolution of iron in ſour beer, in which the linen is to be ſteeped for ſome time, and afterwards boiled in madder. See the article Dyeing, n° 87.

Thread may be eaſily bleached by the oxygenated muriatic acid diſcovered by Mr Scheele. This acid whitens cloth remarkably well, but it is ſtill more advantageous for bleaching thread. M. Welter has formed at Liſle, with two partners, an eſtabliſhment for bleaching thread with great ſucceſs, and he has already begun ſome others. He

(A) We add, on the authority of an experienced farmer, that of the ſix perſons neceſſary to attend the thraſhing machine, only two can in juſtice be charged to the account of the machine; namely, the perſon who manages the horſes, and the one who feeds the machine: For in the uſual mode of thraſhing by the flail, it requires the ſame number of perſons as the thraſhing machine does to clear an equal quantity of corn from the chaff in the ſame time.

Threatening || Thuanus.

has found that 10 or 12 leys and as many immerſions are required for ſome ſorts of thread; and that the thread may be ſurrounded with the liquor, it is neceſſary to place it, quite looſely, in a baſket, which permits the liquor to penetrate to all its ſurfaces: when the liquor is much weakened, it is ſtill fit to be uſed for the bleaching of cotton.

Thoſe who wiſh more information upon the powerful effects of the oxygenated muriatic acid in bleaching, as well as on the cheapeſt method of preparing it, may conſult a Paper written by M. Bertholet, and publiſhed in the *Annales de Chimie*, a tranſlation of which is given in the *Repert. of Arts*, vol. i.

THREATENING LETTERS. Knowingly to ſend any letter without a name, or with a fictitious name, demanding money, or any other valuable thing, or threatening (without any demand) to kill or fire the houſe of any perſon, is made felony without benefit of clergy. And ſending letters, threatening to accuſe any perſon of a crime puniſhable with death, tranſportation, pillory, or other infamous puniſhment, with a view to extort from him any money or other valuable chattels, is puniſhable by ſtatute 30 Geo. II. c. 24. at the diſcretion of the court, with fine, impriſonment, pillory, whipping, or tranſportation for ſeven years.

THRESHING. See THRASHING.

THRIFT, in botany. See STATICE.

THRINAX, SMALL JAMAICA FAN-PALM, in botany; a genus of plants belonging to the natural claſs of *palmæ*, and order of *flabellifoliæ*. The calyx is ſexdentate; there is no corolla; there are ſix ſtamina; the ſtigma is emarginate, and the berry monoſpermous. This plant was brought from Jamaica to Kew garden by Dr William Wright.

THRIPS, a genus of inſects belonging to the order of *hemiptera*. The roſtrum is obſcure, or ſo ſmall as to be ſcarce perceptible. The antennæ are filiform, and as long as the thorax. The body is ſlender, and of equal thickneſs in its whole length. The abdomen is reflexible, or bent upwards. The four wings are extended, incumbent upon the back of the inſect, narrow in proportion to their length, and croſs one another at ſome diſtance from their baſe. The tarſi of the feet are compoſed of only two articulations.

There are eleven ſpecies mentioned by Gmelin; of which three are natives of Britain; the phyſapus, juneperina, and faſciata.

THROAT, the anterior part of an animal, between the head and the ſhoulders.

THROAT-WORT. See CAMPANULA.

THRONE, a royal ſeat or chair of ſtate, enriched with ornaments of architecture and ſculpture, raiſed on one or more ſteps, and covered with a kind of canopy. Such are the thrones in the rooms of audience of kings and other ſovereigns.

THROSTLE, in ornithology. See TURDUS.

THRUSH, in ornithology. See TURDUS.

THRUSH, or *Aphtha*. See MEDICINE, n° 233.

THRYALLIS, in botany: a genus of plants belonging to the claſs of *decandria*, and order of *monogynia*; and in the natural ſyſtem ranging under the 38th order, *Tricoccæ*. The calyx is quinquepartite; there are five petals, and the capſule is tricoccous. There is only one ſpecies known, the *braſilienſis*.

THUANUS (Jacobus Auguſtus), youngeſt ſon of the preſident de Thou, was famous for the depth and erudition of his works. He was born in 1553; and having finiſhed his ſtudies and travels, was made preſident a-Mortier, and took poſſeſſion thereof in 1595. He was employed in ſeveral important offices of ſtate, and in reforming the univerſity of Paris; which he diſcharged with ſo much prudence, that he was eſteemed the Cato of his age, and the ornament of France. He wrote the hiſtory of his own time in Latin, from the year 1543 to 1608, in 138 books; a work, both for ſubject and ſtyle, worthy of the ancients. He alſo left memoirs of his own life, beſides poems; and died at Paris, 1617.

Thucydides.

THUCYDIDES, a celebrated Greek hiſtorian, was born at Athens 471 B. C. He was the ſon of Olorus, and grandſon of Miltiades, who is thought to have been deſcended from Miltiades the famous Athenian general, and to have married the king of Thrace's daughter. He was educated in a manner ſuitable to his quality, that is, in the ſtudy of philoſophy and eloquence. His maſter in the former was Anaxagoras, in the latter Antiphon; one, by his deſcription in the eighth book of his Hiſtory, for power of ſpeech almoſt a miracle, and feared by the people on that account. Suidas and Photius relate, that when Herodotus recited his hiſtory in public, a faſhion in uſe then and many ages after, Thucydides felt ſo great a ſting of emulation, that it drew tears from him; inſomuch that Herodotus himſelf took notice of it, and congratulated his father on having a ſon who ſhowed ſo wonderful an affection to the Muſes. Herodotus was then 29 years of age, Thucydides about 16.

When the Peloponneſian war began to break out, Thucydides conjectured truly, that it would prove a ſubject worthy of his labour; and it no ſooner commenced than he began to keep a journal. This explains the reaſon why he has attended more to chronological order than to unity of deſign. During the ſame war he was commiſſioned by his countrymen to relieve Amphipolis; but the quick march of Braſidas the Lacedæmonian general defeated his operations; and Thucydides, unſucceſsful in his expedition, was baniſhed from Athens. This happened in the eighth year of this celebrated war; and in the place of his baniſhment the general began to write an impartial hiſtory of the important events which had happened during his adminiſtration, and which ſtill continued to agitate the ſeveral ſtates of Greece. This famous hiſtory is continued only to the 21ſt year of the war, and the remaining part of the time till the demolition of the walls of Athens was deſcribed by the pen of Theopompus and Xenophon. Thucydides wrote in the Attic dialect, as being poſſeſſed of moſt vigour, purity, elegance, and energy. He ſpared neither time nor money to procure authentic materials; and the Athenians, as well as their enemies, furniſhed him with many valuable communications, which contributed to throw great light on the different tranſactions of the war. His hiſtory has been divided into eight books; the laſt of which is imperfect, and ſuppoſed to have been written by his daughter. Lempriere's Dictionary.

The hiſtorian of Halicarnaſſus has often been compared with the ſon of Olorus, but each has his peculiar excellence. Sweetneſs of ſtyle, grace and elegance of expreſſion, may be called the characteriſtics of the former; while Thucydides ſtands unequalled for the fire of his deſcriptions, the conciſeneſs, and at the ſame time the ſtrong and energetic manner of his narratives. His relations are authentic, as he himſelf was intereſted in the events he mentions; his impartiality is undubitable, as he nowhere betrays the leaſt reſentment againſt his countrymen, and the factious partizans of Cleon, who had baniſhed him from Athens. The hiſtory of Thucydides was ſo admired by Demoſthenes, that he tranſcribed it eight different times, and read it with ſuch attention, that he could almoſt repeat it by heart. Thucydides died at Athens, where he had been recalled from his exile about 411 years before Chriſt.

Thuja ‖ Thunbergia.

The beſt edition of Thucydides is that of Oxford, publiſhed in 1696, folio, and that of Duker, publiſhed at Amſterdam in 1731, folio.

THUJA, the ARBOR VITÆ, in botany: A genus of plants belonging to the claſs of *monodelphia*, and order of *monœcia*; and in the natural ſyſtem ranging under the 51ſt order, *Coniferæ*. There are four ſpecies known; the orientalis, occidentalis, apylla, and dolabrata; of which the two firſt are moſt remarkable.

The *occidentalis*, or common arbor vitæ, grows naturally in Canada, Siberia, and other northern countries. In ſome of the Engliſh gardens a few of theſe trees are to be met with of a large ſize: it has a ſtrong woody trunk, which riſes to the height of 40 feet or more. The bark, while young, is ſmooth, and of a dark brown colour; but as the trees advance, the bark becomes cracked, and leſs ſmooth. The branches are produced irregularly on every ſide, ſtanding almoſt horizontal, and the young ſlender ſhoots frequently hang downward, thinly garniſhed with leaves; ſo that when the trees are grown large they make but an indifferent appearance. The young branches are flat, and their ſmall leaves lie imbricated over each other like the ſcales of a fiſh; the flowers are produced from the ſide of the young branches pretty near to the foot-ſtalk; the male flowers grow in oblong catkins, and between theſe the female flowers are collected in form of cones. When the former have ſhed their farina, they ſoon after drop off; but the female flowers are ſucceeded by oblong cones, having obtuſe ſmooth ſcales, containing one or two oblong ſeeds. The leaves of this tree have a rank oily ſcent when bruiſed.

2. The *orientalis*, or China arbor vitæ, grows naturally in the northern parts of China, where it riſes to a conſiderable height; but this has not been long enough in Europe to have any trees of large ſize. The ſeeds of this ſort were firſt ſent to Paris by ſome of the miſſionaries; and there are ſome of the trees growing in the gardens of the curious there, which are more than 20 feet high. The branches of this ſort grow cloſer together, are much better adorned with leaves, which are of a brighter green colour, ſo make a much better appearance than the other, and being very hardy, it is eſteemed preferable to moſt of the evergreen trees with ſmall leaves, for ornament in gardens. The branches of this tree croſs each other at right angles: the leaves are flat; but the ſingle diviſions of the leaves are ſlender, and the ſcales are ſmaller and lie cloſer over each other than thoſe of the firſt ſort. The cones are alſo much larger, and of a beautiful grey colour; their ſcales end in acute reflexed points.

Theſe trees are propagated by ſeeds, layers, or cuttings.

THULE, or THYLÆ, (anc. geog.), an iſland in the moſt northern parts of the German Ocean. Its ſituation was never accurately aſcertained by the ancients, hence its preſent name is unknown by modern hiſtorians. Some ſuppoſe that it is the iſland now called Iceland, or part of Greenland, and others that it was *Foula*. See FOULA.

THUMB, in anatomy, one of the extremities of the hand.

THUMB-Cap, an iſland in the South Sea, lies about ſeven leagues north-weſt of Lagoon-iſland; it is a low, woody iſland, of a circular form, and not much above a mile in compaſs. There was no appearance of inhabitants; the land was covered with verdure of many hues.

THUMMIM. See URIM.

THUNBERGIA, in botany; a genus of plants belonging to the claſs of *didynamia*, and order of *angioſpermia*. The calyx is double; the exterior one is diphyllous, and the interior one multipartite. The capſule is globoſe, beaked, and bilocular. There is only one ſpecies known, the *capenſis*.

Thunder.

THUNDER, the noiſe occaſioned by the exploſion of a flaſh of lightning echoed back from the inequalities on the ſurface of the earth, in like manner as the noiſe of a cannon is echoed, and in particular circumſtances forms a rolling lengthened ſound.

Although *thunder*, properly ſpeaking, is only a mere ſound, capable of producing very little effect, yet the word is generally ſuppoſed to include the phenomena of lightning alſo; and electrified clouds are by univerſal conſent call *thunder-clouds*, and the exploſions of many flaſhes of lightning proceeding from them are generally called *thunder-ſtorms*. Though the phenomena of lightning, therefore, have been at a great length explained and accounted for under the articles ELECTRICITY and LIGHTNING, and though the immediate cauſe of electrical exploſions from clouds is explained under the article RAIN; yet the ultimate cauſe remains ſtill to be ſhown, and properly belongs to the preſent article.

It is univerſally allowed, that the variation of the electricity in different parts of the atmoſphere is the cauſe of thunder. Under the article ELECTRICITY, it has been ſhown why lightning explodes after the thunder-clouds are charged. Under the article LIGHTNING, it is ſhown why that meteor puts on the various forms in which we ſee it, why it ſometimes ſtrikes houſes or animals, and ſometimes not, &c.; and under the article RAIN, why the atmoſphere in ſome caſes parts with the vapours which at other times it ſo obſtinately retains. It remains therefore only to mention the theory by which ſome philoſophers explain the reaſon why rains are ſometimes attended with thunder, and ſometimes not; which, to thoſe who attentively peruſe the articles above-mentioned, may be done in few words.

