It is not very eaſy to ſettle the number of troops neceſſary to defend a town; the nature of the ground on which the place is ſituated, and the number of outworks, ought to determine the ſtrength of the garriſon. M. Vauban in his Memoirs reckons, that in a place regularly fortified with good baſtions, half-moons, and covert-ways, we ſhould allow 500 or 600 men to each baſtion: That if the town has horn-works, 600 men may be likewiſe aſſigned to each of theſe; and in proportion for the other outworks, according to the relation which their defence may require to that of the horn-work; and the horſe ſhould be the tenth part of the number of the infantry.

This being premiſed, ſuppoſe a place has ſix baſtions, there muſt be a garriſon of ſix times ſix hundred foot, which makes 3600, and the tenth part of that number in horſe, which makes 360. Hence a ſufficient garriſon for ſuch a place will be 3960 men.

In order to compute, as near as poſſible, the quantity of ammunition and proviſions that may be required for ſuch a garriſon, we muſt calculate how many days they will be able to maintain a ſiege. The following are M. Vauban's remarks on this ſubject.

	Days.
For the inveſting the place and the tracing the lines - - -	4
For the opening of the trenches to the attack of the covert-way - -	9
For the attack and taking of the covert-way, and making lodgments in it - -	4
For the deſcent and paſſage over the ditch before the half-moon - -	3
For fixing the miners, or for the batteries till the making of a reaſonable breach -	4
Carry over	24

Brought over	24
For taking and ſecuring the interior part of the half-moon - -	3
For the paſſage over the great ditch before the two baſtions, ſuppoſed to be begun before the taking of the half-moon -	4
For fixing the miners, or erecting batteries on the covert-way, to lay the place open and make a reaſonable breach - -	4
For the defence and ſupport of the breach after the place is laid open - -	2
For the miſtakes which the enemy may happen to commit, and their neglect in their works	4
Total of the defence -	41

In this defence it is plain we ſuppoſe a town to be fortified only with half moons and a covert-way; but if the half-moon had a reduit with a revetement and rampart, it might hold out four days longer. If there were retrenchments in the baſtions, they might retard the taking of the place five or ſix days. If the ditch was ſtrengthened with tenailles and caponniers, the paſſage over it might be protracted two or three days. If there was a good horn-work, or ſome other like fortification properly ſtrengthened with a half-moon, a covert-way, and retrenchments within the work, the taking of it would coſt about 12 or 14 days. If this work had tenailles, the paſſage over its ditch would be later by two or three days. If there was a fore-ditch and a ſecond covert-way, the progreſs of the attacks would ſtill be leſs rapid, and we might reckon 10 or 12 days for the taking of this ſecond covert-way and the paſſage over its ditch. If there were redoubts near the place, they would ſtill protract the taking of it for ſome days.

From this eſtimate, though not very exact, an idea may be formed of the duration of a ſiege: a point abſolutely neceſſary for ſecuring, at leaſt, a ſufficient quantity of ammunition during the time; we ſay at leaſt, becauſe it is always prudent, if poſſible, to have a greater quantity of ammunition than is ſuppoſed to be wanted. When once the number of the garriſon, together with the duration of the ſiege, is fixed, it is then very eaſy to calculate the quantity of powder and ammunition with which the place is to be provided.

It is judged, that to be well provided with cannon, eight pieces ſhould be allowed to each baſtion. Therefore in a place of ſix baſtions there ought to be 48 pieces.

As a town is never attacked on all ſides, and there are ſeldom above two or three attacks at the moſt, the cannon belonging to thoſe baſtions that are not attacked, ſerve to ſtrengthen the baſtions attacked, and they are placed alſo in the outworks of the fronts attacked.

Among the cannon for the defence of the town there ſhould be ſome of 24, of 16, of 12, of 8, and of 4 pounders, and even of 2 and 1. The latter are of very great ſervice, becauſe of their being ſo convenient to remove with eaſe, and with few men, from one place to another; for this diſturbs the enemy, who find it difficult to deſtroy theſe ſmall pieces. The largeſt ſerve to fire againſt their batteries and their works. The ſmall ones are carried to the outworks, and to the covert-way, from whence they are fired *en barbette*. It is cuſtomary to make uſe of ſea carriages for theſe ſmall pieces.

Beſides cannon, the town ought to be provided with a great number of wall guns, carabines, muſkets, &c. We are to ſuppoſe that moſt of the ordinary arms will be broke in the ſervice, and therefore care muſt be taken to provide new ones when wanted.

The number of mortars neceſſary may be eſtimated at,

Of Sieges.

two to every baſtion. They muſt be of different bores, of 12 and 8 inches diameter. There ought alſo to be ſeveral ſtone mortars.

The garriſon of a place of ſix baſtions, conſiſting, as we have already obſerved, of 3600 foot, are to be employed or diſtributed in the following manner.

We ſhould, firſt of all, reckon about 600 ſoldiers wounded and ſick, in the firſt 12 or 15 days of the ſiege, and for the ſervice of the batteries, the removing of ammunition, &c. And then there will remain 3000 for the defence of the place.

Theſe are to be divided into three equal bodies; one for the guard, the other for the biovac under arms, ready to march on the firſt notice where wanted, and the third to reſt.

The horſe are alſo divided into three bodies like the foot; that for the guard is chiefly placed on the right and left of the attack; that for the biovac is generally quartered by brigades, in different parts of the town, where they may be of ſervice, either to keep the inhabitants in awe, or to be ready to act in ſallies. In regard to the third corps, who are to reſt, their horſes muſt be ſaddled in the day; and the horſe or dragoons muſt be ready to mount inſtantly, ſhould there be any occaſion for their ſervice.

The guard of infantry and the biovac ought to be under arms, at the ſeveral poſts aſſigned them in the works of the place; and for the corps at reſt, they muſt be ready to ſupport the troops on guard, in caſe theſe ſhould have need of their aſſiſtance.

The guard of foot of 1000 men may be ſubdivided nearly into three equal bodies; two of which to defend the poſts attacked, and the third the other poſts not attacked. And in regard to the two firſt, they may be ſubdivided alſo into three equal bodies; two of which are to fire the firſt two hours of the night, the other is to relieve one of them at the end of that time, the next is relieved two hours after; and ſo on alternately, that there may be always two thirds of this guard in action, and the other third at reſt.

There is no occaſion for ſo briſk a firing by day as by night; becauſe the beſieged are more capable of ſeeing what the enemy are about, and of oppoſing their attempts; but in the night nothing but a ſtrong cannonading can guard againſt their enterpriſes. By day the troops fire from between baſkets, ſand-bags, or gabions, placed on the upper part of the parapet, to the end that being under cover they may take better aim at the enemy.

As the moſt perfect fortifications cannot hold out long without the neceſſary ammunitions, too much care cannot be taken in regard to this article.

"The ancients, ſays Mr Folard, were accuſtomed to lay in a great ſtore of proviſions, when a place was threatened with a ſiege; a ſtore ſufficient not only for three or four months, but for three or four years at leaſt. This they were induced to do for two reaſons; the fear of being blockaded; and the inviolable law of defending themſelves to the laſt extremity. The moderns take leſs precaution in reſpect to proviſions, as well as to every thing elſe; they think it ſufficient to lay in a ſtock for three or four months in towns of the greateſt ſtrength and importance; which is very wrong. I grant indeed (continues Mr Folard), that the law of holding out to the very laſt extremity is looked upon as chimerical at preſent, and entirely left to the ancients, but it ſhould be conſidered, that an enemy well acquainted with the ſtate of things will meaſure the ſtrength of the place by the quantity of proviſions contained therein; and making a calculation of the loſs of men in the attack, together with the expence of a long ſiege, they will chooſe, if they are wiſe (and certainly they will gain by it in the end), to take it rather by blockade than by a ſiege in form: at leaſt they will be ſure of becoming maſters of it in three or four months through want of proviſions; whereas a ſiege may laſt that time, if the garriſon are obſtinate. Such a town as Liſle in Flanders, and as Bergues, both of which are out of the line of communication of our frontier, cannot be too well ſtocked with proviſions. A wiſe and experienced miniſter will victual them at leaſt for eighteen months, becauſe they may be blockaded. It is much the ſame in regard to Straſburg and to Landau. The latter was never victualled for more than three or four months: how imprudent, therefore, muſt it be to lay ſiege to it, when it may be taken by a blockade almoſt as ſoon as by a ſiege, which is attended moreover with an infinite loſs of brave men, and a monſtrous expence?"

Of Sieges.

Theſe reflections of M. Folard are very ſolid; but circumſtances will not always permit a place to be ſo well provided as one could wiſh.

When a governor finds that the enemy threatens to lay ſiege to a town under his care, and that the place is in want of the chief things neceſſary for a vigorous defence, he is to exert all his abilities, in order to remedy this inconvenience as much as poſſible. The greateſt want of all is that of proviſions; he muſt therefore endeavour to get a ſupply, both from the country and from the people of the town; which is to be diſtributed among the garriſon with the greateſt economy. The uſeleſs mouths ſhould be all ſent out, and an inquiry ought to be made after thoſe who are ſuſpected of having hoarded any corn; and upon paying them for it, or upon giving them ſecurity of payment, they ſhould be obliged to deliver it up for the ſubſiſtence of the garriſon.

Hitherto we have made no mention of the inhabitants; yet they may be rendered ſerviceable in contributing to eaſe the garriſon. The governor ſhould make uſe of ſuch workmen who exerciſe handicraft trades for every thing relating to their reſpective branches; and thoſe who are not artificers, ſhould watch the fire that may be kindled by the ſhells and red-hot bullets; they ought likewiſe to tranſport the materials to the places aſſigned them; and even to work at the different retrenchments which the governor ſhould think fit to order in the town, provided however that they be not too much expoſed to the fire of the beſiegers. An article of the greateſt importance in regard to the inhabitants, is to oblige them to lay in a ſtock of proviſions for ſix months, and thoſe that are able ſhould be obliged to make ſtill a greater proviſion, which will be a reſource to the garriſon when their own ſtock is exhauſted.

§ 2. *Neceſſary Preparations for maintaining a Siege.*

When a town is threatened with a ſiege, the governor ought not only to take care to have a plentiful ſtock of ammunition and proviſions, but moreover he ſhould uſe all the precautions requiſite for retarding the enemy's approaches, and rendering them more difficult and dangerous.

He ought therefore to leave nothing in the neighbourhood that may ſerve to cover the enemy; he ſhould clear the adjacent country of all houſes that are within reach of cannon-ſhot, and fill up, if poſſible, the caverns or hollow ways that may be concealed, or build ſome redoubts and other works under the protection of the place, by which they may be enfiladed. He ought to cut down all the trees: in a word, he ſhould prevent the enemy's having any cover within reach of the cannon of the place; he ſhould ſee that the fortifications be all in a good condition, and that the covert-way be well paliſaded; in fine, he ſhould cauſe arrows to be built on the ſaliant angles of the glacis,

Of Sieges. glacis. Retrenchments may alſo be made in the re-entering places of arms of the covert-way, by raiſing a parapet within them, and parallel to their faces, with a ſmall ditch before it. Nor ſhould the galleries for the mines be forgotten; on the contrary, they ought to be begun betimes, and carried out into the country as far as the ground will permit: and chambers ſhould be made under all the angles of the glacis. If there are any houſes within the rampart which may obſtruct the defence, the governor ought to ſee them demoliſhed; and nothing ſhould be left, either within or without, which can any way be of ſervice to the beſiegers. If there are new raiſed troops, care ſhould be taken to diſcipline them well.

The governor ſhould alſo ſee that the hoſpitals be in a good condition, that the ſick and wounded be taken care of, nor think it beneath his character to viſit them himſelf, and to let the ſoldiers ſee how greatly he has their preſervation at heart. This is the ſureſt way to gain their confidence and affection, and to engage them to do their utmoſt towards defending the place.

As it is now the cuſtom to throw a great number of ſhells into a town beſieged, it is neceſſary to have vaulted places under ground bomb-proof, where part of the garriſon not on duty may reſt in ſafety. They are not ſo much wanted in large cities, where there are always different quarters ſecure from the enemy's ſhells: but a ſmall town is in every part expoſed to the bombs; ſo that ſome places under ground are abſolutely neceſſary for the garriſon to take their reſt, and to prevent the troops from being continually incommoded. Theſe ſubterraneous caverns are generally made in the gorges of the baſtions, and ſometimes under the rampart behind the curtains.

Where there are none of thoſe ſubterraneous places, it will be neceſſary, as ſoon as the town is inveſted, to erect defences to ſhelter the men from the bombs; theſe are made of ſtrong pieces of timber, laid ſloping againſt the parts the leaſt expoſed, and they may be covered with thick planks laid in the ſame manner. The large houſes ſhould alſo be ſhored, that is, all the floors, from to top to bottom, ſhould be ſupported with ſtrong upright timbers, and the upper floor covered with large beams laid acroſs one another, and theſe again with earth, faſcines, dung, &c. When they are thus fitted up, they may ſerve either for the accommodation of the troops or for hoſpitals, &c. But what deſerves a more ſpecial care, is the powder-magazines. They ought to be bomb-proof; but as there are very few that can reſiſt the ſhock of a great number of ſhells, they ſhould therefore be covered with ſeven or eight feet thick of earth, and a layer of faſcines, dung, and ſtrong planks laid over them, ſo as to form a kind of roof. But if it ſhould happen, either from their ſituation or height, that this cannot be done, then a range of large trees, well faſtened together, muſt be laid over them, ſo as to diminiſh the ſhock of the ſhells. The windows of the powder-magazines ſhould have no proſpect towards the beſiegers; and to prevent all accidents, nobody ſhould be permitted to go in or out of the doors, but when the fire of the enemy is ſlackened.

When there are no powder-magazines in a town, it is very difficult to preſerve the powder during a ſiege; all that can be done, is to diſtribute it in different places, as in cellars and caves made under the ramparts, or in gardens, &c. and to cover theſe places well with thick planks, earth, faſcines, &c.

The miſchief done by ſhells conſiſts not only in demoliſhing the buildings on which they fall, but likewiſe in ſetting fire to moſt places they fall upon; and when they are followed by red-hot balls, it is very difficult to hinder the town from being burnt. In order to remedy this evil, timely precautions ſhould be taken, and the inhabitants employed in extinguiſhing the fire. Of Sieges.

Firſt of all, a great number of caſks, filled with water, ſhould be placed in the ſtreets; and the ſoldiers and inhabitants ought to be divided into companies, to prevent the ſpreading of the flames. It will be proper to divide theſe into ſmall bodies, and to allot different quarters to each of them, for extinguiſhing any fire that may happen to particular houſes. By theſe means each corps, or company, will become anſwerable, in ſome meaſure, for the houſes entruſted to their care, and uſe the utmoſt endeavours to preſerve them. The pavements muſt alſo be taken up, and dung laid in the ſtreets, to prevent further miſchief from the burſting of the ſhells.

§ 3. *Of the defence from the inveſting to the Attack of the Covert-way.*

When the place is inveſted, and the beſiegers begin to work upon the line of circumvallation, the governor ought not at firſt to fire upon the enemy's troops with the largeſt cannon, but with his ſmall pieces only. For as the enemy ought to pitch their camp as near as poſſible to the place, provided they are out of reach of cannon-ſhot, they will think themſelves at a ſufficient diſtance when out of the reach of thoſe ſmall pieces; but as ſoon as they are encamped, the garriſon are to give them a full volley with their great guns, which will oblige them to decamp once more, and make them loſe time.

While the beſiegers are conſtructing the lines, their engineers ſpare no pains to get an exact knowledge of the adjacent ground, and to reconnoitre the fortifications, that they may form the plan of attack, which they will be ſure to make on the weakeſt ſide. To prevent this, M. Goulan propoſes the following ſcheme.

As ſoon as the town is inveſted, the governor ſhould ſend 200 or 300 men every night to that ſide which he knows to be the weakeſt, with orders to lie upon their faces, in the form of a ſemicircle, of which the paliſades of the covert-way may be conſidered as the diameter. Theſe men ſhould be divided into ſmall parties, of three or four men each, at the diſtance of 20 or 30 paces from one another, ſo as to occupy a large tract of ground. All theſe different parties ought to agree upon a ſignal, to give notice when any body paſſes by them, and they ſhould remain there in ſilence till day, without ſtirring, unleſs ſomebody happens to paſs by; in which caſe, the firſt that ſees them ſhould riſe, and give the ſignal to the reſt, who are to do the ſame; then all drawing cloſe together, and advancing to the paliſades, they will take thoſe who paſſed, as it were in a net, without any poſſibility of relief from their eſcort, who cannot be numerous enough to reſcue them from the hands of 200 or 300 men, protected by the fire of the covert-way. If the men who advance to reconnoitre the place, inſtead of paſſing through the intervals, ſhould fall in with ſome of theſe parties, and endeavour to get off, they muſt be fired upon: thus the enemy may be eaſily hindered from reconnoitering, and thereby acquiring a knowledge of the ground, or the ſide moſt proper to be attacked.

From the time the place is inveſted, the beſieged ſhould ſend every night ſmall parties of eight or ten men, commanded by a ſerjeant, with orders to lie upon their faces all round the border of the glacis, and to liſten carefully to every thing that paſſes. Whatever care the beſiegers may take to open the trenches in ſilence, ſtill it will be very difficult for this operation to be made, without ſuch a motion as muſt be heard or perceived from the neighbourhood of the glacis. Theſe ſmall parties may even advance a little

Of Sieges. further, obſerving ſilence, and taking care not to be ſurpriſed by the parties which the enemy alſo may ſend out on that ſide, to watch whether there are any troops of the garriſon ready to fall upon the workmen.

When the ſide on which the enemy open their trenches is known, the great pieces of ordnance are mounted on the rampart of the town *en barbette*, and the ſmall ones on the covert-way, from whence they are to fire briſkly upon the trenches. And to point more exactly, fire-balls are thrown from the mortars, which will give light enough to diſcover the workmen. Juſt at this time, the beſieged ſhould make the greateſt fire againſt the enemy, becauſe it is then they are moſt uncovered, and conſequently moſt expoſed. As the beſieged cannot have their batteries ready till the ſecond or third day after the opening of the trenches, during that time the guns may continue to fire *en barbette*; but it will hardly be poſſible to fire in that manner when the enemy's batteries are once erected. Mortars ſhould likewiſe be uſed for throwing ſhells on the workmen and thoſe employed on the batteries; in ſhort, the beſt uſe ſhould be made of the artillery, before the enemy are in a condition to ſilence it.

It is cuſtomary to make two or three attacks in order to divide the attention of the garriſon; and of theſe, generally ſpeaking, there is only one real: they muſt therefore endeavour to find out this real attack, and to uſe the utmoſt diligence in making good retrenchments, as well in the outworks, which the enemy muſt take before they can come to the body of the place, as in the gorge of the baſtion of the front attacked. But to render theſe retrenchments ſtrong and firm, they ſhould have been begun and even finiſhed before the opening of the trenches. A governor, who has a proper knowledge of fortification, ought to judge on which ſide a town is moſt acceſſible, and to preſume that here the enemy will commence their attack; conſequently he ought to think of every method of defence, the beſt adapted to retard the approaches, and diſpute every inch of ground.

The beſieged ſhould ſo diſpoſe their artillery at the beginning of a ſiege, as to enfilade the branches, and to direct their fire againſt the head of the trenches or the ſaps. This muſt be their principal effort; for it is by continually firing upon them that they may reaſonably hope to retard the works.

When the enemy have erected their batteries, it is very difficult for the beſieged to maintain theirs, eſpecially if they are placed on the produced faces of the pieces attacked. For as the cannon are continually firing *à ricochet* againſt theſe faces, and it being difficult to guard againſt this firing, it will be very dangerous for the ſoldiers to remain there: all that can be done is to make ſome traverſes, in order to diminiſh their effect; which is difficult indeed to compaſs, becauſe the ſhot falling upon the traverſes will bound between them. It is adviſable not to perſiſt in firing always from the ſame place againſt the enemy's batteries. By ceaſing to fire from that part where the beſiegers know there was a battery, they may be induced to think they have deſtroyed it, which will prevent their continuing to fire againſt it, and be a means of preſerving the battery for future ſervice. But in order to give them trouble, ſmaller guns may be placed in the outworks, on the faces of the baſtions, from whence the trenches and batteries of the beſiegers can be diſcovered; and they muſt often change place to perplex the enemy, who will find it very difficult to diſmount thoſe moving pieces. The beſieged however muſt endeavour to repair the parapets deſtroyed by the enemy, and to take proper meaſures for firing again from thence, as ſoon as the beſiegers have ſhifted their guns.

It is alſo adviſable that the batteries of the beſieged ſhould not fire in ſalvos, or all at a time; for it is well known, that the beſiegers place ſoldiers in the trenches to obſerve, through ſmall loop-holes made with ſand-bags in the parapet of the trench, when the batteries of the town are fired, and to give notice to thoſe who are at work in the trenches, which way the guns are pointed, that they may put themſelves under cover. If the beſieged have only ſix pieces on a battery, and they fire them all at a time, the enemy have ſome moments of ſecurity to look over the parapet and to examine the ground where they intend to work and to conduct the trenches: but when the garriſon vary their manner of firing, they give more uneaſineſs to thoſe who are at work in the trenches, who will not be ſo ready to look over the parapet; which, though it be neceſſary, in order to view the ſituation of the ground towards which the works are to be directed, is ever dangerous, but eſpecially when the trenches are brought within muſket-ſhot of the place. Of Sieges.

§ 4. *Of Sallies.*

A Garrison that keeps within a place without making ſallies, is, as the chevalier de Ville ſays, like thoſe who are not concerned when their neighbour's houſe is on fire, and will not ſtir to extinguiſh it till it has reached their own. And indeed, as the beſiegers continually carry on their approaches towards the town, it is of the utmoſt importance to endeavour, in time, to ſtop their progreſs; to which end, the making of ſallies is extremely conducive, eſpecially when they are well conducted, otherwiſe they would rather accelerate than retard the taking of the place.

How great ſoever the advantage of ſallies may be, they are proper only when a garriſon is numerous. A ſmall garriſon, although well ſtocked with all the kinds of neceſſary ammunitions for making a defence, and for holding out, ought to be very careful how they venture to make a ſally. But a numerous garriſon, not ſo well provided, ought to fatigue the enemy as much as poſſible by frequent ſallies. The ſame meaſure ought to be followed when a town is but ill fortified; the garriſon ſhould not ſhut themſelves up ſo as to be obliged to ſurrender, as it were, without making much reſiſtance. It is beſt in thoſe caſes to haraſs the enemy continually, to keep them at a diſtance as long as poſſible, and to uſe every ſtratagem and endeavour that may retard their approaching the glacis, and the taking of the covert-way. Thus it was that the marquis of Uxelles, afterwards marſhal of France, behaved at the ſiege of Mentz in 1689. He defended that large and ill fortified town upwards of two months, with the help of a very brave garriſon; but was obliged to capitulate for want of powder and ammunition, though he was ſtill maſter of the covert-way, and even in ſome meaſure of the glacis.

When the beſiegers are at a diſtance from the place, ſallies are very dangerous, becauſe the enemy may cut them off from the town with their horſe: but when they have made their ſecond parallel, and advanced the branches of the trenches towards the third parallel at the foot of the glacis, then is the time for the garriſon to ſally. They may even venture, though with great caution, when the beſiegers are at work upon the ſecond parallel, and before it is entirely finiſhed; but the moſt favourable opportunity of ſallying, is when the beſiegers are come to the third parallel, and want to make a lodgment on the glacis. Then there is no danger of being cut off; and the enemy may be ſurpriſed the more eaſily, as the garriſon have it in their power to fall upon them all at once, and to throw them into confuſion, without giving them time to recover themſelves.

Sallies may be either great or ſmall; the former ought

to

Of Sieges. to be with 500 or 600 men at leaſt, or proportioned to the guard in the trenches; the latter are only with 10, 15, or 20 men.

The intent of great ſallies ſhould be to deſtroy a conſiderable part of the works of the beſiegers, in order to oblige them to begin again; to nail up their guns; to retake ſome poſt which had been abandoned; and laſtly, to obſtruct the enemy's works as much as poſſible, and thereby retard the taking of the place.

In regard to ſmall ſallies, they ſerve for no other end than to interrupt the workmen at the head of the trenches, ſo as to frighten them, and oblige them to run away. As it requires ſome time to bring them back, and to make them return to their work, this will occaſion delay, and retard the approaches.

The beſt time for great ſallies, is two hours before day-light, the troops being then fatigued and ſleepy; therefore more eaſily ſurpriſed, and leſs capable of making a vigorous reſiſtance. And when it has rained very hard in the night, ſo that the guard in the trenches may be unable to make uſe of their fire arms, this is alſo a favourable circumſtance: in ſhort, no opportunity ſhould be neglected to ſurpriſe the enemy; for ſallies ſeldom prove advantageous any other way. The following is the order which M. Vauban propoſes to be obſerved.

There ſhould be a detachment of 90 men drawn up, 30 in front, and three deep; to which muſt be added a fourth rank of 30 grenadiers. The three firſt ranks of this detachment ſhould be armed with cuiraſſes; each ſoldier ſhould have a ſword and piſtol at his belt, and a partizan, or long iron fork with a hook, in his hand. This detachment is to be followed by another of 180 men, 30 in front, and ſix deep; the firſt rank of theſe is to be armed as the former, with cuiraſſes and long weapons, the reſt as uſual. The firſt rank in this detachment is to make up the rear in the retreat. After this ſecond detachment 200 workmen are to follow with proper tools to deſtroy the enemy's works, and ſeveral of theſe with combuſtibles to burn what they cannot otherwiſe deſtroy. Some of them are to be provided with long nails of ſteel, and of different magnitude, to ſpike the cannon; there muſt be ſome of a very large ſize, becauſe the touch-holes happen frequently to be ſo very wide, that common nails will not fill them up exactly.

Beſides the two detachments and workmen above mentioned, another body of 300 or 400 men ſhould be ordered to ſupport them, and to follow them ſlowly as far as the head of the trenches; where, if they find that thoſe who went before them have no need of aſſiſtance, they ſhould halt to be ready to act if occaſion requires it. If the guard of the trenches ſhould make a vigorous attack upon the ſally, this detachment will ſupport them, and jointly encounter the beſiegers. If the latter are repulſed, which muſt be the caſe if the ſally is not foreſeen and expected, the workmen muſt ſet about demoliſhing the works, and filling up the trenches as faſt as poſſible. Theſe troops ſhould alſo endeavour to penetrate as far as the batteries, in order to nail up the cannon, and to maintain themſelves in the trenches long enough for the workmen to deſtroy great part of them. When they have done what they propoſed, they retreat to the covert-way in good order; and if the enemy ſhould be ſo imprudent as to purſue them as far as the glacis, they muſt be received with a briſk fire as well from the cannon of the ramparts as from the troops in the covert-way.

In ſallies, and generally in all actions performed by night, the ſoldiers ſhould put ſomething in their hats, as a white paper or handkerchief, to know one another in the dark. The troops deſigned for this purpoſe are drawn up in the place of arms within the town, or in the ditch if it be dry, or elſe in the c[illegible]rt-way. When they are to march out by different gates, ſome ſignal ſhould be agreed upon, that they may all move at the ſame time. If there are more attacks than one againſt the town, as generally is the caſe, then ſeveral ſallies may be made at the ſame time upon theſe attacks. It might be proper to make a great noiſe on one ſide, in order to draw all the attention of the enemy that way; and while they are buſy in the repulſe, to act vigorouſly on the other ſide; for then they will meet with leſs reſiſtance, and will be more capable of hurting the beſiegers. However, as a ſally which has not all the ſucceſs that might be expected, ought not to diſcourage the garriſon from repeating the attempt; ſo one that has been crowned with ſucceſs ought not to render them too confident, or inſpire them with too great a contempt for the enemy. The miſtakes the latter may have committed, will rouſe their attention, and put them upon their guard. We ought ever to ſuppoſe, that they will do all that we ſhould do, were we in their place, and that they will take proper meaſures to remove every obſtacle that may oppoſe them. Of Sieges.

Hitherto we have taken no notice of the uſe of cavalry in ſallies; and yet on ſome occaſions they may be of ſervice, which is when the beſiegers are at a diſtance from the place. In this caſe, two detachments of horſe are ordered to the right and left to ſupport the ſallies, and to hinder the enemy's horſe from falling upon them. Theſe detachments ſerve alſo to protect their retreat, and to prevent their being cut off; but when the beſiegers have finiſhed their third parallel, the ſallies are then made with foot only, and ſhould, as we have above obſerved, be often repeated, provided the garriſon is numerous enough to diſpute every inch of ground with the enemy.

As ſoon as the troops are returned from the ſally, fire-balls ſhould be thrown into the trenches, to diſcover the workmen who are employed in repairing the miſchief that has been done, and are at that time in ſome meaſure uncovered. The fire of the place well ſerved at this juncture, muſt kill a great many of the enemy. So far relates to great ſallies.

The ſmall ſallies, which are intended merely to diſturb the beſiegers without being able to do them much hurt, are conducted in the manner following. The governor orders out parties of 10, 15, or 20 ſtout men only, as hath been already obſerved, who are to advance ſoftly to the head of the trenches, and to jump into them quickly, making a great noiſe, and throwing grenades; after which they are to retire with all expedition: the alarm which they will occaſion is ſufficient to make the workmen take to their heels, who deſire nothing better than to have a ſpecious pretence, as M. Goulon obſerves, to run away upon the leaſt alarm; and it is impoſſible to prevent it, or to bring them back the ſame night; ſo that the beſiegers muſt loſe all this time. If, ſays the ſame author, the beſiegers become accuſtomed to theſe little ſallies, ſo as to grow ſecure and take no notice of them, the beſieged obſerving this muſt make one in good earneſt, which coming unexpected, will eaſily overturn the workmen and the troops that cover them; after which they may retire without fighting, leſt they ſhould draw the whole guard of the trenches upon their backs.

§ 5. *Of the Defence of the Glacis and the Covert-way.*

Beſides the ſallies which retard the lodgment of the beſiegers on the glacis, mines may increaſe the difficulty of approaching. We have already taken notice of theſe in the ſection of *Attack*; we have only to obſerve here in general, that the beſieged muſt make the beſt uſe of them poſſible, in order to blow up the enemy as often as the ground will permit;

permit; this is the ſureſt way to keep the beſiegers in awe, and to oblige them to advance with the greateſt circumſpection.

Beſides the galleries and mines which ought to be under the glacis, the beſieged may alſo lay oppoſite to its angles large planks, ſtuck full of very long nails, with the points upwards, to incommode the enemy in paſſing over the glacis. Theſe planks ought to be ſtrongly fixed, to prevent their being eaſily taken away. The burying of caiſſons in the glacis is alſo productive of a good effect; but they ought never to be placed nearer than ſix or eight feet to the inſide of the covert-way, leſt they ſhould do any damage to the troops that defend this poſt.

When the enemy endeavour to make a lodgment on the glacis, the garriſon muſt repeat their ſallies with greater vigour; which may be done without any inconvenience, becauſe of the facility of retreating. When the troops are returned from the ſally, fire is ſet to the chambers and caiſſons, which will greatly diſconcert the beſiegers. If the chambers are well diſpoſed, they muſt hurt their lodgments prodigiouſly; and as ſoon as they are ſprung, the beſieged may fall upon the enemy, this being a favourable opportunity for ſurpriſing them in diſorder, and conſequently of deſtroying part of their works. This manner of proceeding ſhould be often repeated, in order to fatigue the beſiegers, and to retard the taking of the covert-way.

When the enemy are ready to ſtorm it, the garriſon muſt prepare to give them a warm reception. The difficulty of making a lodgment in the covert-way may be increaſed by a double row of paliſades: the ſecond ſhould be lower than the firſt, to the end that the enemy may not perceive them. Theſe two rows ought to be at the diſtance of four or five feet from one another, to prevent the beſiegers from jumping over them into the covert-way. Between them may be made a ſmall ditch; into which moſt of the enemy's grenades will fall, and cauſe leſs miſchief to the troops. Care muſt be taken to make ſtrong retrenchments in the places of arms, either by raiſing a parapet withinſide, and parallel to their faces, with a ſmall ditch at the foot of it, or by ſimple rows of paliſades, which will hinder the enemy from forcing their way ſo eaſily as they would otherwiſe be capable of doing. In each place of arms there ſhould be one or two barrels of powder, with balls and ſmall arms neceſſary for the defence of the covert-way.

All the batteries muſt be got ready to fire with the utmoſt briſkneſs upon the enemy, when they are at work upon their lodgment. Every part of the place that looks into the covert-way ought to be lined with troops, who are to fire upon the beſiegers; but there ought to be no troops in the parts oppoſite to the places of arms, that the troops poſted there may not be hurt by the fire from the body of the place.

The garriſon ſhould endeavour to be informed by deſerters at what time the enemy intend to make their attack; the motions of the latter may be alſo obſerved by perſons poſted on ſteeples; and as ſoon as the troops are perceived to make an extraordinary motion, and the trenches to be filled more than uſual, this is a ſign that they are going to attack. The vicinity of the enemy's works may alſo enable the beſieged to judge of their forwardneſs; and all this together direct them to take ſuch meaſures as are proper for giving a warm reception to the beſiegers.

As ſoon as the garriſon perceive that the enemy are marching out of their trenches, they ſhould keep firing upon them continually with great and ſmall arms from all the works facing the attack. This will deſtroy a great many of their men before they can reach the paliſades: the two rows of which in the covert-way will prevent their jumping into it directly. They will be under a neceſſity of breaking them ſucceſſively with hatchets; and while this is doing, a general diſcharge is to be made from the batteries of the town, which will do great execution. When, after a vigorous reſiſtance, the garriſon find themſelves hard preſſed by the enemy, they may abandon the covert-way, and retire into the places of arms; and while the beſiegers are working upon their lodgment, they will be expoſed to the fire of the place, which takes them in front; and to that of the places of arms, by which they are taken in flank; ſo that their loſs muſt increaſe conſiderably. If they have mines ready, as we ſuppoſe they have, they muſt ſpring them, after having ſuffered the enemy to work for ſome time upon their lodgments; and after having kept firing againſt them continually with great and ſmall arms, then immediately they ſhould make a ſtrong ſally from the places of arms, and taking advantage of the diſorder into which the beſiegers muſt inevitably be thrown, they will oblige them to abandon the covert-way.

Of Sieges.

If there is no poſſibility of hindering the enemy from making lodgments on the creſt of the covert-way, or, which is the ſame thing, on the ridge of the glacis, the beſieged muſt endeavour to retard them, and to diſpute as long as poſſible their taking poſſeſſion of the places of arms. On this occaſion fougaſſes are employed with ſucceſs, and ſhould be repeated ſeveral times if the ground will permit. When the beſiegers have once completed their lodgment, and ſupported it in a proper manner, they want nothing further than a little time to extend themſelves, and to become maſters of the covert-way. The obſtinacy of the beſieged can only retard, but not abſolutely hinder, the taking of this outwork.

Let us ſuppoſe that the enemy reſolve to approach the covert-way by ſap, and that they have raiſed cavaliers in the trenches to plunge into this outwork, the beſieged muſt ſtrive to retard this operation by every ſtratagem imaginable; for when the cavaliers are once conſtructed, it will be very dangerous to abide any longer in the covert-way. They muſt ſtop the beſiegers at every ſtep with mines; they muſt haraſs them with a conſtant diſcharge of fire-arms, and diſpute every inch of ground, defending themſelves behind every traverſe, and in the places of arms, as well as they can, without running too great a riſk of having their retreat cut off.

§ 6. Of the Defence of the Paſſage over the Ditch before the Half-moon.

The enemy having made themſelves maſters of the covert-way, and perfected all their lodgments, will erect their batteries for making a breach, and prepare for the deſcent into the ditch. All this while the beſieged muſt keep firing both with their great and ſmall arms, in order to incommode the enemy in the conſtruction of their batteries. If the ditch is dry, the ſoldiers may mount with ladders along the counterſcarp, and from thence throw grenades into the enemy's works; and when they cover themſelves in the covert-way with ſand-bags, gabions, &c. againſt the fire of the place, theſe very ſoldiers ſhould, with great ſap-hooks, pull down part of them, and afterwards jump nimbly into the ditch, leaving the enemy expoſed to the fire of the town while they are putting their materials again into order. Mines may be likewiſe uſed here with great advantage; they furniſh various means to haraſs the enemy, to obſtruct their works, and to make them loſe time and men.

The batteries of the beſiegers being deſtroyed by mines made under them, muſt oblige them to loſe a great deal of time in repairing them, and in endeavouring to make themſelves maſters of the mines, otherwiſe they can never be ſecure.

Of Sieges. fecure. When the beſieged have blown up the batteries that were to open the breach, they muſt make good uſe of the time which the enemy will ſpend in repairing them, and ſtrive to perfect the retrenchments, which ſhould have been ſet about at the commencement of the ſiege, in the gorge of the half-moon, and in thoſe of the baſtions of the front attacked.

The mines for blowing up the batteries of the covert-way may be diſpoſed in ſuch a manner as to tumble the guns into the ditch, as may be ſeen in the courſe of mathematics by M. Belidor, who performed it with ſucceſs at the academy of La Fere.

It is certainly a great advantage thus to be able to become maſters of the cannon of the beſiegers, and to oblige them to erect new batteries, which muſt take them up a conſiderable time. A doubt here may ariſe, whether if theſe batteries are oppoſite to that part where the enemy intend to paſs the ditch, this would not be helping to fill it up, ſhould the beſieged blow up the guns: but this inconvenience is of no great conſequence, eſpecially as it may eaſily be remedied, by clearing away the rubbiſh of the mine which tumbles into the ditch along with the battery.

As the beſiegers work at the deſcent into the ditch at the ſame time that they are preparing their batteries, the beſieged muſt think of retarding both theſe operations alſo at the ſame time. If the deſcent into the ditch is made under ground, miners ſhould be employed to interrupt the work; and if the ditch is dry, ſmall detachments, as M. Goulon obſerves, of five or ſix men, may be placed near the counterſcarp, to watch the moment that the enemy break through it, and immediately to fire into the gallery: this diſcharge will either kill or frighten the miners; and at leaſt will retard the works. Thoſe who have fired, ſhould retire on each ſide of the opening to load their arms again, which may be repeated ſeveral times. Fire-balls and grenades may be likewiſe thrown into this opening, which will oblige the ſappers to retreat.

If the ditch is filled with water, the ſame operations may likewiſe be performed with ſmall boats made on purpoſe; and to cover theſe boats a kind of parapet ſhould alſo be raiſed by means of ſtrong boards, with holes to fire through upon the ſoldiers, who upon opening the gallery will throw faſcines into the ditch. At the ſiege of Liſle, marſhal Bouffiers contrived ſome boats of this kind to retard the paſſage over the ditch, before the grand lunettes or tenaillons in the front attacked, and that before the half-moon.

When the enemy make their opening into the dry ditch, they muſt be oppoſed with a ſtrong fire, as well from the face of the baſtion which flanks the ditch before the half-moon, as from the place of arms or traverſe, which ought to be conſtructed the whole breadth of the ditch, in order to ſtrengthen the defence. By night ſmall ſallies ſhould be made from this place of arms, with a view to interrupt the paſſage over the ditch, and to retard, as much as poſſible, the fixing of the miner.

There are two ways of paſſing the dry ditch, and of bringing the miner to the foot of the revetement which he is to enter. The firſt conſiſts in making a gallery ſix feet wide, with a double row of barrels. Theſe muſt be filled with ſand-bags, and ſo muſt the ſpaces between them, in order to render the paſſage of the gallery more ſafe; and that there may be a ſhelter from fire works, ſtrong planks are laid over it, and theſe again are covered with raw hides, or with earth and dung. This gallery is continued within three or four feet of the revetement; and in this ſpace a good epaulement is raiſed with ſand-bags to cover the miner on the ſide expoſed to the place. In regard to the other ſide, it is of no uſe to ſtop it up; nay, it ſerves for an opening to fill the ditch with the earth dug out of the galleries, Of Sieges. which the miners are making in the rampart of the work attacked. It is eaſy to oppoſe the progreſs of this gallery with a continual fire, and with ſeveral leſſer works conſtructed within the ditch.

The other way, which, as we have already ſeen in treating of the attack, conſiſts only in getting to the foot of the breach by ſap, with an epaulement on the ſide expoſed to the place, may be covered, in order to protect the paſſage from the fire-works and grenades of the beſieged. But this ſap may be retarded by ſallies; the beſieged may likewiſe ſteal away the earth by night from the epaulements, and endeavour with hooks, &c. to diſplace the gabions and faſcines.

If the ditch is filled with water, the beſieged muſt interrupt the enemy's bridge with a continual fire from their great and ſmall guns, as well as with grenades and ſhells, if they are in a condition to fire upon the bridge and its epaulement. If the water has a ſtrong current, they muſt open ſluices in order to break down the bridge, or at leaſt to carry away the faſcines. They ſhould alſo attempt to ſet fire to it with artificial works prepared for this purpoſe. They may likewiſe approach the epaulement in the night, and draw away the faſcines with hooks. They may even throw anchors upon it; and by means of capſtans placed in thoſe parts which flank the ditch, they may draw theſe anchors with cords faſtened to them, and tumble part of the epaulement into the ditch. In ſhort, every expedient muſt be tried that may poſſibly retard the enemy's approaches: for when once they have perfected their bridge, they will ſoon be maſters of the outwork to which that bridge leads, whatever precaution the garriſon may take to defend the breach; becauſe, as the beſiegers can always pour in freſh men to ſupply the room of thoſe that are loſt in the attack, they muſt at length ſurmount all oppoſition.

§ 7. *Of the Defence of the Half-moon.*

While the enemy are effecting the paſſage over the ditch, beſides the difficulties that are raiſed to retard the work, all proper precautions ſhould be uſed to defend the breach, and prevent the taking of the half-moon. For this purpoſe guns are placed in all the works from which the breach may be ſeen; and they ſhould be placed on carriages or on pieces of wood, as the garriſon find moſt commodious, of leaſt hindrance to the defence, and productive of the beſt effect.

If the half-moon has no reduit, as here we ſuppoſe it has none, the retrenchments, which ought to have been made there, muſt be put into good condition; a row of paliſades muſt be placed before it, in order to ſtop the firſt fury of the enemy after they have made themſelves maſters of the breach; in a word, the beſieged muſt prepare to diſpute every inch of ground, and to retire from the half-moon into the town, when they find themſelves hard preſſed and no longer able to maintain that poſt.

When the enemy preſent themſelves at the foot of the breach, a great number of grenades, and ſacks filled with powder, are thrown among them, with a view to fling them into diſorder. Glaſs or earthen bottles filled with powder, and burning matches twiſted round them, are capable of doing them a deal of miſchief. A great quantity of looſe powder may be ſcattered about the breach when the enemy are ready to mount to the aſſault; and when they are mounted, lighted matches or burning coals may be thrown among the powder to ſet it on fire; which will burn and diſable a number of thoſe who are in the breach. It will be proper alſo to throw into the breach a quantity of harrows, ſtuck full of large nails with the points upwards: and to prevent

the

Of Sieges. the enemy from removing them, they muſt be faſtened with chains, or with great cords. It is adviſable to be provided with crows-feet, and to ſpread them about; as alſo with chevaux-de-friize, and with heriſſons, that ſhall extend the whole width of the breach (ſee HERISSON.) Shells alſo faſtened to the ends of chains, in order to confine them to that part where they may do moſt damage to the enemy, are an excellent contrivance. Their fuſees are made ſhorter than uſual, to the end that they may produce their effect more readily. Faſcines, ſmeared over with tar, and, in ſhort, every ſtratagem ought to be tried to hinder the enemy from lodging themſelves in the breach.

When the beſiegers have ſurmounted all theſe obſtacles, and at laſt have got poſſeſſion of the breach, the mines are ſprung in order to blow them up, and chevaux-de-frize are placed along the whole breadth of the breach. The troops poſt themſelves behind, and continue to make a vigorous fire upon the beſiegers while they are uſing their utmoſt endeavours to penetrate into the half-moon; and when they begin to force their way, the firſt rank of men that defend it, being armed with partiſans or halberts, and ſupported by the other troops, ought to fall upon the enemy, and cut them in pieces. But if the beſiegers at length by dint of numbers ſhould drive the garriſon from the breach, the latter ought to retire into the retrenchment, and from thence make a very briſk firing; and when they find that this is alſo upon the point of being forced, then they are to withdraw their cannon, and whatever ammunition they may have, into the place; and laſt of all, if they have any mines under that ſpot, they muſt ſpring them as they retire, in order to do all the miſchief and to create all the confuſion they can to the beſiegers.

Sometimes it ſhall happen that the enemy, after having made themſelves maſters of the half-moon, omit to leave a ſufficient number of troops to guard the lodgment, upon a preſumption that the beſieged will not attempt to retake it. Whenever they ſhow a confidence of this kind, a ſtrong body of the garriſon ſhould return in the night and ſtorm this work, either by the gorge, or by ſome other part. There are great odds, but ſuch a vigorous and ſudden ſurpriſe will be productive of a very good effect; at leaſt there is no great riſk in trying, if the ſtrength of the garriſon will permit; and ſhould they ſucceed, the taking of the town will be retarded ſeveral days.

Here we have ſuppoſed that the enemy are reſolved to ſtorm the half-moon; but if they ſhould attempt to get poſſeſſion of it by means of ſaps, in that caſe the workmen muſt be continually haraſſed by blowing up mines, and kept as long as poſſible from the breach by means of fire-works of all kinds. When they begin to make a lodgment in the breach, then the beſieged ſhould fall upon them briſkly, and deſtroy the lodgment; in ſhort, every artifice imaginable ſhould be uſed to retard their progreſs.

This laſt method is leſs bloody than the other; but on the other hand, it may be very tedious, when the beſieged ſpare no pains to diſturb the enemy's ſappers and miners.

One thing that greatly deſerves attention, and may render it very difficult for the beſiegers to mount to the aſſault, or to lodge themſelves in the breach by means of ſaps, is to clear away the rubbiſh in the breach. In a dry ditch this may be eaſily done; but in a wet one, the thing is more difficult: on the other hand, in the latter caſe the breach is more eaſy to defend than in the former; becauſe as the enemy cannot come to the foot of it but by the bridge of faſcines, which is made in the ditch, and is ſeldom above 10 or 12 feet wide, they cannot of courſe preſent themſelves with ſo large a front before the breach as in a dry ditch; conſequently the garriſon muſt find it much eaſier to repel them. Of Sieges.

§ 8. *Of the Defence of the Paſſage over the Ditch before the Baſtion.*

AT the ſame time that the enemy are carrying on the attacks of the half-moon, they work at the paſſage over the ditch before the baſtion. What has been ſaid in regard to the defence of the ditch before the half-moon, may be applied on this occaſion; we have only to add, that when this ditch is dry, the caponier will be of great uſe to fire upon the enemy in their paſſage over the ditch, and to ſally from thence in order to deſtroy their works. If the ditch be wet, it muſt be defended in the ſame manner as that before the half-moon: here only we ſhall add, that if there is a tenaille oppoſite to the curtain of the front attacked, the fire from thence will greatly annoy thoſe who are employed in filling up the ditch. Beſides, the boats by which we obſerved that the enemy might be incommoded in the paſſage over the ditch, the beſieged may likewiſe have recourſe to a kind of floats, made with double joiſts, at the end of which are faſtened empty barrels, to prevent their ſinking too deep in the water; and theſe floats ſhould be loaded with ſhells, barrels of gunpowder, faſcines, pitch and tar; and in ſhort, with all ſorts of combuſtibles proper for ſetting fire to the bridge, and to the enemy's epaulement: theſe are brought forward and faſtened to the epaulement, and afterwards they are ſet on fire with a match, or with tow laid amidſt the combuſtibles.

When there are dikes or ſluices, by means of which the ditch may be filled with water at any time, every art muſt be tried to defend it while it is dry; and when all the defences are exhauſted, then the water is let in, and the enemy will be obliged to begin their work again.

§ 9. *Of the Defence of the Baſtions in the Front attacked.*

HERE the reader muſt recollect what has been ſaid in regard to the defence of the breach in the half-moon. The defence of the baſtions is more eaſy, becauſe it is not ſo difficult to retreat from thence by means of the retrenchment: and this retrenchment ſhould be larger, and more ſpacious than that of the half-moon, and more difficult to force.

Beſides all the precautions we have been mentioning, as mines under the breaches, within the baſtions, &c. the beſieged ſhould alſo mount ſeveral pieces of cannon on the breach, charged with cartridge-ſhot, and pointed downwards, ſo as to be able to ſweep the whole ſurface of the ground on which the enemy muſt form in order to march to the aſſault. Care muſt alſo be taken, leſt the enemy, diſcouraged with the difficulty of ſtorming the breach, attempt to ſcale the baſtion, as hath been practiſed ſeveral times, and particularly by the duke de Noailles, marſhal of France, at the ſiege of Gironne, in 1712. The way to guard againſt this attempt, is to place along the parapet of the works that may be inſulted, large pieces of timber, which are to be tumbled upon the ladders as ſoon as the enemy offer to mount. They ſhould alſo have loaded ſhells all along the rampart, faſtened to chains, and to let down towards the middle of the ladders, where they will burſt and kill thoſe who are mounted. They ſhould likewiſe be provided with combuſtibles of different kinds, to throw upon the beſiegers, and to keep them off from the foot of the revetement. When the garriſon are well prepared againſt this attempt, it will be very difficult for the enemy to ſucceed.

The entrance of the baſtion may likewiſe be defended, by

Of Sieges. by making a ditch in the upper part of the breach, and filling it with all ſorts of combuſtible matter. This will form an impenetrable barrier againſt the enemy, at leaſt for ſome days; which time is to be employed in ſtrengthening the retrenchments, and throwing up others, one behind another, if the ground will permit, and it be reſolved to defend the place to the laſt extremity. Though it is uſual for the enemy to force their way into the town by the baſtion, and therefore the principal retrenchments for defending the entrance of the place ſhould be raiſed in this part; yet it is proper not to neglect the curtain. The enemy may be appriſed of theſe retrenchments, and as it is not the practice to make any behind the curtain, they may take it into their heads to batter it in breach, and to conſtruct a bridge in the ditch before it, in order to penetrate into the town. Thus did prince Eugene act at Liſle; as the back part of the curtain was open, the place was obliged to capitulate. The breaches may likewiſe be defended by repairing them with large trees laid acroſs one another, the branches pointed towards the enemy. Cannon will make no great impreſſion on this kind of wall; which was the principal defence of the ancients when a breach was made.

When the beſiegers have triumphed over all theſe obſtacles, ſo as to be maſters of the breach, and to extend their lodgments on the baſtion; then it is no longer poſſible to defer capitulating, unleſs there are ſeveral retrenchments one behind the other. In that caſe, indeed, the beſieged, if they think proper, may defend themſelves to the very laſt; but this deſperate defence is very rare, becauſe every wiſe governor chooſes to preſerve the garriſon, and to ſave the town from being plundered, which would be the caſe, according to the laws of war, if it was taken by ſtorm.

§ 10. *Of Precautions to be uſed againſt the ſurpriſing of Towns, Scalades, ſudden Attacks, &c.*

The right way to prevent ſurpriſes, is to think that the enemy have a deſign upon the town, and to uſe all the precautions poſſible in order to fruſtrate their deſigns. With this view a governor ſhould put the fortifications into a good ſtate of defence, ſhould ſee that the ſeveral poſts, whether acceſſible or inacceſſible, be well guarded, that parties be ſent to range in all the principal avenues of the place; in a word, he ſhould moſt exactly obſerve whatever is preſcribed in the military ordinances concerning the guard of towns, the opening and ſhutting of gates, &c. We ſhall make no mention of any of theſe particulars, becauſe a very ſhort ſtay in a garriſon is ſufficient for learning every thing that may relate to the daily and cuſtomary duty, as well for the ſafety of the town, as for the preſerving peace and good order among the inhabitants, and for preventing any ſtrangers or ſuſpected perſons from entering the place, &c.

We ſhall only obſerve, that when a fortreſs is ſituated upon a river, care ſhould be taken to have boats in the night, filled with ſoldiers, both above and below the town, to hinder any body from getting in that way undiſcovered. If the ditches are filled with water, in froſty weather the ice ſhould be broke every day; in ſhort, nothing ſhould be neglected that tends to ſecure the place againſt any enterpriſe either from within or without.

But chiefly on fair or market days this vigilance ſhould be exerted; the guards ought to be doubled at all the gates, and the garriſon ſhould be diſpoſed in ſuch a manner as to be ready to fly to their arms upon the firſt beat of drum: care ſhould be alſo taken to make the cavalry mount on horſeback, ready to act in all events. By uſing theſe precautions, it will be very difficult for the enemy to ſurpriſe the town; nay, the conſequence may be, that hearing of the exact diſcipline obſerved by the garriſon, they will relinquiſh their deſign; for ſurpriſes ſeldom ſucceed, except through neglect of military duty, and too great ſecurity in the governor. Of Sieges.

With regard to precautions againſt ſcalades, they conſiſt in having ſmall parties continually about the avenues of the place, in order to be better informed of the enemy's motions, and to keep a patrole all night, to ſee that nobody ſhall enter the ditch unperceived. A cuvett (f) may be likewiſe dug within the ditch, and paliſades planted within ſome diſtance of the wall, to hinder the enemy from fixing their ladders to it; the flanks of the baſtions ſhould be furniſhed with cannon, charged with cartridge-ſhot, with balls of a quarter of a pound weight, or with pieces of old iron, to fire upon thoſe who ſhould attempt to ſcale the place oppoſite the curtains; in the corps de gardes, within reach of the rampart, a proviſion ſhould be made of halberts, with all other offenſive weapons fit for repelling the enemy when they appear on the top of the ladder, and for driving them into the ditch; the ramparts ſhould be ſtocked with a great quantity of cylindrical timber, to roll down upon the ladders, and thoſe that are upon them; and if the garriſon are not ſo numerous as to be able to cover the whole ramparts, they ſhould fix chevaux-de-frize, or ſomething elſe, to the upper part of the parapet, which will hinder the enemy from getting over, in order to jump upon the rampart. There ought alſo to be a ſtock of ſhells and grenades all loaden upon the walls, in order to roll them down into the ditch upon the enemy. There ſhould likewiſe be fire-works ready to throw upon them, as faſcines done over with pitch and tar, powder-barrels, fire-pots, &c.; a great number of fire-balls ſhould be alſo flung into the ditch in order to give light, and that the cannon of the place may do good execution upon thoſe who are got into it; the ditch ſhould likewiſe be filled with crows feet, or little holes dug and covered with hurdles and earth, ſo that the enemy ſhall not perceive them, but tumble into them: in the middle of theſe little ditches there ſhould be a paliſade, or ſome long iron-ſpikes, ranged in ſuch a manner as to run thoſe through that ſhall fall upon them. Neither are the gates to be neglected; the enemy will not fail to try to fix a petard to them, while the troops are endeavouring to make themſelves maſters of the rampart. Soldiers muſt be placed in a convenient ſituation for firing on the perſon that fixes the petard: in all events the gates muſt be ſtrengthened withinſide, and large trees muſt be got ready to debar the enemy from entering the town, ſhould they be able to break open the gate.

At the firſt alarm of an attack, all the troops ought to run to the place aſſigned them, in order to be led from thence to the ramparts. With regard to the cavalry, they ought alſo to mount on horſeback, and to divide themſelves into ſeveral ſmall bodies, which are to be at the foot of the rampart, ready at all events to charge the enemy, ſhould they find means to penetrate by ſome way or other into the town.

If the enemy make ſeveral attacks at the ſame time, it will not be proper to quit thoſe parts where they do not ſhow themſelves; this perhaps is a feint only to draw the troops from the ſide which they really intend to attack; therefore the garriſon ſhould be equally on their guard on all ſides, and leave no poſts naked, unleſs the enemy have forced their way into the town: then indeed the buſi-

(f) A cuvett is a ſmall ditch dug in the middle of the large one.

Of Sieges. fineſs is to charge them vigorouſly, in order to oblige them to retire.

Upon the whole, it is eaſy to withſtand a ſcalade when there is no ſurpriſe: and therefore it rarely happens that a governor, who takes the neceſſary precautions againſt any ſuch accidents, will loſe a town by this kind of attack.

A ſcalade may be attempted in the day as well as by night; the latter indeed is more favourable to the aſſailants, yet they will not ſucceed a whit the better, if they find that the garriſon are prepared to receive them, agreeable to what we have already mentioned.

There remains only to mention a word or two in regard to accelerated ſieges; which is, that a governor will not be expoſed to this ſort of ſiege, if he takes the proper precautions to be informed of the ſteps and approaches of the beſiegers.

If the enemy pretend to carry on a ſiege in form, and at the ſame time accelerate their approaches on one ſide of the place, the garriſon muſt fall vigorouſly upon them, and ſpare no pains to drive them out of what works they have ſeized upon. One may ſuſpect their deſign, if it appears that they do not make their attack on the ſide of the town where naturally they ought to make it, that they want to become maſters of the place with greater eaſe; and then the beſieged ſhould double their guard on that ſide. In general, there ſhould be a conſtant attention to all the fronts of the place, and they ſhould be all equally guarded, till it appears clearly by the enemy's works on which ſide they form their attack, and which way they direct their works; neither are the other ſides to be even then neglected, leſt the enemy ſhould lay hold of this opportunity to attack them. It is always to be ſuppoſed that they are informed of every thing that paſſes within the town, either by their ſpies, or by deſerters; for which reaſon the poſt that ſeems leaſt acceſſible ought not to be neglected.

§ 11. *Of Capitulations.*

The capitulation being the laſt tranſaction, both in the attack and defence of a town, this ſeems to be the moſt natural place for ſpeaking of it, as it ſeems to be the moſt proper ſubject for terminating this article.

When the governor, who defends a town, finds himſelf reduced to the laſt extremity, or is ordered by his court to ſurrender, with a view of obtaining better conditions of the enemy, both for the town and garriſon, he orders the chamade to be beat. For this purpoſe one or more drummers are directed to beat their drums on the rampart, on the ſide next to the attack, to give notice to the beſiegers that the governor has ſomething to propoſe to them; one or more white colours are likewiſe hung out for the ſame purpoſe, and one of them remains either on the rampart or on the breach during the time of negociation. The ſame is practiſed in demanding a ſuſpenſion of arms, after a very violent attack, to bury the dead, carry off the wounded, &c.

As ſoon as the chamade is beat, the firing ceaſes on both ſides, and the governor ſends ſome officers of diſtinction to the general who commands the ſiege, with the conditions on which it is propoſed to ſurrender. As a ſecurity, or as hoſtages for thoſe officers, the beſiegers ſend at the ſame time the ſame number into the town; if the governor's propoſals are not agreeable to the commander of the beſieging army, he rejects them, and mentions what terms he is willing to grant. Generally ſpeaking, he threatens the governor to allow him no conditions at all, if he does not determine to ſurrender quickly; for inſtance, when the paſſage over the ditch of the place is finiſhed, or batteries are erected oppoſite the flanks, &c. If the beſieged find the conditions too hard, the hoſtages are reſtored, and the drums are beat again upon the rampart, to make every body withdraw before hoſtilities are renewed, which is done very ſoon after. It is to be obſerved, that during the negotiation they ought to be quiet on both ſides, and by no means ſhould go on with the operations of the ſiege. The governor ought during this time to be upon his guard, for fear of being ſurpriſed by ſtratagem; which might expoſe him to the diſcretion of the beſieger. Of Sieges.

Suppoſe that the terms of capitulation are agreed upon, two or three of the principal officers of the garriſon are ſent as hoſtages to the enemy; and the general of the beſieging army ſends back the ſame number, and of equal degree, as a ſecurity for fulfilling the capitulation.

The conditions inſiſted upon by the beſieged muſt vary according to the different circumſtances and ſituations in which they find themſelves. But when the capitulation is entirely ſettled, an officer of artillery from the beſiegers enters the town, to take an inventory of all the artillery and ammunition remaining in the place, in conjunction with an officer of artillery from the garriſon. A commiſſory of ſtores enters likewiſe to take an account of the proviſions.

When a governor finds that he muſt ſurrender, and that there are conſiderable magazines of ammunition and proviſions, he ſhould deſtroy moſt of them before he offers to ſurrender, to the end that there may remain no more in the place than what is neceſſary for a capitulation, and that the enemy may reap no advantage from thence. If he ſhould not, before he enters into a capitulation, burn or deſtroy thoſe magazines, the enemy might inſiſt on their being preſerved; but they can think nothing of it when thoſe precautions are taken beforehand.

As ſoon as the beſieged have delivered up a gate of the town to the enemy, the firſt regiment of the army enters, and mounts guard.

When the day is come that the garriſon are to leave the place, the beſieging army is drawn up in two files of battalions and ſquadrons, and the garriſon are to paſs between them. The hour for their marching out being arrived, the general and the principal officers put themſelves at the head of the troops, to ſee the garriſon defile before them.

The governor puts himſelf at the head, followed by the principal officers; and he makes the garriſon march in the beſt order poſſible. The oldeſt regiments move commonly in the van and the rear, and the others in the centre with their baggage. When there is any cavalry, it is divided in the ſame manner into three corps, for the van, the centre, and the rear. Small detachments of horſe and foot are made to march along with the baggage, and to take care of its not being rifled.

The artillery granted by the capitulation marches after the firſt battalion. When the garriſon arrive at the place agreed upon, they deliver up the hoſtages of the beſiegers to the eſcort; and when the latter have rejoined the army, they ſend back the hoſtages which the beſieged left for the ſecurity of the eſcort, with the waggons, and other things granted by the beſieging army for eſcorting the garriſon.

When the garriſon are made priſoners of war, they are likewiſe eſcorted to the town agreed upon by the terms of the capitulation.

Every thing ſettled in the capitulation ought to be ſacred and inviolable, and ſhould be underſtood in its genuine and moſt natural ſenſe: yet as this is not always practiſed, the governor ſhould take the utmoſt precaution to have no word inſerted that ſhall be in the leaſt equivocal, or liable to different interpretations. There are a great many examples which prove the neceſſity of this precaution.

When

Of Sieges. When the garriſon of a town capitulate in order to retire to the citadel, there are ſome particular conditions to be obſerved; ſuch as follow.

That the citadel ſhall not be attacked on the ſide next the town; that the ſick and wounded, who cannot be removed, ſhall ſtay in their preſent lodgings; and when they are recovered, they ſhall be provided with carriages and tranſports to retire in ſafety to the place agreed on in the capitulation. None ſhould be ſuffered to enter the citadel, but thoſe who may be of uſe in defending it; the reſt, who are called *uſeleſs mouths*, by no means ought to be admitted. Mention ſhould be made in the capitulation, that thoſe people ſhall be conducted to ſome neighbouring place in the dominions of their ſovereign, which ſhould be named. A certain time ought alſo to be allowed for the whole garriſon to enter the citadel; and it ſhould be expreſsly mentioned, that during this time the beſiegers ſhall conſtruct no works that are neceſſary for the reduction of the citadel. Of Sieges.

A maritime town requires alſo ſome particular attention, in regard to the ſhips that may be in the harbour. It ſhould be ſtipulated, that they ſhall quit the harbour the ſame day as the garriſon march out of the town, or when the weather permits to ſail to the port agreed upon. They ſhould preſerve their artillery, rigging, ammunition and proviſions, &c. If they ſhould be obliged by ſtreſs of weather to put into any harbour of the beſiegers by the way, it ought to be mentioned in the capitulation, that they ſhall be received there, and ſupplied with neceſſaries for continuing their voyage; they ought alſo to be provided with paſſports, and, in a word, to have every kind of ſecurity, that they ſhall not be inſulted by the enemy's ſhips, but ſuffered without the leaſt obſtacle to ſteer to the port agreed upon.

Man of War Bird. See Pelicanus.

War ‖ Warburton. *War-Cry* was formerly cuſtomary in the armies of moſt nations, when juſt upon the point of engaging. Sometimes they were only tumultuous ſhouts, or horrid yells, uttered with an intent to ſtrike terror into their adverſaries; ſuch as is now uſed by the Indians in America, called the *war-whoop*.

WARBLES, in farriery. See there § xxxii.

WARBURTON (William), who has been juſtly ſtyled *vir magnus, acer, memorabilis*, was deſcended from an ancient and conſiderable family in Cheſhire. His grandfather diſtinguiſhed himſelf in the civil wars of the laſt century; and being of the royal party, probably injured his fortune by his attachment to his king and the conſtitution of his country. He married a lady of the county of Nottingham, by whom he had three ſons; the ſecond of whom, George, being bred to the law, practiſed as an attorney at Newark in that county.

William, the ſubject of this memoir, and the ſecond ſon of Mr George Warburton, was born at Newark, December 24. 1698. He was firſt put to ſchool there under a Mr Twells, but had the chief part of his education at Okeham in Rutlandſhire, where he continued till the beginning of the year 1714, when, his couſin being made head maſter of the ſchool at Newark, he returned to his native place, and was for a very ſhort time under the care of that learned and reſpectable relation. In the month of April of the ſame year, he was put out clerk to Mr Kirke, an eminent attorney of Great Markham in Nottinghamſhire; and continued with that gentleman till the ſpring of the year 1719. He then returned to his family at Newark; but whether he practiſed there or elſewhere as an attorney, is not known to his accompliſhed biographer, the biſhop of Worceſter.

He had always expreſſed a ſtrong inclination to take orders; and the love of letters, which tended to retard, rather than forward, his progreſs in the profeſſion choſen for him by his friends, growing every day ſtronger in him, it was deemed expedient to give way to that inclination. In the ſtudies neceſſary to fit him for the church, he was directed by his couſin the ſchoolmaſter of Newark; to whom, long afterwards, when he ſtood himſelf in the very front of literature, he gratefully acknowledged his obligations. At length, on the 22d of December 1723, he was ordained deacon by archbiſhop Davis of York, and prieſt on the firſt of March 1727, by biſhop Gibſon of London.

Though he never liked the profeſſion of an attorney, he had certainly acquired a very conſiderable knowledge of the laws of England: for in a diſpute which aroſe in 1726, about the judicial power of the court of chancery, he combated with ſucceſs the opinions of no leſs a man than the lord chancellor Hardwicke, then attorney-general. Warburton.

In 1728 he was preſented by Sir Robert Sutton to the rectory of Brand-Broughton, in the dioceſe of Lincoln, where he ſpent the greater part of his life, and compoſed all the great works which will carry his fame down to poſterity. In the ſame year he was put upon the king's liſt of Maſters of Arts, erected on his majeſty's viſit to the univerſity of Cambridge. He had already publiſhed ſome juvenile performances, which diſplayed genius and reading, and attracted conſiderable notice; but it was not till the year 1736 that he may be ſaid to have emerged from the obſcurity of a private life into the notice of the world.—The firſt publication which rendered him afterwards famous now appeared, under the title of "The Alliance between Church and State; or, the Neceſſity and Equity of an Eſtabliſhed religion and a Teſt Law; demonſtrated from the Eſſence and End of Civil Society, upon the fundamental Principles of the Law of Nature and Nations." In this treatiſe, ſays Biſhop Horſley ‡, the author "hath ſhown the general good policy of an eſtabliſhment, and the neceſſity of a Test for its ſecurity, upon principles which republicans themſelves cannot eaſily deny. His work is one of the fineſt ſpecimens that are to be found perhaps in any language, of ſcientific reaſoning applied to a political ſubject." ‡ Review of the Caſe of the Proteſtant Diſſenters, Lond. 1787. Pref.

At the cloſe of the Alliance was announced the ſcheme of the Divine Legation of Moſes, in which he had then made a conſiderable progreſs. The firſt volume of this work was publiſhed in January 1738, under the title of "The Divine Legation of Moſes demonſtrated on the Principles of a Religious Deiſt, from the Omiſſion of the Doctrine of a future State of Rewards and Puniſhments in the Jewiſh Diſpenſation, in ſix books, by William Warburton, M. A. author of the Alliance between Church and State;" and met with a reception which neither the ſubject, nor the manner in which it was treated, ſeemed to authoriſe. It was, as the author afterwards obſerved, fallen upon in ſo outrageous and brutal a manner as had been ſcarce pardonable, had it been "The Divine Legation of Mahomet."—It produced ſeveral anſwers, and ſo much abuſe from the authors of "The Weekly Miſcellany," that in leſs than two months he was conſtrained to defend himſelf, in "A Vindication of the Author of the Divine Le-

Warburton.

gation of Moſes, from the Aſperſions of the Country Clergyman's Letter in the Weekly Miſcellany of February 24. 1737-8, 8vo."

Mr Warburton's extraordinary merit had now attracted the notice of the heir apparent to the crown, in whoſe immediate ſervice we find him in June 1738, when he publiſhed "Faith working by Charity to Chriſtian Edification, a Sermon, preached at the laſt epiſcopal Viſitation for Confirmation in the Dioceſe of Lincoln; with a Preface, ſhowing the Reaſons of its Publication; and a Poſtſcript, occaſioned by ſome Letters lately publiſhed in the Weekly Miſcellany, by William Warburton, M. A. Chaplain to his Royal Highneſs the Prince of Wales."

In March 1737, the world was in danger of being deprived of this extraordinary genius by an intermitting fever, which with ſome difficulty was relieved by a plentiful uſe of the bark.

The "Eſſay on Man" had been now publiſhed ſome years; and it is univerſally ſuppoſed, that the author had, in the compoſition of it, adopted the philoſophy of the Lord Bolingbroke, whom, on this occaſion, he had followed as his guide, without underſtanding the tendency of his principles. In 1738. M. de Crouſaz wrote ſome remarks on it, accuſing the author of Spinoziſm and Naturaliſm; which falling into Mr Warburton's hands, he publiſhed a defence of the firſt epiſtle, and ſoon after of the remaining three, in ſeven letters; of which ſix were printed in 1739, and the ſeventh in June 1740, under the title of "A Vindication of Mr Pope's Eſſay on Man, by the author of the Divine Legation." The opinion which Mr Pope conceived of theſe defences, as well as of their author, will be beſt ſeen in his letters. In conſequence, a firm friendſhip was eſtabliſhed between them, which continued with undiminiſhed fervour until the death of Mr Pope; who, during the remainder of his life, paid a deference and reſpect to his friend's judgment and abilities, which will be conſidered by many as almoſt bordering on ſervility.

Towards the end of the year 1739, Mr Warburton publiſhed a new and improved edition of the firſt volume of the Divine Legation; and in May 1741, appeared the ſecond part, which completed the argument, though not the entire plan of that work. "A work, ſays Biſhop Hurd ‡, in all views of the moſt tranſcendant merit, whether we conſider the invention or the execution. A plain ſimple argument, yet perfectly new, proving the divinity of the Moſaic law, and laying a ſure foundation for the ſupport of Chriſtianity, is there drawn out to a great length by a chain of reaſoning ſo elegantly connected, that the reader is carried along it with eaſe and pleaſure; while the matter preſented to him is ſo ſtriking for its own importance, ſo embelliſhed by a lively fancy, and illuſtrated from all quarters by exquiſite learning and the moſt ingenious diſquiſition, that in the whole compaſs of modern or ancient theology, there is nothing equal or ſimilar to this extraordinary performance."

‡ Life of Warburton prefixed to his Works.

This is the panegyric of a man reflecting with tenderneſs on the memory of his friend and benefactor; but it approaches much nearer to the truth than the cenſures of thoſe cabaliſtic critics, who, faſtening upon ſome weak part of the Divine Legation, or perhaps never having looked into it, have ridiculouſly contended that the author was far from being eminent as a ſcholar (A), and that his work is inimical to the cauſe of Chriſtianity! Putting partiality aſide, there is in the Divine Legation of Moſes abundant evidence of the malignant folly of this charge, as no man can read and underſtand that work without being convinced that its author was a Chriſtian, not only ſincere but zealous; that he was, what Johnſon calls him *, "a man of vigorous faculties, of a mind fervid and vehement, ſupplied by unlimited and inceſſant inquiry, with a wonderful extent and variety of knowledge, which had neither depreſſed his imagination nor clouded his perſpicuity; and that to every work, and this work in particular, he brought a memory full fraught, with a fancy fertile of original combinations, exerting at once the powers of the ſcholar, the reaſoner, and the wit." But we think it muſt be acknowledged, that his learning was too multifarious to be always exact, and his inquiries too eagerly puſhed to be always cautious. We have no heſitation, however, to ſay, that to the divine this great work, with all its imperfections, is, in our opinion, one of the moſt valuable that is to be found in any language.

Warburton.

* Life of Pope.

In the ſummer 1741, Mr Pope and Mr Warburton, in a country ramble, took Oxford in their way. The univerſity was naturally pleaſed at the arrival of two ſuch ſtrangers, and ſeemed deſirous of inrolling their names among their graduates. The degree of D. D. was intended for the divine, and that of L. L. D. for the poet: but intrigue and envy defeated this ſcheme; and the univerſity loſt the honour of decorating at the ſame time the two greateſt geniuſes of the age, by the fault of one or two of its members. Pope retired with ſome indignation to Twickenham, where he conſoled himſelf and his friend with this ſarcaſtic reflection—"We ſhall take our degree together in fame, whatever we do at the univerſity."

The friendſhip of this eminent poet was of ſervice to Mr Warburton in more reſpects than that of increaſing his fame. He introduced and warmly recommended him to moſt of his friends, and among others to Mr Murray, afterwards earl of Mansfield, and Ralph Allen, Eſq; of Prior-park. In conſequence of this introduction, we find Mr Warburton at Bath 1742; where he printed a ſermon which had been preached at the Abbey-church on the 24th of October, for the benefit of Mr Allen's favourite charity, the General Hoſpital or Infirmary. In this year alſo he printed a Diſſertation on the origin of books of chivalry, at the end of Jarvis's Preface to a tranſlation of Don Quixote, which Mr Pope tells him, he had not got over two paragraphs of, before he cried out, *Aut Eraſmus, aut Diabolus.*

In 1742, Mr Warburton publiſhed "A Critical and Philoſophical Commentary on Mr Pope's Eſſay on Man. In which is contained a Vindication of the ſaid Eſſay from the Miſrepreſentation of M. de Reſnal, the French tranſlator, and of M. de Crouſaz, Profeſſor of Philoſophy and Mathematics in the Academy of Lauſanne, the Commentator." It was at this period, when Mr Warburton had the entire confidence of Mr Pope, that he adviſed him to complete the Dunciad, by changing the hero, and adding to it a fourth book. This was accordingly executed in 1742, and publiſhed early in 1743, with notes by our author; who, in conſequence of it, received his ſhare of the abuſe which Mr Cibber liberally beſtowed on both Mr Pope and his annotator. In the latter end of the ſame year he publiſhed complete editions of "The Eſſay on Man," and "The Eſſay on Criticiſm;" and from the ſpecimen which he there exhibited of his abilities, it may be preſumed Mr Pope

(A) We have heard this affirmed by narrow-minded clergymen, who were deſtitute themſelves of every ſpark of ſcience, and had no other claim to literature than what aroſe from a ſlight acquaintance with Hebrew critics of a very peculiar caſt; to whom, it muſt be owned, that no great reſpect was indeed ever paid by the author of the Divine Legation of Moſes.

Warburton.

Pope determined to commit the publication of thoſe works which he ſhould leave to Mr Warburton's care. At Mr Pope's deſire, he, about this time, reviſed and corrected the "Eſſay on Homer," as it now ſtands in the laſt edition of that tranſlation.

The publication of "The Dunciad" was the laſt ſervice which our author rendered Mr Pope in his lifetime. After a lingering and tedious illneſs, the event of which had been long foreſeen, this great poet died on the 30th of May 1744; and by his will, dated the 12th of the preceding December, bequeathed to Mr Warburton one half of his library and the property of all ſuch of his works already printed as he had not otherwiſe diſpoſed of or alienated, and all the profits which ſhould ariſe from any edition to be printed after his death: but at the ſame time directed that they ſhould be publiſhed without any future alterations.

"In 1744, Mr Warburton turned his attention to the ſeveral attacks which had been made on the "Divine Legation," and defended himſelf in a manner which, if it did not prove him to be poſſeſſed of much humility or diffidence, at leaſt demonſtrated that he knew how to wield the weapons of controverſy with the hand of a maſter. His firſt defence now appeared, under the title of "Remarks on ſeveral occaſional Reflections, in Anſwer to the Reverend Dr Middleton, Dr Pococke, the Maſter of the Charter-Houſe, Dr Richard Grey, and others; ſerving to explain and juſtify divers Paſſages in the Divine Legation, objected to by thoſe learned Writers. To which is added, A General Review of the Argument of the Divine Legation, as far as it is yet advanced; wherein is conſidered the Relation the ſeveral Parts bear to each other and the whole. Together with an Appendix, in Anſwer to a late Pamphlet intitled, An Examination of Mr W——'s ſecond Propoſition." This was followed next year by "Remarks on ſeveral occaſional Reflections, in Anſwer to the Reverend Doctors Stebbing and Sykes; ſerving to explain and juſtify the Two Diſſertations in the Divine Legation, concerning the Command to Abraham to offer up his Son, and the Nature of the Jewiſh Theocracy, objected to by theſe learned Writers. Part II. and laſt." Both theſe anſwers are couched in thoſe high terms of confident ſuperiority, which marked almoſt every performance that fell from his pen during the remainder of his life.

On the 5th of September 1745, the friendſhip between him and Mr Allen was more cloſely cemented by his marriage with Miſs Tucker, who ſurvived him, and is now, if alive, Mrs Stafford Smith of Prior-park. At that important criſis our author preached and publiſhed three ſeaſonable ſermons: 1. "A faithful Portrait of Popery, by which it is ſeen to be the Reverſe of Chriſtianity, as it is the Deſtruction of Morality, Piety, and Civil Liberty. Preached at St James's, Weſtminſter, October 1745." 2. "A Sermon occaſioned by the preſent unnatural Rebellion, &c. Preached in Mr Allen's Chapel at Prior-park, near Bath, November 1745." 3. "The Nature of National Offences truly ſtated.—Preached on the General Faſt-day, December 18. 1745-6." On account of the laſt of theſe ſermons, he was again involved in a controverſy with his former antagoniſt Dr Stebbing, which occaſioned "An Apologetical Dedication to the Reverend Dr Henry Stebbing, in Anſwer to his Cenſure and Miſrepreſentations of the Sermon preached on the General Faſt, &c."

Notwithſtanding his great connections, his acknowledged abilities, and his eſtabliſhed reputation, a reputation founded on the durable baſis of learning, and upheld by the decent and attentive performance of every duty incident to his ſtation; yet we do not find that he received any addition to the preferment given him in 1728 by Sir Robert Sutton (except the chaplain ſhip to the prince of Wales), until April 1746, when he was unanimouſly called by the Society of Lincoln's Inn to be their preacher. In November he publiſhed "A Sermon preached on Thankſgiving appointed to be obſerved the 9th of October, for the Suppreſſion of the late unnatural Rebellion." In 1747 appeared his edition of Shakeſpear, and his Preface to Clariſſa; and in the ſame year he publiſhed, 1. "A Letter from an Author to a member of Parliament concerning Literary Property." 2. "Preface to Mrs Cockburn's Remarks upon the Principles and Reaſonings of Dr Rutherford's Eſſay on the Nature and Obligations of Virtue," &c. 3. "Preface to a Critical Inquiry into the Opinions and Practice of the ancient Philoſophers, concerning the Nature of a Future State, and their method of teaching by double Doctrine," (by Mr Towne) 1747, ſecond edition. In 1748, a third edition of "The Alliance between Church and State, corrected and enlarged."

Warburton.

"In 1749, a very extraordinary attack was made on the moral character of Mr Pope, from a quarter where it could be the leaſt expected. An inſignificant pamphlet, under the name of *A Patriot King*, was that year publiſhed by Lord Bolingbroke, or by his direction, with a preface to it, reflecting highly on Mr Pope's honour. The provocation was ſimply this: The manuſcript of that trivial declamation had been intruſted to the care of Mr Pope, with the charge (as it was pretended) that only a *certain* number of copies ſhould be printed. Mr Pope, in his exceſſive admiration of his *guide, philoſopher*, and friend, took that opportunity, for fear ſo invaluable a treaſure of patriot eloquence ſhould be loſt to the public, to exceed his commiſſion, and to run off more copies, which were found, after his death, in the printer's warehouſe. This charge, however frivolous, was aggravated beyond meaſure; and, notwithſtanding the proofs which Lord Bolingbroke had received of Pope's devotion to him, envenomed with the utmoſt malignity. Mr Warburton thought it became him to vindicate his deceaſed friend; and he did it ſo effectually, as not only to ſilence his accuſer, but to cover him with confuſion‡."

‡ Hurd's Life of Warburton.

About this time the publication of Dr Middleton's Inquiry concerning the miraculous Powers of the Chriſtian Church, gave riſe to a controverſy, which was managed with great warmth and aſperity on both ſides, and not much to the credit of either party. On this occaſion Mr Warburton publiſhed an excellent performance, written with a degree of candour and temper, which, it is to be lamented, he did not always exerciſe. The title of it was "*Julian*; or a Diſcourſe concerning the Earthquake and fiery Eruption which defeated that Emperor's attempt to rebuild the Temple at Jeruſalem, 1750." A ſecond edition of this diſcourſe, "with Additions." appeared in 1751, in which year he gave the public his edition of Mr Pope's Works, with Notes, in nine volumes 8vo; and in the ſame year printed "An Anſwer to a Letter to Dr Middleton, inſerted in a Pamphlet intitled, The Argument of the Divine Legation fairly ſtated," &c.; and "An Account of the Prophecies of Ariſe Evans, the Welſh Prophet in the laſt Century," annexed to the firſt volume of Dr Jortin's Remarks on Eccleſiaſtical Hiſtory, which afterwards ſubjected him to much trouble.

In 1752, Mr Warburton publiſhed the firſt volume of a courſe of ſermons, preached at Lincoln's Inn, intitled, "The Principles of Natural and Revealed Religion, occaſionally opened and explained;" and this was two years afterwards followed by a ſecond. After the public had been ſome time promiſed, it may, from the alarm which was taken, be almoſt ſaid threatened with, the appearance of Lord Bolingbroke's Works, they were about this time printed.

Warburton.

printed. The known abilities and infidelity of this nobleman had created apprehenſions in the minds of many people, of the pernicious effects of his doctrines; and nothing but the appearance of his whole force could have convinced his friends, how little there was to be dreaded from arguments againſt religion ſo weakly ſupported. Many anſwers were ſoon publiſhed, but none with more acuteneſs, ſolidity, and ſprightlineſs, than "A View of Lord Bolingbroke's Philoſophy, in two Letters to a Friend, 1754;" the third and fourth letters were publiſhed in 1755, with another edition of the two former; and in the ſame year a ſmaller edition of the whole; which, though it came into the world without a name, was univerſally aſcribed to Mr Warburton, and afterwards publicly owned by him. To ſome copies of this is prefixed an excellent complimentary epiſtle from the Preſident Monteſquieu, dated May 26. 1754.

At this advanced period of his life, that preferment which his abilities might have claimed, and which had hitherto been withheld, ſeemed to be approaching towards him. In September 1754, he was appointed one of his Majeſty's chaplains in ordinary, and in the next year was preſented to a prebend in the cathedral of Durham, on the death of Dr Mangey. About this time the degree of Doctor of Divinity was conferred on him by Dr Herring, then archbiſhop of Canterbury. A new impreſſion of The Divine Legation being now called for, he printed a fourth edition of the firſt part of it, corrected and enlarged, divided into two volumes, with a dedication to the earl of Hardwicke. The ſame year appeared "A Sermon preached before his Grace Charles Duke of Marlborough, Preſident, and the Governors of the Hoſpital for the Small-pox and for inoculation, at the Pariſh-church of St Andrew, Holborn, April the 24th, 1755." And in 1756. "Natural and Civil Events the Inſtruments of God's Moral Government; a Sermon, preached on the laſt public Faſt-day, at Lincoln's Inn Chapel."

In 1757, Dr Warburton meeting with Mr Hume's tract, entitled, The Natural Hiſtory of Religion, filled the margin of the book, as well as ſome interleaved ſlips of paper, with many ſevere and ſhrewd remarks on the infidelity and naturaliſm of the author. Theſe he put into the hands of his friend Dr Hurd, who, making a few alterations of the ſtyle, added a ſhort introduction and concluſion, and publiſhed them in a pamphlet, entitled "Remarks on Mr David Hume's Natural Hiſtory of Religion, by a Gentleman of Cambridge, in a Letter to the Reverend Dr Warburton." This lively attack upon Mr Hume gave him ſo much offence, that he thought proper to vent his ſpleen on the ſuppoſed author, in the poſthumous diſcourſe which he called his *Life*; and thus to do greater honour to Dr Hurd than to any other of his numerous antagoniſts.

Towards the end of the year 1757, Dr Warburton was promoted to the deanery of Briſtol; and in the beginning of the year 1760, he was, through Mr Allen's intereſt with Mr Pitt, afterwards earl of Chatham, advanced to the biſhoprick of Glouceſter. That great miniſter is known to have declared, "that nothing of a private nature, ſince he had been in office, had given him ſo much pleaſure as bringing our author on the bench." There was, however, another miniſter, who dreaded his promotion, and thought that he ſaw a ſecond Atterbury in the new biſhop of Glouceſter; but Warburton, ſays biſhop Hurd, had neither talents nor inclination for parliamentary intrigue or parliamentary eloquence: he had other inſtruments of fame in his hands, and was infinitely above the vanity of being caught

"With the fine notion of a buſy man ‡."

‡ Dryden.

He was conſecrated on the 20th of January 1760, and on the 30th of the ſame month preached before the houſe of lords. In the next year he printed "A Rational Account of the Nature and End of the Sacrament of the Lord's Supper." In 1762, he publiſhed "The Doctrine of Grace; or the Office and Operations of the Holy Spirit vindicated from the Inſults of Infidelity and the Abuſes of Fanaticiſm," 2 vols 12mo; and in the ſucceeding year drew upon himſelf much illiberal abuſe from ſome writers of the popular party, on occaſion of his complaint in the houſe of lords, on the 15th of November 1763, againſt Mr Wilkes, for putting his name to certain notes on the infamous "Eſſay on Woman."

In 1765 he publiſhed a new edition of the ſecond part of the Divine Legation, in three volumes; and as it had now received his laſt hand, he preſented it to his great friend Lord Mansfield, in a dedication which deſerves to be read by every perſon who eſteems the well-being of ſociety as a concern of any importance. It was the appendix to this edition which produced the well-known controverſy between him and Dr Lowth, which we have noticed elſewhere (ſee LOWTH), as doing no great honour, by the mode in which it was conducted, to either party. In the next year he gave a new and much improved edition of the Alliance between the Church and State. This was followed, in 1767, by a third volume of ſermons, to which is added, his firſt Triennial Charge to the Clergy of the Dioceſe of Glouceſter; which may be ſafely pronounced one of the moſt valuable diſcourſes of the kind that is to be found in our own or any other language. With this publication he cloſed his literary courſe; except that he made an effort towards publiſhing, and actually printed, the ninth and laſt book of the Divine Legation. This book, with one or two occaſional ſermons, and ſome valuable directions for the ſtudy of *theology*, have been given to the world in the ſplendid edition of his works in ſeven volumes 4to, by his friend and biographer the preſent biſhop of Worceſter. That prelate confeſſes, that the ninth book of the Divine Legation diſplays little of that vigour of mind and fertility of invention which appear ſo conſpicuous in the former volumes; but he adds, perhaps truly, that under all the diſadvantages with which it appears, it is the nobleſt effort which has hitherto been made to give a *rationale* of Chriſtianity.

While the biſhop of Glouceſter was thus exerting his laſt ſtrength in the cauſe of religion, he projected a method by which he hoped to render it effectual ſervice after his death. He transferred L. 500 to Lord Mansfield, Sir Eardley Wilmot, and Mr Charles Yorke, upon truſt, to found a lecture, in the form of a courſe of ſermons, to prove the truth of revealed religion in general, and of the Chriſtian in particular, from the completion of the prophecies in the Old and New Teſtament, which relate to the Chriſtian church, eſpecially to the apoſtacy of Papal Rome. To this foundation we owe the admirable Introductory Lectures of Hurd, and the well-adapted Continuation of Halifax and Bagot.

It is a melancholy reflection, that a life ſpent in the conſtant purſuit of knowledge, frequently terminates in the loſs of thoſe powers, the cultivation and improvement of which are attended to with too ſtrict and unabated a degree of ardour. This was in ſome degree the misfortune of Dr Warburton. Like Swift, and the great duke of Marlborough, he gradually ſunk into a ſituation in which it was a fatigue to him to enter into general converſation. There were, however, a few old and valuable friends, in whoſe company, even to the laſt, his mental faculties were exerted in their wonted force; and at ſuch times he would appear cheerful for ſeveral hours, and on the departure of his friends retreat as it were within himſelf. This melancholy

habit

Warburton, Ward.

habit was aggravated by the loſs of his only ſon, a very promiſing young gentleman, who died of a conſumption but a ſhort time before the Biſhop, who himſelf reſigned to fate in the 81ſt year of his age. A neat marble monument has been erected to him in the cathedral of Glouceſter, with this inſcription—

To the Memory of
WILLIAM WARBURTON, D. D.
For more than 19 Years Biſhop of this See;
A Prelate
Of the moſt ſublime Genius, and exquiſite Learning.
Both which Talents
He employed through a long Life,
In the Support
Of what he firmly believed,
THE CHRISTIAN RELIGION;
And
Of what he eſteemed the beſt Eſtabliſhment of it,
THE CHURCH OF ENGLAND.
He was born at Newark upon Trent,
Dec. 24. 1698.
Was conſecrated BISHOP of Glouceſter,
Jan. 20. 1760.
Died at his Palace, in this city,
June 7. 1779.
And was buried near this Place.

WARD (Dr Seth,) an Engliſh prelate, chiefly famous for his knowledge in mathematics and aſtronomy, was born at Buntingford in Hertfordſhire, about the year 1617. He was admitted of Sidney college, Cambridge, where he applied with great vigour to his ſtudies, particularly to the mathematics, and was choſen fellow of his college. He was involved not a little in the conſequences of the civil war, but ſoon after the Reſtoration obtained the biſhopric of Exeter; in 1667, he was tranſlated to Saliſbury; and in 1671 was made chancellor of the order of the garter; he was the firſt Proteſtant biſhop that enjoyed that honour, and he procured it to be annexed to the ſee of Saliſbury. Biſhop Ward was one of thoſe unhappy perſons who have the misfortune to ſurvive their ſenſes, which happened in conſequence of a fever ill cured; he lived to the revolution, without knowing any thing of the matter, and died in 1690. He was the author of ſeveral Latin works in mathematics and aſtronomy, which were thought excellent in their day; but their uſe has been ſuperſeded by later diſcoveries and the Newtonian philoſophy.

WARD (Dr John), was the ſon of a diſſenting miniſter, and born at London in 1679. He for ſome years kept a ſchool in Tenter-alley, Moorfields; but rendered himſelf ſo eminent in the ſtudy of antiquity, that in 1720 he was choſen profeſſor of rhetoric in Greſham college: and in 1723, during the preſidency of Sir Iſaac Newton, he was elected a fellow of the Royal Society; and in 1752, one of the vice-preſidents, in which office he was continued to his death. He was elected one of the truſtees of the Britiſh Muſeum in 1753, and died at Greſham college in 1758. The work for which he is beſt known, is his Lives of the Profeſſors of Greſham College; which is a conſiderable addition to the hiſtory of learning in our country. His Lectures on Oratory were publiſhed after his death, in two volumes 8vo.

WARD, is variouſly uſed in our old books: a ward in London is a diſtrict or diviſion of the city, committed to the ſpecial charge of one of the aldermen; and in London there are 26 wards, according to the number of the mayor and aldermen, of which every one has his ward for his proper guard and juriſdiction. A foreſt is divided into wards; and a priſon is called a *ward*. Laſtly, the heir of the king's tenant, that held *in capite*, was termed a *ward* during his nonage; but this wardſhip is taken away by the ſtatute 12 Car. II. c. 24.

Ward ‖ Wardſhip.

WARD-Holding, in Scots law. See LAW, n° clxv. 1. and clxvi. 3.

WARD-Hook, or *Wadd-hook*, in gunnery, a rod or ſtaff, with an iron end turned ſerpentwiſe, or like a ſcrew, to draw the wadding out of a gun when it is to be unloaded.