In this part of Great Britain, and for a conſiderable way along the eaſtern coaſt, although thunder may happen at any time of the year, yet the month of July is that in which it may almoſt certainly be expected. Its duration is of very uncertain continuance; ſometimes only a few peals will be heard at any particular place during the whole ſeaſon; at other times the ſtorm will return at the interval of three or four days for a month, ſix weeks, or even longer: not that we have violent thunder in this country directly vertical in any one place ſo frequently in any year, but in many ſeaſons it will be perceptible that thunder-clouds are formed in the neighbourhood even at theſe ſhort intervals. Hence it appears, that during this particular period there muſt be ſome natural cauſe operating for the production of this phenomenon, which does not take place at other times. This cannot be the mere heat of the weather, for we have often a long tract of hot weather without any thunder; and beſides, though not common, thunder is ſometimes heard in the winter alſo. As therefore the heat of the weather is common to the whole ſummer, whether there be thunder or not, we muſt look for the cauſes of it in thoſe phenomena, whatever they are, which are peculiar to the months of July, Auguſt, and the beginning of September. Now it is generally obſerved, in the tract of country of which we now ſpeak, that from the month of April an eaſt or ſouth-eaſt wind generally takes place, and continues with little interruption till towards the end of June. At that time, ſometimes ſooner and ſometimes later, a weſterly wind takes place; but as the cauſes producing the eaſt wind are not removed, the latter oppoſes the weſt wind with its whole force. At the place of meeting, there is naturally a moſt vehement preſſure of the atmoſphere, and friction of its parts againſt one another; a calm enſues, and the vapours brought by both winds begin to collect and form dark clouds, which

can

Thunder. can have little motion either way, becauſe they are preſſed almoſt equally on all ſides. For the moſt part, however, the weſt wind prevails, and what little motion the clouds have is towards the eaſt: whence the common remark in this country, that "thunder-clouds move againſt the wind." But this is by no means univerſally true: for if the weſt wind happens to be excited by any temporary cauſe before its natural period when it ſhould take place, the eaſt wind will very frequently get the better of it; and the clouds, even although thunder is produced, will move weſtward. Yet in either caſe the motion is ſo ſlow, that the moſt ſuperficial obſervers cannot help taking notice of a conſiderable reſiſtance in the atmoſphere.

That when two ſtreams of air are thus driven againſt each other, the ſpace where they meet muſt become highly electrified, is as plain as that an electric globe muſt be excited when friction is applied. It is true, as the ſubſtances here to be excited are both electrics *per ſe*, it may be objected, that no electricity could be produced; for we cannot excite one electric by rubbing it with another. Yet it is obſerved, that glaſs may be electrified by blowing ſtrongly upon it, or by the exploſion of cannon; and even when glaſs is ſtrongly preſſed upon glaſs, both pieces become electrified as ſoon as they are ſeparated. When glaſs is rubbed upon glaſs, no attraction nor repulſion can be perceived, nor is any ſign of electricity obſerved on bodies brought near to it; yet a very bright electric light always appears on the glaſſes, and a phoſphoreal ſmell is felt; which ſhows, that though the electricity does not fly out through the air in the uſual way, yet the fluid within the glaſs is agitated; and there is little reaſon to doubt that any conducting body incloſed within the ſubſtance of the glaſs would be electrified alſo. The vapours therefore, which are the conducting ſubſtances in the atmoſphere, become immediately electrified in conſequence of the preſſure above-mentioned, and all the phenomena deſcribed under the various articles already referred to take place.

In like manner, by the ſtruggle of two other winds as well as thoſe of the eaſt and weſt, may a thunder-ſtorm be produced; but it is always neceſſary that the reſiſtance of the air to the motion of the clouds ſhould be very great, and nearly equal all round. For if the vapour ſhould get off to a ſide, no thunder would take place; the electricity would then be carried off as faſt as it was collected, and rain would only be the conſequence, by reaſon of the electrified vapours parting with their latent heat, as is explained under the article RAIN. In fact, we very often obſerve, that in the time of rain the clouds evidently move acroſs the wind, and the nearer their motion is to a direct oppoſition, the heavier will the rain be; while, on the other hand, if they move briſkly before the wind, let the direction be what it will, the atmoſphere ſoon clears up.

That rattling in the noiſe of thunder which makes it ſeem as if it paſſed thro' arches, or were variouſly broken, is probably owing to the ſound being excited among clouds hanging over one another, and the agitated air paſſing irregularly between them. The exploſion, if high in the air, and remote from us, will do no miſchief; but when near, it may deſtroy trees, animals, &c. This proximity or ſmall diſtance may be eſtimated nearly by the interval of time between ſeeing the flaſh of lightning and hearing the report of the thunder, eſtimating the diſtance after the rate of 1142 feet *per* ſecond of time, or three two-third ſeconds to the mile. Dr Wallis obſerves, that commonly the difference between the two is about ſeven ſeconds, which, at the rate above-mentioned, gives the diſtance almoſt two miles. But ſometimes it comes in a ſecond or two, which argues the exploſion very near us, and even among us. And in ſuch caſes, the Doctor aſſures us, he has ſometimes foretold the miſchiefs that happened. Thunder-bolt || Thurloe.

The noiſe of thunder and the flame of lightning are eaſily made by art. If a mixture of oil or ſpirit of vitriol be made with water, and ſome filings of ſteel added to it, there will immediately ariſe a thick ſmoke or vapour out of the mouth of the veſſel; and if a lighted candle be applied to this, it will take fire, and the flame will immediately deſcend into the veſſel, which will be burſt to pieces with a noiſe like that of a cannon.

This is ſo far analogous to thunder and lightning, that a great exploſion and fire are occaſioned by it; but in this they differ, that this matter when once fired is deſtroyed, and can give no more exploſions; whereas, in the heavens, one clap of thunder uſually follows another, and there is a continued ſucceſſion of them for a long time. Mr Homberg explained this by the lightneſs of the air above us in compariſon of that near, which therefore would not ſuffer all the matter ſo kindled to be diſſipated at once, but keeps it for ſeveral returns.

Reſpecting the phenomena of thunder, we have many obſervations to communicate; ſome of which, we flatter ourſelves, are new, and all of them valuable; but our bounds oblige us, though with great reluctance, to paſs them over.

THUNDERBOLT. When lightning acts with extraordinary violence, and breaks or ſhatters any thing, it is called a *thunderbolt*, which the vulgar, to fit it for ſuch effects, ſuppoſe to be a hard body, and even a ſtone. But that we need not have recourſe to a hard ſolid body to account for the effects commonly attributed to the thunderbolt, will be evident to any one who conſiders thoſe of the pulvis fulminans and of gunpowder; but more eſpecially the aſtoniſhing powers of electricity, when only collected and employed by human art, and much more when directed and exerciſed in the courſe of nature.

When we conſider the known effects of electrical exploſions, and thoſe produced by lightning, we ſhall be at no loſs to account for the extraordinary operations vulgarly aſcribed to thunderbolts. As ſtones and bricks ſtruck by lightning are often found in a vitrified ſtate, we may reaſonably ſuppoſe, with Beccaria, that ſome ſtones in the earth having been ſtruck in this manner, gave occaſion to the vulgar opinion of the thunderbolt.

Thunder-Houſe. See ELECTRICITY, p. 474.

THURINGIA, a diviſion of the circle of Upper Saxony in Germany. It is a fruitful tract, abounding in corn, eſpecially wheat; in black cattle, ſheep, and horſes. It is about 73 miles in length, and as much in breadth. It contains 47 towns, 14 boroughs, betwixt 700 and 800 villages, 300 noble eſtates, 7 ſuperintendencies, and 5 under-conſiſtories. Thuringia, the country of the ancient Thuringi, or Catti, a branch of the Vandals, mentioned by Tacitus, was formerly a kingdom, afterwards a county, then a landgravate, and was governed by its own princes for many ages, till 1124, when it devolved to the marquis of Miſnia, and, with that country, afterwards to the duke of Saxony. But the modern Thuringia is only a part of the ancient, nay, but a part of the ancient South Thuringia, which comprehends beſides, a large ſhare of the modern Franconia, Heſſe, &c. On the extinction of the male line of the ancient landgraves in 1247, it came to the margraves of Meiſſen, anceſtors to the preſent electoral family. The elector has no voice in the diet, on account of his ſhare in the landgravate or circle of Thuringia. Erfurt is the capital.

THURLOE (John), an Engliſh ſtateſman under Oliver Cromwell, was born at Abots Roding in Eſſex in 1616, of which pariſh his father was rector, and was educated to the

Thurſday, ‖ Tiara.

the ſtudy of the law. In 1648 he was made receiver or clerk of the curſitor fines; and though his attachments were entirely on the ſide of the parliament, he declares himſelf totally unconcerned in all counſels relative to the death of the king: however, on that event, and on the eſtabliſhment of the commonwealth, he was diverted from proſecuting his employments in the law by engaging in public buſineſs. When Cromwell aſſumed the protectorſhip, he became ſecretary of ſtate; in 1655, he had the care and charge both of foreign and inland poſtage committed to him by the protector; and was afterward ſworn one of his privy-council, according to "The humble petition and advice." He was continued in the ſame capacities under Richard Cromwell, and until meaſures were taken for the Reſtoration; when he made an offer of his ſervices to that end, which, however, were not accepted. May 15th 1660, he was committed to the cuſtody of the ſerjeant at arms on a charge of high treaſon; but being ſoon releaſed, he retired to Great Milton in Oxfordſhire: and though he was afterward often ſolicited by Charles II. to engage in the adminiſtration of public buſineſs, he thought proper to decline the offers. He died in 1668: and was a man of an amiable private character, who in the higheſt of his power exerciſed all poſſible moderation towards perſons of every party. The moſt authentic teſtimony of his abilities is that vaſt collection of ſtate-papers, ſeven volumes folio, now in the hands of the public; which place the affairs of Great Britain, and of Europe in general, during that remarkable period, in the cleareſt light.

THURSDAY, the fifth day of the Chriſtian week, but the ſixth of that of the Jews.

THUS, Frankincense, a ſolid brittle reſin, brought to us in little globes or maſſes, of a browniſh or yelloviſh colour on the outſide, internally whitiſh or variegated with whitiſh ſpecks. It is ſuppoſed to be the produce of the pine that yields the common turpentine, and to concrete upon the ſurface of the terebinthinate juice ſoon after it has iſſued from the tree. See Incense.

THUYA. See Thuja.

THYMUS, Thyme, in botany: A genus of plants belonging to the claſs of *didynamia*, and order of *gymnoſpermia*; and in the natural ſyſtem ranging under the 42d order, *Verticillatæ*. The calyx is bilabiate, and its throat cloſed with ſoft hairs. There are 11 ſpecies; of which two only are natives of Britain, the *ſerpyllum* and *acinas*.

1. The *ſerpyllum*, or mother of thyme, has pale red flowers growing on round heads, terminal; the ſtalks are procumbent, and the leaves plane, obtuſe, and ciliated at the baſe. 2. The *acinas*, or wild baſil, has flowers growing in whirls on ſingle footſtalks; the ſtalks are erect and branched; the leaves acute and ſerrated, The *thymus vulgaris*, or garden thyme, is a native of France, Spain, and Italy.—The attachment of bees to this and other aromatic plants is well known. In the experiments made at Upſal, ſheep and goats were obſerved to eat it, and ſwine to refuſe it.

Thymus, in anatomy. See Anatomy, n° 114.

THYRSUS, in antiquity, the ſceptre which the poets put into the hand of Bacchus, and wherewith they furniſhed the menades in their Bacchanalia.

Thyrsus, in botany, a mode of flowering reſembling the cone of a pine. It is, ſays Linnæus, a panicle contracted into an oval or egg-ſhaped form. The lower footſtalks, which are longer, extend horizontally, whilſt the upper ones are ſhorter and mount vertically. Lilac and butter-bur furniſh examples.

TIARA, an ornament or habit wherewith the ancient Perſians covered their heads; and with which the Armenians and kings of Pontus are repreſented on medals; theſe laſt, becauſe they were deſcended from the Perſians. Latin authors call it indifferently *tiara* and *cidaris*. Strabo ſays, the tiara was in form of a tower; and the ſcholiaſt on Ariſtophanes's comedy, Ἀχαρνῆς, act 1. ſcene 2. affirms, that it was adorned with peacock's feathers.