WARDEN, or GUARDIAN, one who has the charge or keeping of any perſon, or thing, by office. Such is the warden of the Fleet, the keeper of the Fleet priſon; who has the charge of the priſoners there, eſpecially ſuch as are committed from the court of chancery for contempt.

WARDHUYS, a port of Norwegian Lapland, 120 miles ſouth-eaſt of the North Cape. E. Long. 31. 12. N. Lat. 70. 23.

WARDMOTE, in London, is a court ſo called, which is kept in every ward of the city; anſwering to the *curiata comita* of Rome.

WARDROBE, a cloſet or little room adjoining to a bed-chamber, ſerving to diſpoſe and keep a perſon's apparel in; or for a ſervant to lodge in, to be at hand to wait, &c.

Wardrobe, in a prince's court, is an apartment wherein his robes, wearing apparel, and other neceſſaries, are preſerved under the care and direction of proper officers.

In Britain, the *Maſter or Keeper of the Great* WARDROBE was an officer of great antiquity and dignity. High privileges and immunities were conferred on him by king Henry VI. which were confirmed by his ſucceſſors; and king James I. not only enlarged them, but ordained that this office ſhould be a corporation or body politic for ever.

It was the duty of this office to provide robes for the coronations, marriages, and funerals of the royal family: to furniſh the court with hangings, cloths of ſtate, carpets, beds, and other neceſſaries; to furniſh houſes for ambaſſadors at their firſt arrival; cloths of ſtate and other furniture, for the lord lieutenant of Ireland, and all his majeſty's ambaſſadors abroad; to provide all robes for foreign knights of the garter, robes for the knights of the garter at home; robes and all other furniture for the officers of the garter; coats for kings, heralds, and purſuivants at arms; robes for the lords of the treaſury, and chancellor of the exchequer, &c. livery for the lord chamberlain, grooms of his majeſty's privy chamber, officers of his majeſty's robes; for the two chief juſtices, for all the barons of the exchequer, and ſeveral officers of theſe courts; all liveries for his majeſty's ſervants, as yeomen of the guard, and wardens of the Tower, trumpeters, kettle-drummers, drummers, and fifers; the meſſengers, and all belonging to the ſtables, as coachmen, footmen, littermen, poſtilions, and grooms, &c. all the king's coaches, chariots, harneſſes, ſaddles, bits, bridles, &c. the king's water-men, game-keepers, &c. alſo furniture for the royal yachts, and all rich embroidered tilts, and other furniture for the barges.

Beatſon's Political Index, vol. ii.

Beſides the maſter or keeper of the wardrobe, who had a ſalary of L. 2000, there was his deputy, who had L. 150, and comptroller and a patent clerk, each of whom has a ſalary of L. 300. Beſides many other inferior officers and ſervants, who were all ſworn ſervants to the king.

There was likewiſe a removing wardrobe, who had its own ſet of officers, and ſtanding wardrobe-keepers at St James's, Windſor Caſtle, Hampton Court, Kenſington, and Somerſet Houſe; but the whole of the wardrobe eſtabliſhment was aboliſhed by act of Parliament in 1782, and the duty of it in future to be done by the lord chamberlain.

WARDSHIP, in chivalry, one of the incidents of tenure

Wardſhip nure by knight-ſervice. See *Feodal Syſtem*, *Knight Service*, and Tenure.

Upon the death of a tenant, if the heir was under the age of 21, being a male, or 14, being a female, the lord was intitled to the wardſhip of the heir, and was called the *guardian in chivalry*. This wardſhip conſiſted in having the cuſtody of the body and lands of ſuch heir, without any account of the profits, till the age of 21 in males, and 16 in females. For the law ſuppoſes the heir-male unable to perform knight ſervice till 21; but as for the female, ſhe was ſuppoſed capable at 14 to marry, and then her huſband might perform the ſervice. The lord therefore had no wardſhip, if at the death of the anceſtor the heir-male was of the full age of 21, or the heir female of 14: yet if ſhe was then under 14, and the lord once had her in ward, he might keep her ſo till 16, by virtue of the ſtatute of Weſtminſter, 1. 3 Edw. I. c. 22. the two additional years being given by the legiſlature for no other reaſon but merely to benefit the lord.

This wardſhip, ſo far as it related to land, though it was not nor could be part of the law of feuds, ſo long as they were arbitrary, temporary, or for life only; yet when they became hereditary, and did conſequently often deſcend upon infants, who by reaſon of their age could neither perform nor ſtipulate for the ſervices of the feud, does not ſeem upon feodal principles to have been unreaſonable. For the wardſhip of the land, or cuſtody of the feud, was retained by the lord, that he might out of the profits thereof provide a fit perſon to ſupply the infant's ſervices till he ſhould be of age to perform them himſelf. And if we conſider a feud in its original import, as a ſtipend, fee, or reward, for actual ſervice, it could not be thought hard that the lord ſhould withhold the ſtipend ſo long as the ſervice was ſuſpended. Though undoubtedly to our Engliſh anceſtors, where ſuch ſtipendary donation was a mere ſuppoſition or figment, it carried abundance of hardſhip; and accordingly it was relieved by the charter of Henry I. which took this cuſtody from the lord, and ordained that the cuſtody, both of the land and the children, ſhould belong to the widow or next of kin. But this nobe immunity did not continue many years.

The wardſhip of the body was a conſequence of the wardſhip of the land; for he who enjoyed the infant's eſtate was the propereſt perſon to educate and maintain him in his infancy: and alſo in a political view, the lord was moſt concerned to give his tenant a ſuitable education, in order to qualify him the better to perform thoſe ſervices which in his maturity he was bound to render.

When the male heir arrived to the age of 21, or the heir-female to that of 16, they might ſue out their livery or *ouſterlemain*; that is, the delivery of their lands out of their guardian's hands. For this they were obliged to pay a fine, namely, half-a-year's profits of the land; though this ſeems expreſsly contrary to *magna charta*. However, in conſideration of their lands having been ſo long in ward, they were excuſed all reliefs, and the king's tenants alſo all primer ſeiſins. In order to aſcertain the profits that aroſe to the crown by theſe fruits of tenure, and to grant the heir his livery, the itinerant juſtices, or juſtices in eyre, had it formerly in charge to make inquiſition concerning them by a jury of the country, commonly called an *inquiſitio poſt mortem*; which was inſtituted to inquire (at the death of any man of fortune) the value of his eſtate, the tenure by which it was holden, and who, and of what age, his heir was; thereby to aſcertain the relief and value of the primer ſeiſin, or the wardſhip and livery accruing to the king thereupon. A manner of proceeding that came in proceſs of time to be greatly abuſed, and at length an intolerable grievance; it being one of the principal accuſations againſt Empſon and Dudley, the wicked engines of Henry VII. that by colour of falſe inquiſitions they compelled many perſons to ſue out livery from the crown who by no means tenants were thereunto. And afterwards a court of wards and liveries was erected, for conducting the ſame inquiries in a more ſolemn and legal manner. Ware ‖ Warp.

When the heir thus came of full age, provided he held a knight's fee, he was to receive the order of knighthood, and was compellable to take it upon him, or elſe pay a fine to the king. For in thoſe heroical times no perſon was qualified for deeds of arms and chivalry who had not received this order, which was conferred with much preparation and ſolemnity. We may plainly diſcover the footſteps of a ſimilar cuſtom in what Tacitus relates of the Germans, who, in order to qualify their young men to bear arms, preſented them in a full aſſembly with a ſhield and lance; which ceremony is ſuppoſed to have been the original of the feodal knighthood. This prerogative, of compelling the vaſſals to be knighted, or to pay a fine, was expreſsly recogniſed in parliament by the ſtatute *de militibus*, 1 Edw. II.; was exerted as an expedient for raiſing money by many of our beſt princes, particularly by Edw. VI. and Q. Elizabeth; but this was the occaſion of heavy murmurs when exerted by Charles I.; among whoſe many misfortunes it was, that neither himſelf nor his people ſeemed able to diſtinguiſh between the arbitrary ſtretch and the legal exertion of prerogative. However, among the other conceſſions made by that unhappy prince before the fatal recourſe to arms, he agreed to diveſt himſelf of this undoubted flower of the crown; and it was accordingly aboliſhed by ſtatute 16 Car. I. c. 20.

WARE, a town of Hertfordſhire, with a market on Tueſdays, and a fair on the laſt Tueſday in April, and Tueſday before St Matthew's day (Sep. 21.) for horſes and other cattle. It is a large, well frequented, and well inhabited thoroughfare town, ſeated on the river Lea, 21 miles north of London. It carries on a great trade in malt and corn, which they are continually ſending in large quantities to London. E. Lon. 0. 3 N. Lat. 51. 50.

WARN, in law, is to ſummon a perſon to appear in a cour of juſtice.

WARNING *of Tenants*, in Scots law. See Law, n° cvlxii. 16.

WARP, in the manufactures, a name for the threads, whether of ſilk, wool, linen, hemp, &c. that are extended lengthwiſe on the weaver's loom; and acroſs which the workman, by means of his ſhuttle, paſſes the threads of the woof, to form a cloth, riband, fuſtian, or the like.

Warp, a ſmall rope employed occaſionally to remove a ſhip from one place to another, in a port, road, or river. And hence,

To Warp, is to change the ſituation of a ſhip, by pulling her from one part of a harbour, &c. to ſome other, by means of warps, which are attached to buoys; to anchors ſunk in the bottom; or to certain ſtations upon the ſhore, as poſts, rings, trees, &c. The ſhip is accordingly drawn forwards to thoſe ſtations, either by pulling on the warps by hand, or by the application of ſome purchaſe, as a tackle, windlaſs, or capſtern, upon her deck.

When this operation is performed by the ſhip's leſſer anchors, theſe machines, together with their warps, are carried out in the boats alternately, towards the place where the ſhip is endeavouring to arrive: ſo that when ſhe is drawn up cloſe to one anchor, the other is carried out to a competent diſtance before her, and being ſunk, ſerves to fix the other warp, by which ſhe is farther advanced.

Warping is generally uſed whe the ſails are unbent, or when

Warrandice || Warren.

when they cannot be ſucceſsfully employed, which may either ariſe from the unfavourable ſtate of the wind, the oppoſition of the tide, or the narrow limits of the channel.

WARRANDICE, in Scots law. See LAW, N° clxiv. 11.

WARRANT, is a power and charge to a conſtable or other officer to apprehend a perſon accuſed of any crime. It may be iſſued in extraordinary caſes by the privy council, or ſecretaries of ſtate; but moſt commonly it is iſſued by juſtices of the peace. This they may do in any caſes where they have a juriſdiction over the offence, in order to compel the perſon accuſed to appear before them; for it would be abſurd to give them power to examine an offender, unleſs they had alſo power to compel him to attend and ſubmit to ſuch examination. And this extends to all treaſonable felonies, and breaches of the peace; and alſo to all ſuch offences as they have power to puniſh by ſtatute. Before the granting of the warrant, it is fitting to examine upon oath the party requiring it, as well to aſcertain that there is a felony or other crime actually committed, without which no warrant ſhould be granted; as alſo to prove the cauſe and probability of ſuſpecting the party againſt whom the warrant is prayed.

Blackſt. Comment. vol. iv. p. 290.

This warrant ought to be under the hand and ſeal of the juſtice; ſhould ſet forth the time and place of making, and the cauſe for which it is made; and ſhould be directed to the conſtable, or other peace officer, or it may be to any private perſon by name. A general warrant to apprehend all perſons ſuſpected, without naming or particularly deſcribing any perſon in ſpecial, is illegal and void for its uncertainty; for it is the duty of the magiſtrate, and ought not to be left to the officer, to judge of the ground of ſuſpicion. Alſo a warrant to apprehend all perſons guilty of ſuch a crime, is no legal warrant; for the point upon which its authority reſts, is a fact to be decided on a ſubſequent trial; namely whether the perſon apprehended thereupon be guilty or not guilty. When a warrant is received by the officer, he is bound to execute it, ſo far as the juriſdiction of the magiſtrate and himſelf extends. A warrant from any of the juſtices of the court of king's bench extends over all the kingdom, and is teſted or dated *England:* but a warrant of a juſtice of the peace in one county, muſt be backed, that is, ſigned, by a juſtice of another county, before it can be executed there. And a warrant for apprehending an Engliſh or a Scotch offender may be indorſed in the oppoſite kingdom, and the offender carried back to that part of the united kingdom in which the offence was committed.

WARRANTY, WARRANTIA, in law, a promiſe, or covenant, by deed, made by the bargainer for himſelf and his heirs, to warrant and ſecure the bargainee and his heirs, againſt all men, for enjoying the thing agreed on or granted between them.

WARREN (Sir Peter), an admiral, diſtinguiſhed by his virtue, learning, and undaunted courage, was deſcended from an ancient family in Ireland, and received a ſuitable education to qualify him for a command in the royal navy, in which he ſerved for ſeveral years with great reputation; but the tranſaction which placed his great abilities in their full light, was the taking of Louiſbourg in the year 1745, when he was appointed commodore of the Britiſh ſquadron ſent on that ſervice. He joined the fleet of tranſports from Boſton in Canſo bay on the 25th of April, having under his command the Superb of 60, and the Launceſton and Eltham of 40 guns; he was afterwards joined by ſeveral other men of war ſent from England, and took poſſeſſion of Louiſbourg on the 17th of June. The French, exaſperated at this loſs, were conſtantly on the watch to retake it; and in 1747 fitted out a large fleet for that purpoſe, and at the ſame time another ſquadron to proſecute their ſucceſs in the Eaſt Indies. Theſe ſquadrons ſailed at the ſame time; but the views of the French were rendered abortive by the gallant admiral Anſon and Sir Peter Warren, who had been created rear-admiral, who with a large fleet of ſhips fell in with the French, defeated the whole fleet, and took the greateſt part of the men of war. This was the laſt ſervice Sir Peter rendered to his country as a commander in the Britiſh fleet; for a peace being concluded in the ſucceeding year, the fleet was laid up in the ſeveral harbours.

Warren, Warſaw.

He was now choſen one of the repreſentatives in parliament for Weſtminſter; and in the midſt of his popularity he paid a viſit to Ireland, his native country, where he died of an inflammatory fever in 1752, ſincerely lamented by all ranks of people; and an elegant monument of white marble was erected to his memory in Weſtminſter abbey.

WARREN, is a franchiſe or place privileged by preſcription or grant from the king, for the keeping of beaſts and fowls of the warren; which are hares and coneys, partridges pheaſants, and ſome add quails, woodcocks, and water-fowl, &c. Theſe being *feræ naturæ*, every one had a natural right to kill as he could: but upon the introduction of the foreſt laws at the Norman conqueſt, theſe animals being looked upon as royal game, and the ſole property of our ſavage monarchs, this franchiſe of free-warren was invented to protect them, by giving the grantee a ſole and excluſive power of killing ſuch game, ſo far as his warren extended, on condition of his preventing other perſons. A man therefore that has the franchiſe of warren, is in reality no more than a royal game-keeper: but no man, not even a lord of a manor, could by common law juſtify ſporting on another's ſoil, or even on his own, unleſs he had the liberty of free warren. This franchiſe is almoſt fallen into diſregard ſince the new ſtatutes for preſerving the game; the name being now chiefly preſerved in grounds that are ſet apart for breeding hares and rabbits. There are many inſtances of keen ſportſmen in ancient times, who have ſold their eſtates, and reſerved the free-warren, or right of killing game, to themſelves: by which means it comes to paſs that a man and his heirs have ſometimes free-warren over another's ground.

A warren may lie open; and there is no neceſſity of incloſing it as there is of a park. If any perſon offend in a free-warren, he is puniſhable by the common law, and by ſtatute 21 Edw. III. And if any one enter wrongfully into any warren, and chaſe, take, or kill, any coneys without the conſent of the owner, he ſhall forfeit treble damages, and ſuffer three months impriſonment, &c. by 22 and 23 Car. II. c. 25. When coneys are on the ſoil of the party, he hath a property in them by reaſon of the poſſeſſion, and action lies for killing them; but if they run out of the warren and eat up a neighbour's corn, the owner of the land may kill them, and no action will lie.

WARSAW, a large city of Poland, the capital of that country, and of the province of Maſovia. It is built partly in a plain, and partly on a gentle aſcent riſing from the banks of the Viſtula, which is about as broad as the Thames at Weſtminſter, but very ſhallow in ſummer. This city and its ſuburbs occupy a vaſt extent of ground, and are ſuppoſed to contain 70,000 inhabitants, among whom are a great number of foreigners. The whole has a melancholy appearance, exhibiting the ſtrong contraſt of wealth and poverty, luxury and diſtreſs, which pervades every part of this unhappy country. The ſtreets are ſpacious, but ill paved; the churches and public buildings are large and magnificent: the palaces of the nobility are numerous and ſplen-

Wart ‖ Washington.

did; but the greateſt part of the houſes, particularly in the ſuburbs, are mean and ill-conſtructed wooden hovels.—Warſaw is 160 miles ſouth-eaſt by ſouth of Dantzic, 130 north north-eaſt of Cracow, and 300 north-eaſt by north of Vienna. E. Long, 21. 6. N. Lat. 50. 14.

WART. See *Surgery-Index*.

WARWICK, the capital of Warwickſhire in England, and from which this county derives its name. It is very ancient, and ſuppoſed by Cambden to be the place called by the Romans *Præſidium*, where the Dalmatian horſe were poſted. It ſtands on a rock of free-ſtone, of which all the public edifices in the town are built. At the Norman invaſion it was a conſiderable place; and had many burgeſſes, of whom 12 were obliged by their tenure to accompany the king in his wars. It is ſupplied with water brought in pipes from ſprings half a mile from the town, beſides what it derives from the wells within it made in the rock: and it is eaſily kept clean, by being ſituated upon a declivity. Four ſtreets, from the four cardinal points of the compaſs, meet in the centre of the town. The principal public buildings are St Mary's, a very ſtately edifice, an hoſpital, a town-houſe of free-ſtone, three charity ſchools, and a noble bridge over the Avon. It has had ſeveral charters; but is governed at preſent by a mayor, 12 brethren, 24 burgeſſes, &c. It is a very handſome populous town, and gives title of earl to the family of the Grevilles. W. Long. 1. 36. N. Lat. 52. 20.

WASH, among diſtillers, the fermentable liquor uſed by the malt diſtillers. See Brewery.

WASHING, in painting, is when a deſign, drawn with a pen or crayon, has ſome one colour laid over it with a pencil, as Indian ink, biſtre, or the like, to make it appear the more natural, by adding the ſhadow of prominences, apertures, &c. and by imitating the particular matters whereof the thing is ſuppoſed to conſiſt.

Thus they waſh with a pale red, to imitate brick and tile; with a pale Indian blue, to imitate water and ſlate; with green for trees and meadows; with ſaffron or French berries, for gold or braſs; and with ſeveral colours for marbles.

Washing of Ores, the purifying an ore of any metal, by means of water, from earths and ſtones, which would otherwiſe render it difficult of fuſion.

WASHINGTON, a city of North America, now building for the metropolis of the United States. It is ſeated at the junction of the rivers Potomac and the Eaſtern Branch, extending about four miles up each, including a tract of territory ſcarcely to be exceeded, in point of convenience, ſalubrity, and beauty, by any in the world. This territory, which is called *Columbia*, lies partly in the ſtate of Virginia, and partly in that of Maryland, and was ceded by theſe two ſtates to the United States of America, and by them eſtabliſhed to be the ſeat of government after the year 1800. It is divided into ſquares or grand diviſions, by ſtreets running due north, and ſouth, and eaſt, and weſt, which form the ground-work of the plan. However, from the Capitol, the preſident's houſe, and ſome of the important areas in the city, run diagonal ſtreets, from one material object to another, which not only produce a variety of charming proſpects, but remove the inſipid ſameneſs which renders ſome other great cities unpleaſing. The great leading ſtreets are all 160 feet wide, including a pavement of 10 feet, and a gravel walk of 30 feet planted with trees on each ſide, which will leave 80 feet of paved ſtreet for carriages. The reſt of the ſtreets are in general 110 feet wide, with a few only 90 feet, except North, South, and Eaſt Capitol Streets, which are 160 feet. The diagonal ſtreets are named after the reſpective ſtates compoſing the Union, while thoſe running north and ſouth are, from the Capitol eaſtward, named *Eaſt Firſt Street*, *Eaſt Second Street*, &c. and thoſe weſt of it are in the ſame manner called *Weſt Firſt Street*, *Weſt Second Street*, &c. Thoſe running eaſt and weſt are from the Capitol northward named *North A Street*, *North B Street*, &c. and thoſe ſouth of it are called *South A Street*, *South B Street*, &c. The ſquares or diviſions of the city amount to 1150. The rectangular ſquares generally contain from three to ſix acres, and are divided into lots of from 40 to 80 feet in front, and their depth from about 110 to 300 feet, according to the ſize of the ſquare. The irregular diviſions produced by the diagonal ſtreets are ſome of them ſmall, but generally in valuable ſituations. Their acute points are all to be cut off at 40 feet, ſo that no houſe in the city will have an acute corner. All the houſes muſt be of brick or ſtone. The area for the Capitol (or houſe for the legiſlative bodies) is ſituated upon the moſt beautiful eminence in the city, about a mile from the Eaſtern Branch, and not much more from the Potomac, commanding a full view of every part of the city, as well as a conſiderable extent of the country around. The preſident's houſe will ſtand upon a riſing ground, not far from the banks of the Potomac, poſſeſſing a delightful water proſpect, with a commanding view of the Capitol, and ſome other material parts of the city.

Waſhington. ‖ Watch.

The city being ſituated upon the great poſt road, exactly equidiſtant from the northern and ſouthern extremities of the Union, and nearly ſo from the Atlantic Ocean to the river Ohio, upon the beſt navigation, and in the midſt of the richeſt commercial territory in America, commanding the moſt extenſive internal reſources, is by far the moſt eligible ſituation for the reſidence of congreſs; and it is now preſſing forward, by the public-ſpirited enterpriſe, not only of the people of the United States, but alſo of foreigners.

WASP, in zoology. See Vespa.

Watch, in the art of war, a number of men poſted at any paſſage, or a company of the guards who go on the patrole.

Watch, in the navy, the ſpace of time wherein one diviſion of a ſhip's crew remains upon deck, to perform the neceſſary ſervices, whilſt the reſt are relieved from duty, either when the veſſel is under ſail or at anchor.

The length of the ſea-watch is not equal in the ſhipping of different nations. It is always kept four hours by the Britiſh ſeamen, if we except the dog-watch, between four and eight in the evening, that contains two reliefs, each of which are only two hours on deck. The intent of this is to change the period of the night-watch every 24 hours; ſo that the party watching from 8 till 12 in one night, ſhall watch from midnight till four in the morning on the ſucceeding one. In France the duration of the watch is extremely different, being in ſome places ſix hours, and in others ſeven or eight; and in Turky and Barbary it is uſually five or ſix hours.

A ſhip's company is uſually claſſed into two parties; one of which is called the *ſtarboard* and the other the *larboard* watch. It is however, occaſionally ſeparated into three diviſions, as in a road or in particular voyages.

In a ſhip of war the watch is generally commanded by a lieutenant, and in merchant-ſhips by one of the mates; ſo that if there are four mates in the latter, there are two in each watch; the firſt and third being in the larboard, and the ſecond and fourth in the ſtarboard-watch: but in the navy, the officers who command the watch uſually divide themſelves into three parties, in order to lighten their duty.

Watch, is alſo uſed for a ſmall portable movement, or machine, for the meaſuring of time; having its motion regulated by a ſpiral ſpring.

Watches,

Watch. Watches, ſtrictly taken, are all ſuch movements as ſhow the parts of time; as clocks are ſuch as publiſh it, by ſtriking on a bell, &c. But commonly the name *watch* is appropriated to ſuch as are carried in the pocket; and *clock* to the large movements, whether they ſtrike the hour or not. See CLOCK.

The invention of ſpring or pocket-watches belongs to the preſent age. It is true, we find mention made of a watch preſented to Charles V. in the hiſtory of that prince: but this, in all probability, was no more than a kind of clock to be ſet on a table, ſome reſemblance whereof we have ſtill remaining in the ancient pieces made before the year 1670. There was alſo a ſtory of a watch having been diſcovered in Scotland belonging to king Robert Bruce; but this we believe has turned out altogether apocryphal. The glory of this very uſeful invention lies between Dr Hooke and M. Huyghens; but to which of them it properly belongs, has been greatly diſputed; the Engliſh aſcribing it to the former, and the French, Dutch, &c. to the latter. Mr Derham, in his Artificial Clockmaker, ſays roundly, that Dr Hooke was the inventer; and adds, that he contrived various ways of regulation. One way was with a loadſtone: Another with a tender ſtraight ſpring, one end whereof played backwards and forwards with the balance; ſo that the balance was to the ſpring as the bob to a pendulum, and the ſpring as the rod thereof: A third method was with two balances, of which there were divers ſorts; ſome having a ſpiral ſpring to the balance for a regulator, and others without. But the way that prevailed, and which continues in mode, was with one balance, and one ſpring running round the upper part of the verge thereof: Though this has a diſadvantage, which thoſe with two ſprings, &c. were free from; in that a ſudden jerk, or confuſed ſhake, will alter its vibrations, and put it in an unuſual hurry.

The time of theſe inventions was about the year 1658; as appears, among other evidences, from an inſcription on one of the double balance watches preſented to king Charles II. *viz.* Rob. Hooke *inven.* 1658. T. Tompion *fecit*, 1675. The invention preſently got into reputation, both at home and abroad; and two of them were ſent for by the dauphin of France. Soon after this, M. Huygens's watch with a ſpiral ſpring got abroad, and made a great noiſe in England, as if the longitude could be found by it. It is certain, however, that his invention was later than the year 1673, when his book *de Horol. Oſcillat.* was publiſhed; wherein he has not one word of this, though he has of ſeveral other contrivances in the ſame way. Watch.

One of theſe the lord Brouncker ſent for out of France, where M. Huygens had got a patent for them. This watch agreed with Dr Hooke's in the application of the ſpring to the balance; only M. Huygens's had a longer ſpiral ſpring, and the pulſes and beats were much ſlower. The balance, inſtead of turning quite round, as Dr Hooke's, turns ſeveral rounds every vibration.

Mr Derham ſuggeſts, that he has reaſon to doubt M. Huygens's fancy firſt was ſet to work by ſome intelligence he might have of Dr Hooke's invention from Mr Oldenburg, or ſome other of his correſpondents in Egland; and this, notwithſtanding Mr Oldenſworth's attempt to vindicate himſelf in the Philoſophical Tranſactions, appears to be the truth (A). Huygens invented divers other kinds of watches, ſome of them without any ſtring or chain at all; which he called, particularly, *pendulum watches*.

Striking WATCHES are ſuch as, beſides the proper watch-part for meaſuring of time, have a clock-part for ſtriking the hours, &c.

Repeating WATCHES, are ſuch as by pulling a ſtring, &c. repeat the hour, quarter, or minute, at any time of the day

(A) To expect perfection in a work of this extent would be unreaſonable, and we truſt to the candour of our readers for their acceptance of our beſt endeavours: we hold ourſelves much obliged to them for their communications of every remark which may enable us to render the Encyclopædia Britannica more worthy of that moſt encouraging reception which it has met with from the Public. To the regular ſeries of articles, the preſent Editor had once reaſon to believe that a Supplement was to be annexed, which ſhould include not only thoſe additions which have been made to the circle of the ſciences during the progreſs of the work, but likewiſe ſuch articles as he or his predeceſſor had, through their unremitting occupation or their ignorance, ſuffered to eſcape their notice. In that Supplement he would have corrected all ſuch errors or miſtakes in the work as might have been diſcovered by himſelf or pointed out to him by his Correſpondents. But he is no Proprietor, and cannot announce the publication of a Supplement but as an event of great uncertainty. He is therefore much obliged to his highly reſpected friend and correſpondent who has put it in his power at preſent to do juſtice to the memory of Dr Robert Hooke; one of the greateſt ornaments of the Royal Society of London during the time of its infant ſtate and juvenile vigour, and one of the moſt extenſive and inventive geniuſes that the world has ever ſeen.

In the article HAUTEFEUILLE, we aſcribe to that author the invention of the regulating or balance ſpring of a watch, by which its motion is made as truly equable as by a pendulum. This is verified by the watches of Harriſon, Arnold, and others, which do not deviate from equable motion above one ſecond in ſeveral days. That the importance of this is acknowledged by the intelligent Public, is evident from the ſerious and repeated deliberations of the Britiſh Senate, and the high rewards which it has given to the makers of ſuch watches; and we truſt that this will appear to ſuch of our readers as are not ſo much intereſted in mechanical performances a ſufficient excuſe for our anxiety to give the honour of the invention to its right owner. We had collected from our ſearches that Mr Huyghens had diſcovered, by his analyſis of pendulous motions, what kind of motion would be produced by any kind of varying force, and that a force varying in the proportion of its diſtance from the place of reſt would produce iſochronous vibrations, whatever might be their extent; and had made experiments on the force of ſprings, and found them to vary according to this very law. In conſequence of this, he ſaw that a balance-watch might be made to anſwer the ſame end with his cycloidal pendulum-clock, which he had been for ſeveral years trying to fit for the diſcovery of the longitude of a ſhip at ſea, under the protection of the States of Holland and the court of France, having obtained a patent monopoly from the States and from Louis XIV. When, after repeated diſappointments, he introduced his propoſed watches, with ſanguine hopes of their performance, but before any trial, and applied for ſuch an extenſion of his patent as ſhould alſo comprehend a balance regulated by a ſpring, he was oppoſed by the watch-makers. They had willingly acquieſced in his excluſive right to the pendulum-clock, which was entirely his own demeſne; but they could not help conſidering this extenſion of his patent as an encroachment on a common which they had poſſeſſed from time immemorial. The oppoſition was general both in

Holland

Watch. or night.—This repetition was the invention of Mr Barlow, and firſt put in practice by him in larger movements or clocks about the year 1676. The contrivance immediately ſet the other artiſts to work, who ſoon contrived divers ways of effecting the ſame. But its application to pocket-watches was not known before king James the Second's reign; when the ingenious inventer above-mentioned, having directed Mr Tompſon to make a repeating watch, was ſoliciting a patent for the ſame. The talk of a patent engaged Mr Quare to reſume the thoughts of a like contrivance, which he had had in view ſome years before: he now effected it; and being preſſed to endeavour to prevent Mr Barlow's patent, a watch of each kind was produced before the king and council; upon trial of which, the preference was given to Mr Quare's. The difference between them was, that Barlow's was made to repeat by puſhing in two pieces on each ſide the watch-box; one of which repeated the hour, and the other the quarter: whereas Quare's was made to repeat by a pin that ſtuck out near the pendant, which being thruſt in (as now it is done by thruſting in the pendant itſelf), repeated both the hour and quarter with the ſame thruſt. Watch.

Of the Mechaniſm of a WATCH, properly ſo called. Watches, as well as clocks, are compoſed of wheels, and pinions, and a regulator to direct the quickneſs or ſlowneſs of the wheels, and of a ſpring which communicates motion to the

---

Holland and in France, and naturally came to the knowledge of Mr Hautefeuille. This perſon was conſcious of a double right to oppoſe this encroachment, having alſo, though perhaps empirically, and without principle, diſcovered that a ſpring, applied to the balance of a watch, produced a ſurpriſing equability of vibration; and hoped by its means to produce a perfect iſochroniſm. By Mr Hautefeuille's oppoſition the effect of the French patent was ſtopped for want of regiſtration. The Dutch patent was however expeded, and trials were made. But their reſult was unfavourable; many things were wanting beſides the true adjuſtment of the regulating power of the balance-ſpring. Scientific mechanics was then in its infancy, Galileo was dead, Newton was but beginning his glorious career; Huyghens therefore had few aſſiſtants.

The Royal Society of London was juſt founded, and Charles II. or his brother the duke of York, ſaw, *like a prince*, how conducive their labours would be to public proſperity, and particularly to the improvement of navigation. The king therefore enjoined them to turn much of their attention to this object; he eſtabliſhed the Royal Obſervatory at Greenwich *for this expreſs purpoſe*; and the parliament held out encouragement for the diſcovery of the longitude. It was natural therefore for Mr Huyghens to look to this quarter for encouragement; and if any one will take the pains to compare the dates of Mr Huyghens's mathematical labours, after his diſſertation on the pendulum, and his correſpondence with the Britiſh literati, till he was elected member of the Royal Society, his *private* correſpondence afterwards with Mr Oldenburgh, a German, their ſecretary, and his public correſpondence with him as ſecretary for the Society, he will obſerve the operation of ſomething more than ſcientific zeal.

This correſpondence, however, did not anſwer Mr Huyghens's hopes; for it informed him that the ground had been preoccupied by Mr Hooke, who had long before diſcovered, that a ſpring properly applied to a watch-balance would produce iſochronous vibrations, and had alſo long ago applied for a royal patent for the monopoly. The hiſtory of this application is curious, as a mere matter of anecdote; and it is inſtructive, while it is humiliating to human vanity, ſhowing us, that even in the greateſt characters, genius and talents, and noble and undoubted virtues, may exiſt along with ſome of our leſs honourable propenſities, and cannot altogether hinder their operation. There never was a time in which it was more proper that every one of us ſhould have a monitor, who ſhould ſometimes call out aloud to us, "Remember that thou art a man," than the preſent, when fanatic vanity, under the falſe and abuſed name of *philoſophy*, is waging war with every thing that is good or true, and threatens to plunge the cultivated portions of the human race into their former barbariſm, with the horrid addition of the habits of ſavage atrocity; while the voice of religion, which would call us together as the children of one parent, is ſtifled amidſt the yells of brother fiends. We hope for indulgence, then, while we endeavour, in a few words, to make the hiſtory of this invention as clear as can be expected in a ſubject which does not ſo ſenſibly intereſt the public in general, and after ſuch a long interval of time.

Mr Hooke, from his infancy, had a ſtrong predilection for mechanics; he had alſo a ſtrong propenſity to ſyſtem-making; and, from his firſt years of ſerious occupations, entertained a notion, that every thing might be formed into a ſyſtem, and that nothing could be proſecuted with any well-founded proſpect of improvement unleſs it was ſo treated. His amazingly comprehenſive genius graſped at every thing which came under his obſervation; and he immediately began to form a ſyſtem about it.—His writings are full of ſcraps of ſuch ſyſtematic views; many of them, it muſt be acknowledged, haſty, inaccurate, and futile, but ſtill ſyſtematical. He called them algebras, and conſidered them as having a ſort of inventive power, or rather as means of diſcovering things unknown by a proceſs ſomewhat ſimilar to that art. He valued himſelf highly on account of this view of ſcience, which he thought peculiar to himſelf; and he frequently ſpeaks of others, even of the moſt eminent, as childiſhly contenting themſelves with partial views of the corners of things. He was likewiſe very apt to conſider other inventors as encroachers on his ſyſtems, which he held as a kind of property, being ſeriouſly determined to proſecute them all in their turn, and never recollecting that any new object immediately called him off, and engaged him for a while in the moſt eager purſuit. His algebras had already given him many ſignal helps; and he had no doubt of their carrying him through in every inveſtigation. Stimulated by this overfond expectation, when a diſcovery was mentioned to him he was too apt to think and to ſay, that he had long ago invented the ſame thing; when the truth probably was, that the courſe of his ſyſtematic thoughts on the ſubject with which it was connected had really ſuggeſted it to him, with ſuch vivacity, or with ſuch notions of its importance, as to make him ſet it down in his regiſter in its own ſyſtematic place (for this was his conſtant practice, worthy of ſuch a genius, and of immenſe ſervice to all inquiſitive men.) But it was put out of his mind by ſome new object of purſuit. We, at this time, can hardly conceive the ardour with which every thing was treated in thoſe youthful days of ſcientific novelty.

His favourite algebra, of which he frequently ſpeaks as an invaluable treaſure, and the ſource of all his reputation, was his Mechanical Algebra or Method of Mechanic Invention. He ſays, that no queſtion in mechanics could be propoſed to him, but he could quickly tell whether it were poſſible to ſolve it, and could get into the proper track for the ſolution. Unfortunately,

Watch. Plate DXXXVII

the whole machine. But the regulator and ſpring of a watch are vaſtly inferior to the weight and pendulum of a clock, neither of which can be employed in watches. In place of a pendulum, therefore, we are obliged to uſe a balance (fig. 1.) to regulate the motion of a watch; and a ſpring (fig. 2.) which ſerves in place of a weight, to give motion to the wheels and balance.

The wheels of a watch, like thoſe of a clock, are placed in a frame formed of two plates and four pillars. Fig. 3. repreſents the inſide of a watch, after the plate (fig. 4.) is taken off. A is the barrel which contains the ſpring (fig. 2.); the chain is rolled about the barrel, with one end of it fixed to the barrel A (fig. 5.), and the other to the fuſee B.

When a watch is wound up, the chain which was upon the barrel winds about the fuſee, and by this means the ſpring is ſtretched; for the interior end of the ſpring is fixed by a hook to the immoveable axis, about which the barrel revolves; the exterior end of the ſpring is fixed to the inſide of the barrel, which turns upon an axis. It is therefore eaſy to perceive how the ſpring extends itſelf, and how its elaſticity forces the barrel to turn round, and conſequently obliges the chain which is upon the fuſee to unfold and turn the fuſee; the motion of the fuſee is communicated to the wheel C (fig. 5.); then, by means of the teeth, to the pinion *c*, which carries the wheel D; then to the pinion *d*, which carries the wheel E; then to the pinion *e*, which

Watch.

Unfortunately this periſhed in the burning of Greſham College, where Mr Hooke had apartments from the Royal Society; and he does not ſeem to have replaced it. It was perhaps, like the reſt, nothing more than ſcraps. The Correſpondent who favours us with theſe obſervations ſaw, in 1768, many papers of Mr Hooke's writings in the Society's archives, which had evidently been reſcued from the flames, and had been in the poſſeſſion of Mr Waller; part of which he publiſhed, and would have given more had he lived. Many of the leaves were ſcraps, perhaps ſingle lines; many had dates; many of them were ſuch as would be fragments of this mechanical algebra. Mr Hooke poſitively ſays, that it was by this ſyſtem that he diſcovered the regulating power of a ſpring. And this brings us to the ſubject in hand, to which we hope the foregoing obſervations will not be thought too long a preface.

In 1655 he was admitted into the Invisible Society at Oxford, and was particularly patroniſed by Dr Ward, afterwards biſhop of Saliſbury, who inſtructed him in aſtronomy, and ſtrongly recommended to his mechanical genius the diſcovery of ſome method of maintaining the vibrations of a pendulum, as of immenſe ſervice to the aſtronomer. This Hooke accompliſhed immediately, and thought of uſing pendulum clocks for diſcovering the longitude at ſea; and *his method* of mechanic inventions *quickly* led him, he ſays, to the diſcovery of the regulating power of ſprings as equivalent (nay, he ſays, ſuperior) to that of gravity. This is remarkable; for it appears that he had at that time mathematics enough to inform him, that nothing would produce iſochronous vibrations but an accelerative force proportional to the ſpace *to be paſſed through*, a truth neither obvious nor eaſily come at; and that the accelerative action of gravity on a common pendulum was not exactly in this proportion: but he did not then know the mechanical properties of the cycloid, a diſcovery reſerved to do honour to Mr. Huyghens. Our correſpondent farther informs us, that he recollects ſeeing, among the ſcraps of Mr. Hooke's writing, words nearly to the following purpoſe: "To produce a tranſlation of a moveable thus ——— or thus —— in the ſame time, requires a preſſing power thus or thus ." This will evidently appear to be a haſty expreſſion of a force at the diſtance to be run through. He had found by experiments, made probably with other views, that the force of a ſpring was proportional to its deviation from its quieſcent ſhape, and this whatever was its ſhape. Of this truth he now ſaw the value, and marked it in his regiſter, and gave it to his friends, agreeably to the cuſtom of the times, in the form of a cipher *cc, iii, no, sss, tt, uu*; which was afterwards explained "*Ut tenſio, ſic vis.*"

Mr Boyle was then his chief patron, and to him he communicated his ſcheme of meaſuring time accurately by a balance-watch regulated by a ſpring; and ſhowed him watches ſo conſtructed, which performed with ſurpriſing accuracy. Immediately after the Reſtoration, Mr Boyle acquainted Lord Brouncker and Sir Robert Moray, the moſt eminent gentlemen of the age for mathematical learning, and for natural knowledge in general, with Mr Hooke's diſcovery and ſcheme; and thoſe gentlemen encouraged him to apply for a patent, and even drew up a form for an act of parliament, to give him a profit on his invention by a duty on ſhipping. This draught was ſhown to the king, and he granted a warrant for a patent to Mr Hooke for 14 years; which warrant was in the poſſeſſion of Mr Waller.

It appears that theſe gentlemen were ſo ſenſible of the merits of the invention, and ſo confident of its ſucceſs, that they aſſociated themſelves with Dr Hooke in the proſecution of it. But in what reſpect they were to contribute, beſides their influence in procuring the patent and the act of parliament, does not appear. There remained, however, in Mr Waller's poſſeſſion ſeveral ſcrolls and drafts of a mutual agreement between them to this effect: In one of them it was agreed, that if the profits ſhould exceed L. 6000, Mr Hooke ſhould have $\frac{3}{4}$ths of the overplus; if it ſhould be only L. 4000, he ſhould have $\frac{2}{3}$ds, &c. they having the reſt, and that Dr Hooke ſhould be declared the author and inventor. It is probable that they were to advance the money neceſſary for carrying on the trade of watchmaking.—Many alterations were made in the terms of agreement; and it appears, that before any thing definitive was done, Hooke was diſguſted, becauſe they inſiſted, that if they or any other perſon ſhould fall on any way of improving on theſe principles, they ſhould enjoy the benefit of it during the currency of the patent. This he flatly refuſed; ſaying that it was *facile inventis addere*. It is probable that his manner of refuſal, which never was gracious or polite, might offend perſons of their rank, and contribute to put an end to the whole affair; for it never went farther, and Hooke became much more retentive and cloſe than formerly.

But while things were on a friendly footing, there occurred ſufficient proofs of Dr Hooke's being the author of the invention, and that even Mr Huyghens could hardly fail of knowing ſomething of it when he was in England in 1663, ten or eleven years before he publiſhed his claim, and even before he had analyſed the motion of pendulous bodies. In page 247 of the Society's Regiſter, in 1660, mention is made of Hooke's watches for the pocket, where the motion is regulated by ſprings. Now Hooke, in his firſt watches, employed two oppoſite ſprings, ſtraight, and acting on the balance

Watch. which carries the wheel F; then to the pinion *f*, upon which is the balance-wheel G, whoſe pivot runs in the pieces A called the *potance*, and B called a *follower*, which are fixed on the plate fig. 4. This plate, of which only a part is repreſented, is applied to that of fig. 3. in ſuch a manner that the pivots of the wheels enter into holes made in the plate fig. 3. Thus the impreſſed force of the ſpring is communicated to the wheels: and the pinion *f* being then connected to the wheel F, obliges it to turn (fig. 5.) This wheel acts upon the palettes of the verge 1, 2, (fig. 1.), the axis of which carries the balance HH, (fig. 1.) The pivot I, in the end of the verge, enters into the hole *c* in the potance A (fig. 4.) In this figure the palettes are repreſented; but the balance is on the other ſide of the plate, as may be ſeen in fig. 6. The pivot 3 of the balance enters into a hole of the cock BC (fig. 7.), a perſpective view of which is repreſented in fig. 8. Thus the balance turns between the cock and the potance *c* (fig. 4.), as in a kind of cage. The action of the balance-wheel upon the palettes 1, 2 (fig. 1.), is the ſame with what we have deſcribed with regard to the ſame wheel in the clock; *i. e.* in a watch, the balance-wheel obliges the balance to vibrate backwards and forwards like a pendulum. At each vibration of the balance a palette allows a tooth of the balance-wheel to eſcape; ſo that the quickneſs of the motion of the wheels is entirely determined by the quickneſs of the vibrations of the balance; and theſe vibrations of the balance and motion of the wheels are produced by the action of the ſpring.

But the quickneſs or ſlowneſs of the vibrations of the balance depend not ſolely upon the action of the great ſpring, but chiefly upon the action of the ſpring *a*, *b*, *c*, called *the ſpiral ſpring* (fig. 9.), ſituated under the balance H, and repreſented in perſpective (fig. 6.). The exterior end of the ſpiral is fixed to the pin *a*, (fig. 9.). This pin is applied near the plate in *a*, (fig. 6.); the interior end of the ſpiral is fixed by a peg to the centre of the balance. Hence if the balance is turned upon itſelf, the plates remaining immoveable, the ſpring will extend itſelf, and make the balance perform one revolution. Now, after the ſpiral is thus extended, if the balance be left to itſelf, the elaſticity of the ſpiral will bring back the balance, and in this manner the alternate vibrations of the balance are produced.

In fig. 5. all the wheels above deſcribed are repreſented in ſuch a manner, that you may eaſily perceive at firſt ſight how the motion is communicated from the barrel to the balance. Watch || Water.

In fig. 10. are repreſented the wheels under the dial-plate by which the hands are moved. The pinion *a* is adjuſted to the force of the prolonged pivot of the wheel D (fig. 5.), and is called a *cannon pinion*. This wheel revolves in an hour. The end of the axis of the pinion *a*, upon which the minute-hand is fixed, is ſquare; the pinion (fig. 10) is indented into the wheel *b*, which is carried by the pinion *a*. Fig. 11. is a wheel fixed upon a barrel, into the cavity of which the pinion *a* enters, and upon which it turns freely. This wheel revolves in 12 hours, and carries along with it the hour-hand. For a full account of the principles upon which watches and all time-keepers are conſtructed, we muſt refer our readers to a ſhort treatiſe, entitled *Thoughts on the Means of improving Watches*, by Thomas Mudge.

Watch-glaſſes, in a ſhip, are glaſſes employed to meaſure the period of the watch, or to divide it into any number of equal parts, as hours, half-hours, &c. ſo that the ſeveral ſtations therein may be regularly kept and relieved, as at the helm, pump, look-out, &c.

WATCHING, in medicine, is when the patient cannot ſleep. In fevers it is a dangerous ſymptom, and if long continued ends in a delirium.

WATER, a well known fluid, diffuſed through the atmoſphere, and over the ſurface of the globe, and abounding in a certain proportion in animals, vegetables, and minerals.

1 Uſes of water.

The uſes of water are ſo univerſally known, that it would be ſuperfluous to enumerate them in this article. It is eſſential to animal and vegetable life; it makes eaſy the intercourſe between the moſt diſtant regions of the world; and it is one of the moſt uſeful powers in the mechanic arts. It is often found combined with various ſubſtances, and is then frequently beneficial in curing or alleviating diſeaſes.

Thoſe properties of water which fit it for anſwering mechanical purpoſes are explained in other articles of this Work (ſee HYDROSTATICS, PNEUMATICS, n° 3. RESISTANCE, and RIVERS); but it ſtill remains for us to give an account of the late celebrated diſcovery of the compoſition of water, and the various ſubſtances which are often found chemically united with it.

2 Not tranſmutable into earth.

The ancient philoſophers conſidered water as one of the four elements. During the age of the alchymiſts, when it was believed that different ſubſtances could be converted into gold, it was alſo an opinion, adopted by many, that water could be changed into earth. Even ſo late as the time of Mr Boyle

---

lance by a ſilk fibre rolled round the cylindric axis of the balance. Mr Hooke, long after this complained to the Society of Mr Oldenburgh's communicating this and other things to Huyghens, with whom he had an intimate correſpondence. In 1665 Sir Robert Moray wrote a letter to Mr Oldenburgh, preſuming, from his intimacy with Mr Huyghens, that he would know how ſoon his watches would be ready, and deſired him to aſk Mr Huyghens, "Whether he did not apply a ſpring to *the axis* of the balance?" and if he ſhould ſay any thing to that purpoſe, then to tell him WHAT *Hooke had done in that way*, and that he intended more. *N. B.* Before this time the treaty had been dropped, and there appeared to Sir Robert no farther need of concealment.

From theſe and other facts that might be produced, we think it moſt evident that Mr Hooke invented the regulating ſpring of a watch, by which it is made perfectly adequate to the purpoſe of finding the longitude at ſea; that he invented it eight or ten years before Mr Huyghens thought of ſuch a thing, and fifteen years before he publiſhed it in the *Journal des Sçavans* in 1674.

Our readers cannot fail of making ſome remarks on this anecdote, which will perhaps extenuate a little Mr Hooke's moroſe behaviour, and explain, and perhaps excuſe, his diſpoſition to boaſt of his own inventions and arrogate thoſe of others. If any of the expreſſions in the article allotted to his name ſhould have made too unfavourable an impreſſion, this note may help to ſoften it. We do not think that it can be inferred from thoſe facts that either Hautefeuille or Huyghens *purloined* Hooke's invention. The one might fall upon it in the courſe of his many experiments; and the other, from his mathematical diſcoveries of the requiſites for iſochronous vibrations, might be induced to *try* whether ſprings afforded ſuch a force. But there can remain no doubt but that Hooke made the diſcovery LIKE A PHILOSOPHER. If to this Work any Supplement ſhall be given by the preſent Editor, he will endeavour ſtill farther to wipe away the obloquy which has been caſt upon the memory of Dr Hooke for his arrogance in claiming the merit of inventions *ſuppoſed* to be the property of others.

Water. Boyle this ſentiment was not laid aſide. He relates, that a friend of his by diſtilling a quantity of water an hundred times, found at length that he had got ſix-tenths of the firſt quantity in earth: whence he concludes, that the whole water, by further proſecuting the operation, might be converted into earth. Others have made experiments to the ſame purpoſe, and ſeemingly with the ſame ſucceſs; but the deception is now found out. Water has the power of corroding the hardeſt bodies, even glaſs itſelf, by long digeſtion, eſpecially when aſſiſted by heat; and hence thoſe who have made the experiments juſt mentioned, have been themſelves deceived, by ſuppoſing the earth which really came from the containing veſſel to come from the water.

Margraaf made ſeveral experiments to determine whether water be tranſmutable into earth, and found that after every diſtillation a ſediment was left. Lavoiſier repeated Margraaf's experiments, and gave the explanation which we alluded to, that the ſediment conſiſted of portions of the glaſs ſeparated by the water. Dr Black, in the valuable courſe of lectures which he has for many years delivered, with ſo much honour to himſelf, and ſo much to the advancement of the ſcience of chemiſtry, goes ſtill farther: he ingeniouſly ſuppoſes, that the alkali, which is an eſſential ingredient in the compoſition of glaſs, unites with the water, and makes the glaſs ſwell, and thus occaſions ſmall portions of it to be detached.

Hiſtorical Account of the Diſcovery of the Compoſition of Water.

THAT water is not a ſimple but a compound ſubſtance, conſiſting of a mixture of vital and inflammable air, is one of the moſt aſtoniſhing and important diſcoveries which has been made ſince the origin of chemiſtry, or indeed ſince the origin of ſcience. The hiſtory of this curious and intereſting diſcovery we ſhall trace back with as much preciſion and impartiality as poſſible to the firſt hints which were thrown out upon the ſubject, and endeavour at the ſame time to aſſign to all who have contributed to the diſcovery the merit to which they are reſpectively entitled.

3 Mr Warltire's experiment gives the firſt hint.

The firſt thing that led chemiſts to make experiments concerning the compoſition of water, was a letter which Mr John Warltire, lecturer in natural philoſophy, wrote to Dr Prieſtley, dated Birmingham 18th April 1781, and publiſhed in the Appendix to the 5th volume of Dr Prieſtley's *Experiments and Obſervations*. This gentleman had long entertained an opinion that the queſtion "whether heat be a heavy body," might be determined by burning inflammable air mixed with atmoſpherical air. For ſome time he was deterred from trying the experiment, from an apprehenſion that the conſequences of paſſing the electrical ſpark through ſo combuſtible a mixture might be attended with danger; but at length, being encouraged by Dr Prieſtley, he prepared an apparatus for the purpoſe. He got a copper ball weighing 14 oz. and ſufficient to contain three wine pints, with a ſcrew ſtopper adapted to it, ſo that no air could eſcape. When he filled this ball with inflammable and common air, and made the electric ſpark to paſs through it, a loſs of weight was obſerved, upon an average, about two grains. When the ſame experiment was made in cloſe glaſs veſſels, the inſide of the glaſs, though clean and dry before the operation, became immediately wet with dew, and was lined with a ſooty ſubſtance. When Mr Warltire ſaw the moiſture, he ſaid to Dr Prieſtley, that it confirmed an opinion which he had long entertained, that common air depoſits its moiſture when it is phlogiſticated. After this experiment had been repeated by Dr Prieſtley and Mr Warltire in company, they next fired a mixture of vital and inflammable air; but the only effects which they obſerved were, that the light was much more intenſe, and the heat much greater.

Water. 4 Mr Cavendiſh repeats it with more ſucceſs. Phil. Tranſ. for 1784, p. 126, &c.

During the ſame year, and after the publication of the volume of Dr Prieſtley's works, referred to above, Mr Cavendiſh repeated the experiments of Mr. Warltire; but though the veſſel which he uſed held 24,000 grains of water, and though the experiment was repeated ſeveral times with common and inflammable air, he could never perceive a loſs of weight of more than one-fifth of a grain, and commonly none at all. In all theſe experiments Mr Cavendiſh did not perceive the leaſt footy matter; but the inſide of the glaſs globe became dewy, as Mr Warltire had obſerved. The inflammable air was procured from zinc.

That he might examine the nature of the dew, he burned 500,000 grain meaſures of inflammable air with two and a half times that quantity of common air, and the burned air was made to paſs through a glaſs cylinder eight feet long, and three quarters of an inch diameter, in order to depoſit the dew. Theſe two kinds of air were mixed and ſet on fire by a lighted candle. In a ſhort time 135 grains of water were condenſed in the cylinder, which had no taſte nor ſmell, and which left no ſenſible ſediment when evaporated to dryneſs; neither did it yield any pungent ſmell during the evaporation: in ſhort, it ſeemed pure water. From this experiment Mr Cavendiſh concluded, that when inflammable and common air are exploded in a proper proportion, almoſt all the inflammable air, and near one-fifth of the common air loſe their elaſticity, and are condenſed into dew; which, when examined, is found to be pure water.

5 He obtains a quantity of water by firing vital and inflammable air.

He wiſhed next to examine the effect produced by firing a mixture of vital and inflammable air. He took a glaſs globe holding 8800 grain meaſures, furniſhed with a braſs cock, and an apparatus for firing air by electricity. The globe was exhauſted of its air by an air-pump, and then a mixture of 19,500 grain meaſures of dephlogiſticated air, and 37,000 of inflammable air, was conveyed ſucceſſively from a glaſs jar, inverted in water, into the globe, and there fired by electricity. At the end of the experiment, when the whole air was conſumed, a condenſed liquor was found in the globe, weighing about 30 grains, which was ſenſibly acid to the taſte; and, by ſaturation with fixed alkali and evaporation, yielded near two grains of nitre. This product of nitre muſt have been occaſioned by a mixture of azotic gas, which had combined with part of the oxygene, or dephlogiſticated air; which are now well known to be the component parts of the nitric acid. Theſe experiments, Mr Cavendiſh informs us, were made in 1781.

6 The experiments of Mr Cavendiſh repeated by Dr Prieſtley.

Mr Cavendiſh having mentioned theſe experiments to Dr Prieſtley, that gentleman made a courſe of experiments in order to inveſtigate the ſame ſubject; an account of which is publiſhed in the Philoſophical Tranſactions for 1783, and in the laſt volume of his Experiments. Having formerly obſerved ſeveral remarkable changes in fluid ſubſtances, in conſequence of long expoſure to heat in glaſs veſſels hermetically ſealed, Dr Prieſtley formed a deſign of expoſing all kinds of ſolid ſubſtances to great heats in cloſe veſſels. As many ſubſtances conſiſt of parts ſo volatile as to fly off before attaining any conſiderable degree of heat in the uſual preſſure of the atmoſphere, he imagined that if the ſame ſubſtances were compelled to bear great heats under a greater preſſure, they might aſſume new forms, and undergo remarkable changes. Happening to mention theſe ideas to Mr Watt, the ingenious improver of the ſteam-engine, Mr Watt mentioned a ſimilar idea of his, that it might be poſſible to convert water or ſteam into permanent air.

For

Water.

7 Account of Mr Watt's theory. Phil. Tranſ. for 1784, p. 335.

For many years before this period, Mr Watt tells us he had entertained an opinion, that air was a modification of water, which was originally founded on the facts, that in moſt caſes wherein air was actually made (which ſhould be diſtinguiſhed from thoſe wherein it is only extricated from ſubſtances containing it in their pores, or otherwiſe united to them in the ſtate of air), the ſubſtances were ſuch as were known to contain water as one of their conſtituent parts; yet no water was obtained in the proceſſes, except what was known only to be looſely connected with them, ſuch as the water of the cryſtallization of ſalts. This opinion aroſe from a diſcovery, that the latent heat contained in ſteam diminiſhed in proportion as the ſenſible heat of the water from which it was produced increaſed. In other words, the denſer the ſteam was, the leſs latent heat it contained.

Having been informed by Dr. Prieſtley of the reſult of the experiment of firing a mixture of dephlogiſticated and inflammable air, Mr Watt was enabled to form the very theory which has been ſince demonſtrated to be true. "Let us conſider (ſays he) what obviouſly happens in the caſe of the deflagration of the inflammable and dephlogiſticated air. Theſe two kinds of air unite with violence, they become red hot, and upon cooling totally diſappear. When the veſſel is cooled, a quantity of water is found in it equal to the weight of the air employed. The water is then the only remaining product of the proceſs; and water, light, and heat are all the products, unleſs there be ſome other matter ſet free which eſcapes our ſenſes. Are we not then authoriſed to conclude, that water is compoſed of dephlogiſticated air and phlogiſton deprived of part of their latent or elementary heat; that dephlogiſticated or pure air is compoſed of water deprived of its phlogiſton and united to elementary heat and light; and that the latter are contained in it in a latent ſtate, ſo as not to be ſenſible to the thermometer or to the eye; and if light be only a modification of heat, or a circumſtance attending it, or a component part of the inflammable air, then pure or dephlogiſticated air is compoſed of water deprived of its phlogiſton and united to elementary heat?"

Phil. Tranſ. for 1784, & Idées ſur la Meteor. par J. A. De Luc, tom. i p. 213,

We have ſaid that the theory of Mr Watt is now demonſtrated to be true. To this aſſertion an objection may be raiſed from the language in which he ſtates his theory; for he explains it by uſing the word *phlogiſton*, a word which is now exploded from philoſophy as the name of an imaginary ſubſtance. But it is ſufficient to reply, that Mr Watt uſes the word phlogiſton as ſynonymous with inflammable air. It may be proper alſo to add, that the paſſage quoted above was contained in a letter from Mr Watt to Dr Prieſtley, dated the 26th of April 1783.

Moſt of the experiments hitherto made favoured the concluſion which Mr Watt had drawn; but ſo many difficulties occurred to Mr Cavendiſh and Dr Prieſtley, that they ſeemed to heſitate about the theory. Dr Prieſtley in particular, after conſideration declared againſt it; while Mr Cavendiſh only waited till the difficulties ſhould be removed. In the mean time experiments were made in a different quarter, which gave the moſt inconteſtable proofs of the truth of the theory.

8 Which is eſtabliſhed by experiments at Paris. Idées ſur la Meteor. par De Luc, tom ii. part iii. chap. iv.

M. de Luc had gone to Paris in January 1783. During his reſidence there, he received a letter from Dr Prieſtley, announcing the reſult of his experiments concerning the converſion of water into air. M. de Luc immediately communicated the contents of this letter to ſeveral members of the Academy of Sciences. But the difficulties which had occurred to Dr Prieſtley, prevented them from acquieſcing in Mr Watt's theory. In the month of June following, Dr Blagden, who was well acquainted with all the experiments both of Mr Cavendiſh and of Dr Prieſtley, and of the opinions of Mr. Watt, made a journey to Paris, in which he had an opportunity of converſing on this ſubject with the ſame gentlemen of the Academy to whom M. de Luc had formerly imparted the experiments of Dr Prieſtley. Notwithſtanding the additional facts which he was enabled to lay before them, he found them averſe from admitting the theory. They ſuppoſed that the water collected after the combuſtion of the two kinds of air had been diſſolved in them before. As the queſtion depended upon the proof of a fact, they reſolved however to make the proper experiments for examining it. The celebrated Lavoiſier took this experiment upon himſelf. It was made on the 24th of June in the preſence of Dr Blagden and many gentlemen of the academy; and the ſucceſs was as complete as the moſt ſanguine imagination could have conceived. It was repeated by Meſſrs Monge and Meunier, and the ſame reſult was found. The compoſition of water was now therefore put beyond doubt, and is now almoſt univerſally received as an unqueſtionable fact.

Water.

9 Attempt to eſtimate the merit of thoſe concerned in this diſcovery.

As we wiſh upon all occaſions to aſcribe to all eminent men the honour which they deſerve, we ſhould willingly eſtimate the comparative merit of thoſe philoſophers who were moſt active in this diſcovery; but though we feel ourſelves diſpoſed to be altogether impartial, it is attended with ſo many difficulties, that we will not preſume to affirm that our opinions are formed with perfect accuracy. With reſpect to Mr Watt, we think it appears that he was the firſt perſon who formed the true theory. He had for many years before thought it probable, that if the latent heat of ſteam could be wholly converted into ſenſible heat by a great increaſe of heat, the ſteam might ſuffer ſome remarkable change, ſuch as into permanent air. And no ſooner had he heard of the deflagration of oxygenous and hydrogenous gas by Dr Prieſtley, than he formed this theory.

10 Merit of Mr Watt; Phil. Tranſ. for 1784, p. 335.

Mr Cavendiſh had the merit of making a proper uſe of Dr Prieſtley's account of Mr Warltire's experiment, from which Dr Prieſtley had been able to draw no concluſions, but had conſidered it merely as a curious fact. Without knowing any thing of Mr Watt's ideas, as far as appears to us, he made a number of ingenious experiments, which led him to conclude, that it was highly probable that water was a compoſition of air. The air which he employed ſeems not to have been pure; ſo that beſides the water he procured a quantity of nitrous acid. He however acted like an able and candid philoſopher; he went as far as his experiments would permit him, and he went no farther. In one point he continued to differ from Mr Watt after his theory was made public. Mr Watt ſuppoſed that water conſiſted of dephlogiſticated air (oxygenous gas) and phlogiſton (hydrogenous gas according to him), deprived of part of their latent heat; whereas Mr Cavendiſh thought there was no ſuch thing as elementary heat. We muſt further add, that it was Mr Cavendiſh who taught Dr Prieſtley to turn to a proper account the experiment of Mr Warltire; and therefore, that it was in fact from Mr Cavendiſh's experiments ultimately, that Mr Watt was enabled to eſtabliſh his theory.

11 Of Mr Cavendiſh.

The merit of Dr Prieſtley lies wholly in his being the inſtrument of promoting this diſcovery. He firſt publiſhed the experiment of Mr Warltire; and when Mr Cavendiſh had informed him of the ſucceſs he had met with in repeating that experiment, he began alſo to ſtudy the ſame ſubject. His diſcoveries were more uſeful to Mr Watt than to the author himſelf; for Mr Watt formed the theory which he had formerly been meditating: but Dr Prieſtley never came to a ſteady concluſion on the ſubject. We have read over carefully all his papers concerning the converſion of

12 Of Dr Prieſtley.

Water. water into air, but cannot help ſaying, that we went along with the bewildered author weary and fatigued. His experiments are very often made at random, almoſt always founded on falſe principles, and ſeldom lead to any thing but to doubt and perplexity. M. Lavoiſier ſent him a copy of his ingenious paper on the compoſition of water; he repeated ſome of the experiments of that illuſtrious chemiſt, but he drew very different concluſions from them. Doctor Prieſtley ſtill appears to retain his doubts on the ſubject, and continues his experiments; the reaſonings and concluſions of Lavoiſier he does not conſider as ſatisfactory; and he has lately publiſhed ſome obſervations on Phlogiſton, inviting farther diſcuſſion. With peculiar pleaſure we mention Dr Black on this occaſion. That gentleman, no leſs conſpicuous for his candour and modeſty than for his ingenuity, had, along with all other chemiſts of the time, believed the doctrine of phlogiſton, and taught it in his public lectures; but, upon examining the Lavoiſierian ſyſtem, he was convinced of its truth, and had the honeſty to confeſs it, though he was thus obliged to acknowledge to his ſtudents, that he had for many years been teaching errors. This acknowledgment does much honour to Dr Black, and proves that he is well entitled to the high character which he has ſo long held.

13 And of M. Lavoiſier. The merit of M. Lavoiſier was great upon the preſent occaſion. From England indeed he received the theory and the firſt experiments on the compoſition of water; but he was the firſt perſon who demonſtrated the theory, and put it beyond doubt. His knowledge of the diſtinction between carbone and hydrogene, as well as the perfect accuracy with which his experiments were made, enabled him to prove, with as much certainty as phyſical ſcience generally admits, that water is compoſed of vital and inflammable air. We will now give ſome account of the proofs of this fact; and, as we have never ſeen them ſtated with more clearneſs and preciſion than by M. Lavoiſier himſelf in his Elements of Chemiſtry, we ſhall take our account of them from him.

Proofs of the Compoſition of Water.

14 Proof of the compoſition of water by analyſis. Plate DXXXVIII. Fig. 1. *Exper.* 1. Take a glaſs tube from 8 to 12 lines diameter, and place it acroſs the furnace EFCD, with a gentle inclination from E to F (A). The higher extremity of the tube is then luted to the glaſs retort A, containing a known quantity of diſtilled water. To the lower extremity F is luted the worm SS, the lower end of which is fixed in the neck of the bottle H, which bottle has the bent tube KK fixed to a ſecond opening. This bent tube is intended to carry off any elaſtic fluids which may eſcape into the bottle H. A fire is then lighted in the furnace EFCD, ſufficient to keep the tube EF red hot, but not to melt it. The water in the retort A is kept boiling by a fire in the furnace VVXX. The water is gradually changed into ſteam by the heat of the two furnaces. It paſſes through the glaſs tube EF into the worm SS, where it is condenſed, and then drops into the bottle H. When the whole water is evaporated, and all the communicating veſſels are emptied into the bottle H, it is found to contain exactly the ſame quantity which was put into the retort. This experiment therefore is a ſimple diſtillation. Water.

Exper. 2. Every thing being diſpoſed as in the laſt experiment, let 28 grains of pure charcoal, broken into ſmall parts, and which has been expoſed to a red heat in a cloſe veſſel, be introduced into the tube EF. The experiment is then performed in the ſame manner as the former. The water is evaporated, and a portion of it is again condenſed in the worm SS, and then falls into the bottle H; but at the ſame time a conſiderable quantity of an elaſtic fluid eſcapes through the tube KK, which is received in veſſels. When the water is entirely evaporated, and the tube examined, the 28 grains of charcoal have wholly diſappeared.

When the water in the bottle H is examined, it is found to have loſt 85.7 grains of its weight; and when the elaſtic fluid which paſſed off by the tube KK is weighed, it is found to weigh 113.7 grains, which is exactly the weight which the water has loſt, added to the 28 grains of charcoal which had diſappeared. The elaſtic fluid, on examination, is diſcovered to be of two kinds; namely, 144 cubical inches of carbonic acid gas weighing 100 grains, and 380 cubical inches of a very light gas weighing only 13.7 grains. Now 100 grains of carbonic acid gas conſiſt of 72 grains of oxygene, combined with 28 grains of carbone. It is therefore evident, that the 28 grains of charcoal muſt have acquired 72 grains of oxygene from the water. It is alſo evident, that 85.7 grains of water are compoſed of 72 grains of oxygene, combined with 13.7 grains of a gas capable of being burned.

Exper. 3. Every thing being put in the ſame order as in the two former experiments, with this difference, that inſtead of the 28 grains of charcoal, 274 grains of ſoft iron, in thin plates rolled up ſpirally, are introduced into the tube EF. The tube is kept red hot while the water is evaporating from the retort. After the water has been diſtilled, it is found to have loſt 100 grains. The gas or elaſtic fluid weighs 15 grains, and the iron has gained 85 grains additional weight, which put together make up 100 grains, the weight which the water has loſt. The iron has all the qualities which it would have received by being burned in oxygene gas. It is a true oxyd (or calx) of iron. We have the ſame reſult as in the laſt experiment, and have therefore another proof for concluding, that 100 grains of water conſiſt of 85 grains of oxygene, and 15 of the baſe of inflammable gas (B).

15 Proof of the compoſition of water by ſyntheſis. We have now exhibited two ſufficient proofs, that water is compoſed of oxygene and hydrogene; but as the compoſition of water is ſo intereſting and important a ſubject, M. Lavoiſier was not ſatisfied with theſe proofs alone. He juſtly concluded, that if water be a compound of two ſubſtances, it ought to follow, that by reuniting theſe two ſubſtances, water would be produced. He accordingly proved the truth of this concluſion by the following experiment.

(A) The tube EF ſhould be made of glaſs which can bear a ſtrong heat without melting. It ſhould alſo be coated over with a lute compoſed of clay and powdered ſtone-ware; and to prevent it from bending during the experiment, it muſt be ſupported about the middle by an iron bar.

(B) This elementary ſubſtance Mr Lavoiſier has denominated *hydrogene*, which ſignifies "the generative principle of water;" from ὑδωρ "water," and γεινομαι "I produce." When this ſubſtance is combined with caloric, it is called *hydrogenous gas*. It is the lighteſt ſubſtance yet known, being $\frac{1}{11}$th of the weight of an equal bulk of atmoſpheric air. It is very combuſtible, for it has ſo great an attraction for oxygene, that it attracts it from caloric; ſo that its inflammable property is merely its power of decompoſing oxygenous gas, for it will not burn by itſelf. When drawn into the lungs, it produces inſtant death. See AEROLOGY.

Water.

Exper. 4. He took a large cryſtal balloon A, fig. 2. containing about 30 pints, and having a large mouth; round which was cemented the plate of copper BC, pierced with four holes, through which four tubes paſs. The firſt tube H*b* is intended to exhauſt the balloon of its air, by adapting it to an air pump. The ſecond tube *gg* communicates with a reſervoir of oxygenous gas placed at MM. The third tube *d* D ♂ is connected with a reſervoir of hydrogenous gas at NN. The fourth tube contains a metallic wire GL, having a knob at its lower extremity L, from which an electric ſpark is paſſed to ♂, in order to ſet fire to the hydrogenous gas. The metallic wire is moveable in the tube, that the knob L may be either turned towards ♂, or away from it, as there is occaſion. We muſt alſo add, that the three tubes H *b*, *gg*, *d* D ♂ are furniſhed with ſtop-cocks.

It is neceſſary that the oxygenous gas, before being put into the reſervoir, ſhould be completely purified from carbonic acid. This may be done by keeping it for a long time in contact with a ſolution of cauſtic potaſh. The hydrogenous gas ought to be purified in the ſame manner. The quantity employed ought to be double the bulk of the oxygenous gas. It is beſt procured from water by means of iron, as was deſcribed in Experiment Third.

Great care muſt alſo be taken to deprive the oxygenous and hydrogenous gas of every particle of water. For this purpoſe they are made to paſs in their way to the balloon A, through ſalts which have a ſtrong attraction for water; as the acetite of potaſh (a compound of vinegar and vegetable alkali), or the muriate or nitrate of lime (the muriatic or nitric acid combined with lime). Theſe ſalts are diſpoſed in the tubes MM and NN of one inch diameter, and are reduced only to a coarſe powder, that they may not unite into lumps, and interrupt the paſſage of the gaſſes.

Every thing being thus prepared for the experiment, the balloon is exhauſted of its air by the tube H *b*, and is filled with oxygenous gas. The hydrogenous gas is alſo preſſed in through the tube *d* D ♂ by a weight of one or two inches of water. As ſoon as the hydrogenous gas enters the balloon, it is ſet fire to by an electric ſpark. The combuſtion can be kept up as long as we pleaſe, by ſupplying the balloon with freſh quantities of theſe two gaſſes. As the combuſtion advances, a quantity of water is collected on the ſides of the balloon, and trickles down in drops to the bottom of it. By knowing the weight of the gaſſes conſumed, and the weight of the water produced, we ſhall find that they are preciſely equal. M. Lavoiſier and M. Meuſnier found that it required 85 parts by weight of oxygenous gas and 15 parts of hydrogenous gas to produce 100 parts of water.

Thus we have complete proofs, both analytical and ſynthetical, that water is not a ſimple elementary ſubſtance, as it has been long ſuppoſed, but is compounded of two elements, oxygene and hydrogene. We muſt add, that M. Lavoiſier uſed the moſt ſcrupulous accuracy in making the experiments which we have deſcribed; and that he is of opinion that the proportions given above cannot be $\frac{1}{200}$ from the real truth. Such then is the hiſtory and proof of the compoſition of water. We come next to conſider what ſubſtances are chemically united or diſſolved in it.

Analyſis of the different Subſtances contained in Water.

16 Advantages of analyzing water.

Since it is made certain by obſervation and experiment, that water contains many different kinds of ſubſtances; and as its qualities, and conſequently its uſes, differ much according to the nature of the ſubſtances combined with it—the knowledge of an eaſy and accurate method of analyſing waters is become a matter of the utmoſt importance. By ſuch an analyſis we ſhall be enabled to ſelect the pureſt water for the purpoſes of life, and to avoid water which might be improper and hurtful; or, when good water cannot be had, to ſeparate thoſe ſubſtances from it which render it impure. By the ſame important art we ſhall find it eaſy to diſtinguiſh thoſe waters which are beſt adapted to the arts and manufactures; we ſhall alſo be able to compare different mineral waters, to explain the cauſes of their effects in medicine, and to imitate thoſe by art which are moſt efficacious.

Water.

All natural waters are more or leſs impure; for water has ſo ſtrong an attraction for different ſubſtances, that it imbibes part of them in every ſituation in which it is found, not only when it flows over beds of earth, but when it filters through ſtrata of metals, and even when it is diſſolved in the atmoſphere. Water cannot be procured in a pure ſtate without undergoing the proceſs of diſtillation.

Before we proceed to ſtate the methods by which the different ſubſtances found in water may be detected, it will be proper to point out to the reader ſuch ſenſible qualities of particular waters as may enable him to inſtitute the proceſs by which the analyſis ought to be conducted. In every courſe of experiments, that order ought to be followed which will lead with moſt eaſe and certainty to the end which is in view; but unleſs a man from general knowledge be able to conjecture with ſome degree of accuracy what are the reſults to be expected in particular caſes, he cannot be able to determine what experiments he ought to make.

17 The general circumſtances to be attended to are,

The general circumſtances which are firſt to be attended to in the examination of waters, are their colour, ſmell, taſte, ſpecific gravity, temperature, and local ſituation.

18 The colour,

1. The firſt thing to be attended to in water is its colour. Pure water is tranſparent like cryſtal. Muddineſs or a brown colour is a certain proof that ſome extraneous ſubſtance is diffuſed through the water. A green colour indicates the preſence of iron, and a blue that of copper. If upon agitation airy bubbles appear in the water, we are ſure that it contains carbonic acid or fixed air. The water which is to be examined with reſpect to colour ſhould be put into a deep glaſs, that we may look down into a conſiderable body of it; for we ſhall thus diſcover any muddineſs much better than by viewing the water horizontally through the glaſs.

19 The ſmell,

2. We are next to obſerve whether the water has any ſmell. If it be pure, it will have no ſmell; if it diffuſe a ſubtile penetrating odour, we have reaſon to conclude that it contains carbonic acid; if the ſmell of putrid eggs or of the ſcourings of a gun ariſe from it, we infer that it is impregnated with hepar ſulphuris, or ſulphur combined with an alkali.

21 The taſte,

3. Pure water has no taſte. Water containing carbonic acid has a mild ſouriſh taſte. If it have a bitter taſte, it may contain ſulphate of ſoda or Glauber's ſalt, nitre or the ſulphate, nitrate or muriate of magneſia, or lime combined with the nitric or muriatic acid. If the water has a ſlight auſterity of taſte, we may expect that it contains lime or gypſum; if it be ſaltiſh, it contains common ſalt; if the taſte be lixivious, alkali is preſent; if æruginous, there is copper; if ferruginous or inky, we have reaſon to ſuppoſe that it contains iron.

20 Specific gravity,

4. The ſpecific gravity of water can enable us to diſcover that it contains ſome extraneous matter, but does not point out what ſort of matter it is. We are always ſure that the lighteſt waters are the pureſt. The ſtandard to be employed for comparing the ſpecific gravity of water to be examined is diſtilled water.

22 Temperature,

5. Another circumſtance to be conſidered is the temperature of the water, whether it be hot, cold, or tepid. We muſt determine whether the temperature be the ſame during the whole year, or whether it depends on the weather; whether

Fig. 1.

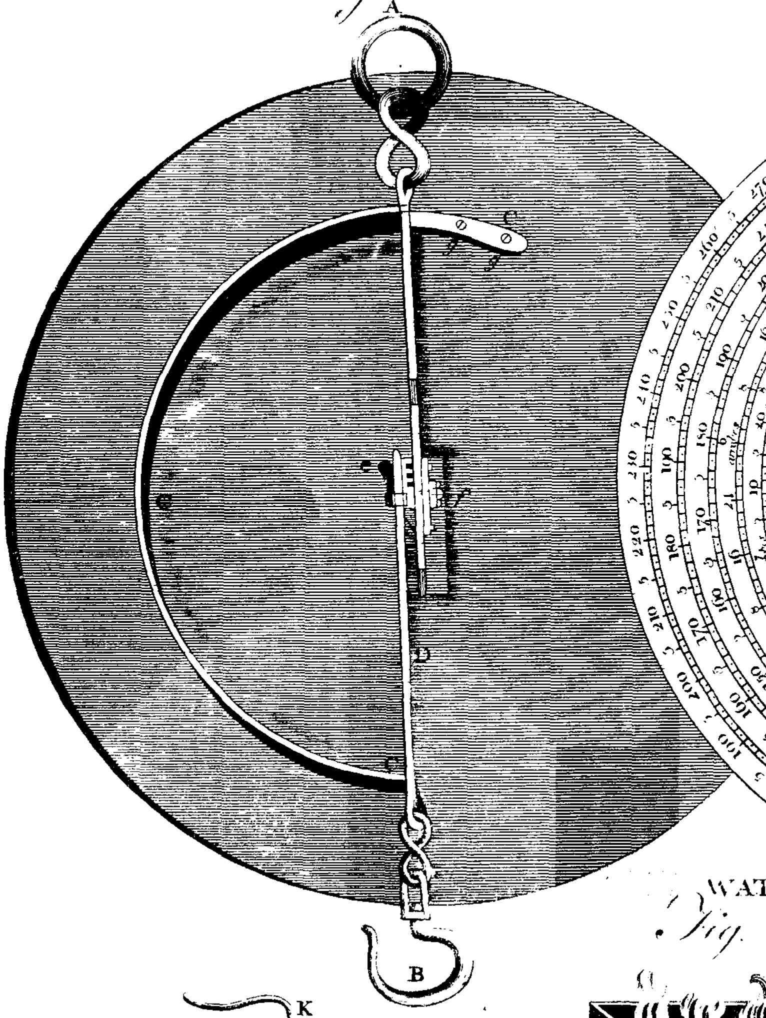

Fig. 2.

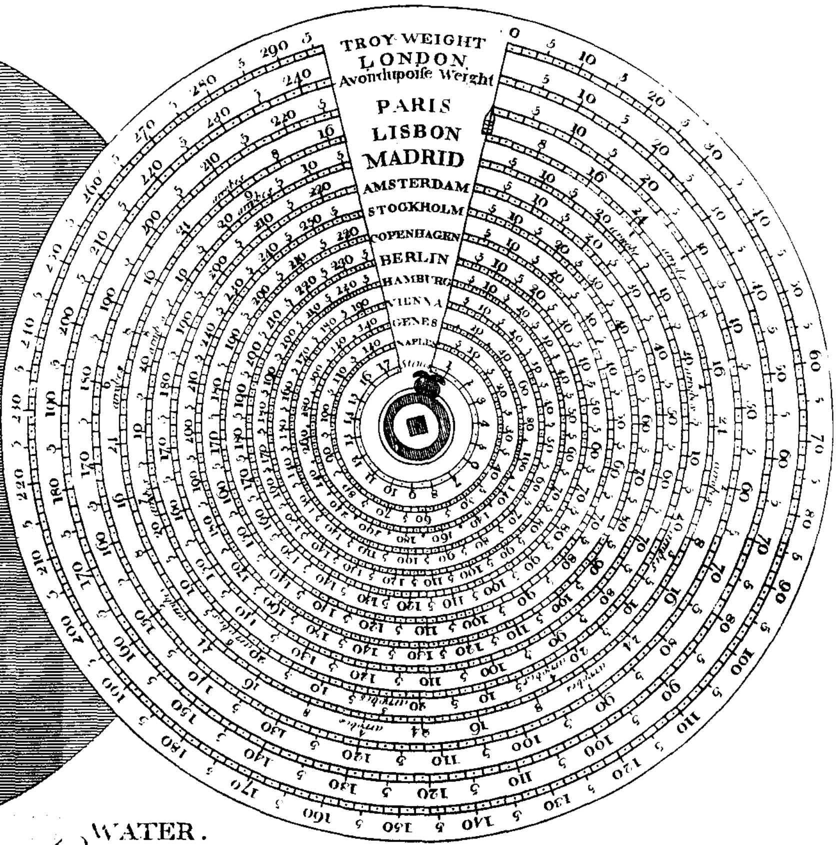

WATER.

Fig. 1.

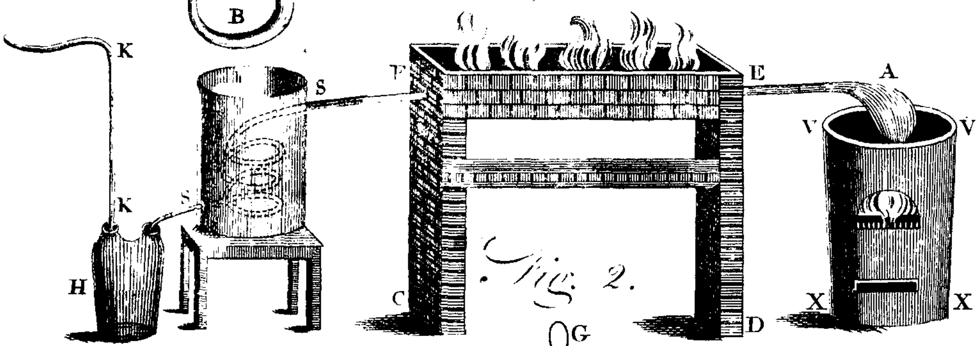

Fig. 2.

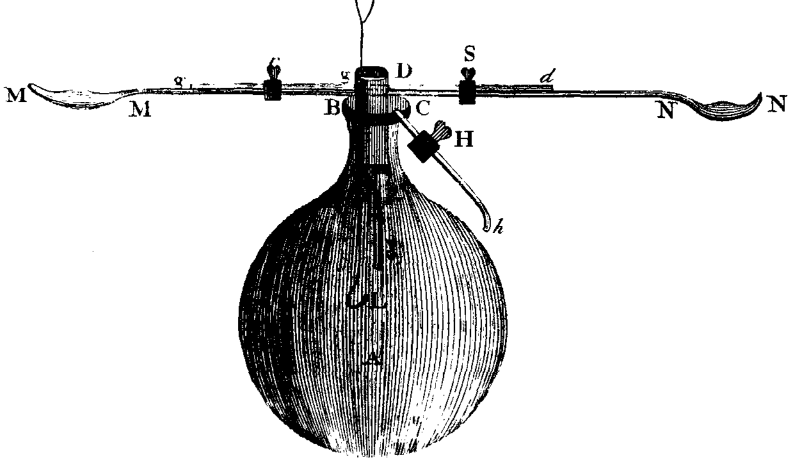

Scot sc.

Water. whether it freezes in winter; if hot, whether, when allowed to cool, it depoſits any ſediment, and loſes its taſte and ſmell.

23 Local ſituation. 6. The local ſituation of the water muſt alſo be taken into review. We muſt conſider the ſoil through which it flows, and inquire whether there be mines or veins of metals near, or any kind of ſubſtance which water can diſſolve. We muſt alſo inquire whether the water flows in equal quantity during the whole year, or increaſes with rain, and decreaſes with dry weather: whether it is ſtagnant or flowing; if it flows, whether it flows ſwiftly or ſlowly: whether it depoſits any ſediment; and if it does, of what ſort it is, whether a ſalt, earth, metal, or metallic ochre: whether it petrifies bodies thrown into it: and whether there be any ſulphur to be found near it in a ſublimed ſtate.

It is alſo proper to obſerve whether it be hard or ſoft; whether any animalcules live or vegetables grow in it; and whether it has any reputation for its effects in medicine.

24 General diviſion of water. Water may be divided into two great diviſions, *freſh* and *ſalt water*.—Freſh water may be divided into *atmoſpheric*, *ſtagnant*, and *running*.

25 Salt water, Salt water comprehends moſt of the ſeas on the globe, but eſpecially thoſe of the torrid and the greater part of the temperate zones. It contains common ſalt in great quantity, ſulphate or muriate of magneſia, and ſulphate of lime, beſides a great quantity of putrid matter brought into it by the rivers, or produced by the decompoſition of the numerous tribes of animals which live and die in it. See SEA and *SEA-Water*.

26 Rain and ſnow water; Atmoſpheric water comprehends rain and ſnow water. Rain is the water which is evaporated from the ſea and land, diſſolved in the air, and afterwards diſcharged on the earth; it ought therefore to reſemble diſtilled water in purity; and it would certainly do ſo, if the atmoſphere did not abound with vapours and exhalations capable of being combined with it. It contains a ſmall quantity of ſulphate of lime, together with a very ſmall portion of nitrous acid. The rain that drops from the tops of houſes is always mixed with ſoot. Some ſhowers have contained a quantity of the pollen of flowers, which has given riſe to the ſtories of ſhowers of ſulphur. The rain which falls at a diſtance from towns, or after a long tract of wet weather, is pureſt; for the atmoſphere is then in ſome meaſure waſhed, if we may uſe the expreſſion, from all heterogeneous ſubſtances.—Snow water is contaminated with the ſame ſubſtances as rain water. When newly melted, it is deſtitute both of common air and of fixed air, or the carbonic acid. It is probably from the want of theſe that ſnow water is injurious to health.

27 Water of lakes and marſhes; Stagnant water forms a lake; and when a great quantity of earth is diffuſed through it, it forms a marſh. The water of lakes is generally very pure and tranſparent; for as they are not ſubject to ſo much agitation as ſtreams, the ſubſtances that happen to fall into them are not much diffuſed, but ſoon ſubſide to the bottom. Some lakes are ſalt.—Marſhes are much more impure. They are generally contaminated with the putrid matter produced by the decompoſition of animals and vegetables, and are often of a yelloviſh or browniſh colour.

28 Spring and river water; Running water comprehends ſpring and river water.—Spring water is the rain water, which, after diſcharging itſelf upon the earth, and being imbibed by it, again iſſues out. As it runs below the ſurface through different ſubſtances, it carries along with it ſuch as it can diſſolve, and is therefore not ſo pure as rain water. It often contains ſalts, earths, or metals.—Rivers conſiſt of a collection of ſprings, and generally partake of the ſoil through which they paſs. Rivers which run through great towns are loaded with animal and vegetable ſubſtances. But thoſe which run at a diſtance from towns are purer than moſt ſprings; becauſe, as they run with more rapidity, and to a greater diſtance, a great part of their impurities are thus volatilized. If the ſoil be ſoft through which a river runs, it will be full of earth; but if hard and rocky, the water is very clear and pure. Water.

22 Hard water, Water is called *hard* when it does not diſſolve ſoap, or boil vegetables, or make an infuſion of tea. It generally contains ſome acid combined with abſorbent earth, for which it has leſs attraction than for the alkali of the ſoap. When ſoap is put into ſuch water, its alkali is immediately attracted by the acid of the water, the ſoap is decompounded, and the oil of it ſwims on the ſurface of the water. Water is not reckoned hard if it contains leſs than 10 grains of extraneous ſubſtances in the pound weight.

30 How corrected. If the acid with which the abſorbent earth is united be the carbonic, the water may be purified by boiling. But in order to make it agreeable to the palate after the calcareous earth is depoſited, it ought to be expoſed in the open air in broad ſhallow veſſels. It will thus recover a portion of the air which was expelled by the boiling. But if the earth be ſuſpended by any other acid, the water can be corrected by the addition of ſome fixed alkali, which immediately joins itſelf to the acid, while the earth is depoſited. A ſolution of potaſh, or of any other alkali, may be poured into the water till it ceaſe to produce any turbid appearance, or till no more is precipitated. The water muſt then be decanted from the ſediment, or filtered if neceſſary.

31 Two methods of analyzing water, by preci; itation, Having now mentioned the different kinds of waters, it will be next proper to deſcribe the moſt accurate methods of analyzing them. Theſe are two, by precipitation and evaporation. Precipitants are ſubſtances which, being thrown into any impure water, ſeparate the impurities, and throw them to the bottom of the veſſel. Precipitation is the moſt expeditious method of examining waters; but it does not enable us to form ſo accurate an eſtimate as is often neceſſary of the preciſe quantity of extraneous ſubſtances contained in them.

32 And by evaporation. The other method of analyzing water is by evaporation, which conſiſts in ſeparating the water from the impurities, by converting the water into ſteam, and cryſtallizing the ſalts contained in it. Both theſe methods are often neceſſary to be employed, either of them ſeparately being defective. As the precipitants indicate the proper method of conducting the evaporation, it will be proper, before we deſcribe how to analyze water by evaporation, to deſcribe particularly the effects produced on it by applying different precipitants.

Method of analyzing Water by Precipitation.

33 Subſtances contained in water. THE ſubſtances hitherto found in water are, common atmoſpherical air, acids, alkalis, earths, ſulphurs, and metals.

34 Teſts for diſcovering them. Acids, when diſengaged, may be diſcovered by turnſol or ſyrup of violets; and when combined with any baſe, they may be detected by the nitrate of ſilver, muriate of barytes, and lime-water. Uncombined alkalis are aſcertained by Brazil wood and turmeric; in combination with acids, they may be detected by ſpirt of wine. Earths are precipitated by the acid of ſugar and the acetous acid. Sulphur is diſcovered by the mineral acids; and metals are precipitated by lime-water and tincture of galls.

35 Method of analyzing water containing common air and carbonic acid. Moſt waters contain common atmoſpherical air. Fixed air, now called *carbonic acid*, is alſo found in all waters in quantity from $\frac{1}{100}$th part of the bulk of the water to a bulk equal to the water itſelf. That ſome ſpecies of air is contained in water, is evident from the ſmall bubbles which may

may be often ſeen to riſe in it when poured into a glaſs. Theſe bubbles are ſtill more diſtinguiſhable in water placed under the exhauſted receiver of an air-pump; for the weight of the atmoſphere being removed, the water expands; and the air contained in its interſtices is thus let looſe, and riſes to the ſurface. The air may alſo be ſeparated from water by boiling, and may be eaſily collected by a proper apparatus. Experiments may then be made upon it to determine its ſpecies and quantity.

36 Teſts for diſcovering carbonic acid in water,

Carbonic acid is known to be contained in water by the following marks: The taſte is ſomewhat pungent, aceſcent, cooling, and very agreeable. The ſmell is ſubtile and penetrating. When agitated, it emits a number of air-bubbles, which give it the appearance of briſkneſs. Theſe are the ſenſible appearances which aerated water exhibits; but there are teſts which chemiſtry furniſhes much more deciſive.

From a pigment called *litmus* is obtained a tincture called the *tincture of turnſol*. The litmus is wrapped up in a clean linen cloth, and ſteeped in diſtilled water; the water ſoon aſſumes a blue or violet colour, and is then fit for uſe. The tincture enables the chemiſt to diſcover the ſmalleſt particle of diſengaged acid; for a few drops of it poured into water containing an acid immediately communicates a red colour to the whole fluid.

There is a more convenient method of uſing the turnſol: The ſaturated tincture is boiled with a little ſtarch, and then a piece of paper is dipped into it, ſo as to tinge it completely. Paper thus tinged, when dipped into water containing an acid, inſtantly receives a red colour. The tincture is, however, a more delicate and ſenſible teſt than the tinged paper; for water ſaturated with aerial acid does not make any change in the colour of the paper; yet one part of aerated water gives a diſtinct red to 50 parts of the tincture.

37 And of collecting it,

The method of collecting and aſcertaining the elaſtic fluids contained in water was unknown till the preſent age. The eaſieſt method is to fill a veſſel terminating in a narrow neck with aerated water, then tie to the neck a bladder from which all the air has been carefully ſqueezed. Let the aerated water be boiled; the elaſtic fluid is then expelled, and aſcends into the bladder, where it is collected. The bladder may then be removed from the veſſel, and its mouth tied up.

There is another method, which is much more accurate, for determining the quantity contained in any quantity of water: Fill a bottle or retort with aerated water, and let a ſtopper be put into its mouth, with a hole in it. Let one end of a crooked tube be inſerted into the hole of the ſtopper, ſo cloſely that no air may eſcape at the joining; and let the other end of the tube be bent upwards into an inverted veſſel full of mercury. Fire is then applied to the bottle or retort, and continued till the water boil. The heat carries off the air which is conveyed through the crooked tube into the inverted veſſel of mercury. If the water be kept boiling for a ſhort time, the whole or greater part of the elaſtic fluid will be expelled, and its bulk is eſtimated by the bulk of mercury which it has diſplaced. But it muſt be remembered, that the elaſtic fluid above the mercury is in a ſtate of greater dilation than the external air, for it is not preſſed by the whole weight of the atmoſphere; but, as M. Sauſſure obſerves, it is only charged with that weight diminiſhed by the column of mercury.

38 And ſeparate it from common air.

When the aerial fluid is thus collected, if we wiſh to ſeparate the carbonic acid from the common air, the proceſs is eaſy: Let the aerial fluid be ſeparated from the mercury, while the external air is carefully excluded; and let the veſſel containing it be inverted into another veſſel containing lime-water. The lime will immediately abſorb the carbonic acid, and form calcareous earth, while the atmoſpherical air is left behind. The calcareous earth may then be weighed; and the carbonic acid being afterwards expelled, the loſs of weight will give the quantity of carbonic acid.

39 Method of diſcovering the ſulphuric acid,

The only other acids hitherto found in water beſides the carbonic, are the ſulphuric and muriatic acids. The preſence of the ſulphuric acid is moſt accurately aſcertained by the muriate of barytes, which is a compound of the muriatic acid with barytes or ponderous earth. Barytes has ſo ſtrong an attraction for the ſulphuric acid, that it ſeparates it from all other acids, and forms with it a compound called *ponderous ſpar*, which is inſoluble in water. As the carbonate of alkali, or an aerated alkali, may produce a muddineſs and precipitation reſembling the effects of the ſulphuric acid, it is neceſſary to add to it a few drops of the nitric acid, which will diſſolve any portion of barytes precipitated by the aerated alkali.

40 And muriatic acid.

The muriatic acid may be eaſily diſcovered, by throwing into the water impregnated with it a little nitrate of ſilver (a compound of the nitric acid with ſilver). If there be the ſmalleſt portion of muriatic acid, it inſtantly ſeizes the ſilver, and is precipitated along with it in the appearance of a white mucilage. As the muriatic acid conſtitutes about one fourth of the muriate of ſilver, we may eaſily determine its quantity, by ſubtracting one-fourth from the weight of the precipitate. Along with the nitrate of ſilver a little nitric acid ſhould be added, for the reaſon mentioned in the laſt experiment.

41 How alkalis are detected.

Alkalis are known to exiſt in water by the lixivious or ſaltiſh taſte which they communicate, by their effervescence with acids, and by ſeveral precipitants.

There are three teſts which may be employed for diſcovering the preſence of alkalis. 1. Paper tinged blue by the tincture of turnſol, and made red by diſtilled vinegar, recovers its blue colour when dipped into water containing an alkali. 2. The watery tincture of Brazil wood alſo ſerves to diſcover alkalis. It may either be uſed in the ſtate of tincture, or a piece of paper may be tinged with it after being boiled with a little ſtarch. In both caſes it receives a blue colour from the alkali. One grain of ſoda diſſolved in 4295 grains of water changes the colour of the tinged paper to a blue, which, though delicate, may be eaſily diſtinguiſhed. 3. Watery tincture of turmeric is changed to a brown colour by alkalis. Paper tinged with this tincture boiled with ſtarch is alſo affected in the ſame way. A ſingle grain of ſoda diſſolved in 859 grains of diſtilled water will obſcure the yellow colour of the tinged paper, and turn it into a browniſh hue.

The tincture of Brazil wood is remarkable for its ſenſibility in diſcovering the preſence of an alkali. The tincture of turmeric is much ſlower in its deciſion; but this circumſtance enables us, with ſome degree of accuracy, to eſtimate the quantity of alkali contained. The turmeric, too, anſwers beſt when there is occaſion to examine an alkaline water by candle light, as the change of colour which it produces is eaſily diſtinguiſhable.—Beſides theſe teſts now mentioned, any of the infuſions of vegetables which are moſt eaſily affected by alkalis may be uſed with ſucceſs, ſuch as flowers of mallows and ſyrup of violets; but they are not on all occaſions ſo deciſive.

42 Method of diſtinguiſhing the alkalis from one another.

After being aſſured of the preſence of an alkali, we muſt next determine what alkali it is. The alkalis moſt commonly found in water are the mineral and volatile, the vegetable ſeldom occurring. The mineral alkali is combined with the carbonic, ſulphuric, or muriatic acid; the volatile is probably communicated by putrid animal or vegetable ſubſtances; and the vegetable is united with the ſulphuric

Water. or muriatic acid, but more frequently with the nitric acid. Bergman ſays, that mercury, diſſolved in the nitric acid without heat, enables us to diſtinguiſh theſe alkalis. When a little of this ſolution is thrown into water, if a yellowiſh white ſubſtance is precipitated, we may conclude that a cauſtic vegetable alkali is preſent; if the precipitate be white, there is vegetable alkali ſaturated with the carbonic acid. If the precipitate be firſt yellow, and afterwards become white, mineral alkali is preſent; and if it be of a greyiſh black, we know that volatile alkali is preſent.

43 A better method. The ſpecies of alkali may be more eaſily aſcertained, by pouring into the water a little ſulphuric acid, or, what Morveau recommends as anſwering the purpoſe better, a little diſtilled vinegar, which with potaſh forms a deliqueſcent ſalt, and with ſoda a foliated cryſtallizable ſalt.

44 How the preſence of earths may be diſcovered. The earths which are moſtly found in waters are lime and magneſia. If any other earth has been diſcovered, it has been by ſo few chemiſts, and in ſuch ſmall portions, that it has been little attended to (c). Lime and magneſia are always united with the carbonic or ſome of the foſſil acids. The carbonic acid is eaſily expelled by boiling the water, and the earth falls to the bottom, and may then be eaſily examined by applying ſulphuric acid. If the earth be calcareous, with ſulphuric acid it forms gypſum; if it be magneſia, Epſom ſalt is produced; and if it be clay, the product is alum.

Scarcely any water is entirely free from lime; even the pureſt water, after ſtanding 24 hours, depoſits ſome ſaccharated lime. The acid of ſugar is one of the moſt ſenſible teſts for diſcovering it. A ſmall quantity of diſtilled water, in which there is diſſolved a ſingle grain of pure lime, will become muddy if the ſmalleſt quantity of the acid of ſugar be thrown in. The preſence of calcareous earth may alſo be diſcovered by employing the acetite of lead. It precipitates the earth in the form of a white powder. But as ſulphuric acid alſo precipitates the acetite of lead, to make the experiment accurately, it is neceſſary to add a little diſtilled vinegar to the precipitate, and if it conſiſt of calcareous earth, it will be immediately diſſolved; but if it be a ſulphate of lime, the vinegar will have no effect upon it.—When lime or magneſia is diſſolved in any of the mineral acids, it may be detected by adding a little carbonate of potaſh. The nature of the earth may be afterwards eaſily determined.

45 How ſulphur is diſcovered. Of the inflammable bodies, perhaps none has been found diſſolved in water except ſulphur. Sulphur is combined either with an alkali or with hydrogene, forming a ſulphuret of hydrogene. Sulphuric or hepatic waters are eaſily known by the following marks: 1. A fetid ſmell, which is felt in approaching the ſpring. 2. The taſte is ſtrong, ſomewhat ſweet, not unlike that of putrid eggs, but more diſagreeable. 3. When a piece of ſilver is put into it, it becomes tarniſhed. 4. But the niceſt teſt is a mark made on paper with the tartarite of biſmuth or acetite of lead, which becomes black when expoſed to the vapour of the hepatic water.

When we wiſh to diſcover the quantity of ſulphur which is diſſolved in an alkali, it may be precipitated by the ſulphuric or muriatic acid, but much more plentifully by the nitric acid. To render the experiment ſucceſsful, it is neceſſary that the mixture ſhould be heated. When the nitric acid is dropped in, the ſulphureous ſmell is inſtantly diſſipated, the water grows turbid, and a white ſubtile powder ſlowly ſubſides. When dried, it is found to be genuine ſulphur. When the water contains a fixed alkali, the acid has no effect in decompoſing the ſulphureous water till the alkali be ſaturated; but after the alkali is ſaturated, the hepatic air is then driven off by the acid, and the ſulphur falls down. Water.

Sulphureous water may eaſily be formed artificially: A quantity of hepar ſulphuris, conſiſting of equal parts of ſulphur and potaſh, is to be put into a veſſel which communicates by a crooked tube with an inverted glaſs filled with water. Sulphuric acid is then poured into the veſſel containing hepar ſulphuris, a few drops at a time. The veſſel containing the acid muſt communicate with the veſſel containing the hepar ſulphuris by a tube, that while the acid may be poured in at pleaſure, the elaſtic gas which iſſues from the action of the acid on the hepar ſulphuris may not be diſſipated, but may paſs into the inverted glaſs. This gas, if a candle be applied, will burn, and a reſiduum of ſulphur of a whitiſh colour remains. The water in the inverted veſſel muſt be frequently agitated, that the gas may be abſorbed. 46 Method of making ſulphureous water artificially.

The metals hitherto found diſſolved in waters are two, iron and copper. The former occurs often, the latter rarely. Iron is united with the carbonic or ſulphuric acid, and may generally be detected by a greeniſh or yellowiſh colour, by its inky taſte, by an ochre which it depoſits, by tincture of galls, and by the Pruſſian alkali. Only the two laſt of theſe methods require any deſcription. Spirit of wine ſaturated with powdered galls precipitates iron ſlowly; the precipitate is purple when the quantity of iron is ſmall; but when the quantity is large, it is black. In ſome caſes indeed iron may be preſent in water without giving a dark colour to the galls. This is owing to a ſuperfluity of acid. But if a ſufficient quantity of alkali be added to ſaturate the acid, the black colour will then appear.—The Pruſſian alkali is prepared from four parts of Pruſſian blue, boiled with one part of alkali in a ſufficient quantity of water. The clear liquor muſt then be ſaturated with an acid, and filtered, that it may be freed from the ſmall portion of Pruſſian blue which is ſeparated. A ſingle drop of this alkali dropped into water containing the ſulphate of iron immediately forms a Pruſſian blue. In making experiments with this alkali, it is proper to add a little muriatic acid. 47 How iron is diſcovered.

The quantity of iron contained in water may be aſcertained with conſiderable accuracy, by the colour communicated by the tincture of galls: for if the tincture be poured into diſtilled water, then ſmall pieces of iron may be added, till the liquor has acquired the colour of the chalybeate water; and then we may conclude, that the quantity of iron contained in the chalybeate water is equal to the artificial mixture, if the colour be the ſame. There is alſo another way of eſtimating the quantity of iron. When precipitated, let the reſiduum be waſhed in pure water, then dried and weighed. Pour upon it one of the mineral acids, and digeſt them together, and after pouring it off, waſh what remains undiſſolved; then dry and weigh it again, and from the diminution of weight collect that of the iron. In this experiment the acid employed ought not to be very ſtrong nor great in quantity, nor ought the digeſtion to be continued long; for if the reſiduum ſhould contain any ſelenite which is ſoluble by acids, the ſelenite might ſeize upon a conſiderable portion of the acid, and conſequently the experiment be inaccurate. 48 And its quantity aſcertained.

Copper is ſometimes united in water with the ſulphuric acid. It is diſcovered by the blue colour which it imparts to 49 How copper is detected.

(c) A ſmall quantity of ſiliceous earth was found by Bergman in an acidulous ſpring, as alſo by Dr Black in the Geyzer ſpring in Iceland. Clay may alſo be often found in waters; but it is probably only diffuſed, not chemically diſſolved.

Water. to the water, by an æruginous taſte, and by the ochre which it depoſits. It may alſo be detected by throwing into the water a piece of poliſhed iron; the copper will be precipitated upon the iron.

Method of analyzing Water by Evaporation.

50 General circumſtances to be attended to.

HAVING now deſcribed the methods of detecting the various ſubſtances contained in water by *precipitation*, we come next to deſcribe how they are diſcovered by *evaporation*.

The veſſels employed in evaporating the water ought to be broad, for fluids evaporate more quickly in proportion to the extent of the ſurface. If earthen veſſels can be found of ſo cloſe a texture as not to abſorb any ſaline matter, they may be ſafely employed. Iron and copper veſſels are improper, becauſe they are liable to be corroded. The moſt convenient are thin glaſs veſſels, which may without danger be expoſed to a ſtrong heat. The capacity of the veſſels depends on the quantity of water which is neceſſary for the ſeveral experiments. The quantity of water may be ſmall if it contain a large proportion of extraneous matter. The evaporation ſhould be ſlow and gentle. The veſſel employed ought to have a cover to keep out duſt; but muſt have a hole ſeveral inches in diameter, that the vapours may iſſue out. The hole ſhould not be opened till the vapour be ſo much condenſed as to iſſue with ſuch force as to keep the duſt from falling in.

51 Order in which ſubſtances uſually appear while water is evaporating.

Some ſubſtances require more water to diſſolve them than others. As the quantity of water is diminiſhed by evaporation, they appear therefore in an order correſponding to their different degrees of ſolubility; thoſe which are leaſt ſoluble appearing firſt. The following is the order in which they are diſcovered; Firſt carbonate of lime and carbonate of iron, then gypſum, then the ſulphate of potaſh, then the ſulphate of iron, then the nitrate of potaſh, and next in order the ſulphate of copper; afterwards the muriate of potaſh, then ſoda, then the muriate of ſoda, then the ſulphate of magneſia, and laſtly the deliqueſcent ſalts. Aerated magneſia, or carbonate of magneſia, is not ſeparated all at once, but continues to fall during the whole proceſs. This order is often altered by the ſuperabundance of any particular ſubſtance.

52 How the reſiduum ſhould be treated.

The different ſubſtances may be ſeparated as they ſucceſſively appear; but it is better to continue the evaporation to dryneſs. The reſiduum ſhould be carefully collected and well dried. It is then put into a bottle, and alcohol poured on till it riſe an inch above it. The bottle ſhould then be cloſed and ſhaken. After ſtanding for a few hours, the liquor may be filtered. What paſſes through the filter is preſerved for a future analyſis, and what remains behind has eight times its weight of cold diſtilled water poured upon it; the mixture is then ſhaken, allowed to ſtand for ſome time, and again filtered. What was diſſolved by the water is preſerved for future examination, and the reſiduum is then boiled for a quarter of an hour in ſomewhat more than four or five hundred times its weight of diſtilled water, and afterwards filtered.

53 When it ſhows a brown colour, ſhould be expoſed to the air.

Being now purified by alcohol, cold water and hot water, the reſiduum is no longer ſoluble in alcohol or water. If it ſhow a brown colour, this is a mark that iron is contained in it. To aſcertain this point, it may be expoſed for ſome weeks in an open veſſel to the rays of the ſun, care being taken to moiſten it from time to time. By the expoſure to the air, the iron will imbibe oxygene, and is then no longer ſoluble in vinegar. The reſiduum may then be weighed; a quantity of acetous acid or diſtilled vinegar is then to be poured on it, and the mixture to be digeſted. By the digeſtion the acid will diſſolve the carbonate of lime and magneſia, if there be any in the reſiduum. What the acid has not diſſolved may be waſhed, dried, and weighed, and by its loſs of weight it may eaſily be determined what the acid has taken up.

Water.

54 The acetous acid is then to be poured upon it;

The matter diſſolved by the acetous acid is then to be evaporated to dryneſs. It may be determined whether it contains calcareous earth or magneſia by this circumſtance; if it conſiſt of calcareous earth, it continues dry in a moiſt air; but if it contain magneſia, it is deliqueſcent. The ſame point may alſo be aſcertained by the ſulphuric acid. This acid added to calcareous earth, forms gypſum, or the ſulphate of lime; but when added to magneſia, it diſſolves it, forming the ſulphate of magneſia or Epſom ſalt; or if the reſiduum contain both lime and magneſia, there will be produced both ſulphate of lime and ſulphate of magneſia. The preciſe quantity of the ſimple ſubſtances contained in each may be known by weighing the compound, and remembering that 100 parts of the ſulphate of lime contain about 32 of pure lime, 46 of ſulphuric acid, and 22 of water (D); and 100 parts of the ſulphate of magneſia contain 19 of pure magneſia, 33 of ſulphuric acid, and 48 of water (E).

55 Then to be evaporated to dryneſs and examined.

That matter which was not diſſolved by the acetous acid is either iron or ſilex. The iron is ſoluble by muriatic acid or by an alkali. The portion which reſiſts the action of the muriatic acid is ſiliceous earth, which may be farther examined by the blow-pipe; for ſiliceous earth, when added to ſoda in a ſtate of fuſion, combines with it with a violent efferveſcence, and is thus changed into glaſs.

Having now ſhown how to examine the reſidue which was inſoluble in alcohol and water, it will next be proper to deſcribe how to analyze the ſolutions obtained by alcohol, cold water, and hot water.

56 How to treat the ſolution obtained by alcohol.

1. The ſolution obtained by alcohol contains lime and magneſia, combined with the muriatic acid or with the nitric acid. To enable us to diſcover the nature and quantity of the ingredients, we evaporate them to dryneſs, and then pour ſulphuric acid on the reſidue; the ſulphuric immediately diſplaces the other acids, and unites with the baſe. If the baſe be lime, it forms a ſulphate of lime; if it be magneſia, it produces the ſulphate of magneſia.

57 And the ſolution obtained by cold water.

2. The ſolution obtained by cold water muſt be examined by evaporation. The evaporation ought to be gentle, that the cryſtals may aſſume regular forms. The cryſtals, as they ſucceſſively appear, are then to be placed on bibulous paper and dried; but not ſo much as to expel any of the water of cryſtallization. The ſpecies of the ſalt thus formed may be diſtinguiſhed by the taſte and ſhape of the cryſtals. But that they may be diſtinguiſhed with accuracy, we ſhall mention other methods: The ſolution obtained by cold water may contain alkalis, neutral ſalts, ſalts united with earths, ſalts united with metals, and neutral ſalts combined with earths or metals.

The alkalis can eaſily be diſcovered by the methods men-

(D) The proportions given above are Bergman's; but Dr Kirwan eſtimates them differently. According to him, 100 parts of the ſulphate of lime contain 32 of earth, 29,44 of acid, and 38,56 of water. When well dried, it loſes about 24 of water, and therefore contains 42 of earth, 39 of acid, and 19 of water.

(E) According to Dr Kirwan, 100 grains of the ſulphate of magneſia perfectly dry contain 45,67 of ſulphuric acid, 36,54 of pure earth, and 17,83 of water. In cryſtals they contain 23,75 of acid, 19 of earth, and 57,25 of water.

Water. mentioned above, but the neutral or compound ſalts will occaſion more difficulty. We muſt firſt determine what the acid is, and with what baſe it is united. The ſulphuric acid is detected by the muriate of barytes, as deſcribed above. The nitrous acid, when preſent, is expelled by the ſulphuric acid, and may be eaſily diſtinguiſhed by its ſmell and red fumes. It will be made ſtill more evident by expoſing its fumes to a paper moiſtened with ammonia or volatile alkali. The muriatic acid is eaſily detected by expoſing the fumes of it to a paper moiſtened with water. This acid may alſo be diſcovered by the nitrate of ſilver.

It is more difficult to diſcover the baſes of the neutral ſalts which are always alkalis. We formerly deſcribed the method of detecting them in water when diſengaged, but we have now to ſeparate them from an acid. Potaſh may be ſeparated by barytes, ſoda is expelled by potaſh, and ammonia is expelled either by potaſh or ſoda.

We have mentioned already the method of diſcovering and diſtinguiſhing the earths and metals diſſolved in water; but there is one compound which is extremely difficult to ſeparate, viz. ſoda from common ſalt. The beſt method for effecting this is the proceſs of M. Giaonetti: "It conſiſts (ſays M. Fourcroy,) in waſhing the mixed ſalt with diſtilled vinegar. The acid diſſolves the mild ſoda; the mixture is dried, and waſhed afreſh with ſpirit of wine, which is charged with the terra foliata mineralis, without touching the marine ſalt; the ſpirituous ſolution is evaporated to dryneſs, and the reſiduum calcined; the vinegar is decompoſed and burned; we have then nothing but the mineral alkali, whoſe quantity is exactly found."

§ Fourcroy's Lectures on Chemiſtry vol. ii.

58 How to treat the ſolution obtained by boiling water.

3. The ſolution obtained by boiling water contains only ſelenite or gypſum. This may be ſeparated in chryſtals by evaporation to dryneſs, or it may be decompoſed by an alkali.

59 Fourcroy's general method of analyſis.

We have now ſaid every thing that is neceſſary reſpecting the two modes of analyzing water by precipitation and evaporation; but as a difficulty may occur to the unexperienced chemiſt reſpecting the order in which he ought to proceed in making his experiments, we ſhall lay before our readers the method recommended by M. Fourcroy.

He firſt examines the ſenſible properties of the water, the taſte, colour, weight, &c. and then pours upon four pounds of water the ſame weight of lime-water. If no precipitate falls in 24 hours, he concludes that the water contains no diſengaged carbonic acid, nor mild fixed alkali, nor earthy ſalts with baſe of aluminous earth or magneſia, nor metallic ſalts. If a precipitate be inſtantly formed, he proceeds to filter the liquid, and to examine the chemical qualities of the precipitate. If it has no taſte, if it is inſoluble in water, if it effervеſces with acids, and if it forms with ſulphuric acid an inſipid ſalt almoſt inſoluble in water, he concludes that it is chalk, and that the lime-water attracted only the aerial acid diſſolved in the water. On the contrary, if the precipitate be not copious, if it collects ſlowly, if it excites no effervеſcence, if, with the ſulphuric acid it forms a bitter ſalt, it is magneſia; but if with the ſame acid it forms a ſweetiſh aſtringent ſalt, it is aluminous earth or clay. Sometimes it may be a compound of both.

Being now examined by lime-water, he pours upon it other four pounds of the ſame water, a gros or two (E) of volatile cauſtic alkali, or he paſſes it through ſome alkaline gas diſengaged by means of heat. When the water is ſaturated, he leaves it in a cloſe veſſel for 24 hours; then if a precipitate be formed, as it muſt contain ſalts, with iron, magneſia, or aluminous earth for its baſe, he inveſtigates the nature of it. It muſt be obſerved, that the alkaline gas is not to be depended upon alone, but may be uſed as an auxiliary. Water.

M. Fourcroy next pours into a certain quantity of the water under examination a portion of cauſtic mineral alkali diſſolved. He continues to pour it in till no farther muddineſs is produced, as it diſcompoſes the ſalts with a baſe of aluminous earth, or a baſe of lime. If the precipitate reſembles in form, colour, and quantity, that which is yielded by lime-water, it may be preſumed that the water contains no calcareous earth; but if it be more weighty, copious, and has formed more quickly than the precipitate formed by the lime-water, then it contains lime mixed with magneſia or aluminous earth. If the precipitate contain any iron, it is eaſily detected by its colour and taſte.

Theſe obſervations of M. Fourcroy will be of great uſe to the young chemiſt, in pointing out the order which he may follow with facility and advantage in the analyſis of waters; and after he has formed his opinion concerning the ingredients contained in the water, he may examine the truth of it by applying the particular teſts which have already been deſcribed.

In the account which we have given of the method of analyzing waters, the chemical reader will obſerve, that we have chiefly followed Bergman. We have done ſo, becauſe we reckon him the beſt writer on the ſubject, and becauſe we have been more anxious to ſtudy truth and utility than novelty. We ardently wiſh that ſome able chemiſt would exhibit an accurate and eaſy mode of analyzing earths, which every farmer could practiſe without a deep knowledge of chemiſtry. Farmers would then be enabled to apply the manures proper to particular ſoils, in which they would be much aſſiſted by Dr Kirwan's valuable Treatiſe on Manures.

Under the title of *Mineral Waters*, we have given an analyſis of the moſt remarkable waters in Europe. (See alſo Spa, Seltzer, Pyrmont, and the names of other celebrated waters). Thoſe who wiſh for more information concerning the mode of analyzing water, may conſult Bergman's Chemical Eſſays, Fourcroy's Lectures on Chemiſtry, and the different books referred to by theſe authors.

Holy Water, which is made uſe of in the Church of Rome, as alſo by the Greeks, and by the other Chriſtians of the Eaſt of all denominations, is water with a mixture of ſalt, bleſſed by a prieſt according to a ſet form of benediction. It is uſed in the bleſſing of perſons, things, and places; and is likewiſe conſidered as a ceremony to excite pious thoughts in the minds of the faithful.

The prieſt, in bleſſing it, firſt, in the name of God, commands the devils not to hurt the perſons who ſhall be ſprinkled with it, nor to abuſe the things, nor diſquiet the places, which ſhall likewiſe be ſo ſprinkled. He then prays that health, ſafety, and the favour of heaven may be enjoyed by ſuch perſons, and by thoſe who ſhall uſe ſuch things, or dwell in ſuch places. Veſtments, veſſels, and other ſuch things that are ſet apart for divine ſervice, are ſprinkled with it. It is ſometimes ſprinkled on cattle, with an intention to free or preſerve them from diabolical enchantments; and in ſome ritual books there are prayers to be ſaid on ſuch occaſions, by which the ſafety of ſuch animals, as being a temporal bleſſing to the poſſeſſors, is begged of God, whoſe providential care is exended to all his creatures. The hope which Catholics entertain of obtaining ſuch good effects from the devout uſe of holy water, is grounded

(E) A gros is equal to 59,0703 of Engliſh Troy grains.

Water. grounded on the promiſe made to believers by Chriſt (St Mark xvi. 17.), and on the general efficacy of the prayers of the church, the petition of which prayers God is often pleaſed to grant; though ſometimes in his providence, he ſees it not expedient to do ſo. That ſuch effects have been produced by holy water in a remarkable manner, has been aſſerted by many authors of no ſmall weight; as, namely, by St Epiphanius, Haer. 30th; St Hierom, in the Life of St. Hilarion; Theodoret *Hiſt. Eccl.* lib. v. cap. 21; Palladius, *Hiſt. Lauſ.*; Bede, lib. v. cap. 4.

As a ceremony (ſays the Catholic), water brings to our remembrance our baptiſm; in which by water we were cleanſed from original ſin. It alſo puts us in mind of that purity of conſcience which we ought to endeavour always to have, but eſpecially when we are going to worſhip our God. The ſalt which is put into the water to preſerve it from corrupting, is alſo a figure of divine grace, which preſerves our ſouls from the corruption of ſin; and is likewiſe an emblem of that wiſdom and diſcretion which ought to ſeaſon every action that a Chriſtian does, and every word that he ſays. It is wont to be bleſſed and ſprinkled in churches on Sundays, in the beginning of the ſolemn office. It is kept in veſſels at the doors of the ſame churches, that it may be taken by the faithful as they enter in. It is alſo often kept in private houſes and chambers (A).

Putrid WATER, is that which has acquired an offenſive ſmell and taſte by the putreſcence of animal or vegetable ſubſtances contained in it. It is in the higheſt degree pernicious to the human frame, and capable of bringing on mortal diſeaſes even by its ſmell. It is not always from the apparent muddineſs of waters that we can judge of their diſpoſition to putrify; ſome which are ſeemingly very pure being more apt to become putrid than others which appear much more mixed with heterogeneous matters. Under the article ANIMALCULE, n° 33, is mentioned a ſpecies of inſects which have the property of making water ſtink to an incredible degree, though their bulk in proportion to the fluid which ſurrounds them is leſs than that of one to a million. Other ſubſtances no doubt there are, which have the ſame property: and hence almoſt all water which is confined from the air is apt to become offenſive, even though kept in glaſs or ſtone-ware veſſels. Indeed it is a common obſervation, that water keeps much longer ſweet in glaſs-veſſels, or in thoſe of earthen or ſtone-ware, than in thoſe of wood, where it is exceedingly apt to putrify. Hence, as ſhips can only be ſupplied with water kept in wooden caſks, ſailors are extremely liable to thoſe diſeaſes which ariſe from putrid water; and the diſcovery of a method by which water could eaſily be prevented from becoming putrid at ſea would be exceedingly valuable. This may indeed be done by quicklime; for when water is impregnated with it, all putreſcent matters are either totally deſtroyed, or altered in ſuch a manner as never to be capable of undergoing the putrefactive fermentation again. But a continued uſe of lime-water could not fail of being pernicious, and it is therefore neceſſary to throw down the lime; after which the water will have all the purity neceſſary for preſerving it free from putrefaction. This can only be done by means of fixed air; and mere expoſure in broad ſhallow veſſels to the atmoſphere would do it without any thing elſe, only taking care to break the cruſt which formed upon it. Two methods, however, have been thought of for doing this with more expedition. The one, invented by Dr Alſton, is, by throwing into the water impregnated with lime a quantity of magneſia. The lime attracts fixed air more powerfully than magneſia; in conſequence of which the latter parts with it to the lime: and thus becoming inſoluble, falls along with the cauſtic magneſia to the bottom, and thus leaves the water perfectly pure. Another method is that of Mr Henry, who propoſes to throw down the lime by means of an effervеſcing mixture of oil of vitriol or chalk put down to the bottom of the water-caſk. His apparatus for this purpoſe is as ſimple as it can well be made, though it is hardly probable that ſailors will give themſelves the trouble of uſing it; and Dr Alſton's ſcheme would ſeem better calculated for them, were it not for the expence of the magneſia; which indeed is the only objection made to it by Mr Henry. Putrid water may be reſtored and made potable by a proceſs of the ſame kind. Water.

Of late it has been diſcovered that charcoal poſſeſſes many unexpected properties, and among others, that of preſerving water from corruption, and of purifying it after it has been corrupted. Mr Lowitz, whoſe experiments on charcoal have been publiſhed in Crell's Chemical Journal, has turned his attention to this ſubject in a memoir read to the Economical Society of Peterſburg. He found that the effect of charcoal was rendered much more ſpeedy by uſing along with it ſome ſulphuric acid. One ounce and a half of charcoal in powder, and 24 drops of concentrated ſulphuric acid (oil of vitriol), are ſufficient to purify three pints and a half of corrupted water, and do not communicate to it any ſenſible acidity. This ſmall quantity of acid renders it unneceſſary to uſe more than a third part of the charcoal powder which would otherwiſe be wanted: and the leſs of that powder is employed, the leſs is the quantity of water loſt by the operation, which, in ſea-voyages, is an object worthy of conſideration. In proportion to the quantity of acid made uſe of, the quantity of charcoal may be diminiſhed or augmented. All acids produce nearly the ſame effects: neutral ſalts alſo, particularly nitre and ſea-ſalt, may be uſed, but ſulphuric acid is preferable to any of theſe; water which is purified by means of this acid and charcoal will keep a longer time than that which is purified by charcoal alone. When we mean to purify any given quantity of corrupted water, we ſhould begin by adding to it as much powder of charcoal as is neceſſary to deprive it entirely of its bad ſmell. To aſcertain whether that quantity of powdered charcoal was ſufficient to effect the clarification of the ſaid water, a ſmall quantity of it may be paſſed through a linen bag, two or three inches long; if the water, thus filtrated, ſtill has a turbid appearance, a freſh quantity of powdered charcoal muſt be added, till it is become perfectly clear; the whole of the water may then be paſſed through a filtering bag, the ſize of which ſhould be proportioned to the quantity of water. If ſulphuric acid, or any other, can be procured, a ſmall quantity of it ſhould be added to the water, before the charcoal powder.

The cleaning of the caſks in which water is to be kept in ſea-voyages ſhould never be neglected; they ſhould be well waſhed with hot water and ſand, or with any other ſubſtance capable of removing the mucilaginous particles, and afterwards a quantity of charcoal-duſt ſhould be employed, which will entirely deprive them of the muſty or putrid ſmell they may have contracted.—The charcoal uſed for purifying water ſhould be well burnt, and afterwards beat into a fine powder.

Sea-

(A) This article was furniſhed by an eminent divine of the church of Rome, to whom we are indebted for greater favours.

Water. *Sea-Water.* See *Sea-Water.*

Water Carts, carriages conſtructed for the purpoſe of watering the roads for ſeveral miles round London; a precaution abſolutely neceſſary near the metropolis, where, from ſuch a vaſt daily influx of carriages and horſes, the duſt would otherwiſe become quite inſufferable in hot dry weather. Pumps are placed at proper diſtances to ſupply theſe carts.

Water-Ordeal. See Ordeal.

Water, among jewellers, is properly the colour or luſtre of diamonds and pearls. The term, though leſs properly, is ſometimes uſed for the hue or colour of other ſtones.

Water-Bellows. See *Machines for blowing Air into Furnaces.*

Water-Colours, in painting, are ſuch colours as are only diluted and mixed up with gum-water, in contradiſtinction to oil colours. See *Colour-Making.*

Water-Gang, a channel cut to drain a place by carrying off a ſtream of water.

Water-Hen. See Parra.

Water-Line of a Ship, certain horizontal lines ſuppoſed to be drawn about the outſide of a ſhip's bottom, cloſe to the ſurface of the water in which ſhe floats. They are accordingly higher or lower upon the bottom, in proportion to the depth of the column of water required to float her.

Water-Lodged, the ſtate of a ſhip when, by receiving a great quantity of water into the hold, by leaking, &c. ſhe has become heavy and inactive upon the ſea, ſo as to yield without reſiſtance to the efforts of every wave ruſhing over her decks. As, in this dangerous ſituation, the centre of gravity is no longer fixed, but fluctuating from place to place, the ſtability of the ſhip is utterly loſt: ſhe is therefore almoſt totally deprived of the uſe of her ſails, which would operate to overſet her, or preſs the head under water. Hence there is no reſource for the crew, except to free her by the pumps, or to abandon her by the boats as ſoon as poſſible.

Water-Sail, a ſmall ſail ſpread occaſionally under the lower ſtudding-ſail, or driver-boom, in a fair wind and ſmooth ſea.

Water-Ouzel. See Turdus.

Water-Spout, an extraordinary meteor conſiſting of a large maſs of water collected into a ſort of column, and moved with rapidity along the ſurface of the ſea.

The beſt account of the water-ſpout which we have met with is in the Phil. Tranſ. Abridged, vol. viii. as obſerved by Mr Joſeph Harris, May 21. 1732, about ſunſet, lat. 32° 30′ N. long. 9° E. from Cape Florida.

"When firſt we ſaw the ſpout (ſays he), it was whole and entire, and much of the ſhape and proportion of a ſpeaking trumpet; the ſmall end being downwards, and reaching to the ſea, and the big end terminated in a black thick cloud. The ſpout itſelf was very black, and the more ſo the higher up. It ſeemed to be exactly perpendicular to the horizon, and its ſides perfectly ſmooth, without the leaſt ruggedneſs. Where it fell the ſpray of the ſea roſe to a conſiderable height, which made ſomewhat the appearance of a great ſmoke. From the firſt time we ſaw it it continued whole about a minute, and till it was quite diſſipated about three minutes. It began to waſte from below, and ſo gradually up, while the upper part remained entire, without any viſible alteration, till at laſt it ended in the black cloud above: upon which there ſeemed to fall a very heavy rain in that neighbourhood.—There was but little wind, and the ſky elſewhere was pretty ſerene."

Water-ſpouts have by ſome been ſuppoſed to be merely electrical in their origin; particularly by Signior Beccaria, who ſupported his opinion by ſome experiments. But if we attend to the ſucceſſive phenomena neceſſary to conſtitute a complete water-ſpout through their various ſtages, we ſhall be convinced, that recourſe muſt be had to ſome other principle in order to obtain a complete ſolution. Water.

Dr Franklin, in his Phyſical and Meteorological Obſervations, ſuppoſes a water-ſpout and a whirlwind to proceed from the ſame cauſe; their only difference being, that the latter paſſes over the land, and the former over the water. This opinion is corroborated by M. de la Pryme, in the Philoſophical Tranſactions, where he deſcribes two ſpouts obſerved at different times in Yorkſhire, whoſe appearances in the air were exactly like thoſe of the ſpouts at ſea, and their effects the ſame as thoſe of real whirlwinds.

A fluid moving from all points horizontally towards a centre, muſt at that centre either mount or deſcend. If a hole be opened in the middle of the bottom of a tub filled with water, the water will flow from all ſides to the centre, and there deſcend in a whirl: but air flowing on or near the ſurface of land or water, from all ſides towards a centre, muſt at that centre aſcend; becauſe the land or water will hinder its deſcent.

The Doctor, in proceeding to explain his conceptions, begs to be allowed two or three poſitions, as a foundation for his hypotheſis. 1. That the lower region of air is often more heated, and ſo more rarefied, than the upper, and by conſequence ſpecifically lighter. The coldneſs of the upper region is manifeſted by the hail, which ſometimes falls from it in warm weather. 2. That heated air may be very moiſt, and yet the moiſture ſo equally diffuſed and rarefied as not to be viſible till colder air mixes with it; at which time it condenſes and becomes viſible. Thus our breath, although inviſible in ſummer, becomes viſible in winter.

Theſe circumſtances being granted, he preſuppoſes a tract of land or ſea, of about 60 miles in extent, unſheltered by clouds and unrefreſhed by the wind, during a ſummer's day, or perhaps for ſeveral days without intermiſſion, till it becomes violently heated, together with the lower region of the air in contact with it; ſo that the latter becomes ſpecifically lighter than the ſuperincumbent higher region of the atmoſphere, wherein the clouds are uſually floated: he ſuppoſes alſo that the air ſurrounding this tract has not been ſo much heated during thoſe days, and therefore remains heavier. The conſequence of this, he conceives, ſhould be, that the heated lighter air ſhould aſcend, and the heavier deſcend; and as this riſing cannot operate throughout the whole tract at once, becauſe that would leave too extenſive a vacuum, the riſing will begin preciſely in that column which happens to be lighteſt or moſt rarefied; and the warm air will flow horizontally from all parts of this column, where the ſeveral currents meeting, and joining to riſe, a whirl is naturally formed, in the ſame manner as a whirl is formed in a tub of water, by the deſcending fluid receding from all ſides of the tub towards the hole in the centre.

And as the ſeveral currents arrive at this central riſing column, with a conſiderable degree of horizontal motion, they cannot ſuddenly change it to a vertical motion; therefore as they gradually, in approaching the whirl, decline from right to curve or circular lines, ſo, having joined the whirl, they aſcend by a ſpiral motion: in the ſame manner as the water deſcends ſpirally through the hole in the tub before-mentioned.

Laſtly, as the lower air neareſt the ſurface is more rarefied by the heat of the ſun, it is more impreſſed by the current of the ſurrounding cold and heavy air which is to aſſume its place, and conſequently its motion towards the whirl is ſwifteſt, and ſo the force of the lower part of the

Water. whirl ſtrongeſt, and the centrifugal force of its particles greateſt. Hence the vacuum which incloſes the axis of the whirl ſhould be greateſt near the earth or ſea, and diminiſh gradually as it approaches the region of the clouds, till it ends in a point.

This circle is of various diameters, ſometimes very large.

If the vacuum paſſes over water, the water may riſe in a body or column therein to the height of about 32 feet. This whirl of air may be as inviſible as the air itſelf, though reaching in reality from the water to the region of cool air, in which our low ſummer thunder-clouds commonly float; but it will ſoon become viſible at its extremities. The agitation of the water under the whirling of the circle, and the ſwelling and riſing of the water in the commencement of the vacuum, renders it viſible below. It is perceived above by the warm air being brought up to the cooler region, where its moiſture begins to be condenſed by the cold into thick vapour, and is then firſt diſcovered at the higheſt part, which being now cooled condenſes what riſes behind it, and this latter acts in the ſame manner on the ſucceeding body; where, by the contact of the vapours, the cold operates faſter in a right line downwards, than the vapours themſelves can climb in a ſpiral line upwards: they climb however; and as by continual addition they grow denſer, and by conſequence increaſe their centrifugal force, and being riſen above the concentrating currents that compoſe the whirl, they fly off, and form a cloud.

It ſeems eaſy to conceive, how, by this ſucceſſive condenſation from above, the ſpout appears to drop or deſcend from the cloud, although the materials of which it is compoſed are all the while aſcending. The condenſation of the moiſture contained in ſo great a quantity of warm air as may be ſuppoſed to riſe in a ſhort time in this prodigiouſly rapid whirl, is perhaps ſufficient to form a great extent of cloud; and the friction of the whirling air on the ſides of the column may detach great quantities of its water, diſperſe them into drops, and carry them up in the ſpiral whirl mixed with the air. The heavier drops may indeed fly off, and fall into a ſhower about the ſpout; but much of it will be broken into vapour, and yet remain viſible.

As the whirl weakens, the tube may apparently ſeparate in the middle; the column of water ſubſiding, the ſuperior condenſed part drawing up to the cloud. The tube or whirl of air may nevertheleſs remain entire, the middle only becoming inviſible, as not containing any viſible matter.

Dr Lindſay, however, in ſeveral letters publiſhed in the Gentleman's Magazine, has controverted this theory of Dr Franklin, and endeavoured to prove, that water-ſpouts and whirlwinds are diſtinct phenomena; and that the water which forms the water-ſpout, does not aſcend from the ſea, as Dr Franklin ſuppoſes, but deſcends from the atmoſphere.

Our limits do not permit us to inſert his arguments here, but they may be ſeen in the Gentleman's Magazine, volume li. p. 559, 615; vol. liii. p. 1025; and vol. lv. p. 594. We cannot avoid obſerving, however, that he treats Dr Franklin with a degree of aſperity to which he is by no means intitled, and that his arguments, even if concluſive, prove nothing more than that ſome water-ſpouts certainly do deſcend; which Dr Franklin hardlyever ventured to deny. There are ſome very valuable diſſertations on this ſubject by profeſſor Wilcke of Upſal. Water ‖ Watſon.

Water-Works. See *Water-Works* (A).

Water-Works for entertainment. See Hydrostatics, ſect. 6.

WATERFORD, a city and ſea-port of Ireland, in a county of the ſame name, with a biſhop's ſee. It is the ſecond place in the kingdom, and is a wealthy populous city, enjoying many ample privileges. The ſtreets are narrow, and the air is not very healthy; but it has an excellent harbour, ſeated as well for trade as any in the world, and ſhips of the greateſt burden may ride at the quay. It ſtands on the river Sure, 8 miles north of St George's Channel, 26 ſouth of Kilkenny, and 75 ſouth by weſt of Dublin. W. Long. 6. 54. N. Lat. 52. 18.

Waterford, a county of Ireland, 46 miles in length, and 25 in breadth; bounded on the ſouth by St George's Channel; on the weſt by Cork; on the north by the river Sure, which ſeparates it from Tipperary and Kilkenny; and on the eaſt by Waterford Haven, which parts it from Wexford. It contains 71 pariſhes, and ſends 10 members to parliament. It is a fine country, very pleaſant and rich, and the principal place is of the ſame name.

WATERING, in the manufactures, is to give a luſtre to ſtuffs, &c. by wetting them lightly with gum-water, and then paſſing them through the preſs or calender whether hot or cold. The gum-water ought to be pure, thin, and clear, otherwiſe the folds of the ſtuff will all ſtick together: the operation muſt alſo be performed when the water is very hot, that it may penetrate.

Watering Meadows. See Meadows.

WATERLAND (Dr Daniel) a learned Engliſh divine who diſtinguiſhed himſelf greatly in theological controverſies, was born in 1683 at Waſely in Lincolnſhire, of which place his father was rector. He had his academical learning at Magdalen college, Cambridge, where he drew up a uſeful tract, which went through ſeveral editions, intitled, *Advice to a Young Student, with a Method of Study for the firſt four years.* In 1713 he became maſter of the college, was ſoon after appointed chaplain to George I. and in 1720 preached the firſt courſe of lectures founded by lady Moyer in defence of our Lord's divinity. He went through ſeveral promotions; and at the time of his death in 1740, was canon of Windſor, archdeacon of Middleſex, and vicar of Twickenham. Beſides his controverſial writings, he publiſhed two volumes of ſermons.

WATLING-street. See Way.

WATSON (Dr Robert), an elegant hiſtorian, was born at St Andrew's, in Scotland, about the year 1730. He was the ſon of an apothecary of that place, who was alſo a brewer. Having gone through the uſual courſe of languages and philoſophy at the ſchool and univerſity of his native place, and alſo entered on the ſtudy of divinity, a deſire of being acquainted with a larger circle of literati, and of improving himſelf in every branch of knowledge, carried him, firſt to the univerſity of Glaſgow, and afterwards to that of Edinburgh. The period of theological ſtudies

(A) For referring this article from the word Water to the word Works, an apology is due to the Public; and the apology which we have to offer, we are perſuaded, will be ſuſtained. It is this: The gentleman who contributed the articles *Resistance of Fluids* and River, promiſed to furniſh alſo the article *Water Works*; but ſickneſs has hitherto prevented him from fulfilling that promiſe. We truſt, however, that before our preſſes ſhall reach to the word Works, he may be able to fill up the ſketch which he has long ago drawn of this very important ſubject. And ſuch of our readers as can eſtimate the merit of his two articles, which we have juſt mentioned, will not blame the Editor for deviating a little from the alphabetical order, to give him a chance of furniſhing a third article, to which theſe two are ſo cloſely related.

Watſon. Watts.

ſtudies at the univerſities of Scotland is four years; but during that period, young men of ingenious minds find ſufficient leiſure to carry on and advance the purſuits of general knowledge. Mr Watſon purſued his ſtudies with ardour. Few men ever ſtudied more conſtantly. It was a rule with him to ſtudy eight hours every day; and this law he obſerved during the whole courſe of his life. An acquaintance with the polite writers of England, after the union of the two kingdoms, became general in Scotland; and in Watſon's younger years, an emulation began to prevail of writing pure and elegant Engliſh. Mr Watſon applied himſelf with great induſtry to the principles of philoſophical or univerſal grammar; and by a combination of theſe, with the authority of the beſt Engliſh writers, formed a courſe of lectures on ſtyle or language. He proceeded to the ſtudy of rhetoric or eloquence; the principles of which he endeavoured to trace to the nature of the human mind. He delivered a courſe of lectures in Edinburgh on theſe ſubjects; and met with the countenance, approbation, and friendſhip of Lord Kames, Mr Hume, with other men of genius and learning.

At this time he had become a preacher: and a vacancy having happened in one of the churches of St Andrew's, he offered himſelf a candidate for that living, but was diſappointed. Mr Henry Rymer, who then taught logic in St Salvador's College, was in a very infirm ſtate of health, and entertained thoughts of retiring from the cares and emoluments of his office, to live upon his ſmall ſalary or ſtipend. Mr Watſon underſtanding this, purchaſed, for not a great ſum of money, what, in familiar phraſeology, may be called the good-will of Mr Rymer's place; and, with the conſent of the other maſters of St Salvador's, was appointed profeſſor of logic. He obtained alſo a patent from the crown, conſtituting him profeſſor of rhetoric and belles lettres. The ſtudy of logic, in St Andrew's, as in moſt other places, was at this time confined to ſyllogiſms, modes, and figures. Mr Watſon, whoſe mind had been opened by converſation, and by reading the writings of the wits that had begun to flouriſh in the Scotch capital, prepared and read to his ſtudents a courſe of metaphyſics and logics on the moſt enlightened plan; in which he analyzed the powers of the mind, and entered deeply into the nature of the different ſpecies of evidence of truth or knowledge. By his hiſtory of Philip II. Dr Watſon attained in his lifetime a conſiderable degree of celebrity; and his hiſtory of Philip III. publiſhed after his death, has added to his fame. Of this laſt performance, however, he has only completed the four firſt books; the two laſt were written by the editor of his manuſcript, at the deſire of the guardians of his children.

On the death of principal Tulideph, Dr Watſon, through the earl of Kinnoull, was appointed his ſucceſſor; in which ſtation he lived only a few years. He married a lady of ſingular beauty and virtue, daughter to Mr Shaw, profeſſor of divinity in St Mary's college, St Andrew's. By this lady he had five daughters, who ſurvived him.

WATTS (Dr Iſaac), a learned and eminent diſſenting miniſter, was born at Southampton in 1674, of parents eminent for piety, and conſiderable ſufferers for conſcience-ſake. In 1690 he was ſent up to London for academical education under the tuition of the Rev. Mr Thomas Rowe; and in 1696 was himſelf engaged as tutor to the ſon of Sir John Hartopp, bart. at Stoke Newington. He began to preach in 1698, and met with general acceptance; and after officiating for three years as an aſſiſtant to the Rev. Dr Iſaac Chauncy, he ſucceeded in his paſtoral charge in 1702, and continued to preſide over that church as long as he lived. Though his whole income did not amount to an hundred a-year, he allotted one third of it to the poor. He died in 1748. His numerous works have rendered his name famous among people of every denomination, both in this and other countries, and they have been tranſlated into a variety of languages. His Lyric Poems, his Pſalms and Hymns, and his divine Songs for Children, are a ſufficient proof of his poetical talents, and have had an amazing number of editions. His logic and philoſophy have been much admired. He alſo wrote works upon a variety of other ſubjects, and printed ſeveral volumes of his ſermons. He was admired for the mildneſs and benevolence of his diſpoſition and the ſweetneſs of his manners. After his death, his works were collected, and publiſhed in ſix volumes quarto.

Wave. || Wax.

WAVE, in philoſophy, a cavity in the ſurface of water, or other fluids, with an elevation aſide thereof.

The waves of the ſea are of two kinds, natural and accidental. The natural waves are thoſe which are exactly proportioned in ſize to the ſtrength of the wind, whoſe blowing gives origin to them. The accidental waves are thoſe occaſioned by the wind's reacting upon itſelf by repercuſſion from hills and mountains, or high ſhores, and by the waſhing of the waves themſelves; otherwiſe of the natural kind, againſt rocks and ſhoals: all theſe caſes give the waves an elevation, which they can never have in their natural ſtate. For the height of the waves, ſee SEA.

Stilling WAVES by means of Oil. See SEA.

WAVED, in heraldry, is ſaid of a bordure, or any ordinary or charge, in a coat of arms, having its outlines indented in manner of the riſing and falling of waves: it is uſed to denote, that the firſt of the family in whoſe arms it ſtands, acquired its honours by ſea-ſervice.

WAVING, in the ſea-language, is the making ſigns to a veſſel to come near or keep off.

WAX, or *Bees WAX*, in natural hiſtory, a firm and ſolid ſubſtance, moderately heavy, and of a fine yellow colour, formed by the bees from the pollen of flowers. See APIS.

The beſt ſort is that of a lively yellow colour, and an agreeable ſmell, ſomewhat like that of honey: when new, it is toughiſh, yet eaſy to break; but by age it becomes harder and more brittle, loſes its fine colour, and in a great meaſure its ſmell.

It appears that wax and the pollen have for their baſis a fat oil, which paſſes to the ſtate of reſin by its combination with oxygene. If the nitric or muriatic acid be digeſted upon fixed oil for ſeveral months, it paſſes to a ſtate reſembling wax. Wax, by repeated diſtillations, affords an oil which poſſeſſes all the properties of volatile oils. It is reduced into water and carbonic acid by combuſtion. The colouring matter of wax is inſoluble in water and in alcohol. Chaptal's Chemiſtry, vol. iii.

Fixed alkalis diſſolve wax, and render it ſoluble in water.

It is this ſaponaceous ſolution which forms the punic wax. It may be uſed as the baſis of ſeveral colours; and may be made into an excellent paſte for waſhing the hands. Ammoniac likewiſe diſſolves it; and as this ſolvent is evaporable, it ought to be preferred when it is propoſed to uſe the wax as a varniſh.

From the common yellow wax, by bleaching, is formed white-wax, ſometimes called, very improperly, *virgin-wax*. The greater the ſurface is in proportion to the quantity, the ſooner and more perfectly this operation is performed. The uſual way is to melt the wax in hot water; when melted, they preſs it through a ſtrainer of tolerable fine linen, and pour it into round and very ſhallow moulds. When hardened by cooling, it is taken out and expoſed to the ſun and air, ſprinkling it now and then with water, and often turning it: by this means it ſoon becomes white.

Wax, Way.

The beſt ſort is of a clear and almoſt tranſparent whiteneſs, dry, hard, brittle, and of an agreeable ſmell, like that of the yellow wax, but much weaker.

The common yellow wax is of very great uſe both in medicine and in many of the arts and manufactures. It has been ſometimes given internally in dyſenteries and eroſions of the inteſtines; but its great uſe is in the making ointments and plaſters, and the greater part of thoſe of the ſhops owe their conſiſtence to it. The white wax is alſo an ingredient in ſome of the cerates and ointments of the ſhops; and is uſed in making candles, and in many of the nicer arts and manufactures where wax is required.

Sealing-Wax, or *Spaniſh-Wax*, is a compoſition of gum lac, melted and prepared with reſins, and coloured with ſome ſuitable pigment.

There are two kinds of ſealing-wax in uſe; the one hard, intended for ſealing letters, and other ſuch purpoſes; the other ſoft, deſigned for receiving the impreſſions of ſeals of office to charters, patents, and ſuch written inſtruments. The beſt hard red ſealing-wax is made by mixing two parts of ſhell lac, well powdered, and reſin and vermilion, powdered, of each one part, and melting this combined powder over a gentle fire; and when the ingredients ſeem thoroughly incorporated, working the wax into ſticks. Seed-lac may be ſubſtituted for the ſhell-lac; and inſtead of reſin, boiled Venice turpentine may be uſed. A coarſer, hard, red ſealing-wax, may be made, by mixing two parts of reſin, and of ſhell-lac, or vermilion and red-lead, mixed in the proportion of one part of the vermilion to two of the red-lead, of each one part; and proceeding as in the former preparation. For a cheaper kind, the vermilion may be omitted, and the ſhell-lac alſo, for very coarſe uſes. Wax of other colours is made by ſubſtituting other colouring matters for vermilion, as verditer for blue, ivory black for black wax. For uncoloured, ſoft ſealing-wax, take of bees-wax, one pound; of turpentine, three ounces; and of olive-oil, one ounce; place them in a proper veſſel over the fire, and let them boil for ſome time; and the wax will be then fit to be formed into rolls or cakes for uſe. For red, black, green, blue, yellow, and purple ſoft ſealing-wax, add to the preceding compoſition an ounce or more of any ingredients directed above for colouring the hard ſealing-wax, and ſtir the maſs till the colouring ingredients be incorporated with the wax.

Wax-Work, the repreſentation of the faces, &c. of perſons living or dead; made by applying plaſter of Paris in a kind of paſte, and thus forming a mould containing the exact repreſentation of the features. Into this mould melted wax is poured, and thus a kind of maſks are formed; which being painted and ſet with glaſs eyes, and the figures dreſſed in their proper habits, they bear ſuch a reſemblance that it is difficult to diſtinguiſh between the copy and the original.

WAY, a paſſage or road.

The Roman ways are divided into conſular, prætorian, military, and public; and of theſe we have four remarkable ones in England: the firſt, Watling-ſtreet, or Watheling-ſtreet, leading from Dover to London, Dunſtable, Touceſter, Atterſton, and the Severn, extending as far as Angleſea in Wales. The ſecond, called *Hikenild* or *Ikenild-ſtreet*, ſtretches from Southampton over the river Iſis at Newbridge; thence by Camden and Litchfield; then paſſes the Derwent near Derby, and ends at Tinmouth. The third, called *Foſſe-way*, becauſe in ſome places it was never perfected, but lies as a large ditch, leads from Cornwall through Devonſhire, by Tethbury, near Stow in the Wolds; and beſide Coventry to Leiceſter, Newark, and ſo to Lincoln. The fourth, called *Erming* or *Erminage-ſtreet* extends from St David's in Wales, to Southampton. Way

War Covert, Gang, Hatch. See *Covert Way*, *Gang*, &c. Weather.

War of a Ship, is ſometimes the ſame as her rake, or run forward or backward: but this term is moſt commonly underſtood of her ſailing.

War-Leaves, in the coal buſineſs. See Coalery, n° 3.

Right of Ways, in law. This may be grounded on a ſpecial permiſſion; as when the owner of the land grants to another a liberty of paſſing over his grounds, to go to church, to market, or the like: in which caſe the gift or grant is particular, and confined to the grantee alone; it dies with the perſon; and if the grantee leaves the country, he cannot aſſign over his right to any other; nor can he juſtify taking another perſon in his company. A way may be alſo by preſcription; as if all the owners and occupiers of ſuch a farm have immemorially uſed to croſs another's ground; for this immemorial uſage ſuppoſes an original grant, whereby a right of way thus appurtenant to land may clearly be created. A right of way may alſo ariſe by act and operation of law; for if a man grants me a piece of ground in the middle of his field, he at the ſame time tacitly and impliedly gives me a way to come at it; and I may croſs his land for that purpoſe without treſpaſs. For when the law doth give any thing to one, it giveth impliedly whatſoever is neceſſary for enjoying the ſame. By the law of the twelve tables at Rome, where a man had the right of way over another's land, and the road was out of repair, he who had the right of way might go over any part of the land he pleaſed: which was the eſtabliſhed rule in public as well as private ways. And the law of England, in both caſes, ſeems to correſpond with the Roman.

WAYFARING Tree. See Viburnum.

WAYWODE, is properly a title given to the governors of the chief places in the dominions of the czar of Muſcovy. The palatines, or governors of provinces in Poland, alſo bear the quality of *waywodes*, or *waiwodes*. The Poles likewiſe call the princes of Wallachia and Moldavia *waywodes*; as eſteeming them no other than on the foot of governors; pretending that Wallachia and Moldavia are provinces of Poland. Everywhere elſe theſe are called *hoſpodars*. Du Cange ſays, that the name *waywode* is uſed in Dalmatia, Croatia, and Hungary, for a general of an army: and Leunclavius, in his Pandects of Turkey, tells us, it uſually ſignifies *captain* or *commander*.

WEANING, putting a child away from the breaſt, and bringing it to uſe common food.

WEAR, or Weer, a great ſtank or dam in a river, fitted for the taking of fiſh, or for conveying the ſtream to a mill. New wears are not to be made, or others altered, to the nuiſance of the public, under a certain penalty. See River.

WEARING, or Veering, in ſeamanſhip. See Seamanship, Vol. XVII. p. 219.

WEASEL, in zoology. See Mustela.

WEATHER denotes the ſtate of the atmoſphere with regard to heat and cold, wind, rain, and other meteors.

The phenomena of the weather muſt have at all times attracted much of the attention of mankind, becauſe their ſubſiſtence and their comfort in a great meaſure depended upon them. It was not till the ſeventeenth century, however, that any conſiderable progreſs was made in inveſtigating the laws of meteorology. How deſirous ſoever the ancients might have been to acquire an accurate knowledge of this ſcience, their want of proper inſtruments entirely precluded them from cultivating it. By the diſcovery of the barometer and thermometer in the laſt century, and the invention of accurate electrometers and hygrometers in the preſent,

Weather. preſent, this defect is now pretty well ſupplied; and philoſophers are enabled to make meteorogical obſervations with eaſe and accuracy. Accordingly a very great number of ſuch obſervations have been collected, which have been arranged and examined from time to time by ingenious men, and conſequences deduced from them, on which ſeveral different theories of the weather have been built. But meteorology is a ſcience ſo exceedingly difficult, that, notwithſtanding the united exertions of ſome of the firſt philoſophers of the age, the phenomena of the weather are ſtill very far from being completely underſtood; nor can we expect to ſee the veil removed, till accurate tables of obſervations have been obtained from every part of the world, till the atmoſphere has been more completely analyſed, and the chemical changes which take place in it aſcertained. From the meteorological facts, however, which are already known, we ſhall draw up the beſt account of the weather we can. We ſhall treat of the different phenomena in the following order—heat and cold, wind, rain, thunder, alterations in the gravity of the atmoſphere.

1 Of Heat and Cold. I. Though there is a conſiderable difference in every part of the world between the temperature of the atmoſphere in ſummer and in winter; though in the ſame ſeaſon the temperature of almoſt every day, and even every hour, differs from that which precedes and follows it; though the heat varies continually in the moſt irregular and ſeemingly capricious manner—ſtill there is a certain mean temperature in every climate, which the atmoſphere has always a tendency to obſerve, and which it neither exceeds nor comes ſhort of beyond a certain number of degrees. What this temperature is, may be known by taking the mean of tables of obſervations kept for a number of years; and our knowledge of it muſt be the more accurate the greater the number of obſervations is.

2 Method of diſcovering the mean annual temperature of every place. The mean annual temperature is greateſt at the equator (or at leaſt a degree or two on the north ſide of it), and it diminiſhes gradually towards the poles, where it is leaſt. This diminution takes place in arithmetical progreſſion, or, to ſpeak more properly, the annual temperature of all the latitudes are arithmetical means between the mean annual temperature of the equator and the pole. This was firſt diſcovered by Mr Mayer; and by means of an equation which he founded on it, but rendered conſiderably plainer and ſimpler, Mr Kirwan has calculated the mean annual temperature of every degree of latitude between the equator and the pole. He proceeded on the following principle. Let the mean annual heat at the equator be m and at the pole $m-n$; put Φ for any other latitude; the mean annual temperature of that latitude will be $m-n \times \text{ſin. } \Phi^2$. If therefore the temperature of any two latitudes be known, the value of m and n may be found. Now the temperature of north lat. 40° has been found by the beſt obſervations to be 62,1°, and that of lat. 50°, 52,9°. The ſquare of the ſine of 40° is nearly 0,419, and the ſquare of the ſine of 50° is nearly 0,586. Therefore,

$$m - 0{,}41\,n = 62{,}1 \text{ and}$$
$$m - 0{,}58\,n = 52{,}9 \text{ : therefore}$$
$$62{,}1 + 0{,}41\,n = 52{,}9 + 0{,}58\,n,$$

as each of them, from the two firſt equations, is equal to m. From this laſt equation the value of n is found to be 53 nearly; and m is nearly equal to 84. The mean temperature of the equator therefore is 84°, and that of the pole 31°. To find the mean temperature for every other latitude, we have only to find 88 arithmetical means between 84 and 31. In this manner Mr Kirwan calculated the following table.

Table of the Mean Annual Temperature of the Standard Situation, in every Latitude. Weather.

Lat.	Temper	Lat.	Temper	Lat.	Temper
90	31,	61	43,5	32	69,1
89	31,04	60	44,3	31	69,9
88	31,10	59	45,09	30	70,7
87	31,14	58	45,8	29	71,5
86	31,2	57	46,7	28	72,3
85	31,4	56	47,5	27	72,8
84	31,5	55	48,4	26	73,8
83	31,7	54	49,2	25	74,5
82	32,	53	50,2	24	75,4
81	32,2	52	51,1	23	75,9
80	32,6	51	52,4	22	76,5
79	32,9	50	52,9	21	77,2
78	33,2	49	53,8	20	77,8
77	33,7	48	54,7	19	78,3
76	34,1	47	55,6	18	78,9
75	34,5	46	56,4	17	79,4
74	35,	45	57,5	16	79,9
73	35,5	44	58,4	15	80,4
72	36,	43	59,4	14	80,8
71	36,6	42	60,3	13	81,3
70	37,2	41	61,2	12	81,7
69	37,8	40	62,	11	82,
68	38,4	39	63,	10	82,3
67	39,1	38	63,9	9	82,7
66	39,7	37	64,8	8	82,9
65	40,4	36	65,7	7	83,2
64	41,2	35	66,6	6	83,4
63	41,9	34	67,4	5	83,6
62	42,7	33	68,3	0	84,

3 In the ſtandard ocean. This table, however, only anſwers for the temperature of the atmoſphere of the ocean. It was calculated for that part of the Atlantic ocean which lies between the 80th degree of northern and the 45th of ſouthern latitude, and extends weſtwards as far as the Gulf-ſtream, and to within a few leagues of the coaſt of America; and for all that part of the Pacific ocean reaching from lat. 45° north to lat 40° ſouth, from the 20th to the 275th degree of longitude eaſt of London. This part of the ocean Mr Kirwan calls *the ſtandard*; the reſt of the ocean is ſubject to anomalies which will be afterwards mentioned.

4 And alſo the mean monthly temperature. Mr Kirwan has alſo calculated the mean monthly temperature of the ſtandard ocean. The principles on which he went were theſe: The mean temperature of April ſeems to approach very nearly to the mean annual temperature; and as far as heat depends on the action of the ſolar rays, the mean heat of every month is as the mean altitude of the ſun, or rather as the ſine of the ſun's altitude. The mean heat of April, therefore, and the ſine of the ſun's altitude being given, the mean heat of May is found in this manner: As the ſine of the ſun's mean altitude in April is to the mean heat of April, ſo is the ſine of the ſun's mean altitude in May to the mean heat of May. In the ſame manner the mean heats of June, July, and Auguſt, are found; but the rule would give the temperature of the ſucceeding months too low, becauſe it does not take in the heat derived from the earth, which poſſeſſes a degree of heat nearly equal to the mean annual temperature. The real temperature of

theſe

Weather. these months therefore must be looked upon as an arithmetical mean between the astronomical and terrestrial heats. Thus in latitude 51°, the astronomical heat of the month of September is 44.6°, and the mean annual heat is 52.4°; therefore the real heat of this month should be $\frac{44.6+52.4}{2}$ = 48.5. Mr Kirwan, however, after going through a tedious calculation, found the results to agree so ill with observations, that he drew up the following table partly from principles and partly by studying a variety of sea journals. Weather.

Table of the Monthly Mean Temperature of the Standard from lat. 80° *to lat.* 10°.

Lat.	80°	79°	78°	77°	76°	75°	74°	73°	72°	71°	70°	69°	68°	67°	66°	65°	64°	63°	62°,	61°	60°	59°	58°	57°

From this table it appears, that January is the coldeſt month in every latitude, and that July is the warmeſt month in all latitudes above 48°. In lower latitudes Auguſt is generally warmeſt. The difference between the hotteſt and coldeſt months increaſes in proportion to the diſtance from the equator. Every habitable latitude enjoys a mean heat of 60° for at leaſt two months; this heat ſeems neceſſary for the production of corn. Within ten degrees of the poles the temperatures differ very little, neither do they differ much within ten degrees of the equator; the temperature of different years differ very little near the equator, but they differ more and more as the latitudes approach the poles.

5 The mean temperature of land varies with the height of the place.

The temperature of the earth at the level of the ſea is the ſame with that of the ſtandard ocean; but this temperature gradually diminiſhes as we aſcend above that level till, at a certain height, we arrive at the region of perpetual congelation. This region varies in height according to the latitude of the place; it is higheſt at the equator, and deſcends gradually nearer the earth as we approach the poles. It varies alſo according to the ſeaſon, being higheſt in ſummer and loweſt in winter. M. Bouguer found the cold on the top of Pinchinca, one of the Andes, to extend from ſeven to nine degrees below the freezing point every morning immediately before ſun-riſe. He concluded, therefore, that the mean height of the *term of congelation* (the place where it firſt freezes during ſome part of the day all the year round) between the tropics was 15,677 feet above the level of the ſea; but in lat. 28° he placed it in ſummer at the height of 13,440 feet. Now, if we take the difference between the temperature of the equator and the freezing point, it is evident that it will bear the ſame proportion to the term of congelation at the equator that the difference between the mean temperature of any other degree of latitude and the freezing point bears to the term of congelation in that latitude. Thus the mean heat of the equator being 84°, the difference between it and 32 is 52; the mean heat of lat. 28° is 72.3, the difference between which and 32 is 40.3: Then 52 : 15577 : : 40.3 : 12072. In this manner Mr Kirwan calculated the following table,

Lat.	Mean height of the Term of Congelation, Feet.	Lat.	Mean height of the Term of Congelation. Feet.
0	15577	45	7658
5	15457	50	6260
10	15067	55	4912
15	14498	60	3684
20	13719	65	2516
25	13030	70	1557
30	11592	75	748

40	9016		

6 Methods of finding it.

If the elevation of a country above the level of the ſea proceeds at a greater rate than ſix feet *per* mile, we muſt, according to Mr Kirwan*, for every 200 feet of elevation diminiſh the annual temperature of the ſtandard in that latitude as follows. If the elevation be at the rate of

6 feet *per* mile	$\frac{1}{4}$ of a degree
7 feet -	$\frac{1}{3}$
13 feet -	$\frac{4}{10}$
15 or upwards	$\frac{1}{2}$

* Temperature of Latitudes, page 45.

According to him ‡ alſo, for every 50 miles diſtance from the ſtandard ocean, the mean annual temperature in different latitudes is to be depreſſed or raiſed nearly at the following rate:

† Ibid. page 43.

From lat. 70° to lat. 35° cooled $\frac{1}{3}$ of a degree
35 - $\frac{1}{8}$
30 - 0
25 warmed $\frac{1}{5}$
20 - $\frac{1}{2}$
10 - 1°

7 Cauſe of the heat of the atmoſphere.

The cauſe of the heat of the atmoſphere is evidently the ſun's rays; this has been obſerved and acknowledged in all ages. The heat which they produce is leſs according as they fall more obliquely; hence the temperature conſtantly diminiſhes from the equator to the pole, becauſe their obliquity conſtantly increaſes with the latitude. But if the heat depended on the ſolar rays alone, it would diſappear in the

Weather.

the polar regions during winter when the ſun ceaſes to riſe. This, however, is by no means the caſe; the mean temperature, even at the pole, is 31°; and we find within the arctic circle as hot weather as under the equator. The reaſon of this is, that the ſun's rays heat the earth conſiderably during ſummer: this heat it retains and gives out ſlowly during winter, and thus moderates the violence of the cold; and ſummer returns before the earth has time to be cooled down beyond a certain degree. This is the reaſon that the coldeſt weather does not take place at the winter ſolſtice, but ſome time after when the temperature of the earth is loweſt; and that the greateſt heat takes place alſo ſome conſiderable time after the ſummer ſolſtice, becauſe then the temperature of the earth is higheſt. For pure air is not heated by the ſolar rays which paſs through it, but acquires ſlowly the temperature of the earth with which it is in contact. This is the reaſon why the temperature decreaſes according to the elevation above the level of the ſea (A).

8 And of the difference between the temperature on land and ſea.

Since the atmoſphere is heated by contact with the ſuperficies of the earth, its temperature muſt depend upon the capacity of that ſuperficies for receiving and tranſmitting heat. Now this capacity differs very much in land and water. Land, eſpecially when dry, receives heat with great readineſs, but tranſmits it through its own ſubſtance very ſlowly. Dr Hailes found, that in 1724, when the air and ſurface of the earth were both at 88°, a thermometer placed only two inches below the ſurface ſtood at 85; another 16 inches below the ſurface, at 70°; and another 24 inches deep, at 68°. The two laſt mentioned thermometers retained the ſame temperature till the end of the month, though the temperature of the air frequently varied, and then fell only to 63° or 61°. The earth, at about 80 or 90 feet below its ſurface, conſtantly retains the ſame temperature: and this is nearly equal to the mean annual heat of the country. Hence the mean annual temperature of any country may be found out pretty accurately, by examining the heat of deep wells or ſprings. Water, on the contrary, receives heat ſlowly, on account of its tranſparency; but what it does receive, is very quickly transfuſed through the whole maſs.

Land is often heated and cooled to a much greater degree than ſea is. Dr Raymond often found the earth in the neighbourhood of Marſeilles heated to 170°, but he never found the ſea above 77°; in winter the earth was often cooled down to 14°, but the ſea never lower than 45°. The ſea atmoſphere, therefore, ought to preſerve a much more uniform temperature than the land atmoſphere; and we find this in fact to be the caſe. The cauſe of the greater equability of water than land is evident. In ſummer the ſurface of the ſea is conſtantly cooled down by evaporation; and in winter, whenever the ſurface is cooled, it deſcends to the bottom from its increaſed gravity, and its place is ſupplied by warmer water. This proceſs goes on continually, and the winter is over before the atmoſphere has been able to cool down the water beyond a certain degree. It muſt be remembered alſo, that water has a greater capacity for heat than land has, and therefore is longer either in heating or cooling.

Theſe obſervations will enable us to explain the difference which takes place between the annual temperature of the atmoſphere above the ocean and that of places at ſome conſiderable diſtance from it. As the ſea is never heated ſo highly as the land, the mean ſummer temperature at ſea may be conſidered, all over the world, as lower than on land. During winter, when the power of the ſun's rays in a great meaſure ceaſes, the ſea gives out heat to the air much more readily than the earth; the mean winter temperature, therefore, at ſea is higher than on land; and in cold countries the difference is ſo great, that it more than counterbalances the difference which takes place in ſummer; ſo that in high latitudes the mean annual temperature ought to be greater at ſea than on land. Accordingly from lat. 70° to 35°, to find the temperature of a place, the ſtandard temperature for the ſame latitude ought, according to Dr Kirwan, to be depreſſed $\frac{1}{3}$d of a degree for every 50 miles diſtance; for the cold which takes place in winter always increaſes in proportion to the diſtance from the ſtandard. At a leſs diſtance than 50 miles the temperatures of land and ſea are ſo blended together by ſea and land winds, that there is little difference in the annual mean. In lower latitudes than 30°, the rays of the ſun, even in winter, retain conſiderable power: the ſurface of the earth is never cooled very low, conſequently the difference between the annual temperatures of the ſea and land becomes leſs. As we approach nearer to the equator, the power of the ſolar rays during winter increaſes ſo that the mean winter temperature of the land atmoſphere approaches nearer and nearer to that of the ſea, till at laſt at the equator it equals it. After we paſs lat. 30°, therefore, the mean annual land temperature gradually exceeds that of the ſea more and more till at the equator it exceeds it a degree for every 50 miles diſtance.

Weather.

Such then, in general, is the method of finding the mean annual temperature over the globe. There are, however, ſeveral exceptions to theſe general rules, which come now to be mentioned.

9 Temperature of the northern Pacific Ocean.

That part of the Pacific ocean which lies between north lat. 52° and 66° is no broader at its northern extremity than 42 miles, and at its ſouthern extremity than 1300 miles; it is reaſonable to ſuppoſe, therefore, that its temperature will be conſiderably influenced by the ſurrounding land, which conſiſts of ranges of mountains covered, a great part of the year, with ſnow: and there are beſides a great many high, and conſequently cold, iſlands ſcattered through it. For theſe reaſons Mr Kirwan concludes, that its temperature is at leaſt 4 or 5 degrees below the ſtandard. But we are not yet furniſhed with a ſufficient number of obſervations to determine this with accuracy.

10 Of the ſouthern hemiſphere.

It is the general opinion, that the ſouthern hemiſphere, beyond the 40th degree of latitude, is conſiderably colder than the correſponding parts of the northern hemiſphere. The cauſe of this we ſhall endeavour to aſſign in the article WIND.

11 Of ſmall ſeas.

Small ſeas ſurrounded with land, at leaſt in temperate and cold climates, are generally warmer in ſummer and colder in winter than the ſtandard ocean, becauſe they are a good deal influenced by the temperature of the land. The Gulph of Bothnia, for inſtance, is for the moſt part frozen in winter; but in ſummer it is ſometimes heated to 70°, a degree of heat never to be found in the oppoſite part of the Atlantic*. The German ſea is above three degrees colder in winter, and five degrees warmer in ſummer, than the Atlantic ‡. The Mediterranean Sea is, for the greater part of its extent, warmer both in ſummer and winter than the

* Mem. Stock. 1776.

‡ Kirwan's Temperature of Lat. p. 53.

(A) It was ſome time ago the favourite opinion of philoſophers, that the heat of the earth was derived from a maſs of fire in its centre. But there does not ſeem any probability in the opinion, as the heat of the earth does not increaſe the deeper we go, but remains conſtant nearly at the mean heat of the place. In the mine of Joachimſtahd in Bohemia, one of the deepeſt exiſting, Mr Monnet found the temperature at the depth of 1700 feet to be 50°. The temperature of the earth has even been found to diminiſh the deeper we go, though never lower than 36°.

Weather.

the Atlantic, which therefore flows into it. The Black Sea is colder than the Mediterranean, and flows into it ‡.

‡ Ibid.

12 Temperature of North America.

The eaſtern parts of North America are much colder than the oppoſite coaſt of Europe, and fall ſhort of the *ſtandard* by about 10° or 12°, as appears from American Meteorological Tables. The cauſes of this remarkable difference are many. The higheſt part of North America lies between the 40th and 50th degree of north latitude, and the 100th and 110th degree of longitude weſt from London; for there the greateſt rivers originate. The very height, therefore, makes this ſpot colder than it otherwiſe would be. It is covered with immenſe foreſts, and abounds with large ſwamps and moraſſes, which render it incapable of receiving any great degree of heat; ſo that the rigour of winter is much leſs tempered by the heat of the earth than in the old continent. To the eaſt lie a number of very large lakes; and farther north Hudſon's Bay; about 50 miles on the ſouth of which there is a range of mountains which prevent its receiving any heat from that quarter. This bay is bounded on the eaſt by the mountainous country of Labrador and by a number of iſlands. Hence the coldneſs of the north-weſt winds and the lowneſs of the temperature. But as the cultivated parts of North America are now much warmer than formerly, there is reaſon to expect that the climate will become ſtill milder when the country is better cleared of woods, though perhaps it will never equal the temperature of the old continent.

13 Of iſlands and ſtony countries.

Iſlands are warmer than continents in the ſame degree of latitude; and countries lying to the windward of extenſive mountains or foreſts are warmer than thoſe lying to the leeward. Stones or ſand have a leſs capacity for heat than earth has, which is always ſomewhat moiſt; they heat or cool, therefore, more rapidly and to a greater degree. Hence the violent heat of Arabia and Africa, and the intenſe cold of Terra del Fuego. Living vegetables alter their temperature very ſlowly, but their evaporation is great; and if they be tall and cloſe, as in foreſts, they exclude the ſun's rays from the earth, and ſhelter the winter ſnow from the wind and the ſun. Woody countries, therefore, are much colder than thoſe which are cultivated.

Thus we have endeavoured to aſcertain the mean temperature of every climate, and to aſſign the cauſes by which that temperature is governed. Mr Kirwan, in his admirable Treatiſe on the Temperature of Different Latitudes, has done much to reduce this part of meteorology to regularity, and to ſubject it to calculation; and he has in ſome meaſure ſucceeded. To enable our readers to judge how far his rules agree with facts, we ſhall ſubjoin a table of the mean temperature of a variety of places drawn up from actual obſervations.

14 Cauſes of the daily variations of temperature.

As to the daily variations of the temperature of the atmoſphere, they are owing to a variety of cauſes; many of which are probably unknown. Some of them, however, are the following: 1. Wind. It is evident that winds flowing from cold countries muſt produce cold, and from hot countries heat and that whatever has a tendency to produce ſuch winds muſt be the cauſe of unuſual cold or heat.—2. Evaporation. Water always abſorbs a quantity of heat when it aſſumes the ſtate of vapour. Hence the coldneſs of marſhy countries, and the cold which we often experience during and after violent rains. Hence alſo we may expect a cold winter after a rainy ſummer, becauſe the unuſual evaporation carries off the heat of the earth.—3. Vapour, when condenſed, gives out a quantity of heat; a country, therefore, may be heated by the condenſation over it of vapour brought from a diſtance. Hence the ſultrineſs often felt before rain.—4. Vapours, when they remain long over any country, may produce cold by obſtructing the paſſage of the ſun's rays to the earth. To this cauſe Dr Franklin aſcribed the very ſevere winter which followed 1783; a year remarkable for the thick fog which overſpread Europe and

Weather. America during several months.—5. When, from any of these causes, the winter has been severer than usual, prodigious quantities of ice may accumulate about the pole, which may contribute something perhaps towards lowering the temperature of several succeeding years.

15 Of WINDS

II. The winds evidently have a very great influence on the weather; the causes which produce them, therefore, ought to be examined with the greatest attention. Were we able to regulate their motions, we might, in a great measure, mould the climate of any country according to our pleasure; were able to foresee them, it would be of the greatest importance to navigation and agriculture. In the torrid zone, where they are regular, the mean annual temperature remains almost always the same; their irregularity increases as we approach the pole, and in the same manner the difference between the mean annual temperature increases with the latitude.

Wind is produced chiefly by the action of the sun on the atmosphere; there are many other causes, however, and some perhaps of which we are yet ignorant. But we shall reserve this part of our subject, on account of its importance and extent, for a separate article.

16 Of RAIN.

III. We come now to the most difficult part of our subject, the phenomena and causes of rain. It has been long known, that water is constantly rising from the whole surface of the globe, in the form of vapour, and mixing with the atmosphere. Evaporation has been ascribed to various causes; but the greater number of philosophers have for some time past acquiesced in the theory first advanced by Dr Halley, that it was produced by a real solution of water in air, just as sugar or salt is dissolved in water. This theory is supported by a great many very plausible arguments, which at the first view seem to establish its truth.—These arguments, however, are not all of them so conclusive as they appear. Thus it was thought, that because evaporation was promoted by heat, and retarded by cold, it bore an exact resemblance to the solution of salts in liquids: but it is now known that evaporation is not so much retarded by cold as was at first supposed; that in some circumstances it is even promoted by it; and that it does not depend so much upon the absolute degree of heat or cold, as upon the difference of temperature between the atmosphere and the evaporating surface. Besides, water evaporates much more rapidly in a vacuum than in the open air, which could not possibly be the case if evaporation were owing to the solution of water in air.

17 Causes of evaporation.

Evaporation, then, cannot be owing to solution of water in air; it is produced by the combination of a certain quantity of caloric with the particles of water, by which it is converted into an elastic fluid lighter than air, which therefore immediately ascends and mixes with the atmosphere. This was long ago shown by Dr Black to be the way in which steam or the vapour arising from boiling water is produced. The same principles were afterwards applied by Mr De Luc to spontaneous evaporation; and the proofs upon which this theory rests are quite convincing. But though evaporation is not produced by air, vapour would very soon condense and return to its former state by contact with colder bodies, unless it were attracted and supported by air.

18 Qualities of vapour.

We are indebted to the experiments of Saussure and De Luc for much of our knowledge of the qualities of vapour. It is an elastic invisible fluid like common air, but lighter; being to common air, according to Saussure, as 10 to 14, or, according to Kirwan, as 10 to 12: it cannot pass beyond a certain maximum of density, otherwise the particles of water which compose it unite together, and form small, hollow, visible vesicles, called *vesicular vapour*; which is of the same specific gravity with atmospherical air. It is of this vapour that clouds and fogs are composed. This maximum increases with the temperature; and at the heat of boiling water is so great, that steam can resist the whole pressure of the air, and exist in the atmosphere in any quantity. See METEOROLOGY, n° 7—23. Weather.

19 Quantity of vapour raised annually.

Evaporation, at least in our climate, is about four times greater during the summer than the winter half-year, other things being equal, it is so much the more abundant the greater the difference is between the temperature of the air and of the evaporating surface; so much the less, the nearer they approach to the same temperature; and least of all when they actually arrive at it. Whenever the atmosphere is more than 15 degrees colder than the evaporating surface, little evaporation takes place at all. Evaporation is powerfully promoted by winds, especially cold winds blowing into warm countries, or warm winds blowing into cold countries*. Tracts of land covered with trees or vegetables emit more vapour than the same space covered with water. From the experiments of Mr Williams, the quantity appears to be one-third more ‡. But the method in which these experiments were made (the same objection lies against several of Dr Hailes's experiments, the original discoverer of the fact) prevented him from ascertaining exactly the quantity of vapour emitted by plants. He made the plants grow in a box well closed up from the air, measured the quantity of water with which he supplied them, and at the end of the experiment weighed the box and the plants themselves. By this means he knew pretty accurately the quantity of water which the plants had absorbed, and which had afterwards disappeared; and all this he concluded had been emitted by the plants in the state of vapour. But it is well known that plants have the power of decompounding water, of retaining the hydrogen, and throwing off the oxygen. A part of the water then was decompounded and changed into air; and the quantity of this ought to have been ascertained and subtracted. Still, however, the quantity of vapour emitted by vegetables is very great. Evaporation is promoted by heat, and is therefore much greater in the torrid zone than in our latitudes. There, too, the difference between the quantities in summer and winter is much less than in our climate, because the difference between the temperature of the two seasons is less. Animals also are continually throwing off vapour by insensible perspiration; the quantity of which is exceedingly different, according to the climate, season, and temperament, and cannot therefore be calculated exactly. According to Keil, a single man perspires 31 ounces of vapour in 24 hours, and consequently 707 pounds of water in a year. The quantity of vapour then which is emitted by animals alone must be very great.

*Temperat of Latitudes, p. 12.
‡ Transf. Philad. vol. ii. p. 121.

From an experiment made by Dr Watson in England, during summer, when the earth had been burnt up by a month's drought without rain, it appears that 1600 gallons of water were evaporated from a single acre in 12 hours.—If we were to suppose that this represented the mean daily evaporation all over the globe, it would be easy to calculate the quantity of water annually evaporated from the whole of its surface. And if we consider the state of the earth when the experiment was made, the situation of England nearer the pole than the equator, and the evaporation constantly going on from animals and vegetables, which is not taken in, we will surely not think the mean assumed too great. 1600 gallons in 12 hours is 3200 in 24 hours. Let us call it only 3000, which is equal to 693,000 cubic inches. An acre contains 272,640 square inches; so that the daily evaporation from every square inch will be about .11 of a cubic inch. This in a year will amount to somewhat more than 40 cubic inches for every square inch. From the expe-

Weather.

experiments of Mr Williams *, it appears, that in Bradford in New England, the evaporation during 1772 amounted to 42,65 inches; but from the way that his experiments were conducted, the amount was probably too great. Theſe experiments, however, ſerve to ſhow, that our calculation is not perhaps very remote from the truth. 40 inches from every ſquare inch on the ſuperficies of the globe makes 107,942 cubic miles, equal to the water annually evaporated over the whole globe.

* Tranſ. Philad. vol. ii. p. 135.

20 Quantity contained in the atmoſphere at once.

Were this prodigious maſs of water all to ſubſiſt in the atmoſphere at once, it would increaſe its maſs by about a twelfth, and raiſe the barometer nearly three inches. But this never happens, no day paſſes without rain in ſome part of the earth; ſo that part of the evaporated water is conſtantly precipitated again. Indeed it would be impoſſible for the whole of the evaporated water to ſubſiſt in the atmoſphere at once, at leaſt in the ſtate of vapour.

M. De Sauſſure has ſhown, that when the thermometer is at 66°, a cubic foot of air cannot contain more vapour than what is equivalent to 8 grains of water. If more than this be added, it will paſs its maximum, be converted into veſicular vapour, and at laſt fall down in drops of rain. At the temperature of 32° a cubic foot of air can contain only 4 grains, and the quantity it can contain is increaſed .1109 of a grain by every additional degree of heat. Suppoſing then that the whole atmoſphere was ſaturated with water, it would not amount to the hundredth part of the quantity of water evaporated annually.

21 Never amounts to its maximum.

The quantity of vapour exiſting in the atmoſphere is indicated by the hygrometer. Water has the property of arriving at a ſtate of equilibrium in hygroſcopic ſubſtances: that is, ſuppoſing a certain quantity of water attached to a hygroſcopic ſubſtance, if another hygroſcopic ſubſtance be brought into contact with it containing leſs water, ſome of the water attached to the firſt ſubſtance will leave it, and attach itſelf to the other, till both contain the ſame proportion of water. Air is a hygroſcopic ſubſtance, and ſo is every thing of which hygrometers are made. Now the hygrometer never points at extreme moiſture while the air continues tranſparent, and conſequently contains nothing but inviſible vapour; the atmoſphere therefore, while tranſparent, never contains the greateſt poſſible quantity of vapour.

The higher regions of the atmoſphere contain leſs vapour than the ſtrata near the ſurface of the earth. This was obſerved both by M. De Sauſſure and M. De Luc, who mentions ſeveral ſtriking proofs of it. See METEOROLOGY, n° 10, &c.

At ſome height above the tops of mountains the atmoſphere is probably ſtill drier; for it was obſerved both by Sauſſure and De Luc, that on the tops of mountains the moiſture of the air was rather leſs during the night than the day. And there can be little doubt that every ſtratum of air deſcends a little lower during the night than it was during the day, owing to the cooling and condenſing of the ſtratum neareſt the earth. Vapours, however, muſt aſcend very high, for we ſee clouds forming far above the tops of the higheſt mountains.

22 Formation of clouds

Rain never begins to fall while the air is tranſparent: the inviſible vapours firſt paſs their maximum, and are changed into veſicular vapours; clouds are formed, and theſe clouds gradually diſſolve in rain. Clouds, however, are not formed in all parts of the horizon at once; the formation begins in one particular ſpot, while the reſt of the air remains clear as before: this cloud rapidly increaſes till it overſpreads the whole horizon, and then the rain begins.

It is remarkable, that though the greateſt quantity of vapours exiſt in the lower ſtrata of the atmoſphere, clouds never begin to form there, but always at ſome conſiderable height. It is remarkable, too, that the part of the atmoſphere at which they form has not arrived at the point of extreme moiſture, nor near that point even a moment before their formation. They are not formed then, becauſe a greater quantity of vapour had got into the atmoſphere than could remain there without paſſing its maximum. It is ſtill more remarkable, that when clouds are formed, the temperature of the ſpot in which they are formed is not always lowered, though this may ſometimes be the caſe. On the contrary, the heat of the clouds themſelves is ſometimes greater than that of the ſurrounding air §. Neither then is the formation of clouds owing to the capacity of air for combining with moiſture being leſſened by cold: ſo far from that, we often ſee clouds, which had remained in the atmoſphere during the heat of the day, diſappear in the night, after the heat of the air was diminiſhed.

§ De Luc ſur la Meteorol. vol. ii. p. 100.

23 And rain cannot be accounted for.

The formation of clouds and rain, then, cannot be accounted for by a ſingle principle with which we are acquainted. It is neither owing to the ſaturation of the atmoſphere, nor the diminution of heat, nor the mixture of airs of different temperatures, as Dr Hutton ſuppoſes; for clouds are often formed without any wind at all either above or below them; and even if this mixture conſtantly took place, the precipitation, inſtead of accounting for rain, would be almoſt imperceptible.

It is a very remarkable fact, that evaporation often goes on for a month together in hot weather without any rain. This ſometimes happens in this country; it happens every year in the torrid zone. Thus at Calcutta, during January 1785, it never rained at all *: the mean of the thermometer for the whole month was 66½ degrees; there was no high wind, and indeed during great part of the month little wind at all.

* Aſiat. Reſearches, vol. ii. Appendix.

24 Vapour diſappears,

The quantity of water evaporated during ſuch a drought muſt be very great; yet the moiſture of the air, inſtead of being increaſed, is conſtantly diminiſhing, and at laſt diſappears almoſt entirely. For the dew, which is at firſt copious, diminiſhes every night; and if Dr Watſon's experiment formerly mentioned be attended to, it will not be objected that the quantity of evaporation is alſo very much diminiſhed. Of the very dry ſtate to which the atmoſphere is reduced during long droughts, the violent thunder-ſtorms with which they often conclude is a proof, and a very deciſive one. Now what becomes of all this moiſture? It is not accumulated in the atmoſphere above the country from which it was evaporated, otherwiſe the whole atmoſphere would in a much leſs period than a month be perfectly ſaturated with moiſture. If it be carried up daily through the different ſtrata of the atmoſphere, and wafted to other regions by ſuperior currents of air, how is it poſſible to account for the different electrical ſtate of the clouds ſituated between different ſtrata, which often produces the moſt violent thunder-ſtorms? Are not vapours conductors of the electric fluid; and would they not have daily reſtored the equilibrium of the whole atmoſphere through which they paſſed? Had they traverſed the atmoſphere in this manner, there would have been no negative and poſitive clouds, and conſequently no thunder-ſtorms. They could not have remained in the lower ſtrata of the atmoſphere, and been daily carried off by winds to other countries; for there are often no winds at all during ſeveral days to perform this office: nor in that caſe would the dews diminiſh, nor could their preſence fail to be indicated by the hygrometer.