Tiara. ‖ Tibet.

Tiara is alſo the name of the pope's triple crown. The tiara and keys are the badges of the papal dignity; the tiara of his civil rank, and the keys of his juriſdiction: for as ſoon as the pope is dead, his arms are repreſented with the tiara alone, without the keys. The ancient tiara was a round high cap. John XXIII. firſt encompaſſed it with a crown. Boniface VIII. added a ſecond crown; and Benedict XII. a third.

TIARELLA, in botany: A genus of plants belonging to the claſs of *decandria*, and order of *digynia*; and in the natural ſyſtem ranging under the 13th order, *Succulentæ*. The calyx is quinquepartite; the corolla pentapetalous, and inſerted into the calyx; the petals are entire; the capſule is unilocular and bivalve, the one valve being leſs than the other. There are two ſpecies, the *cordifolia* and *trifoliata*.

TIBER, a great river of Italy, which runs through the pope's territories, paſſing by Perugia and Orvietto; and having viſited Rome, falls into the Tuſcan ſea at Oſtia, fifteen miles below that city.

TIBET, called by the Tartars *Barantola*, *Bootan*, or *Tangoot*, and by the Chineſe *Tſang*, is ſituated between 26° and 39° north latitude; and according to Abbé Groſier, is reckoned to be 640 leagues from eaſt to weſt, and 650 from north to ſouth. It is bounded on the north by the country of the Mongols and the deſert of Kobi; on the eaſt by China; on the weſt by Hindoſtan, and on the ſouth by the ſame country and the kingdom of Ava. In the valleys lying between the lower mountains are many tribes of Indian people; and a diſpute happening between the heirs of one of the rajahs or petty princes, one party called to their aſſiſtance the Boutaners, and the other the Britiſh. The latter prevailed; and the fame of Britiſh valour being carried to the court of Tibet, the Teeſhoo-Lama, who ruled the ſtate under the Delai-Lama, at that time in his minority, ſent a deputation to Bengal, deſiring peace for the prince who had been engaged in war with the Britiſh. This was readily granted by the governor; and Mr Bogle was ſent ambaſſador to the court of Tibet, where he reſided ſeveral months; and after an abſence of a year and a quarter, returned to Calcutta. The account of this gentleman's expedition hath not been publiſhed by himſelf; but from Mr Stewart's letter to Sir John Pringle, publiſhed in the Philoſophical Tranſactions, vol. 67. we learn the following particulars, collected from his papers.

"Mr Bogle divides the territories of the Delai-Lama into two different parts. That which lies immediately contiguous to Bengal, and which is called by the inhabitants *Doopo*, he diſtinguiſhes by the name of *Bootan*; and the other, which extends to the northward as far as the frontiers of Tartary, called by the natives *Pu*, he ſtyles *Tibet*. Bootan is ruled by the Dah Terriah, or Deb Rajah. It is a country of ſteep and inacceſſible mountains, whoſe ſummits are crowned with eternal ſnow; they are interſected with deep valleys, through which pour numberleſs torrents that increaſe in their courſe, and at laſt, gaining the plains, loſe themſelves in the great rivers of Bengal. Theſe mountains are covered down their ſides with foreſts of ſtately trees of various ſorts; ſome (ſuch as pines, &c.) which are known in Europe; others, ſuch as are peculiar to the country and climate. The valleys and ſides of the hills which admit of cultivation are not unfruitful, but produce crops of wheat, barley, and rice. The inhabitants are a ſtout and warlike people, of a copper complexion, in ſize rather

above

Tibet. above the middle European ſtature, haſty and quarrelſome in their temper, and addicted to the uſe of ſpirituous liquors; but honeſt in their dealings, robbery by violence being almoſt unknown among them. The chief city is Taſſey Seddein ſituated on the Patchoo. Tibet begins properly from the top of the great ridge of the Caucaſus, and extends from thence in breadth to the confines of Great Tartary, and perhaps to ſome of the dominions of the Ruſſian empire. The woods, which every where cover the mountains in Boutan, are here totally unknown; and, except a few ſtraggling trees near the villages, nothing of the ſort to be ſeen. The climate is extremely ſevere and rude. At Chamnanning, where he wintered, although it be in latitude 31° 39′, only 8° to the northward of Calcutta, he often found the thermometer in his room at 29° by Fahrenheit's ſcale; and in the middle of April the ſtanding waters were all frozen, and heavy ſhowers of ſnow perpetually fell. This, no doubt, muſt be owing to the great elevation of the country, and to the vaſt frozen ſpace over which the north wind blows uninterruptedly from the pole, through the vaſt deſerts of Siberia and Tartary, till it is ſtopped by this formidable wall.

"The Tibetians are of a ſmaller ſize than their ſouthern neighbours, and of a leſs robuſt make. Their complexions are alſo fairer, and many of them have even a ruddineſs in their countenances unknown in the other climates of the eaſt. Thoſe whom Mr Bogle ſaw at Calcutta appeared to have quite the Tartar face. They are of a mild and cheerful temper; the higher ranks are polite and entertaining in converſation, in which they never mix either ſtrained compliments or flattery. The common people, both in Bootan and Tibet, are clothed in coarſe woollen ſtuffs of their own manufacture, lined with ſuch ſkins as they can procure; but the better orders of men are dreſſed in European cloth, or China ſilk, lined with the fineſt Siberian furs. The uſe of linen is totally unknown among them. The chief food of the inhabitants is the milk of their cattle, prepared into cheeſe, butter, or mixed with the flour of a coarſe barley or of peaſe, the only grain which their ſoil produces; and even theſe articles are in a ſcanty proportion; but they are furniſhed with rice and wheat from Bengal and other countries in their neighbourhood. They alſo are ſupplied with fiſh from the rivers in their own and the neighbouring provinces, ſalted and ſent into the interior parts. They have no want of animal food from the cattle, ſheep, and hogs, which are raiſed on their hills; and are not deſtitute of game. They have a ſingular method of preparing their mutton, by expoſing the carcaſe entire, after the bowels are taken out, to the ſun and bleak northern winds which blow in the months of Auguſt and September, without froſt, and ſo dry up the juices and parch the ſkin, that the meat will keep uncorrupted for the year round. This they generally eat raw, without any other preparation.

"The religion and political conſtitution of this country, which are intimately blended together, would make a conſiderable chapter in its hiſtory. It ſuffices to ſay, that at preſent, and ever ſince the expulſion of the Eluth Tartars, the kingdom of Tibet is regarded as depending on the empire of China, which they call *Cathay*; and there actually reſide two mandarines, with a garriſon of a thouſand Chineſe, at Lahaſſa the capital, to ſupport the government; but their power does not extend far: and in fact the Lama, whoſe empire is founded on the ſureſt grounds, perſonal affection and religious reverence, governs every thing internally with unbounded authority. Every body knows that the Delai Lama is the great object of adoration for the various tribes of heathen Tartars, who roam through the vaſt tract of continent which ſtretches from the banks of the Volga to Correa on the ſea of Japan, the moſt extenſive religious dominion, perhaps, on the face of the globe. See Lama. Tibet.

"It is an old notion, that the religion of Tibet is a corrupted Chriſtianity: and even Father Diſederii, a Jeſuit (but not of the Chineſe miſſion) who viſited the country about the beginning of this century, thinks he can reſolve all their myſteries into ours; and aſſerts, with a truly myſtical penetration, that they have certainly a good notion of the Trinity, ſince in their addreſs to the Deity, they ſay as often *konciok-oik* in the plural as *konciok* in the ſingular, and with their roſaries pronounce theſe words, *om*, *ha*, *hum*. The truth is, that the religion of Tibet, from whatever ſource it ſprung, is pure and ſimple in its ſource, conveying very exalted notions of the Deity, with no contemptible ſyſtem of morality: but in its progreſs it has been greatly altered and corrupted by the inventions of worldly men; a fate we can hardly regret in a ſyſtem of error, ſince we know that that of truth has been ſubject to the ſame. Polygamy, at leaſt in the ſenſe we commonly receive the word, is not in practice among them; but it exiſts in a manner ſtill more repugnant to European ideas; for there is a plurality of huſbands, which is firmly eſtabliſhed and highly reſpected there. In a country where the means of ſubſiſting a family are not eaſily found, it ſeems not impolitic to allow a ſet of brothers to agree in raiſing one, which is to be maintained by their joint efforts. In ſhort, it is uſual in Tibet for the brothers in the family to have a wife in common, and they generally live in great harmony and comfort with her; not but ſometimes little diſſenſions will ariſe (as may happen in families conſtituted upon different principles), an inſtance of which Mr Bogle mentions in the caſe of a modeſt and virtuous lady, the wife of half a dozen of the Teeſhoo Lama's nephews, who complained to the uncle that the two youngeſt of her huſbands did not furniſh that ſhare of love and benevolence to the common ſtock which duty and religion required of them. In ſhort, however ſtrange this cuſtom may appear to us, it is an undoubted fact that it prevails in Tibet.

"The manner of beſtowing their dead is alſo ſingular: they neither put them in the ground like the Europeans, nor burn them like the Hindoos; but expoſe them on the bleak pinnacle of ſome neighbouring mountain, to be devoured by wild beaſts and birds of prey, or waſted away by time and the viciſſitudes of the weather in which they lie. The mangled carcaſes and bleached bones lie ſcattered about; and amidſt this ſcene of horror, ſome miſerable old wretch, man or woman, loſt to all feelings but thoſe of ſuperſtition, generally ſets up an abode, to perform the diſmal office of receiving the bodies, aſſigning each a place, and gathering up the remains when too widely diſperſed."

To the account of Tibet which we have given from the communications of Mr Bogle, we may add the information which we have obtained from a later traveller, Mr Saunders* ſurgeon at Boglepoer in Bengal, who made a journey into Tibet in the year 1783. His obſervations chiefly reſpect the natural productions and diſeaſes of the country.

* Paper to the Phil. Tranſ. Vol. LXXIX.

The plants which Mr Saunders found were almoſt all European plants, a great number of them being natives of Britain. From the appearance of the hills he concludes that they muſt contain many ores of metal and pyrites. There are inexhauſtible quantities of Tincal (ſee that article), and rock ſalt is plentiful; gold-duſt is found in great quantities in the beds of rivers, and ſometimes in large maſſes, lumps, and irregular veins; lead, cinnabar, containing a large proportion of quickſilver, copper, and iron, he thinks, might eaſily be procured. But the inhabitants of Tibet have no better fuel than the dung of animals. A coal

mine

Tibet, Tibullus.

mine would be a valuable diſcovery. We are told, that in ſome parts of China bordering on Tibet coal is found and uſed as fuel.

It is remarkable that the ſame diſeaſe prevails at the foot of the mountains of Tibet as in Switzerland at the foot of the Alps, a glandular ſwelling in the throat commonly called *goitre*. This diſeaſe has been aſcribed to the uſe of ſnow-water, which flows down in ſtreams from the mountains in both countries. But in many countries where ſnow-water is abundant it does not prevail, and in other places far remote from ſnow it is not unfrequent, as in Sumatra. Mr Saunders thinks that it ariſes from the air peculiar to the vicinity of certain mountains; and finding the vegetable productions of the mountains of Tibet the ſame with thoſe of the Alps, that they alſo may have their influence. An analyſis of the water where this diſeaſe prevails might throw ſome light on the ſubject. We have heard it attributed to the impregnation of water with *tufa*. This very extraordinary diſeaſe has been little attended to, from obvious reaſons; it is unaccompanied with pain, ſeldom fatal, and generally confined to the poorer ſort of people. The tumor is unſightly, and grows to a troubleſome ſize, being often as large as a perſon's head. It is certainly not exaggerating to ſay, that one in ſix of the Rungpore diſtrict, and country of Bootan, has the diſeaſe.

As thoſe who labour moſt, and are the leaſt protected from the changes of weather, are moſt ſubject to the diſeaſe, we univerſally find it in Bootan more common with the women than men. It generally appears in Bootan at the age of thirteen or fourteen, and in Bengal at the age of eleven or twelve; ſo that in both countries the diſeaſe ſhows itſelf about the age of puberty. I do not believe this diſeaſe has ever been removed, though a mercurial courſe ſeemed to check its progreſs, but did not prevent its advance after intermitting the uſe of mercury. An attention to the primary cauſe will firſt lead to a proper method of treating the diſeaſe; a change of ſituation for a ſhort while, at that particular period when it appears, might be the means of preventing it.