25 And aſſumes a new form in the atmoſphere.

It is impoſſible for us to account for this remarkable fact upon any principle with which we are acquainted. The water can neither remain in the atmoſphere, nor paſs thro' it

Weather.

it in the ſtate of vapour. It muſt therefore aſſume ſome other form; but what that form is, or how it aſſumes it, we know not.

26 Its converſion into oxygen and hydrogen improbable.

It will immediately occur to every body, that vapour is decompoſed in the atmoſphere, and changed into oxygen and hydrogen gas. But is it true that a greater quantity of oxygen exiſts in the atmoſphere after a long drought than immediately after rain? Have ſuch prodigious quantities of hydrogen been found in the atmoſphere as muſt always exiſt in it if this hypotheſis were true? Has any hydrogen ever been found in analyzing atmoſpheric air? Or if hydrogen, from its lightneſs, aſcends to the higher regions of the atmoſphere, what cauſes it to deſcend at particular times, contrary to that lightneſs, in order to come into contact with oxygen? Do not clouds often form on mountains round the habitations of men? Yet has the preſence of hydrogen been ever aſcertained by any phenomena? Would it not produce dangerous conflagrations when it came into contact with fire? But has this been the caſe in a ſingle inſtance? If this hypotheſis were true, could rain take place at all without a conflagration in the atmoſphere? Yet has any ſuch conflagration been ever obſerved? The hypotheſis, then, that vapour is changed into oxygen and hydrogen in the atmoſphere, and that rain is produced by the reunion of theſe elements, cannot be admitted, though it is not improbable that ſome ſmall part of it actually undergoes this change. See WIND.

We do not take notice of M. De Luc's conjecture about the compoſition of the atmoſphere, becauſe it is not ſupported by a ſingle proof, and becauſe he refuſes to believe the analyſis of the atmoſphere reſulting from the very deciſive experiments of Scheele, Lavoiſier, and Prieſtley, though he has ſeen them often performed, and has nothing to urge againſt their force. There is no philoſopher to whom meteorology lies under greater obligations than to M. De Luc. His diſcoveries have been many and important, his experiments ingenious, and his application unwearied; but his conjectures are like thoſe of every other man who attempts to fathom the wiſdom of the Almighty. Were we poſſeſſed of an underſtanding equal to that of the Author of Nature, we might expect, with reaſon, to dive by our conjectures into the myſteries of his operations; but in our preſent ſtate they are vain.

Evaporation goes on longeſt without producing rain in the torrid zone, where the heat is greateſt; it goes on longeſt alſo in every place in ſummer, when the heat is alſo greateſt: heat therefore ſeems to be an agent.

27 Theory of rain imperfect.

There are then two ſteps of the proceſs between evaporation and rain, of which at preſent we are completely ignorant: 1. What becomes of the vapour after it enters into the atmoſphere? 2. What makes it lay aſide the new form which it muſt have aſſumed, and return again to its ſtate of vapour, and fall down in rain? And till theſe two ſteps be diſcovered by experiments and obſervations, it will be impoſſible for us to give a rational or a uſeful theory of rain.

28 Whether owing to electricity.

It has for ſome time paſt been the opinion of philoſophers, that electricity is the principal agent in producing rain; and M. Bertholon aſſures us, that by raiſing proper conductors to draw off the electrical matter from the atmoſphere, the quantity of rain may be diminiſhed at pleaſure. That the electric fluid acts a very important part in nature, cannot be doubted, and it is not improbable that it may be the agent in producing rain. This ſuppoſition indeed is ſupported by many facts. Dew at leaſt exhibits a great many electrical phenomena; it is attracted by points, and attaches itſelf to ſome ſubſtances, while it avoids others. Whenever there are no clouds, the electricity of the atmoſphere is always poſitive; but the formation of clouds produces conſiderable changes in the ſtate of its electricity. The atmoſphere alſo gives ſigns of electricity conſtantly during rain; and clouds are evidently attracted by mountains. In what manner, however, the electrical fluid produces rain (if it is the agent at all) is ſtill unknown. Some philoſophers aſſure us, that clouds are induced to diſſolve in rain by becoming negative, others by becoming ſtrongly poſitive, and both ſupport their opinion by experiments. We do not ſee the analogy, however, between clouds and plates of metal covered with drops of water. And even if their opinion were well founded, the production of the clouds themſelves would remain to be accounted for.

Weather.

29 Quantity of rain different according to the latitude,

The mean annual quantity of rain is greateſt at the equator, and decreaſes gradually as we approach the poles.

Thus at * Granada, Antilles,	12° N. lat.		it is 126 inches.
* Cape François, St Domingo	19°	46′	120
‡ Calcutta -	22	23	81
* Rome -	41	54	39
‖ England -	33		32
¶ Peterſburgh	59	16	16

On the contrary, the number of rainy days is ſmalleſt at the equator, and increaſes in proportion to the diſtance from it. From north latitude 12° to 43° the mean number of rainy days is 78; from 43° to 46° the mean number is 103; from 46° to 50° it is 134; from 51° to 60°, 161 †.

The number of rainy days is often greater in winter than in ſummer; but the quantity of rain is greater in ſummer than in winter ‡. At Peterſburgh, the number of rainy or ſnowy days during winter is 84, and the quantity which falls is only about five inches; during ſummer the number of rainy days is nearly the ſame, but the quantity which falls is about 11 inches ‖.

30 Seaſon,

More rain falls in mountainous countries than in plains. Among the Andes it is ſaid to rain almoſt perpetually, while in Egypt it hardly ever rains at all. If a rain-gauge be placed on the ground, and another at ſome height perpendicularly above it, more rain will be collected into the lower than into the higher; a proof that the quantity of rain increaſes as it deſcends, owing perhaps to the drops attracting vapour during their paſſage through the lower ſtrata of the atmoſphere where the greateſt quantity reſides. This, however, is not always the caſe, as Mr Copland of Dumfries diſcovered in the courſe of his experiments *. He obſerved alſo, that when the quantity of rain collected in the lower gauge was greateſt, the rain commonly continued for ſome time; and that the greateſt quantity was collected in the higher gauge only either at the end of great rains, or during rains which did not laſt long. Theſe obſervations are important, and may, if followed out, give us new knowledge of the cauſes of rain. They ſeem to ſhow, that during rain the atmoſphere is ſomehow or other brought into a ſtate which induces it to part with its moiſture; and that the rain continues as long as this ſtate continues. Were a ſufficient number of obſervations made on this ſubject in different places, and were the atmoſphere carefully analyſed during dry weather, during rain, and immediately after rain, we might ſoon perhaps diſcover the true theory of rain.

31 And ſituation.

Rain falls in all ſeaſons of the year, at all times of the day, and during the night as well as the day; though, according to M. Toaldo, a greater quantity falls during the day than the night. The cauſe of rain, then, whatever it may be, muſt be ſomething which operates at all times and ſeaſons. Rain falls alſo during the continuance of every wind, but oftneſt when the wind blows from the ſouth. Falls of rain often happen likewiſe during perfect calms.

It

Weather.

32 Mean annual quantity of rain.

It appears from a paper publiſhed by M. Cotte in the *Journal de Phyſique* for October 1791, containing the mean quantity of rain falling at 147 places, ſituated between north latitude 11° and 60°, deduced from tables kept at theſe places, that the mean annual quantity of rain falling in all theſe places is 34.7 inches. Let us ſuppoſe then (which cannot be very far from the truth) that the mean annual quantity of rain for the whole globe is 34 inches. The ſuperficies of the globe conſiſts of 170,981,012 ſquare miles, or 686,401,498,471,475,200 ſquare inches. The quantity of rain therefore falling annually will amount to 23, 337,650,812,030,156,800 cubic inches, or ſomewhat more than 21,751 cubic miles of water. This is 16,191 cubic miles of water leſs than the quantity of water evaporated. It ſeems probable therefore, if the imperfection of our data warrant any concluſion, that ſome of the vapour is actually decompoſed in the atmoſphere, and converted into oxygen and hydrogen gas.

The dry land amounts to 52,745,253 ſquare miles (ſee the article SEA, n° 1.); the quantity of rain falling on it annually therefore will amount to 30,960 cubic miles. The quantity of water running annually into the ſea (ſee SEA, n° 3.) is 13,140 cubic miles; a quantity of water equal to which muſt be ſupplied by evaporation from the ſea, otherwiſe the land would ſoon be completely drained of its moiſture.

The quantity of rain falling annually in Great Britain may be ſeen from the following table:

In this country it generally rains leſs in March than in November, in the proportion at a medium of 7 to 12. It generally rains leſs in April than in October in the proportion of 1 to 2 nearly at a medium. It generally rains leſs in May than September, the chances that it does ſo are at leaſt as 4 to 3; but when it rains plentifully in May (as 1.8 inches or more), it generally rains but little in September; and when it rains one inch or leſs in May, it rains plentifully in September.*

* Kirwan, Iriſh Tranſ. vol. v. p. 21.

33 Of Thunder.

IV. Thunder has been explained at ſuch great length in the article ELECTRICITY, that we ſhall content ourſelves at preſent with a few remarks.

Thunder is exceedingly frequent in the torrid zone, and it ſeems to decreaſe gradually till we approach latitude 60°, or perhaps farther north. During the year 1785, for inſtance, there were 90 thunder-ſtorms at Calcutta. According to Profeſſor Muſchenbroek, it thunders at Utrecht at a medium 15 times annually: in this country the medium is conſiderably below that number. Thunder, too, ſeems to be very common in ſome polar regions. The Abbé Chappe informs us, that he obſerved thunder much more frequently at Tobolſki and in other parts of Siberia than in any other country. Muſchenbroek, however, affirms, we know not upon what authority, that it never thunders at all in Greenland and at Hudſon's Bay. Thunder-ſtorms happen almoſt always during the ſummer, and very ſeldom in winter. During the year 1785, above mentioned, it never thundered at Calcutta in January, November, nor December. In this country a thunder-ſtorm during winter is exceedingly rare.

Weather.

The phenomena of thunder are now no longer a ſecret, ſince the great Franklin diſcovered the identity of lightning and electricity; a diſcovery inferior to none in the annals of philoſophy. But though we can explain the nature of thunder in general, and the manner in which it is produced, there are ſeveral difficulties ſtill remaining, which future experiments and obſervations only can remove. Air is an electric *per ſe*, and cannot therefore when dry conduct electrical matter from one part to another. We know from the experiments of Dr Franklin and others, that the atmoſphere conſtantly contains in it a quantity of electric matter. If a ſtratum of dry air were electrified poſitively, it would occaſion a negative electricity in the neighbouring ſtratum. Suppoſe now, that an imperfect conductor were to come into contact with each of theſe ſtrata, we know from the principles of electricity that the equilibrium would be reſtored, and that this would be attended with a loud noiſe, and with a flaſh of light. Clouds which conſiſt of veſicular vapours mixed with particles of air, are imperfect conductors; if a cloud therefore come into contact with two ſuch ſtrata, a thunder clap would follow. If a poſitive ſtratum be ſituated near the earth, the intervention of a cloud will, by ſerving as a ſtepping-ſtone, bring the ſtratum within the ſtriking diſtance, and a thunder clap will be heard while the electrical fluid is diſcharging itſelf into the earth. If the ſtratum be negative, the contrary effects will take place. It does not appear, however, that thunder is often occaſioned by a diſcharge of electric matter from the earth into the atmoſphere. The accidents, moſt of them at leaſt, which were formerly aſcribed to this cauſe, are now much more ſatisfactorily accounted for by Lord Stanhope's Theory of the Returning Stroke. Neither does it appear that electricity is often diſcharged into the earth, as the effects of few thunder-ſtorms are viſible upon the earth; that it is ſo ſometimes, however, is certain. The experiments of Mr Sauſſure have demonſtrated, that electrical matter is carried into the atmoſphere by ſimple evaporation; ſo that there is no difficulty in underſtanding how particular ſtrata of air may be ſupplied with a ſufficient quantity of electrical fluid to be charged poſitively; and we know that in that caſe a negative ſtate muſt be produced in the neighbouring ſtratum. In what particular manner, however, this electrical matter is accumulated in particular ſtrata of air, and how it comes to be ſeparated from the vapour to which it was united, remain ſtill ſecrets. They are intimately connected with the cauſes of evaporation and rain, whatever they may be, and probably the diſcovery of the cauſes of either would lead to that of the others.

34 Of the changes in the Gravity of the Atmoſphere.

V. The gravity of the atmoſphere was firſt demonſtrated by Torricelli, the diſciple of Galileo (ſee PNEUMATICS, n° 25). A column of air, the baſis of which is a ſquare inch, weighs at a medium 15 pounds. The weight of the atmoſphere is meaſured by the barometer. It is greateſt at

Weather.

at the level of the ſea, becauſe there the column of air is longeſt: there the mean height of the barometer is 30 inches. This Sir George Shuckburg found to be the caſe in the Mediterranean and the Channel, in the temperature of 55° and 60°; Mr Bouguer, on the coaſt of Peru, in the temperature of 84°; and Lord Mulgrave, in latitude 80°. The mean height of the barometer is leſs the higher any place is ſituated above the level of the ſea, becauſe the column of air which ſupports the mercury is the ſhorter.

35 Indicated by the barometer.

The barometer has accordingly been uſed for meaſuring heights. It indicates, too, with a great deal of accuracy, all the variations in the gravity of the atmoſphere; falling when the atmoſphere is lighter, and riſing when it is heavier, than uſual. Theſe changes have attracted the attention of philoſophers ever ſince the diſcovery of the barometer; and many attempts have been made to explain them, ſome of which have been mentioned under the word BAROMETER. Theſe variations come naturally to be examined here, becauſe the cauſes which produce them, whatever they are, muſt have a great deal of influence on the weather.

Between the tropics the variations of the barometer are exceedingly ſmall; and it is remarkable, that in that part of the world it does not deſcend above half as much for every 200 feet of elevation as it does beyond the tropics*.—In the torrid zone, too, the barometer is elevated about two-thirds of a line twice every day; and this elevation happens at the ſame time with the tides of the ſea§.

* M. Caſan Journal de Phyſique, April 1790, p. 268.

§ Ibid.

As the latitude advances towards the poles, the range of the barometer gradually increaſes, till at laſt it amounts to two or three inches. This gradual increaſe will appear from the following table:

36 Range of the barometer.

TABLE of the Range of the Barometer.

Latitude.	Places.	Range of the Barometer, Greateſt.	Annual.

* Kirwan, Iriſh Tranſ. vol. iii. p. 47.

† Aſiatic Reſearches, vol. ii. Appendix.

§ Mancheſt. Tranſ. vol. iv.

‡ Edin. Tranſ. vol. ii. p.

In North America, however, the range of the barometer is a great deal leſs than the correſponding European latitudes. In Virginia, for inſtance, it never exceeds 1.1 ¶.

¶ Tranſ. Philadel. vol. ii. p. 142.

The range of the barometer is greater at the level of the ſea than on mountains, and in the ſame degree of latitude the extent of the range is in the inverſe ratio of the height of the place above the level of the ſea.

From a table publiſhed by Mr Cotte in the *Journal de Phyſique* †, it ſeems exceedingly probable that the barometer has always a tendency to riſe from the morning to the evening; and that this tendency is greateſt between two o'clock in the afternoon, and nine at night, at which hour the greateſt elevation takes place; that the elevation of nine o'clock differs from that of two by $\frac{4}{7}\frac{1}{2}$ths, while that at two differs from the morning elevation only by $\frac{1}{7}\frac{1}{2}$th; and that in certain climates the greateſt elevation takes place at two o'clock. We ſhall inſert a part of the table on which theſe obſervations are founded, which we have reduced to the Engliſh ſtandard.

† Aug. 1790, p. 110.

Weather.

The range of the barometer is greater in winter than in ſummer. Thus at Kendal the mean range of the barometer for five years, during October, November, December, January, February, March, was 7.982; and for the ſix ſummer months 5.447*.

* Mancheſt. Tranſ. vol. iv. p. 547.

In ſerene and ſettled weather it is generally high; and low in calm weather, when the air is inclined to rain; it ſinks on high winds, riſes higheſt on eaſterly and northerly winds, and ſinks when the wind blows from the ſouth †.—At Calcutta§, however, it is always higheſt when the wind blows from the north-weſt and north, and loweſt when it blows from the ſouth-eaſt.

† Dr Halley.

§ Aſiatic Reſearches, vol. ii. Appendix.

The barometer falls ſuddenly before tempeſts, and undergoes great oſcillations during their continuance.—Mr Copeland‖ of Dumfries has remarked, that a high barometer is attended with a temperature above, and a low barometer with one below, the monthly mean. Such are the variations of the barometer as far as they have yet been obſerved. Let us now endeavour to account for them as well as we can.

‖ Mancheſt. Tranſ. vol. iv.

38 Accounted for.

It is evident that the denſity of the atmoſphere is leaſt at the equator, and greateſt at the poles; for at the equator the centrifugal force, the diſtance from the centre of the earth, and the heat, all of which tend to diminiſh the denſity of the air, are at their maximum, while at the pole they are at their minimum. The mean height of the barometer at the level of the ſea, all over the globe, is 30 inches; the weight of the atmoſphere, therefore, is the ſame all over the globe. The weight of the atmoſphere depends on its denſity and height: where the denſity of the atmoſphere is greateſt, its height muſt be leaſt; and, on the contrary, where its denſity is leaſt, its height muſt be greateſt. The height of the atmoſphere, therefore, muſt be greateſt at the equator, and leaſt at the poles; and it muſt decreaſe gradually between the equator and the poles, ſo that its upper ſurface will reſemble two inclined planes, meeting above the equator their higheſt part*.

* Kirwan, Iriſh Tranſ. vol. ii. p. 43, &c.

During ſummer, when the ſun is in our hemiſphere, the mean

Weather.

mean heat between the equator and the pole does not differ ſo much as in winter. Indeed the heat of northern countries at that time equals the heat of the torrid zone: thus in Ruſſia, during July and Auguſt, the thermometer riſes to 85° †. Hence the rarity of the atmoſphere at the pole, and conſequently its height, will be increaſed. The upper ſurface of the atmoſphere, therefore, in the northern hemiſphere will be leſs inclined; while that of the ſouthern hemiſphere, from contrary cauſes, will be much more inclined. The very reverſe will take place during our winter.

39 By variations in the denſity of the atmoſphere.

† Dr Guthrie, Edin. Tranſ. vol. ii. p. 229.

The denſity of the atmoſphere depends in a great meaſure on the preſſure of the ſuperincumbent column, and therefore decreaſes, according to the height, as the preſſure of the ſuperincumbent column conſtantly decreaſes. But the denſity of the atmoſphere in the torrid zone will not decreaſe ſo faſt as in the temperate and frigid zones; becauſe its column is longer, and becauſe there is a greater proportion of air in the higher part of this column. This accounts for the obſervation of Mr Caſſan, that the barometer only ſinks half as much for every 200 feet of elevation in the torrid as in the temperate zones (B). The denſity of the atmoſphere at the equator, therefore, though at the ſurface of the earth it is leſs, muſt at a certain height equal, and at a ſtill greater ſurpaſs, the denſity of the atmoſphere in the temperate zones and at the poles.

In the article Wind we ſhall endeavour to prove, that a quantity of air is conſtantly aſcending at the equator, and that part of it at leaſt reaches and continues in the higher parts of the atmoſphere. From the fluidity of air, it is evident that it cannot accumulate above the equator, but muſt roll down the inclined plane (c) which the upper ſurface of the atmoſphere aſſumes towards the poles. As the ſurface of the atmoſphere of the northern hemiſphere is more inclined during our winter than that of the ſouthern hemiſphere, a greater quantity of the equatorial current of air muſt flow over upon the northern than upon the ſouthern atmoſphere; ſo that the quantity of our atmoſphere will be greater during winter than that of the ſouthern hemiſphere; but during ſummer the very reverſe will take place. Hence the greateſt mercurial heights take place during winter, and the range of the barometer is leſs in ſummer than in winter.

The denſity of the atmoſphere is in a great meaſure regulated by the heat of the place: wherever the cold is greateſt, there the denſity of the atmoſphere will be greateſt, and its column ſhorteſt. High countries, and ranges of lofty mountains, the tops of which are covered with ſnow the greateſt part of the year, muſt be much colder than other places ſituated in the ſame degree of latitude, and conſequently the column of air over them much ſhorter. The current of ſuperior air will linger and accumulate over theſe places in its paſſage towards the poles, and thus occaſion an irregularity in its motion, which will produce a ſimilar irregularity in the barometer. Such accumulations will be formed over the north-weſtern parts of Aſia, and over North America: hence the barometer uſually ſtands higher, and varies leſs there, than in Europe. Accumulations are alſo formed upon the Pyrenees, the Alps, the mountains of Africa, Turkey in Europe, Tartary, and Tibet. When theſe accumulations have gone on for ſome time, the denſity of the air becomes too great to be balanced by the ſurrounding atmoſphere; it ruſhes down on the neighbouring countries, and produces cold winds which raiſe the barometer. Hence the riſe of the barometer which generally attends north-eaſt winds in Europe, as they proceed from accumulations in the north-weſt of Aſia, or about the pole; hence, too, the north-weſt wind from the mountains of Tibet raiſes the barometer at Calcutta.

Weather.

We ſhall endeavour to prove in the article Wind, that conſiderable quantities of air are, occaſionally deſtroyed in the polar regions. When this happens, the atmoſphere to the ſouth ruſhes in to fill up the void. Hence ſouth-weſt winds take place, and the barometer falls.

As the mean heat of our hemiſphere differs in different years, the denſity of the atmoſphere, and conſequently the quantity of equatorial air which flows towards the poles, muſt alſo be variable. Hence the range of the barometer is different in different years. Does this range correſpond to the mean annual heat; that is to ſay, is the range greateſt when the heat is leaſt, and leaſt when the heat is greateſt? In ſome years greater accumulations than uſual take place in the mountainous parts in the ſouth of Europe and Aſia, owing, perhaps, to earlier falls of ſnow, or to the rays of the ſun having been excluded by long continued fogs. When this takes place, the atmoſphere in the polar regions, will be proportionably lighter. Hence the prevalence of ſoutherly winds during ſome winters more than others.

As the heat in the torrid zone never differs much, the denſity, and conſequently the height of the atmoſphere, will not vary much. Hence the range of the barometer within the tropics is comparatively ſmall; and it increaſes gradually as we approach the poles, becauſe the difference of the temperature, and conſequently of the denſity, of the atmoſphere increaſes with the latitude.

The diurnal elevation of the barometer in the torrid zone correſponding to the tides, obſerved by Mr Caſſan and others, muſt be owing to the influence of the moon on the atmoſphere. This influence, notwithſtanding the ingenious attempts of D'Alembert and ſeveral other philoſophers, ſeems altogether inadequate to account for the various phenomena of the winds. It is not ſo eaſy to account for the tendency which the barometer has to riſe as the day advances, which ſeems to be eſtabliſhed by Mr Cotte's table. Perhaps it may be accounted for by the additional quantity of vapour added to the atmoſphere, which, by increaſing the quantity of the atmoſphere, may poſſibly be adequate to produce the effect.

The falls of the barometer which preceed, and the oſcillations which acompany, violent ſtorms and hurricanes, ſhow us that theſe phenomena are produced by very great rarefactions, or perhaps deſtruction of air, in particular parts of the atmoſphere. The falls of the barometer, too, that accompany winds proceed from the ſame cauſe. The obſervation made by Mr Copland, that a high barometer is accompanied by a temperature above the mean, will be eaſily accounted for by every one acquainted with Dr Black's theory of latent heat. The higher the mercury ſtands, the denſer the atmoſphere muſt be; and the denſer it becomes, the more latent heat it muſt give out. It is well known that air evolves heat when condenſed artificially.

The

(B) Should it not be examined whether the number of parts which the mercury ſinks for every 200 feet of elevation be not proportioned to the latitude of the place?

(c) It is of no conſequence whether the ſurface of the atmoſphere actually forms an inclined plan, or, becoming rarer in a very ſlow ratio (as is probably the caſe), aſcends much higher than the place at which the equatorial currents begin to flow towards the poles; for ſtill the different heights of air of the ſame denſity in different parts of the atmoſphere will in fact form an inclined plane, over which theſe currents will roll, notwithſtanding the very rare air which they may diſplace.

Weather.

The falling of the barometer which generally precedes rain remains ſtill to be accounted for; but we know too little about the cauſes by which rain is produced to be able to account for it in a ſatisfactory manner. Probably a rarefied ſtate of the atmoſphere is favourable to the production of rain; we know, at leaſt, that it is favourable to evaporation. Suppoſing the obſervations which we made upon the changes which vapour undergoes in the atmoſphere well founded, may not the vapour in its new form accumulate at a conſiderable height in the atmoſphere? and is not the height at which clouds are always formed a proof of this? May not this ſubſtance, whatever it is, when by ſome means or other it returns to the ſtate of vapour, paſſes its maximum, and begins to fall in drops of rain, and conſequently is no longer ſupported by the atmoſphere, cauſe the barometer to fall ſuddenly, at leaſt till new air ruſhes in to ſupply its place?

40 Of prognoſticating the weather.

THUS we have endeavoured to deſcribe the various phenomena of the weather, and to account for them as far as the preſent ſtate of our meteorological knowledge enables us to go.

It will be expected that we ſhould not paſs by unnoticed that branch of meteorology which has in all ages attracted the attention of mankind, and in which, indeed, every other part of the ſcience, as far as utility is concerned, evidently centres; we mean the method of prognoſticating the weather. All philoſophers who have dedicated their attention to meteorology, have built upon the hope of being able to diſcover, by repeated obſervations, ſome rules concerning the periods of the ſeaſons and the changes of the weather, convinced that ſuch diſcoveries would be of the higheſt utility, eſpecially in agriculture; for by foreſeeing, even in part, the circumſtances of the ſeaſons, we would have it in our power to prevent at leaſt a part of the loſſes ariſing from them, as by ſowing, for inſtance, the kind of corn beſt adapted for the rain or the drought which is to enſue.

41 Moon ſuppoſed to influence the weather;

The influence of the moon on the weather has in all ages been believed by the common people; the ancient philoſophers embraced the ſame opinion, and engrafted upon it their pretended ſcience of aſtrology. Several modern philoſophers have thought the opinion worthy of notice; among whom Meſſrs Lambert, Cotte, and Toaldo, deſervedly take the lead. Theſe philoſophers, after examining the ſubject with the greateſt attention, have embraced the opinion of the common people, though not in its full extent. To this they have been induced both by the certainty that the moon actually has an influence on the atmoſphere as it has on the ſea, and by obſerving that certain ſituations of the moon in her orbit have almoſt conſtantly been attended with changes of the weather either to wind, to calm, to rain, or to drought.

42 Eſpecially in ten ſituations,

There are ten ſituations in every revolution of the moon in her orbit, when ſhe muſt particularly exert her influence on the atmoſphere, and when conſequently changes of the weather muſt readily take place. Theſe are (1) the new and (2) full moon, when ſhe exerts her influence in conjunction with or oppoſition to the ſun; (3 and 4) the quadratures: (5) the perigee and (6) apogee (for the difference in the moon's diſtance from the earth is about 27,000 miles), the two paſſages of the moon over the equator, one of which, Mr Toaldo calls (7) the *moon's aſcending*, and (8) the other the *moon's deſcending equinox*, the two luniſtices as M. de la Lande has called them, (9) the *boreal luniſtice*, when the moon approaches as near as ſhe can in each lunation to our zenith, (10) the *auſtral*, when ſhe is at the greateſt diſtance from it, for the action of the moon varies greatly according to her obliquity. With theſe ten points Mr Toaldo compared a table of 48 years obſervations for Lombardy, and found the reſult as follows:

Lunar Points.	Attended with a change of weather.	Attended with no change.	Proportion reduced to the loweſt terms.
New moons	522	82	6 : 1
Full moons	506	92	5 : 1
Firſt quarters	424	189	2½ : 1
Laſt quarters	429	182	2½ : 1
Perigees	546	99	7 : 1
Apogees	517	130	4 : 1
Aſcending equinoxes	465	142	3¼ : 1
Deſcending equinoxes	446	152	2¾ : 1
Southern luniſtices	446	154	3 : 1
Northern luniſtices	448	162	2¾ : 1

And after examining a number of other tables of obſervations, and combining them with his own, he found the proportions between thoſe lunar points on which changes of the weather took place, and thoſe which paſſed without any change when reduced to the loweſt terms, to be as in the laſt column of the above table: ſo that we may wager ſix to one, that this or that new moon will bring a change of weather, and five to one that a full moon will be attended by a change, and ſo on. Several of theſe lunar points often coincide with one another, occaſioned by the inequality of the moon's periodical, anomaliſtical, and ſynodical revolutions, and by the progreſſive motion of the apſes. Thus the new and full moon ſometimes coincide with the apogees, the perigees, &c. Theſe coincidences are the moſt efficacious. Their changing power, according to Mr Toaldo, is as follows:

New moon coinciding with the perigee	33 : 1
——————————with the apogee	7 : 1
Full moon coinciding with the perigee	10 : 1
——————————with the apogee	8 : 1

It ought to be remarked, that theſe changes of the weather ſeldom or never take place exactly when the moon is in theſe lunar points, but ſometime before or after; juſt as the tide, ſay the philoſophers who contend for the influence of the moon, is not at its height till after the moon has paſſed the meridian.

The power of the moon over the ocean and the atmoſphere is diſplayed in a particular manner during the apſes, in conſequence of her different diſtances from the earth during theſe two ſituations. Now the apſes advance about 40° in the zodiac every year, and complete a revolution in about eight years and ten months. It is probable that the ſeaſons and the conſtitutions of years have a period nearly equal to this revolution, and that therefore nearly the ſame ſeaſons return every ten years. This periodical return of the ſeaſons, as Pliny (D) ſeems to inform us, was obſerved by the ancients. Mr Toaldo found, that in Lombardy the quantities of rain which fell during periods of nine ſucceſſive years were nearly equal; but that this was not true of other periods, for inſtance, of ſix, eight, or ten years. By comparing in like manner the quantities of rain publiſhed by the Royal Academy of Sciences at Paris, from 1699 to 1752, he found,

43 And to occaſion a period of ten years,

(D) "Tempeſtates ardores ſuos habere quadrinis annis.—Octonis vero augeri eaſdem centeſimâ revolventi ſe luna." *Lib.* 18. *c.* 25.

Weather. that of six series of nine years, three were greater and three smaller, but on both sides almost equal to one another.

During the revolution of the apses, there are four remarkable points, the two equinoctial and two solstitial points; in which, when the moon is in perigee, her effect will be most powerful on the weather. The moon passes from one equinoctial point to another in about four years; in them its power is greatest: it is probable, therefore, that when an ordinary year happens, a return of another may be expected in about four years. As the apses after their revolution return again in the same order as before, it is probable that the return of the seasons will be nearly the same in every series of nine years.

Such, according to Mr Toaldo, is the period at the end of which we are to expect a return of the seasons. Mr Cotte, however, though he does not deny the influence of the revolution of the apses, places greater confidence in the *lunar period* of 19 years; at the end of which, the new and full moons return to the same day in the Julian year. He supposes, that in like manner the seasons correspond with one another every 19 years. The similarity, he informs us, is striking between the temperatures of the years 1701, 1720, 1739, 1758, and 1777. That of 1758, upon which we have observations much detailed by M. du Hamel, has a remarkable coincidence with 1777: there was scarcely any difference in the temperatures of the corresponding months. The years 1778, 1779, and 1780, have been hot and dry, and they correspond with years which have had the same character. The years corresponding with 1782, especially 1725 and 1763, have been singularly cold, humid, and late, as was the case with 1782 †.

44 And of 19 years.

† P. Cotte, Memoires sur la Meteorologie, vol. i. p. 123.

Such is an imperfect view of the opinions of those philosophers who have endeavoured to establish the influence of the moon over the weather. The most important of their maxims for prognosticating the weather are the following:

45 Maxims for prognosticating the weather from the moon.

1. When the moon is in any of the ten lunar points above mentioned, a change of the weather may be expected. The most efficacious of these points are the conjunctions and apses.

2. The coincidence of the conjunctions with the apses is extremely efficacious: that of the new moon with the perigee gives a moral certainty of a great perturbation.

3. The new and full moons, which sometimes produce no change on the weather, are such as are at a distance from the apses.

4. A lunar point commonly changes the state into which the weather was brought by the preceding point. For the most part the weather never changes but with some lunar point.

5. The apogees, quadratures, and southern luniſtices, commonly bring fair weather, for the barometer then rises; the other points tend to make the air lighter, and thereby to produce bad weather.

6. The most efficacious lunar points become stormy about the equinoxes and solstices.

7. A change of weather seldom happens on the same day with a lunar point, but sometimes before and sometimes after it.

8. At the new and full moons about the equinoxes, and even the solstices, especially the winter solstice, the weather is commonly determined to good or bad for three, or even six months.

9. The seasons and years have a period of eight or nine years corresponding with the revolution of the lunar apses, and another of 19 corresponding to the *lunar period*.

Would it not be worth while to publish a meteorological kalendar yearly, marking the time, to which the lunar points correspond, at which changes of the weather may be expected, especially when any of these points coincide; and marking the probability of a change at any particular time? and might not this be attended by a diary of the weather for the 9 or 19 corresponding years? By this means, if there is any probability in the opinion that the moon has influence over the weather, men would be enabled to foresee changes with a considerable degree of probability; and at any rate, we would be able, by the united observations of a whole nation, to determine whether there be any truth in the opinion; and if there be, as its universality would lead one to suppose, succeeding observations would gradually correct the imperfection of our present rules, and enable us to bring our prognostics of the weather to the greatest exactness. Weather.

We are not so sanguine, however, as Mr Toaldo and P. Cotte on this subject. Even allowing the influence of the moon on the weather to be as great as they could desire, and supposing, which is very far from being the case, that it is not influenced by any other cause, we do not see how the seasons could return in the same order every 9th or 19th year. The motions of the heavenly bodies (especially the moon) are, strictly speaking, incommensurable. The lunar apogee returns to the same situation in eight years ten months (without reckoning hours and minutes): at its first return it will be two months or signs removed from the same situation with the sun; at the end of the second period, four months; and at the end of the third, six months; so that if the season was winter at the beginning, after three revolutions it will be the middle of summer. Now, how in this case can the same seasons return? Supposing the equinoctial points to produce constantly great changes on the weather, if one of them during the first revolution happened in winter, in the second it would happen in spring, and the third in summer; so that what would during the first revolution produce a particular winter, would in the second act upon the spring, and in the third on the summer. Would it in these cases produce similar changes on the weather? Surely not. And whether it did or not, would the same seasons return in every revolution? In six complete revolutions, indeed, or 53 years, the lunar perigee returns to the same situation as at first, very nearly, in the same seasons: it might be expected then that the seasons would perform a complete revolution every 53 years, and that the 54th would exactly resemble the first, and so on. This may possibly be the case, but it is by no means probable; for when Mr Toaldo compared the quantity of rain which fell at Paris during 1699, 1700, 1701, 1702, &c. with what fell in 1752, 1753, 1754, &c. though the first years in each series corresponded pretty exactly, the difference being only eight lines, there was no such resemblance between any of the following years.

46 Remarks on the lunar influence.

Neither are we convinced that the influence of the moon can have such an effect on the weather as the above mentioned philosophers suppose. The moon only acts, as far as we know at least, by producing tides in the atmosphere; for the refined speculations of Mr Toaldo about its electrical influence we cannot admit, as the electricity of the atmosphere is less during the night, when the moon's influence should be greatest, than during the day. Now we do not see how these tides, supposing them greater than they are, can be adequate to the effects ascribed to them.

Mr Kirwan † has lately endeavoured to discover probable rules for prognosticating the different seasons, as far as regards Britain and Ireland, from tables of observations alone. On perusing a number of observations, taken in England from 1677 to 1789, he found,

† Irish Transf. vol. v. p. 19.

47 Mr Kirwan's method of prognosticating the weather.

1. That when there has been no storm before or after the vernal equinox, the ensuing summer is generally *dry* at least five times in six.

2. That

Weather.

2. That when a ſtorm happens from an eaſterly point, either on the 19th, 20th, or 21ſt of May, the ſucceeding ſummer is generally *dry* four times in five.

3. That when a ſtorm ariſes on the 25th, 26th, or 27th of March (and not before), in any point, the ſucceeding ſummer is generally *dry* four times in five.

4. If there be a ſtorm at ſouth-weſt or weſt-ſouth-weſt on the 19th, 20th, 21ſt, or 22d of March the ſucceeding ſummer is generally *wet* five times in ſix.

In this country winters and ſprings, if dry, are moſt commonly cold; if moiſt, warm: on the contrary, dry ſummers and autumns are uſually hot, and moiſt ſummers cold. So that if we know the moiſtneſs or dryneſs of a ſeaſon, we can judge pretty accurately of its temperature.

From a table of the weather kept by Dr Rutty, in Dublin, for 41 years, Mr Kirwan endeavoured to calculate the probabilities of particular ſeaſons being followed by others. Though his rules relate chiefly to the climate of Ireland, yet as probably there is not much difference between that iſland and Britain in the general appearance of the ſeaſons, we ſhall mention his concluſions here.

In 41 years there were 6 wet ſprings, 22 dry, and 13 variable; 20 wet ſummers, 16 dry, and 5 variable; 11 wet autumns, 11 dry, and 19 variable. A ſeaſon, according to Mr Kirwan, is counted *wet* when it contains two wet months. In general the quantity of rain which falls in dry ſeaſons is leſs than five inches, in wet ſeaſons more: variable ſeaſons are thoſe in which there falls between 30lb. and 36lb. a lb. being equal to .157639 of an inch.

The order in which the different ſeaſons followed each other was as in the following table:

	Has been followed by a		Times.	Probability.
A dry ſpring -	Summer.	dry	11	$\frac{11}{22}$
		wet	8	$\frac{8}{22}$
		variable	3	$\frac{3}{22}$
A wet ſpring -		dry	0	0
		wet	5	$\frac{5}{6}$
		variable	1	$\frac{1}{6}$
A variable ſpring -		dry	5	$\frac{5}{13}$
		wet	7	$\frac{7}{13}$
		variable	1	$\frac{1}{13}$
A dry ſummer -	Autumn.	dry	5	$\frac{5}{16}$
		wet	5	$\frac{5}{16}$
		variable	6	$\frac{6}{16}$
A wet ſummer -		dry	5	$\frac{5}{20}$
		wet	3	$\frac{3}{20}$
		variable	12	$\frac{12}{20}$
A variable ſummer -		dry	1	$\frac{1}{5}$
		wet	3	$\frac{3}{5}$
		variable	1	$\frac{1}{5}$
A dry ſpring and dry ſummer - -		dry	3	$\frac{3}{11}$
		wet	4	$\frac{4}{11}$
		variable	4	$\frac{4}{11}$
A dry ſpring and wet ſummer - -		dry	2	$\frac{2}{8}$
		wet	0	0
		variable	6	$\frac{6}{8}$
A wet ſpring and dry ſummer - -		dry	0	0
		wet	0	0
		variable	0	0
A wet ſpring and wet ſummer - -		dry	2	$\frac{2}{5}$
		wet	1	$\frac{1}{5}$
		variable	2	$\frac{2}{5}$
A wet ſpring and variable ſummer -		dry	1	$\frac{1}{41}$
		wet	0	0
		variable	0	0
A dry ſpring and variable ſummer -		dry	0	0
		wet	2	$\frac{2}{3}$
		variable	1	$\frac{1}{3}$
A variable ſpring and dry ſummer -		dry	2	$\frac{2}{4}$
		wet	0	0
		variable	2	$\frac{2}{4}$
A variable ſpring and wet ſummer -		dry	1	$\frac{1}{7}$
		wet	1	$\frac{1}{7}$
		variable	5	$\frac{5}{7}$
A variable ſpring and variable ſummer		dry	0	0
		wet	1	$\frac{1}{41}$
		variable	0	0

Hence Mr Kirwan deduced the probabilitiy of the kind of ſeaſons which would follow others. This probability is expreſſed in the laſt column of the table, and is to be underſtood in this manner: The probability that a dry ſummer will follow a dry ſpring is $\frac{11}{22}$; that a wet ſummer will follow a dry ſpring $\frac{8}{22}$; that a variable ſummer will follow a dry ſpring $\frac{3}{22}$; and ſo on.

This method of Mr Kirwan, if there is ſuch a connection between the different ſeaſons that a particular kind of weather in one has a tendency to produce a particular kind of weather in the next, as it is reaſonable to expect from theory, may in time, by multiplying obſervations, come to a great degree of accuracy, and may at laſt, perhaps, lead to that great deſideratum, a rational theory of the weather. As we wiſh to throw as much light as poſſible on this important ſubject, we ſhall add to theſe a few maxims, the truth of which have either been confirmed by long obſervation, or which the knowledge we have already acquired of the cauſes of the weather has eſtabliſhed on tolerably good grounds.

48 Maxims for prognoſticating the weather.

1. A moiſt autumn with a mild winter is generally followed by a cold and dry ſpring, which greatly retards vegetation.---Such was the year 1741*.

2. If the ſummer be remarkably rainy, it is probable that the enſuing winter will be ſevere; for the unuſual evaporation will have carried off the heat of the earth. Wet ſummers are generally attended with an unuſual quantity of ſeed on the white thorn and dog-roſe buſhes. Hence the unuſual fruitfulneſs of theſe ſhrubs is a ſign of a ſevere winter.

3. The appearance of cranes and birds of paſſage early in autumn announces a very ſevere winter; for it is a ſign that it has already begun in the northern countries.

4. When it rains plentifully in May, it will rain but little in September, and *vice verſa*.

5. When the wind is ſouth-weſt during ſummer or autumn, and the temperature of the air unuſually cold for the ſeaſon, both to the feeling and the thermometer, with a low barometer, much rain is to be expected †.

6. Violent temperatures, as ſtorms or great rains, produce a ſort of criſis in the atmoſphere, which produces a conſtant temperature, good or bad, for ſome months ‖.

7. A rainy winter predicts a ſteril year.----A ſevere autumn announces a windy winter ‡.

Thus we have endeavoured to deſcribe the various phenomena of the weather, and to explain them as far as the infant ſtate of our knowledge of the atmoſphere furniſhed us with principles.

Notwithſtanding the imperfection of our preſent knowledge of this ſubject, the numbers and the abilities of the philoſophers who are at preſent engaged in the ſtudy cannot fail at laſt of being crowned with ſucceſs; and perhaps a rational and ſatisfactory theory of the weather is not ſo far diſtant as we at preſent ſuppoſe. It is a pity, however, that in a ſcience attended with ſo much difficulty as meteorology is, various artificial difficulties ſhould have been thrown in the way, which contribute very much to obſtruct its progreſs. There are no fewer than four thermometers

* Du Hamel.

Weather ‖ Weaving.

meters uſed at preſent in different parts of Europe; and the obſervations made by each of them muſt be reduced to one common ſtandard before it is poſſible to compare them with one another. This is a tedious enough buſineſs, but it is nothing at all to the reduction of obſervations of rain and of the barometer to one common ſtandard. Every nation has its own peculiar meaſure; and the French, to add to the difficulty, have reckoned by lines, and twelfths of lines, inſtead of by decimal parts of an inch. Whether, however, this be the caſe at preſent or not, we know not, as we have ſeen no meteorological tables drawn up in France later than 1792. Philoſophers ought certainly to fix upon ſome common ſtandard of weights and meaſures, otherwiſe the labour in meteorology, and even in chemiſtry, muſt ſoon become intolerable. The only other poſſible way to remedy this evil would be, to conſtruct accurate tables, in which the various weights and meaſures uſed by philoſophers are reduced to one common ſtandard. This has already been done in part; but no table of this kind which we have ſeen is ſufficient to remedy the evil: few of them deſcend to decimal parts of ſmall weights or meaſures; yet without this they ſeldom can ſave the trouble of calculation.

WEATHER, in ſea-language, is uſed as an adjective, and applied by mariners to every thing lying to windward of a particular ſituation: thus, a ſhip is ſaid to have the weather-gage of another, when ſhe is farther to windward. Thus alſo, when a ſhip under ſail preſents either of her ſides to the wind, it is then called the *weather-ſide* or *weather-board*; and all the rigging and furniture ſituated thereon are diſtinguiſhed by the ſame epithet, as the *weather-ſhrouds*, the *weather-lifts*, the *weather-braces*, &c.

To WEATHER, in ſea-language, is to ſail to windward of ſome ſhip, bank, or head-land.

WEATHER-Cock, a moveable vane, in form of a cock, or other ſhape, placed on high, to be turned round according to the direction of the wind, and point out the quarter from whence it blows.

WEATHER-Glaſs. See BAROMETER.

WEATHERING, among ſailors, ſignifies the doubling or ſailing by a head-land or other place.

WEAVING, the art of working a web of cloth, ſilk, or other ſtuff, in a loom with a ſhuttle. For an idea of the manner in which this is performed, ſee CLOTH.

WEAVING-Loom, a machine for weaving cloth, ſilk, &c. by raiſing the threads of the warp in order to throw in the ſhoot, and ſtrike it cloſe. Of theſe there are various kinds, diſtinguiſhed by the different ſorts of cloths, ſtuffs, ſilks, &c. in which they are employed; and which are chiefly diſtinguiſhed by the number and variety of the threads they raiſe in order to work the warp, either plain or in figures, by making more or leſs of the woof or ſhoot appear through the warp. In order to give a general idea of weaving, we ſhall here deſcribe the parts of the common weaver's loom. See Plate DXXXIX. fig. 1. in which *e f*, *e f* are the front poſts, and *g*, *g* the back poſts of the loom; *l l l*, *m m*, *m m* are the *lams* in their place at Q, or, as they are called in ſome parts of Scotland, the *hiddles*, and in others the *ſlaves*. They are compoſed of ſtrong threads, ſtretched between two horizontal bars, an upper and a lower. The threads of one lam are ſo diſpoſed as to paſs between the upper threads of the warp, while they admit the lower threads to paſs through loops or ſmall holes in them, and the diſpoſition of the threads of the other lam is ſuch, that while they paſs between the lower threads of the warp, they admit the upper threads to paſs through the ſmall holes juſt mentioned. The lams are ſuſpended from the croſs bar or *lam-bearer* HH, by means of ropes *n*, *n* paſſing from the upper bars of the *lams* over the pulleys at EE, and balanced by weights at the other ends. From the lower bar of each *lam* or *hiddle* a rope paſſes to the *treadles* or moveable bars at O O: ſo that when a foot preſſes a treadle, the lam faſtened to it ſinks, while the other riſes by means of the balancing weight ſuſpended from the pulley at E. The workman then throws in the woof by means of the ſhuttle, and cloſes it by one or two ſtrokes of the *lay* or *batten*, of which WB, WB are called the *ſwords*, CC the *cap*, or in Scotland the upper *ſhell*, DD the *block* or under *ſhell*, and PP the *reed* or *comb* contained between theſe ſhells. LL is the bench on which the workmen ſit; for the loom which our figure repreſents is conſtructed for weaving cloth of ſuch a breadth as to require two workmen, who have their quills in a box *d* on the middle of the bench on which they ſit. Between the workmens bench and the *batten* or *lay* is the *breaſt-bar* I, I, a ſmooth ſquare beam, in which there is an opening to let the web through as it is wove. From this opening the web S S paſſes to the *knee roll* or *web beam* GG, round which it is rolled by means of the ſpokes, viſible in the figure, and kept from being unrolled by a wheel with teeth and clench, viſible likewiſe in the figure. In ſome looms the web paſſes from the knee-roll to the wooden frame X, to be dried as it is wove. Oppoſite to the breaſt-bar, and on the other ſide of the *batten* or *lay*, is the *cane-roll* or *yarn-beam*, on which the warp is rolled when put into the loom, and from which it is gradually unrolled as the work proceeds. TT are bobbins filled with yarn of the warp to mend ſuch threads of it as may be broke in the weaving; and B *b*, B *b* are clues of the ſame kind of yarn with the borders of the warp, to mend ſuch threads as may there be broken.

Weaving.

Fig. 2. repreſents the common ſhuttle with the vacuity in the middle, in which the quill with the woof is placed on a ſpindle or axis. As this ſhuttle is thrown with one hand in at one ſide of the warp, and received with the other hand at the other ſide, it is obvious, that when the web is of a breadth too great for a man to reach from one ſide of it to the other, two workmen muſt be employed and much time loſt. To remedy this inconveniency, a new ſhuttle has, in Great Britain, been lately brought into very general uſe, and called the *flying ſhuttle*, becauſe it flies through the warp with wonderful rapidity on two ſteel rollers RR (fig. 3.) This ſhuttle is not thrown with the hand, but moved backwards and forwards by a very ſimple piece of machinery, of which fig. 4. will give the reader a ſufficiently accurate conception. To each end of the *batten* or *lay* L is faſtened a kind of open box B, *b*, with the bottom or horizontal ſide exactly on a level with the threads of the warp of the intended web. In each of theſe boxes is a vertical piece of wood D, *d*, of conſiderable thickneſs, called a *driver*. This driver is moved eaſily on an iron ſpindle or axis from one end of the box to the other by means of a ſlender rope CCCD, and a handle H is ſeen in the figure. When the weaver is to begin his work, he lays the ſhuttle on its rollers in the box B with the iron tip T (fig. 3.) touching, or almoſt touching, the driver D (fig. 4.). Then moving the handle H, with a ſudden jerk, towards the box *b*, the driver D forces the ſhuttle with a rapid motion thro' the warp till it ſtrikes *d*, which is impelled by the ſtroke to the further end of the box *b*. The two drivers D and *d* have now changed their poſitions in their reſpective boxes; ſo that the driver which was at the front of its box before, is now at the farther end of it, and *vice verſa*. Then by a ſudden jerk of the hand towards B the ſhuttle is driven back till it ſtrike D; and thus is the work continued without the weaver having occaſion ever to ſtretch his arms from one margin of the web to the other. That the ſhuttle may not, by the unſteadineſs of the work-

Web || Weight.

man's hand, be driven *zig-zag* through the warp or out of the place in which it ought to move, the guiding or driving rope CCCD is made to pass through smooth holes or loops C, C, at the ends of the ropes EC, EC, suspended either from the cross bar on the top of the loom or from the swords of the batten.

This shuttle, we should think, a great improvement in every kind of weaving loom, though some of the older tradesmen, with whom we have conversed on the subject, contend, that it is valuable only in what they call light-work, such as cotton or linen cloth, or when the web, if woollen, is very broad.

WEB, a sort of tissue or texture formed of threads interwoven with each other; some whereof are extended in length, and called the *warp*; others are drawn across, and called the *woof*.

WEDGE, one of the mechanical powers. See MECHANICS.

WEDNESDAY, the fourth day of the week, so called from a Saxon idol named *Woden*, supposed to be Mars, worshipped on this day

Ash-Wednesday, the first day of Lent, so called from the custom observed in the ancient Christian church of penitents expressing their humiliation at this time, by appearing in sack-cloth and ashes.

WEED, a common name for all rank and wild herbs, that grow of themselves, to the detriment of other useful herbs they grow among.

WEED, in the miners language, denotes the degeneracy of a load or vein of fine metal into an useless marcasite.

WEEDS, also denote a peculiar habit, worn by the relicts of persons deceased, by way of mourning.

WEEK, in chronology, a division of time comprising seven days. See *Planetary Days* and SABBATH.

Passion-Week, or the *Holy Week*, is the last week in Lent, wherein the church celebrates the mystery of our Saviour's death and passion.

WEEK or WYCK, in geography, a parliament and port-town of Scotland, in the shire of Caithness. W. Lon. 3. 2. N. Lat. 58. 30.

Weeks Ember. See EMBER.

Feast of Weeks. See PENTECOST.

WEEVEL, *Method of destroying*. See GRANARY.

WEEVER, in ichthyology. See TRACHINUS.

WEEVIL, in zoology, a species of curculio. See CURCULIO.

WEIGH, a weight of cheese, wool, &c. containing 256 pounds avoirdupois. Of corn, the weigh contains 40 bushels; of barley or malt, six quarters. In some places, as Essex, the weigh of cheese is 300 pounds.

WEIGHING, the act of examining a body in the balance to find its weight.

Weighing Anchor, is the drawing it out of the ground it had been cast into, in order to set sail, or quit a port, road, or the like.

WEIGHT, in physics, a quality in natural bodies, whereby they tend downwards towards the centre of the earth. Or, weight may be defined in a less limited manner, to be a power inherent in all bodies whereby they tend to some common point, called the *centre of gravity*, or to speak more accurately, to one another: and that with a greater or less velocity, as they are more or less dense, or as the medium they pass through is more or less rare. See MECHANICS.

WEIGHT, in commerce, denotes a body of a known weight appointed to be put in the balance against other bodies whose weight is required.

Weight.

The security of commerce depending, in a good measure, on the justness of weights, which are usually of lead, iron, or brass, most nations have taken care to prevent the falsification thereof, by stamping or marking them by proper officers, after being adjusted by some original standard. Thus, in England, the standard of weights is kept in the exchequer by a particular officer, called the *clerk of the market*.

Weights may be distinguished into ancient and modern.

I. ANCIENT WEIGHTS.

1. Those of the ancient Jews, reduced to the English troy weight, will stand as in the following table:

		lb.	oz.	dwt.	gr.
Shekel		0	0	9	$2\frac{4}{7}$
60	Maneh	2	3	6	$10\frac{2}{7}$
3000 50	Talent	113	10	1	$10\frac{2}{7}$

2. Roman weights, reduced to English troy weight, will stand as in the following table:

									oz.	dwt.	gr.
Lentes									0	0	$0\frac{8}{11}\frac{5}{12}$
4	Siliquæ								0	0	$3\frac{1}{2}\frac{1}{8}$
12	3	Obolus							0	0	$9\frac{3}{2}\frac{3}{8}$
24	6	2	Scriptulum						0	0	$18\frac{3}{1}\frac{3}{4}$
72	18	6	3	Drachma					0	2	$6\frac{9}{1}\frac{9}{4}$
96	24	8	4	$1\frac{1}{3}$	Sextula				0	3	$0\frac{6}{7}$
144	36	12	6	2	$1\frac{1}{2}$	Sicilicus			0	4	$13\frac{2}{7}$
192	48	16	8	$2\frac{2}{3}$	2	$1\frac{1}{3}$	Duella		0	6	$1\frac{5}{7}$
576	144	48	24	8	6	4	3	Uncia	0	18	$5\frac{1}{7}$
6912	1728	576	288	96	72	48	36	12 Libra	10	18	$13\frac{5}{7}$

The Roman ounce is the English avoirdupois ounce, which they divided into 7 denarii, as well as 8 drachmas.

3. *Attic Weights*

		English Troy Weight. lb.	oz.	dwt.	gr.
Drachma		0	0	2	16.9
100	Mina	1	1	10	10
6000 60	Talent	67	7	5	0

II. MODERN WEIGHTS.

1. *English Weights*.—Mr Renardson, in a paper published in the Philosophical Transactions, has proved, that at first there was but one weight in England, and that this was the avoirdupois. Troy weight was introduced in the time of Henry VII: At present, both the troy and avoirdupois weights are used in England. Troy weight seems to have derived its name from *Troyes*, a town in France, where a celebrated fair was kept. It is used for weighing gold, silver, jewels, silk, and all liquors. The avoirdupois is used for weighing other things.

TABLE

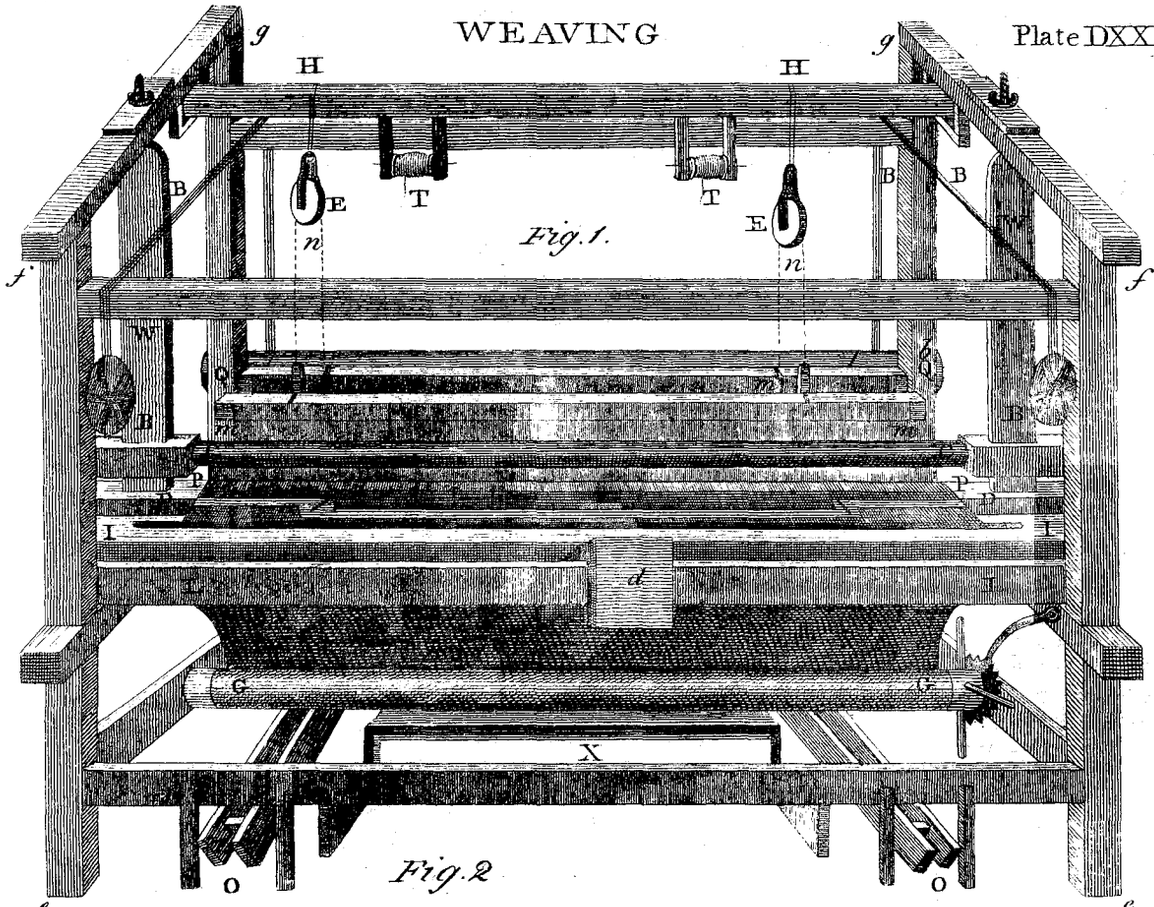

Fig. 1.

Fig. 2

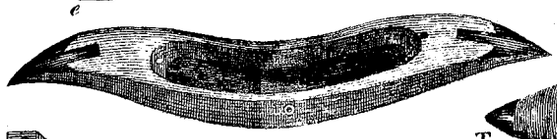

Fig. 3.

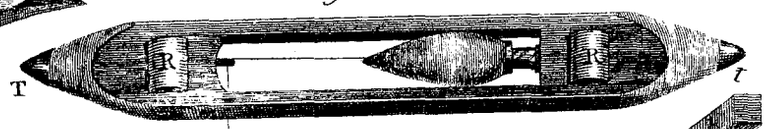

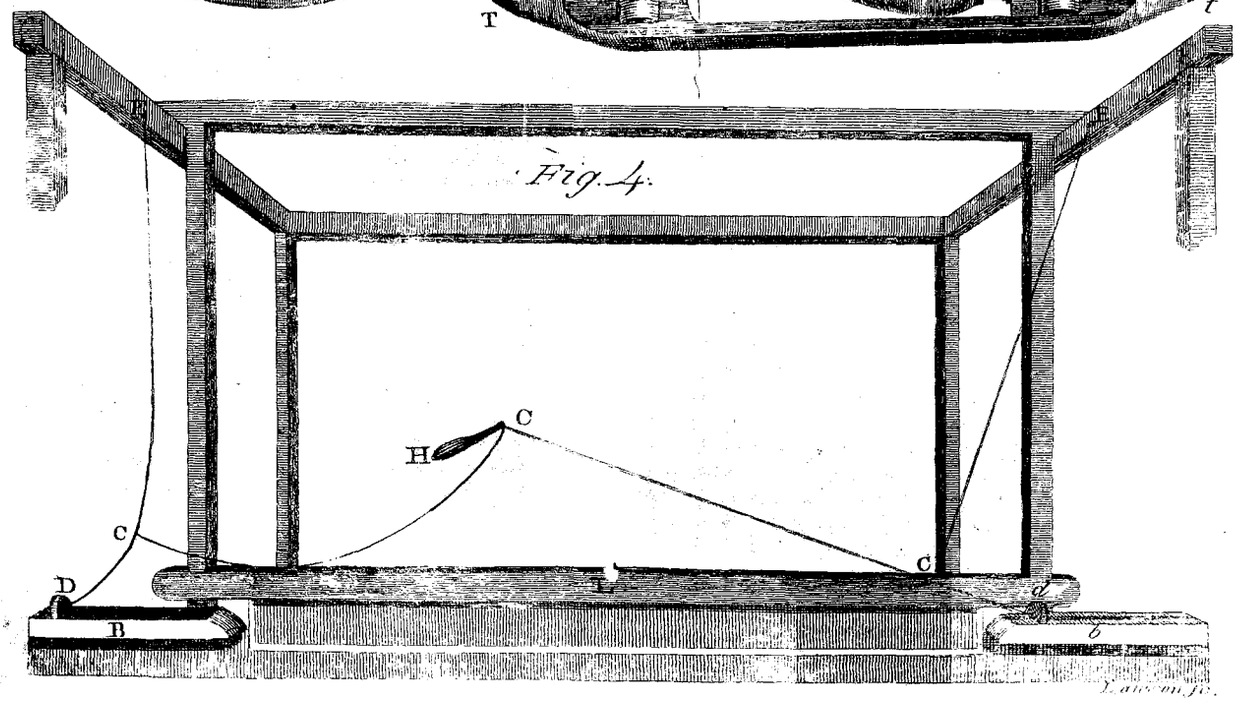

Fig. 4.

Weight.

Table of Troy Weight, as uſed by the Goldſmiths, &c.

Grains			
24	Penny-weight.		
480	20	Ounce.	
5760	240	12	Pound.

Apothecaries.

Grains				
20	Scruple. ℈			
60	3	Dram. ʒ		
480	24	8	Ounce. ℥	
5760	288	96	12	Pound.

The troy pound in Scotland, which by ſtatute is to be the ſame as the French pound is commonly ſuppoſed equal to 15 ounces and three quarters troy Engliſh weight, or 7560 grains. But by a mean of the ſtandards kept by the dean-of-guild of Edinburgh, it weighs $7599\frac{2}{3\frac{1}{2}}$ or 7600 grains.

Table of Avoirdupois Weight.

Drams.					
16	An ounce.				
256	16	A pound.			
7168	448	28	A quarter.		
28672	1792	112	4	A hundred.	
573440	35840	2240	80	20	A ton

The avoirdupois pound is equal to 7004 troy grains, the avoirdupois ounce to 437.75 grains; and it follows of conſequence, that the troy pound is to the avoirdupois pound as 88 to 107 nearly; for as 88 to 107, ſo is 5760 to 7003.636: that the troy ounce is to the avoirdupois ounce as 80 to 73 nearly; for as 80 to 73, ſo is 480 to 438. An avoirdupois pound is equal to 1lb. 2 oz. 11 dwts. 20 gr. troy: a troy ounce is equal to 1 oz. 1.55dr. avoirdupois; an avoirdupois dram contains 27.34375 grains; 175 troy pounds are equal to 144 avoirdupois pounds.

The moneyers have a peculiar ſubdiviſion of the grain troy: thus,

The { Grain, Mite, Droit, Periot } into { 20 Mites., 24 Droits., 20 Periots., 24 Blanks. }

The Engliſh weights are uſed in the United States of America.

2. *French Weights*.—Different weights were formerly uſed in moſt of the different provinces of France: we believe that they have lately undergone ſeveral alterations; a project of this kind is given in the article Revolution of France. Be that as it may, a knowledge of the ancient weights of that country is of importance on account of the books in which they are uſed. The Paris pound contains 16 ounces, and is divided two ways.

Grains				
24	Penny-weight.			
72	3	Gros.		
576	24	8	Ounce.	
4608	192	64	8	Marc.
9216	384	128	16	2 Pound

Half-ounce.						
2	Ounce.					
4	2	Half-quarter pound.				
8	4	2	Quarter-pound.			
16	8	4	2	Half-pound.		
32	16	8	4	2	Pound.	
3200	1600	800	400	200	100	Quintal.

The weights of the firſt diviſion are uſed to weigh gold, ſilver, and the richer commodities; and the weights of the ſecond diviſion for commodities of leſs value.

The Paris 2 marc, or pound weight, is equal to 7560 grains troy, and the Paris ounce equal to 472.5 grains troy.

lb. oz. dwt. gr.

The Paris pound = 1 3 15 0 troy

The Paris ounce = 0 0 19 16.5troy.

A grain troy = 1.2186507 of a Paris grain.

But the pound was not the ſame throughout France. At Lyons, *e. gr.* the city pound made only 14 ounces: ſo that 100 Lyons pounds was only 86 Paris pounds. But beſide the city pound, they had another at Lyons for ſilk, containing 15 ounces. At Thouloufe, and throughout the Upper Languedoc, the pound was 13 ounces and a half of Paris weight. At Marſeilles, and throughout Provence, the pound was $13\frac{1}{2}$ ounces of Paris weight. At Rouen, beſide the common Paris pound and marc, they had the weight of the vicomte; which was 16 ounces, a half, and five-ſixths of the Paris weight. The weights enumerated under the two articles of Engliſh and French weights are the ſame that are uſed throughout the greateſt part of Europe; only under ſomewhat different names, diviſions, and proportions.

French weights are uſed in all the French American ſettlements.

3. *Dutch Weights*.—The weight uſed in Amſterdam and all over Holland is called *Troy Weight*, and is exactly the ſame with that uſed at Bruſſels. The Dutch weights are as follows:

Duſkens.						
2	Troyken.					
4	2	Vierling.				
16	8	4	As.			
512	256	128	32	Angle.		
10240	5120	2560	640	20	Ounce.	
81920	40960	20480	5120	160	8	Marc.

The marc is equal, according to M. Tillet, to 4620 French grains.

The Amſterdam pound uſed in commerce is divided into 16 ounces, 32 loots, or 128 drachms. This pound contains 2 marcs troy, and ought therefore to weigh only 10240 *as*: but it weighs 10280; ſo that it is a little heavier than the troy pound of Amſterdam: 256 lb. of commerce are equal to 257 lb. troy of Holland. Two different pounds are uſed by apothecaries; the one containing 2 marcs, the other only $1\frac{1}{2}$. The firſt is called *arſenic* pound weight;

Weight. weight: it contains 16 ounces, the ounce 8 drachms, the drachm 8 ſcruples, the ſcruple 20 grains. The ſecond is called the *apothecary's* pound; it is divided into 12 ounces, or 24 loots. Three arſenic pounds are equal to 4 apothecary's pounds.

The Dutch ſtone -	= 8 commercial lb.
The Liſpundt, or Ll.	= 15
The hundred weight	= 100
The Schippondt, or Sch. lb.	= 300

4. *Spaniſh Weights.*----The marc of Caſtile, uſed for weighing gold and ſilver, is divided as follows,

Grains (gold weight).						
$1\frac{1}{4}$	Grain (ſilver weight).					
12	$11\frac{12}{25}$	Tomine (gold weight).				
$12\frac{1}{2}$	12	$1\frac{1}{24}$	Tomine (ſilver weight).			
$37\frac{1}{2}$	36	$3\frac{1}{8}$	3	Adarme.		
75	72	$6\frac{1}{4}$	6	2	Ochava.	
96	$92\frac{24}{25}$	8	$7\frac{17}{25}$	$2\frac{14}{25}$	$1\frac{7}{25}$	Caſtellano.
600	576	50	48	16	8	$6\frac{1}{4}$ Ounce.
4800	4608	400	384	128	64	50 8 Marc.

The marc, according to Tillet, is equal to 7 oz. 4 gros, 8 grains French, which is equal to 4785 *as* of Holland. One hundred marcs of Caſtile = about $93\frac{1}{2}$ marcs of Holland; 100 marcs of Holland = 107 marcs of Caſtile. Medicines are ſold by the ſame marc; but it is divided differently, containing 8 ounces, 64 drachms, 192 ſcruples, 384 obolos, 1152 caracteras, 4608 grains.

The Spaniſh commercial pound is divided into two marcs, called *marcs of Tejo*, each of which is equal to the marc of Caſtile. This pound is divided into 16 ounces, 256 adarmes, 9,216 grains.

5. *Weights of Portugal.*—The Liſbon marc for eſſaying ſilver conſiſts of 12 deniers, and the denier of 24 grains. The marc of Portugal for weighing gold and ſilver is equal, according to Tillet, to 7 ounces, $3\frac{1}{2}$ gros, and 34 grains French, which makes 4776 *as* of Holland; ſo that it is exactly the ſame with the Liſbon pound. It is divided into 8 ounces, 64 outavas, 192 ſcruples, 4608 grains.

The pound conſiſts of 2 marcs, 16 ounces, or 96 outavas. The arroba of 32 lb. the quintal of 4 arrobas, or 128 lb. 100 Oporto pounds make $87\frac{1}{6}$th pounds of commerce of Amſterdam.

6. *Weights of Italy.—Genoa.* Two kinds of weights are uſed at Genoa, the *peſo groſſo* (heavy weight), and the *peſo ſottile* (light weight): the latter is uſed for weighing gold and ſilver, the former for other things. The pound of the peſo ſottile is equal, according to Tillet, to 1 marc, 2 ounces, $2\frac{1}{2}$ gros, 30 grains French. It is divided into 8 ounces, the ounce into 24 deniers, and the denier into 24 grains. The pound of the peſo groſſo is equal to 1 marc, 2 ounces, 3 gros, 5 grains, French. It is divided into 12 ounces:

The cantaro	= 100 lbs. peſo groſſo.
The rubbo	= 25 lbs.
The rotolo	= $1\frac{1}{2}$ lb.

100 lbs. peſo groſſo = $64\frac{1}{3}$ lb. of commerce of Amſterdam.
100 lbs. peſo ſottile = 129 marcs troy of Holland.

Rome. The Roman pound conſiſts of 12 ounces, the ounce of 24 deniers, the denier of 24 grains. The Roman pound, according to Tillet, is equal to 1 marc, 3 ounces, $\frac{1}{2}$ gros, 14 grains, French. Weight.

Venice. The marc for weighing gold and ſilver contains 8 ounces, 32 quarti, 1152 carati, or 4608 grani. An hundred marcs of Venice = $97\frac{1}{3}$ marcs troy of Holland, 100 marcs of Holland = 103 of Venice. In Venice they alſo uſe a *peſo groſſo* and *peſſo ſottile*. 100 lbs. peſo groſſo = $94\frac{4}{7}$ commerical lbs. of Amſterdam. 100 lbs. peſo ſottile = $61\frac{2}{7}$ ditto.

7. *Swediſh Weights.*—The marc for weighing gold and ſilver is equal to 16 lods, 64 quentins, or 4384 as. The pound of 32 lods, uſed for weighing food, is equal, according to Tillet, to 1 marc, 5 ounces, 7 gros, 8 grains French, which makes $8848\frac{1}{2}$ as troy of Holland. This anſwers exactly to the weight of the different pounds, as fixed in Sweden, viz. 8848 as = the pound for weighing articles of food; $7821\frac{79}{125}$ as = marc uſed in the mines; $7450\frac{2}{125}$ as = marc uſed in towns and in the country; $7078\frac{2}{5}$ as = marc uſed for weighing iron; 7416 as = pound uſed in medicine.

The ſkippund	= 400 lbs. for weighing food.
The centner	= 120 lbs.
The waag	= 165 lbs.
The ſten	= 32 lbs.
The Swediſh as	= 1 as of Holland troy.

8. *German Weights.—Vienna.* The marc of Vienna for weighing gold and ſilver is divided into 16 loths, 64 quintals, or 256 deniers or pfenings; the loth into 4 quintals, or 16 pfenings. This marc, according to Tillet, is equal to 1 marc, 1 ounce, 1 gros, 16 grains, French, = 5831 as troy Holland. The pound of Vienna is divided into 2 marcs, or 4 viertings; the marc into 8 ounces, 16 loths, 64 quintals, or 266 pfenings.

Hamburgh. The marc for eſſaying gold is divided into 24 carats; the carat into 12 grains. The marc for ſilver is divided into 16 loths, and the loth into 18 grains. Theſe marcs conſiſt each of 288 grains, and are therefore equal. This marc, uſed in Hamburgh for gold and ſilver, is the marc of Cologne, which is equal, according to Tillet, to 7 ounces, 5 gros, $7\frac{3}{4}$ grains, French, = 4866 as troy of Holland. It is divided into 8 ounces, 16 loths, 64 quentins, 256 pfenings, 4352 eſches, or 65536 richt pfenings theile. The apothecary pound uſed in Hamburgh, and almoſt all Germany, is divided into 12 ounces, 96 drachms, 288 ſcruples, or 5760 grains; an ounce is equal to 621 as of Holland. The pound of commerce is equal, according to Tillet, to 10085 as of Holland; for half a pound is equal to 7 ounces, 7 gros, 23 grains, French. This pound is divided into 16 ounces, 32 loths, 128 quentins, or 512 pfenings.

9. *Ruſſian Weights.*—The berckowitz = 400 lbs.

The pound - - -	= 40 lbs.

The pound is divided into 32 loths, or 96 ſolotnuks. One hundred Ruſſian lbs. = $166\frac{1}{2}$ marcs, or $82\frac{4}{5}$ lbs. of Amſterdam. One hundred lbs. of commerce of Amſterdam = $120\frac{3}{4}$th lbs. of Ruſſia.

10. *Weights uſed in the ſeveral parts of Aſia, the Eaſt Indies, China, Perſia,* &c.----In Turkey, at Smyrna, &c. they uſe the batman, or battemant, containing $7\frac{1}{2}$ occos; the occo contains 4 chekys or pounds, each of which, according to Tillet, is equal to 1 marc 2 oz. 3 gros. 28 gr. French. The Turkiſh weights are divided as follows:

Cantaras.	Batmans.	Occos.	Rotolos.	Chekis.	Meſcals.	Drachms.
1 =	$7\frac{1}{2}$ =	44 =	100 =	176 =	$11733\frac{1}{3}$ =	17600
	1 =	6 =	$13\frac{7}{11}$ =	24 =	1600 =	2400
		1 =	$2\frac{3}{11}$ =	4 =	$266\frac{2}{3}$ =	400
			1 =	$1\frac{9}{11}$ =	$117\frac{1}{3}$ =	176
				1 =	$66\frac{2}{3}$ =	100
					1 =	$1\frac{1}{2}$

Weight. At Aleppo there are three ſorts of rottos; the firſt 720 drachms, making about 7 pounds Engliſh, and ſerving to weigh cottons, galls, and other large commodities; the ſecond is 680 drachms, uſed for all ſilks but white ones, which are weighed by the third rotto of 700 drachms. At Seyda the rotto is 600 drachms.

The other ports of the Levant not named here, uſe ſome of theſe weights; particularly the occa, or ocqua, the rottoli, and rotto.

The Chineſe weights are the piece for large commodities; it is divided into 100 catis, or cattis; though ſome ſay into 125; the cati into 16 taels, or tales; each tael equivalent to $1\frac{1}{3}$ of an ounce Engliſh, or the weight of 1 rial and $\frac{1}{12}$, and containing 12 mas, or maſſes, and each mas 10 condrins. So that the Chineſe piece amounts to 137 pounds Engliſh avoirdupois, and the cadi to 1 pound 8 ounces. The picol for ſilk containing 66 catis and $\frac{3}{4}$; the bahar, bakaire, or bar, containing 300 catis.

Tonquin has alſo the ſame weights, meaſures, &c. as China. Japan has only one weight, viz. the cati; which, however, is different from that of China, as containing 20 taels. At Surat, Agra, and throughout the ſtates of the Great Mogul, they uſe the man, or maund, whereof they have two kinds; the king's man, or king's weight; and the man ſimply; the firſt uſed for the weighing of common proviſions, containing 40 ſeers, or ſerres; and each ſeer a juſt Paris pound. The common man, uſed in the weighing of merchandiſe, conſiſts likewiſe of 40 ſeers, but each ſeer is only eſtimated at 12 Paris ounces, or $\frac{3}{4}$ of the other ſeer.

The man may be looked upon as the common weight of the Eaſt Indies, though under ſome difference of name, or rather of pronunciation; it being called *mao* at Cambaya, and in other places *mein*, and *maun*. The ſeer is properly the Indian pound, and of univerſal uſe; the like may be ſaid of the bahar, tael and catti, above mentioned.

The weights of Siam are the piece, containing two ſhans or cattis; but the Siameſe catti is only half the Japaneſe, the latter containing 20 taels, and the former only 10; though ſome make the Chineſe catti only 16 taels, and the Siameſe 8. The tael contains 4 baats or ticals, each about a Paris ounce; the baat 4 ſelings or mayons: the mayon 2 ſouangs; the ſouang 4 payes; the paye 2 clams; the ſompaye half a ſouang.

It is to be obſerved that theſe are the names of their coins as well as weights; ſilver and gold being commodities there ſold, as other things, by their weights.

In the iſle of Java, and particularly at Bantam, they uſe the gantan, which amounts to near three Dutch pounds. In Golconda, at Viſapour, and Goa, they have the ſuratelle, containing 1 pound 14 ounces Engliſh; the mangalis, or mangelin, for weighing diamonds and precious ſtones, weighing at Goa 5 grains, at Golconda, &c. $5\frac{1}{2}$ grains. They have alſo the rotolo, containing $14\frac{1}{4}$ ounces Engliſh; the metricol, containing the ſixth part of an ounce; the wall for piaſtres and ducats, containing the 73d part of a rial.

In Perſia they uſe two kinds of batmans or mans; the one called *cahi* or *cheray* which is the king's weight, and the other *batman of Tauris*. The firſt weighs 13 pounds 10 ounces Engliſh; the ſecond $6\frac{1}{2}$ pounds. Its diviſions are the ratel, or a 16th; the Derhem, or drachm, which is the 50th; the meſchal, which is half the derhem; the dung, which is the 6th part of the meſchal, being equivalent to 6 caret grains; and, laſtly, the grain, which is the fourth part of the dung. They have alſo the vakie, which exceeds, a little, our ounce; the ſah-cheray, equal to the 1170th part of the derhem; and the toman, uſed to weigh out large payments of money without telling; its weight is that of 50 abaſſis.

11. *Weights at Cairo in Egypt.*—Almoſt every kind of goods has its own weight; theſe are regulated by the cantaren or principal weight. Weight.

	Rotels.
The ordinary cantaren, or hundred weight, weighs	100
The cantaren of quickſilver and tin	102
coffee, wine, and iron	105
ivory	100
almonds and other fruits	115
woods for dying	120
arſenic and other drugs	125
minium and cinnabar	130
gum-arabic, aloes, and other aromatics	133

The rotel or rotoli is nearly equal to the pound of Marſeilles; 108 lbs. of Marſeilles are equal to 110 rotels. The Marſeilles pound conſiſts of 13 ounces of Paris; ſo that 100 lbs. of Marſeilles are equal to 81. lbs. Paris, and 100 lbs. Paris = 123 lbs. of Marſeilles.

We ſhall here ſubjoin Mr Ferguſon's table for comparing the Engliſh avoirdupois pound with foreign pounds:

London pound	1.0000	Hamburgh	1.06865
Antwerp	1.04	Liſbon	1.135
Amſterdam	1.1111	Leghorn	0.75
Abeville	1.0989	Norimberg	1.1363
Ancona	0.78	Naples	0.71
Avignon	0.8928	Paris	1.1235
Bourdeaux	1.0989	Prague	1.2048
Bologna	0.8	Placentia	0.72
Bruges	1.0204	Rochelle	0.8928
Calabria	0.73	Rome	0.7874
Calais	0.9345	Rouen	1.1089

Geneva	1.07	Vienna	1.23
Genoa, groſs	0.7		

Ferguſon's Tables and Tracts.

In order to ſhow the proportion of the ſeveral weights uſed throughout Europe, we ſhall add a reduction of them to one ſtandard, viz. the London pound.

The 100 lb. of England, Scotland, and Ireland, are equal to

lb.	oz.	
91	8	of Amſterdam, Paris, &c.
96	8	of Antwerp or Brabant.
88	0	of Rouen, the viſcounty weight.
106	0	of Lyons, the city weight.
90	9	of Rochelle,
107	11	of Tholouſe and Upper Languedoc.
113	0	of Marſeilles or Provence.
81	7	of Geneva.
93	5	of Hamburgh.
89	7	of Francfort, &c.
96	1	of Leipſic, &c.
137	4	of Genoa.
132	11	of Leghorn.
153	11	of Milan.
152	0	of Venice.
154	10	of Naples.
97	0	of Seville, Cadiz, &c.
104	13	of Portugal.
96	5	of Leige.
112	$\frac{1}{3}$	of Ruſſia.
107	$\frac{1}{24}$	of Sweden.
89	$\frac{1}{2}$	of Denmark.

A curious weighing machine was ſome time ago invented by M. Hanin of Paris, whereby the weights of the principal coun-

Weight. countries in Europe, and all the relative proportions they bear to each other, are ſhown at one view. For this he received a bounty of 20 guineas from the Society inſtituted at London, for the Encouragement of Arts, Manufactures, and Commerce. We ſhall inſert a deſcription and figure of this ingenious machine.

Plate CXXXVIII. Figure 1. repreſents the back of the machine, which being ſuſpended by the ring A, and a weight hung to the hook B, the ſpring C, C, C, made faſt by ſtrong ſcrews at *g*, is drawn downwards; and the bar D, having a rack thereon at *e*, turns the pinion *f*, in proportion to the weight of the body hanging thereto. Figure 2. ſhows the face of the machine, on which are a number of concentric circles, and the weights of ſeveral countries of Europe engraved thereon, as expreſſed by the words in a line with them. In the centre of this face is a ring fixed to the ſmall plate, turned by the pinion *f*, ſhown at figure 1. From this ring a hand projects, which, by the turning of the pinion, points to ſuch part of the circle as is marked with the weight, hung to the hook B; and thereby ſhows what weight of any of the countries mentioned, is equal to the pounds troy of London, which are engraved on the outer circle, or to the pounds avoirdupois, which are engraved on the ſecond circle, and ſo of the reſt. A ſlider moves on the hand, which may be brought to any of the circles at pleaſure, in order to point out the relative weight with greater preciſion.

Many attempts have been made to introduce an uniformity of weights and meaſures into the commercial world; but hitherto they have all failed. The accompliſhment of ſuch an undertaking would be of infinite advantage to mankind, and certainly claims the moſt ſerious attention of thoſe who by their ſituation can alone bring it about. The undertaking is indeed difficult, but ſurely not impoſſible. Something of this kind has lately been attempted in France; and if it ſucceed, as the method is ſimple, and exceedingly well adapted for calculation, it ſurely deſerves to be imitated. See *Revolution of France*.

Weight of Air, See Pneumatics, n° 14—19.

Regulation of Weights and Meaſures, is a branch of the king's prerogative. See Prerogative and Measure.

As weight and meaſure are things in their nature arbitrary and uncertain, it is therefore expedient that they be reduced to ſome fixed rule or ſtandard: which ſtandard it is impoſſible to fix by any written law or oral proclamation; for no man can, by words only, give another an adequate idea of a foot rule, or a pound weight. It is therefore neceſſary to have recourſe to ſome viſible, palpable, material ſtandard; by forming a compariſon with which all weights and meaſures may be reduced to one uniform ſize; and the prerogative of fixing this ſtandard, our ancient law veſted in the crown, as in Normandy it belonged to the duke. This ſtandard was originally kept at Wincheſter: and we find in the laws of king Edgar near a century before the conqueſt, an injunction that the one meaſure, which was kept at Wincheſter, ſhould be obſerved throughout the realm. Moſt nations have regulated the ſtandard of meaſures of length by compariſon with the parts of the human body; as the palm, the hand, the ſpan, the foot, the cubit, the ell (*ulna* or arm), the pace, and the fathom. But as theſe are of different dimenſions in men of different proportions, our ancient hiſtorians inform us, that a new ſtandard of longitudinal meaſure was aſcertained by king Henry the Firſt; who commanded that the *ulna*, or ancient ell, which anſwers to the modern yard, ſhould be made of the exact length of his own arm. And one ſtandard of meaſure of length being gained, all others are eaſily derived from thence; thoſe of greater length by multiplying, thoſe of leſs by dividing, that original ſtandard. Thus, by the ſtatute called *compoſitio ulnarum et perticarum*, five yards and an half make a perch; and the yard is ſubdivided into three feet, and each foot into 12 inches; which inches will be each of the length of three grains of barley. Superficial meaſures are derived by ſquaring thoſe of length; and meaſures of capacity by cubing them. The ſtandard of weights was originally taken from corns of wheat, whence the loweſt denomination of weights we have is ſtill called a *grain*; 32 of which are directed, by the ſtatute called *compoſitio menſurarum*, to compoſe a pennyweight, whereof 20 make an ounce, 12 ounces a pound, and ſo upwards. And upon theſe principles the firſt ſtandards were made; which, being originally ſo fixed by the crown, their ſubſequent regulations have been generally made by the king in parliament. Thus, under king Richard I. in his parliament holden at Weſtminſter, A. D. 1197, it was ordained that there ſhould be only one weight and one meaſure throughout the kingdom, and that the cuſtody of the aſſize, or ſtandard of weights and meaſures, ſhould be committed to certain perſons in every city and borough: from whence the ancient office of the king's aulnager ſeems to have been derived, whoſe duty it was, for a certain fee, to meaſure all cloths made for ſale, till the office was aboliſhed by the ſtatute 11th and 12th William III. c. 20. In king John's time, this ordinance of king Richard was frequently diſpenſed with for money; which occaſioned a proviſion to be made for enforcing it, in the great charters of king John and his ſon. Theſe original ſtandards were called *pondus regis*, and *menſura domini regis*, and are directed by a variety of ſubſequent ſtatutes to be kept in the exchequer chamber, by an officer called the *clerk of the market*, except the wine gallon, which is committed to the city of London, and kept in Guildhall.

The *Scottiſh* ſtandards are diſtributed among the oldeſt boroughs. The elwand is kept at Edinburgh, the pint at Stirling, the pound at Lanark, and the firlot at Linlithgow.

Various ſtatutes have been enacted for regulating and enforcing an uniformity of weights and meaſures; and by the articles of union, the Engliſh ſtandards are eſtabliſhed by law over all Great Britain. But the force of cuſtom is ſo ſtrong, that theſe ſtatutes have been ill obſerved. The Scottiſh ſtandards are ſtill univerſally retained for many purpoſes; and likewiſe a variety of local weights and meaſures are uſed in particular places in both countries, which differ from the general ſtandards of either.

WELD, or Wold, in botany. See Reseda.

WELDING-heat, in ſmithery, a degree of heat given to iron, &c. ſufficient to make the ſurfaces of two pieces incorporate upon being beaten together with a hammer.

WENMANNIA, in botany: A genus of plants of the claſs *octandria*, order *monogynia*, and arranged in the natural claſſification with thoſe plants, the order of which is doubtful. The calyx is four-leaved, the corolla has four petals, and the capſule is bilocular and biroſtrated. There are four ſpecies, none of which are natives of Britain.

WELL, a hole under ground, uſually of a cylindrical figure, and walled with ſtone and mortar: its uſe is to collect the water of the ſtrata around it.

Well, an apartment formed in the middle of a ſhip's hold to incloſe the pumps, from the bottom to the lower deck. It is uſed as a barrier to preſerve thoſe machines from being damaged by the friction or compreſſion of the materials contained in the hold, and particularly to prevent the entrance of ballaſt, &c. by which the tubes would preſently be choked, and the pumps rendered incapable of ſervice. By means of this encloſure, the artificers may likewiſe more readily deſcend into the hold, in order to examine

Weight ‖ Well.

Well and Werturian.

amine the ſtate of the pumps, and repair them as occaſion requires.

Well-room of a Boat, the place in the bottom where the water lies, between the ceiling and the platform of the ſtern-ſheets, whence it is thrown out into the ſea with a ſcoop.

Burning-Well. See *Burning-Springs*.

Well of a Fiſhing-veſſel, an apartment in the middle of the hold, which is entirely detached from the reſt, being lined with lead on every ſide, and having the bottom thereof penetrated with a competent number of ſmall holes, paſſing alſo through the ſhip's floor; ſo that the ſalt-water running into the well is always kept as freſh as that in the ſea, and yet prevented from communicating itſelf to the other parts of the hold.

Well-hole, in building, is the hole left in a floor for the ſtairs to come up through.

WELLS, a city of Somerſetſhire, and ſee of a biſhop; the biſhop of Bath being alſo that of Wells.—It is ſuppoſed to take its name from the many ſprings and wells that are near it. It is not very large; but is adorned with handſome buildings, both public and private. Its cathedral is a very beautiful ſtructure, adorned with images and carved ſtone work. The biſhop's palace joins to the cathedral; and on the other ſide are the houſes for the prebendaries. In the market-place is a fine market-houſe, ſupported by pillars. It is governed by a mayor, and ſends two members to parliament. The chief manufacture is knit hoſe. W. Long. 2. 37. N. Lat. 51. 12.

WEN, a tumor or excreſcence ariſing on different parts of the body, and containing a cyſtus or bag filled with ſome peculiar kind of matter. See Nævus.

WEREGILD, the price of *homicide*; paid partly to the king for the loſs of a ſubject, partly to the lord whoſe vaſſal he was, and partly to the next of kin of the perſon ſlain.

WERST, Wurst, or *Verſt*, a Ruſſian meaſure equal to 3500 Engliſh feet. A degree of a great circle of the earth contains about 104 werſts and a half.

WERTURIAN or *Uralian Mountains*, a famous chain of mountains forming part of the boundary of Aſia. It begins diſtinctly (for it may be traced interruptedly farther ſouth) near the town of Kungur, in the goverment of Kaſan, in latitude 57. 20.; runs north, and ends oppoſite to the Waygatz ſtraight, and riſes again in the iſle of *Nova Zemlja*. The Ruſſians alſo call this range *Semennoi Poias*, or, *the girdle of the world*; from a ſuppoſition that it encircled the univerſe. Theſe were the *Riphæi montes: Pars mundi damnata a natura rerum, et denſa merſa caligine* §; of which only the ſouthern part was know to the ancients, and that ſo little as to give riſe to numberleſs fables. Beyond theſe were placed the happy *Hyperborei*, a fiction moſt beautifully related by Pomponius Mela. Moderns have not been behind-hand in exaggerating ſeveral circumſtances relative to theſe noted hills. Yſbrand Ides, who croſſed them in his embaſſy to China, aſſerts that they are 5000 toiſes or fathoms high; others, that they are covered with eternal ſnow. The laſt may be true in their more northern parts; but in the uſual paſſages over them, they are free from it three or four months.

§ Plinii, Hiſt. Nat. lib. iv. cap. 12.

The heights of part of this chain have been taken by M. l'Abbé d'Auteroche: who, with many aſſurances of his accuracy, ſays, that the height of the mountain Kyria near Solikamſkaia, in latitude 60°, does not exceed 471 toiſes from the level of the ſea, or 286 from the ground on which it ſtands. But, according to M. Gmelin, the mountain Pauda is much higher, being 752 toiſes above the ſea. From Peterſburg to this chain is a vaſt plain, mixed with certain elevations or platforms, like iſlands in the midſt of an ocean. The eaſtern ſide deſcends gradually to a great diſtance into the wooded and moraſſy Siberia, which forms an immenſe inclined plane to the Icy Sea. This is evident from all the great rivers taking their riſe on that ſide, ſome at the amazing diſtance of latitude 46°; and, after a courſe of above 27 degrees, falling into the Frozen Ocean, in latitude 73. 30. The Yaik alone, which riſes near the ſouthern part of the eaſtern ſide, takes a ſouthern direction, and drops into the Caſpian Sea. The Dwina, the Peczora, and a few other rivers in European Ruſſia, ſhew the inclined plane of that part. All of them run to the Northern Sea; but their courſe is comparatively ſhort. Another inclination directs the Dnieper and the Don into the Euxine, and the vaſt Wolga into the Caſpian Sea.