The venereal diſeaſe is not uncommon in Tibet; and what will perhaps ſurprize the phyſician, the inhabitants are acquainted with the effects of mercury, and with a method of preparing it ſo as to render it a ſafe and efficacious remedy. They know how to deprive it of its metallic form by mixing it with alum, nitre, and vermilion, and expoſing it to a certain degree of heat, which they judge of by weighing the fuel.

The language ſpoken in Tibet is different from that of the Tartars. The aſtronomers are acquainted with the motion of the heavenly bodies, and able to calculate eclipſes: but the lamas are generally ignorant; few of them can read, much leſs underſtand their ancient books.

TIBULLUS (Aulus Albius), a Roman knight, and a celebrated Latin poet, was born at Rome 43 B. C. He was the friend of Horace, Ovid, Macer, and other great men in the reign of Auguſtus. He accompanied Meſſala Corvinus in his expedition againſt the iſland of Corcyra: but falling ſick, and being unable to ſupport the fatigues of war on account of the weakneſs of his conſtitution, he quitted the profeſſion of arms, and returned to Rome, where he died before the year 17; when Ovid ſhowed his grief for his death by writing a fine elegy upon him. Tibullus wrote four books of elegies, which are ſtill extant: they are written in a tender and agreeable ſtyle, and in very elegant Latin. Muret and Joſeph Scaliger have written learned and curious commentaries on the works of this poet. The beſt edition of Tibullus is that of Janus Broukhuſius, publiſhed at Amſterdam in 1708, in one volume quarto. We have an Engliſh poetical verſion by Mr Grainger.

Tibur ‖ Tide

TIBUR (anc. geog.) a town of Latium, pleaſantly ſituated on the Anio. Here Horace had his villa and houſe; and here he wiſhed to end his days. Here Adrian built an extraordinary villa called *Tiburtina*, inſcribed with the names of the provinces and of the moſt conſiderable places, (Spartian); near which Zenobia had a houſe called *Zenobia*, (Trebellius, Pollio). Hither Auguſtus often retreated on account of its ſalubrity, (Suetonius): for which it is greatly commended, (Martial). Anciently, when the Romans had far extended their territory, it was the utmoſt place of baniſhment, (Ovid). It had a temple of Hercules; and therefore called *Herculeum*. In the temple was a library, (A. Gellius). Now *Tivoli* in the Campagna di Roma on the Teverone.

TICINUS, (anc. geog.) a river in Inſubria, riſing in mount Adula, traverſing the Lacus Verbanus ſouthwards, and falling into the Po near Ticinum. Between this river and the Po Hannibal gained his firſt victory over the Romans under P. Scipio. The general himſelf eſcaped with the utmoſt difficulty, and that by the bravery of his ſon the firſt Scipio Africanus. Now the *Teſino*, riſing in mount Godard, running ſouth through the Lago Maggiore and Milan, by Pavia, into the Po.

TICK, in zoology. See ACARUS.

TICKELL (Thomas), an excellent Engliſh poet, was the ſon of the Reverend Richard Tickell, and was born in 1686, at Bridekirk in Cumberland. He was educated at Queen's college, Oxford, of which he was made fellow; and while he continued at that univerſity, he addreſſed to Mr Addiſon a complimentary copy of verſes on his Opera of Roſamond, which introduced him to an acquaintance with that gentleman, who diſcovering his merit, became his ſincere friend. On Mr Addiſon's being made ſecretary of ſtate, he appointed Mr Tickell his under ſecretary; and on his being obliged to reſign that office on account of his ill health, he recommended him ſo effectually to Mr Craggs his ſucceſſor, that he was continued in his poſt till that gentleman's death. In 1724 Mr Tickell was appointed ſecretary to the lords juſtices in Ireland, and enjoyed that place as long as he lived. He wrote ſome poems, which, when ſeparately publiſhed, met with a favourable reception, and paſſed through ſeveral editions: they are now printed in the ſecond volume of The Minor Poets. After Mr Addiſon's death Mr Tickell had the care of the edition of his works printed in 4 vols 4to; to which he prefixed an account of Mr Addiſon's life, and a poem on his death. Mr Tickell died in the year 1740.

TICKERA, a conſiderable article of merchandiſe in Fezzan in Africa; it is valued by travellers as a portable and highly ſalubrious food. It is a preparation of pounded dates, and the meal of Indian corn, formed into a paſte, and highly dried in an oven.

TICKSEED, SUN-FLOWER. See COREOPSIS.

TICUNAS. See POISON, p. 266.

TIDE, is a word which expreſſes that riſing and falling of the waters which are obſerved on all maritime coaſts.

There is a certain depth of the waters of the ocean which would obtain if all were at reſt: but obſervation ſhows that they are continually varying from this level, and that ſome of theſe variations are regular and periodical.

1ſt, It is obſerved, that on the ſhores of the ocean, and in bays, creeks, and harbours, which communicate freely with the ocean, the waters riſe up above this mean height twice a day, and as often ſink below it, forming what is called a FLOOD and an EBB, a HIGH and a LOW WATER. The whole interval between high and low water is called a TIDE;

Tides. the water is said to FLOW and to EBB; and the rising is called the FLOOD-TIDE, and the falling is called the EBB-TIDE.

2*d*, It is observed that this rise and fall of the waters is variable in quantity. At Plymouth, for instance, it is sometimes 21 feet between the greatest and least depth of the water in one day, and sometimes only 12 feet.

These different heights of tide are observed to succeed each other in a regular series, diminishing from the greatest to the least, and then increasing from the least to the greatest. The greatest is called a SPRING TIDE, and the least is called a NEAP TIDE.

3*d*, This series is completed in about 15 days. More careful observation shows the two series are completed in the exact time of a lunation. For the spring tide in any place is observed to happen precisely at a certain interval of time (generally between two and three days) after new or full moon, and the neap tide at a certain interval after half moon; or, more accurately speaking, it is observed that the spring tide always happens when the moon has got a certain number of degrees eastward of the line of conjunction and opposition, and the neap tide happens when she is a certain number of degrees from her first or last quadrature. Thus the whole series of tides appears to be regulated by the moon.

4*th*, It is observed that high water happens at new and full moon when the moon has a certain determined position with respect to the meridian of the place of observation, preceding or following the moon's southing a certain interval of time; which is constant with respect to that place, but very different in different places.

5*th*, The time of high water in any place appears to be regulated by the moon; for the interval between the time of high water and the moon's southing never changes above three quarters of an hour, whereas the interval between the time of high water and noon changes six hours in the course of a fortnight.

6*th*, The interval between two succeeding high waters is variable. It is least of all about new and full moon, and greatest when the moon is in her quadratures. As two high waters happen every day, we may call the double of their interval a TIDE DAY, as we call the diurnal revolution of the moon a *lunar day*. The tide day is shortest about new and full moon, being then about $24^h\ 37'$; about the time of the moon's quadratures it is $25^h\ 27'$. These values are taken from a mean of many observations made at Barbadoes by Dr Maskelyne.

7*th*, The tides in similar circumstances are greatest when the moon is at her smallest distance from the earth, or in her perigee, and gradually diminishing, are smallest when she is in her apogee.

8*th*, The same remark is made with respect to the sun's distance, and the greatest tides are observed during the winter months of Europe.

9*th*, The tides in any part of the ocean increase as the moon, by changing her declination, approaches the zenith of that place.

10*th*, The tides which happen while the moon is above the horizon are greater than the tides of the same day when the moon is below the horizon.

Such are the regular phenomena of the tides. They are important to all commercial nations, and have therefore been much attended to. It is of the tides, in all probability, that the Bible speaks, when God is said to set bounds to the sea, and to say "this far shall it go, and no farther."

Homer is the earliest profane author who speaks of the tides. Indeed it is not very clear that it is of them that he speaks (in the XIIth book of the Odyssey) when he speaks of Charybdis, which rises and retires thrice in every day. Herodotus and Diodorus Siculus speak more distinctly of the tides in the Red sea. Pytheas of Marseilles is the first who says any thing of their cause. According to Strabo he had been in Britain, where he must have observed the tides of the ocean. Plutarch says expressly that Pytheas ascribed them to the moon. It is somewhat wonderful that Aristotle says so little about the tides. The army of Alexander, his pupil, were startled at their first appearance to them near the Persian Gulph; and we should have thought that Aristotle would be well informed of all that had been observed there. But there are only three passages concerning them in all Aristotle's writings, and they are very trivial. In one place he speaks of great tides observed in the north of Europe; in another he mentions their having been ascribed by some to the moon; and in a third, he says, that the tide in a great sea exceeds that in a small one. Tides.

The Greeks had little opportunity of observing the tides. The conquests and the commerce of the Romans gave them more acquaintance with them. Cæsar speaks of them in the 4th book of his Gallic war. Strabo, after Posidonius, classes the phenomena into daily, monthly, and annual. He observes, that the sea rises as the moon gets near the meridian, whether above or below the horizon, and falls again as she rises or falls; also, that the tides increase at the time of new and full moon, and are greatest at the summer solstice. Pliny explains the phenomena at some length; and says, that both the sun and moon are their cause, dragging the waters along with them (B. II. c. 97). Seneca (*Nat. Quest.* III. 28.) speaks of the tides with correctness; and Macrobius (*Somn. Scip.* I. 6.) gives a very accurate description of their motions.

It is impossible that such phenomena should not exercise human curiosity as to their cause. Plutarch (*Plaut. Phil.* III. 17,) Galileo (*Syst. Mund.* Dial. 4.), Riccioli in his *Almagest*, ii. p. 374, and Gassendi, ii. p. 27, have collected most of the notions of their predecessors on the subject; but they are of so little importance, that they do not deserve our notice. Kepler speaks more like a philosopher (*De Stella Martis*, and *Epit. Astron.* p. 555). He says that all bodies attract each other, and that the waters of the ocean would all go to the moon were they not retained by the attraction of the earth; and then goes on to explain their elevation under the moon and on the opposite side, because the earth is less attracted by the moon than the nearer waters, but more than the waters which are more remote.

The honour of a complete explanation of the tides was reserved for Sir Isaac Newton. He laid hold of this class of phenomena as the most incontestible proof of universal gravitation, and has given a most beautiful and synoptical view of the whole subject; contenting himself, however, with merely exhibiting the chief consequences of the general principle, and applying it to the phenomena with singular address. But the wide steps taken by this great philosopher in his investigation leave ordinary readers frequently at fault: many of his assumptions require the greatest mathematical knowledge to satisfy us of their truth. The academy of Paris therefore proposed to illustrate this among other parts of the principles of natural philosophy, and published the theory of the tides as a prize problem. This produced three excellent dissertations, by M'Laurin, Dan. Bernoulli, and Euler. Aided by these, and chiefly by the second, we shall here give a physical theory, and accommodate it to the purposes of navigation, by giving the rules of calculation. We have demonstrated in our dissertations on the physical principles of the celestial motions, that it is an unexcepted fact, that every particle of matter in the solar system is actually deflected toward every other particle; and

that

Tide. that the deflection of a particle of matter toward any diſtant ſphere is proportional to the quantity of matter in that ſphere directly, and to the ſquare of the diſtance of the particle from the centre of that ſphere inverſely: and having found that the heavineſs of a piece of terreſtial matter is nothing but the ſuppoſed opponent to the force which we exert in carrying this piece of matter, we conceive it is poſſeſſing a property, that is, diſtinguiſhing quality, manifeſted by its being *gravis* or heavy. This is heavineſs, *gravitas*, gravity; and the manifeſtation of this quality, or the event in which it is ſeen, whether it be directly falling, or deflecting in a parabolic curve, or ſtretching a coiled ſpring, or breaking a rope, or ſimply preſſing on its ſupport, is *gravitatio*, gravitation; and the body is ſaid to gravitate. When all obſtacles are removed from the body, as when we cut the ſtring by which a ſtone is hung, it moves directly downwards, *tendit ad terram. Si diſcindatur funis, tenderet lapis ad terram. Dum vero funis integer perſtet, lapis terram verſus niti cenſetur.* By ſome metaphyſical proceſs, which it is needleſs at preſent to trace, this *niſus ad motum* has been called a *tendency* in our language. Indeed the word has now come to ſignify the energy of any active quality in thoſe caſes where its ſimpleſt and moſt immediate manifeſtation is prevented by ſome obſtacle. The ſtone is now ſaid to tend toward the earth, though it does not actually approach it, being withheld by the ſtring. The ſtretching the ſtring in a direction perpendicular to the horizon is conceived as a full manifeſtation of this tendency. This tendency, this inergy of its heavineſs, is therefore named by the word which diſtinguiſhes the quality; and it is called *gravitation*, and it is ſaid to *gravitate*.

But Sir Iſaac Newton diſcovered that this deflection of a heavy body differs in no reſpect from that general deflection obſerved in all the bodies of the ſolar ſyſtem. For 16 feet, which is the deflection of a ſtone in one ſecond, has the very ſame proportion to $\frac{1}{19}$th of an inch, which is the ſimultaneous deflection of the moon, that the ſquare of the moon's diſtance from the centre of the earth has to the ſquare of the ſtone's diſtance from it, namely, that of 3600 to 1.

Thus we are enabled to compare all the effects of the mutual tendencies of the heavenly bodies with the tendency of gravity, whoſe effects and meaſures are familiar to us.

If the earth were a ſphere covered to a great depth with water, the water would form a concentric ſpherical ſhell; for the gravitation of every particle of its ſurface would then be directed to the centre, and would be equal. The curvature of its ſurface therefore would be every where the ſame, that is, it would be the uniform curvature of a ſphere.

Plate DIX.

It has been demonſtrated in former articles, after Sir Iſaac Newton, that the gravitation of a particle C (fig. 1.) to the centre O, is to that of a particle E at the ſurface as CO to EO. In like manner the gravitation of *o* is to that of *p* as *o* O to *p* O. If therefore EO and O *p* are two communicating canals, of equal lengths, the water in both would be in equilibrio, becauſe each column would exert the ſame total preſſure at O. But if the gravitation of each particle in *p* O be diminiſhed by a certain proportion, ſuch as $\frac{1}{100}$th of its whole weight, it is plain that the total preſſure of the column *p* O will be $\frac{1}{100}$th part leſs than that of the column EO. Therefore they will no longer be in equilibrio. The weight of the column EO will prevail; and if a hollow tower P *p* be built at the mouth of the pit *p o*, the water will ſink in EO and riſe in O *p*, till both are again in equilibrio, exerting equal total preſſures at O. Or we may prevent the ſinking at E by pouring in more water into the tower P *p*. The ſame thing muſt happen in the canal *f c* perpendicular to EO, if the gravitation of every particle be diminiſhed by a force acting in the direction CF, and proportional to the diſtance of the particle from C, and ſuch, that when *c* C is equal to *o* O, the force acting on *c* is equal to the force acting on *o*. In order that the former equilibrium may be reſtored after this diminution of the gravitation of the column *f* C, it is plain that more water muſt be poured into the oblique tower F*f*. All this is evident when we conſider the matter hydroſtatically. The gravitation of the particle *c* may be repreſented by *o* O; but the diminution of the preſſure occaſioned by this at O is repreſented by C*c*. Tide.

Hence we can collect this much, that the whole diminution of preſſure at C is to the whole diminution of preſſure at O as the ſum of all the lines *c* C to the ſum of all the lines *o* O, that is, as $f C^2$ to $p O^2$. But the weight of the ſmall quantity of water added in each tower is diminiſhed in the ſame proportion; therefore the quantity added at F*f* muſt be to the quantity added at P *p* as *f* C to *p* O. Therefore we muſt have $F f : P p = f C : p O$, and the points F, F, P, muſt be in the circumference of an ellipſe, of which PO and EO are the tranſverſe and conjugate ſemiaxes.

What we have here ſuppoſed concerning the diminution of gravity in theſe canals is a thing which really obtains in nature. It was demonſtrated, when treating of the *Precession of the Equinoxes*, that if the ſun or moon lie in the direction OP, at a very great diſtance, there reſults from the unequal gravitation of the different particles of the earth a diminution of the gravity of each particle; which diminution is in a direction parallel to OP, and proportional to the diſtance of the particle from a plain paſſige through the centre of the earth at right angles to the line OP.

Thus it happens that the waters of the ocean have their equilibrium diſturbed by the unequal gravitation of their different particles to the ſun or to the moon; and this equilibrium cannot be reſtored till the waters come in from all hands, and riſe up around the line joining the centres of the earth and of the luminary. The ſpherical ocean muſt acquire the form of a prolate ſpheroid generated by the revolution of an ellipſe round its tranſverſe axis. The waters will be higheſt in that place which has the luminary in its zenith, and in the antipodes to that place; and they will be moſt depreſſed in all thoſe places which have the luminary in their horizon. P and P′ will be the poles, and EOQ will be the equator of this prolate ſpheroid.

Mr Ferguſon, in his Aſtronomy, aſſigns another cauſe of this arrangement, *viz.* the difference of the centrifugal forces of the different particles of water, while the earth is turning round the common centre of gravity of the earth and moon. This, however, is a miſtake. It would be juſt if the earth and moon were attached to the ends of a rod, and the earth kept always the ſame face towards the moon.

It is evident that the accumulation at P and P′, and the depreſſion at the equator, muſt augment and diminiſh in the ſame proportion with the diſturbing force. It is alſo evident that its abſolute quantity may be diſcovered by our knowledge of the proportion of the diſturbing force to the force of gravity.—Now this proportion is known; for the proportion of the gravitation of the earth's centre to the ſun or moon, to the force of gravity at the earth's ſurface, is known; and the proportion of the gravitation of the earth's centre to the luminary, to the difference of the gravitations of the centre and of the ſurface, is alſo known, being very nearly the proportion of the diſtance of the luminary to twice the radius of the earth.

Although this reaſoning, by which we have aſcertained the ellipical form of the watery ſpheroid, be ſufficiently convincing, it is very imperfect, being accommodated to one condition only of equilibrium, *viz.* the equilibrium of the

Tide. canals $f c$ and $c o$. There are ſeveral other conditions equally neceſſary to which this lax reaſoning will not apply, ſuch as the direction of the whole remaining gravitation in any point F. This muſt be perpendicular to the ſurface, &c. &c. Nor will this mode of inveſtigation aſcertain the eccentricity of the ſpheroid without a moſt intricate proceſs. We muſt therefore take the ſubject more generally, and ſhow the proportion and directions of gravity in every point of the ſpheroid. We need not, however, again demonſtrate that the gravitation of a particle placed any where without a perfect ſpherical ſhell, or a ſphere conſiſting of concentric ſpherical ſhells, either of uniform denſity, or of denſities varying according to ſome function of the radius, is the ſame as if the whole matter of the ſhell or ſphere were collected in the centre. This has been demonſtrated in the article ASTRONOMY. We need only remind the reader of ſome conſequences of this theorem which are of continual uſe in the preſent inveſtigation.

1*ſt*, The gravitation to a ſphere is proportional to its quantity of matter directly, and to the ſquare of the diſtance of its centre from the gravitating particle inverſely.

2*d*, If the ſpheres be homogeneous and of the ſame denſity, the gravitations of particles placed on their ſurfaces, or at diſtances which are proportional to their diameters, are as the radii; for the quantities of matter are as the cubes of the radii, and the attractions are inverſely as the ſquares of the radii; and therefore the whole gravitations are as $\frac{r^3}{r^2}$, or as r.

3*d*, A particle placed within a ſphere has no tendency to the matter of the ſhell which lies without it, becauſe its tendency to any part is balanced by an oppoſite tendency to the oppoſite part. Therefore,

4*th*, A particle placed any where *within* a homogeneous ſphere gravitates to its centre with a force proportional to its diſtance from it.

It is a much more difficult problem to determine the gravitation of particles to a ſpheroid. To do this in general terms, and for every ſituation of the particle, would require a train of propoſitions which our limits will by no means admit; we muſt content ourſelves with as much as is neceſſary for merely aſcertaining the ratio of the axes. This will be obtained by knowing the ratio of the gravitation at the pole to that at the equator. Therefore

Let N m S q N (fig. 2) be a ſection through the axis of an oblate homogeneous ſpheroid, which differs very little from a ſphere. NS is the axis, $m q$ is the equatorial diameter, O is the centre, and NMSQ is the ſection of the inſcribed ſphere. Let P be a particle ſituated at any diſtance without the ſphere in its axis produced; it is required to determine the gravitation of this particle to the whole matter of the ſpheroid?

Draw two lines PAC, PBD, very near to each other, cutting off two ſmall arches AB, CD; draw GA a, HB b, IC c, KD d, perpendicular to the axis; alſo draw OE and AL, perpendicular to PAC, and OF perpendicular to PD, cutting PC in f. Join OA.

Let OA, the radius of the inſcribed ſphere, be r, and OP the diſtance of the gravitating particle be d, and M m, the elevation of the equator of the ſpheroid, or the ellipticity, be e. Alſo make AE $= x$, and OE $= y$, $= \sqrt{r^2 - x^2}$. Then AE—BF $= \dot{x}$ and F$f = \dot{y}$, $= \frac{x\dot{x}}{\sqrt{r^2 - x^2}}$.

Suppoſe the whole figure to turn round the Axis OP. The little ſpace AB $b a$ will generate a ring of the redundant matter; ſo will CD $d c$. This ring may be conſidered as conſiſting of a number of thin rings generated by the revolution of A a. The ring generated by A a is equal to a parallelogram whoſe baſe is the circumference deſcribed by A, and whoſe height is A a. Therefore let c be the circumference of a circle whoſe radius is 1. The ring will be A $a \times c \times$ AG. But becauſe $m a$ N is an arch of an ellipſe, we have M m: A a = MO: AG $= r$: AG, and A $a =$ M $m \times \frac{AG}{r}$, $= \frac{e}{r}$ AG. Therefore the ſurface of this ring is $= c \frac{e}{r} AG^2$.

We have ſuppoſed the ſpheroid to be very nearly ſpherical, that is, e exceedingly ſmall in compariſon of r. This being the caſe, all the particles in A a, and conſequently all the particles in the ring generated by the revolution of A a, will attract the remote particle P with the ſame force that A does very nearly. We may ſay the ſame thing of the whole matter of the ring generated by the revolution of AB $b a$. This attraction is exerted in the direction PA by each individual particle. But every action of a particle A is accompanied by the action of a particle A′ in the direction PA′. Theſe two compoſe an attraction in the direction PO. The whole attraction in the direction ſimilar to PA is $= c \times \frac{e\ AG^2}{r\ PA^2} \times$ GH, for GH meaſures the number of parallel plates of which the ſolid ring is compoſed. This being decompoſed in the direction PG is $= c \times \frac{e}{r} \times \frac{AG^2 . PG}{PA^3} \times$ GH. But $\frac{AG^2}{PA^2} = \frac{OE^2}{PO^2}$, and $\frac{PG}{PA} = \frac{PE}{PO}$. Therefore the attraction of the ring, eſtimated in the direction PO, is $= c \times \frac{e}{r} \times \frac{OE^2 . PE}{PO^3} \times$ GH.

Farther, by the nature of the circle, we have HG: AB $=$ AG: AO; alſo AB: BL $=$ AO: OE. But PA: AG $=$ PO: OE, and OE $= \frac{AG \times PO}{PA}$. Therefore

AB: BL $=$ AO: $\frac{AG . PO}{PA}$, $=$ AO . PA: PO . AG

Alſo BL: LA $=$ EO: EA,

And LA: Ff $=$ PA: Pf, $=$ ultimately PA: PE. Therefore, by equality, HG: Ff $=$ AG . AO . PA . EO . PA: AO. PO. AG. EA. PE.

Or HG: Ff $=$ EO . PA^2: PO . EA . PE.

And HG $=$ F$f \times \frac{EO . PA^2}{PO . PE . EA}$.