Weſley.

WESLEY (John), one of the moſt extraordinary characters that ever exiſted; whether we conſider him as a various and voluminous writer, a zealous and indefatigable preacher, or the founder of the moſt numerous ſect in the Chriſtian world; was the ſon of the Reverend Samuel Weſley, rector of Epworth in the iſle of Axholme in Lincolnſhire, and was born in that village in the year 1703. His very infancy was diſtinguiſhed by an extraordinary incident. The parſonage-houſe at Epworth was burnt to the ground, and the flames had ſpread with ſuch rapidity, that few things of value could be ſaved. His mother, in a letter to her ſon Samuel Weſley, then on the foundation at Weſtminſter ſchool, thanks God that no lives were loſt, although for ſome time they gave up *Poor Jacky*, as ſhe expreſſes herſelf; for his father had twice attempted to reſcue the child, but was beaten back by the flames. Finding all his efforts ineffectual, he reſigned him to Divine Providence. But parental tenderneſs prevailed over human fears, and Mr Weſley once more attempted to ſave his child. By ſome means equally unexpected and unaccountable, the boy got round to a window in the front of the houſe, and was taken out, by one man's leaping on the ſhoulders of another, and thus getting within his reach. Immediately on his reſcue from this very perilous ſituation the roof fell in. This extraordinary eſcape explains a certain device, in a print of Mr John Weſley, engraved by Vertue, in the year 1745, from a painting by Williams. It repreſents a houſe in flames, with this motto from the prophet, "Is he not a brand plucked out of the burning?" Many have ſuppoſed this device to be merely emblematical of his ſpiritual deliverance; but from this circumſtance it is apparent that it has a primary as well as a ſecondary meaning; it is real as well as alluſive. This fire happened when Mr Weſley was about ſix years old.

In the year 1713 he was entered a ſcholar at the charter-houſe in London, where he continued ſeven years under the tuition of the celebrated Dr Walker, and of the Reverend Andrew Took author of The Pantheon. Being elected to Lincoln college, Oxford, he became a fellow of that college about the year 1725, took the degree of Maſter of Arts in 1726, and was joint tutor with the Reverend Dr Hutchins the rector. He diſcovered very early an elegant turn for poetry. Some of his gayer poetical effuſions are proofs of a lively fancy and a fine claſſical taſte; and ſome tranſlations from the Latin poets, while at college, are allowed to have great merit. He had early a ſtrong impreſſion, like Count Zinzendorf, of his deſignation to ſome extraordinary work. This impreſſion received additional force from ſome domeſtic incidents; all which his active fancy turned to his own account. His wonderful preſervation, already noticed, naturally tended to cheriſh the idea of his being deſigned by Providence to accompliſh ſome purpoſe or other, that was out of the ordinary courſe of human events. The late Reverend

Wesley. Samuel Badcock, in a letter inserted in the Bibliotheca Topographica Britannica, N° XX. says, "There were some strange phenomena perceived at the parsonage at Epworth, and some uncommon noises heard there from time to time, which he was very curious in examining into, and very particular in relating. I have little doubt that he considered himself the chief object of this wonderful visitation. Indeed his father's credulity was in some degree affected by it; since he collected all the evidences that tended to confirm the story, arranged them with scrupulous exactness, in a manuscript consisting of several sheets, and which is still in being. I know not what became of the ghost of Epworth; unless, considered as the prelude to the noise Mr John Wesley made on a more ample stage, it ceased to speak when he began to act."

"The dawn of Mr Wesley's public mission (continues Mr Badcock) wasclouded with mysticism; that species of it which affects silence and solitude; a certain inexplicable introversion of the mind, which abstracts the passions from all sensible objects; and, as the French Quietists express it, perfects itself by an absorption of the will and intellect, and all the faculties, into the Deity." In this *palpable obscure* the excellent Fenelon led himself when he forsook the shades of Pindus, to wander in quest of *pure love* with Madam Guyon! Mr Wesley pursued for a while the same *ignis fatuus* with Mr William Law and the Ghost of De Renty. A state, however, so torpid and ignoble, ill-suited the active genius of this singular man. His elastic mind gained strength by compression; thence bursting glorious, he passed (as he himself somwhere says) "the immense chasm, upborne on an eagle's wings."

The reading of the writings of this Mr William Law, the celebrated author of Christian Perfection, and of A Serious Address to the Christian World, contributed moreover, to lead Mr John Wesley and his brother Charles, with a few of their young fellow-students, into a more than common strictness of religious life. They received the sacrament of the Lord's Supper every week; observed all the fasts of the church; visited the prisons; rose at four in the morning; and refrained from all amusements. From the exact method in which they disposed of every hour, they acquired the appellation of *Methodists*; by which their followers have been ever since distinguished.

But a more particular account of the origin of this sect, we shall give from a celebrated publication. "The Methodists (says the editor of this work) form a very considerable class, principally of the lower people in this country. They sprung up about fifty years ago at Oxford, and were soon divided into two parties; the one under the direction of Mr George Whitfield, and the other under that of two brothers, John and Charles Wesley. These leaders, and, if we except Mr William Law, founders of the Methodists, were educated at Oxford, received episcopal ordination, and always professed themselves advocates for the articles and liturgy of the established church; though they more commonly practised the dissenting mode of worship. But conceiving a design of forming separate communities, superior in sanctity and perfection to all other Christian churches, and impressed to a very considerable degree by a zeal of an extravagant and enthusiastic kind, they became itinerant preachers; and, being excluded from most of our churches, exercised their ministry in private houses, fields, &c. not only in Great Britain and Ireland, but also in America; thus collecting a very considerable number of hearers and proselytes, both among the members of the established church and the dissenters. The theological system of Mr Whitfield and his followers is Calvinistic; that of Mr Wesley and his disciples Arminian; and the latter maintains the possibility of attaining sinless perfection in the present state. Wesley. The subordinate teachers of both these classes of Methodists are generally men of no liberal education; and they pretend to derive their ministerial abilities from special communications of the spirit. The Methodists of both parties, like other enthusiasts, make true religion to consist principally in certain affections and inward feelings which it is impossible to explain; but which, when analysed, seem to be mechanical in their spring and operation; and they generally maintain, that Christians will be most likely to succeed in the pursuit of truth, not by the dictates of reason, or the aids of learning, but by laying their minds open to the direction and influence of divine illumination: and their conduct has been directed by impulses."

Our readers will judge for themselves, according to their various modes of education, and to the different lights in which they may respectively view the doctrines of our common Christianity, whether this representation of the origin of the Methodists, and of their distinguishing tenets, be accurate and just.—Not presuming to sit in judgment on the religious opinions of any man, we shall only observe, that an appellation originally given in reproach, has been gloried in ever since by those who have distinguished themselves as the followers either of Mr Whitfield or of Mr Wesley. "After the way called *Methodism*, so worship they the God of their fathers." But the ridicule and contempt which the singularity of their conduct produced, both John and Charles Wesley were well qualified to bear. They were not to be intimidated by danger, actuated by interest, or deterred by disgrace.

The boundaries of this island were soon deemed by Mr Wesley too confined for a zeal which displayed the piety of an apostle; and of an intrepidity to which few missionaries, had been superior. In 1735 he embarked for Georgia, one of the colonies, which was at that time in a state of political infancy; and the great object of this voyage was to preach the gospel to the Indian nations in the vicinity of that province. He returned to England in 1737. Of his spiritual labours, both in this country and in America, he himself has given a very copious account, in a series of Journals, printed at different periods. These journals drew upon our laborious preacher and his coadjutors some severe animadversions from two right reverend prelates; Dr George Lavington bishop of Exeter, and Dr William Warburton bishop of Gloucester. The former published in three parts, The Enthusiasm of the Methodists and Papists compared; the third part of this performance containing a personal charge of immoral conduct. Mr Wesley, in his vindication, published a letter to his Lordship, which produced a reply from the latter.

Bishop Warburton's attack is contained in his celebrated treatise, entitled the Doctrine of Grace: or, The office and Operations of the Holy Spirit, vindicated from the Insults of Infidelity, and the abuses of Fanaticism: concluding with some thoughts, humbly offered to the consideration of the Established Clergy, with regard to the Right Method of defending Religion against the Attacks of either Party; 2 vols, small 8vo, 1762. There is much acute reasoning, and much poignant and sprightly wit, in his Doctrine of Grace; but there is too much levity in it for a grave bishop, and too much abuse for a candid Christian. On this occasion, Mr Wesley published a letter to the bishop, in which, with great temper and moderation, as well as with great ingenuity and address, he endeavoured to shelter himself from his Lordship's attacks; not only under the authority of the Holy Scriptures, but of the church itself, as by law established.

On his return from Georgia, Mr Wesley paid a visit to

Count

Wesley, Weſt.

Count Zinzendorf, the celebrated founder of the ſect of Moravians or Hernhutters, at Hernuth in Upper Luſatia. In the following year he appeared again in England, and with his brother Charles, at the head of the Methodiſts. He preached his firſt field-ſermon at Briſtol, on the 2d of April 1738, from which time his diſciples have continued to increaſe. In 1741, a ſerious altercation took place between him and Mr Whitfield. In 1744, attempting to preach at an inn at Taunton, he was regularly ſilenced by the magiſtrates. Although he chiefly reſided for the remainder of his life in the metropolis, he occaſionally travelled through every part of Great Britain and Ireland, eſtabliſhing congregations in each kingdom. In 1750 he married a lady, from whom he was afterwards ſeparated. By this lady, who died in 1781, he had no children.

We have already mentioned Mr Weſley as a very various and voluminous writer. Divinity, both devotional and controverſial, biography, hiſtory, philoſophy, politics, and poetry, were all, at different times, the ſubjects of his pen: and, whatever opinion may be entertained of his theological ſentiments, it is impoſſible to deny him the merit of having done very extenſive good among the lower claſſes of people. He certainly poſſeſſed great abilities, and a fluency which was well accommodated to his hearers, and highly acceptable to them. He had been gradually declining for three years before his death; yet he ſtill roſe at four in the morning, and preached, and travelled, and wrote as uſual. He preached at Leatherhead, in Surrey, on the Wedneſday before that event. On the Friday following, appeared the firſt ſymptoms of his approaching diſſolution. The four ſucceeding days he ſpent in praiſing God; and he left this ſcene, in which his labours had been ſo extenſive and ſo uſeful, at a quarter before ten in the morning of the 2d of March 1791, in the 88th year of his age. His remains, after lying in a kind of ſtate at his chapel in the city-road, dreſſed in the ſacerdotal robes which he uſually wore, and on his head the old clerical cap, a bible in one hand, and a white handkerchief in the other, were, agreeable to his own directions, and after the manner of the interment of the late Mr Whitfield, depoſited in the cemetry behind his chapel, on the morning of the 9th March, amid an innumerable concourſe of his friends and admirers; many of whom appeared in deep mourning on the occaſion. One ſingularity was obſervable in the funeral ſervice. Inſtead of, "We give thee hearty thanks, for that it hath pleaſed thee to deliver this our brother;" it was read "our father." A ſermon, previouſly to the funeral, had been preached by Dr Thomas Whitehead, one of the phyſicians to the London hoſpital; and on the 13th the different chapels of his perſuaſion in London were hung with black.

It has been juſtly obſerved of Mr Weſley, that his labours were principally devoted to thoſe who had no inſtructor; to the highways and hedges; to the miners in Cornwall, and the coalliers in Kingſwood. Theſe unhappy creatures married and buried among themſelves, and often committed murders with impunity, before the Methodiſts ſprung up. By the humane and active endeavours of Mr Weſley and his brother Charles, a ſenſe of decency, morals, and religion, was introduced into the loweſt claſſes of mankind; the ignorant were inſtructed, the wretched relieved, and the abandoned reclaimed. His perſonal influence was greater, perhaps, than that of any other private gentleman in any country.---But the limits of this article will not permit us to expatiate further on the character of this extraordinary man.

WEST (Gilbert), was the ſon of Dr Weſt, prebendary of Winchеſter, and chaplain to king George I. but at 12 years of age loſt his father. He ſtudied at Winchеſter and Eton ſchools, and from thence was placed in Chriſt-church college, Oxford. His ſtudious and ſerious turn inclined him to take orders; but lord Cobham, his uncle, diverted him from that purſuit, and gave him a cornetcy in his own regiment. This profeſſion he ſoon quitted, on account of an opening of another nature, which preſented him with a flattering proſpect of advancement in life. A number of young gentlemen were to be elected from the univerſities, and, at the expence of the government, were to be taught foreign languages; and then ſent to the ſecretaries office, to be initiated into buſineſs, and trained there for public ſervices, as envoys, ambaſſadors, &c. Mr Gilbert Weſt was one of the few pitched upon; and on his firſt introduction into that office, lord Townſend, ſecretary of ſtate, treated him with ſingular marks of regard, and the ſtrongeſt inclinations to ſerve him were teſtified from all quarters. But his uncle lord Cobham's ſtrong oppoſition to the meaſures of the government, rendered theſe advantages entirely fruitleſs; and the miniſters honeſtly told Mr Weſt, that he muſt not expect them to diſtinguiſh his merit, as any favours conferred upon him would be imputed as done to his uncle lord Cobham. Mr Weſt now left that office, and all his views of making his fortune; and entering into marriage, retired to Wickham in Kent, where he lived in great domeſtic comfort and tranquil happineſs. He was there viſited by his valuable friends, who held the moſt delightful converſe of wit, humour, and learning, ſupported upon the principles of virtue, ſound reaſoning, and ſolid friendſhip, which rendered the whole cheerful, animating, and inſtructive. Mr William Pitt, who was one of thoſe that compoſed this happy ſociety, becoming paymaſter, appointed Mr Weſt treaſurer to Chelſea-hoſpital; and he obtained a ſeat at the council-board, in conſequence of a friendſhip contracted at ſchool with one of the duke of Devonſhire's ſons, who procured of his grace his being nominated one of the clerks extraordinary of that office. Towards the latter part of Mr Weſt's life, he wholly applied himſelf to the ſtudy of the Scriptures; being extremely anxious to try his utmoſt endeavours to reconcile the ſeeming inconſiſtencies which gave the enemies to revealed religion a handle to doubt and diſcredit their authenticity. His obſervations on the reſurrection, which, it has been ſaid, were written to confirm the wavering faith of his great friends Pitt and Lyttleton, bear ample teſtimony to his reaſoning powers and the ſincerity of his religion; while his tranſlations of Pindar ſhow him to have been an eminent Greek ſcholar, and very conſiderable poet. He had a mind replete with virtue, and was an honour to his country; but died at 50 years of age.

Weſt. Weſtminſter.

WEST, one of the cardinal points of the horizon, diametrically oppoſite to the eaſt; and ſtrictly defined the interſection of the prime vertical with the horizon on that ſide the ſun ſets in.

WESTMINSTER, a city which forms the weſt part of the capital of Britain, but has a government diſtinct from the reſt. This city had its name from the ſituation of its abbey, anciently called a *minſter*, in reſpect of that of St Paul. That part properly called the city of Weſtminſter, comprehending the pariſhes of St John and St Margaret, was once an iſland formed by the Thames, called *Thorney iſland*, from the thorns with which it was over-run; and the abbey that ſtood in it, Thorney-abbey. The liberties of Weſtminſter contain the ſeveral pariſhes of St Martin in the Fields, St James's, St Anne, St Paul, Covent-garden, St Mary le Strand, St Clement, Danes, St George, Hanover Square, and the precinct of the Savoy. The government, both of the city and liberties, is under the juriſdiction of the dean and chapter of Weſtminſter, in civil as well as eccleſiaſtical affairs; and their authority extends

Weſtmoreland. Weſtphalia

to the precinct of St Martin le Grand, by Newgate-ſtreet, and in ſome towns of Eſſex, that are exempted from the juriſdiction of the biſhop of London and the archbiſhop of Canterbury; but the management of the civil part has, ever ſince the Reformation, been in the hands of laymen, elected from time to time, and confirmed by the dean and chapter. The chief of theſe laymen are the high-ſteward, the deputy-ſteward, and the high-bailiff, who hold their offices for life. There are alſo 16 burgeſſes and their aſſiſtants, out of which are elected two head-burgeſſes, one for the city, and the other for the liberties. Another officer is the high-conſtable, who has all the other conſtables under his direction.

WESTMORELAND, a county of England, bounded on the north and north-weſt by Cumberland; on the ſouth and ſouth-eaſt by Yorkſhire; and on the ſouth and ſouth-weſt by Lancaſhire. Its extent from north-eaſt to ſouth, is 40 miles, and its breadth from the eaſt projection to that in the weſt, 42. It is generally divided into the baronies of Kendal and Weſtmoreland: the former is very mountainous, but the latter is a large champaign country. Theſe are the only principal diviſions of this county, which contains 8 market-towns and 26 pariſhes. It lies partly in the dioceſe of Cheſter, and partly in that of Carliſle. The earl of Thanet is hereditary ſheriff of the county, which ſends only four members to parliament. The air is clear, ſharp, and ſalubrious, the natives being ſeldom troubled with diſeaſes, and generally living to old age. The ſoil is various; that on the mountains is very barren, while that in the valleys is fertile, producing good corn and graſs, eſpecially in the meadows near the rivers. In the hilly parts on the weſtern borders it is generally believed there are vaſt quantities of copper ore, and veins of gold; ſome mines of copper are worked, but moſt of the ore lies ſo deep that it will not anſwer the expence. This county yields the fineſt ſlate, and abundance of excellent hams are cured here. The principal rivers are, the Eden, the Lone, and the Ken. It has alſo ſeveral fine lakes, the principal of which is Winander Mere, or Windermere Water. In the foreſt of Martindale, to the ſouth of Ulls-water, the breed of red deer ſtill exiſts in a wild ſtate. Appleby is the county town.

WESTPHALIA, a duchy of Germany, bounded to the eaſt by the biſhopric of Paderborn, and the territories of Waldeck and Heſſe; to the ſouth by the counties of Witgenſtein and Naſſau, and the duchy of Berg; to the north by the biſhopric of Munſter and the county of Lippe. It is about 40 miles in length and 30 in breadth. The lower part of it is very fruitful, yielding plenty of corn and cattle, and ſome ſalt-ſprings. The higher affords iron-ore, calamine, lead, copper, ſome ſilver and gold, fine woods, cattle, game, fiſh, with a little corn. The rivers, that either paſs through the duchy or along its borders, are the Rahr, the Lenne, the Bigge, the Dimel, and the Lippe. There are 28 towns in it, beſides boroughs and cloiſters. The provincial diets are held at Arenſberg. In the year 1180, the emperor Fred. I. made a donation of this duchy to the archbiſhopric of Cologne, which was confirmed by ſucceeding emperors; and in 1638, the laſt duke of Arenſberg ceded to it alſo the county of Arenſberg. The duchy is governed at preſent by a bailiff, under the archbiſhop, and is divided into the Hellwege, the Haarſtrank, and the Surland; or otherwiſe into the Ruden, the Werl, the Bilſtein, and the Brilon quarters.

WESTPHALIA, one of the circles of Germany, anciently the people inhabiting between the Weſer and the Rhine, were called *Weſtphalians;* and hence that tract got the name of *Weſtphalia:* but the circle of that name is of a larger extent, being ſurrounded by the circle of Burgundy, or the Auſtrian Netherlands, the United Provinces, and the North Sea, with the circles of the Upper and Lower Rhine, and compriſing a great many different ſtates.

Wet ‖ Whale.

The ſummoning princes and directors of the circle of Weſtphalia, are the biſhops of Munſter, alternately with the electors of Brandenburg and Palatine, as dukes of Cleve and Juliers. The archives belonging to it were before the preſent war (1797) kept at Duſſeldorp. Its quota of men and money is ſomewhat more than the ninth part of the whole ſum granted by the empire. With reſpect to religion, it is partly Proteſtant and partly Catholic; but the Proteſtants predominate, and are, at leaſt the greater part of them, Calviniſts. The air of this country is not reckoned very wholeſome, and towards the north is extremely cold in winter. The ſoil in general is marſhy and barren; yet there is ſome good corn and paſture land: but the fruit is chiefly uſed to feed hogs; and hence it is that their bacon and hams are ſo much valued and admired.

WET COUCH, *coming heap*, a term uſed by the maltſters for one of the principal articles of malt-making. See BREWING, n° 4.

WETSTEIN (John James), a very learned German divine, born at Baſil in 1693. On his admiſſion to the miniſtry, he maintained a theſis *De variis Novi Teſtamenti Lectionibus;* in which he ſhowed that the great variety of readings of the New Teſtament afford no argument againſt the authenticity of the text. He had made theſe various readings the object of his attention; and travelled into foreign countries to examine all the MSS. he could come at. In 1730, he publiſhed *Prolegomena ad Novi Teſtamenti Græci editionem accuratiſſimam, &c.* Some divines, dreading his unſettling the preſent text, procured a decree of the ſenate of Baſil againſt his undertaking, and even got him prohibited from officiating in the miniſtry; on which he went to Amſterdam, where the Remonſtrants named him to ſucceed the famous Le Clerc, then ſupperannuated, as profeſſor of philoſophy and hiſtory. At laſt he publiſhed his edition of the New Teſtament, in 2 vols folio, 1752; in which he left the text as he found it, placing the various readings, with a critical commentary, underneath; ſubjoining two epiſtles of Clemens Romanus, till then unknown to the learned, but diſcovered by him in a Syriac MS. of the New Teſtament. He alſo publiſhed ſome ſmall works; and is ſaid to have been not only an univerſal ſcholar, but to have abounded in good and amiable qualities. He died at Amſterdam in 1754.

WETTERAVIA, the ſouthern diviſion of the Landgravate of Heſſe in Germany, lying along the northern bank of the river Maine, comprehending the counties of Hanau and Naſſau.

WEXFORD, a county of Ireland, in the province of Munſter, 38 miles in length, and 24 in breadth; bounded on the north by Wicklow, on the eaſt by St George's Channel, on the ſouth by the Atlantic Ocean, on the weſt by Waterford and Kilkenny, and on the north by Catherlough. It contains 109 pariſhes, and ſends 18 members to parliament. It is a fruitful country in corn and graſs; and the principal town is of the ſame name.

WEXFORD, a ſea-port of Ireland, capital of a county of the ſame name. It was once reckoned the chief city in Ireland, being the firſt colony of the Engliſh, and is ſtill a large handſome town, with a very commodious harbour at the mouth of the river Slana, on a bay of St George's Channel, 63 miles ſouth of Dublin. W. Long. 6. 3. N. Lat. 52. 18.

Whale-Fishery. See Fishery.

WHARF, a ſpace on the banks of a haven, creek, or hithe, provided for the convenient loading and unloading of veſſels.

WHARTON (Philip duke of), a nobleman of the moſt brilliant parts, but of the moſt whimſical, extravagant, and inconſiſtent turn of mind, was educated by his father's expreſs order at home. He very early married a young lady, the daughter of major-general Holmes, which diſappointed his father's views of diſpoſing of him in ſuch a marriage as would have been a conſiderable addition to the fortune and grandeur of his illuſtrious family; yet that amiable lady deſerved infinitely more felicity than ſhe met with by this alliance. This precipitate marriage is thought to have haſtened the death of his father; after which the duke, being free from paternal reſtraints, plunged into thoſe exceſſes which rendered him, as Pope expreſſes it,

"A tyrant to the wife his heart approv'd;
"A rebel to the very king he loved."

In the beginning of the year 1716, he began his travels; and as he was deſigned to be inſtructed in the ſtricteſt Whig principles, Geneva was thought a proper place for his reſidence. He firſt paſſed through Holland, and viſited ſeveral courts of Germany; and being arrived at Geneva, conceived ſuch a diſguſt againſt his governor, that he left him, and ſet out poſt for Lyons, where he wrote a letter to the chevalier de St George, who then reſided at Avignon, and preſented him a very fine ſtout horſe; which the chevalier no ſooner received than he ſent a man of quality to him, who took him privately to his court, where he was entertained with the greateſt marks of eſteem, and had the title of duke of Northumberland conferred upon him. He, however, remained there but one day, and then returned poſt to Lyons, whence he ſet out for Paris. He likewiſe paid a viſit to the conſort of James II. who then reſided at St Germains, to whom he alſo paid his court. During his ſtay at Paris, his winning addreſs and abilities gained him the eſteem and admiration of all the Britiſh ſubjects of rank of both parties.

About the latter end of December 1716, he arrived in England, whence he ſoon after ſet out for Ireland, where, though under age, he was allowed the honour to take his ſeat in the houſe of peers, and immediately diſtinguiſhed himſelf, notwithſtanding his former conduct, as a violent partizan for the miniſtry; in conſequence of which zeal the king created him a duke. He no ſooner came of age than he was introduced to the houſe of lords in England with the ſame blaze of reputation. In a little time he oppoſed the court, and appeared one of the moſt vigorous in defence of the biſhop of Rocheſter; and ſoon after printed his thoughts twice a-week, in a paper called the *True Briton*, ſeveral thouſands of which were diſperſed weekly.

The duke's boundleſs profuſion had by this time ſo burdened his eſtate, that by a decree of Chancery it was veſted in the hands of truſtees for the payment of his debts, allowing him a proviſion of L. 1200 *per annum* for his ſubſiſtence. This being not ſufficient to ſupport his title with ſuitable dignity, he went abroad and ſhone to great advantage, with reſpect to his perſonal character, at the imperial court. From thence he made a tour to Spain: the Engliſh miniſter was alarmed at his arrival, fearing that his grace was received in the character of an ambaſſador: upon which the duke received a ſummons under the privy-ſeal to return home; but inſtead of obeying it, he endeavoured to inflame the Spaniſh court againſt that of Great Britain, for exerciſing an act of power, as he calls it, within the juriſdiction of his Catholic majeſty. He then acted openly in the ſervice of the Pretender, and was received at his court with the greateſt marks of favour. Wharton.

While his grace was thus employed, his neglected ducheſs died in England on the 14th of April 1726, without iſſue. Soon after the duke fell violently in love with M. Oberne, one of the maids of honour to the queen of Spain, the daughter of an Iriſh colonel, whoſe fortune chiefly conſiſted in her perſonal accompliſhments. All his friends, and particularly the queen of Spain, oppoſed the match; but he falling into a lingering fever, occaſioned by his diſappointment, the queen gave her conſent, and they were ſoon after married. He then ſpent ſome time at Rome, where he accepted of a blue garter, aſſumed the title of duke of Northumberland, and for a while enjoyed the confidence of the exiled prince. But not always keeping within the bounds of Italian gravity, it became neceſſary for him to remove from hence; when, going by ſea to Barcelona, he wrote a letter to the king of Spain, acquainting him that he would aſſiſt at the ſiege of Gibraltar as a volunteer. Soon after he wrote to the chevalier de St George, expreſſing a deſire to viſit his court; but the chevalier adviſed him to draw near to England.

The duke ſeemed reſolved to follow his advice; and ſetting out with his ducheſs, arrived in Paris in May 1728, whence he ſoon after proceeded to Rouen, where he took up his reſidence; and was ſo far from making any conceſſion to the government of England, that he did not give himſelf the leaſt trouble about his eſtate, or any other concern there; though, on his arrival at Rouen, he had only about L.600 in his poſſeſſion, and a bill of indictment was preferred againſt him in England for high-treaſon. Soon after the chevalier ſent him L. 2000, which he ſquandered away in a courſe of extravagance; when, to ſave the charges of travelling by land, he went from Orleans to Nantz by water, and ſtaid there till he got a remittance from Paris, which was ſquandered almoſt as ſoon as received. At Nantz he was joined by his ragged ſervants, and from hence took ſhipping with them for Bilboa, when the queen of Spain took the ducheſs to attend her perſon. About the beginning of the year 1731, the duke, who commanded a regiment, was at Lerida, but declined ſo faſt that he could not move without aſſiſtance; yet when free from pain did not loſe his gaiety. He, however, received benefit from ſome mineral waters in Catalonia; but ſoon after relapſed at a ſmall village, where he was utterly deſtitute of all the neceſſaries of life, till ſome charitable fathers of a Bernardine convent removed him to their houſe, and gave him all the relief in their power. Under their hoſpitable roof he languiſhed a week, and then died, without one friend or acquaintance to cloſe his eyes, and his funeral was performed in the ſame manner in which the fathers inter thoſe of their own fraternity.

Thus died Philip duke of Wharton, "who, like Buckingham and Rocheſter (ſays Mr Walpole), comforted all the grave and dull, by throwing away the brighteſt profuſion of parts on witty fooleries, debaucheries, and ſcrapes, which mix graces with a great character, but never can compoſe one.

"With attachment to no party, though with talents to govern any party, this lively man changed the free air of Weſtminſter for the gloom of the Eſcurial, the proſpect of king George's garter for the Pretender's; and with indifference to all religion, the frolic lord who had writ the ballad on the archbiſhop of Canterbury, died in the habit of a capuchin. It is difficult to give an account of the works of a man whoſe library was a tavern, and women of pleaſure his muſes. A thouſand ſallies of his imagination may have been loſt. There are only two volumes in 8vo, called

Wheat.

called *his Life and Writings*. These contain nothing of latter, but 74 numbers of the True Briton and his speech in defence of the bishop of Rochester. His other works are the ballads above mentioned; the Drinking Match at Eden-hall, in imitation of the Chevy-Chace, printed in a miscellany called *Whartoniana*; and a parody of a song sung at the opera-house by Mrs Tofts. His lordship also began a play on the story of the queen of Scots."

WHEAT, in botany. See TRITICUM. For the culture of wheat, see AGRICULTURE, n° 122—136.

The three principal kinds of bad wheat are, the *blighted*, the *smutty*, and the *worm-eaten*. Blighted wheat is that of which the stalk is a little twisted and rickety, the blade being of a bluish green and curled up, the grain also is green and tubercled: smutty wheat appears as if great part of the ear had been burnt, some small parts only being free, and, in particular, the stem that rises in the centre of the ear, round which the grain is ranged: worm eaten or rotten wheat is corrupted without losing much of its natural form, or external appearance; the husk is filled with a greasy, black powder, that is insufferably fetid. It appeared, from the experiments of M. Tillet, that there was a kind of infectious quality in all those kinds of wheat; so that if sound wheat was sprinkled with the flour of smutty or rotten wheat, the crop produced would be rotten or smutty. It appeared also, that among the grain which was produced from ground manured with the straw of distempered wheat, there was a much greater proportion of distempered wheat than in that produced from ground manured with the straw of good wheat: the great secret then was to destroy the principle of this contagion in the wheat that was put into the ground; and M. Tillet found, as the result of a great number of experiments, that if the grain, before it is sowed, be well moistened with a solution of sea-salt, or nitre, in common water, none of the ensuing crop will be smutty, or otherwise defective, either in kind or quality; not only supposing the grain that is sowed to be sound, and the soil to be good, but even supposing the grain to be strewed with the flour of smutty wheat, and the ground manured with bad straw.

Prize Dissertation by the Academy of Bourdeaux.

The following receipt for preventing smutty wheat was published in 1769 by order of the Society for the Encouragement of Arts: they received it from Mr John Reynolds of Adisham in Kent.

A tub is to be procured that has a hole at bottom, in which a staff and tap-hose is to be fixed over a whisp of straw, to prevent any small pieces of lime passing (as in the brewing way); this done, we put 70 gallons of water, then a corn bushel heap-full of stone-lime, unslaked, stirring it well till the whole is dissolved or mixed, letting it stand about 30 hours, and then run it off into another tub as clear as we can (as practised in beer): this generally produces a hogshead of good strong lime-water, then add three pecks of salt, 42 pounds, which, with a little stirring, will soon dissolve; thus we have a proper pickle for the purpose of brining and liming our seed-wheat without any manner of obstacle, which is more than can be said in doing it the common way, and greatly facilitates the drilling.

Herein we steep the wheat in a broad-bottomed basket of about 24 inches diameter, and 20 inches deep (for large sowing made on purpose), running in the grain gradually in small quantities from 10 to 12 gallons up to 16 gallons, stirring the same. What floats, we skim off with a strainer, and is not to be sown: then draw up the basket, to drain over the pickle, for a few minutes; all which may be performed within half an hour, sufficiently pickled; and so proceed as before. This done, the wheat will be fit for sowing in 24 hours, if required; but if designed for drilling, two hours steeped will be found best; and if prepared four or five days before-hand, in either case it makes no difference at all; but should the seed be clammy, and stick to the notches in the drill-box, more lime must be added to the lime-water; here the master must use his discretion, as the case requires; for some lime has much more drying or astringent qualities in it than others. If sea-water can be obtained conveniently, much less salt will suffice, but some will be found necessary even then, otherwise the light grains will not float, a thing of more consequence than is generally imagined, and it ought to be skimmed off and thrown aside for poultry, &c.

Wheel ‖ Wheelings.

WHEEL, in mechanics, a simple machine, consisting of a round piece of wood, metal, or other matter, which revolves on its axis. See MECHANICS.

WHEEL-Carriages. See MECHANICS, Sect. iv.

WHEEL-Animal. See ANIMALCULE, n° 16—23.

WHEEL, Persian. See HYDROSTATICS.

WHEEL, Potter's. See POTTERY.

WHEEL is also the name of a kind of punishment to which great criminals are put in divers countries. In some, assassins, parricides, and robbers on the highway, are said to be condemned to the wheel, when they are to have their bones first broken with an iron bar on a scaffold, and then to be exposed, and left to expire on the circumference of a wheel. In Germany they break their bones on the wheel itself. Of this cruel punishment, it is not certain who was the inventor: it was first used in Germany, and was, indeed, but rarely practised anywhere else, till the time of Francis I. of France; who, by an edict of the year 1534, appointed it to be inflicted on robbers on the highway.

WHEELER (Sir George), a learned traveller and divine, was the son of colonel Wheeler of Charing in Kent, and was born in 1650 at Breda, where his parents as royalists were then in exile. He travelled through various parts of Greece and the East in company with Dr James Spon of Lyons; and taking orders on his return, was installed a prebend of Durham, made vicar of Basingstoke, and afterward rector of Houghton le Spring. He published an account of his Travels in 1682 in folio; and in 1689, his Observations on ancient edifices of Churches yet remaining in the East, compared with Eusebius: also the Protestant Monastery, or Christian Œconomics. He died in 1724.

WHEELINGS, in the military art, are different motions made both by horse and foot, either to the right and left, or to the right and left about.

General Rules for WHEELING.—The circle is divided into four equal points: thence, wheeling to the right or left, is only a quarter of the circle; wheeling to the right or left about is one half of the circle.

When you wheel to the right, you are to close to the right, so near as to touch your right-hand man, but without pressing him; and to look to the left, in order to bring the rank about even.

When you wheel to the left, you are to close to the left, and look to the right as above directed. This rule will serve for all the wheeling by ranks; as when a battalion is marching by subdivisions with their ranks open, then each rank wheels distinctly by itself, when it comes to the ground on which the ranks before it wheeled, but not before.

In wheeling, the men are to take particular care neither to open nor close their ranks, and to carry their arms well.

In wheeling, the motion of each man is quicker or slower, according to the distance he is from the right or the left: thus, when you wheel to the right, each man moves quicker than his right-hand man; and wheeling to the left, each man moves quicker than his left-hand man; the circle that every man wheels being larger, according to the distance he

is

Whelk ‖ Whidah.

is from the hand he wheels to; as may be ſeen by deſcribing ſeveral circles within one another, at two feet diſtance from each, which is nearly the ſpace every man is ſuppoſed to take up.

WHELK, in zoology. See BUCCINUM.

WHELP, the young of a dog, fox, lion, or any wild beaſt.

WHELPS, in a ſhip, the ſeaman's term for thoſe brackets which are ſet up on the capſtan cloſe under the bars; they give the ſweep to it, and are ſo contrived that the cable winding about them may not ſurge ſo much as it might otherwiſe do if the body of the capſtan were quite round and ſmooth.

WHESTONE, a ſtone which ſerves for the whetting of knives and other tools upon.

WHEY, the ſerum or watery part of milk.

WHIDAH, a kingdom of Africa, on the coaſt of Guinea, and to the weſt of the Gold Coaſt; extending about 10 miles along the ſea. It is a populous country, well furniſhed with large villages; and there are ſo many ſmall ones, that they are not above a muſket-ſhot from each other.—The houſes are ſmall, round at the top, and encompaſſed with mud walls or hedges, together with a great number of all ſorts of beautiful and lofty trees, which afford the moſt beautiful proſpect in the world, inſomuch that thoſe that have been here repreſent it as a perfect paradiſe. The fields are always green, and they cultivate beans, potatoes, and fruits; nor will the negroes here let a foot of ground remain uncultivated. They ſow again the very next day after they have reaped. The inhabitants are greatly civilized, very reſpectful to each other, eſpecially to their ſuperiors, and very induſtrious. The women brew the beer, dreſs the victuals, and ſell all ſorts of commodities at the market. Thoſe that are rich employ their wives and ſlaves in tilling the land, and they carry on a conſiderable trade with the product, as well as in ſlaves; for ſome of them are able to deliver 1000 of the latter every month. The chief men have generally 40 or 50 wives, the principal captains 300 or 400, and the king 4000 or 5000. They are extremely jealous, and, on the leaſt ſuſpicion, will ſell them to the Europeans for ſlaves. If any one happen to touch one of the king's wives accidentally, he is doomed to perpetual ſlavery. It is no wonder then that the women are not fond of being the king's wives; and ſome of them will prefer a ſpeedy death to ſuch a miſerable life. They have no diſtinction of hours, days, weeks, months, or years. The rite of circumciſion is uſed here, but they are not able to tell why they uſe it, nor whence it is derived. They are ſuch great gameſters, that they will ſtake all they have at play, not excepting their wives and children. They have a vaſt number of idols; and they deify the moſt contemptible animal that they ſee firſt in a morning, and even ſtocks and ſtones. Their principal regard is for ſnakes, very high trees, and the ſea. An Engliſh factor, juſt arrived, found a ſnake in the houſe belonging to the factory, and killed it without the leaſt ſcruple; which ſo incenſed the negroes, that they were for revenging the death of the ſnake, not only upon him that killed it, but upon the whole factory; but by dint of preſents, and the interpoſition of the people of the other factories, this affair was made up, and the ſnake honourably interred. However, to prevent ſuch accidents, they gave them warning not to do the like for the future. They have oxen, cows, goats, ſheep, hogs, turkeys, ducks, and hens; which laſt are extremely plentiful. There are many elephants, buffaloes, tigers, ſeveral kinds of deer, and a ſort of hares. The fruits are citrons, lemons, oranges, bananas, tamarinds, &c. and they have vaſt numbers of palm-trees, from which they obtain wine. Whidah was conquered by the king of Dahomy. Their trade conſiſts of ſlaves, elephants teeth, wax, and honey. The Engliſh factory is 200 miles eaſt of Cape Coaſt Caſtle, within land. Bows, arrows, beautiful aſſaguays, and clubs, are the principal weapons of the nation.

Whidaw ‖ Whirlwind.

WHIDAW-BIRD. See EMBERIZA.

WHIG, a party in Britain, oppoſite to the Tories, from whom they differ chiefly in their political principles. See TORIES.

WHIMBREL. See SCOLOPAX.

WHIN, in botany. See ULEX.

WHINCHET. See MOTACILLA.

WHIP, or *WHIP-Staff*, in a ſhip, a piece of timber, in form of a ſtrong ſtaff, faſtened into the helm, for the ſteerſman, in ſmall ſhips, to hold in his hand, in order to move the rudder, and direct the ſhip.

WHIRLPOOL, an eddy, vortex, or gulf, where the water is continually turning round.

Thoſe in rivers are very common, from various accidents, and are uſually very trivial, and of little conſequence. In the ſea they are more rare, but more dangerous. Sibbald has related the effects of a very remarkable marine whirlpool among the Orcades, which would prove very dangerous to ſtrangers, though it is of no conſequence to the people who are uſed to it. This is not fixed to any particular place, but appears in various parts of the limits of the ſea among theſe iſlands. Wherever it appears, it is very furious; and boats, &c. would inevitably be drawn in and periſh with it; but the people who navigate them are prepared for it, and always carry an empty veſſel, a log of wood, or large bundle of ſtraw, or ſome ſuch thing, in the boat with them; as ſoon as they perceive the whirlpool, they toſs this within its vortex, keeping themſelves out: this ſubſtance, whatever it be, is immediately received into the centre, and carried under water; and as ſoon as this is done, the ſurface of the place where the whirlpool was becomes ſmooth, and they row over it with ſafety: and in about an hour they ſee the vortex begin again in ſome other place, uſually at about a mile's diſtance from the firſt.

WHIRLWIND, a wind which moves in a ſpiral direction, as well as horizontally, which is exceedingly rapid and impetuous, but only of ſhort duration.

Dr Franklin's opinion of the origin of whirlwinds has been already given in the article *WATER Spout*. If his theory be true, it will follow, that no hurricane ever can be ſo violent as to remove an obſtacle of the ſize of only one cubic inch, provided that was ſupported by a power equivalent to 15 pounds; for this is the utmoſt force of the atmoſphere when ruſhing into a perfect vacuum, which never could take place in the centre of a whirlwind or water-ſpout. Indeed, notwithſtanding the dreadful effects ſometimes obſerved from hurricanes and whirlwinds, we ſhall eaſily perceive, that the utmoſt of their power always falls very far ſhort of this. The diminution of the ſpecific gravity of the air by only $\frac{1}{4}$th in the middle of the column, would produce ſuch an afflux of air from all quarters, that an obſtacle preſenting a ſurface of one foot ſquare, would require a force of 504 pounds to prevent it from being carried away; which the ſtrongeſt walls that can be built by human art could ſcarce reſiſt. Nay, even the tenth part of this, or the diminution of the gravity of the atmoſphere by $\frac{1}{40}$th part, would produce a preſſure of upwards of 50 pounds on every ſquare foot of ſurface, which, it is to be doubted, whether any of our common houſes could reſiſt.

Some philoſophers aſcribe the vacuum in the atmoſphere to which, according to Dr Franklin's theory, whirlwinds are owing, to a ſtream of electric matter ruſhing with violence into the atmoſphere out of the earth. But they do not inform

Whirlwind || Whift.

form us how this matter comes to be accumulated in that part of the earth; what induces it to paſs out of the earth: how it paſſes inviſibly through pure air; or what ſerves it for a conductor. It ſeems to be the faſhion among certain philoſophers to aſcribe every phenomenon, with the cauſe of which we are unacquainted, to electricity. But this is merely ſubſtituting a new name, and ſerves rather to retard than advance our knowledge of nature.

Some kinds of whirlwinds move with a ſlow motion, and are injurious only by their vortex; while others ſeem to do miſchief as well by their progreſſive as their whirling motion. Of this kind are thoſe called *typhons*; which, by their frequently following the courſe of rivers, ſeem thus alſo to diſcover their electrical origin. Of the deſtructive effects of theſe, we have an inſtance in what happened at Charleſtown in South Carolina, on the 1ſt of June 1761. It was firſt obſerved about noon, on land, upwards of 50 miles weſt-by-ſouth of Charleſtown, and deſtroyed ſeveral houſes, &c. as it paſſed along, in many places making wide avenues thro' the woods; from whence every tree and ſhrub was torn up, and great branches of trees were driven about in the column as it paſſed along. It directed its courſe to Aſhley river, down which it came with ſurpriſing velocity; in its appearance reſembling a column of ſmoke or vapour, whoſe motion was very irregular and tumultuous. Its momentum was ſo great, that Aſhley river was ploughed to the bottom, and the channel laid bare. As it came down this river, it made a conſtant noiſe like thunder; its diameter being computed about 300 fathoms. It was met at White Point by another of the ſame kind which came down Cooper's river, but with inferior ſtrength; however, on their meeting together, the agitation of the air was much greater, while the clouds, which were driving in all directions to the place, ſeemed to be precipitated, and whirled round with incredible velocity. It then fell upon the ſhipping in the road; entirely deſtroying ſome, and damaging others: being ſcarce three minutes in its paſſage, though the diſtance was near two leagues. In that ſhort time it did damage to the amount of L. 20,000; and had not its direction been altered by that guſt which came down Cooper's river, it muſt have totally deſtroyed Charleſtown, as no obſtacle whatever ſeemed capable of reſiſting its fury.

WHISKY, a term ſignifying *water*, and applied in Scotland and in Ireland to a diſtilled liquor, drawn from barley, which is perhaps preferable to any Engliſh malt brandy: it is ſtrong, but not pungent, and free from the empyreumatic taſte or ſmell.

WHISPERING-Places. See Accoustics, n° 24.

WHIST, a well known game at cards, which requires great attention and ſilence; hence the name.

This game is played by four perſons, who cut for partners; the two higheſt and the two loweſt are together, and the partners ſit oppoſite to each other: the perſon who cuts the loweſt card is to deal firſt, giving one at a time to each perſon, till he comes to the laſt card, which is turned up for the trump, and remains on the table till each perſon has played a card. The perſon on the left hand ſide of the dealer plays firſt, and whoever wins the trick is to play again, thus going on till the cards are played out. The ace, king, queen, and knave of trumps, are called *honours*; in caſe any three of theſe honours have been played between, or by either of the two partners, they reckon for two points towards the game; and if the four honours have been played between, or by either of the two partners, they reckon for four points towards the game, the game conſiſting of ten points. The honours are reckoned after the tricks; all above ſix tricks reckoning alſo towards the game.

General Rules for playing the Game of Whist.—1. He who is to play firſt ſhould lead from the ſtrongeſt ſuit. If he has a ſequence of king, queen, and knave, or queen, knave and ten, he may ſafely lead the higheſt of the ſequence; but if he has five or ſix in number, he muſt begin with the loweſt. He muſt always begin with the higheſt trump, by which he forces out the ſuperior trumps, and can come in again, to make his ſtrong ſuit. Whiſt.

2. He ſhould never be afraid to play trumps when he has five in his hand, even of the ſmalleſt, although he may not have any good cards of any other ſuit.

3. With ace and king of any two ſuits, and only two or three ſmall trumps, the aces and kings ſhould be played out, in order to make as many tricks as poſſible; and having but two or three ſmall trumps, he ſhould never force his partner to trump, if he finds he cannot follow ſuit; but endeavour to throw the lead into his partner's hand.

4. He ſhould in general return his partner's lead, unleſs he has ſome capital cards of his own.

5. As this game is played with the lurch, that is, to ſave half the ſtake, five points muſt be made before the game is out: he ſhould not venture to play trumps when he is four of the game, unleſs he is very ſtrong, having at leaſt an honour and three trumps, or ace, king, and two ſmall ones.

6. When the game is ſcored nine, at which ſtage the honours reckon for nothing, he ſhould be ſtill more cautious how he plays trumps, even if he is ſtrong in hand, and give his partner an opportunity of trumping the adverſaries ſuits, in caſe he is deficient in them.

7. If his adverſaries are ſix or ſeven love of the game, he ſhould play a forward or bold game, that he may have a chance, at the riſk of a trick or two, to come up with them. If he has but three trumps and other good cards, he may play trumps, eſpecially if he has a ſequence, or queen, knave, and a ſmall one.

8. He ſhould always riſk a trick or two when the game is much in his favour; becauſe a new deal is of greater conſequence to the adverſary than one or two points are to him.

9. When the player finds there is a likelihood of either ſaving the game or his lurch, he ſhould riſk the odd trick; but if the game is five all, and he can make two tricks in his own hand, he ſhould make them, in order to ſecure the difference of two points, which make the game near two to one in his favour.

10. A good player ſhould begin with a ſmall trump, when he has ace, king, and four ſmall ones; for this reaſon, if his partner has a better trump than the laſt player, which is an equal wager but he has, he has a chance of fetching out all the trumps, by having three rounds of them.

11. The odds are always in his favour that his partner holds an honour; conſequently if he has king, queen, and four ſmall ones, he ſhould begin with a ſmall one.

12. When queen, knave, and four ſmall trumps are dealt him, he ſhould play a ſmall one firſt, the odds being in his favour that his partner holds an honour; if he has knave, ten, and four ſmall trumps, he ſhould alſo begin with a ſmall one, for the ſame reaſon.

13. If he has knave, ten, eight, and three ſmall trumps, the knave ſhould be played firſt, by which means the nine may be prevented from winning a trick, the odds being in his favour that three honours are played in two rounds.

14. If an honour is turned up againſt him on his left hand, and he has ten, nine, and eight, with two or three ſmall trumps; when he is to play, he ſhould play through the honours with the ten, which will force the dealer to play his honour to a diſadvantage, if the dealer does not

chooſe

Whift. chooſe to leave it to the option of his adverſary whether he will paſs it or not; but if he has ſix trumps of a lower denomination, and not ten, nine, and eight, and no honour turned up againſt him, he ſhould begin with a ſmall one.

15. In general, when he has two capital cards in trumps, and two or three ſmall ones, he ſhould begin with a ſmall one, for the reaſon aſſigned in n° 12.

16. When he has ace, king, knave, and two ſmall trumps, or even one ſmall trump, by firſt playing the king, and putting the lead into his partner's hand, who will pay a trump; judging him to have ace and knave, from his beginning with the king: in this caſe the knave ſhould be fineſſed (A), nothing being againſt him but the queen.

17. If he has knave, ten, eight, and two ſmall trumps, by playing the knave firſt, it is odds but in two rounds of trumps the nine falls, or he may fineſſe the eight when his partner returns trumps.

18. With five trumps of a lower denomination, he ſhould begin with the ſmalleſt, unleſs he has a ſequence of ten, nine, and eight; then he ſhould begin with the ten.

19. When he has king, queen, ten, and one ſmall trump, he muſt begin with the king, and wait for his partner's return of the trumps, in order to fineſſe the ten, by which means he may win the knave.

20. In order to prevent the ten from winning, when he has queen, knave, nine, and one ſmall trump, he muſt begin with the queen. And in caſe he has knave, ten, eight, and one ſmall trump, he ſhould begin with the knave, that the nine may not win.

21. If he has ten, nine, eight, and one ſmall trump, he ſhould begin with the ten; thereby he ſtrengthens his partner's hand, leaving it at his option to take it or not.

22. He ſhould begin with a ſmall one, when he has the ten and three ſmall trumps.

23. If he has a good ſuit, and ace, king, and four ſmall trumps, he muſt play three rounds of trumps, in order to ſecure his ſtrong ſuit from being trumped.

24. When he has king, queen, ten, and three ſmall trumps, he ſhould begin with the king, becauſe he has a chance of the knave's coming down in the ſecond round: and to ſecure his ſtrong ſuit, he ſhould not wait to fineſſe the ten. If he ſhould have queen, knave, and three ſmall trumps, and ſome good ſuit to make, he muſt begin with a ſmall one.

25. If he has knave, ten, eight, and two ſmall trumps, with a ſtrong ſuit, he ſhould begin with the knave, in order to make the nine fall in the ſecond round; but if he has knave, ten, and three ſmall trumps, with a good ſuit, he ſhould play a ſmall one firſt.

26. With ten, nine, eight, and one ſmall trump, provided he has a good ſuit, he ſhould begin with the ten; by which means he may get the trumps out, and have a chance of making his ſtrong ſuit.

The following obſervations will enable a player to know that his partner has no more of a ſuit which either of them has played. Suppoſe he leads from queen, ten, nine, and two ſmall cards of any ſuit, the ſecond hand puts on the knave, his partner plays the eight; in this caſe, he having queen, ten, and nine, it is a demonſtration, if his partner plays well, that he can have no more of that ſuit. By that diſcovery, he may play his game accordingly, either by forcing his partner to trump that ſuit, if he is ſtrong in trumps, or by playing another ſuit. If he has king, queen, and ten of a ſuit, and he leads his king, his partner plays the knave; this alſo demonſtrates he has no more of that ſuit. If he has king, queen, and many more of a ſuit, and begins with the king, in ſome caſes it is good play in a partner, when he has the ace and one ſmall card in that ſuit only, to win the king with the ace; for ſuppoſe the partner to be very ſtrong in trumps, by taking the king with the ace, he gets the lead and trumps out, and having cleared the board of trumps, his partner returns his lead; and the ace being out, there is room for him to make that whole ſuit, which could not have been done if the partner had kept the ace. Suppoſe he has no other good card in his hand beſides that ſuit, he loſes nothing by the ace's taking his king; and if it ſhould ſo happen that he has a good card to bring in that ſuit, he gains all the tricks which he makes in that ſuit by this method of play: as his partner has taken his king with the ace, and trumps out upon it, he has reaſon to imagine that his partner has one of that ſuit to return him; for which reaſon he ſhould not throw away any of that ſuit, even to keep a king or queen guarded. Whift.

Method of playing when an honour is turned up on the right hand.----Suppoſe the knave is turned up on his right hand, and that he has king, queen, and ten; in order to win the knave, he muſt begin with the king; by which means, his partner may ſuppoſe him to have queen and ten remaining, eſpecially if he has a ſecond lead, and he does not proceed to play the queen.

Suppoſe the knave turned up as before, and he has ace, queen, and ten, by playing his queen, it anſwers the purpoſe of the former rule.

When the queen is turned up on his right hand, and he has ace, king, and knave, by playing his king, it anſwers the ſame purpoſe of the former rule.

In caſe an honour is turned up on his left hand, ſuppoſing he ſhould hold no honour, he ſhould play trumps through the honour as ſoon as he gets the lead; but if he ſhould hold an honour (except the ace), he muſt be cautious how he plays trumps, becauſe, in caſe his partner holds no honour, his adverſary will play his own game upon him.

Method of playing the ſequences.----The higheſt in ſequences of trumps ſhould be played, unleſs he has ace, king, and queen; and then he ſhould play the loweſt, which informs his partner of the ſtate of his game.

When he has king, queen, and knave, and two ſmall ones, which are not trumps, he ſhould begin with the knave, whether he is ſtrong in trumps or not, as he makes way for the whole ſuit by getting the ace out.

If he is ſtrong in trumps, and has a ſequence of queen, knave, ten, and two ſmall cards of a ſuit, he ſhould play the higheſt of his ſequence; for if either of the adverſaries ſhould trump that ſuit in the ſecond round, being alſo ſtrong in trumps, he will make the remainder of that ſuit, by fetching out their trumps. When he has knave, ten, and nine, and two ſmall cards of a ſuit, he may play in the like manner.

If king, queen, and knave, and one ſmall card of any ſuit, is the caſe, whether ſtrong in trumps or not, he ſhould play the king; and when there are only four in number, the ſame method of play ſhould be obſerved by inferior ſequences.

When weak in trumps, he ſhould begin by the loweſt of the ſequence, provided he has five in number, becauſe if his partner has the ace of that ſuit he will make it. If he has the ace and four ſmall cards of a ſuit, and weak in trumps, leading from that ſuit, he ſhould play the ace. When ſtrong in trumps, the game may be played otherwiſe.

(A) *Fineſſe*, is to play a ſmall card which may win, keeping the ſuperior card or cards to lay over the right hand adverſary.

Whiſt. *How to make a ſlam, or win every trick.*----Suppoſe A and B partners againſt C and D, and C to deal, A to have the king, knave, nine, and ſeven of hearts, which are trumps, a quart-major in ſpades, a tierce major in diamonds, and the ace and king of clubs. Then ſuppoſe B to have nine ſpades, two clubs, and two diamonds. Alſo ſuppoſe D to have ace, queen, ten, and eight of trumps, with nine clubs, and C to have five trumps and eight diamonds. A leads a trump, which D wins, and D is to play a club, which his partner C is to trump; C leads a trump, which his partner D wins; D then will lead a club, which C will trump; and C will play a trump, which D will win; and D having the beſt trump will play it; after which D having ſeven clubs in his hand, makes them, ſo that he flams A and B.

How to play any hand of cards according to the neareſt calculations of his partner's holding certain winning cards:

1 That he has not one certain winning card, is	2 to	1
2 That he has not two certain winning cards, is	17 to	2
But it is about 5 to 4 that he has one or both, or	32 to	25
3 That he has one card out of any three certain winning cards, is about	5 to	2
4 That he has not three certain winning cards, is about 31 to 1, or	681 to	22
5 That he has not two of them, is about 7 to 2, or	547 to	156
6 That he has not one of them, is about 7 to 6, or	378 to	325
7 That he holds one or two of them, is in his favour about 13 to 6, or	481 to	222
8 And about 5 to 2 that he holds 1, 2, or all three of them.		

The uſe of theſe calculations is for a whiſt-player to play his cards to the moſt advantage. For inſtance,

As the firſt calculation is two to one that his partner does not hold one certain winning card.—Suppoſe then a ſuit is led, of which the ſecond player has the king and a ſmall one only, he ſhould put on the king, becauſe the odds are in his favour that the third player cannot win it. For the ſame reaſon, when he is ſecond player, and to lead, he ſhould play a king in preference to a queen, becauſe it is two to one the ace does not take it; but it is five to four the queen will be taken by either ace or king, which may be in the third hand.

According to the ſecond calculation, of its being five to four that his partner holds one certain winning card out of any two: If he has two honours in any ſuit, he can play to an advantage, knowing it is five to four in favour of his partner's having one of the two honours; and by the ſame rule, if he is ſecond player, having a queen and one ſmall card, by playing the queen he plays five to four againſt himſelf.

It is obvious, from the third calculation, which proves it to be five to two that his partner has one card out of any three certain winning cards, that he who plays the knave ſecond hand, having but the knave and one ſmall card of the ſame ſuit, muſt play five to two againſt himſelf, and diſcovers his game to a great diſadvantage; for which reaſon, he ſhould play the loweſt of any ſequence which he may hold in his hand, as the knave, if he has king, queen, and knave; the ten, if he has queen, knave, and ten, &c. By ſo doing, his partner has an opportunity of judging what card to play in that ſuit, according to the odds for or againſt him.

From the above calculation, if he has ace, king, and two ſmall trumps, he is entitled to win four tricks out of ſix, provided he has four winning cards of any ſuit; or five tricks out of ſeven, if he has five winning cards of any ſuit: by playing two rounds of trumps, and taking out eight of them, it is five to two but his partner has a third trump; and if it ſhould be ſo, he makes the tricks intended. Whiſton. See Hoyle's Games improved by Beaufort.

WHISTON (William), an Engliſh divine of great parts, uncommon learning, and of a ſingular character, was born at Norton near Twycroſſe in the county of Leiceſter, where his father was rector, in 1667. He was admitted of Clarehall, Cambridge, where he purſued his ſtudies, particularly in the mathematics, and commenced tutor; which his ill health at length forced him to decline. Having entered into orders, he, in 1694, became chaplain to Dr More biſhop of Norwich; and in this ſtation he publiſhed his firſt work, intitled, *A new Theory of the Earth*, &c. in which he undertook to prove the Moſaic doctrine of the earth perfectly agreeably to reaſon and philoſophy. This work brought no ſmall reputation to the author. In the beginning of this century he was made Sir Iſaac Newton's deputy, and afterwards his ſucceſſor, in the Lucaſian profeſſorſhip of mathematics; when he reſigned a living he had in Suffolk, and went to reſide at Cambridge. About this time he publiſhed ſeveral ſcientifical works, explanatory of the Newtonian philoſophy; and he had the honour of being one of the firſt, if not the very firſt, who rendered thoſe principles popular and intelligible to the generality of readers. About the year 1710, he was known to have adopted Arian principles, and was forming projects to ſupport and propagate them: among other things, he had tranſlated the Apoſtolical Conſtitutions into Engliſh, which favoured the Arian doctrine, and which he aſſerted to be genuine. The conſequence was, that he was deprived of his profeſſorſhip, and baniſhed the univerſity; he nevertheleſs purſued his ſcheme, by publiſhing the next year his Primitive Chriſtianity Revived, 4 vols, 8vo. for which the convocation fell upon him very vehemently. On his expulſion from Cambridge, Mr Whiſton ſettled in London; where without ſuffering his zeal to be intimidated, he continued to write, and to propagate his Primitive Chriſtianity, with as much ardour as if he had been in the moſt flouriſhing circumſtances. In 1721, a ſubſcription was made for the ſupport of his family, which amounted to 470 l. For though he drew profits from reading aſtronomical and philoſophical lectures, and alſo from his publications, which were very numerous, yet theſe of themſelves would have been very inſufficient: nor, when joined with the benevolence and charity of thoſe who loved and eſteemed him for his learning, integrity, and piety, did they prevent his being frequently in great diſtreſs. He continued long a member of the church of England, and regularly frequented its ſervice, though he diſapproved of many things in it: but at laſt he went over to the Baptiſts, and attended Dr Forſter's meeting at Pinner's Hall, Broad-ſtreet. Among other performances not ſpecified above, he wrote Memoirs of his own life and writings, which contain ſome curious particulars.

He was remarkable for ſpeaking the plaineſt truths on every occaſion, and to perſons of every degree. During the year 1725, that he, with Dr Clarke, Dr Berkeley, and others, had the honour to attend Queen Caroline on a certain day of every week, to talk of the progreſs of ſcience, her Majeſty one evening took occaſion to pay him a juſt compliment on his truth and integrity, requeſting that he would, with his uſual plainneſs, point out to her any fault that he might have obſerved in her conduct. At firſt he begged to be excuſed, adding, that few perſons could bear to have their faults plainly told to them, and leaſt of all royal perſonages, who, from their elevation, are neceſſarily ſurrounded by flatterers, to whoſe lips truth is a ſtranger.

Her

Whiſton || White.

Her Majeſty replied, that he was to conſider her not as a queen, but as a philoſopher; and that philoſophy is of very little uſe, if it cannot enable its profeſſors to bear without offence truths neceſſary to their own improvement. Upon this he told her, that the greateſt fault which he had obſerved in her conduct, was her indecent behaviour in the houſe of God, which, he aſſured her, had made very unfavourable impreſſions on the minds of many perſons, who, coming to town from diſtant parts of the country, had gone to the chapel to obtain a ſight of her majeſty, the king, and the royal family. The Queen made no reply; but in about ſix weeks afterwards renewed her requeſt, that Mr Whiſton would point out the moſt glaring improprieties in her conduct. To this he anſwered, that he had laid down a maxim from which he could not deviate, never to point out to any perſon more than one fault at a time, and never to give a ſecond reproof till he had obſerved ſome good conſequence to have ariſen from the firſt (A). Much to the Queen's honour, ſhe was pleaſed with this plain dealing, and continued to think favourably of Mr Whiſton. This honeſt, but whimſical and credulous man, died in 1762, at the advanced age of 95.

WHITBY (Dr Daniel), a very learned Engliſh writer, was born in 1638, and bred at Oxford; where, in 1664, he was elected perpetual fellow of his college. He afterward became chaplain to Dr Seth Ward, biſhop of Saliſbury; who collated him in 1668 to the prebend of Yateſbury in that church, and ſoon after to that of Huſborn and Burbach. In 1672 he was admitted chanter of the ſaid church, on the death of Mr John South, and then, or ſoon after, rector of St Edmund's church in Saliſbury. He was made a prebendary of Taunton Regis in 1696, and died in 1726. He was ever ſtrangely ignorant of worldly affairs, even to a degree that is ſcarcely to be conceived. His writings are numerous, and well known; particularly his Commentary on the New Teſtament.

WHITBY, a ſea-port town in the North Riding of Yorkſhire, ſeated on the river Eſk, near the place where it falls into the ſea. The houſes are neat, ſtrong, and convenient; the number of inhabitants about 9000. Ship-building is their principal manufacture. W. Long. 0. 24. N. Lat 54. 30.

WHITE, one of the colours of natural bodies.

White of the Eye, denotes the firſt tunic or coat of the eye, called *albuginea*. See ANATOMY, n° 142.

White of an Egg. See ALBUMEN and EGG.

White Friars, a name common to ſeveral orders of monks, from being clothed in a white habit.

White Sea, is a bay of the Frozen Ocean, ſo called in the north part of Muſcovy, lying between Ruſſian Lapland and Samoieda; at the bottom of which ſtands the city of Archangel. This was the chief port the Ruſſians had before their conqueſt of Livonia.

White Colour for painting. See CHEMISTRY, n° 703.

White Copper. See CHEMISTRY, n° 1157.

White Drop, Ward's. See CHEMISTRY, n° 746.

White Iron, or *Tin-plate*, iron-plates, covered over with tin; for the method of making which, ſee LATTEN.

In 1681 tin-plates were manufactured in England by one Andrew Yarranton, who had been ſent to Bohemia to learn the method of making them. But the manufacture was ſoon afterwards diſcontinued. It was revived again in 1740, and is now arrived at as great, if not greater, perfection in this country than in any other.

White Lead. See CHEMISTRY, n° 875.

White Throat, in ornithology. See MOTACILLA.

WHITEFIELD (George), the celebrated preacher among the people called *Methodiſts*, was born in the year 1714, at the Bell in the city of Gloucester, which was then kept by his mother. At about 12 years of age he was put to a grammar-ſchool; but his mother entering into a ſecond marriage, which proved a diſadvantageous one, he, when about 15, put on a blue apron, and ſerved her in the capacity of a drawer or waiter. After continuing about a year in this ſervile employment, ſhe turned over the buſineſs to his brother; who marrying, and George not agreeing with his ſiſter-in-law, he left the inn. Some time after, meeting with an old ſchool-fellow, then a ſervitor in Pembroke college, Oxford, he was induced to attempt getting into the ſame college in a like capacity, and ſucceeded. Here Mr Whitefield, who from his own account appears to have always had a ſtrong tincture of enthuſiaſm in his conſtitution from his very childhood, diſtinguiſhing himſelf by the auſterities of his devotion, and acquired conſiderable eminence in ſome religious aſſemblies in that city. At the age of 21, the fame of his piety recommended him ſo effectually to Dr Benſon, then biſhop of Glouceſter, that he made him a voluntary offer of ordination. Immediately after this regular admiſſion into the miniſtry, Mr Whitefield applied himſelf to the moſt extraordinary, the moſt indefatigable, duties of his character, preaching daily in priſons, fields, and open ſtreets, wherever he thought there would be a likelihood of making proſelytes. Having at length made himſelf univerſally known in England, he embarked for America, where the tenets of Methodiſm began to ſpread very faſt under his friends the Weſleys; and firſt determined upon the inſtitution of the orphan-houſe at Georgia, which he afterwards effected. After a long courſe of peregrination, his fortune increaſed as his fame extended among his followers, and he erected two very extenſive buildings for public worſhip, under the name of *Tabernacles*; one in Tottenham Court Road, and the other in Moorfields. Here, with the help of ſome aſſiſtants, he continued for ſeveral years, attended by very crowded congregations, and quitting the kingdom only occaſionally. Beſides the two tabernacles already mentioned, Mr Whitefield, by being chaplain to the counteſs dowager of Huntingdon, was connected with two other religious meetings, one at Bath, and the other at Tunbridge, chiefly erected under that lady's patronage. By a lively, fertile, and penetrating genius, by the moſt unwearied zeal, and by a forcible and perſuaſive delivery, he never failed of the deſired effect upon his ever crowded and admiring audiences. America, however, which always engaged much of his attention, was deſtined to cloſe his eyes; and he died at Newberry, about 40 miles from Boſton in New England, in 1770.

Whitefield, Whitehaven.

WHITEHAVEN, a ſea-port town of Cumberland, with a market on Thurſdays, and one fair on Auguſt 1ſt for merchandiſe and toys. It is ſeated on a creek of the ſea, on the north end of a great berg or hill, waſhed by the tide of flood on the weſt ſide, where there is a large rock or quarry of hard white ſtone, which gives name to the place, and which, with the help of a ſtrong ſtone wall, ſecures the harbour, into which ſmall barks may enter. It is lately much improved in its buildings, and noted for its trade in pit-coal and ſalt, there being near it a prodigious coal-mine, which runs a conſiderable way under the ſea. They have a cuſtomhouſe here; and they carry on a good trade to Ireland, Scotland, Cheſter, Briſtol, and other parts. It is 10 miles ſouth-weſt of Cockermouth, and 269 north-weſt of London. W. Long. 3. 6. N. Lat. 54 30.

(A) Biſhop Berkeley was preſent at theſe converſations, and from his ſon we received the account which we have given of them. They are likewiſe mentioned, but not ſtated ſo accurately, by Biſhop Newton in his own Life.

Whiteneſs || Whytt.

WHITENESS, the quality which denominates or conſtitutes a body white.

WHITES, or FLUOR *Albus*. See MEDICINE, n° 250.

WHITING, in ichthyology. See GADUS.

WHITLOW, or WHITLOE. See SURGERY.

WHITSUN-FARTHINGS, otherwiſe called *Smoke-farthings* or *Quadrantes Pentecoſtales*, a compoſition for offerings which were anciently made in Whitſun-week by every man in England, who occupied a houſe with a chimney, to the cathedral church of the dioceſe in which he lived.

WHITSUNDAY, a ſolemn feſtival of the Chriſtian church, obſerved on the fiftieth day after Eaſter, in memory of the deſcent of the Holy Ghoſt upon the apoſtles in the viſible appearance of fiery cloven tongues, and of thoſe miraculous powers, which were then conferred upon them.

It is called *Whitſunday* or *White-Sunday*; becauſe this being one of the ſtated times for baptiſm in the ancient church, thoſe who were baptiſed put on white garments, as types of that ſpiritual purity they received in baptiſm. As the deſcent of the Holy Ghoſt upon the apoſtles happened upon the day which the Jews called *Pentecoſt*, this feſtival retained the name of *Pentecoſt* among the Chriſtians.

WHITSUNDAY Iſle, one of the New Hebrides, which lies about four miles to the ſouth, runs in the ſame direction, and is of the ſame length, having more ſloping expoſures than Aurora: it appears to be better inhabited, and to contain more plantations.

WHORTLEBERRY. See VACCINIUM.

WHYTT (Dr Robert), an eminent phyſician, born at Edinburgh on the 6th September 1714, was the ſon of Robert Whytt, Eſq; of Bennochy, advocate. This gentleman died ſix months before the birth of our author, who had alſo the misfortune to be deprived of his mother before he had attained the ſeventh year of his age. After receiving the firſt rudiments of ſchool-education, he was ſent to the univerſity of St Andrew's; and after the uſual courſe of inſtruction there, in claſſical, philoſophical, and mathematical learning, he came to Edinburgh, where he entered upon the ſtudy of medicine, under thoſe eminent medical teachers, Monro, Rutherford, Sinclair, Plummer, Alſton, and Innes. After learning what was to be acquired at this univerſity, in the proſecution of his ſtudies he viſited foreign countries; and after attending the moſt eminent teachers at London, Paris, and Leyden, he had the degree of Doctor of Phyſic conferred upon him by the univerſity of Rheims in 1736, being then in the 22d year of his age.

Upon his return to his native country, he had the ſame honour alſo conferred upon him by the univerſity of St Andrew's; where he had before obtained, with applauſe, the degree of Maſter of Arts.

Not long afterwards, in the year 1737, he was admitted a Licentiate of Medicine by the Royal College of Phyſicians of Edinburgh; and the year following he was raiſed to the rank of a Fellow of the College. From the time of his admiſſion as a licentiate, he entered upon the practice of phyſic at Edinburgh; and the reputation which he acquired for medical learning, pointed him out as a fit ſucceſſor for the firſt vacant chair in the univerſity. Accordingly, when Dr Sinclair, whoſe eminent medical abilities, and perſuaſive powers of oratory, had contributed not a little to the rapid advancement of the medical ſchool of Edinburgh, found that thoſe conſpicuous talents which he poſſeſſed could no longer be exerted in the manner which they once had been when he enjoyed bodily vigour unimpaired by age and powers of mind unclouded by diſeaſe, he reſigned his academical appointments in favour of Dr Whytt.

Whytt.

This admiſſion into the college took place on the 20th of June 1746; and he began his firſt courſe of the inſtitutions of medicine at the commencement of the next winter-ſeſſion. The abilities which he diſplayed from his academical chair, in no particular diſappointed the expectations which had been formed of his lectures. The Latin tongue was the language of the univerſity of Edinburgh; and he both ſpoke and wrote in Latin with ſingular propriety, elegance, and perſpicuity. At that time the ſyſtem and ſentiments of Dr Boerhaave, which, notwithſtanding their errors, muſt challenge the admiration of lateſt ages were very generally received by the moſt intelligent phyſicians in Britain. Dr Whytt had no ſuch idle ardour for novelties as to throw them entirely aſide becauſe he could not follow them in every particular. The inſtitutions of Dr Boerhaave, therefore, furniſhed him with a text for his lectures; and he was no leſs ſucceſsful in explaining, illuſtrating, and eſtabliſhing the ſentiments of the author, when he could freely adopt them, than in refuting them by clear, connected, and deciſive arguments, when he had occaſion to differ from him. The opinions which he himſelf propoſed, were delivered and enforced with ſuch acuteneſs of invention, ſuch diſplay of facts and force of argument, as could rarely fail to gain univerſal aſſent from his numerous auditors; but free from that ſelf-ſufficiency which is ever the offspring of ignorance and conceit, he delivered his concluſions with becoming modeſty and diffidence.

From the time that he firſt entered upon an academical appointment, till the year 1756, his prelections were confined to the inſtitutions of medicine alone. But at that period his learned colleague Dr Rutherford, who then filled the practical chair, who had already taught medicine at Edinburgh with univerſal applauſe for more that thirty years, and who had been the firſt to begin the inſtitution of clinical lectures at the Royal Infirmary, found it neceſſary to retire from the fatiguing duties of an office to which the progreſs of age rendered him unequal. On this criſis Dr Whytt, Dr Monro, ſen. and Dr Cullen, each agreed to take a ſhare in an appointment in which their united exertions promiſed the higheſt advantages to the univerſity. By this arrangement ſtudents, who had an opportunity of daily witneſſing the practice of three ſuch teachers, and of hearing the grounds of that practice explained, could not fail to derive the moſt ſolid advantages.

In theſe two departments, the inſtitutions of medicine in the univerſity, and the clinical lectures in the Royal Infirmary, Dr Whytt's academical labours were attended with the moſt beneficial conſequences both to the ſtudents and to the univerſity. But not long after the period we have laſt mentioned, his lectures on the former of theſe ſubjects underwent a very conſiderable change. About this time the illuſtrious Gaubius, who had ſucceeded to the chair of Boerhaave, favoured the world with his *Inſtitutiones Pathologiæ*. This branch of medicine had indeed a place in the text which Dr Whytt formerly followed; but, without detracting from the character of Dr Boerhave, it may juſtly be ſaid, that the attention he had beſtowed upon it was not equal to its importance. Dr Whytt was ſenſible of the improved ſtate in which pathology now appeared in the writings of Boerhaave's ſucceſſor; and he made no delay in availing himſelf of the advantages which were then afforded.

In the year 1762, his pathological lectures were entirely new-modelled. Following the publication of Gaubius as a text, he delivered a comment, which was read by every intelligent ſtudent with the moſt unfeigned ſatisfaction. In theſe lectures he collected and condenſed the fruits of accurate obſervation and long experience. Enriched by all

the

Whytt. the opportunities of information which he had enjoyed, and by all the diſcernment which he was capble of exerting, they were juſtly conſidered as his moſt finiſhed production.

For a period of more than twenty years, during which he was juſtly held in the higheſt eſteem as a lecturer at Edinburgh, it may readily be ſuppoſed that the extent of his practice correſponded to his reputation. In fact, he received both the firſt emoluments, and the higheſt honours, which could here be obtained. With extenſive practice in Edinburgh, he had numerous conſultations from other places. His opinion on medical ſubjects was daily requeſted by his moſt eminent contemporaries in every part of Britain. Foreigners of the firſt diſtinction, and celebrated phyſicians in the moſt remote parts of the Britiſh empire, courted an intercourſe with him by letter. Beſides private teſtimonies of eſteem, many public marks of honour were conferred upon him both at home and abroad. In 1752, he was elected a fellow of the Royal Society of London; in 1761, he was appointed firſt phyſician to the king in Scotland; and in 1764, he was choſen preſident of the Royal College of Phyſicians at Edinburgh.

But the fame which Dr Whytt acquired as a practitioner and teacher of medicine, was not a little increaſed by the information which he communicated to the medical world in different publications. His celebrity as an author was ſtill more extenſive than his reputation as a profeſſor.

His firſt publication, An Eſſay on the vital and other Involuntary Motions of Animals, although it had been begun ſoon after he had finiſhed his academical courſe of medical education, did not come from the preſs till 1751; a period of fifteen years from the time that he had finiſhed his academical courſe, and obtained a degree in medicine: but the delay of this publication was fully compenſated by the matter which it contained, and the improved form under which it appeared.

The next ſubject which employed the pen of Dr Whytt was one of a nature more immediately practical. His Eſſay on the Virtues of Lime-water and Soap in the Cure of the Stone, firſt made its appearance in a ſeparate volume in 1752. Part of this ſecond work had appeared ſeveral years before in the Edinburgh Medical Eſſays: but it was now preſented to the world as a diſtinct publication with many improvements and additions.

His third work, intitled Phyſiological Eſſays, was firſt publiſhed in the year 1755. This treatiſe conſiſted of two parts; 1ſt, An Inquiry into the Cauſes which promote the Circulation of the Fluids in the very ſmall veſſels of Animals; and 2dly, Obſervations on the Senſibility and Irritability of the Parts of Men and other Animals, occaſioned by Dr Haller's treatiſe on that ſubject. The former of theſe may be conſidered as an extenſion and farther illuſtration of the ſentiments which he had already delivered in his Eſſay on the Vital Motions, while the latter was on a ſubject of a controverſial nature. In both he diſplayed that acuteneſs of genius and ſtrength of judgment which appeared in his former writings.

From the time at which his Phyſiological Eſſays were publiſhed, ſeveral years were probably employed by our author in preparing for the preſs a larger and perhaps a more important work than any yet mentioned, his Obſervations on the Nature, Cauſes, and Cure of thoſe Diſorders which are commonly called *nervous*, *hypochondriac*, and *hyſteric*. This elaborate and uſeful work was publiſhed in the year 1764.

The laſt of Dr Whytt's writings is intitled, Obſervations on the Dropſy in the Brain. This treatiſe did not appear till two years after his death; when all his other works were collected and publiſhed in one quarto volume, under the direction of his ſon and of his intimate friend the late Sir John Pringle. Whytt ‖ Wickliff.

Beſides theſe five works, he wrote many other papers, which appeared in different periodical publications; particularly in the Philoſophical Tranſactions, the Medical Eſſays, the Medical Obſervations, and the Phyſical and Literary Eſſays.

At an early period of life, ſoon after he had ſettled as a medical practitioner at Edinburgh, he entered into the married ſtate. His firſt wife was Miſs Robertſon, ſiſter to General Robertſon governor of New York. By her he had two children; both of whom died in early infancy, and their mother did not long ſurvive them. A few years after the death of his firſt wife, he married as a ſecond wife Miſs Balfour, ſiſter to James Balfour, Eſq. of Pilrig. By her he had fourteen children: but in theſe alſo he was in ſome reſpects unfortunate; for ſix of them only ſurvived him, three ſons and three daughters, and of the former two are ſince dead. Although the feeling heart of Dr Whytt, amidſt the diſtreſſes of his family, muſt have often ſuffered that uneaſineſs and anxiety which in ſuch circumſtances is the unavoidable conſequence of parental affection and conjugal love; yet he enjoyed a large ſhare of matrimonial felicity. But his courſe of happineſs was terminated by the death of his wife, which happened in the year 1764; and it is not improbable that this event had ſome ſhare in haſtening his own death; for in the beginning of the year 1765 his health was ſo far impaired, that he became incapable of his former exertions. A tedious complication of chronical ailments, which chiefly appeared under the form of diabetes, was not to be reſiſted by all the medical ſkill which Edinburgh could afford: and at length terminated in death, on the 15th of April 1766, in the 52d year of his age.

WIBURGH, a conſiderable town of Denmark, in North Jutland, with a biſhop's ſee, remarkable for being the ſeat of the chief court of juſtice in the province. The hall where the council aſſembles has the archives of the country, and eſcaped the terrible fire that happened in the year 1726, and which burned the cathedral-church, that of the Black Friars, the town-houſe, and the biſhop's palace; but they have all been rebuilt more magnificent than before. It is ſeated on the lake Weter, in a peninſula 25 miles north-weſt of Sleſwick, and 110 north-by-weſt of Copenhagen. E. Long. 9. 50. N. Lat. 56. 20.

WICKER, ſignifies made of ſmall twigs.

WICKET, a ſmall door in the gate of a fortified place, &c. or a hole in a door through which to view what paſſes without.

WICKLIFF (John), the firſt divine in Europe who had reſolution to attempt a reformation of religion, was born about the year 1324, in the pariſh of Wycliff, near Richmond, in Yorkſhire. He was educated at Oxford, firſt in Queen's, and afterwards in Merton college, of which he was a probationer-fellow. Having acquired the reputation of a man of great learning and abilities, in 1361 he was choſen maſter of Baliol-hall, and in 1365 conſtituted warden of Canterbury college, by the founder archbiſhop Simeon de Iſlip; but was, in 1367, ejected by the regulars, together with three ſecular fellows. He thought their proceedings arbitrary, and therefore appealed to the pope; but inſtead of obtaining redreſs, in 1370 the ejectment was confirmed. This diſappointment probably contributed ſomewhat towards his enmity to the ſee of Rome, or rather to confirm that enmity; for he had long before written againſt the pope's exactions and corruptions of religion. However, his credit in the univerſity continued; for having taken the degree of doctor in divinity, he read public lectures with

Wickliff, Wicklow.

with great applauſe: in which he frequently expoſed the impoſitions of the Mendicant friars. About this time he publiſhed a defence of his ſovereign Edward III. againſt the pope, who had inſiſted on the homage to which his predeceſſor king John had agreed. This defence was the cauſe of Wickliff's introduction at court, and of his being ſent one of the ambaſſadors in 1374 to Bruges, where they met the pope's nuncios, in order to ſettle ſeveral eccleſiaſtical matters relative to the pope's authority. In the mean time Wickliff was preſented by the king to the rectory of Lutterworth in Leiceſterſhire, and in 1375 he obtained a prebend in the church of Weſtbury in Glouceſterſhire. Wickliff continued hitherto without moleſtation, to oppoſe the papal authority; but in 1377 a bull was ſent over to the archbiſhop of Canterbury, and to Courtney biſhop of London, ordering them to ſecure this arch-heretic, and lay him in irons; at the ſame time the pope wrote to the king, requeſting him to favour the biſhops in the proſecution: he alſo ſent a bull to Oxford, commanding the univerſity to give him up. Before theſe bulls reached England, Edward III. was dead, and Wickliff protected by John duke of Lancaſter, uncle to Richard II. favoured by the queen-mother, and ſupported by the citizens of London, eluded the perſecution of pope Gregory IX. who died in 1378. In the following year this intrepid reformer preſented to parliament a ſevere paper againſt the tyranny of Rome, wrote againſt the papal ſupremacy and infallibility, and publiſhed a book *On the Truth of the Scriptures*, intended to prepare the way for an Engliſh tranſlation of them, in which he had made conſiderable progreſs. In 1381 he publiſhed *Sixteen Concluſions*; in the firſt of which he ventured to expoſe the grand article of tranſubſtantiation. Theſe concluſions being condemned by the chancellor of Oxford, Wickliff appealed to the king and parliament; but being deſerted by his unſteady patron the duke of Lancaſter, he was obliged to make a confeſſion at Oxford; and by an order from the king was expelled the univerſity. He now retired to his living of Lutterworth, where he finiſhed his tranſlation of the bible. This verſion, of which there are ſeveral manuſcript copies in the libraries of the univerſities, Britiſh Muſeum, &c. is a very literal tranſlation from the Latin vulgate. In 1383 he was ſuddenly ſtruck with the palſy; a repetition of which put an end to his life in December 1384. He was buried in his own church, where his bones were ſuffered to reſt in peace till the year 1428, when, by an order from the pope, they were taken up and burnt. —Beſides a number of works that have been printed, he left a prodigious number of manuſcripts; an accurate liſt of which may be ſeen in Biſhop Tanner's *Bib. Brit. Hib.* Some of them are in the Bodleian Library, others in the Britiſh Muſeum, &c.

Wickliff was doubtleſs a very extraordinary man, conſidering the times in which he lived. His natural ſagacity diſcovered the abſurdities and impoſitions of the church of Rome, and he had the honeſty and reſolution to promulgate his opinions, which a little more ſupport would probably have enabled him to eſtabliſh; they were evidently the foundation of the ſubſequent reformation.

WICKLOW, a county of Ireland, in the province of Leinſter; bounded on the north by the county of Dublin; on the eaſt by the Iriſh Sea; on the ſouth by Wexford; and on the weſt by Kildare and Catherlough. It is 33 miles in length, 20 in breadth, and indifferently fruitful. It contains 54 pariſhes, and ſends 10 members to parliament.

Wicklow, the capital of a county of the ſame name, in Ireland; ſeated on the ſea-ſide, with a narrow harbour, at the mouth of the river Leitrim, over which ſtands a rock, inſtead of a caſtle, ſurrounded by a ſtrong wall, 24 miles ſouth of Dublin. W. Long. 6. 7. N. Lat. 52. 55.

Widgeon, Wilderneſs

WIDGEON, in ornithology. See Anas.

WIDOW, a woman who has loſt her huſband.

WIFE, a married woman, or one joined with, and under the protection of, a huſband. See Husband.

Isle of WIGHT, an iſland lying on the ſouth coaſt of Hampſhire, from which it is ſeparated by a narrow channel. It is about 21 miles in length, and 13 in breadth. It is nearly divided into equal parts by the river Mede or Cowes, which riſing in the ſouthern angle, enters at the northern, into the channel, oppoſite the mouth of Southampton Bay. The ſouth coaſt is edged with very ſteep cliffs of chalk and freeſtone, hollowed into caverns in various parts. The weſt ſide is fenced with ridges of rocks, of which the moſt remarkable are thoſe called, from their ſharp extremities, the *Needles*. Between the iſland and the main are various ſand-banks, eſpecially off the eaſtern part, where is the ſafe road of St Helen's. Acroſs the iſland, from eaſt to weſt, runs a ridge of hills, forming a tract of fine downs, with a chalky or marly ſoil, which feed a great number of fine-fleeced ſheep. Rabbits are alſo very plentiful here. To the north of this ridge the land is chiefly paſture: to the ſouth of it is a rich arable country, producing great crops of corn. The variety of proſpects which this iſland affords, its mild air, and the neat manner in which the fields are laid out, render it a very delightful ſpot. It is devoted almoſt ſolely to huſbandry, and has no manufactory. It is one of the principal reſources of the London market for unmalted barley. Among its products are to be reckoned a pure white pipe-clay and a fine white chryſtalline ſand; of the latter of which great quantities are exported for the uſe of the glaſs-works in various parts. Its principal town is the borough of Newport: it likewiſe contains the two ſmall boroughs of Newtown and Yarmouth.

WILD-FIRE. See *Wild-fire*.

WILDERNESS, in gardening, a kind of grove of large trees, in a ſpacious garden, in which the walks are commonly made, either to interſect each other in angles, or have the appearance of meanders and labyrinths.

Wilderneſſes (ſays Mr Miller) ſhould always be proportioned to the extent of the gardens in which they are made; for it is very ridiculous to ſee a large wilderneſs planted with tall trees in a ſmall ſpot of ground; and, on the other hand nothing can be more abſurd than to ſee little paltry ſquares, or quarters of wilderneſs-work, in a magnificent large garden. As to the ſituation of wilderneſſes, they ſhould never be placed too near the habitation, nor ſo as to obſtruct any diſtant proſpect of the country, there being nothing ſo agreeable as an unconfined proſpect: but where, from the ſituation of the place, the ſight is confined within the limits of the garden, nothing can ſo agreeably terminate the proſpect as a beautiful ſcene of the various kinds of trees judiciouſly planted; and if it is ſo contrived that the termination is planted circularly, with the concave towards the ſight, it will have a much better effect than if it end in ſtraight lines or angles. The plants ſhould always be adapted to the ſize of the plantation; for it is very abſurd for tall trees to be planted in the ſmall ſquares of a little garden; and in large deſigns, ſmall ſhrubs will have a mean appearance. It ſhould alſo be obſerved never to plant evergreens among deciduous trees; but always to place the evergreens in a wilderneſs in a ſeparate part by themſelves, and that chiefly in ſight.

As to the walks, thoſe that have the appearance of meanders, where the eye cannot diſcover more than twenty or thirty yards in length, are generally preferable to all

others,

Wilderneſs. Wilkins.

others, and theſe ſhould now and then lead into an open circular piece of graſs; in the centre of which may be placed either an obeliſk, ſtatue, or fountain; and if in the middle of the wilderneſs there be contrived a large opening, in the centre of which may be erected a dome or banqueting houſe, ſurrounded with a green plot of graſs, it will be a conſiderable addition to the beauty of the whole. From the ſides of the walks and openings, the trees ſhould riſe gradually one above another to the middle of the quarters; where ſhould always be planted the largeſt growing trees, ſo that the heads of all the trees may appear to view, while their ſtems will be hid from the ſight. Thus, in thoſe parts which are planted with deciduous trees, roſes, honeyſuckles, ſpiræa frutex, and other kinds of low-flowering ſhrubs, may be planted next the walks and openings; and at their feet, near the ſides of the walks, may be planted primroſes, violets, daffadils, &c. not in a ſtraight line, but ſo as to appear accidental, as in a natural wood. Behind the firſt row of ſhrubs ſhould be planted ſyringas, althæa frutex, mezereons, and other flowering ſhrubs of a middle growth; and theſe may be backed with many other ſorts of trees riſing gradually to the middle of the quarters.

The part planted with evergreens may be diſpoſed in the following manner, *viz.* in the firſt line next the great walks may be placed the lauruſtinus, boxes, ſpurge-laurel, juniper, ſavin, and other dwarf evergreens. Behind theſe may be placed laurels, hollies, arbutuſes, and other evergreens of a larger growth. Next to theſe may be planted alaternuſes, phyllireas, yews, cypreſſes, Virginian cedars, and other trees of the ſame growth; behind theſe may be planted Norway and ſilver firs, the true pine, and other ſorts of the fir growth; and in the middle ſhould be planted Scotch pines, pinaſter, and other ſorts of the larger growing evergreens; which will afford a moſt delightful proſpect if the different ſhades of the greens are curiouſly intermixed.

But beſide the grand walks and openings (which ſhould always be laid with turf, and kept well mowed), there ſhould be ſome ſmaller ſerpentine walks through the middle of the quarters, where perſons may retire for privacy; and by the ſides of theſe private walks may alſo be ſcattered ſome wood-flowers and plants; which, if artfully planted, will have a very good effect.

In the general deſign for theſe wilderneſſes, there ſhould not be a ſtudied and ſtiff correſpondency between the ſeveral parts; for the greater diverſity there is in the diſtribution of theſe, the more pleaſure they will afford.

WILKINS (Dr John), a moſt ingenious and learned Engliſh biſhop, was the ſon of a goldſmith of Oxford, and was born in 1614. He adhered to the parliament during the civil wars, by whom he was made warden of Wadham college in 1648: he married afterwards the ſiſter of Oliver Cromwell, and procured a diſpenſation to retain his wardenſhip notwithſtanding. Richard Cromwell made him maſter of Trinity college, Cambridge, from which he was ejected on the Reſtoration. He then became preacher to Gray's-Inn, rector of St Laurence Jewry, London, dean of Ripon, and in 1668 was promoted to the biſhopric of Cheſter: he died in 1672. Biſhop Wilkins thought it prudent to ſubmit to the powers in being; he therefore ſubſcribed to the ſolemn league and covenant while it was enforced, and was equally ready to ſwear allegiance to king Charles when he was reſtored: this, with his moderate ſpirit toward diſſenters, rendered him not very agreeable to churchmen. His mathematical and philoſophical works, which contain many ingenious and curious pieces, conſidering the time when they were written, have been collected in one vol. 8vo. He publiſhed alſo ſome theological tracts. He was the firſt preſident of the Royal Society.

Will, Williams.

WILL, that faculty of the mind by which it embraces or rejects any thing offered to it. See METAPHYSICS.

WILL, or *Laſt Will*, in law, ſignifies the declaration of a man's mind and intent relating to the diſpoſition of his lands, goods, or other eſtate, or of what he would have done after his death. In the common law there is a diſtinction made between a will and a teſtament: that is called a *will* where lands or tenements are given; and when the diſpoſition concerns goods and chattels alone, it is termed a *teſtament*. See TESTAMENT.

Will-with a-whiſp, or *Jack-with-a-lanthorn*, two popular names for the meteor called *ignis fatuus*. See LIGHT, n° 46.

WILLIAM *of* MALMSBURY, an hiſtorian of conſiderable merit in the reign of king Stephen; but of whoſe life few particulars are known. According to Bale and Pits, he was ſurnamed *Somerſetus*, from the county in which he was born. From his own preface to his ſecond book *De Regibus Anglorum*, it appears that he was addicted to learning from his youth; that he applied himſelf to the ſtudy of logic, phyſic, ethics, and particularly to hiſtory. He retired to the Benedictine convent at Malmſbury, became a monk, and was made precentor and librarian; a ſituation which much favoured his intention of writing the hiſtory of this kingdom. In this monaſtery he ſpent the remainder of his life, and died in the year 1142. He is one of our moſt ancient and moſt faithful hiſtorians. His capital work is that intitled *De Regibus Anglorum*, in five books; with an Appendix, which he ſtyles *Hiſtoriæ Novellæ*, in two more. It is a judicious collection of whatever he found on record relative to England, from the invaſion of the Saxons to his own times.

William of Newbury, ſo called from a monaſtery in Yorkſhire, of which he was a member, wrote a hiſtory which begins at the conqueſt and ends at the year 1197. His Latin ſtyle is preferred to that of Matthew Paris; and he is intitled to particular praiſe, for his honeſt regard to truth, in treating the fables of Jeffery of Monmouth with the contempt they deſerve; as well as for expreſſing his approbation of Henry II.'s deſign of reforming the clergy, by bringing them under the regulation of the ſecular power.

William of Wykeham, biſhop of Wincheſter, was born in the village of Wykeham, in the county of Southampton, in 1324. He had his education at Wincheſter and Oxford. Having continued near ſix years in the univerſity, his patron Nicholas Wedal, governor of the province of Southampton, took him into his family, and appointed him his counſellor and ſecretary. He could not have made choice of a fitter perſon for that employment; no man in that age writing or ſpeaking more politely than Wykeham. For this reaſon Edington, biſhop of Wincheſter, lord high-treaſurer of the kingdom, appointed him his ſecretary three years after, and alſo recommended him to king Edward III. who took him into his ſervice. Being ſkilled in geometry and architecture, he was appointed ſurveyor of the royal buildings, and alſo chief juſtice in eyre: he it was who ſuperintended the building of Windſor-caſtle. He was afterward chief ſecretary of ſtate, a keeper of the privy-ſeal; and in 1367 ſucceeded Edington in the ſee of Wincheſter. A little after he was appointed lord high chancellor and preſident of the privy-council. That he might well diſcharge the ſeveral functions of his employments, both eccleſiaſtical and civil, he endeavoured, on one hand, to regulate his own life according to the ſtricteſt maxims, and to promote ſuch pariſh-prieſts only as were able to give due inſtructions to their pariſhioners, and at the ſame time led exemplary lives: on the other hand, he did all in his power to cauſe juſtice to be exactly adminiſtered. In 1371 he reſigned his chancellorſhip,

William. lordſhip, and ſome time after the great ſeal. Edward being returned to England, after having carried on a very ſucceſsful war in France, found his exchequer in great diſorder. The duke of Lancaſter, one of his ſons, at the head of ſeveral lords, having brought complaints againſt the clergy, who then enjoyed moſt poſts in the kingdom, the king removed them from their employments. But the laymen, who were raiſed to them, behaved ſo ill, that the king was forced to reſtore the eccleſiaſtics. The duke of Lancaſter ſhowed ſtrong animoſity to the clergy, and ſet every engine at work to ruin Wykeham. He impeached him of extortion, and of diſguiſing things, and obliged him to appear at the King's-bench. He got ſuch judges appointed as condemned him; and not ſatisfied with depriving him of all the temporalities of his biſhopric, he adviſed Edward to baniſh him: but this prince rejected the propoſal, and afterward reſtored to Wykeham all that he had been diveſted of. Richard II. was but eleven years old when Edward died: whereby the duke of Lancaſter had an eaſy opportunity of reviving the accuſations againſt the biſhop of Wincheſter: nevertheleſs Wykeham cleared himſelf. Then he founded two noble colleges, the one in Oxford, the other in Wincheſter. Whilſt he was exerting his utmoſt endeavours to improve theſe two fine foundations, he was recalled to court, and in a manner forced to accept of the office of lord high-chancellor in 1389. Having excellently diſcharged the duties of that employment for three years, he obtained leave to reſign it, foreſeeing the diſturbances that were going to break out. Being returned to his church, he finiſhed his college, and built there ſo magnificent a cathedral, that it almoſt equals that of St Paul's in London. He laid out ſeveral ſums in things advantageous to the public and to the poor; notwithſtanding which, in 1397 he was in great danger; for he and ſome others were impeached of high-treaſon in open parliament: however, he was again fully cleared. From that time till his death he kept quiet in his dioceſe, and there employed himſelf in all the duties of a good prelate. He died in 1404, in the 81ſt year of his age.

WILLIAM, the name of ſeveral kings of England. See ENGLAND, n° 87—92, and BRITAIN, n° 302.

Fort-William, a fortreſs in the Highlands of Scotland, erected in king William's reign, as was alſo a ſmall town adjoining, called *Maryburgh*, in honour of his queen. It is ſituated in Inverneſsſhire, on a narrow arm of the ſea called *Loch Eil*, which might eaſily, by a very ſhort canal, be united to the Weſtern ſea. Fort-William is of a triangular form, having two baſtions, and is capable of admitting a garriſon of 800 men; but could not be defended againſt an attack, as it is commanded by ſeveral hills in the neighbourhood.

William's Fort, is a factory of Aſia belonging to the Eaſt-India company, ſeated on one of the branches of the river Ganges, in the kingdom of Bengal. The fort was firſt built in the ſhape of an irregular tetragon of brick and mortar; and the town has nothing regular in it, becauſe every one built a houſe as he liked beſt, and for his own conveniency. The governor's houſe is within the fort, and is the beſt piece of architecture in theſe parts. Here there are alſo convenient lodgings for the factors and writers, with ſtore-houſes for the company's goods, and magazines for ammunition. About 50 yards from the fort is the church, built by the charity of merchants reſiding here. The town is called *Calcutta*, and has a pretty good hoſpital for the ſick, though few come out of it alive. It is governed by a mayor and aldermen, as moſt of the company's factories in the Eaſt Indies now are. In 1757 it was ſurpriſed by the nabob of Bengal, who took it, and put moſt of thoſe that had made reſiſtance into a place called the *Black Hole*, where moſt of them were ſmothered. This nabob was afterwards killed, and another ſet up in his room, more friendly to the Engliſh; and the factory was re-eſtabliſhed. E. Long. 86. 0. N. Lat. 22. 27. William Willis.

Sweet-William. See DIANTHUS.

WILLIAMSBURG, a town of North America, in Virginia, and formerly capital of that ſtate. It is ſituated between two creeks; one falling into James, and the other into York River. The diſtance of each landing place is about a mile from the town, which, with the diſadvantage of not being able to bring up large veſſels, and the want of enterpriſe in the inhabitants has occaſioned its decay. Here is a college, deſigned for the education of the Indians, but which, on account of their averſion to learning, never anſwered the purpoſe. It is 60 miles eaſt of Richmond. W. Long. 76. 30. N. Lat. 37. 10.

WILLIAMSTADT, a ſea-port town of Holland. It is a handſome ſtrong place, and the harbour is well frequented. It was built by William prince of Orange in 1585; and in 1732 belonged to the ſtadtholder of Frieſland. The river near which it is built is called *Butterfliet* or *Holland Diep*; and is one of the Bulwarks of the Dutch on the ſide of Brabant, where they always keep a garriſon. This place made a gallant defence in 1793 againſt the French, who were obliged to raiſe the ſiege. It is 15 miles north-eaſt of Bergen-op-Zoom, and 12 ſouth-weſt of Dort. E. Long. 4. 30. N. Lat. 51. 39.

WILLIS (Dr Thomas), a celebrated Engliſh phyſician, was born at Great Bodwin, in Wiltſhire, in 1621, and ſtudied at Chriſt-church college, Oxford. When that city was garriſoned for the king, he, among other ſcholars, bore arms for his Majeſty, and devoted his leiſure hours to the ſtudy of phyſic. The garriſon of Oxford at length ſurrendering to the parliament, he applied himſelf to the practice of his profeſſion; and ſoon rendered himſelf famous by his care and ſkill. He appropriated a room as an oratory for divine ſervice according to the church of England, whither moſt of the loyaliſts in Oxford daily reſorted. In 1660, he became Sedleian profeſſor of natural philoſophy, and the ſame year took the degree of doctor of phyſic. In 1664, he diſcovered the famous medicinal ſpring at Alſtropp, near Brackley. He was one of the firſt members of the Royal Society, and ſoon made his name illuſtrious by his excellent writings. In 1666, after the fire of London, he removed to Weſtminſter; and his practice became greater than that of any of the phyſicians his contemporaries. Soon after his ſettlement in London, his only ſon Thomas falling into a conſumption, he ſent him to Montpelier in France for the recovery of his health; and it proved ſucceſsful. His wife alſo labouring under the ſame diſorder, he offered to leave the town; but ſhe, not ſuffering him to neglect the means of providing for his family, died in 1670. He died at his houſe in St Martin's in 1675, and was buried near her in Weſtminſter-abbey. Dr Willis was extremely modeſt and unambitious, and refuſed the honour of knighthood. He was remarkably pious: As he roſe early in the morning, that he might be preſent at divine ſervice, which he conſtantly frequented before he viſited his patients, he procured prayers to be read beyond the accuſtomed times while he lived; and at his death ſettled a ſtipend of 20l. *per annum* to continue them. He was a liberal benefactor to the poor wherever he came, having from his early practice allotted part of his profits to charitable uſes. He was exact and regular in all his hours: and though his table was the reſort of moſt of the great men of London, yet he was remarkable

Willughby. Wilmot.

able for his plainneſs, and his being a man of little diſcourſe, complaiſance, or ſociety; but he was juſtly admired for his deep inſight into natural and experimental philoſophy, anatomy, and chemiſtry; for his ſucceſsful practice; and for the elegance and purity of his Latin ſtyle. He wrote, 1. A treatiſe in Engliſh, intitled *A plain and eaſy Method for preſerving thoſe that are well from the Infection of the Plague, and for curing ſuch as are infected.* 2. Several Latin works, which were collected and printed at Amſterdam, in 1682, in 2 vols 4to.

WILLUGHBY (Francis), a celebrated natural hiſtorian, was the only ſon of Sir Francis Willughby, knight. He was fond of ſtudy from his childhood, and held idleneſs in abhorrence; he being ſo great an economiſt with regard to his time, as not willingly to loſe or miſapply the leaſt part of it, by which means he obtained great ſkill in all branches of learning, and particularly in the mathematics. But obſerving that the hiſtory of animals was in a great meaſure neglected by his countrymen, he particularly applied himſelf to that province; and for this purpoſe carefully read over what had been written on that ſubject by others. He then travelled ſeveral times over his native country; and afterwards into France, Spain, Italy, Germany, and the Low Countries, attended by his ingenious friend Mr John Ray. It is remarkable, that, notwithſtanding the advantages of birth, fortune, and parts, he was as humble as any man of the meaneſt fortune; was ſober, temperate, and chaſte: ſcrupulouſly juſt; ſo true to his word and promiſe, that a man might venture his eſtate and life upon it; ſo faithful and conſtant to his friend, as never to deſert him when fortune frowned upon him; and remarkably pious, patient, and ſubmiſſive to the divine will. This is the character given of him by Mr Ray, whoſe veracity none will doubt. This ingenious and learned gentleman died in 1672, at 37 years of age; having impaired his health by his application. He wrote, 1 *Ornithologiæ libri tres*, folio, which was afterwards tranſlated into Engliſh, with an Appendix by Mr Ray, in folio. 2. *Hiſtoriæ Piſcium libri quatuor*, folio. 3. Letters of Francis Willughby, Eſq; added to Philoſophical Letters between the learned Mr Ray and ſeveral of his correſpondents, publiſhed, in 8vo, by William Derham. 4. Several ingenious papers in the Philoſophical Tranſactions.

WILMOT (John), earl of Rocheſter, a great wit in the reign of Charles II. the ſon of Henry earl of Rocheſter, was born in 1648. He was taught grammar and claſſical learning at the free-ſchool at Burford; where he obtained a quick reliſh of the beauties of the Latin tongue, and afterwards became well verſed in the authors of the Auguſtine age. In 1659, he was admitted a nobleman of Wadham college, where he obtained the degree of maſter of arts. He afterwards travelled through France and Italy; and at his return was made one of the gentlemen of the bed-chamber to the king, and comptroller of Woodſtock Park. In 1665, he went to ſea, and was in the Revenge, commanded by Sir Thomas Tiddiman, when an attack was made on the port of Bergen in Norway; during the whole action he ſhowed the greateſt reſolution, and gained a high reputation for courage; which he ſupported in a ſecond expedition, but afterwards loſt it in a private adventure with Lord Mulgrave.

Before the earl of Rocheſter travelled, he had given into the moſt diſorderly and intemperate way of living; at his return, however, he ſeemed to have got the better of it entirely. But falling into the company of the courtiers, who continually practiſed theſe exceſſes, he became ſo ſunk in debauchery, that he was for five years together ſo given up to drinking, that during all that time he was never cool enough to be maſter of himſelf. His violent love of pleaſure, and his diſpoſition to extravagant mirth, carried him to great exceſſes. The firſt involved him in ſenſuality, and the other led him into many adventures and ridiculous frolics. Once diſguiſing himſelf ſo that he could not be known by his neareſt friends, he ſet up in Tower-ſtreet for an Italian mountebank, and there diſperſed his noſtrums for ſome weeks. He often diſguiſed himſelf as a porter, or as a beggar, ſometimes to follow a mean amour; at other times, he would go about merely for diverſion, in odd ſhapes; and acted his part ſo naturally, that he could not be known even by his friends. In ſhort, by his conſtant indulgence in wine, women, and irregular frolics, he entirely wore out an excellent conſtitution before he was 30 years of age. In October 1679, when recovering from a violent diſeaſe, which ended in a conſumption, he was viſited by Dr Burnet, upon an intimation that ſuch a viſit would be agreeable to him. Dr Burnet publiſhed an account of his conferences with Lord Rocheſter; in which it appears, that though he had lived the life of a libertine and atheiſt, yet he died the death of a penitent Chriſtian. His death happened in 1680; ſince which time his poems have been various times printed, both ſeparately and together: but when once he obtained the character of a lewd and obſcene writer, every thing in that ſtrain was fathered upon him; and thus many pieces not of his writing have crept into the later editions of his works. The author of the Catalogue of Royal and Noble Authors ſays, he was "a man whom the Muſes were fond to inſpire, and aſhamed to avow, and who practiſed without the leaſt reſerve that ſecret which can make verſes more read for their defects than their merits. Lord Rocheſter's Poems have much more obſcenity than wit, more wit than poetry, and more poetry than politeneſs." His writings, beſides thoſe already mentioned, are, A Satyre againſt Mankind; Nothing, a poem; Valentinian, a tragedy; Fifty-four Letters to Henry Saville, and others; Seven more to his Wife and Son: a Letter on his deathbed to Dr Burnet. He alſo left behind him ſeveral other papers, and a Hiſtory of the Intrigues of the Court of Charles II. but his mother, a very devout lady, ordered all his papers to be burned.

Wilmot, Wilſon.

WILSON (Florence), known in the republic of letters by the name of *Florentius Voluſinus*, was born at Elgin in the ſhire of Murray in Scotland, and educated in the univerſity of Aberdeen. Travelling to England with an intention to improve his fortune, he had the felicity to be introduced to cardinal Wolſey, who appointed him tutor to one of his nephews. In that capacity he went to Paris, and continued there till the cardinal's death. During his reſidence in that city he became acquainted with the learned cardinal Bellai, archbiſhop of Paris, who allowed him a penſion, and meant to have appointed him royal profeſſor of the Greek and Latin languages in the univerſity of Paris: but Bellai being diſgraced, Wilſon's proſpects faded with the fortunes of his patron, whom nevertheleſs he attended on his journey to Rome. Wilſon was taken ill at Avignon, and the cardinal proceeded without him. After his recovery, he paid a viſit to the celebrated cardinal Sabolet, the Mecænas of his time, who was alſo biſhop of Carpentras, where he then reſided. The cardinal was ſo charmed with his erudition, that he appointed him profeſſor of the learned languages, with a ſtipend of 100 piſtoles *per annum*.

During his reſidence at Carpentras, he wrote his celebrated treatiſe *De Animi Tranquillitate*. Mackenzie ſays that he afterwards taught philoſophy in Italy; and that, being at length deſirous of returning to Scotland, he began his journey homeward, was taken ill at Viene in Dauphiny, and died there in the year 1547. He was generally eſteemed an accompliſhed linguiſt, an admirable philoſopher, and an excellent Latin poet. He wrote, beſide the above treatiſe, 1. *Poemata*. Lond. 1619, 4to. 2. *Commentatio quæ-*

Wilſon. *dam theologica in aphoriſmos diſſecta, per Sebaſt Gryph.* 3. *Philoſophiæ Ariſtot. Synopſis*, lib. iv.

WILSON (Thomas), lord biſhop of Sodor and Man, was born in 1663, at Burton, in the county of Cheſter. He received the rudiments of his education at the county town, and from thence was removed to the univerſity of Dublin. His allowance at the univerſity was 20l. a year; a ſum, ſmall as it may now appear, which was in thoſe days ſufficient for a ſober youth in ſo cheap a country as Ireland.

His firſt intention was to have applied to the ſtudy of phyſic; but from this he was diverted by archdeacon Hewetſon, by whoſe advice he dedicated himſelf to the church. He continued at college till the year 1686, when, on the 29th of June, he was ordained deacon.

The exact time of Mr Wilſon's leaving Dublin is not known: but on account of the political and religious diſputes of thoſe days, it was ſooner than he intended. On the 10th of December, in the ſame year, he was licenſed to the curacy of New Church in Winwick, of which Dr Sherlock, his maternal uncle, was rector. His ſtipend was no more than 30l. a-year; but being an excellent economiſt, and having the advantage of living with his uncle, this ſmall income was not only ſufficient to ſupply his own wants, but it enabled him to ſupply the wants of others; and for this purpoſe he ſet apart one tenth of his income. In 1692 he was appointed domeſtic chaplain to William earl of Derby, and tutor to his ſon James Lord Strange, with a ſalary of 30l. a-year. He was ſoon after elected maſter of the alms houſe at Latham, which brought him in 20l. a-year more. Having now an income far beyond his expectations, or his wiſhes, except as it increaſed his ability to do good, he ſet apart one fifth of his income for pious uſes, and particularly for the poor. In ſhort, as his income increaſed, he increaſed the portion of it which was allotted to the purpoſes of charity. At firſt he ſet apart a tenth, then a fifth, afterwards a third, and laſtly, when he became a biſhop, he dedicated the full half of his revenues to pious and charitable uſes.

He had not been long in the ſervice of Lord Derby, before he was offered the valuable living of Buddeſworth in Yorkſhire; which he refuſed to accept, as being inconſiſtent with the reſolves of his conſcience againſt non-reſidence, Lord Derby chooſing ſtill to retain him as chaplain and tutor to his ſon. In 1697 he was promoted, not without ſome degree of compulſion on the part of his patron, to the biſhopric of the Iſle of Man; a preferment which he held 58 years. In 1698 he married Mary, daughter of Thomas Patten, Eſq; of Warrington. By this lady, who ſurvived her marriage about ſix years, he had four children; none of whom ſurvived him except the late Dr Wilſon, prebendary of Weſtminſter.

"The annual receipts of the biſhopric (ſays the author of his memoirs) did not exceed 300l. in money. Some neceſſaries in his houſe, as ſpices, ſugar, wine, books, &c. muſt be paid for with money; diſtreſſed or ſhipwrecked mariners, and ſome other poor objects, required to be relieved with money; but the poor of the iſland were fed and clothed, and the houſe in general ſupplied from his demeſnes, by exchange, without money. The poor, who could weave or ſpin, found the beſt market at Biſhop's-court, where they bartered the produce of their labour for corn. Taylors and ſhoemakers were kept in the houſe conſtantly employed, to make into garments or ſhoes that cloth or leather which his corn had purchaſed; and the aged and infirm were ſupplied according to their ſeveral wants. Mr Moore of Douglas informed the editor, that he was once witneſs to a pleaſing and ſingular inſtance of the Biſhop's attention to ſome aged poor of the iſland. As he was diſtributing ſpectacles to ſome whoſe eye-ſight failed them, Mr Moore expreſſed his ſurpriſe, as he well knew not one of them could read a letter. 'No matter (ſaid the Biſhop with a ſmile), they will find uſe enough for them; theſe ſpectacles will help them to thread a needle, to mend their clothes, or, if need be, to keep themſelves free from vermin."

So great was the biſhop's attachment to his flock, that no temptation could ſeduce him from their ſervice. He more than once refuſed the offer of an Engliſh biſhopric. There is an anecdote of his lordſhip and cardinal Fleury, which does great credit to them both. The cardinal wanted much to ſee him, and ſent over on purpoſe to inquire after his health, his age, and the date of his conſecration, as they were the two oldeſt biſhops, and he believed the pooreſt, in Europe; at the ſame time inviting him to France. The biſhop ſent the cardinal an anſwer, which gave him ſo high an opinion of him, that the cardinal obtained an order that no French privateer ſhould ravage the Iſle of Man.

This good prelate lived till the year 1755, dying at the advanced age of 93. His works have lately been publiſhed in 2 vols 4to.

WILTON, a market town in Wiltſhire, three miles weſt of Saliſbury. It was once ſo conſiderable as to give title to the county. It formerly had 12 churches; and Odo, brother-in-law to William I. was biſhop of Wilton: only one now remains. It ſends members to parliament, and is the place where the knights of the ſhire are choſen. It has a great manufactory of carpets, which are brought to high perfection. Wilton is famous for lord Pembroke's ſeat, ſo well known through Europe for its containing a grand aſſemblage of the productions of the greateſt and moſt ancient maſters in painting and ſculpture.—Two fairs are held here annually.

Wilton || Winchelſea.

WILTSHIRE, a county of England, bounded on the weſt by Somerſetſhire, on the eaſt by Berkſhire and Hampſhire, on the north by Glouceſterſhire, and on the ſouth by Dorſetſhire and part of Hampſhire. The length amounts to 39 miles; its breadth to 30; and its circumference to 140. It contains 29 hundreds, 23 market-towns, 304 pariſhes, and about 876,000 ſouls. Beſides two members for the ſhire, and two for the city of Saliſbury, each of the following towns ſends two members to parliament, *viz.* Wilton, Downton, Hindon, Heyteſbury, Weſtbury, Calne, Devizes, Chippanham, Malmſbury, Cricklade, Great Bedwin, Ludgerſhall, Old Sarum, Wooton-Baſſet, Marlborough.

The air of this country is very healthy, not only in the more low and level parts, but alſo on the hills. The ſoil of the vales is very rich, and produces corn and graſs in great plenty. The beautiful downs in the ſouth yield the fineſt paſture for ſheep, with which they are overſpread. The greateſt diſadvantage the county labours under is want of fuel, as there are no coal-pits, and but little wood. This county is noted for great quantities of very fine cheeſe, and for its manufacture of broad cloth, to which it was invited by the great plenty and fineneſs of its wool. Beſides a number of leſſer ſtreams, it is watered by the rivers Iſis, Kennet, Upper and Lower Avon, Willy, Burne, and Nadder, which are well ſtored with fiſh.

WINCHELSEA, a town in Suſſex, which has no market, but has one fair on May 14th for cattle and pedlars ware. It was an ancient place, at leaſt the old town, which was ſwallowed up by the ocean in 1250. It is now dwindled to a mean place, though it retains its privileges, and ſends two members to parliament. It is ſeated on a rocky cliff, on an inlet of the ſea; and had a haven, now choked up. It had 18 pariſh-churches, now reduced to one. The market-houſe is in the midſt of the town, from whence

Winchelsea || Winckleman.

whence run four paved ſtreets, at the end of which are four ways, which had formerly buildings on each ſide for a conſiderable diſtance. It is 2 miles ſouth-weſt of Rye, and 71 ſouth-eaſt of London. It is governed by a mayor and jurats, though it has but about 70 houſes. Three of the gates are ſtill ſtanding, but much decayed. E. Long. 0. 44. N. Lat. 50. 58.

WINCHELSEA (Anne counteſs of), a lady of excellent genius, eſpecially in poetry, was maid of honour to the duchеſs of York, ſecond wife to king James II. and was afterwards married to Heneage, ſecond ſon of the earl of Winchelſea. One of the moſt conſiderable of the counteſs of Winchelſea's poems was that on the Spleen. A collection of her poems was printed at London in 1713, containing a tragedy never acted, entitled *Ariſtomenes*. The counteſs died in 1720 without iſſue, as her huſband did in 1726.

WINCHESTER, the capital of the county of Hampſhire in England. It is a very ancient city, ſuppoſed to have been built ſeveral centuries before Chriſt. The Romans called it *Venta Belgarum*, the Britons *Caer Givent*, and the Saxons *Witanceaſter*; whence came the preſent name. It ſtands upon the river Itchin, in a bottom ſurrounded with chalky hills; and is generally allowed to have been a conſiderable place in the time of the Romans. Some of the firſt converts to Chriſtianity are ſuppoſed to have lived here. In the caſtle, near the weſt-gate, many of the Saxon kings anciently kept their courts. The cathedral was founded by Kenegulſe, a king of the Mercians; but there were many Chriſtians, and places for their worſhip here, long before that period. It is a large pile, and has a venerable look, but is not very elegant. Beſides the tombs, there are many curious pieces of workmanſhip in it; the chief of which are, 1. The font, erected in the time of the Saxons. 2. Copper ſtatues of James I. and Charles I. 3. The biſhop's throne. 4. The ſtalls of the dean and prebendaries. 5. The aſcent to the choir and altar. 6. The pavement, inlaid with marble of diverſe colours, in various figures. 7. The altar piece, reckoned the nobleſt in England. 8. The paintings in the windows, eſpecially the great eaſt window. At the hoſpital of the Holy Croſs, every traveller that knocks at the door may claim a manchet of white bread and a cup of beer; of which a great quantity is provided every day for that purpoſe. This hoſpital was intended for the maintenance of a maſter and 30 penſioners, but only 14 are now maintained in it; and the maſter enjoys a revenue of 800l. a-year. This city is about a mile and a half in compaſs, and almoſt ſurrounded with a wall of flint, has ſix gates, large ſuburbs, broad clean ſtreets; but the private houſes are in general but ordinary, many of them being very old. The city is interſperſed with a great many gardens, which contribute to its beauty and healthineſs. The corporation conſiſts of a mayor, high-ſteward, recorder, alderman, two coroners, two bailiffs, 24 common-council men, a town clerk, four conſtables, and four ſerjeants at mace; and the city gives title of *marquis* to the duke of Bolton. A Roman highway leads from hence to Alton; and went formerly, as it is thought, from thence to London. The charming downs in the neighbourhood contribute greatly to the health and pleaſure of the inhabitants. The river Itchin is navigable for barges from hence to Southampton. W. Long. 1. 21. N. Lat. 51. 5.

WINCKLEMAN (Abbé John), was born at Stendall in the old Marche of Brandenburgh, in 1718. His father was a ſhoemaker. This wonderful man, to all appearance deſtined by his birth to ſuperintend a little ſchool in an obſcure town of Germany, raiſed himſelf to the office of preſident of antiquities in the Vatican. After having been ſeven years profeſſor in the college of Seehauſen near Salswedel, he went into Saxony, where he reſided ſeven years more, and was librarian to count Bunau, at Nothenitz. When he left this place, 1754, he went to Dreſden, where he formed an acquaintance with the ableſt artiſts, and particularly with M. Oeſer, an excellent painter, and one of the beſt draughtſmen of the age. In that year he abjured Lutheraniſm, and embraced the Roman Catholic religion. In September 1755, he ſet out for Italy, and arrived at Rome in December following. His principal object was to ſee the Vatican library, and to examine the ruins of Herculaneum. Winckleman.

Mr Winckleman carried with him into Italy a ſenſe of beauty and art, which led him inſtantly to admire the maſter-pieces of the Vatican, and with which he began to ſtudy them. He ſoon increaſed his knowledge; and it was not till after he had thus purified his taſte and conceived an idea of ideal beauty, which led him into the greateſt ſecrets of art, that he began to think of the explanation of other monuments, in which his great learning could not fail to diſtinguiſh him. His erudition enabled him to fill up his principal plan of writing the "Hiſtory of Art." In 1756 he planned his "Reſtoration of Ancient Statues," and a larger work on the "Taſte of the Greek Artiſts;" and deſigned an account of the galleries of Rome and Italy, beginning with a volume on the Belvedere ſtatues, in the manner of Richardſon, who, he ſays, only ran over Rome. He alſo intended a hiſtory of the corruption of taſte in art, the reſtoration of ſtatues, and an illuſtration of the obſcure points of mythology. All theſe different eſſays led him to his "Hiſtory of Art," and his "Monumenti Inediti." It muſt, however, be confeſſed, that the firſt of theſe works has not all the clearneſs and preciſion that might be expected in its general plan and diviſion of its parts and objects; but it has enlarged and extended the ideas both of antiquaries and collectors. The deſcription of the gems and ſulphurs of the Scotch cabinet contributed not a little to extend Mr Winckleman's knowledge. Few perſons have opportunities of contemplating ſuch vaſt collections. The engravings of Lippet and count Caylus are all that many can arrive at. Mr Wickleman's Monumenti Inediti, of which he had begun the third vol. 1767, ſeem to have ſecured him the eſteem of antiquaries. Had he lived, we ſhould have had a work long wiſhed for; a complete collection of the bas-reliefs diſcovered from the time of Bartoli to the preſent, the greater part of which are in the poſſeſſion of cardinal Albani.

When cardinal Albani ſucceeded to the place of librarian of the Vatican, he endeavoured to get a place for the Hebrew language for Winckleman, who refuſed a canonry, becauſe he would not take the tonſure. The elector of Saxony gave him, 1761, unſolicited, the place of counſellor Richter, the direction of the royal cabinet of medals and antiquities at Dreſden. Upon the death of the Abbé Venuti, 1762, he was appointed preſident of the antiquities of the apoſtolic chamber, with power over all diſcoveries and exportations of antiquities and pictures. This is a poſt of honour, with an income of 160 ſcudi *per annum*. He had a proſpect of the place of preſident of antiquities in the Vatican, going to be created at 16 ſcudi *per* month, and was named correſponding member of the Academy of Inſcriptions. The king of Pruſſia offered him by Col. Quintus Icilius the place of librarian and director of his cabinet of medals and antiquities, void by the death of M. Gautier de la Croze, with a handſome appointment. He made no ſcruple of accepting the offer; but when it came to the pope's ears, he added an appointment out of his own purſe, and kept him at Rome.

In April 1768, he left Rome, to go with M. Cavaceppi over Germany and Switzerland. When he came to Vienna,

Winckleman, Wind.

he was ſo pleaſed with the reception he met with, that he made a longer ſtay there than he had intended. But, being ſuddenly ſeized with a ſecret uneaſineſs and extraordinary deſire to return to Rome, he ſet out for Italy, putting off his viſits to his friends in Germany to a future opportunity. As he paſſed through Trieſte, he was aſſaſſinated, June 8. 1768, by a wretch named Arcangeli, a native of Campiglio, a town in the territory of Piſtoia, with whom he had made an acquaintance on the road. This miſcreant had been condemned for a robbery to work in fetters four years, and then to be baniſhed the Auſtrian territories, on an oath never to return. He had obtained a mitigation of one of his ſentences, and retired to Venice; but, changing his quarters backwards and forwards he was ſo reduced in circumſtances that he at length took up his lodgings at the inn to which the Abbé happened to come. Arcangeli paid ſuch aſſiduous court to him, that he entirely gained his confidence; and having been favoured with a ſight of the valuable preſents which he had received at Vienna, formed a deſign to murder and rob him. He bought a new ſharp knife on purpoſe; and as the Abbé (who had in the moſt friendly manner invited him to Rome) was ſitting down in his chair, early in the morning, he threw a rope over his head, and before he could diſengage himſelf, ſtabbed him in five different places. The Abbé had ſtill ſtrength to get down to the ground floor, and call for help; and being laid on a bed in the midſt of the moſt violent pain, he had compoſure ſufficient to receive the laſt ſacraments, and to make his will, in which he appointed cardinal Alexander Albani his reſiduary legatee, and expired in the afternoon. The murderer was ſoon after apprehended; and executed on the wheel oppoſite the inn, June 26.

Abbé Winckleman was a middle-ſized man: he had a very low forehead, ſharp noſe, and little black hollow eyes, which gave him an aſpect rather gloomy than otherwiſe. If he had any thing graceful in his phyſiognomy, it was his mouth. A fiery and impetuous diſpoſition often threw him into extremes. Naturally enthuſiaſtic, he often indulged an extravagant imagination; but as he poſſeſſed a ſtrong and ſolid judgment, he knew how to give things a juſt and intrinſic value. In conſequence of this turn of mind, as well as a neglected education, a cautious reſerve was a quality he little knew. If he was bold in his deciſions as an author, he was ſtill more ſo in his converſation, and has often made his friends tremble for his temerity. If ever man knew what friendſhip was, that man was Mr Winckleman, who regularly practiſed all its duties; and for this reaſon he could boaſt of having friends among perſons of every rank and condition.

WIND is a ſenſible agitation of the atmoſphere, occaſioned by a quantity of air flowing from one place to another.

As navigation depends in a great meaſure upon the direction and force of the winds, as the temperature of climates is greatly influenced by them, and as they are abſolutely neceſſary to preſerve the ſalubrity of the atmoſphere, it is not ſurpriſing that they have very much engaged the attention of mankind. To be acquainted with the laws by which they are regulated, and to be able to calculate beforehand the conſequences of theſe laws, has been in every age the eager wiſh of philoſophers. But whether it has been owing to an improper method of ſtudying this ſubject, or to its lying beyond the reach of the human faculties, philoſophers have not made that progreſs in it which the ſanguine imaginations of ſome individuals led them to expect. Many diſcoveries indeed have been made; and from the numbers and the genius of the philoſophers at preſent engaged in this ſtudy, others equally important may be expected. But, notwithſtanding this, many of the phenomena remain unexplained, and a rational and ſatisfactory theory ſeems ſtill beyond our reach. It will not be expected, that where philoſophers in general have failed, we ſhall ſucceed. If we can collect the facts hitherto aſcertained, and explain ſuch of them as the late diſcoveries have enabled us to underſtand, we truſt we ſhall obtain the indulgence of the Public, though we cannot boaſt of throwing much new light on this difficult ſubject. Wind.

Hiſtory of the Winds.

As the winds of the torrid zone differ in ſeveral important particulars from thoſe which blow without the tropics, we ſhall firſt deſcribe them, and afterwards thoſe of the temperate zones.

1 Winds of the Torrid Zone.

I. In thoſe parts of the Atlantic and Pacific ocean which lie neareſt the equator, there is a regular wind during the whole year called the *trade-wind*. On the north ſide of the equator it blows from the north-eaſt, varying frequently a point or two towards the north or eaſt; and on the ſouth ſide of it, from the ſouth eaſt; changing ſometimes in the ſame manner towards the ſouth or eaſt. The ſpace included between the ſecond and fifth degree of north latitude is the internal limit of theſe two winds. There the winds can neither be ſaid to blow from the north nor the ſouth; calms are frequent, and violent ſtorms. This ſpace varies a little in latitude as the ſun approaches either of the tropics.—In the Atlantic ocean the trade winds extend farther north on the American than on the African coaſt; and as we advance weſtward, they become gradually more eaſterly, and decreaſe in ſtrength*. Their force diminiſhes likewiſe as we approach their utmoſt boundaries. It has been remarked alſo, that as the ſun approaches the tropic of Cancer, the ſouth-eaſt winds become gradually more ſoutherly, and the north-eaſt winds more eaſterly: exactly the contrary takes place when the ſun is approaching the tropic of Capricorn §.

2 The trade-wind.

3 Monſoons.

The trade-wind blows conſtantly in the Indian ocean from the 10th degree of ſouth latitude to near the 30th: But to the northward of this the winds change every ſix months, and blow directly oppoſite to their former courſe. Theſe regular winds are called *monſoons*, from the Malay word *mooſſin*, which ſignifies "a ſeaſon †." When they ſhift their direction, variable winds and violent ſtorms ſucceed, which laſt for a month and frequently longer; and during that time it is dangerous for veſſels to continue at ſea.

The monſoons in the Indian ocean may be reduced to two; one on the north and another on the ſouth ſide of the equator; which extend from Africa to the longitude of New Holland and the eaſt coaſt of China, and which ſuffer partial changes in particular places from the ſituation and inflection of the neighbouring countries.

1. Between the 3d and 10th degrees of ſouth latitude the ſouth-eaſt trade-wind continues from April to October; but during the reſt of the year the wind blows from the north-weſt ‡. Between Sumatra and New Holland this monſoon blows from the ſouth during our ſummer months, approaching gradually to the ſouth-eaſt as we advance towards the coaſt of New Holland; it changes about the end of September, and continues in the oppoſite direction till April §. Between Africa and Madagaſcar its direction is influenced by the coaſt; for it blows from the north-eaſt from October to April, and during the reſt of the year from the ſouth-weſt ¶.

2. Over all the Indian ocean, to the northward of the 3d degree of ſouth latitude, the north-eaſt trade-wind blows from October to April, and a ſouth-weſt wind from April to October ‖. From Borneo, along the coaſt of Malacca and

§ Ibidem.

¶ Bruce's Travels, vol. i. p. 459.

‖ Dr Halley, ibid.

Wind.

and as far as China, this monſoon in ſummer blows nearly from the ſouth, and in winter from the north by eaſt §. Near the coaſt of Africa, between Mozambique and Cape Guardefan, the winds are irregular during the whole year, owing to the different monſoons which ſurround that particular place.—Monſoons are likewiſe regular in the Red Sea; between April and October they blow from the north-weſt, and during the other months from the ſouth-eaſt, keeping conſtantly parallel to the coaſt of Arabia*.

§ Dr Halley, ibid.

* Bruce's Travels, vol. i. ch. 4.

Monſoons are not altogether confined to the Indian Ocean; on the coaſt of Brazil, between Cape St Auguſtine and the iſland of St Catherine, the wind blows between September and April from the eaſt or north-eaſt, and between April and September from the ſouth-weſt†.—The bay of Panama is the only place on the weſt ſide of a great continent where the wind ſhifts regularly at different ſeaſons: there it is eaſterly between September and March; but between March and September it blows chiefly from the ſouth and ſouth-weſt.

† Sir Walter Raleigh's Voyage, Foreſt's Voy. p. 97.

Such in general is the direction of the winds in the torrid zone all over the Atlantic, Pacific, and Indian Oceans; but they are ſubject to particular exceptions, which we ſhall now endeavour to enumerate.—On the coaſt of Africa, from Cape Bayador to Cape Verde, the winds are generally north-weſt; from hence to the iſland of St Thomas near the equator they blow almoſt perpendicular to the ſhore, bending gradually, as we advance ſouthwards, firſt to the weſt and then to the ſouth-weſt ‖. On the coaſt of New Spain likewiſe, from California to the Bay of Panama, the winds blow almoſt conſtantly from the weſt or ſouth-weſt except during May, June, and July, when land-winds prevail, called by the Spaniards *Popogayos*. On the coaſt of Chili and Peru ¶, from 20° or 30° ſouth latitude, to the equator, and on the parallel coaſt of Africa, the wind blows during the whole year from the ſouth, varying according to the direction of the land towards which it inclines, and extending much farther out to ſea on the American than the African coaſt. The trade-winds are alſo interrupted ſometimes by weſterly winds in the Bay of Campeachy and the Bay of Honduras.

‖ Halley, ibid.

¶ Sir Walter Raleigh's Voyage. Dr Gurden, Phil. Tranſ. Abr. vol. ii. p. 132.

As to the countries between the tropics, we are too little acquainted with them to be able to give a ſatisfactory hiſtory of their winds.

4 Sea and land breezes.

In all maritime countries between the tropics of any extent, the wind blows during a certain number of hours every day *from* the ſea, and during a certain number *towards* the ſea from the land; theſe winds are called the *ſea and land breezes*. The ſea breeze generally ſets in about ten in the forenoon, and blows till ſix in the evening; at ſeven the land-breeze begins, and continues till eight in the morning, when it dies away*. During ſummer the ſea breeze is very perceptible on all the coaſts of the Mediterranean Sea‡, and even ſometimes as far north as Norway‖.

* Marſden's Hiſt. of Sumatra, p. 17. Buffon's Nat. Hiſt. vol. i. p. 385.

‡ Volney's Travels.

‖ Pontoppidan's Nat. Hiſt. of Norway.

In the iſland of St Lewis on the coaſt of Africa, in 16° north latitude, and 16° weſt longitude, the wind during the rainy ſeaſon, which laſts from the middle of July to the middle of October, is generally between the ſouth and eaſt; during the reſt of the year it is for the moſt part eaſt or north-eaſt in the morning; but as the ſun riſes, the wind approaches gradually to the north, till about noon it gets to the weſt of north, and is called a *ſea-breeze*. Sometimes it ſhifts to the eaſt as the ſun deſcends, and continues there during the whole night. In February, March, April, May, and June, it blows almoſt conſtantly between the north and weſt §. In the iſland of Balama, which lies likewiſe on the weſt coaſt of Africa, in the 11th degree of north latitude, the wind during nine months of the year blows from the ſouth-weſt; but in November and December a very cold wind blows from the north eaſt*.

5 Winds in St Lewis and Balama.

§ Dr Schotte, Phil. Tranſ. vol. lxx. art. 25.

In the kingdom of Bornou, which lies between the 16th and 20th degree of north latitude, the warm ſeaſon is introduced about the middle of April by ſultry winds from the ſouth-eaſt, which bring along with them a deluge of rain†. In Fezzan, which is ſituated about the 25th degree of north latitude, and the 35th degree of eaſt longitude, the wind from May to Auguſt blows from the eaſt, ſouth-eaſt, or ſouth-weſt, and is intenſely hot ‡.

6 Bornou and Fezzan,

† African Aſſociation, p. 600.

‡ Ibid.

In Abyſſinia the winds generally blow from the weſt, north-weſt, north, and north-eaſt. During the months of June, July, Auguſt, September, and October, the north and north-eaſt winds blow almoſt conſtantly, eſpecially in the morning and evening; and during the reſt of the year they are much more frequent than any other winds*.

7 Abyſſinia,

* Bruce's Travels, vol. iv. p. 651.

At Calcutta, in the province of Bengal, the wind blows during January and February from the ſouth-weſt and ſouth; in March, April, and May, from the ſouth; in June, July, Auguſt, and September, from the ſouth and ſouth-eaſt; in October, November, and December, from the north-weſt*.—At Madras the moſt frequent winds are the north and north-eaſt—At Tivoli in St Domingo, and at Iles de Vaches, the wind blows oftenеſt from the ſouth and ſouth-eaſt‡.—From theſe facts it appears, that in moſt tropical countries with which we are acquainted, the wind generally blows *from* the neareſt ocean, except during the coldeſt months, when it blows *towards* it.

8 Calcutta, Madras,

* Aſiatic Reſearches, vols. i. and ii. Appen.

9 And St Domingo.

‡ P. Cotte, Jour. de Phyſ. 1791.

II. In the temperate zones the direction of the winds is by no means ſo regular as between the tropics. Even in the ſame degree of latitude, we find them often blowing in different directions at the ſame time; while their changes are frequently ſo ſudden and ſo capricious, that to account for them has hitherto been found impoſſible. When winds are violent, and continue long, they generally extend over a large tract of country; and this is more certainly the caſe when they blow from the north or eaſt than from any other points §. By the multiplication and compariſon of Meteorological Tables, ſome regular connection between the changes of the atmoſphere in different places may in time be obſerved, which will at laſt lead to a ſatisfactory theory of the winds. It is from ſuch tables chiefly that the following facts have been collected.

10 Winds of the North Temperate Zone.

§ Derham's Phyſico-Theology, ch. ii.

11 Of America,

In Virginia, the prevailing winds are between the *ſouth-weſt*, *weſt*, *north*, and *north-weſt*; the moſt frequent is the *ſouth-weſt*, which blows more conſtantly in June, July, and Auguſt, than at any other ſeaſon. The *north-weſt* winds blow moſt conſtantly in November, December, January, and February*.—At Ipſwich in New England the prevailing winds are alſo between the *ſouth-weſt*, *weſt*, *north*, and *north-eaſt*; the moſt frequent is the *north-weſt*†: But at Cambridge, in the ſame province, the moſt frequent wind is the *ſouth-eaſt*‡.—The predominant winds at New York are the *north* and *weſt* §: And in Nova Scotia *north-weſt* winds blow for three-fourths of the year‖.—The ſame wind blows moſt frequently at Montreal in Canada; but at Quebec the wind generally follows the direction of the river St Lawrence, blowing either from the *north-eaſt* or *ſouth-weſt* ¶.—At Hudſon's Bay *weſterly* winds blow for three fourths of the year; the *north-weſt* wind occaſions the greateſt cold, but the *north* and *north-eaſt* are the vehicles of ſnow*.

* Jefferſon's Virginia, p. 123.

† Tranſ. Amer. Acad. vol. i. p. 336.

‡ M. Cotte, Journ. de Phyſ. 1791.

§ Ibid.

‖ Preſent State of Nova Scotia and Canada, p. 38.

¶ Cotte, ibid.

* Pennant's Supp. to Arctic Zool. p. 41.

It appears from theſe facts, that weſterly winds are moſt frequent over the whole eaſtern coaſt of North America; that in the ſouthern provinces ſouth-weſt winds predominate; that the north-weſt become gradually more frequent as we approach the frigid zone.

In Egypt, during part of May, and during June, July, Auguſt,

Wind.

August, and September, the wind blows almost constantly from the *north*, varying sometimes in June to the *west*, and in July to the *west* and the *east*; during part of September, and in October and November, the winds are variable, but blow more regularly from the *east* than any other quarter; in December, January, and February, they blow from the *north*, *north-west*, and *west*; towards the end of February they change to the *south*, in which quarter they continue till near the end of March; during the last days of March and in April they blow from the *south-east*, *south*, and *south-west*, and at last from the *east*; and in this direction they continue during a part of May‡.

12 Egypt,

‡ Volney's Travel's, vol. i. p. 58.

13 The Mediterranean,

In the Mediterranean the wind blows nearly three-fourths of the year from the *north*; about the equinoxes there is always an *easterly* wind in that sea, which is generally more constant in spring than in autumn†. These observations do not apply to the gut of Gibraltar, where there are seldom any winds except the *east* and the *west*.—At Bastia, in the island of Corsica, the prevailing wind is the *south-west**.

† Ibid. p. 59 and 65.

* Cotte, ibid.

14 Syria and other parts of Asia,

In Syria the *north* wind blows from the autumnal equinox to November; during December, January, and February, the winds blow from the *west* and *south-west*; in March they blow from the *south*, in May from the *east*, and in June from the *north*. From this month to the autumnal equinox the wind changes gradually as the sun approaches the equator; first to the *east*, then to the *south*, and lastly to the *west*†.—At Bagdad the most frequent winds are the *south-west* and *north-west*; at Pekin, the *north* and the *south*‡; at Kamtschatka, on the north-east coast of Asia, the prevailing winds blow from the *west* §.

† Volney's Trav. vol. i. p. 326.

‡ Cotte, ibid.

§ Pennant's Arctic Zool. p. cxiii.

15 Italy,

In Italy the prevailing winds differ considerably according to the situation of the places where the observations have been made: At Rome and Padua they are *northerly*, at Milan *easterly*†.—All that we have been able to learn concerning Spain and Portugal is, that on the west coast of these countries the *west* is by far the most common wind, particularly in summer; and that at Madrid the wind is *north-east* for the greatest part of the summer, blowing almost constantly from the Pyrenean mountains‡.—At Berne in Switzerland the prevailing winds are the *north* and *west*; at St Gottard, the *north-east*; at Lausanne, the *north-west* and *south-west* §.

† Cotte, ibid.

16 Spain,

‡ Bohun's Hist. of Winds, p. 116.

17 Switzerland,

§ Cotte, ibid.

Father Cotte has given us the result of observations made at 86 different places of France ‖; from which it appears, that along the whole south coast of that kingdom the wind blows most frequently from the *north*, *north-west*, and *north-east*; on the west coast, from the *west*, *south-west*, and *north-west*; and on the north coast, from the *south-west*. That in the interior parts of France the *south-west* wind blows most frequently in 18 places; the *west* wind in 14; the *north* in 13; the *south* in 6; the *north-east* in 4; the *south-east* in 2; the *east* and *north-west* each of them in one.—On the west coast of the Netherlands, as far north as Rotterdam, the prevailing winds are probably the *south-west*, at least this is the case at Dunkirk and Rotterdam‡. It is probable also that along the rest of this coast, from the Hague to Hamburgh, the prevailing winds are the *north-west*, at least these winds are most frequent at the Hague and at Franeker §.—The prevailing wind at Delft is the *south-east*; and at Breda the *north* and the *east*†.

‖ Ibid.

18 France,

19 The Netherlands,

‡ Ibid.

§ Ibid.

† Ibid.

20 Germany,

In Germany the *east* wind is most frequent at Gottingen, Munich, Weissemburg, Dusseldorf, Saganum, Erford, and at Buda in Hungary; the *south-east* at Prague and Wirtzburg; the *north-east* at Ratisbone; and the *west* at Manheim and Berlin ‡.

‡ Ibid.

21 Britain,

From an average of ten years of the register kept by order of the Royal Society, it appears, that at London the winds blow in the following order:

Winds.	Days.	Winds.	Days.
South-west	112	South-east	32
North-east	58	East	26
North-west	50	South	18
West	53	North	16

Wind.

It appears, from the same register, that the *south-west* wind blows at an average more frequently than any other wind during every month of the year, and that it blows longest in July and August; that the *north east* blows most constantly during January, March, April, May, and June, and most seldom during February, July, September and December; and that the *north-west* wind blows oftener from November to March, and more seldom during September and October than any other months. The *south-west* winds are also most frequent at Bristol, and next to them are the *north-east* §.

§ Phil. Trans. vol. lxvi. p. 2.

The following table of the winds at Lancaster has been drawn up from a register kept for seven years at that place ¶:

¶ Manch. Trans. vol. iv. p. 234.

Winds.	Days.	Winds.	Days.
South-west	92	South-east	35
North-east	67	North	30
South	51	North-west	26
West	41	East	17

The following table is an abstract of nine years observations made at Dumfries by Mr Copland†.

† Ibid.

Winds.	Days.	Winds	Days.
South	82½	North	36½
West	69	North-west	25½
East	68	South-east	18½
South-west	50½	North-east	14½

The following table is an abstract of seven year's observations made by Mr Meek at Cambuslang near Glasgow‡:

‡ Statistical Account of Scotland, vol. v. p. 245.

Winds.	Days.	Winds.	Days.
South-west	174	North-east	104
North-west	140	South-east	47

It appears, from the register from which this table was extracted, that the *north-east* wind blows much more frequently in April, May, and June, and the *south-west* in July, August, and September, than at any other period. We learn from the Statistical account of Scotland, that the *south-west* is by far the most frequent wind all over that kingdom, especially on the west coast. At Saltcoats in Airshire, for instance, it blows three-fourths of the year; and along the whole coast of Murray, on the *north-east* side of Scotland, it blows for two-thirds of the year. East winds are common over all Great Britain during April and May; but their influence is felt most severely on the eastern coast.

The following table exhibits a view of the number of days during which the westerly and easterly winds blow in a year at different parts of the island. Under the term *westerly* are included the north-west, west, south west, and south; the term *easterly* is taken in the same latitude.

Years of Obser.	Places.	Wind Westerly.	Wind Easterly.
10	London	233	132,
7	Lancaster	216	149
51	Liverpool‡	170	175
9	Dumfries	227,5	137,5
10	Branxholm, 54 miles south west of Berwick §,	232	133
7	Cambuslang	214	151
8	Hawkhill, near Edinburgh†,	229,5	135.5
	Mean	217,4	144,7

‡ Manchester Trans. vol. iv.

§ Edinburgh Trans. vol. i. p. 203.

† Ibid

In

Wind.

22 Ireland, ‡ Rutty's Hiſt. of the Weather, &c. in Dublin.

In Ireland the *ſouth-weſt* and *weſt* are the grand trade-winds, blowing moſt in ſummer, autumn and winter, and leaſt in ſpring. The *north-eaſt* blows moſt in ſpring, and nearly double to what it does in autumn and winter. The *ſouth-eaſt* and *north-weſt* are nearly equal and moſt frequent after the north-weſt and weſt ‡.

23 North of Europe. ‖ Cotte, Jour. de Phyſ. 1791.

At Copenhagen the prevailing winds are the *eaſt* and *ſouth-eaſt*; at Stockholm, the *weſt* and *north* ‖. In Ruſſia, from an average of a regiſter of 16 years, the winds blow from November to April in the following order:

	Weſt.	N. W.	Eaſt.	S. W.	South.	N. E.	N.	S. E.
Days	45	26	23	22	20	19	14	12

And during the other ſix months,

	Weſt.	N. W.	Eaſt.	S. W.	South.	N. E.	N.	S. E.
Days	27	27	19	24	22	15	32	18

The *weſt* wind blows during the whole year 72 days; the *north-weſt* 53; the *ſouth-weſt* and *north* 46 days each. During ſummer it is calm for 41 days, and during winter for 21*. In Norway the moſt frequent winds are the *ſouth*, the *ſouth-weſt*, and *ſouth-eaſt*. The wind at Bergen is ſeldom directly weſt, but generally ſouth-weſt or ſouth-eaſt; a north-weſt, and eſpecially a north-eaſt wind, are but little known there†.

* Guthrie on the climate of Ruſſia, Edin. Tranſ. vol. ii.

† Pontoppidan's Nat. Hiſt. of Norway part i.

From the whole of theſe facts, it appears that the moſt frequent winds on the ſouth coaſts of Europe are the north, the north-eaſt, and north-weſt; and on the weſtern coaſt, the ſouth-weſt, that in the interior parts which lie moſt contiguous to the Atlantic Ocean, ſouth-weſt winds are alſo moſt frequent, but that eaſterly winds prevail in Germany. Weſterly winds are alſo moſt frequent on the north-eaſt coaſt of Aſia.

24 Winds of the South Temperate Zone.

It is probable that the winds are more conſtant in the ſouth temperate zone, which is in a great meaſure covered with water, than in the north temperate zone, where their direction muſt be frequently interrupted and altered by mountains and other cauſes.

25 Of the Cape of Good Hope,

M. de la Baille, who was ſent thither by the French king to make aſtronomical obſervations, informs us, that at the Cape of Good Hope the main winds are the *ſouth-eaſt* and *north-weſt*; that other winds ſeldom laſt longer than a few hours; and that the *eaſt* and *north-eaſt* winds blow very ſeldom. The *ſouth-eaſt* wind blows in moſt months of the year, but chiefly from October to April; the *north-weſt* prevails during the other ſix months, bringing along with it rain, and tempeſts, and hurricanes. Between the Cape of Good Hope and New Holland the winds are commonly weſterly, and blow in the following order: *north-weſt*, *ſouth-weſt*, *weſt*, *north*‡.

‡ Meteor. Tables at the end of Philip's & White's voyages.

26 Of the South Sea.

In the great South Sea, from latitude 30° to 40° ſouth, the *ſouth-eaſt* trade-wind blows moſt frequently, eſpecially when the ſun approaches the tropic of Capricorn; the wind next to it in frequency is the *north-weſt*, and next to that is the *ſouth-weſt*. From ſouth latitude 40° to 50° the prevailing wind is the *north-weſt*, and next the *ſouth-weſt*. From 50° to 60° the moſt frequent wind is alſo the *north-weſt*, and next to it is the *weſt*.*

* Walc's Meteor. Tables.

Thus it appears that the trade-winds ſometimes extend farther into the ſouth temperate zone than their uſual limits, particularly during ſummer; that beyond their influence the winds are commonly weſterly, and that they blow in the following order: *north-weſt*, *ſouth-weſt*, *weſt*.

27 General obſervations.

Thus have we finiſhed the hiſtory of the direction of the winds. In the torrid zone they blow conſtantly from the north-eaſt, on the north ſide of the equator, and from the ſouth-eaſt on the ſouth ſide of it. In the north temperate zone they blow moſt frequently from the ſouth-weſt; in the ſouth temperate zone from the north-weſt, changing, however, frequently to all points of the compaſs, and in the north temperate zone blowing particularly during ſpring from the north-eaſt.

Wind.

28 Velocity of wind.

As to the velocity of the wind, its variations are almoſt infinite; from the gentleſt breeze to the hurricane, which tears up trees and blows down houſes. It has been remarked, that our moſt violent winds take place when neither the heat nor the cold is greateſt; that violent winds generally extend over a great tract of country; and that they are accompanied with ſudden and great falls in the mercury of the barometer. The wind is ſometimes very violent at a diſtance from the earth, while it is quite calm at its ſurface. On one occaſion Lunardi went at the rate of 70 miles an hour in his balloon, though it was quite calm at Edinburgh when he aſcended, and continued ſo during his whole voyage. See PNEUMATICS.

For the inſtruments invented to meaſure the velocity of the wind, ſee ANEMOSCOPE and ANEMOMETER.

Theory of the Winds.

29 The atmoſphere a fluid

THE atmoſphere is a fluid ſurrounding the earth, and extending to an unknown height. Now all fluids tend invariably to a level: if a quantity of water be taken out of any part of a veſſel, the ſurrounding water will immediately flow in to ſupply its place, and the ſurface will become level as before; or if an additional quantity of water be poured into any part of the veſſel, it will not remain there, but diffuſe itſelf equally over the whole. Such exactly would be the caſe with the atmoſphere. Whatever therefore deſtroys the equilibrium of this fluid, either by increaſing or diminiſhing its bulk in any particular place, muſt at the ſame time occaſion a wind.

30 Capable of dilatation and expanſion

Air, beſides its qualities in common with other fluids, is alſo capable of being dilated and compreſſed. Suppoſe a veſſel filled with air: if half the quantity which it contains be drawn out by means of an air-pump, the remainder will ſtill fill the veſſel completely, or if twice or three times the original quantity be forced in by a condenſer, the veſſel will ſtill be capable of holding it.

Rarefied air is lighter, and condenſed air heavier, than common air. When fluids of unequal ſpecific gravities are mixed together, the heavier always deſcend, and the lighter aſcend. Were quickſilver, water, and oil, thrown into the ſame veſſel together, the quickſilver would uniformly occupy the bottom, the water the middle, and the oil the top. Were water to be thrown into a veſſel of oil, it would immediately deſcend, becauſe it is heavier than oil. Exactly the ſame thing takes place in the atmoſphere. Were a quantity of air, for inſtance, to be ſuddenly condenſed at a diſtance from the ſurface of the earth, being now heavier than before, it would deſcend till it came to air of its own denſity; or, were a portion of the atmoſphere at the ſurface of the earth to be ſuddenly rarefied, being now lighter than the ſurrounding air, it would immediately aſcend.

31 By heat and cold.

If a bladder half filled with air be expoſed to the heat of a fire, the air within will ſoon expand, and diſtend the bladder; if it be now removed to a cold place, it will ſoon become flaccid as before. This ſhows that heat rarefies and that cold condenſes air. The ſurface of the torrid zone is much more heated by the rays of the ſun than the frozen or temperate zones, becauſe the rays fall upon it much more perpendicularly. This heat is communicated to the air near the ſurface of the torrid zone, which being thereby rarefied, aſcends; and its place is ſupplied by colder air, which ruſhes in from the north and ſouth.

32 The heat of the ſun,

The diurnal motion of the earth is greateſt at the equator, and diminiſhes gradually as we approach the poles, where it

Wind. it ceaſes altogether. Every ſpot of the earth's ſurface at the equator moves at the rate of 15 geographical miles in a minute; at the 40° of latitude, it moves at about 11½ miles in a minute; and at the 30°, at nearly 13 miles. The atmoſphere, by moving continually round along with the earth, has acquired the ſame degree of motion; ſo that thoſe parts of it which are above the equator move faſter than thoſe which are at a diſtance. Were a portion of the atmoſphere to be tranſported in an inſtant from latitude 30° to the equator, it would not immediately acquire the velocity of the equator; the eminences of the earth therefore would ſtrike againſt it, and it would aſſume the appearance of an eaſt wind. This is the caſe in a ſmaller degree with the air that flows towards the equator, to ſupply the place of the rarefied air, which is continually aſcending: and this when combined with its real motion from the north and ſouth, muſt cauſe it to aſſume the appearance of a north-eaſterly wind on this ſide the equator, and of a ſouth-eaſterly beyond it.

33 The earth's diurnal motion. The motion weſtwards occaſioned by this difference in celerity alone would not be great; but it is farther increaſed by another circumſtance. Since the rarefaction of the air in the torrid zone is owing to the heat derived from the contiguous earth, and ſince this heat is owing to the perpendicular rays of the ſun, thoſe parts muſt be hotteſt where the ſun is actually vertical, and conſequently the air over them muſt be moſt rarefied; the contiguous parts of the atmoſphere will therefore be drawn moſt forcibly to that particular ſpot. Now, ſince the diurnal motion of the ſun is from eaſt to weſt, this hotteſt ſpot will be continually ſhifting weſtwards, and this will occaſion a current of the atmoſphere in that direction. That this cauſe really operates, appears from a circumſtance already mentioned: when the ſun approaches either of the tropics, the trade-wind on the ſame ſide of the equator aſſumes a more eaſterly direction, evidently from the cauſe here mentioned; while the oppoſite trade-wind, being deprived of this additional impulſe, blows in a direction more perpendicular to the equator.

34 And the action of the moon, The weſterly direction of the trade-winds is ſtill farther increaſed by another cauſe. Since the attraction of the ſun and moon produces ſo remarkable an effect upon the ocean, we cannot but ſuppoſe that an effect equally great at leaſt is produced upon the atmoſphere. Indeed as the atmoſphere is nearer the moon than the ſea is, the effect produced by attraction upon it ought to be greater. When we add to this the elaſticity of the air, or that diſpoſition which it has to dilate itſelf when freed from any of its preſſure, we cannot but conclude that the tides in the atmoſphere are conſiderable. Now ſince the apparent diurnal motion of the moon is from eaſt to weſt, the tides muſt follow it in the ſame manner, and conſequently produce a conſtant motion in the atmoſphere from eaſt to weſt. This reaſoning is confirmed by the obſervations of ſeveral philoſophers, particularly of M. Caſſan §, that in the torrid zone the barometer is always two-thirds of a line higher twice every 24 hours than during the reſt of the day; and that the time of this riſe always correſponds with the tides of the ſea; a proof that it proceeds from the ſame cauſe.

§ Journal de Phyſique, April 1790.

35 Produce the trade-winds. All theſe different cauſes probably combine in the production of the trade-winds; and from their being ſometimes united, and ſometimes diſtinct or oppoſite, ariſe all thoſe little irregularities which take place in the direction and force of the trade-winds.

Since the great cauſe of theſe winds is the rarefaction of the atmoſphere by the heat of the ſun, its aſcenſion, and the conſequent ruſhing of colder air from the north and ſouth, the internal boundary of the trade-winds muſt be that parallel of the torrid zone which is hotteſt, becauſe there the aſcenſion of the rarefied air muſt take place. Now ſince the ſun does not remain ſtationary, but is conſtantly ſhifting from one tropic to the other, we ought naturally to expect that this boundary would vary together with its exciting cauſe; that therefore when the ſun is perpendicular to the tropic of Cancer, the north-eaſt trade-winds would extend no farther ſouth than north latitude 23,5°; that the ſouth-eaſt wind would extend as far north; and that when the ſun was in the tropic of Capricorn, the very contrary would take place. We have ſeen, however, that though this boundary be ſubject to conſiderable changes from this very cauſe, it may in general be conſidered as fixed between the ſecond and fifth degrees of north latitude. Wind.

36 The internal limit of which

Though the ſun be perpendicular to each of the tropics during part of the year, he is for one half of it at a conſiderable diſtance; ſo that the heat which they acquire while he is preſent, is more than loſt during his abſence. But the ſun is perpendicular to the equator twice in a year, and never farther diſtant from it than 23½°; being therefore twice every year as much heated, and never ſo much cooled, as the tropics, its mean heat muſt be greater, and the atmoſphere in conſequence generally moſt rarefied at that place. Why then, it will be aſked, is not the equator the boundary of the two trade-winds? To ſpeak more accurately than we have hitherto done, the internal limit of theſe winds muſt be that parallel where the mean heat of the earth is greateſt. This would be the equator, were it not for a reaſon which ſhall now be explained.

37 Is the parallel of greateſt mean heat,

38 Which is on the north ſide of the equator; It has been ſhown by aſtronomers, that the orbit of the earth is an ellipſis and that the ſun is placed in one of the phoci. Were this orbit to be divided into two parts by a ſtraight line perpendicular to the tranſverſe axis, and paſſing through the centre of the ſun, one of theſe parts would be leſs than the other; and the earth, during its paſſage through this ſmaller part of its orbit, would conſtantly be nearer the ſun than while it moved through the other portion. The celerity of the earth's motion in any part of its orbit is always proportioned to its diſtance from the ſun; the nearer it is to the ſun, it moves the faſter; the farther diſtant, the ſlower. The earth paſſes over the ſmaller portion of its orbit during our winter; which muſt therefore be ſhorter than our ſummer, both on account of this part of the orbit being ſmaller than the other, and on account of the increaſed celerity of the earth's motion. The difference, according to Caſſini, is 7 days, 23 hours, and 53 minutes. While it is winter in the northern, it is ſummer in the ſouthern, hemiſphere; wherefore the ſummer in the ſouthern hemiſphere muſt be juſt as much ſhorter than the winter as our winter is ſhorter than our ſummer. The difference, therefore, between the length of the ſummer in the two hemiſpheres is almoſt 16 days. The ſummer in the northern hemiſphere conſiſts of 190½ days, while in the ſouthern it conſiſts only of 174½. They are to one another nearly in the proportion of 14 to 12,8; and the heat of the two hemiſpheres may probably have nearly the ſame proportion to one another. The internal limit of the trade-winds, ought to be that parallel where the mean heat of the globe is greateſt: this would be the equator, if both hemiſpheres were equally hot; but ſince the northern hemiſphere is the hotteſt, that parallel ought to be ſituated ſomewhere in it; and ſince the difference between the heat of two hemiſpheres is not great, the parallel ought not to be far diſtant from the equator (A).

39 Becauſe the mean heat of the north hemiſphere is greateſt,

The

(A) This parallel could be determined by calculation, provided the mean heat of both the ſegments into which it divides

Wind. 40 Cauſe of the monſoons.

The trade-wind would blow regularly round the whole globe if the torrid zone were all covered with water. If the Indian Ocean were not bounded by land on the north, it would blow there in the ſame manner as it does in the Atlantic and Pacific Oceans. The rays of light paſs through a tranſparent body without communicating any, or at leaſt but a ſmall degree of heat. If a piece of wood be incloſed in a glaſs veſſel, and the focus of a burning glaſs directed upon it, the wood will be burnt to aſhes, while the glaſs through which all the rays paſſed is not even heated. When an opaque body is expoſed to the ſun's rays, it is heated in proportion to its opacity. If the bulb of a thermometer be expoſed to the ſun, the quickſilver will not riſe ſo high as it would do if this bulb were painted black. Land is much more opaque than water; it becomes therefore much warmer when both are equally expoſed to the influence of the ſun. For this reaſon, when the ſun approaches the tropic of Cancer, India, China, and the adjacent countries, become much hotter than the ocean which waſhes their ſouthern coaſts. The air over them becomes rarefied, and aſcends, while colder air ruſhes in from the Indian Ocean to ſupply its place. As this current of air moves from the equator northward, it muſt, for a reaſon already explained, aſſume the appearance of a ſouth-weſt wind; and this tendency eaſtward is increaſed by the ſituation of the countries to which it flows. This is the cauſe of the ſouth-weſt monſoon, which blows during ſummer in the northern parts of the Indian Ocean. Between Borneo and the coaſt of China its direction is almoſt due north, becauſe the country to which the current is directed lies rather to the weſt of north; a circumſtance which counteracts its greater velocity.

In winter, when the ſun is on the ſouth ſide of the equator, theſe countries become cool, and the north-eaſt trade-wind reſumes its courſe, which, had it not been for the interference of theſe countries, would have continued the whole year.

As the ſun approaches the tropic of Capricorn, it becomes almoſt perpendicular to New Holland: that continent is heated in its turn, the air over it is rarefied, and colder air ruſhes in from the north and weſt to ſupply its place. This is the cauſe of the north-weſt monſoon, which blows from October to April, from the third to the tenth degree of ſouth latitude. Near Sumatra its direction is regulated by the coaſt: this is the caſe alſo between Africa and Madagaſcar.

The ſame cauſe which occaſions the monſoons, gives riſe to the winds which blow on the weſt coaſts of Africa and America. The air above the land is hotter and rarer, and conſequently lighter than the air above the ſea; the ſea air therefore flows in, and forces the lighter land atmoſphere to aſcend. Wind. 41 And of the ſea and land breezes.

The ſame thing will account for the phenomena of the ſea and land breezes. During the day, the cool air of the ſea, loaded with vapours, flows in upon the land, and takes the place of the rarefied land air. As the ſun declines, the rarefaction of the land air is diminiſhed: thus an equilibrium is reſtored. As the ſea is not ſo much heated during the day as the land, neither is it ſo much cooled during the night; becauſe it is conſtantly expoſing a new ſurface to the atmoſphere. As the night approaches, therefore, the cooler and denſer air of the hills (for where there are no hills there are no ſea and land breezes) falls down upon the plains, and preſſing upon the now comparatively lighter air of the ſea, cauſes the land-breeze.

The rarefied air which aſcends between the ſecond and fifth degrees of north latitude, has been ſhown to be the principal cauſe of the trade-winds. As this air aſcends, it muſt become gradually colder, and conſequently heavier; it would therefore deſcend again if it were not buoyed up by the conſtant aſcent of new rarefied air. It muſt therefore ſpread itſelf to the north and ſouth, and gradually mix in its paſſage with the lower air; and the greater part of it probably does not reach far beyond the 30°, which is the external limit of the trade-wind. Thus there is a conſtant circulation of the atmoſphere in the torrid zone; it aſcends near the equator, diffuſes itſelf toward the north and ſouth, deſcends gradually as it approaches the 30°, and returning again towards the equator, performs the ſame circuit. It has been the opinion of the greater part of thoſe who have conſidered this ſubject, that the whole of the rarefied air which aſcends near the equator, advances towards the poles and deſcends there. But if this were the caſe, a conſtant wind would blow from both poles towards the equator, the trade-winds would extend over the whole earth; for otherwiſe the aſcent of air in the torrid zone would very ſoon ceaſe. A little reflection muſt convince us that it cannot be true: rarefied air differs nothing from the common air except in containing a greater quantity of heat. As it aſcends, it gradually loſes this ſuperfluous heat. What then ſhould hinder it from deſcending, and mixing with the atmoſphere below? That there is a conſtant current of ſuperior air, however, towards the poles, cannot be doubted; but it conſiſts principally of hydrogen gas. We ſhall immediately attempt to aſſign the reaſon why its accumulation at the pole is not always attended with a north wind. 42 Air circulates in the torrid zone.

If the attraction of the moon and the diurnal motion of the ſun have any effect upon the atmoſphere, and that they have ſome effect can hardly be diſputed, there muſt be a 43 And moves weſtward,

---

vides the globe were known. Let the radius of this globe be = 1, the circumference of a great circle = 6, and conſequently the arc of a great circle = 3, and the ſolid contents of a hemiſphere = 2. Since the internal limit of the trade-winds is not far diſtant from the equator, we may conſider that portion of the ſphere intercepted between it and the equator as a cylinder, the baſe of which is the equator, and its height the arc intercepted between the equator and the internal limit of the trade-winds. Let this arc be x, and conſequently the cylinder itſelf = $3x$, equal to the exceſs of the ſouthern ſegment into which this internal limit divides the globe above the northern. Let the heat of the northern ſegment be = n, and that of the ſouthern = s. The ſouthern ſegment is = $2 + 3x$, the northern = $2 - 3x$. Now let us ſuppoſe that the bulk of each ſegment is reciprocally as its heat, and we ſhall have this formula, $2 + 3x : 2 - 3x :: n : s$. Wherefore $x = \frac{2n - 2s}{3n + 3s}$. Now if we ſuppoſe $n = 14$, and $s = 12.8$, $\frac{2n - 2s}{3n + 3s}$ is = $\frac{2,4}{80,4}$. To reduce this value of x to degrees, we muſt multiply it by 60, ſince a great circle was made = 6: it gives 1° 48′ 27″ as the internal limit of the trade-wind. This is too ſmall by 2° 11′ 33″. But the value which we have found is only that of the ſine of the arc intercepted between the equator and the internal limit; the arc itſelf would be ſomewhat greater; beſides, the proportion between the heat of the two ſegments is an aſſumed quantity, and may probably be greater than their difference in bulk: and one reaſon for this may be, the great proportion of land in the northern compared with the ſouthern ſegment. See the *Journal de Phyſique, Mai* 1791.

Wind.

real motion of the air weſtwards within the limits of the trade-winds. When this body of air reaches America, its

44 And ſtrikes againſt the American mountains;

further paſſage weſtwards is ſtopt by the mountains which extend from one extremity of that continent to the other. From the momentum of this air, when it ſtrikes againſt the ſides of theſe mountains, and from its elaſticity, it muſt acquire from them a conſiderable velocity, in a direction contrary to the firſt, and would therefore return eaſtwards again if this were not prevented by the trade-winds. It muſt therefore ruſh forwards in that direction where it meets with the leaſt reſiſtance; that is, towards the north and ſouth. As air is nearly a perfectly elaſtic body, when it ſtrikes againſt the ſides of the American mountains its velocity will not be perceptibly diminiſhed, though its direction be changed. Continuing, therefore, to move with the velocity of the equator, when it arrives at the temperate zones it will aſſume the appearance of a north-eaſt or

45 Which occaſions our ſouth-weſt winds.

ſouth-eaſt wind. To this is to be aſcribed the frequency of ſouth-weſt winds over the Atlantic Ocean and weſtern parts of Europe. Whether theſe winds are equally frequent in the Northern Pacific Ocean, we have not been able to aſcertain; but it is probable that the mountains in Aſia produce the ſame effect as thoſe in America.

It is not impoſſible that another circumſtance may alſo contribute to the production of theſe winds. In the article Weather, we endeavoured to prove that the annual evaporation exceeds conſiderably the quantity of rain which falls; and found reaſon to conclude, therefore, that part of the evaporated water was decompounded in the atmoſphere.

46 Air generated in the torrid zone,

In that caſe, the oxygen, which is rather heavier than common air, would mix with the atmoſphere; but the hydrogen (a cubic foot of which weighs only 41.41 grains, while a cubic foot of oxygen weighs 593.32 grains) would aſcend to the higher regions of the atmoſphere.

By what means this decompoſition is accompliſhed (if it takes place at all) we cannot tell. There are probably a thouſand cauſes in nature of which we are entirely ignorant. Whether heat and light, when long applied to vapours, may not be able to decompound them, by uniting with the hydrogen, which ſeems to have a greater attraction for heat than oxygen has; or whether the electrical fluid may not be capable of producing this effect—are queſtions which future obſervations and experiments muſt determine. Dr Franklin filled a glaſs tube with water, and paſſed an electrical ſhock through it; the tube was broken in pieces, and the whole water diſappeared. He repeated the experiment with ink inſtead of water, and placed the tube upon white paper: the ſame effects followed; and the ink, though it diſappeared completely, left no ſtain on the paper. Whether the water in theſe caſes was decompoſed or not, it is impoſſible to ſay; but the ſuppoſition that it was, is not improbable. An experiment might eaſily be contrived to determine the point.

This decompoſition would account for the frequency of ſouth-weſt winds, particularly in ſummer; for thus new air is furniſhed to ſupply the place of that which is forced northwards by the cauſes already explained. Perhaps it may be a confirmation of this conjecture, that the ſouth-weſt winds generally extend over a greater tract of country than moſt other winds which blow in the temperate zones. What has been ſaid of ſouth-weſt winds, holds equally with regard to north-weſt winds in the ſouth temperate zone.

Wind.

47 And accumulating at the pole,

After ſouth-weſt winds have blown for ſome time, a great quantity of air will be accumulated at the pole, at leaſt if they extend over all the northern hemiſphere: and it appears from comparing the tables kept by ſome of our late navigators in the Northern Pacific Ocean with ſimilar tables kept in this iſland, that this is ſometimes the caſe ſo far as relates to the Atlantic and Pacific Oceans. When this accumulation becomes great, it muſt, from the nature of fluids, and from the elaſticity of air, preſs with a conſiderable and increaſing force on the advancing air; ſo that in time it becomes ſtronger than the ſouth-weſt wind. This will occaſion at firſt a calm, and afterwards a north wind; which will become gradually eaſterly as it advances ſouthwards, from its not aſſuming immediately the velocity of the earth. The maſs of the atmoſphere will be increaſed in all thoſe places over which this north-eaſt wind blows: this is confirmed by the almoſt conſtant riſe of the barometer during a north-eaſt wind.

48 Produces north-eaſt winds.

Whatever tends to increaſe the bulk of the atmoſphere near the pole, muſt tend alſo to increaſe the frequency of north-eaſt winds; and if there be any ſeaſon when this increaſe takes place more particularly, that ſeaſon will be moſt liable to theſe winds. During winter the northern parts of Europe are covered with ſnow, which is melted in the beginning of ſummer, when the heat of the ſun becomes more powerful. Great quantities of vapour are during that time raiſed, which will augment both the bulk and weight of the atmoſphere; eſpecially if the conjecture about the converſion of vapour into air has any foundation. Hence north-eaſt winds are moſt prevalent during May and June (B).

But it will be ſaid, if this hypotheſis were true, the ſouth-weſt and north-eaſt winds ought to blow alternately, and continue each of them for a ſtated time; whereas the ſouth-weſt wind blows ſometimes longer and ſometimes ſhorter, neither is it always followed by a north-eaſt wind.

If the conjecture about the decompoſition of vapour in the torrid zone be true, the hydrogen which formed a part of it will aſcend from its lightneſs, and form a ſtratum above the atmoſpherical air, and gradually extend itſelf, as additional hydrogen riſes, towards the north and ſouth, till at laſt it reaches the poles. The lightneſs of hydrogen is owing to the great quantity of heat which it contains: as it approaches the poles it muſt loſe a great part of this heat, and may in conſequence become heavy enough to mix with the atmoſphere below. Oxygen makes a part of the atmoſphere; and its proportion near the poles may ſometimes be greater than ordinary, on account of the additional quantity brought thither from the torrid zone. Mr Cavendiſh mixed oxygen and hydrogen together in a glaſs jar; and upon making an electrical ſpark paſs through them, they immediately combined, and formed water.

49 Decompoſitions of air at the pole,

That there is electric matter at the poles, cannot be doubted. The Abbé Chappe informs us, that he ſaw thunder and lightning much more frequently at Tobolſki and other parts of Siberia than in any other part of the world. In the north of Europe the air, during very cold weather, is exceedingly electric: ſparks can be drawn from a perſon's hands and face, by combing his hair, or even powdering

(B) The frequency of north-eaſt winds during theſe months is the greateſt defect in the climate of Scotland, and is felt indeed ſeverely over all Great Britain. In the united ſtates of America, theſe winds keep pace with the clearing of the land. Some time ago, in Virginia, they did not reach farther than Williamſburgh; now they reach to Richmond, which is ſituated conſiderably farther weſt, and are even beginning to be felt ſtill farther within the country*. Might it not be poſſible then to prevent the frequency of theſe winds in this country, by planting trees along the whole eaſt coaſt? It is a pity that the experiment were not tried: were it to ſucceed, it would very materially improve the climate.

* Jefferſon's State of Virginia, p. 128.

Wind

dering him with a puff. Æpinus was an eye-witneſs to this fact, and to ſtill more aſtoniſhing proofs of the electricity of the atmoſphere during great colds.

50 By electricity.

May not the appearance of the aurora borealis be owing to the union of oxygen and hydrogen by the intervention of the electric fluid? That it is an electrical phenomenon at leaſt, can hardly be doubted. Artificial electricity is much ſtrengthened during an aurora, as Mr Volta and Mr Canton have obſerved; and the magnetic needle moves with the ſame irregularity during an aurora that has been obſerved in other electrical phenomena. This fact we learn from Bergman and De la Lande. Many philoſophers have attempted to demonſtrate, that auroræ boreales are beyond the earth's atmoſphere; but the very different reſults of their calculations evidently prove that they were not poſſeſſed of ſufficient data.

51 Another cauſe of ſouth-eaſt Winds;

If this conjecture be true, part of the atmoſphere near the poles muſt at times be converted into water. This would account for the long continuance of ſouth-weſt winds at particular times: when they do ſo, a decompoſition of the atmoſphere is going on at the pole. It would render this conjecture more probable, if the barometer fell always when a ſouth-weſt wind continues long.

If this hypotheſis be true, a ſouth-weſt wind ought always to blow after auroræ boreales; and we are informed by Mr Winn*, that this is actually the caſe. This he found never to fail in 23 inſtances. He obſerved alſo, that when the aurora was bright, the gale came on within 24 hours, but did not laſt long; but if it was faint and dull, the gale was longer in beginning, and leſs violent, but it continued longer. This looks like a confirmation of our conjecture. Bright auroræ are probably nearer than thoſe which are dull. Now, if the aurora borealis be attended with a decompoſition of a quantity of air, that part of the atmoſphere which is neareſt muſt firſt ruſh in to ſupply the defect, and the motion will gradually extend itſelf to more diſtant parts. Juſt as if a hole were bored in the end of a long veſſel filled with water, the water neareſt the hole would flow out immediately, and it would be ſome time before the water at the other end of the veſſel began to move. The nearer we are to the place of precipitation, the ſooner will we feel the ſouth-weſt wind. It ought therefore to begin ſooner after a bright aurora, becauſe it is nearer than a dull and faint one. Precipitations of the atmoſphere at a diſtance from the pole cannot be ſo great as thoſe which take place near it; becauſe the cold will not be ſufficient to condenſe ſo great a quantity of hydrogen; ſouth-weſt winds, therefore, ought not to laſt ſo long after bright as after dull auroræ. Winds are more violent after bright auroræ, becauſe they are nearer the place of precipitation; juſt as the water near the hole in the veſſel runs ſwifter than that which is at a conſiderable diſtance.

* Philoſophical Tranſactions for 1772.

If theſe conjectures have any foundation in nature, there are two ſources of ſouth-weſt winds; the firſt has its origin in the trade-winds, the ſecond in precipitations of the atmoſphere near the pole (c). When they originate from the firſt cauſe, they will blow in countries farther ſouth for ſome time before they are felt in thoſe which are farther north; but the contrary will take place when they are owing to the ſecond cauſe. In this laſt caſe, too, the barometer will ſink conſiderably; and it actually does ſo conſtantly after auroræ, as we are informed by Mr Madiſon ‡, who paid particular attention to this ſubject. By keeping accurate meteorological tables in different latitudes, it might eaſily be diſcovered whether theſe conſequences be true, and conſequently whether the above conjectures be well or ill grounded.

‡ Philad. Tranſ. vol. ii. p. 142.

52 Another cauſe of north-eaſt winds.

There are alſo two ſources of north-eaſt winds; the firſt is an accumulation of air at the pole (d), the ſecond a precipitation of the atmoſphere in the torrid zone. For the diſcovery of this laſt cauſe we are indebted to Dr Franklin. In 1740 he was prevented from obſerving an eclipſe of the moon at Philadelphia by a north-eaſt ſtorm, which came on about ſeven o'clock in the evening. He was ſurpriſed to find afterwards that it had not come on at Boſton till near 11 o'clock: and upon comparing all the accounts which he received from the ſeveral colonies of the beginning of this and other ſtorms of the ſame kind, he found it to be always an hour later the farther north-eaſt, for every 100 miles.

"From hence (ſays he) I formed an idea of the courſe of the ſtorm, which I will explain by a familiar inſtance. I ſuppoſe a long canal of water ſtopped at the end by a gate. The water is at reſt till the gate is opened: then it begins to move out through the gate, and the water next the gate is firſt in motion, and moves on towards the gate; and ſo on ſucceſſively, till the water at the head of the canal is in motion, which it is laſt of all. In this caſe all the water moves indeed towards the gate; but the ſucceſſive times of beginning the motion are in the contrary way, viz. from the gate back to the head of the canal. Thus, to produce a north-eaſt ſtorm, I ſuppoſe ſome great rarefaction of the air in or near the gulph of Mexico; the air riſing thence has its place ſupplied by the next more northern, cooler, and therefore denſer, and heavier air; a ſucceſſive current is formed, to which our coaſt and inland mountains give a north-eaſt direction †."

†Franklin's Philoſophical Letters, p. 389.

53 Cauſe of north-weſt winds.

Currents of air from the poles naturally, as has been obſerved, aſſume a north-eaſt direction as they advance ſouthwards; becauſe their diurnal motion becomes leſs than that of the earth. Various circumſtances, however, may change this direction, and cauſe them to become north, or even north-weſt, winds. The ſouth-weſt winds themſelves may often prove ſufficient for this; and violent rains, or great

(c) We are now rather doubtful whether the firſt cauſe here aſſigned be ſo general as we at firſt imagined. The almoſt conſtant ſinking of the barometer when a ſouth wind blows, ſeems to indicate, that it is generally occaſioned by decompoſitions of the atmoſphere. Nor are we certain that *mountains* are adequate to produce the effect aſſigned them.

(d) When the ice, which, in Ruſſia accumulates on the inſides of the windows of the common people's houſes, thaws, it lets looſe a quantity of mephitic air, producing all the dangerous effects of charcoal (*Dr Guthrie of the Climate of Ruſſia, Edin. Tranſ.* vol. ii. p. 220.). May not then a quantity or air be extricated from ice during its thawing? And may not this be another ſource of north-eaſt winds? We are not ignorant of the experiment which Dr Garnet made to diſcover this (ſee *Manchſter Tranſactions*, vol. iv.); and that he found that ice in this country ſets looſe no air in the act of thawing. But Dr Guthrie has ſhown us, in the eſſay above referred to, that water, by being long expoſed to intenſe cold, changes its nature, and acquires qualities which it had not before. Would it not be worth the while of the philoſophers in Ruſſia, and other cold countries, to inveſtigate this a little farther? We would recommend it to the conſideration of the ingenious Dr Guthrie himſelf; who, from his ſituation, has the beſt opportunities of inveſtigating the matter completely. It is certainly of very great importance, and might lead to diſcoveries that would remove our preſent difficulties in meteorology, and enable us to give a ſatisfactory and uſeful theory of the weather.

Wind.

heat, by leſſening or rarefying the atmoſphere in any country, will produce the ſame effect in countries to the weſtwards when north winds happen to be blowing.

54 Why they are ſo frequent in North America.

In North America, the north-weſt winds become gradually more frequent as we advance northwards. The eaſt coaſt of this continent, where the obſervations were made from which this concluſion was drawn, is alone cultivated; the reſt of the country is covered with wood. Now cultivated countries are well known to be warmer than thoſe which are uncultivated; the earth in the latter is ſhaded from the ſun, and never heated by his rays. The air, therefore, in the interior parts of America, muſt be conſtantly colder than near the eaſt coaſt. This difference will hardly be perceptible in the ſouthern parts, becauſe there the influence of the ſun is very powerful; but it will become gradually greater as we advance northwards, becauſe the influence of the ſun diminiſhes, and the continent becomes broader. Hence north-weſt winds ought to become more frequent upon the eaſt coaſt as we advance northwards; and they will probably ceaſe to blow ſo often as ſoon as the whole continent of North America becomes cultivated.

55 Cauſes of eaſt and weſt winds.

Thus have we attempted to explain the cauſes which produce the more general winds that prevail in the torrid and temperate zones. The eaſt and weſt winds, when they are not partial and confined to a very ſmall portion of the atmoſphere, ſeem to be nothing elſe but currents of air brought from the north or ſouth by the cauſes already mentioned, and prevented from proceeding farther by contrary currents. If theſe currents have come from the north, they will aſſume the appearance of eaſt winds; becauſe their diurnal motion will be leſs than that of the more ſouthern latitudes over which they are forced to remain ſtationary. The ſouthern currents will become weſt winds, for a contrary reaſon. This will furniſh us with a reaſon for the coldneſs of eaſt winds, compared with weſt winds. If this account be true, there ought very frequently to be a weſt wind in a latitude to the ſouth of thoſe places where an eaſt wind blows. This might eaſily be determined by keeping accurate regiſters of the winds in different latitudes, and as nearly as poſſible under the ſame meridian; and upon the reſult of theſe obſervations the truth or falſehood of the above conjecture muſt finally reſt.

56 Partial winds.

Beſides theſe more general winds, there are others which extend only over a very ſmall part of the earth. Theſe originate from many different cauſes. The atmoſphere is compoſed of three different kinds of air, oxygen, azote, and carbonic acid; to which may be added water. Great quantities of each of theſe ingredients are conſtantly changing their aerial form, and combining with various ſubſtances; or they are ſeparating from other bodies, aſſuming the form of air, and mixing with the atmoſphere. Partial voids, therefore, and partial accumulations, muſt be continually taking place in different parts of the atmoſphere, which will occaſion winds varying in direction, violence, and continuance, according to the ſuddenneſs and the quantity of air deſtroyed or produced. Beſides theſe there are many other ingredients conſtantly mixing with the atmoſphere, and many partial cauſes of condenſation and rarefaction in particular places. To theſe, and other cauſes probably hitherto unknown, are to be aſcribed all thoſe winds which blow in any place beſides the general ones already explained; and which, as they depend on cauſes hitherto at leaſt reckoned contingent, will probably for ever prevent uniformity and regularity in the winds. All theſe cauſes, however, may, and probably will, be diſcovered: the circumſtances in which they will take place, and the effects which they will produce, may be known; and whenever this is the caſe, the winds of any place may in ſome meaſure be reduced to calculation.

Wind Windage.

It is of importance, in the firſt place, to know the general winds, and the cauſes which produce them; they will blow oftener in every country, continue longeſt, and in a great meaſure ſtamp the nature of the climate. To explain theſe has been the intention of this eſſay; and though we have probably failed of ſucceſs, our attempt, we hope, will not be altogether uſeleſs. The facts which are here collected will at leaſt facilitate the labours of the future inquirer. Were accurate obſervations made over the whole globe of the direction and velocity of the winds, and eſpecially of the time when they begin and ceaſe to blow, ſo much light would be thrown in a ſhort time upon this important ſubject, that a theory of the winds might be formed, capable of explaining all the phenomena, and really uſeful to the human race.

Hot WINDS. See SAMIEL.

Wind-Flower. See ANEMONY.

Wind-Mill, a kind of mill, the internal parts of which are much the ſame with thoſe of a water-mill: from which, however, it differs, in being moved by the impulſe of the wind upon its ſails or vanes, which are to be conſidered as a wheel in axis. See MECHANICS, n° 62.

Wind Gage. See *Wind-Gage*.

Wind-Galls, in farriery. See there § xxxiii.

Wind-Gun. See *Air-Gun*.

Inſtruments for meaſuring the ſtrength, velocity, &c. *of the* WIND. See *Wind-Gage*, ANEMOMETER, and ANEMOSCOPE.

Wind-Hatch, in mining, a term uſed to expreſs the place at which the ore is taken out of the mines.

Wind-Shock, a name given by our farmers to a diſtemper to which fruit-trees, and ſometimes timber-trees, are ſubject. It is a ſort of bruiſe and ſhiver throughout the whole ſubſtance of the tree; but the bark being often not affected by it, it is not ſeen on the outſide, while the inſide is twiſted round, and greatly injured. It is by ſome ſuppoſed to be occaſioned by high winds; but others attribute it to lightning. Thoſe trees are moſt uſually affected by it whoſe boughs grow more out on one ſide than on the other. The beſt way of preventing this in valuable trees, is to take care in the plantation that they are ſheltered well, and to cut them frequently in a regular manner while young.