Now ſubſtitute this value of HG in the formula expreſſing the attraction of the ring. This changes it to $c \frac{e}{r} \times \frac{OE^2 . PE}{PO^3} \times \frac{OE . PA^2}{PO . PE . EA} \times$ Ff, or $c \frac{e}{r} \times \frac{OE^3 . PA^2}{PO^4 . EA} \times$ Ff. In like manner, the attraction of the ring generated by the revolution of CD $d c$ is $c \frac{e}{r} \times \frac{OE^3 . PC^2}{PO^4 . EA} \times$ Ff. Therefore the attraction of both is $= c \frac{e}{r} \times$ F$f \times \frac{OE^3}{PO^4 . EA} \times \overline{PA^2 + PC^2}$, $= c \frac{e}{r} \times$ F$f \frac{y^3}{d^4 . x} \times \overline{PA^2 + PC^2}$. But PA^2 + PC^2 $=$ 2 PE^2 + 2 EA^2, $=$ 2 PE^2 + 2 x^2. Therefore the attraction is $2 c \frac{e}{r\ d^4} \times$ F$f \frac{y^3}{x} \times \overline{PE^2 + x^2}$. But F$f$ $= \dot{y}$, $= \frac{x}{y}\dot{x}$. Therefore F$f \frac{y^3}{x} = \frac{x}{y}\dot{x} \times \frac{y^3}{x}$, $= y^2\ \dot{x}$,

=

Tide. $= \overline{r^2 - x^2}\,\dot{x}$. Therefore the attraction of the two rings is $2c\frac{e}{r\,d^4} \times \overline{r^2-x^2} \times \overline{PE^2+x^2} \times \dot{x}$. But $PE^2 = PO^2 - OE^2$, $= d^2 - (r^2 - x^2) = d^2 - r^2 + x^2$. Therefore the attraction of the two rings is

$$2c\frac{e}{r\,d^4} \times \overline{r^2-x^2} \times \overline{d^2-r^2+2x^2}\,\dot{x}, = 2c\frac{e}{r\,d^4} \times$$

$$\overline{r^2 d^2 \dot{x} - r^4 \dot{x} + 2r^2 x^2 \dot{x} - d^2 x^2 \dot{x} + r^2 x^2 \dot{x} - 2x^4 \dot{x}} = 2c\frac{e}{r\,d^4}$$

$$\times \overline{r^2 d^2 \dot{x} + 3r^2 x^2 \dot{x} - r^4 \dot{x} - d^2 x^2 \dot{x} - 2x^4 \dot{x}}.$$

The attraction of the whole ſhell of redundant matter will be had by taking the fluent of this formula, which is

$$2c\frac{e}{r\,d^4} \times \left(r^2 d^2 x + \frac{3r^2 x^3}{3} - r^4 x - \frac{d^2 x^3}{3} - \frac{2x^5}{5}\right),$$

and then make $x = r$. This gives $2c\frac{e}{r\,d^4}\left(d^2 r^3 + r^5 - r^5 - \frac{1}{3} d^2 r^3 - \frac{2}{5} r^5\right)$, which is $= 2c\frac{e}{r\,d^4}\left(\frac{2}{3} d^2 r^3 - \frac{2}{5} r^5\right)$, $= \frac{4cer^2}{3d^2} - \frac{4r^4}{5d^4}$. To this add the attraction of the inſcribed ſphere, which is $\frac{1}{3}\frac{cr^3}{d^2}$, and we have the attraction of the whole ſpheroid

$$= \frac{1}{3}\frac{cr^3}{d^2} + \frac{4}{3}\frac{cer^2}{d^2} - \frac{4}{5}\frac{cer^4}{d^4}$$

Cor. 1. If the particle P is ſituated preciſely in N, the pole of the ſpheroid, the attraction of the ſpheroid, is $\frac{2}{3} cr + \frac{8}{15} ce$.

If the ſpheroid is not oblate, but oblong, and if the greater ſemiaxis be r, and the depreſſion at the equator be e, the analyſis is the ſame, taking e negatively. Therefore the attraction for a particle in the pole, or the gravitation of a particle in the pole, is $\frac{2}{3} cr - \frac{8}{15} ce$.

But if the polar ſemiaxis be $r + e$, and the equatorial radius be r, ſo that this oblong ſpheroid has the ſame axis with the former oblate one, the gravitation of a particle in the pole is $\frac{2}{3} cr + \frac{8}{15} ce$.

Cor. 2. If a number of parallel planes are drawn perpendicular to the equator of an oblong ſpheroid, whoſe longer ſemiaxis is $r + e$, and equatorial radius r, they will divide the ſpheroid into a number of ſimilar ellipſes; and ſince the ellipſe through the axis has $r + e$ and r for its two ſemiaxes, and the radius of a circle of equal area with this ellipſe is a mean proportional between r and $r + e$, and therefore very nearly $= r + \frac{1}{2} e$, when e is very ſmall in compariſon of r, a particle on the equator of the oblong ſpheroid will be as much attracted by theſe circles of equal areas, with their correſponding ellipſes, as by the ellipſes. Now the attraction at the pole of an oblate ſpheroid was $\frac{2}{3} cr + \frac{8}{15} ce$. Therefore putting $\frac{1}{2} e$ in place of e, the attraction on the equator of the oblong ſpheroid will be equal to $\frac{1}{3} cr + \frac{4}{15} ce$.

Thus we have aſcertained the gravitations of a particle ſituated in the pole, and of one ſituated in the equator, of a homogeneous oblong ſpheroid. This will enable us to ſolve the following problem:

If the particles of a homogeneous oblong fluid ſpheroid attract each other with a force inverſely as the ſquares of their diſtances, and if they are attracted by a very diſtant body by the ſame law, and if the ratio of the equatorial gravity to this external force be given; to find what muſt be the proportion of the ſemiaxes, ſo that all may be in equilibrio, and the ſpheroid preſerve its form?

Let r be the equatorial radius, and $r + e$ be the polar ſemiaxis. Then the gravitation at the pole m is $\frac{2}{3} cr + \frac{1}{15} ce$, and the gravitation at the equator is $\frac{1}{3} cr + \frac{4}{15} ce$. Now by the gravitation towards the diſtant body placed in the direction of the polar axis, the polar gravitation is diminiſhed, and the equatorial gravitation is increaſed; and the increaſe of the equatorial gravitation is to the diminution of the polar gravitation as NO to 2 m O. Therefore if the whole attraction of the oblong ſpheroid for a particle on its equator be to the force which the diſtant body exerts there, as G to P, and if the ſpheroid is very nearly ſpherical, the abſolute weight at the equator will be $\frac{2}{3} cr + \frac{4}{15} ce + \frac{1}{3} cr\frac{P}{G}$. And the abſolute weight at the pole will be $\frac{2}{3} cr + \frac{2}{15} ce - \frac{1}{3} cr\frac{2P}{G}$. Their difference is $\frac{1}{15} ce + 2cr\frac{P}{G}$.

Tide.

Now if we ſuppoſe this ſpheroid to be compoſed of ſimilar concentric ſhells, all the forces will decreaſe in the ſame ratio. Therefore the weight of a particle in a column reaching from the equator to the centre will be to the weight of a ſimilarly ſituated particle of a column reaching from the pole to the centre, as the weight of a particle at the equator to the weight of a particle at the pole. But the whole weights of the two columns muſt be equal, that they may balance each other at the centre. Their lengths muſt therefore be reciprocally as the weights of ſimilarly ſituated particles; that is, the polar ſemiaxis muſt be to the equatorial radius, as the weight of a particle at the equator to the weight of a particle at the pole. Therefore we muſt have $\frac{1}{15} ce + 2cr\frac{P}{G} : \frac{1}{3} cr + \frac{1}{15} ce - \frac{4}{3} cr\frac{P}{G} = e : r$.

Hence we derive $2r\frac{P}{G} = \frac{8}{15} e$, or $4\,G : 15\,P = r : e$. This determines the form of the fluid ſpheroid when the ratio of G to P is given.

It is well known that the gravitation of the moon to the earth is to the diſturbing force of the ſun as 178,725 to 1 very nearly. The lunar gravitation is increaſed as ſhe approaches the earth in the reciprocal duplicate ratio of the diſtances. The diſturbing force of the ſun diminiſhes in the ſimple ratio of the diſtances; therefore the weight of a body on the ſurface of the earth is to the diſturbing force of the ſun on the ſame body, in a ratio compounded of the ratio of 178,725 to 1, the ratio of 3600 to 1, and the ratio of 60 to 1; that is, in the ratio of 38604600 to 1. If the mean radius of the earth be 20934500 feet, the difference of the axis, or the elevation of the pole of the watery ſpheroid produced by the gravitation to the ſun, will be $\frac{15}{4} \times \frac{20934500}{38604600}$ feet, or very nearly 24 $\frac{1}{2}$ inches. This is the tide produced by the ſun on a homogeneous fluid ſphere.

It is plain, that if the earth conſiſts of a ſolid nucleus of the ſame denſity with the water, the form of the ſolar tide will be the ſame. But if the denſity of the nucleus be different, the form of the tide will be different, and will depend both on the denſity and on the figure of the nucleus.

If the nucleus be of the ſame form as the ſurrounding fluid, the whole will ſtill maintain its form with the ſame proportion of the axis. If the nucleus be ſpherical, its action on the ſurrounding fluid will be the ſame as if all the matter of the nucleus by which it exceeds an equal bulk of the fluid were collected at the centre. In this caſe, the ocean cannot maintain the ſame form: for the action of this central body being proportional to the ſquare of the diſtance inverſely, will augment the gravity of the equatorial fluid more than it augments that of the circumpolar fluid; and the ocean, which was in equilibrio (by ſuppoſition), muſt now become more protuberant at the poles. It may, however,

Tide. ever be again balanced in an elliptical form, when it has acquired a juſt proportion of the axes. The proceſs for determining this is tedious, but preciſely ſimilar to the preceding.

If the denſity of the nucleus exceed that of the fluid about $\frac{1}{5\frac{1}{2}}$, we ſhall have $r : e = G : 3P$, which is nearly the form which has been determined for the earth, by the menſuration of degrees of the meridian, and by the vibration of pendulums. The curious reader will do well to conſult the excellent diſſertations by Clairaut and Boſcovich on the Figure of the earth, where this curious problem is treated in the moſt complete manner. Mr Bernoulli, in his diſſertation on the Tides, has committed a great miſtake in this particular. On the other hand, if the nucleus be leſs denſe than the waters, or if there be a great central hollow, the elevation produced by the ſun will exceed $24\frac{1}{2}$ inches.

It is needleſs to examine this any farther. We have collected enough for explaining the chief affections of the tides.

It is known that the earth is not a ſphere, but ſwelled out at the equator by the diurnal rotation. But the change of form is ſo very ſmall in proportion to the whole bulk, that it cannot ſenſibly affect the change of form afterwards induced by the ſun on the waters of the ocean. For the diſturbing force of the ſun would produce a certain protuberance on a fluid ſphere; and this protuberance depends on the ratio of the diſturbing force to the force of gravity at the ſurface of this ſphere. If the gravity be changed in any proportion, the protuberance will change in the ſame proportion. Therefore if the body be a ſpheroid, the protuberance produced at any point by the ſun will increaſe or diminiſh in the ſame proportion that the gravity at this point has been changed by the change of form. Now the change of gravity, even at the pole of the terreſtrial ſpheroid, is extremely ſmall in compariſon with the whole gravity. Therefore the change produced on the ſpheroid will not ſenſibly differ from that produced on the ſphere; and the elevations of the waters above the ſurface, which they would have aſſumed independent of the ſun's action, will be the ſame on the ſpheroid as on the ſphere. For the ſame reaſon, the moon will change the ſurface already changed by the ſun, in the ſame manner as ſhe would have changed the ſurface of the undiſturbed ocean. Therefore the change produced by both theſe luminaries in any place will be the ſame when acting together as when acting ſeparately; and it will be equal to the ſum, or the difference of their ſeparate changes, according as theſe would have been in the ſame or in oppoſite directions.

Let us now conſider the moſt intereſting circumſtances of the form of an elliptical tide, which differs very little from a ſphere.

Let T (fig. 2.) be a point in the ſurface of the inſcribed ſphere, and let Z expreſs the angular diſtance TOQ from the longer axis of the ſurrounding ſpheroid $S\,m\,N\,q$. Let TR, TW be perpendicular to the equatorial diameter and to the axis, ſo that they are the coſine and the ſine of TOQ to the radius TO or QO. Let $S'\,q\,N'$ be a ſection of the circumſcribed ſphere. Draw OT cutting the ſpheroid in Z and the circumſcribed ſphere in t. Alſo let $s\,o\,n$ be a ſection of a ſphere which has the ſame capacity with the ſpheroid, and let it cut the radius in r. Then,

1. The elevation TZ of the point Z of the ſpheroid above the inſcribed ſphere is $= Q\,q \times \text{cof.}^2 Z$, and the depreſſion $t\,Z$ below the circumſcribed ſphere is $= Q\,q \times \text{ſine}^2\,Z$. Produce RT till it meet the ſurface of the ſpheroid in V. The minute triangle VTZ may be conſidered as a rectilineal, right-angled at Z, and therefore ſimilar to OTR. Therefore $OT : TR = TV : TZ$. But in the ellipſe OQ, or $OT : TR = Q\,q : TV$, Therefore $OT^2 : TR^2 = Q\,q : TZ$, and $TZ = \frac{Q\,q \cdot TR^2}{OT^2}$, $= Q\,q : \frac{Q\,q \times \text{cof.}^2 Z}{1} = Q\,q \times \text{cof.}^2 Z$. Tide.