Wind Taught, in ſea-language, denotes the ſame as ſtiff in the wind. Too much rigging, high maſts, or any thing catching or holding wind aloft, is ſaid to hold a ſhip wind-taught; by which they mean, that ſhe ſtoops too much in her ſailing in a ſtiff gale of wind. Again, when a ſhip rides in a main ſtreſs of wind and weather, they ſtrike down her top-maſts, and bring her yards down, which elſe would hold too much wind, or be too much diſtended and wind-taught.

Wind-Sails, a ſort of wide tube or funnel of canvas, employed to convey a ſtream of freſh air downward into the lower apartments of a ſhip.

This machine is uſually extended by large hoops ſituated in different parts of its height. It is let down perpendicularly through the hatches, being expanded at the lower end like the baſe of a cone; and having its under ſide open on the ſide which is placed to windward, ſo as to receive the full current of wind; which entering the cavity, fills the tube, and ruſhes downwards into the lower regions of the ſhip. There are generally three or four of theſe in our capital ſhips of war, which, together with the ventilators, contribute greatly to preſerve the health of the crew.

WINDAGE *of a* GUN, is the difference between the diameter of the bore and the diameter of the ball.

Windlaſs ‖ Wine.

WINDLASS, a machine uſed for raiſing huge weights, as guns, ſtones, anchors, &c.

It is very ſimple, conſiſting only of an axis or roller, ſupported horizontally at the two ends by two pieces of wood and a pulley; the two pieces of wood meet at top, being placed diagonally ſo as to prop each other; the axis or roller goes through the two pieces, and turns in them. The pulley is faſtened at top where the pieces join. Laſtly, there are two ſtaves or handſpikes which go through the roller, whereby it is turned, and the rope which comes over the pulley is wound off and on the ſame.

WINDLASS, in a ſhip, is an inſtrument in ſmall ſhips, placed upon the deck, juſt abaft the fore-maſt. It is made of a piece of timber ſix or eight feet ſquare, in form of an axle-tree, whoſe length is placed horizontally upon two pieces of wood at the ends thereof, and upon which it is turned about by the help of handſpikes put into holes made for that purpoſe. This inſtrument ſerves for weighing anchors, or hoiſting of any weight in or out of the ſhip, and will purchaſe much more than any capſtan, and that without any danger to thoſe that heave; for if in heaving the windlaſs about, any of the handſpikes ſhould happen to break, the windlaſs would fall of itſelf.

WINDOW, an aperture or open place in the wall of a houſe to let in the light. See ARCHITECTURE, n° 78.

The word is Welch, *uynt dor*, ſignifying the paſſage for the wind. Window is yet provincially denominated *winder* in Lancaſhire; i. e. *wind-door*, or the paſſage for air, as that for people was peculiarly called the *door*.

Before the uſe of glaſs became general, which was not till towards the end of the 12th century, the windows in Britain ſeem generally to have been compoſed of paper. Properly prepared with oil, this forms no contemptible defence againſt the intruſions of the weather, and makes no incompetent opening for the admiſſion of the light. It is ſtill uſed by our architects for the temporary windows of unfiniſhed houſes, and not unfrequently for the regular ones of our work-ſhops. But ſome of the principal buildings we may reaſonably ſuppoſe to have been windowed in a ſuperior manner. They could, however, be furniſhed merely with lattices of wood or ſheets of linen, as theſe two remained the only furniture of our cathedrals nearly to the eighth century; and the lattices continued in ſome of the meaner towns of Lancaſhire to the 18th; and in many diſtricts of Wales, and many of the adjoining parts of England, are in uſe even to the preſent moment. Theſe ſeem all to have been fixed in frames that were called *capſamenta*, and now therefore *caſements* in Wales and Lancaſhire.

WINDSOR, a borough-town of Berkſhire, 22 miles weſt of London, moſt remarkable for the magnificent palace or caſtle ſituated there on an eminence, which commands the adjacent country for many miles, the river Thames running at the foot of the hill. The knights of the garter are inſtalled in the royal chapel here. It ſends two members to parliament. W. Long. 0. 36. N. Lat. 51. 30.

WINDWARD, in the ſea language, denotes any thing towards that point from whence the wind blows, in reſpect of a ſhip: thus windward-tide, is the tide which runs againſt the wind.

WINE, an agreeable ſpirituous liquor, produced by fermentation from thoſe vegetable ſubſtances that contain ſaccharine matter. A very great number of vegetable ſubſtances may be made to afford wine, as grapes, currants, mulberries, elder, cherries, apples, pulſe, beans, peas, turneps, radiſhes, and even graſs itſelf. Hence, under the claſs of wines or vinous liquors, come not only wines, abſolutely ſo called, but alſo ale, cyder, &c.

Wine. Chaptal's Chemiſtry, part iv. ſect. v. chap. 6.

Wine, however, is in a more particular manner appropriated to the liquor drawn from the fruit of the vine. The proceſs of making wine is as follows: when the grapes are ripe, and the ſaccharine principle is developed, they are then preſſed, and the juice which flows out is received in veſſels of a proper capacity, in which the fermentation appears, and proceeds in the following manner: At the end of ſeveral days, and frequently after a few hours, according to the heat of the atmoſphere, the nature of the grapes, the quantity of the liquid, and the temperature of the place in which the operation is performed, a movement is produced in the liquor, which continually increaſes; the volume of the fluid increaſes; it becomes turbid and oily; carbonic acid is diſengaged, which fills all the unoccupied part of the veſſel, and the temperature riſes to the 72,5th degree. At the end of ſeveral days theſe tumultuous motions ſubſide, the maſs falls, the liquor becomes clearer, and is found to be leſs ſaccharine, more odorant, and of a red colour, from the reaction of the ardent ſpirit upon the colouring matter of the pellicle of the grape. 1 Method of making wine.

The wine is uſually taken out of the fermenting veſſels at the period when all the phenomena of fermentation have ſubſided. When the maſs is ſettled, the colour of the liquor is well developed, when it has become clear, and its heat has diſappeared; it is put into caſks, where, by a ſecond inſenſible fermentation, the wine is clarified, its principles combine more perfectly together, and its taſte and ſmell become more and more developed. If this fermentation be ſtopped or ſuffocated, the gaſeous principles are retained, and the wine is briſker, and more of the nature of muſt.

It appears, from the intereſting experiments of the Marquis de Bullion, that the vinous fermentation does not take place unleſs tartar be preſent.

2 Cauſes of imperfect fermentation.

The cauſes of an imperfect fermentation are the following: 1. If the heat be too little, the fermentation languiſhes, the ſaccharine and oily matters are not ſufficiently elaborated, and the wine is unctuous and ſweet. 2. If the ſaccharine body be not ſufficiently abundant, as happens in rainy ſeaſons, the wine is weak, and the mucilage which predominates cauſes it to become ſour by its decompoſition. 3. If the juice be too watery, concentrated and boiling muſt is added. 4. If the ſaccharine principle be not ſufficiently abundant, the defect may be remedied by the addition of ſugar. Macquer has proved that excellent wine may be made of verjuice and ſugar; and M. de Bullion has made wine at Bellejames with the verjuice of his vine rows and moiſt ſugar.

There have been many diſputes to determine whether grapes ſhould be preſſed with the ſtalks or without. This depends on the nature of the fruit. When they are highly charged with ſaccharine and mucilaginous matter, the ſtalk corrects the inſipidity of the wine by its bitter principle: but when, on the contrary, the juice is not too ſweet, the ſtalk renders it drier, and very rough.

3 Colouring matter of wine.

The colouring principle of wine is of a reſinous nature, and is contained in the pellicle of the grape; and the fluid is not coloured until the wine is formed; for until then there is nothing which can diſſolve it: and hence it is that white wine may be made of red grapes, when the juice of the grape is expreſſed, and the huſk thrown away. If wine be evaporated, the colouring principle remains in the reſidue, and may be extracted by ſpirit of wine. Old wines loſe their colour, a pellicle being precipitated, which is either depoſited on the ſides of the bottles, or falls to the bottom. If

wine

Wine. wine be expoſed to the heat of the ſun during the ſummer, the colouring matter is detached in a pellicle, which falls to the bottom: when the veſſel is opened, the diſcolouring is more ſpeedy, and it is effected in two or three days during the ſummer. The wine thus deprived of its colour is not perceptibly weakened.

4 Vinous fermentation explained. The vinous fermentation has been examined with great accuracy by M. Lavoiſier. According to him, the vegetable juice of which wine is to be made conſiſts of oxygen, hydrogen, and carbon, combined with one another in different proportions, ſo as to form chiefly water and ſugar. The fermentation produces a ſeparation of the elements, and a new combination of them; a quantity of the oxygen and carbon combine and fly off in the ſtate of carbonic acid; part of the carbon, oxygen, and hydrogen, combine firſt with each other, and then altogether, to form alcohol; another part forms acetous acid; the water ſtill remains, and a reſiduum falls to the bottom compoſed of the three elements combined in other proportions.

5 Ingredients in different wines. The different kinds of wines produced in Europe and other parts of the world are many; the principal of them and their qualities are well known: a catalogue of them would ſerve no purpoſe here. We ſhall, however, ſubjoin a table of the quantities of the ingredients of the principal kinds from Newmann's Chemiſtry.

A quart of	Highly rectified Spirit.			Thick, oily, unctuous, reſinous matter.			Gummy and tartarous matter.			Water.

The colour of wine is frequently artificial; a deep red is almoſt always the effect of artificial additions, as of the red-woods, elder-berries, bilberries, &c. In France no ſecret is made of theſe practices, the colouring matters being publicly thrown out after they have been uſed.

It is well known to be a common practice among wine-coopers, innkeepers, and other dealers in wines, to adulterate bad wine in order to conceal its defects: if, for inſtance, the wine be ſour, they throw into it a quantity of ſugar of lead, which entirely takes away the ſour taſte. For ſimilar purpoſes alum is often mixed with wine. Such ſubſtances, however, are well known to be extremely pernicious to the human conſtitution; it becomes of importance therefore to be able to detect them whenever they happen to be contained in wine. Several chemiſts who have turned their attention to this ſubject, have furniſhed us with teſts for this purpoſe.

Wine. 6 Adulteration of wine.

7 To detect lead in wine. To diſcover lead diſſolved in wine, boil together in a pint of water an ounce of quicklime and half an ounce of flour of brimſtone; and when the liquor, which will be of a yellow colour, is cold, pour it into a bottle, and cork it up for uſe. A few drops of this liquor being dropt into a glaſs of wine or cyder containing *lead*, will change the whole into a colour more or leſs *brown*, according to the quantity of lead which it contains. If the wine be wholly free from lead, it will be rendered turbid by the liquor, but the colour will be rather a dirty white than a black brown.

Watſon's Chemical Eſſays, vol. iii. p. 371.

By this teſt, however, iron is alſo precipitated when diſſolved in wine, and is apt to be taken for lead; a miſtake which has ruined ſeveral honeſt merchants. The following teſt is therefore preferable, as not liable to the ſame inconvenience.

8 Another method. Take equal parts of calcined oyſter-ſhells and crude ſulphur in fine powder, and put them in a crucible, which put into a fire, and raiſe the heat ſuddenly till it has been expoſed to a white heat for 15 minutes. Then take it out, let it cool, beat the ingredients to powder, and put them into a well corked bottle. To prepare the teſt-liquor, put 20 grains of this powder, together with 120 grains of cream of tartar, and put them into a ſtrong bottle, fill it up with water, boil it for an hour, and let it cool. Cork the bottle immediately, and ſhake it from time to time. After ſome hours repoſe, decant off the clear liquor into an ounce vial, having firſt put 22 drops of muriatic acid into each vial. Cork theſe vials accurately with a little wax mixed up with a little turpentine. One part of this liquor, mixed with three parts of ſuſpected wine, will diſcover the preſence of the ſmalleſt quantity of lead or copper, by a very ſenſible black precipitate, and of arſenic by an orange precipitate; but will have no effect on iron, if there be any: the preſence of which, however, may be aſcertained by adding a little potaſh, which will turn the liquor black if there be any iron. Pure wine remains limpid after the addition of this liquor ‡.

‡ Journal de Phyſique, October 1791.

9 State of lead in wine. As this ſubject is of importance, we ſhall add M. Fourcroy's obſervations on the ſtate in which lead exiſts in wine, and on the methods of diſcovering its preſence: "Of the different principles which compoſe wine, there was no doubt (ſays he) but that acids were the only ones which were capable of diſſolving oxyd *(calx)* of lead. But was it the tartareous acid always contained in larger or ſmaller quantity in wine, or the acetous acid developed in thoſe which have become ſharp, and which there is a greater temptation to ſweeten? Experience had proved to me that the acidulous tartrite of potaſh, or the cream of tartar, takes oxyd of lead from the acetous acid, and a precipitate of tartrite of lead is formed; the pure tartareous acid prepared in Scheele's method produces the ſame effect. In order to underſtand how the ſharp wine which contains theſe two acids can hold the oxyd of lead in ſolution, I made the experiments which gave me the following reſults: 1. The acidulous tartrite *(crem. tart.)* has no ſenſible action upon the oxyds of lead; 2. The pure tartareous acid has a ſlight action upon the oxyds, and forms on their ſurface a little tartrite of lead *(tartariſed lead)*, in

a

Wine. a white powder; 3. Wine which only contains the tarareous acidule, would not have any action upon the ſemivitrous oxyd of lead or litharge; 4. Sharp wine which we attempt to ſweeten by this oxyd of lead, acts firſt upon it by the acetous acid it contains; 5. When this acetite of lead is formed, the tartareous acid precipitates it in the form of tartrite of lead: this is proved by the precipitate which the ſolution of the acetite of lead or ſugar of lead forms in the wine; 6. But the acetous acid, if it be in large enough quantity, rediſſolves the tartrite of lead in the wine juſt as diſtilled water would. Bergman has pointed out this ſolution of tartrite of lead in acetous acid for diſtinguiſhing the tartareous ſalt from the ſulfat of lead *(vitriol of lead)*; 7. As this ſolution of tartrite of lead in the acetous acid is much quicker, and more eaſy in ſharp wines than in diſtilled water and vinegar, it is probable that the cauſe of this difference depends upon the citric and malic acids which I have found in wine, and which I ſhall take notice of again on another occaſion; 8. Litharged wine then, or wine ſweetened with lead, contains tartrite diſſolved in the acetous acid, and perhaps at the ſame time in the malic and citric acids.

10 It forms an aceto-tartrite of lead.

"It was neceſſary afterwards to know the properties of this combination. What experience has taught me is as follows: I particularly examined the tartrite of lead and its ſolution in acetous acid. The tartrite of lead is ſcarcely at all ſoluble in water; it is in the form of powder, or of ſmall white grains which have no ſenſible taſte; when it is diſſolved in vinegar, the vinegar is ſoftened, its ſharpneſs is diminiſhed remarkably, and the ſolution takes a ſlight ſweetiſh taſte, much leſs ſtrong than that of the pure acetite of lead. This taſte proves that the union of the tartrite of lead with vinegar is not only a ſolution like that of ſalt in water, by which the properties of the ſalt are not changed, but a combination which gives occaſion to new properties. It is a kind of a triple ſalt, different from thoſe we have hitherto known, formed of two acids and of one baſe; whereas the other triple ſalts deſcribed hitherto are compoſed of one acid and two baſes. I name this new triple ſalt *aceto-tartrite of lead*. The acetous acid adheres to it more than water in a common ſolution: what is remarkable in this combination is, that the two acids appear to adhere to the baſe with an equal force, although they have a different attraction for it: nothing is neceſſary to produce this equilibrium, but to unite firſt the oxyd of lead with the acid to which it adheres the moſt ſtrongly, and afterwards to put this firſt compound in contact with the weaker acid.

11 Other methods of detecting this ſalt.

"It was neceſſary, in order to diſcover eaſy and certain methods of aſcertaining the preſence of lead in wine, to examine with care the properties and phenomena of the decompoſitions of the aceto-tartrite of lead. Fixed alkalis and ammoniac (*volatile alkali*) precipitate from this ſalt an oxyd of lead, which is of a greyiſh white colour; but as they occaſion a precipitate in pure wine, they cannot be of any uſe. The ſulphuric (*vitriolic*) acid decompoſes the aceto-tartrite of lead, and forms with it inſtantly ſulfat of lead; which being very little ſoluble, and very heavy, is precipated. The oxalic, or pure ſaccharine acid, and the acidulous oxalat, or the ſalt of ſorrel of the ſhops, likewiſe decompoſe this ſalt, and take from it the lead. The oxalat of lead is precipitated in great abundance: theſe two acids, the ſulphuric and oxalic acids, not producing any precipitate in pure wine, are very proper to ſhow the preſence of lead in wine. The ſulfat and oxalat of lead, when they are precipitated from wine, are coloured, whereas they are very white when they are formed in diſtilled water; but their red or brown colour does not prevent us from diſcovering them by a very ſimple method. If the precipitates be collected with care, and are cautiouſly heated upon a coal with a blow-pipe, they ſmoke, become white, exhale vapours, paſs ſucceſſively thro' the ſtates of the red and yellow oxyds of lead, and at length are reduced into metallic globules at the inſtant they are perceived to be agitated by a very evident efferveſcence: if we ceaſe to blow at this inſtant, we obtain globules upon the charcoal. In order to this, it is neceſſary, however, that the charcoal be ſolid, and be not cracked, and that we ſhould not have blowed too ſtrongly; otherwiſe the globules would be abſorbed, and would diſappear. The ſulfat of lead requires a longer time to be reduced than the oxalat of the ſame metal, and there is a greater hazard of loſing the metallic particles, which, beſide, are in ſmall quantity.

Wine.

"To theſe two firſt proceſſes, already ſufficiently certain of themſelves, I wiſhed to be able to add one which might be capable of pointing out inſtantly the preſence of lead, by an appearance belonging excluſively to this metal, and which might unite to this advantage that of manifeſting very ſmall quantities of it. Diſtilled water impregnated with ſulphurated hydrogenous gas, or hepatic gas, extricated from ſolid alkaline ſulphurets (*livers of ſulphur*) by acids, preſented me with theſe properties. This ſolution blackens very deeply that of the aceto-tartrite of lead, and renders $\frac{1}{1000}$th of this ſalt in water or in wine very ſenſible. The ſenſibility of this reactive is ſuch, that we may dilute litharged wine with a ſufficient quantity of water to take away almoſt entirely the colour of the wine, and this reactive will ſtill produce a very manifeſt alteration. The ſulphurated water has, beſides, the advantage not to occaſion any change in the wines which do not contain a metallic ſubſtance, and it is not precipitated by the acids of wine, like the ſolutions of alkaline ſulphurets. In order to procure this reactive pure, it is neceſſary to prepare it at the inſtant of the experiment, by receiving in a vial full of diſtilled water, and inverted upon a ſhelf of a ſmall hydro-pneumatice apparatus, filled with diſtilled water, the ſulphurated hydrogenous gas, ſeparated from the ſolid ſulphuret of potaſh by the ſulphuric or muriatic acid, and firſt filtered through water in another vial; when the ſecond vial contains the third of its volume of the ſulphurated hydrogenous gas, the gas is ſhaken ſtrongly with the water, which fills the two thirds of the vial; and when the abſorption is over, the teſt liquor is prepared. This reactive changes very quickly in the air: it is neceſſary to make it the moment it is to be employed, and to keep it in a veſſel quite full and well corked. If there were any fear that the black colour and the precipitation by the gaſeous ſulphurated water ſhould not be ſufficient to prove the preſence of lead in ſpirituous liquors, I would obſerve that this fear would be diminiſhed by employing the three reactives mentioned in this memoir, and by depending only on the correſpondent effects of theſe three reactives: but all ſuſpicion would be removed, by reducing the three precipitates by the blow-pipe, and obtaining globules of lead from each of them."

12 Method of detecting alum diſſolved in wine.

Some years ago, the Academy of Lyons propoſed the following prize queſtion, What is the beſt method of aſcertaining the preſence and the quantity of *alum* diſſolved in wine, eſpecially in very deep coloured red wine? The prize was gained by M. J. S. Beraud. From his experiments, it appears that a mixture of lime-water and wine in any proportion whatever, will at the end of 12 or 15 hours furniſh a quantity of cryſtals, which may be ſeparated by filtration, and that theſe cryſtals will be eaſieſt diſcovered when the quantities of wine and lime water are equal; but that wine containing alum diſſolved in it, will not form cryſtals when mixed with lime-water, but merely depoſits a muddy ſediment. To know therefore whether any wine contains alum

Wine. or not, we have only to mix a ſmall quantity of it with lime-water: if cryſtals are formed, it contains no alum; if not, it does. Again, if wine contains alum, the reſiduum that remains after filtration will, as it dries, ſplit into quadrilateral ſegments, which will detach themſelves from the paper which contains them; but if the wine contains no alum, the reſiduum, after it is dry, will remain united and attached to the paper. If one meaſure of wine and two-thirds of a meaſure of lime-water depoſit cryſtals, we are certain that if the wine contains alum, the proportion of that alum to the wine will be leſs than 1 to 1152; if, when equal parts of wine and lime-water are mixed, no cryſtals be depoſited, we may be ſure that more than $\frac{1}{400}$th part of the maſs of wine conſiſts of alum.

A great proportion of the wine conſumed in Britain is brought from Spain and Portugal; government has always diſcouraged the importation of French wines by heavy taxes. We are not ſure how far ſuch conduct is founded on good policy, as the French wines are confeſſedly the beſt, and might be the cheapeſt; but ſuch is the jealouſy and enmity that has always ſubſiſted between Britain and France, that both nations have been contented to injure themſelves provided they could do a greater injury to their neighbours. Beſides, the advantages which Britain derives from the Portugal trade are very great, and it would not be eaſy perhaps to ſecure them on any other terms.

13 Directions for the treatment of imported wines.

It may be worth while to inſert here a few directions about the treatment of wines after they have been imported into this country.—On landing, the leſs they are expoſed the better; for they are affected by the ſeaſons, and more or leſs by climate. March and April are the proper times for ſhipping wines from France, and they will be landed in England and Ireland in the ſame degree of temperature. The great art in keeping wines is to prevent their fretting, which is done by keeping them in the ſame degree of heat. In ſpring and fall, the wines in Bourdeaux are ſubject to changes that may be dangerous, if not prevented by neceſſary rackings: theſe changes are ſolely the effect of the ſeaſons. If wines are chilled, and of courſe turn foul, from being ſhipped and landed in cold weather, they will ſoon recover by putting them in a warm vault, well covered with ſaw-duſt. As ſoon as they are in the vault, they ought to be covered up. But if ſhipped and landed in ſummer, if the ſmalleſt degree of fermentation be found on them, it will be requiſite to dip the bung clothes in brandy, and leave the bungs looſe for ſome days, to give it time to cool; and if in a fortnight or three weeks the fermentation do not ceaſe, and the wine become bright, it will be proper to rack it (matching the hogſheads well with brimſtone), and force it with the whites of eight eggs. If it then becomes fine, bung it tight, and let it remain ſo until it is bottled. If wines new landed are wanted ſoon for the bottle, it will be neceſſary to force them immediately, and let them remain bunged cloſe for at leaſt a month, to recover from the forcing, or if two months the better; for wines bottled in high order come much ſooner into drinking than if bottled when flat, which all wines are after forcing. Wine muſt never be bottled the leaſt foul, which produces a tendency to fret; and if bottled in this ſtate, will never come in order, but may poſſibly be loſt: for this there is no remedy but repeated rackings; and care muſt be taken (after rinſing the hogſheads well and drawing them) to burn a good piece of match in them. This cools the wine, and there is no danger of hurting the colour, for it recovers it in a little time: but if it did, it is abſolutely neceſſary; for if wine is ſuffered to continue on the fret, it will wear itſelf to nothing. Wines bottled in good order may be fit to drink in ſix months; but they are not in perfection before twelve: from that to two years they may continue ſo; but it would be improper to keep them longer, for wines in general have not the body they had formerly, from the vines being too much forced. Wine.

It ſometimes happens that wines ſcuddy and ſtubborn will not fall with one or even two forcings. It will then be proper to give them five or ſix gallons of good ſtrong wine, and force them with the whites of a dozen eggs, with a tea-ſpoonful of ſand produced from ſawing marble, or a ſmall ſpoonful of fine ſalt. Bottled wine in winter ſhould be well covered with ſaw-duſt, and if the vaults are cold and damp, ſtrew it deep on the floor; if ſaw-duſt is thrown upon the hogſheads, and their ſides are bedded ſome inches thick, it will keep them from the fret.

The ſame treatment is to be regarded with white wines, except that they require to be higher matched, particularly Muſcat wines; ſuch as Frontignac, Beziers, &c. which being often ſweetened with honey, are very ſubject to fret; and theſe only frequent rackings, with a great deal of brimſtone, can cool. Hermitage, from not being ſufficiently dried, and poſſeſſing more richneſs than claret is alſo very liable to come on the fret, and will require much the ſame treatment as the Muſcat wines. Attention ſhould be had to bottle in fine weather, when the wind is north; but to avoid cold or froſty weather. The months of April and October are favourable. The beſt time to bottle port wine is four years after the vintage, and to keep them two years in bottle before you begin to uſe them. When wines are racked, and the lees immediately paſſed thro' flannel bags into cloſe-necked jars, and directly bottled, there will be very little loſt by rackings, as the wine when fine may ſerve for filling up.

When wines are deſtined for warm climates, it may be proper to rinſe the hogſheads with brandy; and in bottling many rinſe the bottles and corks with it. Wines that have remained a certain time (three or four months) in a vault and made leſs or more lee, ought never to be ſent into the country without firſt racking them, otherwiſe they may be liable to fret; and if bottled in that ſtate, may riſk being loſt.

Wines which may be ordered for immediate drinking will be forced on the ſhipping, and in a few weeks after they are landed will be fit for the bottle. The forcings proper for claret are the whites of a dozen eggs, beat up with a tea-ſpoonful of fine ſalt, and well worked with a forcing rod. Take care to uſe no bad egg. This is for one hogſhead.

The forcing for white wine is iſinglas diſſolved in wine. One ounce is ſufficient for two hogſheads. No ſalt is to be uſed in forcing the white wines. See *Croft on Wines*, 8vo, 1788.

14 Receipt for making raiſin-wine.

We ſhall here inſert the following receipt for making *raiſin-wine*.—To a 20 gallon veſſel take 100 pounds of raiſins; pick off the ſtalks, chop them groſsly, and put them into an open tub more wide than deep. Add two parts in three of the water to them, and let them ſtand 15 days, ſtirring them well every day. Then ſtrain and preſs them, putting aſide the liquor that runs from them. Add the remainder of the water to the raiſins that have thus been preſſed, and let it ſtand upon them one week, frequently ſtirring them as before. Then preſs off the liquor, and add it to what you firſt collected; putting both runnings together into your veſſel, together with one quart of brandy. To colour it, burn three-fourths of a pound of ſugar into a ſmall quantity of the liquor, and add this to the wine. When the liquor in the barrel has done ſinging, ſtop the veſſel cloſe, and let it ſtand till fit to be bottled. The greater the quantity which the veſſel holds, and the longer it is kept in the wood, the better will it be.

Wine-Preſs, a machine contrived to ſqueeze the juice out of

Wine ‖ Wintera.

of grapes, and conſiſting of ſeveral pieces of timber, variouſly diſpoſed, which compoſe three bodies of timber-work, cloſely united to the axis, which ſerves as a ſwing whereby it may be moved by the vice. Of theſe there are different ſizes as well as different conſtructions; for an account of which, illuſtrated by figures, ſee Miller's Gardener's Dictionary, article *Wine Preſs*.

Spirit of Wine, or *alcohol*, a name given by chemiſts to every ardent ſpirit produced by diſtillation. See *Chemistry-Index*.

WING, that part of a bird, inſect, &c. whereby it is enabled to fly. See Bird and Ornithology.

Wings, in military affairs, are the two flanks or extremes of an army, ranged in form of a battle; being the right and left ſides thereof.

WINTER, one of the four ſeaſons or quarters of the year. See Season, &c.

Winter commences on the day when the ſun's diſtance from the zenith of the place is greateſt, and ends on the day when its diſtance is at a mean between the greateſt and leaſt.

Under the equator, the winter as well as other ſeaſons return twice every year; but all other places have only one winter in the year; which in the northern hemiſphere begins when the ſun is in the tropic of Capricorn, and in the ſouthern hemiſphere when in the tropic of Cancer; ſo that all places in the ſame hemiſphere have their winter at the ſame time.

Winter-Berry. See Physalis.

WINTERA, in botany: A genus of plants of the claſs of *polyandria*, and order of *pentagynia*; and in the natural ſyſtem arranged under the 12th order, *Holoraceæ*. The calyx is three lobed; there are ſix or twelve petals; there is no ſtyle; the fruit is a berry, which is club-ſhaped as well as the germen. There are two ſpecies; the aromatica and granadenſis.

Wintera aromatica, is one of the largeſt foreſt trees upon Terra del Fuego; it often riſes to the height of 50 feet. Its outward bark is on the trunk grey and very little wrinkled, on the branches quite ſmooth and green. The branches do not ſpread horizontally, but are bent upwards, and form an elegant head of an oval ſhape. The leaves come out, without order, of an oval elliptic ſhape, quite entire, obtuſe, flat, ſmooth, ſhining, of a thick leathery ſubſtance, evergreen, on the upper ſide of a lively deep green colour, and of a pale bluiſh colour underneath, without any nerves, and their veins ſcarcely viſible; they are ſomewhat narrower near the footſtalks, and there their margins are bent downwards. In general, the leaves are from three to four inches long, and between one and two broad; they have very ſhort footſtalks, ſeldom half an inch long, which are ſmooth, concave on the upper ſide, and convex underneath. From the ſcars of the old footſtalks the branches are often tuberculated.

The peduncles, or footſtalks for the flowers, come out of the *axillæ foliorum*, near the extremity of the branches; they are flat, of a pale colour, twice or three times ſhorter than the leaves; now and then they ſupport only one flower, but are oftener near the top divided into three ſhort branches, each with one flower. The bracteæ are oblong, pointed, concave, entire, thick, whitiſh, and ſituated one at the baſis of each peduncle.

There is no calyx; but in its place the flower is ſurrounded with a ſpathaceous gem, of a thick leathery ſubſtance, green, but reddiſh on the ſide which has faced the ſun: before this gem burſts, it is of a round form, and its ſize is that of a ſmall pea. It burſts commonly ſo, that one ſide is higher than the other, and the ſegments are pointed. The corolla conſiſts always of ſeven petals, which are oval, obtuſe, concave, erect, white, have ſmall veins, and are of an unequal ſize, the largeſt ſcarcely four lines long; they very ſoon fade, and drop off almoſt as ſoon as the gem burſts. The filaments are from 15 to 30, and are placed on the flattened ſide of the receptacle; they are much ſhorter than the petals, and gradually decreaſe in length towards the ſides. The antheræ are large, oval, longitudinally divided into two, or as if each was made up of two oblong antheræ. The germina are from three to ſix, placed above the receptacle, turbinated, or of the ſhape of an inverted fig; flat on the inſide, and ſomewhat higher than the ſtamina; they have no ſtyles, but terminate in a ſtigma, which is divided into two or three ſmall lobes. Wintera.

Dr Solander, to whom the world is indebted for the deſcription, never ſaw the fruit in its perfectly ripe ſtate; but could conclude from the unripe fruit which he ſaw in abundance, that each germen becomes a ſeparate ſeed-veſſel, of a thick fleſhy ſubſtance, and unilocular; and in each the rudiments of three, four, or five ſeeds were plainly diſcernible. See Plate DXL. where n° 1. repreſents the ſpathaceous gem, after it is burſt open. 2. The ſame. 3. The ſame (*a*) with the corolla (*b*) remaining within it. 4. One of the petals ſpread out. 5. The ſtamina (*a*) and the piſtilla (*b*) after the gem and the corolla are taken away. 6. The outſide of an anthera (*a*) with its filament (*b*). 7. The inſide of the ſame. 8. The germina (*a*) ſituated on the centre of the receptacle, after the ſtamina have been removed; the lobated ſtigma (*b*). 9. The convex or outermoſt ſide of a germen (*a*) with its ſtigma (*b*). 10. The inſide of the ſame. 11. A germen cut open longitudinally, ſo as to ſhow the rudiments of the ſeeds. 12. A germen cut through tranſverſely.

The weather is much more ſevere in the climate where theſe trees are natives than in Britain; here, therefore, it is thought they would thrive very well.

The bark of the wintera, or winter's cinnamon, brought over by the Dolphin, in reſpect to figure, exactly reſembles that which was delineated by Cluſius. The pieces are about three or four inches ſquare, of different degrees of thickneſs, from a quarter to three quarters of an inch. It is of a dark brown cinnamon colour; an aromatic ſmell, if rubbed; and of a pungent hot ſpicy taſte, which is laſting on the palate, though imparted ſlowly. It has the name of *winter's cinnamon*, from a faint reſemblance in colour and flavour to that grateful aromatic, though differing from it greatly in every other reſpect. This bark is only brought to us from the Straits of Magellan, and is the produce of the tree above deſcribed; much celebrated as an antiſcorbutic by the firſt diſcoverers, but unknown in the practice of phyſic, no quantity, except as a curioſity, having been brought to Europe till the return of the ſhips ſent out on the expeditions to the South Seas. The bark which was ſubſtituted in the room of this is the canella alba of the ſhops. See Canella.

From ſeveral experiments made by Dr Morris, the cortex magellanicus appears to be an aſtringent of a particular kind, and therefore likely to be of uſe in ſeveral manufactures. Water is the proper ſolvent of this bark; though the ſaline, gummy, and reſinous parts are ſo blended in it, as in ſaffron and ſome other vegetables, that it parts with them readily in proof and rectified ſpirits of wine, though not in ſo great a quantity.

The infuſion and decoction of this bark were of ſo grateful an aromatic bitter taſte, that it ſeems likely to be a pleaſant vehicle for ſome of the naufeous drugs. With this view, on ſubſtituting the powder of this bark for the cardamom ſeeds in making the infuſion of ſenna, as directed in the London Diſpenſatory, the naufeous ſmell and taſte of

Wire ‖ Wit.

that excellent purgative was ſo effectually covered, as to be ſcarcely diſtinguiſhed by the niceſt palate. Tincture of rhubarb alſo prepared with this bark inſtead of cardamoms ſeemed far leſs diſagreeable.

WIRE, a piece of metal drawn through the hole of an iron into a thread of a fineneſs anſwerable to the hole it paſſed through,

Wires are frequently drawn ſo fine as to be wrought along with other threads of ſilk, wool, flax, &c.

The metals moſt commonly drawn into wire are gold, ſilver, copper, and iron. Gold-wire is made of cylindrical ingots of ſilver, covered over with a ſkin of gold, and thus drawn ſucceſſively through a vaſt number of holes, each ſmaller and ſmaller, till at laſt it is brought to a fineneſs exceeding that of a hair. That admirable ductility which makes one of the diſtinguiſhing characters of gold, is nowhere more conſpicuous than in this gilt wire. A cylinder of 48 ounces of ſilver, covered with a coat of gold, only weighing one ounce, as Dr Hally informs us, is uſually drawn into a wire, two yards of which weigh no more than one grain: whence 98 yards of the wire weigh no more than 49 grains, and one ſingle grain of gold covers the 98 yards; ſo that the ten thouſandth part of a grain is above one-eighth of an inch long.

Wire of Lapland. The inhabitants of Lapland have a ſort of ſhining ſlender ſubſtance in uſe among them on ſeveral occaſions, which is much of the thickneſs and appearance of our ſilver-wire, and is therefore called, by thoſe who do not examine its ſtructure or ſubſtance, *Lapland wire*. It is made of the ſinews of the rein-deer, which being carefully ſeparated in the eating, are, by the women, after ſoaking in water and beating, ſpun into a ſort of thread, of admirable fineneſs and ſtrength, when wrought to the ſmalleſt filaments; but when larger, is very ſtrong, and fit for the purpoſes of ſtrength and force. Their wire, as it is called, is made of the fineſt of theſe threads covered with tin. The women do this buſineſs; and the way they take is to melt a piece of tin, and placing at the edge of it a horn, with a hole through it, they draw theſe ſinewy threads, covered with the tin, through the hole, which prevents their coming out too thick covered. This drawing is performed with their teeth; and there is a ſmall piece of bone placed at the top of the hole, where the wire is made flat; ſo that we always find it rounded on all ſides but one, where it is flat.

This wire they uſe in embroidering their clothes as we do gold and ſilver; they often ſell it to ſtrangers, under the notion of its having certain magical virtues.

WISDOM, uſually denotes a higher and more refined notion of things immediately preſented to the mind, as it were, by intuition, without the aſſiſtance of ratiocination.

Sometimes the word is more immediately uſed, in a moral ſenſe, for what we call *prudence* or *diſcretion*, which conſiſts in the ſoundneſs of the judgment, and a conduct anſwerable thereto.

Wisdom of Solomon, one of the books of the Apocrypha. It abounds with Platonic language, and was probably written after the Caballiſtic philoſophy was introduced among the Jews.

WIT, is a quality of certain thoughts and expreſſions, much eaſier perceived than defined. According to Mr Locke, wit lies in the aſſemblage of ideas, and putting thoſe together with quickneſs and variety, wherein can be found any reſemblance or congruity, thereby to make up pleaſant pictures and agreeable viſions to the fancy. Mr Addiſon limited this definition conſiderably, by obſerving, that every reſemblance of ideas does not conſtitute wit, but thoſe only which produce delight and ſurpriſe. Mr Pope defined wit to be a quick conception and an eaſy delivery: while, according to a late writer, it conſiſts in an aſſimilation of diſtant ideas. Wit.

The word *wit* originally ſignified *wiſdom*. A *witte* was anciently a *wiſe man;* the *wittenagemot*, or Saxon parliament, an aſſemblage of wiſe men. So late as the reign of Elizabeth, a man of pregnant *wit*, of great *wit* was a man of vaſt *judgment*. We ſtill ſay, *in his wits*, *out of his wits*, for in or out of ſound mind. The word, however, is now applied in a more limited ſenſe.

Without attempting to expoſe the inaccuracy of the definitions above mentioned, or hazarding a definition of our own where ſo many eminent men have failed, we ſhall endeavour to ſhow in what true wit conſiſts.

It is evident that wit excites in the mind an agreeable ſurpriſe, and that this is owing entirely to the ſtrange aſſemblage of related ideas preſented to the mind. This end is effected, 1. By debaſing things pompous or *ſeemingly* grave; 2. By aggrandiſing things little or frivolous; 3. By ſetting ordinary objects in a particular and uncommon point of view, by means not only remote but apparently contrary. Of ſo much conſequence are ſurpriſe and novelty, that nothing is more taſteleſs, and ſometimes diſguſting, than a joke that has become ſtale by frequent repetition. For the ſame reaſon, even a pun or happy alluſion will appear excellent when thrown out extempore in converſation, which would be deemed execrable in print. In like manner, a witty repartee is infinitely more pleaſing than a witty attack: for though, in both caſes, the thing may be equally new to the reader or hearer, the effect on him is greatly injured, when there is acceſs to ſuppoſe that it may be the ſlow production of ſtudy and premeditation. This, however, holds moſt with regard to the inferior tribes of witticiſms, of which their readineſs is the beſt recommendation. Campbel's Philoſophy of Rhetoric, vol. i.

We ſhall illuſtrate theſe obſervations by ſubjoining a ſpecimen or two of each of theſe ſorts of wit:

Of the firſt ſort, which conſiſts in the debaſement of things great and eminent, Butler, amongſt a thouſand other inſtances, hath given us thoſe which follow:

And now had Phœbus in the lap
Of Thetis taken out his nap:
And, like a lobſter boil'd, the morn
From black to red began to turn.

Hudibras, part ii. *canto* 2.

Here the low allegorical ſtyle of the firſt couplet, and the ſimile uſed in the ſecond, afford us a juſt notion of this loweſt ſpecies, which is diſtinguiſhed by the name of the *ludicrous*. Another ſpecimen from the ſame author you have in theſe lines:

Great on the bench, great in the ſaddle,
That could as well bind o'er as ſwaddle,
Mighty he was at both of theſe,
And ſtyl'd of *war*, as well as *peace*:
So ſome rats of amphibious nature,
Are either for the *land* or *water*.

Ibid. part i. *canto* 1.

In this coarſe kind of drollery, thoſe laughable tranſlations or paraphraſes of heroic and other ſerious poems, wherein the authors are ſaid to be traveſtied, chiefly abound.

The ſecond kind, conſiſting in the aggrandiſement of little things, which is by far the moſt ſplendid, and diſplays a ſoaring imagination, theſe lines of Pope will ſerve to illuſtrate:

As Berecynthia, while her offſpring vie
In homage to the mother of the ſky,
Surveys around her in the bleſt abode,
An hundred ſons, and every ſon a god:
Not with leſs glory mighty dulneſs crown'd,
Shall take thro' Grubſtreet her triumphant round;

And

WINTERA Aromatica. Plate DXL.

Wit. And her Parnaſſus glancing o'er at once,
Behold a hundred ſons, and each a dunce.

This whole ſimilitude is ſpirited. The parent of the celeſtials is contraſted by the daughter of night and chaos; heaven by Grubſtreet; gods by dunces. Beſides the parody it contains on a beautiful paſſage in Virgil adds a particular luſtre to it. This ſpecies we may term the *thraſonical*, or the *mock-majeſtic*. It affects the moſt pompous language, and ſonorous phraſeology, as much as the other affects the reverſe, the vileſt and moſt grovelling dialect.

To this claſs alſo we muſt refer the application of grave reflections to mere trifles. For that *great* and *ſerious* are naturally aſſociated by the mind, and likewiſe little and trifling, is ſufficiently evinced by the common modes of expreſſion on theſe ſubjects uſed in every tongue. An appoſite inſtance of ſuch an application we have from Philips:

My galligaſkins, that have long withſtood
The winter's fury and encroaching froſts,
By time ſubdued, (*What will not time ſubdue!*)
An horrid chaſm diſcloſe. *Splendid Shilling.*

Of the third ſpecies of wit, which is by far the moſt multifarious, and which reſults from what may be called the queerneſs or ſingularity of the imagery, we ſhall give a few ſpecimens that will ſerve to mark ſome of its principal varieties. To illuſtrate all would be impoſſible. The firſt ſhall be where there is an apparent contrariety in the things ſhe exhibits as connected. This kind of contraſt we have in theſe lines of Garth:

Then Hydrops next appears amongſt the throng;
Bloated and big ſhe ſlowly ſails along:
But like a miſer in exceſs ſhe's poor,
And pines for thirſt amidſt her watery ſtore.
Diſpenſary.

A ſecond ſort is, where the things compared are what with dialecticians would come under the denomination of *diſparates*, being ſuch as can be ranked under no common genus. Of this we ſhall ſubjoin an example from Young:

Health chiefly keeps an Atheiſt in the dark;
A fever argues better than a *Clarke*:
Let but the logic in his pulſe decay,
The Grecian he'll renounce, and learn to pray.
Univerſal Paſſion.

A third variety in this ſpecies ſprings from confounding artfully the proper and the metaphorical ſenſe of an expreſſion. In this way, one will aſſign as a motive what is diſcovered to be perfectly abſurd, when but ever ſo little attended to; and yet, from the ordinary meaning of the words, hath a ſpecious appearance on a ſingle glance. Of this kind we have an inſtance in the ſubſequent lines:

While thus the lady talk'd, the knight
Turn'd th' outſide of his eyes to white,
As men of inward light are wont
To turn their optics in upon't.
Hudibras, part iii. *canto* 1.

For whither can they turn their eyes more properly than to the light?

A fourth variety much reſembling the former, is when the argument or compariſon (for all argument is a kind of compariſon) is founded on the ſuppoſal of corporeal or perſonal attributes in what is ſtrictly not ſuſceptible of them; as in this,

But Hudibras gave him a twitch
As quick as lightning in the breech,
Juſt in the place where honour's lodg'd,
As wiſe philoſophers have judg'd:
Becauſe a kick in that place more
Hurts honour than deep wounds before.
Ibid. part ii. *canto* 3.

Wit, || Witchcraft.

The fifth, and only other variety which we ſhall mention, is that which ariſes from a relation, not in the things ſignified, but in the ſigns of all relations, no doubt the ſlighteſt. Identity here gives riſe to puns and clinches; reſemblance to quibbles, cranks, and rhimes: of theſe it is quite unneceſſary to exhibit ſpecimens.

WIT (John de), a celebrated penſioner of Holland, and one of the greateſt politicians of his time, was the ſon of Jacob de Wit, burgomaſter of Dort, and was born in 1625. He became well ſkilled in civil law, politics, mathematics, and other ſciences, and wrote a treatiſe on the Elements of Curved Lines, publiſhed by Francis Schooten. Having taken his degree of doctor of law, he travelled into foreign courts, where he became eſteemed for his genius and prudence. At his return to his native country in 1650, he became penſioner of Dort, then counſellor-penſionary of Holland, and Weſt Frieſland, intendant and regiſter of the fiefs, and keeper of the great ſeal. He was thus at the head of affairs in Holland; but his oppoſition to the re-eſtabliſhment of the office of ſtadtholder, which he thought a violation of the freedom and independence of the republic, coſt him his life, when the prince of Orange's party prevailed. He and his brother Cornelius were aſſaſſinated by the populace at the Hague in 1674, aged 47.

WITCH, a perſon guilty of witchcraft.

WITCHCRAFT, a ſupernatural power which perſons were formerly ſuppoſed to obtain the poſſeſſion of by entering into a compact with the devil. They gave themſelves up to him body and ſoul; and he engaged, that they ſhould want for nothing, and that he would avenge them upon all their enemies. As ſoon as the bargain was concluded, the devil delivered to the witch an imp, or familiar ſpirit, to be ready at a call, and do whatever it was directed. By the aſſiſtance of this imp, and the devil together, the witch, who was almoſt always an old woman, was enabled to tranſport herſelf in the air on a broomſtick or a ſpit to diſtant places to attend the meetings of the witches. At theſe meetings the devil always preſided. They were enabled alſo to transform themſelves into various ſhapes, particularly to aſſume the forms of cats and hares, in which they moſt delighted; to inflict diſeaſes on whomſoever they thought proper; and to puniſh their enemies in a variety of ways.

The belief that certain perſons were endowed with ſupernatural power; and that they were aſſiſted by inviſible ſpirits, is very ancient. The *fagae* of the Romans ſeem rather to have been ſorcerers than witches; indeed the idea of a witch, as above deſcribed, could not have been prevalent till after the propagation of Chriſtianity, as the heathens had no knowledge of the Chriſtian *devil*.

Witchcraft was univerſally believed in Europe till the 16th century, and even maintained its ground with tolerable firmneſs till the middle of the 17th. Vaſt numbers of reputed witches were convicted and condemned to be burnt every year. The methods of diſcovering them were various. One was, to weigh the ſuppoſed criminal againſt the church bible, which, if ſhe was guilty would preponderate: another, by making her attempt to ſay the Lord's Prayer; this no witch was able to repeat entirely, but would omit ſome part or ſentence thereof. It is remarkable, that all witches did not heſitate at the ſame place; ſome leaving out one part, and ſome another. Teats, through which the imps ſucked, were indubitable marks of a witch; theſe were always raw, and alſo inſenſible; and, if ſqueezed, ſometimes yielded a drop of blood. A witch could not weep more than three tears, and that only out of the left eye. This want of tears Provincial Gloſſary.

Witchcraft.

was, by the witch-finders, and even by ſome judges, conſidered as a very ſubſtantial proof of guilt. Swimming a witch was another kind of popular ordeal generally practiſed; for this ſhe was ſtripped naked, and croſs-bound, the right thumb to the left toe, and the left thumb to the right toe. Thus prepared, ſhe was thrown into a pond or river, in which, if guilty, ſhe could not ſink, for having, by her compact with the devil, renounced the benefit of the water of baptiſm, that element, in its turn, renounced her, and refuſed to receive her into its boſom. Sir Robert Filmer mentions two others by fire: the firſt, by burning the thatch of the houſe of the ſuſpected witch; the other, burning any animal ſuppoſed to be bewitched by her, as a hog or ox. Theſe, it was held, would force a witch to confeſs.

The trial by the ſtool was another method uſed for the diſcovery of witches. It was thus managed: Having taken the ſuſpected witch, ſhe was placed in the middle of a room upon a ſtool or table, croſs-legged, or in ſome other uneaſy poſture; to which if ſhe ſubmitted not, ſhe was then bound with cords: there ſhe was watched, and kept without meat or ſleep for the ſpace of 24 hours (for they ſaid, within that time they ſhould ſee her imp come and ſuck). A little hole was likewiſe made in the door for imps to come in at; and leſt it ſhould come in ſome leſs diſcernible ſhape, they that watched were taught to be ever and anon ſweeping the room, and if they ſaw any ſpiders or flies, to kill them; if they could not kill them, then they might be ſure they were imps. If witches, under examination or torture, would not confeſs, all their apparel was changed, and every hair of their body ſhaven off with a ſharp razor, leſt they ſhould ſecrete magical charms to prevent their confeſſing. Witches were moſt apt to confeſs on Fridays.

By ſuch trials as theſe, and by the accuſation of children, old women and fools, were thouſands of unhappy women condemned for witchcraft, and burnt at the ſtake. In the 18th volume of the Statiſtical Account of Scotland there is the trial of two witches, William Coke and Alinſon Dick, in Kirkaldy, in 1636. The evidence on which they were condemned, is abſolutely ridiculous: they were, however, burnt for witchcraft. The expences which the town and kirk-ſeſſion were put to on this occaſion were as follows:

In primis.—To Mr James Miller, when he went to Preſtowne for a man to try them, 47s. - -	L.	2	7
Item.—To the man of Culroſs, (the executioner), when he went away the firſt time, 12s. - -		0	12
Item.—For coals for the witches, 24s.		1	4
Item.—In purchaſing the commiſſion,		9	3
Item.—For one to go to Finmouth for the laird to ſit upon their aſſize as judge,		0	6
Item.—For harden to be jumps to them,		3	10
Item.—For making of them, - -		0	8
Summa for the kirk's part	L.	17	10 Scots.

The town's part of expences deburſed extraordinarily upon William Coke and Aliſon Dick.

In primis.—For ten loads of coals to burn them, 5 merks, - -	L.	3	6 8
Item.—For a tar barrel, 14s. -		0	14 0
Item.—For towes, - - -		0	6 0
Item.—To him that brought the executioner,		2	18 0
Item.—To the executioner for his pains,		8	14 0
Item.—For his expences here, -		0	16 4
Carry over	L.	16	15 0

Brought over	L.	16	15 0
Item.—For one to go to Finmouth for the laird, - - -		0	6 0
Summa town part,	L.	17	1 Scots
Both,	L.	34	11
Or	L.	2	17 7 Ster.

Witchcraft.

Dr Farrier, Manchester Tranſ. vol. iii.

For a conſiderable time after the inquiſition was erected, the trials of witches (as heretics) were confined to that tribunal; but the goods of thoſe who were condemned being confiſcated to the holy office, its miniſters were ſo active in diſcovering ſorcerers, that the different governments found it neceſſary to deprive them of the cogniſance of this crime. On the continent, commiſſioners were then appointed for the diſcovery and conviction of witches, who, though leſs active than the inquiſitors, were but too zealous in proſecuting their function. In 1494, Sprenger and Inſtitor, two perſons employed in this commiſſion, publiſhed a collection of trials, moſt of which had come before themſelves, under the title of *Malleus Maleficarum:* this ſerved as a kind of inſtitute for their ſucceſſors.

The firſt writers againſt witchcraft were ſtigmatized as Atheiſts, though they only endeavoured to prove the imbecility of the perſons accuſed, and the infatuation or the knavery of their accuſers. Such were the epithets beſtowed by Dr Henry More, and even by Cudworth himſelf. Wierus, the diſciple of the celebrated Agrippa, gave riſe to the firſt great controverſy on this ſubject. His maſter had taught him humanity; and he endeavoured, but with too feeble a hand, to ſtop the bloody proceedings of the judges. Wierus appears to have been a well-diſpoſed, weak man, with extenſive reading on his ſubject, but too narow minded to comprehend it thoroughly. He involved himſelf in unſpeakable difficulties, by admitting the action of ſupernatural powers in certain diſeaſes, and in poſſeſſions, while he denied that witches had any concurrence in them. Theſe appearances (ſaid he) are illuſions of the devil, who perſuades ſimple and melancholy perſons that the miſchief he himſelf performs, is done by them, and at their pleaſure. He was weak enough to attempt the explanation of every ſtory alledged by his antagoniſts, without queſtioning the truth of the facts.

Bodinus, a French lawyer of eminence, who had aſſiſted at ſeveral trials of witches, wrote againſt Wierus, in his *Demonomania.* He urged the concurrent teſtimonies of ſufficient witneſſes, and the confeſſions of the witches themſelves, to eſtabliſh the exiſtence of ſorcery. Wierus owned that the unhappy perſons believed themſelves to be guilty of the crimes alledged againſt them, but that they were deceived by the devil. But what do you make of the witches meetings, cried Bodinus? The witches (replied his antagoniſt) are atrabilious. This explanation was ſo unſatisfactory that Wierus paſſed for a magician, whom the devil had furniſhed with ſpecious arguments to ſave others from puniſhment. Lerchemer, Godelmann, Ewichius, Ewaldus, and ſome others followed him, notwithſtanding this ſtigma; but they were oppoſed by men of more acuteneſs and conſiſtency than themſelves; by Remigius, who had condemned ſeveral hundreds of ſorcerers to the flames; Delrio, whoſe book is a complete Corpus Magiæ; Cujas, Eraſtus, Scribonius, Camerarius, and a crowd of others.

In this country, while the belief in witchcraft was ſupported by royal authority (for James I. is univerſally known to have written on demonology) countenanced by Bacon, and generally adopted among the people, only one writer was hardy enough to oppoſe it. This was Reginald Scott, who publiſhed a collection of impoſtures detected, under the title of Diſcoveries of Witchcraft. James ordered the book

to

Witchcraft || Witneſs.

to be burnt by the common executioner, and the judges continued to burn witches as uſual. During the civil wars, upwards of eighty were hanged in Suffolk, on the accuſation of Hopkins the witch-finder. Webſter was the next writer againſt witchcraft; but he had a different fate from that of Scott, for moſt of his arguments were refuted by Glanville. This very acute writer was induced to publiſh his Philoſophical Conſiderations about Witchcraft, by the apprehenſion, that the increaſing diſbelief of witches and apparitions tended to affect the evidence of religion, and even of a Deity. In reſpect of argument, he was certainly ſuperior to his adverſaries; his reaſoning is perſpicuous, though ſometimes ſubtile, reſted on the moſt ſpecious foundations of evidences, and arranged with great ſkill.

On the continent, this controverſy ſeemed almoſt forgotten, till Bekker publiſhed his *Monde Enchantée*, in which he denied the exiſtence of witches on the Carteſian principle, that the Deity is the ſource of all action, conſequently actions ſo oppoſite to his nature and attributes cannot be ſuppoſed to exiſt. He was anſwered by Frederick Hoffman, the father of the modern theory and practice of medicine, in his diſſertation *De Diaboli Potentia in Corpora*.

The lateſt witchcraft frenzy was in New England, about 1692, when the execution of witches became a calamity more dreadful than the ſword or the peſtilence. The accuſers became ſo daring, that neither civil nor religious authority would have proved a ſecurity againſt their attacks, if all the proſecutions had not been ſuddenly dropped, and the priſoners ſet at liberty. So far did thoſe wretches proceed in abſurdity, that a dog was accuſed of throwing perſons into fits by looking at them. As ſoon as the proſecutions were ſtopped, all reports of witchcraft ceaſed.

It would be ridiculous to attempt a ſerious refutation of the exiſtence of witches; and at preſent, luckily, the taſk is unneceſſary. In this country, at leaſt, the diſcouragement long given to all ſuſpicion of witchcraft, and the repeal of the ſtatutes againſt that crime, have very much weakened, though perhaps they have not entirely eradicated, the perſuaſion. On the continent, too, it is evidently on the decline; and notwithſtanding the exertions of Dr De Haen, and of the celebrated Lavater, we have little doubt but that in a ſhort time poſterity will wonder at the credulity of their anceſtors. That there ever were witches, is an opinion that cannot for a moment be believed by a thinking man. The actions imputed to them were either abſurd or impoſſible; the witneſſes by whoſe evidence they were condemned, either weak enthuſiaſts or downright villains; and the confeſſions aſcribed to the witches themſelves, the effects of a diſordered imagination produced by cruel treatment and exceſſive watches. As to the nightly meetings, demonologiſts themſelves have been obliged to confeſs, that they were nothing elſe but uneaſy dreams, often produced by ſoporific compoſitions. The facts which have been brought forward by the advocates for witchcraft bear in their front the moſt evident marks of trick and impoſture; and this has conſtantly been found out whenever theſe facts have been properly examined. See Sorcery.

WITENA MOT, or WITENA *Gemot*, among the Anglo-Saxons, was a term which literally ſignified the aſſembly of the wiſe men; and was applied to the great council of the nation of latter days called the *parliament*.

WITHERS *of a* HORSE, the juncture of the ſhoulder-bones at the bottom of the neck and mane, towards the upper part of the ſhoulder.

WITNESS, in law, a perſon who gives evidence in any cauſe, and is ſworn to ſpeak the truth, the whole truth, and nothing but the truth.

Trial by WITNESSES, a ſpecies of trial without the intervention of a jury. This is the only method of trial known to the civil law, in which the judge is left to form in his own breaſt his ſentence upon the credit of the witneſſes examined: but it is very rarely uſed in the Engliſh law, which prefers the trial by jury before it in almoſt every inſtance. Save only that when a widow brings a writ of dower, and the tenant pleads that the huſband is not dead; this being looked upon as a dilatory plea, is in favour of the widow, and for greater expedition allowed to be tried by witneſſes examined before the judges: and ſo, ſaith Finch, ſhall no other caſe in our law. But Sir Edward Coke mentions ſome others; as to try whether the tenant in a real action was duly ſummoned, or the validity of a challenge to a juror: ſo that Finch's obſervation muſt be confined to the trial of direct and not collateral iſſues. And in every caſe Sir Edward Coke lays it down, that the affirmative muſt be proved by two witneſſes at the leaſt.

Witſius || Woad.

WITSIUS (Herman), a learned and eminent divine of North Holland, born at Enckhuiſen in 1626. He was profeſſor of divinity ſucceſſively at Franeker, Utrecht, and Leyden; and applied himſelf ſucceſsfully to oriental learning, of which his capital work *Ægyptiaca* affords ſufficient proof. His Œconomy of the Covenants between God and Men, is warmly recommended by Mr Hervey in his Theron and Aſpaſio. He died in 1708.

WITTENBURG, a city of Germany, capital of the circle of Upper Saxony, 50 miles north of Dreſden. It is under immediate vaſſalage, and the ſeat of an aulic judicatory, a general ſuperintendency, an inſpection and conſiſtory. The town is not large; but is well fortified, and contains a famous univerſity, in which Melancthon was a profeſſor. In this place Martin Luther firſt began to preach againſt the pope's indulgences; and in the cathedral of All Saints he is ſaid to have been buried. In the old citadel of this town the ancient Saxon electors uſed to reſide. Beſides the univerſity, there is a Latin ſchool in the town, with ſix maſters. The library belonging to the univerſity is ſaid to be very valuable. In 1756 the Pruſſians being maſters of the town, deſtroyed a part of its fortifications. E. Long. 12. 47. N. Lat. 51. 49.

WOAD, in botany. See ISATIS.

The preparation of woad for dying, as practiſed in France, is minutely deſcribed by Aſtruc, in his Memoirs for a Natural Hiſtory of Languedoc. The plant puts forth at firſt five or ſix upright leaves, about a foot long and ſix inches broad: when theſe hang downwards, and turn yellow, they are fit for gathering: five crops are gathered in one year. The leaves are carried directly to a mill, much reſembling the oil or tan mills, and ground into a ſmooth paſte. If this proceſs was deferred for ſome time, they would putrefy, and ſend forth an inſupportable ſtench. The paſte is laid in heaps, preſſed cloſe and ſmooth, and the blackiſh cruſt, which forms on the outſide, reunited if it happens to crack: if this was neglected, little worms would be produced in the cracks, and the woad would loſe a part of its ſtrength. After lying for fifteen days, the heaps are opened, the cruſt rubbed and mixed with the inſide, and the matter formed into oval balls, which are preſſed cloſe and ſolid in wooden moulds. Theſe are dried upon hurdles in the ſun, they turn black on the outſide; in a cloſe place, yellowiſh, eſpecially if the weather be rainy. The dealers in this commodity prefer the firſt, though it is ſaid the workmen find no conſiderable difference betwixt the two. The good balls are diſtinguiſhed by their being weighty, of an agreeable ſmell, and when rubbed, of a violet colour within. For the uſe of the dyer, theſe balls require a farther preparation: they are beat with wooden mallets, on a brick or ſtone floor, into a groſs powder; which is heaped up in

the

Woad. || Woahoo.

the middle of the room to the height of four feet,, a ſpace being left for paſſing round the ſides. The powder, moiſtened with water, ferments, grows hot, and throws out a thick fetid fume. It is ſhovelled backwards and forwards, and moiſtened every day for twelve days; after which it is ſtirred leſs frequently, without watering, and at length made into a heap for the dyer.

Woad not only affords a laſting and ſubſtantial blue, which, according to the ſcale of the dyers, may be reduced into many different ſhades, but is alſo of great uſe in dyeing and fixing many other colours. But notwithſtanding this, and its being a commodity of our own, the uſe of it has very much declined ſince the introduction of indigo; for the purchaſe of which large ſums go annually out of the nation. The reaſon of this is, that indigo affords a more lively and pleaſing colour, is managed with more eaſe by the dyers, and does their buſineſs more expeditiouſly. Yet with all theſe advantages, it is univerſally acknowledged, that the colour which indigo affords is inferior to that of woad in many reſpects, and particularly in permanency; for which reaſon, they are frequently uſed in conjunction; woad to give ſolidity and ſubſtance, and indigo to give brightneſs and colour. But the worſt conſequence that has attended the uſe of indigo is, not barely leſſening the conſumption, but abating the price and depreciating the intrinſic value of woad; ſo that leſs care is taken in the management of it; to which in a great meaſure the inferiority of its colour, at leaſt in ſome places, is at preſent owing. The declenſion in its conſumption is not the caſe here only, but alſo in other countries; for it was once the great ſtaple of Languedoc, and was cultivated alſo in Normandy, and in other provinces of France; as it alſo is in Spain, Portugal, the Azores, and Canary iſlands, Switzerland, in the neighbourhood of Geneva, in different parts of Germany, and in Sweden.

An idea has been entertained, that by an alteration in the manner of curing it, the inconveniences that are ſuppoſed to attend the uſe of it might be removed, and that woad might be brought to anſwer all the purpoſes of indigo; which, if it could be accompliſhed, would be moſt certainly a great advantage, and an advantage which every true lover of his country would wiſh ſhould take place here rather that any where elſe. The author of the Natural Hiſtory of Languedoc ſuggeſts, that woad, if cured in the ſame manner as indigo, might produce as lively a colour; and adds, that from ſome experiments made by himſelf, he is convinced the method would effectually anſwer. The celebrated M. Du Hamel du Monçeau informs us, that having propoſed to Mr Fontenelle, a phyſician in Louiſiana, the cultivating the paſtel there in the manner of indigo, that gentleman acquainted him, that by treating indigo after the manner of paſtel, he had obtained a very beautiful green: which indeed is always the caſe when the indigo is only allowed to abſorb a ſmall quantity of oxygen; for it is now well known that its blue colour is owing to the abſorption of that gas.

WOAHOO, one of the Sandwich Iſlands, lying to the north-weſt of Morotoi, at the diſtance of ſeven leagues. From the appearance of the north-eaſt and north-weſt parts, it is the fineſt iſland of the group. Nothing can exceed the verdure of the hills, the variety of wood and lawn, and rich cultivated valleys, which the whole face of the country diſplays. A bay is formed by the north and weſt extremities, into which a fine river empties itſelf, through a deep valley; but as the water is brackiſh for 200 yards from the entrance, watering in it is not convenient. It contains about 60,000 inhabitants. Lieutenant Hergeſt, commander of the Dædalus ſtoreſhip, who had been ſent from England, in 1791, to New South Wales, and thence to the Southern Pacific Ocean, with a ſupply of proviſions for the Diſcovery ſloop, Captain Vancouver, then on a voyage of diſcovery, was here ſurpriſed and murdered by the natives, together with Mr Gooch, the aſtronomer. W. Long. 157. 51. N. Lat. 21. 43.

Woden || Wolfe.

WODEN. See Odin, and Mythology, n° 40.

WODEVILE (Anthony), earl of Rivers, brother to the queen of Edward IV. was born in the end of 1442, or in the beginning of 1443. Though one of the moſt accompliſhed men of his age, very little is known of his private hiſtory. He was early and conſtantly employed either in the tumults of thoſe turbulent times, or in diſcharging the duties of ſome of the higheſt offices of the ſtate, with which he was inveſted. Yet he found leiſure to cultivate letters, and to be the author of works which, though of little value now, made ſome noiſe in that age, when learning was at a low ebb in England. Theſe conſiſted chiefly of tranſlations from the French; and his Lordſhip, with his printer Caxton, were the firſt Engliſh writers who had the pleaſure to ſee their works publiſhed from the preſs. This accompliſhed, brave, and amiable nobleman was treacherouſly impriſoned by Richard III. in Pomfret caſtle, where, during his confinement, he compoſed a ſhort poem, which has been preſerved by John Rous of Warwick, and breathes, ſays Dr Henry, a noble ſpirit of pious reſignation to his approaching fate. He was beheaded on the 23d of June 1483, in the 41ſt year of his age.

WOLAW, a town in Germany, in Sileſia, and capital of a duchy of the ſame name. It is ſurrounded with ſtrong walls and a moraſs, and one part of the houſes are built with ſtone. The caſtle is alſo encompaſſed with deep ditches, and the greateſt part of the inhabitants are employed in a woollen manufactory. In 1709 a proteſtant church was allowed to be built here. It is ſeated on the river Oder, 20 miles north-weſt of Breſlau, and 32 ſouth-eaſt of Glogau. E. Long. 16. 54. N. Lat. 51. 18.

WOLD, Weld, or *Dyers Weed.* See Reseda.

WOLF, in zoology. See Canis.

Wolf-Fiſh, or *Sea-Wolf.* See Anarchicas.

Wolf or *Wolf Poiſon.* See Poison.

WOLFE (Major-general James), was born at Weſterham in the county of Kent, about the beginning of the year 1726. His father was Lieutenant-general Edward Wolfe. He went into the army when very young; and applying himſelf with unwearied aſſiduity to the ſtudy of his profeſſion, ſoon became remarkable for his knowledge and his genius. He diſtinguiſhed himſelf at the battle of Lafelt when little more than 20, and received the higheſt encomiums from the commander in chief. After the peace he ſtill continued to cultivate the art of war. He contrived to introduce the greateſt regularity and the exacteſt diſcipline into his corps, and at the ſame time to preſerve the affection of every ſoldier. In 1758 he was preſent as a brigadier-general at the ſiege of Louiſbourg. He landed firſt on the iſland at the head of his diviſion; and in ſpite of the violence of the ſurf, and the force and well directed fire of the enemy, drove them from their poſt with great precipitation. The ſurrender of the town, which happened ſoon after, was in a great meaſure owing to his activity, bravery, and ſkill. The fame which he acquired during this ſiege pointed him out to Mr Pitt, who was then miniſter, as the propereſt perſon to command the army deſtined to attack Quebec. This was the moſt difficult and the moſt arduous undertaking of the whole war. Quebec was the capital of the French dominions in North America; it was well fortified, ſituated in the midſt of an hoſtile country, and defended by an army of 20,000 men, regulars and militia, beſides a conſiderable

Wolfe.

ſiderable number of Indian allies. The troops deſtined for this expedition conſiſted of ten battalions, making up altogether about 7000 men. Such was the army deſtined to oppoſe three times their own number, defended by fortifications, in a country altogether unknown, and in a late ſeaſon in that climate for military operations. But this little army, ſays an officer who was preſent at that expedition, and who has been ſo obliging as to communicate all the information we deſired, was always ſanguine of ſucceſs; for they were commanded by General Wolfe, who, by a very uncommon magnanimity and nobleneſs of behaviour, had attached the troops ſo much to his perſon, and inſpired them with ſuch reſolution and ſteadineſs in the execution of their duty, that nothing ſeemed too difficult for them to accompliſh. The admirable ſkill with which his meaſures were planned, and the prudence and vigour with which they were executed, is well known. He landed his army on the northern ſhore of the river St Lawrence in ſpite of the enemy, and forced them to a battle, in which they were completely defeated. The conſequence of this battle was the reduction of Quebec, and the conqueſt of Canada. In the beginning of the battle General Wolfe was wounded in the wriſt by a muſket-ball: he wrapt his handkerchief round it, continued to give his orders with his uſual calmneſs and perſpicuity, and informed the ſoldiers that the advanced parties on the front had his orders to retire, and that they needed not be ſurpriſed when it happened. Towards the end of the battle he received a new wound in the breaſt; he immediately retired behind the rear-rank ſupported by a grenadier, and laid himſelf down on the ground. Soon after a ſhout was heard; and one of the officers who ſtood by him exclaimed, "See how they run!" The dying hero aſked with ſome emotion, "Who run?" "The enemy (replied the officer); they give way every where." The general then ſaid, "Pray, do one of you run to Colonel Burton, and tell him to march Webb's regiment with all ſpeed down to Charles river, to cut off the retreat of the fugitives from the bridge. Now, God be praiſed, I ſhall die happy!" He then turned on his ſide, cloſed his eyes, and expired.

The death of General Wolfe was a national loſs univerſally lamented. He inherited from nature an animating fervour of ſentiment, an intuitive perception, an extenſive capacity, and a paſſion for glory, which ſtimulated him to acquire every ſpecies of military knowledge that ſtudy could comprehend, that actual ſervice could illuſtrate and confirm. This noble warmth of diſpoſition ſeldom fails to call forth and unfold all the liberal virtues of the ſoul. Brave above all eſtimation of danger; generous, gentle, complacent, and humane; the pattern of the officer, the darling of the ſoldier. There was a ſublimity in his genius which ſoared above the pitch of ordinary minds; and had his faculties been exerciſed to their full extent by opportunity and action, had his judgment been fully matured by age and experience, he would, without doubt, have rivalled in reputation the moſt celebrated captains of antiquity. His body was brought to England, and buried with military honours in Weſtminſter abbey, where a magnificent monument is erected to his memory.

Wolfe (Chriſtian), a celebrated German philoſopher, was born at Breſlau in 1679. After having been well inſtructed in the rudiments of learning and ſcience in his own country, Wolfe proſecuted his ſtudies ſucceſſively in the univerſities of Jena, Hamburgh, and Leipſic. At the age of 26 he had acquired ſo much diſtinction, that he was appointed profeſſor of mathematics, and ſoon afterwards of philoſophy in general, in the univerſity of Hall. After Leibnitz had publiſhed his *Theodicea*, Wolfe, ſtruck with the novelty of the edifice which that philoſopher had raiſed, aſſiduouſly laboured in the inveſtigation of new metaphyſical truths. He alſo digeſted the Elements of Mathematics in a new method, and attempted an improvement of the art of reaſoning in a treatiſe On the Powers of the Human Underſtanding. Upon the foundation of Leibnitz's doctrine of Monads, he formed a new ſyſtem of Coſmology and Pneumatology, digeſted and demonſtrated in a mathematical method. This work, entitled Thoughts on God, the World, and the Human Soul, was publiſhed in the year 1719; to which were added, in a ſubſequent edition, Heads of Ethics and Policy.

Enfield's Hiſt. of Philoſophy, vol. ii.

Wolfe ‖ Wolfram.

Wolfe was now riſing towards the ſummit of philoſophical reputation, when the opinion which he entertained on the doctrine of neceſſity being deemed by his colleagues inimical to religion, and an oration which he delivered in praiſe of the morality of the Chineſe having given much offence, an accuſation of hereſy was publicly brought againſt him; and, though he attempted to juſtify himſelf in a treatiſe which he wrote on the ſubject of fatality, a royal mandate was iſſued in November 1723, requiring him to leave the Pruſſian dominions. Having been formerly invited by the landgrave of Heſſe-Caſſel to fill a profeſſor's chair in the univerſity of Caſſel, Wolfe now put himſelf under the patronage of that prince, who had the liberality to afford him a ſecure aſylum, and appointed him profeſſor of mathematics and philoſophy. The queſtion concerning the grounds of the cenſure which had been paſſed upon Wolfe was now every where freely canvaſſed; almoſt every German univerſity was inflamed with diſputes on the ſubject of liberty and neceſſity; and the names of Wolfians and Anti-Wolfians were every where heard. After an interval of nine years, the king of Pruſſia reverſed his ſentence of exile, and appointed him vice-chancellor of the univerſity of Hall; where his return was welcomed with every expreſſion of triumph. From this time he was employed in completing his Inſtitutes of Philoſophy, which he lived to accompliſh in every branch except policy. In 1745 he was created a baron by the elector of Bavaria, and ſucceeded Ludowig in the office of chancellor of the univerſity. He continued to enjoy theſe honours till the year 1754, when he expired. He poſſeſſed a clear and methodical underſtanding; which by long exerciſe in mathematical inveſtigations was particularly fitted for the employment of digeſting the ſeveral branches of knowledge into regular ſyſtems; and his fertile powers of invention enabled him to enrich almoſt every field of ſcience in which he laboured, with ſome valuable additions. The lucid order which appears in all his writings enables his reader to follow his conceptions with eaſe and certainty, through the longeſt trains of reaſoning.

WOLFEMBUTTLE, a conſiderable town of Germany, in the circle of Lower Saxony, and duchy of Brunſwick, with a caſtle where the duke of Brunſwick Wolfembuttle reſides. It is one of the ſtrongeſt places in Germany, though the fortifications want repairing in ſeveral places. There is an excellent library, kept in a building lately erected for that purpoſe, conſiſting of 116,000 printed books, and 2000 uncommon books, with a cabinet of curioſities, relating to natural hiſtory. It is ſeated on the river Ocker, five miles ſouth of Brunſwick, and 30 weſt of Halberſtadt. E. Long. 10. 42. N. Lat. 52. 18,

WOLFRAM, or Tungsten. See Tungsten.

Wolfram, in natural hiſtory and chemiſtry, the name of a peculiar mineral, lately ranged among the ſemi-metals. See Mineralogy, p. 134, col. 2.

This mineral, which the Germans have called *wolfram* or *wolfruth*, a name tranſlated into Latin *ſpuma lupi*, or rather *lupus Jovis*, has been met with hitherto only in mines of tin; for, though many authors would make it more common, it is

Cronſtadt's Mineralogy tranſlated by Magellan, vol. ii.

Wolfram. is an error owing to their confounding ſome gloſſy iron ores with the true wolfram, as appears by the ſpecimens which are frequently found in cabinets under this name. It has been, on account of the bad effects produced by this mineral in the ſmelting of tin-ores, from which it is very difficult to ſeparate it by waſhing, becauſe of its great ſpecific weight, that the names of *ſpuma lupi*, *lupus Jovis*, and *wolfram*, have been given to it by the miners and ſmelters.

This is really a metallic ore, and contains the very ſemi-metal lately diſcovered in the tungſten; both being mineralized, or rather formed by the ſame tungſtenic acid.

1. It is of a black or brown ſhining colour, of a radiated or foliated texture, of a moderate hardneſs, and ſometimes ſo brittle as to be eaſily broken between the fingers; but it is very weighty, its ſpecific gravity being = 7,119.

2. When ſcratched it ſhows a red trace, and this diſtinguiſhes it from the tungſten, MINERALOGY, part ii. p. 73. col. 1. which is a variety of the ore of the ſame ſemi-metal.

3. It is found in ſcattered maſſes, cryſtallized into hexaedral flat priſms, coming to a point, with four ſides, and theſe points terminated obliquely.

4. Internally it is ſhining, with the luſtre almoſt of a metal.

5. When it is broken, its texture appears leafy; and the leaves are flat, but ſomewhat confuſed.

6. On ſome ſides they are unequal, and very ſeldom ſtriated.

7. It is always opaque; and when ſcraped, it yields a powder of a dark reddiſh grey.

8. The wolfram will not melt by itſelf with the blow-pipe, the angles being only rounded; but,

9. Internally it preſerves its ſtructure and colour without change.

10. With microcoſmic ſalt *(phoſphate of ammoniac)* it fuſes with efferveſcence; and forms a glaſs of a pale red in the exterior flame, and much darker in the interior.

11. With borax it likewiſes efferveſces, and forms by the interior flame a glaſs of a greeniſh yellow, which by the exterior turns reddiſh.

12. Being expoſed in a crucible to a ſtrong fire for one hour, it ſwelled, became ſpongy, and of a browniſh colour; entered into a ſemi-vitrification; and was attracted by the magnet.

13. Equal parts of nitre and wolfram being put in a red-hot crucible, they detonated, or rather boiled up with a blue flame round the edges, and a nitrous vapour aroſe; the matter, when cold, on being put into water, partly diſſolved; and a few drops of acid produced a white precipitation.

14. Pounded wolfram, digeſted in a ſand-heat with a ſufficient quantity of marine acid, to the depth of the thickneſs of a finger above the matter, after one hour's boiling, the powder turned yellow; which is the ſame phenomenon as happens with the tungſtenic acid. See CHEMISTRY-*Index*.

15. It appears by the chemical analyſis of wolfram made by Meſſ. John and Fauſt de Luyart, that its contents conſiſt of 22 parts of manganeſe in the ſtate of black oxyd; 13,5 of iron, 65 of a yellow wolfranic oxyd, and of quartz and tin.

16. A good quantity of this yellow oxyd being collected, it was obſerved that it was entirely inſipid, and that its ſpecific gravity was = 6,120. It efferveſces with microcoſmic ſalt; produces a tranſparent blue colour without any ſhade of red; and efferveſces alſo with borax and with mineral alkali. This ſame matter does not diſſolve in water; but when triturated with it, forms a kind of emulſion: to which the acetous acid gives a blue colour, but does not diſſolve it. This matter, however, diſſolves completely in cauſtic vegetable alkali, both by the dry and moiſt way; and the liquor acquires a great bitterneſs. By pouring on it ſome nitrous acid a precipitate enſues, which leaves on the filtre a white ſalt; and this being well edulcorated, has a taſte at firſt ſweet, afterwards ſharp and bitter, producing a very diſagreeable ſenſation on the throat. It is in fact a true acid combined with a portion of the alkali and precipitating acid. Wolfram ‖ Wollaſton.

17. This acid melts, if alone, by the flame urged with the blow-pipe.

18. This white ſalt is a true metallic triple ſalt, as appears by putting 100 grains in a crucible with powdered charcoal; for after one hour and a half of a ſtrong fire, when cooled a button was found, which fell to powder between the fingers. Its colour was brown; and, on examining it with a magnifier, there was a congeries of metallic globules, of the bigneſs of pins heads; which, when broken, exhibit the metallic appearance of a ſteel colour in the fracture; and their ſpecific gravity was = 17,600.

19. Theſe metallic globules, melted with other metals, gold and platina excepted, afford ductile alloys with ſilver or copper; and hard ones with caſt iron, tin, antimony, biſmuth, and manganeſe.

It has been ſuppoſed that this is a new metal before unknown: That this was evinced, 1. by its ſpecific gravity, equal to 17,600; 2. by the tinges it gives to different glaſſes; 3. by its great difficulty to fuſe, which is greater than that of manganeſe; 4. by the yellow colour of its calx; 5. its alloys with other metals; 6. its inſolubility, at leaſt by a direct method, with mineral acids; 7. its eaſy ſolution in alkalis; 8. the emulſion it gives with water; 9. and by the blue colour it gives to acetous acid. We are not certain, however, how far this opinion has been corroborated by later experiments.

WOLFSPERG, a town of Germany, in Lower Carinthia, with a caſtle, on which the diſtrict about it depends, which is 20 miles in length, and 10 in breadth. It is ſeated on the river Lavand, at the foot of a mountain covered with wood, and full of wolves, from whence the town took its name. It is 36 miles eaſt of Clagenfurt. E. Long. 15. 0. N. Lat. 46. 56.

WOLGAST, a pretty conſiderable town of Germany, in the circle of Upper Saxony, and in Pomerania, capital of a territory of the ſame name, with a caſtle, and one of the beſt and largeſt harbours on the Baltic Sea. It is a well-built place, ſubject to Sweden, and ſeated on the river Pfin. E. Long. 14. 4. N. Lat. 54. 1.

WOLLASTON (William), deſcended of an ancient family in Staffordſhire, was born in 1659. He was in 1674 admitted a penſioner in Sidney college, Cambridge, where, notwithſtanding ſeveral diſadvantages, he acquired a great degree of reputation. In 1682, ſeeing no proſpect of preferment, he became aſſiſtant to the head maſter of Birmingham ſchool. Some time after, he got a ſmall lecture about two miles diſtant, but did the duty the whole Sunday; which, together with the buſineſs of a great free-ſchool for about four years, began to break his conſtitution. During this ſpace he likewiſe underwent a great deal of trouble and uneaſineſs, in order to extricate two of his brothers from ſome inconveniences, to which their own imprudence had ſubjected them. In 1688 affairs took a new turn. He found himſelf by a couſin's will intitled to a very ample eſtate; and came to London that ſame year, where he ſettled; chooſing a private, retired, and ſtudious life. Not long before his death, he publiſhed his treatiſe, intitled the Religion of Nature Delineated; a work for which ſo great a demand was made, that more than 10,000 were ſold in a very few years. He had ſcarcely completed the publication

Wolſey ‖ Wood.

cation of it, when he unfortunately broke an arm; and this adding ſtrength to diſtempers that had been growing upon him for ſome time, accelerated his death; which happened upon the 29th of October 1724. He was a tender, humane, and in all reſpects worthy man; but is repreſented to have had ſomething of the iraſcible in his conſtitution and temperament. His Religion of Nature Delineated expoſed him to ſome cenſure, as if he had put a ſlight upon Chriſtianity by laying ſo much ſtreſs, as he does in this work, upon the obligations of truth, reaſon, and virtue; and by making no mention of revealed religion. But this cenſure muſt have been the offspring of ignorance or envy, ſince it appears from the introduction to his work, that he intended to treat of revealed religion in a ſecond part, which he lived not to finiſh.

WOLSEY (Thomas), a famous cardinal and archbiſhop of York, is ſaid to have been the ſon of a butcher at Ipſwich. He ſtudied at Magdalen college, Oxford, where he became acquainted with the learned Eraſmus; and in the year 1500 became rector of Lymington in Somerſetſhire: he was afterwards made chaplain to king Henry VIII. and obtained ſeveral preferments. Having gradually acquired an entire aſcendency over the mind of Henry VIII. he ſucceſſively obtained ſeveral biſhoprics, and at length was made archbiſhop of York, lord high-chancellor of England, and prime miniſter; and was for ſeveral years the arbiter of Europe. Pope Leo X. created him cardinal in 1515, and made him *legate à latere;* and the emperor Charles V. and the French king Francis I. loaded him with favours, in order to gain him over to their intereſt: but after having firſt ſided with the emperor, he deſerted him to eſpouſe the intereſt of France. As his revenues were immenſe, his pride and oſtentation were carried to the greateſt height. He had 500 ſervants; among whom were 9 or 10 lords, 15 knights, and 40 eſquires. His ambition to be pope, his pride, his exactions, and his political delay of Henry's divorce, occaſioned his diſgrace. In the earlier part of his life he ſeems to have been licentious in his manners; for there goes a ſtory, that ſoon after his preferment to the living of Lymington in Somerſetſhire, he was put into the ſtocks by Sir Amias Paulet, a neighbouring juſtice of the peace, for getting drunk and making a riot at a fair. This treatment Wolſey did not forget when he arrived at the high ſtation of lord-chancellor of England; but ſummoned his corrector up to London, and, after a ſevere reprimand, enjoined him ſix years cloſe confinement in the Temple. Whatever may have been his faults, there can be no doubt of their having been aggravated both by the zealous reformers and by the creatures of Henry VIII. who was himſelf neither Papiſt nor Proteſtant; but there is every reaſon to believe that the cardinal was ſincere in his religion; and ſincerity, or at leaſt conſiſtency, was then a crime. Wolſey was the patron of learned men; a judge and munificent encourager of the polite arts; and ought to be conſidered as the founder of Chriſt-church college, Oxford; where, as well as in other places, many remains of his magnificent ideas in architecture ſtill exiſt. He died in 1530.

WOMB, or UTERUS. See ANATOMY, n° 108.

WOOD (Anthony), an eminent biographer and antiquarian, was the ſon of Thomas Wood, bachelor of arts and of the civil law, and was born at Oxford in 1632. He ſtudied at Merton college, and in 1655 took the degree of maſter of arts. He wrote, 1. The Hiſtory and Antiquities of the Univerſity of Oxford; which was afterwards tranſlated into Latin by Mr Waſe and Mr Peers, under the title of *Hiſtoria & Antiquitates Univerſitatis, Oxonienſis*, 2 vols folio. 2. *Athenæ Oxonienſes;* or an exact Account of all the Writers and Biſhops who have had their Education in the Univerſity of Oxford, from the Year 1500 to 1600, 2 vols folio; which was greatly enlarged in a ſecond edition publiſhed in 1721 by biſhop Tanner. Upon the firſt publication of this work the author was attacked by the univerſity, in defence of Edward earl of Clarendon, lord high-chancellor of England, and chancellor of the univerſity, and was likewiſe animadverted upon by biſhop Burnet; upon which he publiſhed a Vindication of the Hiſtoriographer of the Univerſity of Oxford. He died at Oxford of a retention of urine in 1695. Wood.

WOOD, a ſubſtance whereof the trunks and branches of trees conſiſt. It is compoſed of a number of concentric circles or zones, one of which is formed every year; conſequently their number correſponds to the age of the tree. Theſe zones vary in thickneſs according to the degree of vegetation that took place the year of their formation. They are alſo of different degrees of thickneſs in different parts, that part of the tree which is moſt expoſed to the ſun and beſt ſheltered growing faſteſt: hence in this country that part of the zone which looked towards the ſouth while the tree was growing is generally thickeſt. The innermoſt circle or zone is the one which was firſt formed, the outermoſt was formed the year before the tree was cut down. Theſe zones are at firſt very ſoft and tender, and harden by degrees as the tree becomes older: this is the reaſon that the middle of a tree is ſo often much better wood than the outſide of it.

The proper ligneous part of the wood conſiſts of longitudinal fibres, diſpoſed in faſciculi, and poſſeſſed of conſiderable hardneſs. It is this longitudinal direction of the fibres that renders it ſo much eaſier to cleave wood lengthwiſe than acroſs the tree or in any other direction. See PLANT.

Chemiſts have attempted to aſcertain the ingredients which enter into the compoſition of wood. The taſk, however, is ſo difficult, that they have by no means made the ſame progreſs that they have done in analyſing the various mineral productions of nature. When wood is diſtilled, water comes over firſt; ſoon after it begins to be impregnated with oil, then an empyreumatic oil comes over, then carbonic acid gas, then hydrogen gas, and laſtly carbonated hydrogen gas: a coal remains behind, which is compoſed of charcoal, fixed alkali, various earths, and ſometimes alſo of ſeveral neutral ſalts and metallic ſubſtances. This was once looked upon by chemiſts as a perfect analyſis, and it was ſuppoſed that all the various ſubſtances above-mentioned exiſted in plants in their proper form. But this is now known to be a miſtake: the action of the fire produces new combinations in the ultimate ingredients of the plant, and thus produces new ſubſtances; and it is only theſe that are obtained by the above proceſs. It is ſufficient however to ſhow, that wood is compoſed in a great meaſure of carbon, oxygen, and hydrogen, combined variouſly and in unknown proportions with one another; as moſt of the products of the diſtillation can be reſolved into theſe ſubſtances.

There are many varieties of wood poſſeſſed of diſtinguiſhing properties, as cedar, box, ebony, &c. See theſe articles.

For the *Method of Staining or Dyeing Wood*, ſee TURNING.

For more complete information concerning wood, ſee alſo PLANT, TREE, *STRENGTH of Materials*.

Foſſil Wood. Foſſil wood, or whole trees, or parts of them, are very frequently found buried in the earth, and that in different ſtrata; ſometimes in ſtone, but more uſually

Wood. in earth; and ſometimes in ſmall pieces looſe among gravel. Theſe, according to the time they have lain in the earth, or the matter they have lain among, are found differently altered from their original ſtate; ſome of them having ſuffered very little change; and others being ſo highly impregnated with cryſtalline, ſparry, pyritical, or other extraneous matter, as to appear mere maſſes of ſtone, or lumps of the common matter of the pyrites, &c. of the dimenſions, and, more or leſs, of the internal figure of the vegetable bodies into the pores of which they have made their way.

The foſſil woods which we find at this day are, according to theſe differences, arranged by Dr Hill into three kinds; 1. The leſs altered: 2. The pyritical: and, 3. The petrified.

Of the trees, or parts of them, leſs altered from their original ſtate, the greateſt ſtore is found in digging to ſmall depths in bogs, and among what is called *peat* or *turf earth*, a ſubſtance uſed in many parts of the kingdom for fuel. In digging among this, uſually very near the ſurface, immenſe quantities of vegetable matter of various kinds are found buried; in ſome places there are whole trees ſcarce altered, except in colour; the oaks in particular being uſually turned to a jetty black; the pines and firs, which are alſo very frequent, are leſs altered, and are as inflammable as ever, and often contain between the bark and wood a black reſin. Large parts of trees have alſo been not unfrequently met with unaltered in beds of another kind, and at much greater depths, as in the ſtrata of clay and loam, among gravel, and ſometimes even in ſolid ſtone.

Beſide theſe harder parts of trees, there are frequently found alſo in the peat earth vaſt quantities of the leaves and fruit and catkins of the hazel and ſimilar trees: theſe are uſually mixed with ſedge and roots of graſs, and are ſcarce at all altered from their uſual texture. The moſt common of theſe are hazel-nuts; but there are frequently found alſo the twigs and leaves of the white poplar; and a little deeper uſually there lies a cracked and ſhattered wood, the crevices of which are full of a bituminous black matter: and among this the ſtones of plums and other ſtone fruits are ſometimes found, but more rarely.

In this ſtate the fruits and larger parts of trees are uſually found: what we find of them more altered, are ſometimes large and long, ſometimes ſmaller and ſhorter branches of trees, ſometimes ſmall fragments of branches, and more frequently ſmall ſhapeleſs pieces of wood. The larger and longer branches are uſually found bedded in the ſtrata of ſtone, and are more or leſs altered into the nature of the ſtratum they lie in. The ſhorter and ſmaller branches are found in vaſt variety in the ſtrata of blue clay uſed for making tiles in the neighbourhood of London. Theſe are prodigiouſly plentiful in all the clay-pits of this kind, and uſually carry the whole external reſemblance of what they once were, but nothing of the inner ſtructure; their pores being wholy filled, and undiſtinguiſhably cloſed by the matter of the common pyrites, ſo as to appear mere ſimple maſſes of that matter. Theſe fall to pieces on being long expoſed to moiſture; and are ſo impregnated with vitriol that they are what is principally uſed for making the green vitriol or copperas at Deptford and other places.

The irregular maſſes or fragments of petrified wood are principally of oak, and are moſt uſually found among gravel; though ſometimes in other ſtrata. Theſe are variouſly altered by the inſinuation of cryſtalline and ſtony particles; and make a very beautiful figure when cut and poliſhed, as they uſually keep the regular grain of the wood, and ſhow exactly the ſeveral circles which mark the different years growth. Theſe, according to the different matter which has filled their pores, aſſume various colours, and the appearance of the various foſſils that have impregnated them; ſome are perfectly white, and but moderately hard; others of a brownish black, or perfectly black, and much harder; others of a reddiſh black, others yellowiſh, and others greyiſh, and ſome of a ferruginous colour. They are of different weights alſo and hardneſſes, according to the nature and quantity of the ſtony particles they contain: of theſe ſome pieces have been found with every pore filled with pure pellucid cryſtal: and others in large maſſes, part of which is wholly petrified and ſeems mere ſtone, while the reſt is crumbly and is unaltered wood. That this alteration is made in wood, even at this time, is alſo abundantly proved by the inſtances of wood being put into the hollows of mines, as props and ſupports to the roofs, which is found after a number of years as truly petrified as that which is dug up from the natural ſtrata of the earth. In the pieces of petrified wood found in Germany, there are frequently veins of ſpar or of pure cryſtal, ſometimes of earthy ſubſtances, and often of the matter of the common pebbles: theſe fragments of wood ſometimes have the appearance of parts of the branches of trees in their natural ſtate, but more frequently they reſemble pieces of broken boards; theſe are uſually capable of a high and elegant poliſh. Wood ‖ Woodſtock.