And in the very ſame manner it may be ſhewn, that $t\,Z = Q\,q \times \text{ſin.}^2 Z$.

2. The elevation of the point T above another point T′ whoſe angular diſtance TOT′ from the point T is 90°, is $= Q\,q \times \overline{\text{cof.}^2 Z - \text{ſin.}^2 Z}$. Call the angle QOT′ Z'. Then $T'\,Z' = Q\,q \times \text{cof.}^2 Z'$, and $TZ - T',Z', = Q\,q \times \overline{\text{cof.}^2 Z - \text{cof.}^2 Z'}$. But the arch QT′ is the complement of QT, and therefore $\text{cof.}^2 Z' = \text{ſin.}^2 Z$. Therefore $TZ - T',Z' = Q\,q \times \overline{\text{cof.}^2 Z - \text{ſin.}^2 Z}$.

3. $Q\,o = \frac{1}{3}\,Q\,q$. For the inſcribed ſphere is to the ſpheroid as OQ to O q. But the inſcribed ſphere is to the ſphere $s\,o\,n$ as OQ^3 to $O\,o^3$. Therefore becauſe the ſphere $s\,o\,n$ is equal to the ſpheroid $S\,q\,N$, we have $OQ : O\,q = OQ^3 : O\,o^3$, and O o is the firſt of two mean proportionals between OQ and O q. But $Q\,q$ is very ſmall in compariſon with OQ. Therefore $Q\,o$ is very nearly $\frac{1}{3}$ of $Q\,q$.

Since $s\,o\,n$ is the ſphere of equal capacity, it is the form of the undiſturbed ocean. The beſt way therefore of conceiving the changes of form produced by the ſun or moon, or by both together, is to conſider the elevations or depreſſions which they produce above or below this ſurface. Therefore,

4. The elevation $r\,Z$ of the point Z above the equicapacious ſphere is evidently $= Q\,q \times \text{cof.}^2 Z - \frac{1}{3}\,Q\,q$. Alſo the depreſſion $r'\,Z'$ of the point Z′ is $= Q\,q \times \text{ſin.}^2 Z' - \frac{2}{3}\,Q\,q$.

N. B. Either of theſe formulæ will anſwer for either the elevation above, or the depreſſion below, the natural ocean: For if $\text{cof.}^2 Z$ is leſs than $\frac{1}{3}$, the elevation given by the formula will be negative; that is, the point is below the natural ſurface. In like manner, when $\text{ſin.}^2 Z'$ is leſs than $\frac{2}{3}$, the depreſſion is negative, and the point is above the ſurface. But if $\text{cof.}^2 Z$ be $= \frac{1}{3}$, or $\text{ſin.}^2 Z$ be $= \frac{2}{3}$, the point is in the natural ſurface. This marks the place where the ſpheroid and the equal ſphere interſect each other, viz. in P′, the arch P′ o being 54° 44′ very nearly, and PS = 35° 16′.

Let S repreſent the whole elevation of the pole of the ſolar tide above its equator, or the difference between high and low water produced by the ſun; and let M repreſent the whole elevation produced by the moon. Let x and y repreſent the zenith diſtances of the ſun and moon with reſpect to any point whatever on the ocean. Then x and y will be the arches intercepted between that point and the ſummits of the ſolar and lunar tides. Then the elevation produced by both luminaries in that plane is $S \cdot \text{cof.}^2 x - \frac{1}{3}S + M \cdot \text{cof.}^2 y - \frac{1}{3}M$; or, more conciſely, $S \cdot \text{cof.}^2 x + M \cdot \text{cof.}^2 y - \frac{1}{3}\overline{S + M}$, and the depreſſion is $S \cdot \text{ſin.}^2 x + M \cdot \text{ſin.}^2 y - \frac{1}{3}S + M$.

Let the ſun and moon be in the ſame point of the heavens. The ſolar and lunar tides will have the ſame axis; the coſines of x and y will each be 1, and the elevation at the compound pole will be $S + M - \frac{1}{3}\overline{S + M} = \frac{2}{3}\overline{S + M}$. The depreſſion at any point 90° from this pole will be $\frac{1}{3}\overline{S + M}$, and the whole tide is $S + M$.

Let the moon be in quadrature, as in a (fig. 3). The appearance at s will be known, by conſidering that in this place the coſine of x is 1, and the coſine of y is 0. Therefore the elevation at $s = S - \frac{1}{3}\overline{S + M}$, $= \frac{2}{3}\,S - \frac{1}{3}\,M$. The depreſſion at $a = S - \frac{2}{3}\overline{S + M} = \frac{1}{3}\,S - \frac{2}{3}\,M$. The difference or whole tide $= \overline{S - M}$.

In

Tide. In like manner, the whole elevation at *a* above the inſcribed ſphere is M — S.

Hence we ſee that the whole tide, when the moon is in quadrature, is the difference of S and M. We alſo ſee, that if M exceeds S, the water will be higher at *a* than at *s*. Now it is a matter of obſervation, that in the quadratures it is high water under the moon, and low water under the ſun. It is alſo a matter of obſervation, that in the free ocean, the ebb tide, or the water at *s*, immediately under the ſun, is below the natural ſurface of the ocean. Hence we muſt conclude, that $\frac{2}{3}$ S is leſs than $\frac{1}{3}$ M, or that M is more than double of S. This agrees with the phenomena of nutation and preceſſion, which ſeem to make S = $\frac{2}{5}$ of M.

In all other poſitions of the ſun and moon, the place of high water will be different. It is high water where the ſum of the elevations produced by both luminaries above the natural ocean is greateſt; and the place of low water is where the depreſſion below the natural ocean is greateſt. Therefore, in order that it may be high water, we muſt have S · cof.^{2} *x* + M · cof.^{2} *y* — $\frac{1}{3}$ S + M a maximum; or, neglecting the conſtant quantity $\frac{S + M}{3}$, we muſt have S · cof.^{2} *x* + M · cof.^{2} *y* a maximum.

In like manner, to have low water in a place where the zenith diſtances of the ſun and moon are *v* and *w*, we muſt have S · ſin.^{2} *v* + M · ſin.^{2} *w* a maximum.

Lemma 1. If we conſider the ſines and coſines of angles as numeral fractions of the radius 1, then we have cof.^{2} Z = $\frac{1}{2}$ + $\frac{1}{2}$ cof.^{2} Z, and ſin.^{2} Z = $\frac{1}{2}$ — $\frac{1}{2}$ cof. Z.

Let *a m s* (fig. 3.) be a quadrant of a circle of which O is the centre, and O *s* is the radius. On O *s* deſcribe the ſemicircle OMS, cutting O *m* in M. Draw *s* M, and produce it till it cut the quadrant in *n*. Alſo draw MC to the centre of the ſemicircle, and MD and *n d* perpendicular to O *s*.

It is plain that *s* M is perpendicular to OM; and if O *s* be radius, *s* M is the ſine of the angle *s* OM, which we may call Z; OM is its coſine; and becauſe O *s*: OM = OM: OD, and O *s*: OD = O *s*^{2}: OM^2, and OD may repreſent cof.^{2} Z. Now OD = OC + CD. If O *s* = 1, then OC = $\frac{1}{2}$. CD = CM · cof. MCD, = CM · cof. 2 MOD, = $\frac{1}{2}$ · cof. 2 Z. Therefore cof.^{2} Z = $\frac{1}{2}$ + $\frac{1}{2}$ cof. 2 Z.

In like manner, becauſe O *s*: *s* M = *s* M: *s* D, *s* D is = ſin.^{2} Z. This is evidently = $\frac{1}{2}$ — $\frac{1}{2}$ cof. 2 Z.

Lemma 2. Cof.^{2} Z — ſin.^{2} Z = cof. 2 Z. For, becauſe *s* M is perpendicular to OM, the arch *s n* is double of the arch *s m*, and becauſe MD is parallel to *n d*, *s d* is = 2 *s* D, and *d* D = ſin.^{2} Z. Therefore O *d* = cof.^{2} Z — ſin.^{2} Z. But O *d* is the coſine of *n s*, = cof. 2Z, and cof.^{2} Z, — ſin.^{2} Z = cof. 2Z.

By the firſt Lemma we ſee, that in order that there may be high water at any place, when the zenith diſtances of the ſun and moon are *x* and *y*, we muſt have S · cof. 2 *x* + M · cof. 2 *y* a maximum.

That this may be the caſe, the fluxion of this formula muſt be = 0. Now we know that the fluxions of the coſines of two arches are as the ſines of thoſe arches. Therefore we muſt have S · ſin. 2 *x* + M · ſin. 2 *y* = 0, or S · ſin. 2 *x* = — M · ſin. 2 *y*, which gives us ſin. 2 *x*: ſin. 2 *y* = M: S.

In like manner, the place of low water requires ſin. 2 *v*: ſin. 2 *w* = M: S.

From this laſt circumſtance we learn, that the place of low water is 0, removed 90° from the place of high water; whereas we might have expected, that the ſpheroid would have been moſt protuberant on that ſide on which the moon is: For the ſines of 2 *v* and of 2 *w* have the ſame proportion with the ſines of 2 *x* and of 2 *y*. Now we know that the ſine of the double of any arch is the ſame with the ſine of the double of its complement. Therefore if low water be really diſtant 90° from high water, we ſhall have ſin. 2 *x*: ſin. 2 *y* = ſin. 2 *v*: ſin. 2 *w*. But if it is at any other place, the ſines cannot have this proportion. Tide.

Now let *s* be the point of the earth's ſurface which has the ſun in the zenith, and *m* the point which has the moon in the zenith. Let *h* be any other point. Draw O *h* cutting the ſemicircle OM *s* in H. Make CM to CS as the diſturbing force of the moon to that of the ſun; and draw S *v* parallel, and S *t*, M *r* perpendicular to HH'. Join MH and MH'. The angle H C *s* is double of the angle HO*s*, and MCH is double of MH'H, or of its equal MOH. Becauſe H'MH is a ſemicircle, HM is perpendicular to MO. Therefore if HH' be conſidered as radius, HM is the ſine, and H'M is the coſine of MH'H. And C *r* is = MC · cof. 2 *y*, = M · cof. 2 *y*. And C *t* is SC · cof. 2 *x*. Therefore *t r* or S' *v* is = S · cof. 2 *x* + M · cof. 2 *y*. Therefore *t r* or S *v* will expreſs the whole difference of elevation between *h* and the points that are 90 degrees from it on either ſide (by *Lemma* 2.); and if *h* be the place of high water, it will expreſs the whole tide, becauſe the high and low waters were ſhown to be 90° aſunder. But when *h* is the place of high water, S *v* is a maximum. Becauſe the place of the moon, and therefore the point M, is given, S *v* will be a maximum when it coincides with SM, and CH is parallel to SM.

This ſuggeſted to us the following new, and not inelegant, ſolution of the problem for determining the place of high water.

Let *s* Q *o q s* (fig. 4. and 5.) be a ſection of the terraqueous globe, by a plane paſſing through the ſun and moon, and let O be its centre. Let *s* be the point which is immediately under the ſun, and *m* the place immediately under the moon. Biſect O *s* in C, and deſcribe round C the circle OM *s* LO, cutting O *m* in M. Take C *s* to repreſent the diſturbing force of the moon, and make C *s* to CS as the force of the moon to that of the ſun (ſuppoſing this ratio to be known). Join MS, and draw CH parallel to it. Draw OH *h*, and *l* OL *l* perpendicular to it. And laſtly, draw CI perpendicular to SM. Then we ſay that *m* and its oppoſite *m'* are the places of high water, *l* and *l'* are the places of low water, MS is the height of the tide, and MI, SI are the portion of this tide produced by the moon and ſun.

For it is plain, that in this caſe the line S *v* of the laſt propoſition coincides with MS, and is a maximum. We may alſo obſerve, that MC: CS = ſin. MSC: ſin. SMC, = ſin. HCS: ſin. MCH, = ſin. 2 *h* O *s*: ſin. 2 *h* O *m*, = ſin. 2 *x*: ſin. 2 *y*, or M: S = ſin. 2 *x*: ſin. 2 *y*, agreeably to what was required for the maximum.

It is alſo evident, that MI = MC · cof. CMI, = M · cof. 2 *y*, and SI = SC · cof. ISC, = S · cof. 2 *x*; and therefore MS is the difference of elevation between *h* and the points *l* and *l'*, which are 90° from it, and is therefore the place of low water; that is, MS is the whole tide.

The elevation of every other point may be determined in the ſame way, and thus may the form of the ſpheroid be completely determined.

If we ſuppoſe the figure to repreſent a ſection through the earth's equator (which is the caſe when the ſun and moon are in the equator), and farther ſuppoſe the two luminaries to be in conjunction, the ocean is an oblong ſpheroid, whoſe axis is in the line of the ſyzigies, and whoſe equator coincides with the ſix hour circle. But if the moon be in any other point of the equator, the figure of the ocean will be very complicated. It will not be any figure of revolution; becauſe neither its equator (or moſt depreſſed

part)

Tide. part), nor its meridians, are circles. The moſt depreſſed part of its equator will be in that ſection through the axis which is perpendicular to the plane in which the luminaries are ſituated. And this greateſt depreſſion, and its ſhorteſt equatorial diameter, will be conſtant, while its other dimenſions vary with the moon's place. We need not inquire more minutely into its form; and it is ſufficient to know, that all the ſections perpendicular to the plane paſſing thro' the ſun and moon are ellipſes.

This conſtruction will afford us a very ſimple, and, we hope, a very perſpicuous explanation of the chief phenomena of the tides. The well informed reader will be pleaſed with obſerving its coincidence with the algebraic ſolution of the problem given by Daniel Bernoulli, in his excellent diſſertation on the Tides, which ſhared with M'Laurin and Euler the prize given by the Academy of Sciences at Paris, and with the eaſe and perſpicuity with which the phenomena are deducible from it, being in ſome ſort exhibited to the eye.

In our application, we ſhall begin with the ſimpleſt caſes, and gradually introduce the complicating circumſtances which accommodate the theory to the true ſtate of things.

We begin, therefore, by ſuppoſing the earth covered, to a proper depth, with water, forming an ocean concentric with its ſolid nucleus.

In the next place, we ſuppoſe that this ocean adopts in an inſtant the form which is conſiſtent with the equilibrium of gravity and the diſturbing forces.

Thirdly, We ſuppoſe the ſun ſtationary, and the moon to move eaſtward from him above $12\frac{1}{2}°$ every day.

Fourthly, We ſuppoſe that the ſolid nucleus turns round its proper axis to the eaſtward, making a rotation in 24 ſolar hours. Thus any place of obſervation will ſucceſſively experience all the different depths of water.

Thus we ſhall obtain a certain Succession of phenomena, preciſely ſimilar to the ſucceſſion obſerved in nature, with this ſole difference, that they do not correſpond to the contemporaneous ſituations of the ſun and moon. When we ſhall have accounted for this difference, we ſhall preſume to think that we have given a juſt theory of the tides.

We begin with the ſimpleſt caſe, ſuppoſing the ſun and moon to be always in the equator. Let the ſeries begin with the ſun and moon in conjunction in the line O *s*. In this caſe the points *s*, *m*, and *h* coincide, and we have high water at 12 o'clock noon and midnight.

While the moon moves from *s* to Q, O *m* cuts the upper ſemicircle in M; and therefore CH, which is always parallel to MS, lies between MC and C *s*. Therefore *h* is between *m* and *s*, and we have high water after 12 o'clock, but before the moon's ſouthing. The ſame thing happens while the moon moves from *o* to *q*, during her third quarter.

But while the moon moves from her firſt quadrature in Q to oppoſition in *o* (as in fig. 5.), the line *m* O drawn from the moon's place, cuts the lower ſemicircle in M and CH, parallel to SM, again lies between M and *s*, and therefore *h* lies between *m* and *o*. The place of high water is to the eaſtward of the moon, and we have high water after the moon's ſouthing. The ſame thing happens while the moon is moving from her laſt quadrature in *q* to the next ſyzigy. In ſhort, the point H is always between M and *s*, and the place of high water is always between the moon and the *neareſt* ſyzigy. The place of high water overtakes the moon in each quadrature, and is overtaken by the moon in each ſyzigy. Therefore during the firſt and third quarters, the place of high water gradually falls behind the moon for ſome time, and then gains upon her again, ſo as to overtake her in the next quadrature. But during the ſecond and fourth quarters, the place of high water advances before the moon to a certain diſtance, and then the moon gains upon it, and overtakes it in the next ſyzigy. Tide.

If therefore we ſuppoſe the moon to advance uniformly along the equator, the place of high water moves unequally, ſloweſt in the times of new and full moon, and ſwifteſt in the time of the quadratures. There muſt be ſome intermediate ſituations where the place of high water neither gains nor loſes upon the moon, but moves with the ſame velocity.

The rate of motion of the point *h* may be determined as follows: Draw C *i*, S *n*, making very ſmall and equal angles with HC and MS. Draw *n* C, and about S, with the diſtance S *n*, deſcribe the arch *n v*, which may be conſidered as a ſtraight line perpendicular to *n* S, or to MS.

Then, becauſe SM and S *n* are parallel to CH and C *i*, the points *n* and *i* are contemporaneous ſituations of M and H, and the arches *n* M, *i* H, are in the ratio of the angular motions of *m* and *h*. Alſo, becauſe *n v* and *n* M are perpendicular to *n* S and *n* C, the angle *v n* M is equal to the angle S *n* C, or SMC. Alſo, becauſe the angles *n v* M and MIC are right angles, and the angles *v n* M, CMI, are alſo equal, the triangles *v n* M, CMI, are ſimilar. Therefore

n M : *n v* = MC : MI. And

n v : *i*H = *n* S : *i* C, or = MS : MC; therefore

n M : *i*H = MS : MI. Therefore the angular motion of the moon is to the angular motion of the place of high water as MS to MI.

Therefore, when M'S is perpendicular to SC, and the point I coincides with S, the motion of high water is equal to that of the moon. But when M'S is perpendicular to SC, H'C is alſo perpendicular to C *s*, and the angle *h'* O *s* is 45, and the high water is in the octant. While the moon paſſes from *s* to *m'*, or the high water from *s* to *h'*, the point I falls between M and S, and the motion of high water is ſlower than that of the moon. The contrary obtains while the moon moves from *m'* to Q, or the high water from the octant to the quadrature.

It is evident, that the motion of *h* in the third quarter of the lunation, that is, in paſſing from *o* to *q*, is ſimilar to its motion from *s* to Q. Alſo, that its motion from Q to *o* muſt retard by the ſame degrees as it accelerated in paſſing from *s* to Q, and that its motion in the laſt quarter from *q* to *s* is ſimilar to its motion from Q to *o*.

At new and full moon the point I coincides with C, and the point M coincides with *s*. Therefore the motion of the high water at full and change is to the motion of the moon as *s* C to *s* S. But when the moon is in quadrature, I coincides with C, and M with *o*. Therefore the motion of the moon is to that of high water as OS to OC or *s* C. Therefore the motion of high water at full and change is to its motion in the quadratures as OS to S *s*, or as the difference of the diſturbing forces to their ſum. The motion of the tide is therefore ſloweſt in the ſyzigies and ſwifteſt in the quadratures; yet even in the ſyzigies it paſſes the ſun along with the moon, but more ſlowly.

Let the interval between the morning tide of one day and that of the next day be called a *tide-day*. This is always greater than a ſolar day, or 24 hours, becauſe the place of high water is moving faſter to the eaſtward than the ſun. It is leſs than a lunar day, or 24h. 50', while the high water paſſes from the ſecond to the third octant, or from the fourth to the firſt. It is equal to a lunar day when high water is in the octants, and it exceeds a lunar day while high water paſſes from the firſt to the ſecond octant, or from the third to the fourth.

The difference between a ſolar day and a tide-day is called,

Tide. called the PRIMING or the RETARDATION of the tides. This is evidently equal to the time of the earth's describing in its rotation an angle equal to the motion of the high water in a day from the sun. The smallest of these retardations is to the greatest as the difference of the disturbing forces to their sum. Of all the phenomena of the tides, this seems liable to the fewest and most inconsiderable derangements from local and accidental circumstances. It therefore affords the best means for determining the proportion of the disturbing forces. By a comparison of a great number of observations made by Dr Maskelyne at St Helena and at Barbadoes (places situated in the open sea), it appears that the shortest tide-day is 24h. 37′, and the longest is 25h. 27′. This gives M — S : M + S = 37 : 87, and S : M = 2 : 4,96; which differs only 1 part in 124 from the proportion of 2 to 5, which Daniel Bernoulli collected from a variety of different observations. We shall therefore adopt the proportion of 2 to 5 as abundantly exact. It also agrees exactly with the phenomena of the nutation of the earth's axis and the precession of the equinoxes; and the astronomers affect to have deduced this proportion from these phenomena. But an intelligent reader of their writings will perceive more finesse than justice in this assertion. The nutation and precession *do not* afford phenomena of which we can assign the share to each luminary with sufficient precision for determining the proportion of their disturbing forces; and it is by means of many arbitrary combinations, and without necessity, that D'Alembert has made out this ratio. We cannot help being of opinion, that D'Alembert has accommodated his distribution of the phenomena to this ratio of 2 to 5, which Daniel Bernoulli (the best philosopher and the most candid man of that illustrious family of mathematicians) had, with so much sagacity and justness of inference, deduced from the phenomena of the tides. D'Alembert could not but see the value of this inference; but he wanted to show his own address in deducing it *proprio marte* forsooth from the nutation and precession. His procedure in this resembles that of his no less vain countryman De la Place, who affects to be highly pleased with finding that Mr Bode's discovery that Meyer had seen the Georgium Sidus in 1756, perfectly agreed with the theory of its motions which he (De la Place) had deduced from his own doctrines. Any well informed mathematician will see, that De la Place's data afforded no such precision; and the book on the Elliptical Motions of the Planets, to which he alludes, contains no grounds for his inference. This observation we owe to the author of a paper on that subject in the Transactions of the Royal Society of Edinburgh. We hope that our readers will excuse this occasional observation, by which we wish to do justice to the merit of a modest man, and one of the greatest philosophers of his time. Our only claim in the present dissertation is the making his excellent performance on the tides accessible to an English reader not much versant in mathematical researches; and we are sorry that our limits do not admit any thing more than a sketch of it. But to proceed.

Assuming 2 : 5 as the ratio of SC to CM′, we have the angle CM′S = 23° 34′ nearly, and $m' o b' = 11° 47'$; and this is the greatest difference between the moon's place and the place of high water. And when this obtains, the moon's elongation $m' o s$ is 56° 47′ from the nearest syzigy. Hence it follows, that while the moon moves uniformly from 56° 47′ west elongation to 56° 47′ east, or from 123° 13′ east to 123° 13′ west, the tide day is shorter than the lunar day; and while she moves from 56° 47′ east to 123° 13′, or from 123° 13′ west to 56° 47′, the tide-day is longer than the lunar-day.

We now see the reason why

——The swelling tides obey the moon.

The time of high water, when the sun and moon are in the equator, is never more than 47 minutes different from that of the moon's southing (+ or — a certain fixed quantity, to be determined once for all by observation.)

It is now an easy matter to determine the hour of high water corresponding to any position of the sun and moon in the equator. Suppose that on the noon of a certain day the moon's distance from the sun is $m s$. The construction of this problem gives us $s h$, and the length of the tide day. Call this T. Then say 360° : $s m$ = T : t, and t is the hour of high water.

Or, if we choose to refer the time of high water to the moon's southing, we must find the value of $m h$ at the time of the moon's southing, and the difference d between the tide day and a mean lunar day L, and say 360 : $m h = d : s$, the time of high water before the moon's southing in the first and third quarters, but after it in the second and fourth. The following table by Daniel Bernoulli exhibits these times for every 10th degree of the moon's elongation from the sun. The first or leading column is the moon's elongation from the sun or from the point of opposition. The second column is the minutes of time between the moon's southing and the place of high water. The marks — and + distinguish whether the high water is before or after the moon's southing. The third column is the hour and minute of high water. But we must remark, that the first column exhibits the elongation, not on the noon of any day, but at the very time of high water. The two remaining columns express the heights of the tides and their daily variations.