Many ſubſtances, it is certain, have been preſerved in the cabinets of collectors, under the title of *petrified wood*, which have very little right to that name. But where the whole outer figure of the wood, the exact lineaments of the bark, or the fibrous and fiſtular texture of the ſtriæ, and the veſtiges of the utriculi and tracheæ or air-veſſels, are yet remaining, and the ſeveral circles yet viſible which denoted the ſeveral years growth of the tree, none can deny theſe ſubſtances to be real foſſil wood. See PETRIFACTION.

Compoſition for preſerving WOOD. See CHEMISTRY, n° 621 and 700.

WOOD *(ſylva)*, in geography, a multitude of trees extended over a large continued track of land, and propagated without culture. The generality of woods only conſiſt of trees of one kind.—The ancient Saxons had ſuch a veneration for woods, that they made them ſanctuaries.—It is ordained, that none ſhall deſtroy any wood, by turning it into tillage or paſture, &c. where there are two acres or more in quantity, on pain of forfeiting 40s. an acre, by 35 Henry VIII. c. 17. All woods that are felled at 14 years growth, are to be preſerved from deſtruction for eight years; and no cattle put into the ground till five years after the felling thereof, &c. 13 Eliz. c. 25. The burning of woods or underwood is declared to be felony; alſo thoſe perſons that maliciouſly cut or ſpoil timber-trees, or any fruit trees, &c. ſhall be ſent to the houſe of correction, there to be kept three months, and whipt once a month.

WOODSTOCK, a town of Oxfordſhire, in England, pleaſantly ſeated on a riſing ground, and on a rivulet; a well compacted borough-town, and ſends two members to parliament; but is chiefly noted for Blenheim-houſe, a fine palace, built in memory of the victory obtained by the duke of Marlborough over the French and Bavarians in Auguſt 1704. It was erected at the public expence, and is one of the nobleſt ſeats in Europe. One of the paſſages to it is over a bridge with one arch, 190 feet in diameter, reſembling the Rialto at Venice. The gardens take up 100 acres of ground; and the offices, which are very grand, have room enough to accommodate 300 people. The apart-

ments

Woodward ‖ Wool.

ments of the place are magnificently furniſhed; and the ſtaircaſes, ſtatues, paintings, and tapeſtry, ſurpriſingly fine. The town is about half a mile from the palace, having ſeveral good inns; and a manufacture of ſteel chains for watches, and excellent gloves. It is 8 miles north of Oxford, and 60 weſt-north-weſt of London. W. Long. 1. 15. N. Lat. 51. 52.

WOODWARD (Dr John), was born in 1665, and educated at a country ſchool, where he learned the Latin and Greek languages, and was afterwards ſent to London, where he is ſaid to have been put apprentice to a linen-draper. He was not long in that ſtation, till he became acquainted with Dr Peter Barwick, an eminent phyſician, who took him under his tuition and into his family. Here he proſecuted with great vigour and ſucceſs the ſtudy of philoſophy, anatomy, and phyſic. In 1692, Dr Stillingfleet quitting the place of profeſſor of phyſic in Greſham college, our author was choſen to ſucceed him, and the year following was elected F. R. S. In 1695. he obtained the degree of M. D. by patent from archbiſhop Tenniſon; and the ſame year he publiſhed his Eſſay toward a Natural Hiſtory of the Earth. He afterwards wrote many other pieces which have been well received by the learned world. He founded a lecture in the univerſity of Cambridge, to be read there upon his Eſſay, &c. and handſomely endowed it. He died in 1728.

WOOF, among manufacturers, the threads which the weavers ſhoot acroſs with an inſtrument called the *ſhuttle*. See CLOTH.

WOOKEY or *Oker Hole*, a remarkable cavern two miles from the city of Wells in Somerſetſhire; for an account of which, ſee the article GROTTO.

WOOL, the covering of ſheep. See OVIS, and SHEEP.

Wool reſembles hair in a great many particulars; but beſides its fineneſs, which conſtitutes an obvious difference, there are other particulars which may ſerve alſo to diſtinguiſh them from one another. Wool, like the hair of horſes, cattle, and moſt other animals, completes its growth in a year, and then falls off as hair does, and is ſucceeded by a freſh crop. It differs from hair, however, in the uniformity of its growth, and the regularity of its ſhedding. Every filament of wool ſeems to keep exact pace with another in the ſame part of the body of the animal; the whole crop ſprings up at once; the whole advances uniformly together; the whole looſens from the ſkin nearly at the ſame period, and thus falls off if not previouſly ſhorn, leaving the animal covered with a ſhort coat of young wool, which in its turn undergoes the ſame regular mutations.

Bee, vol. xviii. p. 57.

Hairs are commonly of the ſame thickneſs in every part; but wool conſtantly varies in thickneſs in different parts, being generally thicker at the points than at the roots. That part of the fleece of ſheep which grows during the winter is finer than what grows in ſummer. This was firſt obſerved by Dr Anderſon, the editor of the Bee, and publiſhed in his *Obſervations on the Means of exciting a Spirit of National Induſtry*.

While the wool remains in the ſtate it was firſt ſhorn off the ſheep's back, and not ſorted into its different kinds, it is called *fleece*. Each fleece conſiſts of wool of divers qualities and degrees of fineneſs, which the dealers therein take care to ſeparate. The French and Engliſh uſually ſeparate each fleece into three ſorts, *viz.* 1. Mother-wool, which is that of the back and neck. 2. The wool of the tails and legs. 3. That of the breaſt and under the belly. The Spaniards make the like diviſion into three ſorts, which they call *prime*, *ſecond*, and *third*; and for the greater eaſe, denote each bale or pack with a capital letter, denoting the ſort. If the triage or ſeparation be well made, in 15 bales there will be 12 marked R, that is, refine, or prime; two marked F, for fine, or ſecond; and one S, for thirds. Wool.

The wools moſt eſteemed are the Engliſh, chiefly thoſe about Leominſter, Cotſwold, and the Iſle of weight; the Spaniſh, principally thoſe about Segovia; and the French, about Berry: which laſt are ſaid to have this peculiar property, that they will knot or bind with any other ſort; whereas the reſt will only knot with their own kind.

Among the ancients, the wools of Attica, Megara, Laodicea, Apulia, and eſpecially thoſe of Tarentum, Parma, and Altino, were the moſt valued. Varro aſſures us, that the people there uſed to clothe their ſheep with ſkins, to ſecure the wool from being damaged.

Of late a great deal of attention has been paid to wool in Britain as well as ſeveral others. Several very ſpirited attempts have been made to improve it, by introducing ſuperior breeds of ſheep, and better methods of managing them. For this purpoſe has been formed the *Britiſh Wool Society*.

Britiſh Wool Society, an aſſociation formed for the purpoſe of obtaining the beſt breeds of fine-woolled ſheep, with a view of aſcertaining, by actual experiments, how far each ſpecies or variety is calculated for the climate of Great Britain; the qualities of their wool reſpectively; the uſes to which each kind of wool could be moſt profitably employed in different manufactures; and the comparative value of each ſpecies of ſheep, ſo far as the ſame can be determined.

Attention had for ſome time been paid by the Highland Society to a famous breed of fine-woolled ſheep in Shetland; but it occurred to Sir John Sinclair of Ulbſter, baronet, and to Dr James Anderſon, well known as the author of many uſeful publications, that the improvement of Britiſh wool was a matter of too much importance to be entruſted to a ſociety which is obliged to devote its attention to ſuch a variety of objects as the general improvement of the Highlands of Scotland. The latter of theſe gentlemen, therefore, in an Appendix to the Report of the Committee of the Highland Society of Scotland, for the year 1790, propoſed *the plan of a patriotic aſſociation for the improvement of Britiſh wool*; and the former, who was convener of the committee to whom the ſubject of Shetland wool had been referred, wrote circular letters, recommending the plan. The conſequence of which was, that, on the 31ſt of January 1791, ſeveral noblemen and gentlemen of the higheſt reſpectability met in Edinburgh, and conſtituted themſelves into *a Society for the Improvement of Britiſh Wool*. Of this ſociety Sir John Sinclair was elected preſident; after which, in an excellent ſpeech, he pointed out to the members the objects of the inſtitution, the means by which thoſe objects could be attained, and the advantages which would reſult from their united labours. This addreſs was afterwards printed by order of the ſociety.

The particular breeds of ſheep to which the ſociety propoſed to direct its attention, were ſheep for the hilly parts of Scotland; ſheep for the plains, or the Lowland breed: and ſheep for the iſlands. They were to try experiments alſo with ſheep from foreign countries, diſtinguiſhed by any particular property.

The principal objects which the members had in view, during the firſt year of their aſſociation, were, 1. To collect ſpecimens of the beſt breeds which Great Britain at that period afforded, in order to aſcertain the degree of perfection to which ſheep had already been brought in this kingdom. 2. To procure from every country, diſtinguiſhed for the quality of its ſheep and wool, ſpecimens of the different breeds it poſſeſſed, in order to aſcertain how far the original breed, or a mixed breed from it and the native

Wool. sheep of the country, could thrive in Scotland. 3. To disperse as much as possible all these breeds, both foreign and domestic, over the whole kingdom, wherever proper persons could be found to take charge of them, in order to try experiments on a more extensive scale than the society itself could do; to spread information, and to excite a spirit for the improvement of sheep and wool in every part of the country.

Sir John Sinclair had previously collected a flock, consisting of sheep of the Spanish, Herefordshire, Southdown, Cheviot, Lomond hills, and Shetland breeds, and of a mixed breed from these different sheep. This flock amounted to 110 rams, ewes, and lambs. M. D'Aubenton, in consequence of a correspondence with Sir John Sinclair, sent over to the society ten rams and five ewes, of real Spanish breed, which had been originally intrusted to his care by the late king of France: these, after encountering a number of obstacles, and after being stopped and threatened to be slaughtered at the customhouse of Brighthelmstone for the use of the poor, arrived safe at Leith. Lord Sheffield, at the same time, sent to the society four rams and six ewes of the Southdown and Spanish breeds. Mr Bishton of Kilsall, in Shropshire, presented them with three Hereford rams, reckoned by many the best breed in England; the society at the same time ordered 150 ewes of the same breed, and two ewes of the Long Mountain breed, reckoned the best in Wales, to be sent along with them. They purchased 57 rams and 173 ewes of the Cheviot breed, reckoned the best in Scotland, for the hilly parts of the country. Lord Daer sent them 20 ewes of an excellent breed which existed at Mochrum in Galloway. The late earl of Oxford sent them in a present three rams of the Norfolk crossed by the Cape of Good Hope breed. Mr Isaac Grant junior of Leghorn, in conjunction with Mr Sibbald merchant at Leith, presented them an Apulian ram and ewe; the ram arrived in safety, but the ewe unfortunately died on the passage. Mr Baron Seton of Preston, in Linlithgowshire, sent them a ram and two ewes of a Spanish breed, which had been for some time kept in Sweden unmixed with any other. They purchased 100 ewes of a small breed existing in the parish of Leuchars in Fife, much resembling the Shetland. The Right Honourable William Conynghame of Ireland sent them 11 Spanish rams, 7 Spanish ewes, 15 three-fourth breed and 16 one-half breed Spanish and Irish ewes. Lord Sheffield sent them 8 rams and 18 ewes: and his Majesty made them a present of two rams.

Thus, in the course of one year, the society acquired by donation or purchase about 800 sheep of different sorts and ages, and many of them from foreign countries: about 500 of these were distributed over different parts of Scotland, the greater number of which were sold to gentlemen anxious to promote the views of the society, and well qualified to make experiments on the different breeds which they had obtained. The greatest part of the remainder were taken by different gentlemen who kept them for the society, and according to their directions, without any expence.

It is impossible to produce an instance of so much having been accomplished by a society of private individuals in so short a time. Nor was this all; the same year Mr Andrew Kerr, a very intelligent sheep-farmer on the borders of England, was sent, at the expence of the society, to examine the state of sheep-farming along the east coast of Scotland and the interior parts of the Highlands. His tour was printed by order of the society, and contains the first intimation of the possibility of the Cheviot breed thriving in the north of Scotland.

In the year 1792, Messrs Redhead, Laing, and Marshall, were sent by the society, to make a survey of the state of sheep-farming through some of the principal counties of England; the result of which was also published by the society, and contains more information on the subject of the different breeds of England than any work hitherto published; and in 1794, Mr John Naismyth was sent on a tour through the southern districts of Scotland, which completed the circuit of almost the whole kingdom. Woolston Woolwich.

Thus a few private individuals, unaided by the public purse, had boldness enough to undertake ascertaining the comparative value of the different kinds of sheep in their own country, and to introduce some of the most celebrated breeds of other countries, and succeeded in the spirited attempt. It is impossible in this place to state more minutely the various other transactions of the society; to enter into any detail of the premiums given by this respectable institution for the improvement of the celebrated Shetland breed; or to explain how, as if it were by magic, in a country where the manufacture of wool was little known, articles manufactured of that material were made, rivalling, and in some cases surpassing, the most celebrated fabrics of other countries. A war having unfortunately arisen, it became impossible to pay the same attention, or to carry on with the same success, novel enterprizes; even old establishments often fall a sacrifice amidst the horrors of war. The utmost that the British Wool Society could expect to do, was to preserve the institution in such a state, that when peace shall be happily restored it may revive with double energy and spirit.

WOOLSTON (Thomas), an English divine, was born at Northampton in 1669, and educated at Cambridge. His first appearance in the learned world was in 1705, in a work entitled, The old Apology for the Truth of the Christian Religion, against the Jews and Gentiles, revived. He afterwards wrote many pieces: but what made the most noise, were his Six Discourses on the Miracles of Christ; which occasioned a great number of books and pamphlets upon the subject, and raised a prosecution against him. At his trial in Guildhall, before the lord chief-justice Raymond, he spoke several times himself; and urged, that "he thought it very hard that he should be tried by a set of men who, though otherwise very learned and worthy persons, were no more judges of the subjects on which he wrote, than himself was a judge of the most crabbed points of the law." He was sentenced to a year's imprisonment, and to pay a fine of 100l. He purchased the liberty of the rules of the King's-bench, where he continued after the expiration of the year, being unable to pay the fine. The greatest obstruction to his deliverance from confinement was, the obligation of giving security not to offend by any future writings, he being resolved to write again as freely as before. Whilst some supposed that this author wrote with the settled intention of subverting Christianity under the pretence of defending it, others believed him disordered in his mind; and many circumstances concurred which gave countenance to this opinion. He died, January 27, 1732-3, after an illness of four days; and, a few minutes before his death, uttered these words: "This is a struggle which all men must go through, and which I bear not only patiently, but with willingness." His body was interred in St George's church-yard, Southwark.

WOOLWICH, a town in Kent, with a market on Fridays, but no fair. It is seated on the river Thames, and of great note for its fine docks and yards, where men of war are built; as also for its vast magazines of great guns, mortars, bombs, cannon-balls, powder, and other warlike stores. It has likewise an academy, where the mathematics are taught, and young officers instructed in the military art.

It

Worceſter, Worceſterſhire.

It is nine miles eaſt of London. E. Lon. 0. 10. N. Lat. 51. 30.

WORCESTER, in Latin *Wigornia*, the capital of a county of England of the ſame name, ſtands on the river Severn, but ſo low that it can hardly be ſeen till one is cloſe upon it. It is ſuppoſed to be the Branonium of Antoninus, the Branogenium of Ptolemy, and to have been built by the Romans to awe the Britons on the other ſide of the Severn. It was made an epiſcopal ſee about the year 680 by Sexulphus biſhop of the Mercians; but the preſent cathedral was begun by Wulſton in the year 1084. The town hath been ſeveral times burnt down; firſt, in 1041, by Hardicanute, who alſo maſſacred the citizens; ſecondly, not long after William Rufus's time; and a third time, when king Stephen beſieged and took it. Here, in latter times, was fought that battle, in which Charles II. with his Scots army was defeated by Cromwell. In a garden, near the ſouth gate of the city, where the action was hotteſt, the bones of the ſlain are often dug up. It had formerly ſtrong walls and a caſtle; but theſe have been demoliſhed long ago. It is now a large city, the ſtreets broad and well paved, and ſome of them very regular and well built, particularly Foregate-ſtreet; ſo that in general it is a very agreeable place. The cathedral is a ſtately edifice, and among other monuments in it are thoſe of king John, of Arthur, elder brother to Henry VIII. and of the counteſs of Saliſbnry, who gave occaſion to the inſtitution of the order of the Garter. There are ſeven or eight hoſpitals in and about the city; of which that built and endowed by Robert Berkley, of Spetchley, Eſq. is a very noble one. There is a ſchool founded by Henry VIII. three other ſchools, and ſix charity ſchools. The Guildhall and the workhouſe are ſtately ſtructures. The churches, St Nicholas and All-Saints, have been lately rebuilt, and are very handſome edifices. The city carries on a great trade; for which it is chiefly indebted to its ſituation upon the Severn. A prodigious number of people are employed in and about it in the manufacture of broad-cloth and gloves. The Welch inhabit a part of it, and ſpeak their own language. Its market is well ſupplied with proviſions, corn, and cattle, and its quay is much frequented by ſhips. By a charter from James I. it is governed by a mayor, ſix aldermen, who are juſtices of the peace, and choſen out of 24 capital citizens; a ſheriff, the city being a county of itſelf, a common council, conſiſting of 48 other citizens, out of which two chamberlains are yearly choſen, a recorder, town-clerk, two coroners, a ſword-bearer, 13 conſtables, and four ſergeants at mace. Of the biſhops of this ſee, there have been, it is ſaid, one pope, four ſaints, ſeven lord high-chancellors, 11 archbiſhops, two lord treaſurers, one chancellor to the queen, one lord preſident of Wales, and one vice-preſident. The city at preſent gives title of earl and marquis to the duke of Beaufort. W. Long. 1. 55. N. Lat. 52. 10.

WORCESTER (earl of) See TIPTOFT.

WORCESTERSHIRE, a county of England, bounded by Warwickſhire on the eaſt, by Glouceſterſhire on the ſouth, by the counties of Hereford and Salop on the weſt, and on the north by Staffordſhire. According to Templeman, it is 36 miles in length, 28 in breadth, and about 130 in circumference, within which it contains ſeven hundreds, and a part of two others, 11 market towns, of which three are boroughs, one city, namely *Worceſter*, 152 pariſhes, about 540,000 acres, and 103,000 inhabitants.

This being an inland county, well cultivated, and free from lakes, marſhes, or ſtagnant waters, the air is very ſweet and wholeſome all over it. The ſoil in general is very rich, producing corn, fruit, eſpecially pears, of which they make a great deal of perry; hops and paſture. The hills are covered with ſheep, and the meadows with cattle. Hence they have wool, cloth, ſtuffs, butter, and cheeſe in abundance. They are alſo well ſupplied with fuel, either wood or coal, and ſalt from their brine pits and ſalt ſprings. Of the laſt they have not only enough for themſelves, but export large quantities by the Severn; which noble river, to the great convenience and emolument of the inhabitants, runs from north to ſouth through the very middle of the country, enriching the ſoil, and yielding it plenty of fiſh, and an eaſy expeditious conveyance of goods to and from it. The other rivers by which it is watered are the Stour, Avon, Teme, &c. It ſends nine members to parliament, viz. two for the county, two for the city of Worceſter, two for Droitwich, two for Eveſham, and one for Bewdley; and lies in the dioceſe of Worceſter, and Oxford circuit.

Word, Work.

WORD, in language, an articulate ſound deſigned to repreſent ſome idea or notion. See GRAMMAR and LANGUAGE. See alſo LOGIC, Part I. chap. 1.

WORD, or *Watch-Word*, in military affairs, is ſome peculiar word or ſentence, by which the ſoldiers know and diſtinguiſh one another in the night, &c. and by which ſpies and deſigning perſons are diſcovered. It is uſed alſo to prevent ſurpriſes. The word is given out in an army every night to the lieutenant, or major-general of the day, who gives it to the majors of the brigades, and they to the adjutants; who give it firſt to the field-officers, and afterwards to a ſergeant of each company, who carry it to the ſubalterns. In garriſons it is given after the gate is ſhut to the town major, who gives it to the adjutants, and they to the ſergeants.

WORDS of Command. See EXERCISE and MANUAL.

Signals by the Drum, made uſe of in exerciſing of the Army, inſtead of the WORD of Command, viz.

Signals by the Drum,	*Operations.*
A ſhort roll,	To caution.
A flam	To perform any diſtinct thing.
To arms,	To form the line or battalion.
The march,	To advance, except when intended for a ſalute.
The quick march,	To advance quick.
The point of war,	To march and charge.
The retreat,	To retreat.
Drum ceaſing,	To halt.
Two ſhort rolls,	To perform the flank firing.
The dragoon march,	To open the battalion.
The grenadier march,	To form the column.
The troop,	To double diviſions.
The long roll,	To form the ſquare.
The grenadier march,	To reduce the ſquare to the column.
The preparative,	To make ready and fire.
The general,	To ceaſe firing.
Two long rolls,	To bring or lodge the colours.

WORK, in the manege. To work a horſe, is to exerciſe him at pace, trot, or gallop, and ride him at the manege. To work a horſe upon volts, or head and haunches in or between two heels, is to paſſage him, or make him go ſidewiſe upon parallel lines.

To WORK, in ſea language, is to direct the movements of a ſhip, by adapting the ſails to the force and direction of the wind. See SEAMANSHIP.

WORK, Carpenters, Clock, Crown, Field, Fire, Fret, Groteſque, Horn, Moſaic. See the ſeveral articles, together with FORTIFICATION and PYROTECHNEY.

WORK-Houſe, a place where indigent, vagrant, and idle people, are ſet to work, and ſupplied with food and clothing.

Work-

Work-houſe.

Work-houſes are of two kinds, or at leaſt are employed for two different purpoſes. Some are uſed as priſons for vagrants, or ſturdy beggars, who are there confined, and compelled to labour for the benefit of the ſociety which maintains them; whilſt others, ſometimes called *poor-houſes*, are charitable aſylums for ſuch indigent perſons as through age or infirmity are unable to ſupport themſelves by their own labour. The former kind of work-houſe, when under proper management may be made to ſerve the beſt of purpoſes; of the latter we are acquainted with none which entirely commands our approbation.

To make confinement in a work-houſe operate to the correction of vagrants and diſorderly perſons (and if it produce not this effect it can hardly be conſidered as a beneficial inſtitution), the priſoners ſhould be ſhut up in ſeparate cells, and compelled to labour for their own ſubſiſtence. A crew of thieves and vagabonds aſſociating with each other is a hell upon earth, in which every individual is hardened in his crimes by the countenance and converſation of his companions; and wretches who, when at liberty, chooſe to beg or ſteal rather than to earn a comfortable livelihood by honeſt induſtry, will ſubmit to any puniſhment which a humane overſeer can inflict rather than work for the benefit of others. No puniſhment indeed will compel a vagrant to labour. He may aſſume the appearance of it, but he will make no progreſs; and the pretext of ſickneſs or weakneſs is ever at hand for an excuſe. Hence it is that thieves and ſtrumpets are too often diſmiſſed from work-houſes and bridewells ten times more the children of the devil than when they entered them.

To remedy theſe evils, we can think of no better method than to confine each priſoner in a cell by himſelf, and to furniſh him daily with ſuch an allowance of bread and water as may preſerve him from *immediate* death; for the only compulſion to make ſuch men work ſeriouſly is the fear of want, and the only way to reform them is to leave them to their own meditations on the conſequences of their paſt conduct. There are ſurely very few perſons, if any, whoſe averſion from labour would not be conquered by the pinchings of hunger and the certain proſpect of periſhing by famine; and it is to be hoped that there are not many ſo totally diveſted of every latent principle of virtue as not to be brought by ſuch ſolitude to a due ſenſe of their former wickedneſs. Should one or two, however, be occaſionally found ſo very obdurate as to ſuffer themſelves to periſh rather than work, their deaths would prove a ſalutary beacon to others, and their blood would be on their own heads; for we have the expreſs command of St Paul himſelf, that "if any will not work, neither ſhould he eat."

No doubt it would be proper that the meditations of vagabonds confined in a work-houſe ſhould be directed by the private admonitions of a pious and intelligent clergyman; but it is not every clergyman who is qualified to diſcharge ſuch a duty. If he be actuated by a zeal not according to knowledge, or if he have not with equal care ſtudied human nature and the word of God, his admonitions will be more likely to provoke the profane ridicule of his auditor, and harden him in his wickedneſs, than to excite in his breaſt ſuch ſorrow for his ſins as ſhall "bring forth fruits meet for repentance." To render the inſtruction of thieves and vagrants of any uſe, it muſt be accurately adapted to the caſe of each individual; and however excellent it may be in itſelf, it will not be liſtened to unleſs offered at ſeaſons of uncommon ſerioufneſs, which the inſtructor ſhould therefore carefully obſerve.

That ſuch wholeſome ſeverity as this would often reform the inhabitants of work-houſes, appears extremely probable from the effects of a ſimilar treatment of common proſtitutes mentioned by Lord Kames in his Sketches of the Hiſtory of Man: "A number of thoſe wretches were in Edinburgh confined in a houſe of correction, on a daily allowance of threepence, of which part was embezzled by the ſervants of the houſe. Pinching hunger did not reform their manners; for being abſolutely idle, they encouraged each other in vice, waiting impatiently for the hour of deliverance. Mr Stirling the ſuperintendant, with the conſent of the magiſtrates, removed them to a clean houſe; and inſtead of money, appointed for each a pound of oat-meal daily, with ſalt, water, and fire for cooking. Relieved now from diſtreſs, they longed for comfort. What would they not give for milk or ale? Work (ſays he) will procure you plenty. To ſome who offered to ſpin, he gave flax and wheels, engaging to pay them half the price of their yarn, retaining the other half for the materials furniſhed. The ſpinners earned about ninepence weekly; a comfortable addition to what they had before. The reſt undertook to ſpin, one after another; and before the end of the firſt quarter they were all of them intent upon work. It was a branch of his plan to ſet free ſuch as merited that favour; and ſome of them appeared to be ſo thoroughly reformed as to be in no danger of a relapſe."

Work-houſes erected as charitable aſylums appear to us, in every view that we can take of them, as inſtitutions which can ſerve no good purpoſe. Economy is the great motive which inclines people to this mode of providing for the poor. There is comparatively but a very ſmall number of mankind in any country ſo aged and infirm as not to be able to contribute, in ſome degree, to their ſubſiſtence by their own labour; and in ſuch houſes it is thought that proper work may be provided for them, ſo that the public ſhall have nothing to give in charity but what the poor are abſolutely unable to procure for themſelves. It is imagined likewiſe, that numbers collected at a common table, can be maintained at leſs expence than in ſeparate houſes; and foot ſoldiers are given for an example, who could not live on their pay if they did not meſs together. But the caſes are not parallel. "Soldiers having the management of their pay, can club for a bit of meat; but as the inhabitants of a poor-houſe are maintained by the public, the ſame quantity of proviſions muſt be allotted to each. The conſequence is what might be expected: the bulk of them reſerve part of their victuals for purchaſing ale or ſpirits. It is vain to expect work from them: poor wretches void of ſhame will never work ſeriouſly, where the profit accrues to the public, not to themſelves. Hunger is the only effectual means for compelling ſuch perſons to work."* The poor, therefore, ſhould be ſupported in their own houſes; and to ſupport them properly, the firſt thing to be done is, to eſtimate what each can earn by his own labour; for as far only as that falls ſhort of maintenance is there room for charity. In repairing thoſe evils which ſociety did not or could not prevent, it ought to be careful not to counteract the wiſe purpoſes of nature, nor to do more than to give the poor a fair chance to work for themſelves. The preſent diſtreſs muſt be relieved, the ſick and the aged provided for; but the children muſt be inſtructed; and labour, not alms, offered to thoſe who have ſome ability to work, however ſmall that ability may be. They will be as induſtrious as poſſible, becauſe they work for themſelves; and a weekly ſum of charity under their own management will turn to better account than in a poor-houſe under the direction of mercenaries. Not a penny of it will be laid out on fermented liquors, unleſs perhaps as a medicine in ſickneſs. Nor does ſuch low fare call for pity to thoſe who can afford no better. Ale makes no part of the maintenance of thoſe, who, in many parts of Scotland

Work-houſe.

* Kames's Sketches.

Work-house,

Scotland, live by the ſweat of their brows; and yet the perſon who ſhould baniſh all from a charity work-houſe, would be exclaimed againſt as hard-hearted, and even void of humanity.

That ſuch a mode of ſupporting the poor in their own houſes is practicable, will hardly admit of a diſpute; for it has been actually put in practice in the city of Hamburgh ever ſince the year 1788. At that period ſuch revenues as had till then been expended in alms by the ſeveral church-wardens, and thoſe of which the adminiſtration had been connected with the work-houſe, were united under one adminiſtration with ſuch ſums as were collected from private benevolence. The city was divided into ſixty diſtricts, containing each an equal number of poor; and over theſe 180 overſeers were appointed. Actual relief was the firſt object; but at the very moment that this proviſion was ſecured, meaſures were taken to prevent any man from receiving a ſhilling which he could have been able to earn for himſelf. By methods, which our limits will not permit us to ſtate, the overſeers were able to make a calculation tolerably exact of what each pauper wanted for bare ſubſiſtence, in addition to the fruits of his own labour. A flax-yarn-ſpinning manufacture was eſtabliſhed, in which the yarn is paid for, not by its weight, but by its meaſure. The clean flax is ſold to the poor at a low price, and a certain meaſure of yarn again bought from them at 30 *per cent.* above the uſual price; ſo that the overſeers are ſure that all the yarn ſpun by the poor will be brought into their office. Every pauper brings with him a book in which the quantity delivered is carefully noted down, which furniſhes the overſeers with a continual average of the ſtate of induſtry among their poor.

As ſoon as this inſtitution was eſtabliſhed, the overſeers went through their diſtricts, and aſked, in all ſuch manſions as could be ſuppoſed to harbour want, if the inhabitants ſtood in need of ſupport? The queſtion to all ſuch poor as wiſhed for relief, and were able to ſpin, was, Whether they did earn by their work 1s. 6d. a-week? for experience had taught the inhabitants of Hamburg, that many poor live upon the ſum; and they knew enough of their poor to ſuppoſe, that 1s. 6d. avowed earning was equal to ſomething more. If the anſwer was affirmative, the pauper ſtood not in need of weekly aſſiſtance. If it was negative, work was given him, which, by being paid 30 *per cent.* above its value, afforded him 1s. 6d. a-week eaſily, if he was even an indifferent hand. The far more frequent caſes were partial inability by age, or weakneſs, or want of ſkill. For poor of the latter deſcription a ſchool was opened, and in three months time the buſineſs was eaſily learnt. During that time, the pauper got firſt 2s. a-week, and every week afterwards 2 d. leſs, till in the twelfth week he got nothing at all but his earnings, and was diſmiſſed, with a wheel and a pound of flax *gratis*.

The quantity of work which diſabled poor were capable of doing in a week was eaſily and accurately aſcertained by a week's trial in the ſpinning-ſchool. The reſult was produced weekly before appointed members of the committee; and the ſum which the poor could earn was noted down in their ſmall books. The overſeer was directed to pay them weekly what their earnings fell ſhort of 1s. 6d, in every ſuch week, when it appeared from their books that they had earned to the known extent of their abilities. From that moment applications became leſs frequent; and the committee had an infallible ſtandard for diſtinguiſhing real want: for whenever the pauper, if in health (if not, he was peculiarly provided for), had not earned what he could, then he had either been lazy, or had found more lucrative work: in either caſe, he was not entitled to relief for that week, whatever he might be for the following.

Water-Works.

This mode of providing for the poor, which attracted the notice and obtained the eulogium of the miniſter in the Britiſh houſe of commons, has for ſix years been in Hamburgh attended with the happieſt conſequences. In the ſtreets of that city a beggar is rarely to be ſeen, whilſt thoſe, who ſtand in need of the charitable contributions of the rich, are much more comfortably, as well as at much leſs expence, maintained at home, with their children about them, than they could be in work-houſes, under the management of mercenary overſeers. For a fuller account of this judicious inſtitution, we muſt refer the reader to Vought's *Account of the Management of the Poor in Hamburgh, ſince the year* 1788, *in a letter to ſome friends of the poor in Gr. Britain.*

WATERWORKS. Under this name may be comprehended almoſt every hydraulic ſtructure or contrivance; ſuch as, canals, conduits, locks, mills, water-engines, &c. But they may be conveniently arranged under two general heads, 1*ſt*, Works which have for their object the conducting, raiſing, or otherwiſe managing, of water; and, 2*dly*. Works which derive their efficacy from the impulſe or other action of water. The *firſt* claſs comprehends the methods of ſimply conducting water in aqueducts or in pipes for the ſupply of domeſtic conſumption or the working of machinery: It comprehends alſo the methods of procuring the ſupplies neceſſary for theſe purpoſes, by means of pumps, water, or fire engines. It alſo comprehends the ſubſequent management of the water thus conducted, whether in order to make the proper diſtribution of it according to the demand, or to employ it for the purpoſe of navigation, by lockage, or other contrivances—And in the proſecution of theſe things many ſubordinate problems will occur, in which practice will derive great advantages from a ſcientific acquaintance with the ſubject. The *ſecond* claſs of water-works is of much greater variety, comprehending almoſt every kind of hydraulic machine: and would of itſelf fill volumes. Many of theſe have already occurred in various articles of this Dictionary. In deſcribing or treating them, we have tacitly referred the diſcuſſion of their general principles, in which they all reſemble each other, to ſome article where they could be taken in a connected body, ſuſceptible of general ſcientific diſcuſſion, independent of the circumſtances which of neceſſity introduced the particular modifications required by the uſes to which the ſtructures were to be applied. That part of the preſent article, therefore, which embraces theſe common principles, will chiefly relate to the theory of water-mills, or rather of water-wheels; becauſe, when the neceſſary motion is given to the axis of the water-wheel, this may be ſet to the performance of any taſk whatever.

CLASS I.

1. *Of the conducting of Water.*

THIS is undoubtedly a buſineſs of great importance, and makes a principal part of the practice of the civil engineer: It is alſo a buſineſs ſo imperfectly underſtood, that we believe that very few engineers can venture to ſay, with tolerable preciſion, what will be the quantity of water which his work will convey, or what plan and dimenſions of conduit will convey the quantity which may be propoſed. For proof of this we ſhall only refer our readers to the facts mentioned in the article RIVERS, n° 27, &c.

In that article we have given a ſort of hiſtory of the progreſs of our knowledge in hydraulics, a branch of mechanical philoſophy which ſeems to have been entirely unknown

to

Water-works.

to the ancients. Even Archimedes, the author of almoſt all that we know in hydroſtatics, ſeems to have been entirely ignorant of any principles by which he could determine the motion of water. The mechanical ſcience of the ancients ſeems to have reached no farther than the doctrine of equilibrium among bodies at reſt. Guglielmini firſt ventured to conſider the motion of water in open canals and in rivers. Its motion in pipes had been partially conſidered in detached ſcraps by others, but not ſo as to make a body of doctrine. Sir Iſaac Newton firſt endeavoured to render hydraulics ſuſceptible of mathematical demonſtration: But his fundamental propoſition has not yet been freed from very ſerious objections; nor have the attempts of his ſucceſſors, ſuch as the Bernoullis, Euler, D'Alembert, and others, been much more ſucceſsful: ſo that hydraulics may ſtill be conſidered as very imperfect, and the general concluſions which we are accuſtomed to receive as fundamental propoſitions are not much better than matters of obſervation, little ſupported by principle, and therefore requiring the moſt ſcrupulous caution in the application of them to any hitherto untried caſe. When experiments are multiplied ſo as to include as great a variety of caſes as poſſible; and when theſe are cleared of extraneous circumſtances, and properly arranged, we muſt receive the concluſions drawn from them as the general laws of hydraulics. The experiments of the Abbé Boſſut, narrated in his *Hydrodynamique*, are of the greateſt value, having been made in the caſes of moſt general frequency, and being made with great care. The greateſt ſervice, however, has been done by the chevalier Buat, who ſaw the folly of attempting to deduce an accurate theory from any principles that we have as yet learned, and the neceſſity of adhering to ſuch a theory as could be deduced from experiment alone, independent of any more general principles. Such a theory muſt be a juſt one, if the experiments are really general, unaffected by the particular circumſtances of the caſe, and if the claſſes of experiment are ſufficiently comprehenſive to include all the caſes which occur in the moſt important practical queſtions. Some principle was neceſſary, however, for connecting theſe experiments. The ſufficiency of this principle was not eaſily aſcertained. M. Buat's way of eſtabliſhing this was judicious. If the principle is ill-founded, the reſults of its combination in caſes of actual experiments muſt be irregular; but if experiments, ſeemingly very unlike, and in a vaſt variety of diſſimilar caſes, give a train of reſults which is extremely regular and conſiſtent, we may preſume that the principle, which in this manner harmonizes and reconciles things ſo unlike, is founded in the nature of things; and if this prineiple be ſuch as is agreeable to our cleareſt notions of the internal mechaniſm of the motions of fluids, our preſumption approaches to conviction.

Proceeding in this way, the chevalier Buat has collected a prodigious number of facts, comprehending almoſt every caſe of the motion of fluids. He firſt claſſed them according to their reſemblance in ſome one particular, and obſerved the differences which accompanied their differences in other circumſtances; and by conſidering what could produce theſe differences, he obtained general rules, deduced from fact, by which theſe differences could be made to fall into a regular ſeries. He then arranged all the experiments under ſome other circumſtance of reſemblance, and purſued the ſame method; and by following this out, he has produced a general propoſition, which applies to the whole of this numerous liſt of experiments with a preciſion far exceeding our utmoſt hopes. This propoſition is contained in n° 59. of the article Rivers, and is there offered as one of the moſt valuable reſults of modern ſcience.

Water-works.

We muſt, however, obſerve, that of this liſt of experiments there is a very large claſs, which is not direct, but requires a good deal of reflection to enable us to draw a confident concluſion; and this is in caſes which are very frequent and important, *viz.* where the declivity is exceedingly ſmall, as in open canals and rivers. The experiments were of the following forms: Two large ciſterns were made to communicate with each other by means of a pipe. The ſurfaces of the water in theſe ciſterns were made to differ only by a ſmall fraction of an inch: and it is ſuppoſed that the motion in the communicating pipe will be the ſame as in a very long pipe, or an open canal, having this very minute declivity. We have no difficulty in admitting the concluſion; but we have ſeen it conteſted, and it is by no means intuitive. We had hopes that ere now this important caſe would have been determined by direct experiments, which the writer of this article was commiſſioned to make by the Board for Encouraging Improvements and Manufactures in Scotland: But this has been prevented hitherto by his want of health; and we cannot expect that it will be accompliſhed before the cloſe of this Work. This, however, need not occaſion any heſitation in the adoption of M. Buat's general propoſition, becauſe the experiments which we are now criticiſing fall in preciſely with the general train of the reſt, and ſhow no *general* deviation which would indicate a fallacy in principle.

We apprehend it to be quite unneceſſary to add much to what has been already delivered on the motion of waters in an open canal. Their *general progreſſive* motion, and conſequently the quantity delivered by an aqueduct of any ſlope and dimenſion, are ſufficiently determined; and all that is wanted is the tables which we promiſed in n° 65. of the article Rivers, by which any perſon who underſtands common arithmetic may, in five minutes time or leſs, compute the quantity of water which will be delivered by the aqueduct, canal, conduit, or pipe; for the theorem in n° 59. of this article applies to them all without diſtinction. We therefore take this opportunity of inſerting theſe tables, which have been computed on purpoſe for this Work with great labour.

TABLE I. *Logarithms of the Values of the Numerator of the Fraction* $\frac{307(\sqrt{d}-0,1)}{\sqrt{5}-1,\sqrt{5}+1,6}$ *for every Value of the Hydraulic mean Depth* d: *Alſo the Values of* 0.3 $(\sqrt{d}-0,1)$.

Water-works.

TABLE I. consists of three columns.—*Column* 1. entitled *d*, contains the hydraulic mean depths of any conduit in inches. This is set down for every 10th of an inch in the first 10 inches, that the answers may be more accurately obtained for pipes, the mean depth of which seldom exceeds three or four inches. The column is continued to 100 inches, which is fully equal to the hydraulic mean depth of any canal.

Column 2. contains the logarithms of the values of $\sqrt{d} - 0{,}1$, multiplied by 307; that is, the logarithm of the numerator of the fraction $\frac{307(\sqrt{d} - 0{,}1)}{\sqrt{s} - \mathrm{L}\sqrt{s + 1{,}6}}$ in n° 65. of the article RIVERS.

Column 3. contains the products of the values of $\sqrt{d} - 0{,}1$ multiplied by 0,3.

TABLE II. consists of two columns.—*Column* 1. entitled *s*, contains the denominator of the fraction expressing the slope or declivity of any pipe or canal; that is, the quotient of its length divided by the elevation of one extremity above the other. Thus, if a canal of one mile in length be three feet higher at one end than the other, then *s* is $\frac{5280}{3}$, = 1760.

Column 2. contains the logarithms of the denominators of the above mentioned fraction, or of the different values of the quantity $\sqrt{s - \mathrm{L}\sqrt{s + 1{,}6}}$

These quantities were computed true to the third decimal place. Notwithstanding this, the last figure in about a dozen of the first logarithms of each table is not absolutely certain to the nearest unit. But this cannot produce an error of 1 in 100,000.

Examples of the Use of these Tables.

Example 1. Water is brought into the city of Edinburgh in several mains. One of these is a pipe of five inches diameter. The length of the pipe is 14,637 feet; and the reservoir at Comiston is 44 feet higher than the reservoir into which it delivers the water on the Castle Hill. *Query*, The number of Scotch pints which this pipe should deliver in a minute?

1. We have $d = \frac{5}{4} = 1{,}25$ inches. The logarithm corresponding to this *d*, being nearly the mean between the logarithms corresponding to 1,2 and 1,3, is 2.49472.

2. We have $s = \frac{14637}{44}$, or 332,7. The logarithm corresponding to this in Table II. is had by taking proportional parts for the difference between the logarithms for $s = 330$ and $s = 340$, and is 1.18533.

3. From 2.49472
Take 1.18533
Remains 1.30939, the logarithm of 20,385 inches.

4. In column 3. of Table I. opposite to $d = 1{,}2$ and $d = 1{,}3$ are 0,3 and 0,31, of which the mean is 0,305 inches, the correction for viscidity.

5. Therefore the velocity in inches *per* second is 20,385 — 0,305, or 20,08.

6. To obtain the Scotch pints *per* minute (each containing 103,4 cubic inches), multiply the velocity by 60, and this product by 5^2, and this by 0,7854 (the area of a circle whose diameter is 1), and divide by 103,4. Or, by logarithms,

Add the log. of 20,08	1,30276
log. of 60″ - -	1.77815
log. of 5^2 or 25 - -	1.39794
log. of 0,7854 -	9.89509
Carry over	4.37394
Brought over	4.37394
Subtract the log. of 103,4 -	2.01451
Remains the log. of 228,8 pints -	2.35943

Example 2. The canal mentioned in the article RIVERS, n° 63. was 18 feet broad at the surface, and 7 feet at the bottom. It was 4 feet deep, and had a declivity of 4 inches in a mile. *Query*, The mean velocity?

1. The slant side of the canal corresponding to 4 feet deep and $5\frac{1}{2}$ projection, is 6,8 feet; therefore the border touched by the water is 6,8 + 7 + 6,8 = 20,6. The area is $4 \times \frac{18 + 7}{2}$, = 50 square feet. Therefore $d = \frac{50}{20{,}6}$, = 2,427 feet, or 29,124 inches. The logarithm corresponding to this in Table I. is 3.21113, and the correction for viscidity from the third column of the same Table is 1,58.

2. The slope is one-third of a foot in a mile, or one foot in three miles. Therefore *s* is 15,840. The logarithm corresponding to this is 2.08280.

3. From 3.21113
Subtract 2.08280
Remains 1.12833 = log. of 13,438 inches.
Subtract for viscidity - 1.58
Velocity *per* second - 11,858.

This velocity is considerably smaller than what was observed by Mr Watt. And indeed we observe, that in the very small declivities of rivers and canals, the formula is a little different. We have made several comparisons with a formula which is essentially the same with Buat's, and comes nearer in these cases. Instead of taking the hyperbolic logarithm of $\sqrt{s + 1{,}6}$, multiply its common logarithm by $2\frac{1}{4}$, or multiply it by 9, and divide the product by 4; and this process is vastly easier than taking the hyperbolic logarithm.

We have not, however, presumed to calculate tables on the authority of our own observations, thinking too respectfully of this gentleman's labours and observations. But this subject will, ere long, be fully established on a series of observations on canals of various dimensions and declivities, made by several eminent engineers during the execution of them. Fortunately Mr Buat's formula is chiefly founded on observations on small canals; and is therefore most accurate in such works where it is most necessary, viz. in mill courses, and other derivations for working machinery.

We now proceed to take notice of a few circumstances which deserve attention, in the construction of canals, in addition to those delivered in the article RIVERS.

When a canal or aqueduct is brought off from a bason or larger stream, it ought always to be widened at the entry, if it is intended for drawing off a continued stream of water: For such a canal has a slope, without which it can have no current. Suppose it filled to a dead level to the farther end. Take away the bar, and the water immediately begins to flow off at that end. But it is some time before any motion is perceived at the head of the canal, during all which time the motion of the water is augmenting in every part of the canal; consequently the slope is increasing in every part, this being the sole cause of its stream. When the water at the entry *begins* to move, the slope is scarcely sensible there; but it sensibly steepens every moment with the increase of velocity, which at last attains its maximum relative to the slope and dimensions of the whole canal; and this regulates the depth of water in every point down the stream. When all has attained a state of permanency, the slope at the entry *remains* much greater than in any other

Water-works.

part of the canal: for this ſlope muſt be ſuch as will produce a velocity ſufficient for ſupplying its TRAIN.

And it muſt be remembered, that the velocity which muſt be produced greatly exceeds the mean velocity correſponding to the train of the canal. Suppoſe that this is 25 inches. There muſt be a velocity of 30 inches at the ſurface, as appears by the Table in the article RIVERS, n° 80. This muſt be produced by a real fall at the entry.

In every other part the ſlope is ſufficient, if it merely ſerves to give the water (already in motion) force enough for overcoming the friction and other reſiſtances. But at the entry the water is ſtagnant, if in a baſon, or it is moving paſt laterally, if the aqueduct is derived from a river; and, having no velocity whatever in the direction of the canal, it muſt derive it from its ſlope. The water therefore which has acquired a permanent form in ſuch an aqueduct, muſt neceſſarily take that form which exactly performs the offices requiſite in its different portions. The ſurface remains horizontal in the baſon, as at KC (fig. 1.), till it comes near the entry of the canal A B, and there it acquires the form of an undulated curve CDE; and then the ſurface acquires an uniform ſlope EF, in the lower part of the canal, where the water is in train.

Plate DXLI.

If this is a drain, the diſcharge is much leſs than might be produced by the ſame bed if this ſudden ſlope could be avoided. If it is to be navigated, having only a very gentle ſlope in its whole length, this ſudden ſlope is a very great imperfection, both by diminiſhing the depth of water, which might otherwiſe be obtained along the canal, and by rendering the paſſage of boats into the baſon very difficult, and the coming out very hazardous.

All this may be avoided, and the velocity at the entry may be kept equal to that which forms the train of the canal, by the ſimple proceſs of enlarging the entry. Suppoſe that the water could accelerate along the ſlopes of the canal, as a heavy body would do on a finely poliſhed plane. If we now make the width of the entry in its different parts inverſely proportional to the fictitious velocities in thoſe parts, it is plain that the ſlope of the ſurface will be made parallel to that of the canal which is in train. This will require a form ſomewhat like a bell or ſpeaking-trumpet, as may eaſily be ſhown by a mathematical diſcuſſion. It would, however, be ſo much evaſated at the baſon as to occupy much room, and it would be very expenſive to make ſuch an excavation. But we may, at a very moderate expence of money and room, make the increaſe of velocity at the entry almoſt inſenſible. This ſhould always be done, and it is not all expence: for if it be not done, the water will undermine the banks on each ſide, becauſe it is moving very ſwiftly, and will make an excavation for itſelf, leaving all the mud in the canal below. We may obſerve this enlargement at the entry of all natural derivations from a baſon or lake. It is a very inſtructive experiment, to fill up this enlargement, continuing the parallel ſides of the drain quite to the ſide of the lake. We ſhall immediately obſerve the water grow ſhallower in the drain, and its performance will diminiſh. Suppoſing the ditch carried on with parallel ſides quite to the ſide of the baſon, if we build two walls or dykes from the extremities of thoſe ſides, bending outwards with a proper curvature (and this will often be leſs coſtly than widening the drain), the diſcharge will be greatly increaſed. We have ſeen inſtances where it was nearly doubled.

The enlargement at the mouths of rivers is generally owing to the ſame cauſe. The tide of flood up the river produces a ſuperficial ſlope oppoſite to that of the river, and this widens the mouth. This is moſt remarkable when the tides are high, and the river has little ſlope.

Water-works.

After this great fall at the entry of a canal, in which all the filaments are much accelerated, and the inferior ones moſt of all, things take a contrary turn. The water, by rubbing on the bottom and the ſides, is retarded; and therefore the ſection muſt, from being ſhallow, become a little deeper, and the ſurface will be convex for ſome diſtance till all comes into train. When this is eſtabliſhed, the filaments neareſt the bottom and ſide are moving ſloweſt, and the ſurface (in the middle eſpecially) retains the greateſt velocity, gliding over the reſt. The velocity in the canal, and the depth of the ſection, adjuſt themſelves in ſuch a manner that the difference between the ſurface of the baſon and the ſurface of the uniform ſection of the canal correſponds exactly to the velocity. Thus, if this be obſerved to be two feet in a ſecond, the difference of height will be $\frac{3}{10}$ths of an inch.

All the practical queſtions that are of conſiderable importance reſpecting the motion of water in aqueducts, may be eaſily, though not elegantly, ſolved by means of the tables.

But it is to be remembered, that theſe tables relate only to uniform motion, that is, to water that is in train, and where the velocity ſuffers no change by lengthening the conduit, provided the ſlope remain the ſame. It is much more difficult to determine what will be the velocity, &c. in a canal of which nothing is given but the form, and ſlope, and depth of the entry, without ſaying how deep the water runs in it. And it is here that the common doctrines of hydraulics are moſt in fault, and unable to teach us how deep the water will run in a canal, though the depth of the baſon at the entry be perfectly known. Between the part of the canal which is in train and the baſon, there is an interval where the water is in a ſtate of acceleration, and is afterwards retarded.

The determination of the motions in this interval is exceedingly difficult, even in a rectangular canal. It was one great aim of Mr Buat's experiments to aſcertain this by meaſuring accurately the depth of the water. But he found that when the ſlope was but a very few inches in the whole length of his canal, it was not in train for want of greater length; and when the ſlope was ſtill leſs, the ſmall fractions of an inch, by which he was to judge of the variations of depth, could not be meaſured with ſufficient accuracy. It would be a moſt deſirable point to determine the length of a canal, whoſe ſlope and other dimenſions are given, which will bring it into train; and what is the ratio which will then obtain between the depth at the entry and the depth which will be maintained. Till this be done, the engineer cannot aſcertain by a direct proceſs what quantity of water will be drawn off from a reſervoir by a given canal. But as yet this is out of our reach. Experiments, however, are in view which will promote the inveſtigation.

But this and ſimilar queſtions are of ſuch importance, that we cannot be ſaid to have improved hydraulics, unleſs we can give a tolerably preciſe anſwer. This we can do by a ſort of retrograde proceſs, proceeding on the principles of uniform motion eſtabliſhed by the Chevalier Buat. We may ſuppoſe a train maintained in the canal, and then examine whether this train *can* be produced by any fall that is poſſible at the entry. If it can, we may be certain that it is ſo produced, and our problem is ſolved.

We ſhall now point out the methods of anſwering ſome chief queſtions of this kind.

Queſt. 1. Given the ſlope s and the breadth w of a canal, and the height H of the ſurface of the water in the baſon above the bottom of the entry, to find the depth b

and

Water-work.

and velocity V of the ſtream, and the quantity of water Q which is diſcharged?

The chief difficulty is to find the depth of the ſtream where it is in train. For this end, we may ſimplify the hydraulic theorem of uniform motion in n° 59 of the article RIVER; making $V=\frac{\sqrt{Ngd}}{\sqrt{S}}$, where g is the velocity (in inches) acquired in a ſecond by falling, d is the hydraulic mean depth, and $\sqrt{S}$ ſtands for $\sqrt{S}$—L $\sqrt{S+1,6}$. N is a number to be fixed by experiment (ſee RIVER, n° 53.) depending on the contraction or obſtruction ſuſtained at the entry of the canal, and it may in moſt common caſes be taken = 244; ſo that $\sqrt{Ng}$ may be ſomewhat leſs than 307. To find it, we may begin by taking for our depth of ſtream a quantity h, ſomewhat ſmaller than H the height of the ſurface of the baſon above the bottom of the canal. With this depth, and the known width w of the canal, we can find the hydraulic depth d (RIVER, n° 48). Then with $\sqrt{d}$ and the ſlope find V by the Table: make this $V=\frac{\sqrt{Ngd}}{\sqrt{S}}$. This gives $\sqrt{Ng}=\frac{V\sqrt{S}}{\sqrt{d}}$. This value of Ng is ſufficiently exact; for a ſmall error of depth hardly affects the hydraulic mean depth.

After this preparation, the expreſſion of the mean velocity in the canal will be $\frac{\sqrt{Ng}\sqrt{\frac{wh}{w+2h}}}{\sqrt{S}}$. The height which will produce this velocity is $\frac{Ng}{2GS}\left(\frac{wh}{w+2h}\right)$. Now this is the ſlope at the entry of the canal which produces the velocity that is afterwards maintained againſt the obſtructions by the ſlope of the canal. It is therefore $=H-h$. Hence we deduce $h=\frac{-\left(w\left(\frac{Ng}{2GS}+1\right)-2H\right)}{4}+\sqrt{\frac{8Hw+\left(w\left(\frac{Ng}{2GS}+1\right)-2H\right)^2}{4}}$. If there be no contraction at the entry, $g=G$ and $\frac{9}{2G}=\frac{1}{2}$.

Having thus obtained the depth h of the ſtream, we obtain the quantity of water by combining this with the width w and the velocity V.

But as this was but an approximation, it is neceſſary to examine whether the velocity V be poſſible. This is very eaſy. It muſt be produced by the fall $H-h$. We ſhall have no occaſion for any correction of our firſt aſſumption, if h has not been extravagantly erroneous, becauſe a ſmall miſtake in h produces almoſt the ſame variation in d. The teſt of accuracy, however, is, that h, together with the height which will produce the velocity V, muſt make up the whole height H. Aſſuming h too ſmall leaves $H-h$ too great, and will give a ſmall velocity V, which requires a ſmall value of $H-h$. The error of $H-h$ therefore is always greater than the error we have committed in our firſt aſſumption. Therefore when this error of $H-h$ is but a trifle, ſuch as one-fourth of an inch, we may reſt ſatisfied with our anſwer.

Perhaps the eaſieſt proceſs may be the following: Suppoſe the whole ſtream in train to have the depth H. The velocity V obtained for this depth and ſlope by the Table requires a certain productive height u. Make $\sqrt{H+u}:H=H:h$, and h will be exceedingly near the truth. The reaſon is obvious. Water-works.

Queſt. 2. Given the diſcharge (or quantity to be furniſhed in a ſecond) Q, the height H of the baſon above the bottom of the canal, and the ſlope, to find the dimenſions of the canal?

Let x and y be the depth and mean width. It is plain that the equation $\frac{Q}{xy}=\sqrt{2G}\sqrt{H-x}$ will give a value of y in terms of x. Compare this with the value of y obtained from the equation $\frac{Q}{xy}=\frac{\sqrt{Ng}}{\sqrt{S}}\sqrt{\frac{xy}{y+2x}}$. This will give an equation containing only x and known quantities. But it will be very complicated, and we muſt have recourſe to an approximation. This will be beſt underſtood in the form of an example.

Suppoſe the depth at the entry to be 18 inches, and the ſlope $\frac{1}{1000}$. Let 1200 cubic feet of water *per* minute be the quantity of water to be drawn off, for working machinery or any other purpoſe; and let the canal be ſuppoſed of the beſt form, recommended in n° 69. of the article RIVER, where the baſe of the ſloping ſide is $\frac{4}{3}$ds of the height.

The ſlighteſt conſideration will ſhow us that if $\frac{V^2}{744}$ be taken for the height producing the velocity, it cannot exceed 3 inches, nor be leſs than 1. Suppoſe it = 2, and therefore the depth of the ſtream in the canal to be 16 inches; find the mean width of the canal by the equation $w=\frac{Q}{h\left(\sqrt{d}-0,1\right)\left(\frac{307}{\sqrt{S}}-0,3\right)}$, in which Q is 20 cubic feet (the 60th part of 1200), $\sqrt{S}$ is = 28,153, = $\sqrt{1000}$— L $\sqrt{1000+1,6}$, and h = 16. This gives w = 5,52 feet. The ſection u = 7,36 feet, and V = 32,6 inches. This requires a fall of 1,52 inches inſtead of 2 inches. Take this from 18, and there remains 16,48, which we ſhall find not to differ $\frac{1}{10}$th of an inch from the exact depth which the water will acquire and maintain. We may therefore be ſatisfied with aſſuming 5,36 feet as the mean width, and 3,53 feet for the width at the bottom.

This approximation proceeds on this conſideration, that when the width diminiſhes by a ſmall quantity, and in the ſame proportion that the depth increaſes, the hydraulic mean depth remains the ſame, and therefore the velocity alſo remains, and the quantity diſcharged changes in the exact proportion of the ſection. Any minute error which may reſult from this ſuppoſition, may be corrected by increaſing the fall producing the velocity in the proportion of the firſt hydraulic mean depth to the mean depth correſponding to the new dimenſions found for the canal. It will now become 1,53, and V will be 32,72, and the depth will be 16,47. The quantity diſcharged being divided by V, will give the ſection=7,335 feet, from which, and the new depth, we obtain 5,344 for the width.

This and the foregoing are the moſt common queſtions propoſed to an engineer. We aſſerted with ſome confidence that few of the profeſſion are able to anſwer them with tolerable preciſion. We cannot offend the profeſſional gentlemen by this, when we inform them, that the Academy of Sciences at Paris were occupied during ſeveral months with an examination of a plan propoſed by M. Parcieux, for bringing the waters of the Yvette into Paris; and after the moſt mature conſideration, gave in a report of the quantity of water

Water-works.

water which M. De Parcieux's aqueduct would yield, and that their report has been found erroneous in the proportion of at leaſt 2 to 5: For the waters have been brought in, and exceed the report in this proportion. Indeed long after the giving in the report, M. Perronet, the moſt celebrated engineer in France, affirmed that the dimenſions propoſed were much greater than were neceſſary, and ſaid, that an aqueduct of $5\frac{1}{2}$ feet wide, and $3\frac{1}{2}$ deep, with a ſlope of 15 inches in a thouſand fathoms, would have a velocity of 12 or 13 inches *per* ſecond, which would bring in all the water furniſhed by the propoſed ſources. The great diminution of expence occaſioned by the alteration encouraged the community to undertake the work. It was accordingly begun, and a part executed. The water was found to run with a velocity of near 19 inches when it was $3\frac{1}{2}$ feet deep. M. Perronet founded his computation on his own experience alone, acknowledging that he had no theory to inſtruct him. The work was carried no farther, it being found that the city could be ſupplied at a much ſmaller expence by ſteam engines erected by Boulton and Watt. But the facts which occurred in the partial execution of the aqueduct are very valuable. If M. Perronet's aqueduct be examined by our general formula, s will be found $= \frac{1}{4800}$, and $d = 1872$, from which we deduce the velocity $= 18\frac{2}{3}$, agreeing with the obſervation with aſtoniſhing preciſion.

The experiments at Turin by Michælotti on canals were very numerous, but complicated with many circumſtances which would render the diſcuſſion too long for this place. When cleared of theſe circumſtances, which we have done with ſcrupulous care, they are alſo abundantly conformable to our theory of the uniform motion of running waters. But to return to our ſubject:

Should it be required to bring off at once from the baſon a mill courſe, having a determined velocity for driving an under-ſhot wheel, the problem becomes eaſier, becauſe the velocity and ſlope combined determine the hydraulic mean depth at once; and the depth of the ſtream will be had by means of the height which muſt be taken for the whole depth at the entry, in order to produce the required velocity.

In like manner, having given the quantity to be diſcharged, and the velocity and the depth at the entry, we can find the other dimenſions of the channel; and the mean depth being found, we can determine the ſlope.

When the ſlope of a canal is very ſmall, ſo that the depth of the uniform ſtream differs but a little from that at the entry, the quantity diſcharged is but ſmall. But a great velocity, requiring a great fall at the entry, produces a great diminution of depth, and therefore it may not compenſate for this diminution, and the quantity diſcharged may be ſmaller. Improbable as this may appear, it is not demonſtrably falſe; and hence we may ſee the propriety of the following

Queſtion 3. Given the depth H at the entry of a rectangular canal, and alſo its width w, required the ſlope, depth, and velocity, which will produce the greateſt poſſible diſcharge?

Let x be the unknown depth of the ſtream. $H - x$ is the productive fall, and the velocity is $\sqrt{2G}\sqrt{H-x}$. This multiplied by $w\,x$ will give the quantity diſcharged. Therefore $w\,x\sqrt{2G}\sqrt{H-x}$ muſt be made a maximum. The common proceſs for this will give the equation $2H = 3x$, or $x = \frac{2}{3}H$. The mean velocity will be $\sqrt{2G}\sqrt{\frac{1}{3}H}$; the ſection will be $\frac{2}{3}w\,H$, and the diſcharge $= \frac{2}{3}\sqrt{2G}\,w\,H\sqrt{\frac{1}{3}H}$, and $d = \frac{\frac{2}{3}w\,H}{w + \frac{4}{3}H}$. With theſe data the ſlope is eaſily had by the formula for uniform motion.

Water-works.

If the canal is of the trapezoidal form, the inveſtigation is more troubleſome, and requires the reſolution of a cubic equation.

It may appear ſtrange that increaſing the ſlope of a canal beyond the quantity determined by this problem can diminiſh the quantity of water conveyed. But one of theſe two things muſt happen; either the motion will not acquire uniformity in ſuch a canal for want of length, or the diſcharge muſt diminiſh. Suppoſing, however, that it could augment, we can judge how far this can go. Let us take the extreme caſe, by making the canal vertical. In this caſe it becomes a ſimple weir or waſteboard. Now the diſcharge of a waſteboard is $\frac{2}{3}\sqrt{2G}\,w\,(h^{\frac{3}{2}} - (\frac{1}{2}h)^{\frac{3}{2}}$. The maximum determined by the preceding problem is to that of the waſteboard of the ſame dimenſions as $H\sqrt{\frac{1}{3}H} : H^{\frac{3}{2}} - (\frac{1}{2}H)^{\frac{3}{2}}$, or as $H\sqrt{\frac{1}{3}H} : H\sqrt{H} - \frac{1}{2}H\sqrt{\frac{1}{2}H}$, $= 5773 : 6465$, nearly $= 9 : 10$.

Having given the dimenſions and ſlope of a canal, we can diſcover the relation between its expenditure and the time; or we can tell how much it will ſink the ſurface of a pond in 24 hours, and the gradual progreſs of this effect; and this might be made the ſubject of a particular problem. But it is complicated and difficult. In caſes where this is an intereſting object, we may ſolve the queſtion with ſufficient accuracy, by calculating the expenditure at the beginning, ſuppoſing the baſon kept full. Then, from the known area of the pond, we can tell in what time this expenditure will ſink an inch; do the ſame on the ſuppoſition that the water is one-third lower, and that it is two-thirds lower (noticing the contraction of the ſurface of the pond occaſioned by this abſtraction of its waters. Thus we ſhall obtain three rates of diminution, from which we can eaſily deduce the deſired relation between the expenditure and the time.

Aqueducts derived from a baſon or river are commonly furniſhed with a ſluice at the entry. This changes exceedingly the ſtate of things. The ſlope of the canal may be preciſely ſuch as will maintain the mean velocity of the water which paſſes under the ſluice; in which caſe the depth of the ſtream is equal to that of the ſluice, and the velocity is produced at once by the head of water above it. But if the ſlope is leſs than this, the velocity of the iſſuing water is diminiſhed, and the water muſt riſe in the canal. This muſt check the efflux at the ſluice, and the water will be as it were ſtagnant above what comes through below it. It is extremely difficult to determine at what preciſe ſlope the water will begin to check the efflux. The contraction at the lower edge of the board hinders the water from attaining at once the whole depth which it acquires afterwards, when its velocity diminiſhes by the obſtructions. While the regorging which theſe obſtructions occaſion does not reach back to the ſluice, the efflux is not affected by it.—Even when it does reach to the ſluice, there will be a leſs depth immediately behind it than farther down the canal, where it is in train; becauſe the ſwift moving water which is next the bottom drags with it the regorged water which lies on it: but the canal muſt be rapid to make this difference of depth ſenſible. In ordinary canals, with moderate ſlopes and velocities, the velocity at the ſluice may be ſafely taken as if it were that which correſponds to the difference of depths above and below the ſluice, where both are in train.

Let therefore H be the depth above the ſluice, and h the depth in the canal. Let e be the elevation of the ſluice above the ſole, and let b be its breadth. The diſcharge will

Water-works.

will be $e\,b\,\sqrt{H-b}\,\sqrt{2G}$ for the ſluice, and $w\,h\,\frac{\sqrt{Ng}}{\sqrt{s}}\sqrt{\frac{w\,h}{w+2h}}$ for the canal. Theſe muſt be the ſame. This gives the equation $e\,b\,\sqrt{H-b}\,\sqrt{2G} = w\,h\,\frac{\sqrt{Ng}}{\sqrt{s}}\sqrt{\frac{w\,h}{w+2h}}$ containing the ſolution of all the queſtions which can be propoſed. The only uncertainty is in the quantity G, which expreſſes the velocity competent to the paſſage of the water through the orifice, circumſtanced as it is, namely, ſubjected to contraction. This may be regulated by a proper form given to the entry into this orifice. The contraction may be almoſt annihilated by making the maſonry of a cycloidal form on both ſides, and alſo at the lower edge of the ſluice-board, ſo as to give the orifice a form reſembling fig. 5. D, in the article Rivers. If the ſluice is thin in the face of a baſon, the contraction will reduce 2 G to 296. If the ſluice be as wide as the canal, 2 G will be nearly 500.

Queſtion 4. Given the head of water in the baſon H, the breadth b, and elevation e of the ſluice, and the breadth w and ſlope s of the canal, to find the depth h of the ſtream, the velocity, and the diſcharge?

We muſt (as in *Queſtion* 2.) make a firſt ſuppoſition for h, in order to find the proper value of d. Then the equation $e\,b\,\sqrt{H-h}\,\sqrt{2G} = w\,h\,\frac{\sqrt{Ng}}{\sqrt{s}}$ gives $h = \frac{G\,e^2\,b^2\,s}{w^2\,N\,g\,d} + \sqrt{\frac{G\,e^2\,b^2\,s\,H}{w^2\,N\,g\,d} + \left(\frac{G\,e^2\,b^2\,s}{w^2\,N\,g\,d}\right)^2}$. If this value ſhall differ conſiderably from the one which we aſſumed in order to begin the computation, make uſe of it for obtaining a new value of d, and repeat the operation. We ſhall rarely be obliged to perform a third operation.

The following is of frequent uſe:

Queſtion 5. Given the dimenſions and the ſlope, with the velocity and diſcharge of a river in its ordinary ſtate, required the area or ſection of the ſluice which will raiſe the waters to a certain height, ſtill allowing the ſame quantity of water to paſs through? Such an operation may render the river navigable for ſmall craft or rafts above the ſluice.

The problem is reduced to the determination of the ſize of orifice which will diſcharge this water with a velocity competent to the height to which the river is to be raiſed; only we muſt take into conſideration the velocity of the water above the ſluice, conſidering it as produced by a fall which makes a part of the height productive of the whole velocity at the ſluice. Therefore H, in our inveſtigation, muſt conſiſt of the height to which we mean to raiſe the waters, and the height which will produce the velocity with which the waters approach the ſluice: h, or the depth of the ſtream, is the ordinary depth of the river. Then (uſing the former ſymbols) we have $e\,b\,\frac{w\,h\,\sqrt{N\,g\,d}}{\sqrt{2\,G\,s\,(H-h)^3}} = \frac{Q}{\sqrt{2\,G\,(H-h)}}$.

If the area of the ſluice is known, and we would learn the height to which it will raiſe the river, we have $H-h = \frac{Q^2}{2\,G\,e^2\,b^2}$ for the expreſſion of the riſe of the water above its ordinary level. But from this we muſt take the height which would produce the velocity of the river; ſo that if the ſluice were as wide as the river, and were raiſed to the ordinary ſurface of the water, $\frac{Q^2}{2\,G\,e^2\,b^2}$, which expreſſes the height that produces the velocity under the ſluice, muſt be equal to the depth of the river, and $H-h$ will be $= 0$.

Water-works.

The performance of aqueduct drains is a very important thing, and merits our attention in this place. While the art of managing waters, and of conducting them ſo as to anſwer our demands, renders us very important ſervice by embelliſhing our habitations, or promoting our commercial intercourſe, the art of draining creates as it were new riches, fertilizing tracts of bog or marſh, which was not only uſeleſs, but hurtful by its unwholeſome exhalations, and converting them into rich paſtures and gay meadows. A wild country, occupied by marſhes which are inacceſſible to herds or flocks, and ſerve only for the haunts of water-fowls, or the retreat of a few poor fiſhermen, when once it is freed from the waters in which it is drowned, opens its lap to receive the moſt precious ſeeds, is ſoon clothed in the richeſt garb, gives life and abundance to numerous herds, and never fails to become the delight of the induſtrious cultivator who has enfranchiſed it, and is attached to it by the labour which it coſt him. In return, it procures him abundance, and ſupplies him with the means of daily augmenting its fertility. No ſpecies of agriculture exhibits ſuch long, continued, and progreſſive improvement. New families flock to the ſpot, and there multiply; and there nature ſeems the more eager to repay their labours, in proportion as ſhe has been obliged, againſt her will, to keep her treaſures locked up for a longer time, chilled by the waters. The countries newly inhabited by the human race, as is a great part of America, eſpecially to the ſouthward, are ſtill covered to a great extent with marſhes and lakes; and they would long remain in this condition, if population, daily making new advances, did not increaſe induſtry, by multiplying the cultivating hands, at the ſame time that it increaſes their wants. The Author of this beautiful world has at the beginning formed the great maſſes of mountain, has ſcooped out the dales and ſloping hills, has traced out the courſes, and even formed the beds of the rivers: but he has left to man the care of making his place of abode, and the field which muſt feed him, dry and comfortable. For this taſk is not beyond his powers, as the others are. Nay, by having this given to him in charge, he is richly repaid for his labour by the very ſtate in which he finds thoſe countries into which he penetrates for the firſt time. Being covered with lakes and foreſts, the juices of the ſoil are kept for him as it were in reſerve. The air, the burning heat of the ſun, and the continual waſhing of rains, would have combined to expend and diſſipate their vegetative powers, had the fields been expoſed in the ſame degree to their action as in the inhabited and cultivated countries, the moſt fertile moulds of which are long ſince lodged in the bottom of the ocean. All this would have been completely loſt through the whole extent of South America, had it not been protected by the foreſts which man muſt cut down, by the rank herbage which he muſt burn, and by the marſh and bog which he muſt deſtroy by draining. Let not ungrateful man complain of this. It is his duty to take on himſelf the taſk of opening up treaſures, preſerved on purpoſe for him with ſo much judgment and care. If he has diſcernment and ſenſibility, he will even thank the Author of all good, who has thus huſbanded them for his uſe. He will co-operate with his beneficent views, and will be careful not to proceed by wantonly ſnatching at preſent and partial good, and by picking out what is moſt eaſily got at, regardleſs of him

who

Water-works.

who is to come afterwards to uncover and extract the remaining riches of the ground. A wise administration of such a country will think it their duty to leave a just share of this inheritance to their descendants, who are entitled to expect it as the last legatees. National plans of cultivation should be formed on this principle, that the steps taken by the present cultivators for realizing part of the riches of the infant country shall not obstruct the works which will afterwards be necessary for also obtaining the remainder. This is carefully attended to in Holland and in China. No man is allowed to conduct the drains, by which he recovers a piece of marsh, in such a way as to render it much more difficult for a neighbour, or even for his own successor, to drain another piece, although it may at present be quite inaccessible. There remains in the middle of the most cultivated countries many marshes, which industry has not yet attempted to drain, and where the legislature has not been at pains to prevent many little abuses which have produced elevations in the beds of rivers, and rendered the complete draining of some spots impossible. Administration should attend to such things, because their consequences are great. The sciences and arts, by which alone these difficult and costly jobs can be performed, should be protected, encouraged, and cherished. It is only from science that we can obtain principles to direct these arts. The problem of draining canals is one of the most important, and yet has hardly ever occupied the attention of the hydraulic speculatist. We apprehend that Mr Buat's theory will throw great light on it; and regret that the very limited condition of our present Work will hardly afford room for a slight sketch of what may be done on the subject. We shall, however, attempt it by a general problem, which will involve most of the chief circumstances which occur in works of that kind.

Quest. 6. Let the hollow ground A (fig. 2.) be inundated by rains or springs, and have no outlet but the canal AB, by which it discharges its water into the neighbouring river BCDE, and that its surface is nearly on a level with that of the river at B. It can only drain when the river sinks in the droughts of summer; and even if it could then drain completely, the putrid marsh would only be an infecting neighbour. It may be proposed to drain it by one or more canals; and it is required to determine their lengths and other dimensions, so as to produce the best effects?

It is evident that there are many circumstances to determine the choice, and many conditions to be attended to.

If the canals AC, AD, AE, are respectively equal to the portions BC, BD, BE, of the river, and have the same slopes, they will have the same discharge: but they are not for this reason equivalent. The long canal AE may drain the marsh completely, while the short one AC will only do it in part; because the difference of level between A and C is but inconsiderable. Also the freshes of the river may totally obstruct the operation of AC, while the canal AE cannot be hurt by them, E being so much lower than C. Therefore the canal must be carried so far down the river, that no freshes there shall ever raise the waters in the canal so high as to reduce the slope in the upper part of it to such a level that the current shall not be sufficient to carry off the ordinary produce of water in the marsh.

Still the problem is indeterminate, admitting many solutions. This requisite discharge may be accomplished by a short but wide canal, or by a longer and narrower. Let us first see what solution can be made, so as to accomplish our purpose in the most economical manner, that is, by means of the smallest equation.—We shall give the solution in the form of an example.

Water-works.

Suppose that the daily produce of rains and springs raises the water $1\frac{1}{2}$ inch on an area of a square league, which gives about 120,000 cubic fathoms of water. Let the bottom of the bason be three feet below the surface of the freshes in the river at B in winter. Also, that the slope of the river is 2 inches in 100 fathoms, or $\frac{1}{3000}$dth, and that the canal is to be 6 feet deep.

The canal being supposed nearly parallel to the river, it must be at least 1800 fathoms long before it can be admitted into the river, otherwise the bottom of the bog will be lower than the mouth of the canal; and even then a hundred or two more fathoms added to this will give it so little slope, that an immense breadth will be necessary to make the discharge with so small a velocity. On the other hand, if the slope of the canal be made nearly equal to that of the river, an extravagant length will be necessary before its admission into the river, and many obstacles may then intervene. And even then it must have a breadth of 13 feet, as may easily be calculated by the general hydraulic theorem. By receding from each of these extremes, we shall diminish the expence of excavation. Therefore,

Let x and y be the breadth and length, and h the depth (6 feet), of the canal. Let q be the depth of the bog below the surface of the river, opposite to the bason, D the discharge in a second, and $\frac{1}{a}$ the slope of the river. We must make $h\,x\,y$ a minimum, or $x\dot{y} + y\dot{x} = o$.

The general formula gives the velocity $V = \frac{\sqrt{ng}\,(\sqrt{d} - o,1)}{\sqrt{s} - L\sqrt{r + 1,6}} - o,3\,(\sqrt{d} - o,1)$. This would give x and y; but the logarithmic term renders it very complicated. We may make use of the simple form $V = \frac{\sqrt{N g d}}{\sqrt{S}}$, making $\sqrt{Ng}$ nearly $2y\,b$. This will be sufficiently exact for all cases which do not deviate far from this, because the velocities are very nearly in the subduplicate ratio of the slopes.

To introduce these data into the equation, recollect that $V = \frac{D}{h\,x}$; $d = \frac{h\,x}{x + 2\,h}$. As to S, recollect that the canal being supposed of nearly equal length with the river, $\frac{y}{a}$ will express the whole difference of height, and $\frac{y}{a} - q$ is the difference of height for the canal. This quantity being divided by y, gives the value of $\frac{I}{S} = \frac{\frac{y}{a} - q}{y}$. Therefore the equation for the canal becomes $\sqrt{Ng}\,\sqrt{\frac{h\,x}{x + 2\,h}}\,\sqrt{\frac{\frac{y}{a} - q}{y}}$. Hence we deduce $y = \frac{N g q h^3 x^3}{\frac{N g h^3 x^3}{a} - D^2\,(x + 2h)}$;

and $\dot{y} = \frac{3\,N g q h^3 x^2 \dot{x}}{\frac{N g h^3 x^3}{a} - D^2\,(x + 2h)} - \frac{N g q h^3 x^3 \dot{x}\left(\frac{3\,N g h^3 x^2}{a} - D^2\right)}{\left(\frac{N g h^3 x^3}{a} - D^2\,(x + 2h)\right)^2}$. If we substitute these values in the equation $y\dot{x} + x\dot{y} = o$, and reduce it, we obtain finally,

$$\frac{N g h^3 x^3}{a D^2} - 3x = 8h.$$

If

Water-works.

If we reſolve this equation by making $Ng = (296)^2$, or 87616 inches; $h = 72$, $\frac{1}{a} = \frac{1}{1000}$, and $D = 518400$, we obtain $x = 392$ inches, or 32 feet 8 inches, and $\frac{D}{hx}$ or $V = 18,36$ inches. Now, putting theſe values in the exact formula for the velocity, we obtain the ſlope of the canal, which is $\frac{1}{11004}$, nearly 0,62 inches in 100 fathoms.

Let l be the length of the canal in fathoms. As the river has 2 inches fall in 100 fathoms, the whole fall is $\frac{2l}{100}$, and that of the canal is $\frac{062\,l}{100}$. The difference of theſe two muſt be 3 feet, which is the difference between the river and the entry of the canal. We have therefore $\left(\frac{2 - 0,62}{100}\right)l = 36$ inches. Hence $l = 2604$ fathoms; and this multiplied by the ſection of the canal gives 14177 cubic fathoms of earth to be removed.

This may ſurely be done, in moſt caſes, for eight ſhillings each cubic fathom, which does not amount to 6000l. a very moderate ſum for completely draining of nine ſquare miles of country.

In order to judge of the importance of this problem, we have added two other canals, one longer and the other ſhorter, having their widths and ſlopes ſo adjuſted as to enſure the ſame performance.

Width. *Feet.*	Velocity. *Inches.*	Slope.	Length.	Excavation.
42	14,28	$\frac{1}{18788}$	2221	15547
$32\frac{2}{7}$	18,36	$\frac{1}{11004}$	2604	14177
21	28,57	$\frac{1}{4701}$	7381	25833

We have conſidered this important problem in its moſt ſimple ſtate. If the baſon is far from the river, ſo that the drains are not nearly parallel to it, and therefore have leſs ſlope attainable in their courſe, it is more difficult. Perhaps the beſt method is to try two very extreme caſes and a middle one, and then a fourth, nearer to that extreme which differs leaſt from the middle one in the quantity of excavation. This will point out on which ſide the minimum of excavation lies, and alſo the law by which it diminiſhes and afterwards increaſes. Then draw a line, on which ſet off from one end the lengths of the canals. At each length erect an ordinate repreſenting the excavation; and draw a regular curve through the extremities of the ordinates. From that point of the curve which is neareſt to the baſe line, draw another ordinate to the baſe. This will point out the beſt length of the canal with ſufficient accuracy. The length will determine the ſlope, and this will give the width, by means of the general theorem. *N. B.* Theſe draining canals muſt always come off from the baſon with evaſated entries. This will prevent the loſs of much fall at the entry.

Two canals may ſometimes be neceſſary. In this caſe expence may frequently be ſaved, by making one canal flow into the other. This, however, muſt be at ſuch a diſtance from the baſon, that the ſwell produced in the other by this addition may not reach back to the immediate neighbourhood of the baſon, otherwiſe it would impede the performance of both. For this purpoſe, recourſe muſt be had to the problem iii. in n° 104. of the article RIVER. We muſt here obſerve, that in this reſpect canals differ exceedingly from rivers: rivers enlarge their beds, ſo as always to convey every increaſe of waters; but a canal may be gorged through its whole length, and will then greatly diminiſh its diſcharge. In order that the lower extremity of a canal may convey the waters of an equal canal admitted into it, their junction muſt be ſo far from the baſon, that the ſwell occaſioned by raiſing its waters nearly $\frac{1}{2}$ more (viz. in the ſubduplicate ratio of 1 to 2) may not reach back to the baſon. Water-works.

This obſervation points out another method of economy. Inſtead of one wide canal, we may make a narrower one of the whole length, and another narrow one reaching part of the way, and communicating with the long canal at a proper diſtance from the baſon. But the lower extremity will now be too ſhallow to convey the waters of both. Therefore raiſe its banks by uſing the earth taken from its bed, which muſt at any rate be diſpoſed of. Thus the waters will be conveyed, and the expence, even of the lower part of the long canal, will ſcarcely be increaſed.

Theſe obſervations muſt ſuffice for an account of the management of open canals; and we proceed to the conſideration of the conduct of water in pipes.

THIS is much more ſimple and regular, and the general theorem requires very trifling modifications for adapting it to the caſes or queſtions that occur in the practice of the civil engineer. Pipes are always made round, and therefore d is always $\frac{1}{4}$th of the diameter. The velocity of water in a pipe which is in train, is $= V$, $= \frac{307\,(\sqrt{d} - 0,1)}{\sqrt{s} - L\sqrt{s + 1,6}} - 0,3\,(\sqrt{d} - 0,1)$ or $= (\sqrt{d} - 0,1)\left(\frac{307}{\sqrt{s} - L\sqrt{s + 1,6}} - 0,3\right)$.

The chief queſtions are the following:

Queſt. 1. Given the height H of the reſervoir above the place of delivery, and the diameter and length of the pipe, to find the quantity of water diſcharged in a ſecond?

Let L be the length, and h the fall which would produce the velocity with which the water enters the pipe, and actually flows in it, after overcoming all obſtructions. This may be expreſſed in terms of the velocity by $\frac{V^2}{2G}$, G denoting the acceleration of gravity, correſponding to the manner of entry. When no methods are adopted for facilitating the entry of the water, by a bell-ſhaped funnel or otherwiſe, 2G may be aſſumed as $= 500$ inches, or 42 feet, according as we meaſure the velocity in inches or feet. The ſlope is $\frac{1}{s} = \frac{H - \frac{V^2}{2G}}{L}$ which muſt be put into the general formula. This would make it very complicated. We may ſimplify it by the conſideration that the velocity is very ſmall in compariſon of that ariſing from the height H: conſequently h is very ſmall. Alſo, in the ſame pipe, the reſiſtances are nearly in the duplicate ratio of the velocities when theſe are ſmall, and when they differ little among themſelves. Therefore make $b = \frac{L}{h}$, taking h by gueſs, a very little leſs than H. Then compute the mean velocity v correſponding to theſe data, or take it from the table. If $h + \frac{v^2}{2G}$ be $= H$, we have found the mean velocity $V = v$. If not, make the following proportion:

$h : \frac{v^2}{2G} = H - \frac{V^2}{2G} : \frac{V^2}{2G}$, which is the ſame with this $h + \frac{v^2}{2G} : v^2 = H : V^2$, and V^2 is $= \frac{v^2 H}{h + \frac{v^2}{2G}} = \frac{v^2 H}{\frac{2Gh + v^2}{2G}} = \frac{v^2 \cdot 2GH}{v^2 + 2Gh}$.

Water-works

If the pipe has any bendings, they muſt be calculated for in the manner mentioned in the article RIVER, n° 101; and the head of water neceſſary for overcoming this additional reſiſtance being called $\frac{V^2}{m}$, the laſt proportion muſt be changed for

$$h + v^2\left(\frac{1}{2G} + \frac{1}{m}\right) : v^2 = H : V^2.$$

Queſt. 2*d*. Given the height of the reſervoir, the length of the pipe, and the quantity of water which is to be drawn off in a ſecond, to find the diameter of the pipe which will draw it off?

Let d be conſidered as $= \frac{1}{4}$th of the diameter, and let $1 : c$ repreſent the ratio of the diameter of a circle to its circumference. The ſection of the pipe is $4cd^2$. Let the quantity of water *per* ſecond be Q; then $\frac{Q}{4cd^2}$ is the mean velocity. Divide the length of the pipe by the height of the reſervoir above the place of delivery, diminiſhed by a very ſmall quantity, and call the quotient S. Conſider this as the ſlope of the conduit; the general formula now becomes.

$$\frac{Q}{4^{\frac{4}{5}}} = \frac{307\,(\sqrt{d} - 0{,}1)}{\sqrt{s - L\sqrt{s} + 1{,}06}} - 0{,}3\,(\sqrt{d} - 0{,}1),$$

or $\frac{dQ}{4cd^2} = \frac{(307(\sqrt{d} - 0{,}1)}{\sqrt{S}} - 0{,}3\,(\sqrt{d} - 0{,}1)$. We may neglect the laſt term in every caſe of civil practice, and alſo the ſmall quantity 0,1. This gives the very ſimple formula.

$$\frac{Q}{4cd^2} = \frac{307\sqrt{d}}{\sqrt{S}}$$

from which we readily deduce

$$d = \left|\frac{Q\sqrt{S}}{4c \times 307}\right|^{\frac{2}{5}} = \left|\frac{QS\sqrt{}}{3858}\right|^{\frac{2}{5}}$$

This proceſs gives the diameter ſomewhat too ſmall. But we eaſily rectify this error by computing the quantity delivered by the pipe, which will differ a little from the quantity propoſed. Then obſerving, by this equation, that two pipes having the ſame length and the ſame ſlope give quantities of water, of which the ſquares are nearly as the 5th powers of the diameter, we form a new diameter in this proportion, which will be almoſt perfectly exact.

It may be obſerved that the height aſſumed for determining the ſlope in theſe two queſtions will ſeldom differ more than an inch or two from the whole height of the reſervoir above the place of delivery; for in conduits of a few hundred feet long the velocity ſeldom exceeds four feet *per* ſecond, which requires only a head of 3 inches.

As no inconvenience worth minding reſults from making the pipes a tenth of an inch or ſo wider than is barely ſufficient, and as this generally is more than the error ariſing from even a very erroneous aſſumption of h, the anſwer firſt obtained may be augmented by one or two tenths of an inch, and then we may be confident that our conduit will draw off the intended quantity of water.

We preſume that every perſon who aſſumes the name of engineer knows how to reduce the quantity of water meaſured in gallons, pints, or other denominations, to cubic-inches, and can calculate the gallons, &c. furniſhed by a pipe of known diameter, moving with a velocity that is meaſured in inches *per* ſecond. We farther ſuppoſe that all care is taken in the conſtruction of the conduit, to avoid obſtructions occaſioned by lumps of ſolder hanging in the inſide of the pipes; and, particularly, that all the cocks and plugs by the way have waterways equal to the ſection of the pipe. Undertakers are moſt tempted to fail here, by making the cocks too ſmall, becauſe large cocks are very coſtly. But the employer ſhould be ſcrupulouſly attentive to this; becauſe a ſimple contraction of this kind may be the throwing away of many hundred pounds in a wide pipe, which yields no more water than can paſs through the ſmall cock.

Water-works

The chief obſtructions ariſe from the depoſition of ſand or mud in the lower parts of pipes, or the collection of air in the upper parts of their bendings. The velocity being always very moderate, ſuch depoſitions of heavy matters are unavoidable. The utmoſt care ſhould therefore be taken to have the water freed from all ſuch things at its entry by proper filtration; and there ought to be cleanſing plugs at the lower parts of the bendings, or rather a very little way beyond them. When theſe are opened, the water iſſues with greater velocity, and carries the depoſitions with it.

It is much more difficult to get rid of the air which choaks the pipes by lodging in their upper parts. This is ſometimes taken in along with the water at the reſervoir, when the entry of the pipe is too near the ſurface. This ſhould be carefully avoided, and it coſts no trouble to do ſo. If the entry of the pipe is two feet under the ſurface, no air can ever get in. Floats ſhould be placed above the entries, having lids hanging from them, which will ſhut the pipe before the water runs too low.

But air is alſo diſengaged from ſpring-water by merely paſſing along the pipe. When pipes are ſupplied by an engine, air is very often drawn in by the pumps in a diſengaged ſtate. It is alſo diſengaged from its ſtate of chemical union, when the pumps have a ſuction-pipe of 10 or 12 feet, which is very common. In whatever way it is introduced, it collects in all the upper part of bendings, and choaks the paſſage, ſo that ſometimes not a drop of water is delivered. Our cocks ſhould be placed there, which ſhould be opened frequently by perſons who have this in charge. Deſaguliers deſcribes a contrivance to be placed on all ſuch eminences, which does this of itſelf. It is a pipe with a cock, terminating in a ſmall ciſtern. The key of the cock has a hollow ball of copper at the end of a lever. When there is no air in the main pipe, water comes out by this diſcharger, fills the ciſtern, raiſes the ball, and thus ſhuts the cock. But when the bend of the main contains air, it riſes into the ciſtern, and occupies the upper part of it. Thus the floating ball falls down, the cock opens and lets out the air, and the ciſtern again filling with water, the ball riſes, and the cock is again ſhut.

A very neat contrivance for this purpoſe was invented by the late profeſſor Ruſſel of Edinburgh. The cylindrical pipe BCDE (fig. 3.), at the upper part of a bending of the main, is ſcrewed on, the upper end of which is a flat plate perforated with a ſmall hole F. This pipe contains a hollow copper cylinder G, to the upper part of which is faſtened a piece of ſoft leather H. When there is air in the pipe, it comes out by the hole A, and occupies the diſcharger, and then eſcapes through the hole F. The water follows, and, riſing in the diſcharger, lifts up the hollow cylinder G, cauſing the leather H to apply itſelf to the plate CD, and ſhut the hole. Thus the air is diſcharged without the ſmalleſt loſs of water.

It is of the moſt material conſequence that there be no contraction in any part of a conduit. This is evident; but it is alſo prudent to avoid all unneceſſary enlargements. For, when the conduit is full of water moving along it, the velocity in every ſection is inverſely proportional to the area of the ſection: it is therefore diminiſhed wherever the pipe is enlarged; but it muſt again be increaſed where the pipe contracts. This cannot be without expending force in the acceleration. This conſumes part of the impelling power, whether

Water-works.

whether this be a head of water, or the force of an engine. See what is ſaid on this ſubject in the article PUMPS, n° 83, &c. Nothing is gained by any enlargement; and every contraction, by requiring an augmentation of velocity, employs a part of the impelling force preciſely equal to the weight of a column of water whoſe baſe is the contracted paſſage, and whoſe height is the fall which would produce a velocity equal to this augmentation. This point ſeems to have been quite overlooked by engineers of the firſt eminence, and has in many inſtances greatly diminiſhed the performance of their beſt works. It is no leſs detrimental in open canals; becauſe at every contraction a ſmall fall is required for reſtoring the velocity loſt in the enlargement of the canal, by which the general ſlope and velocity are diminiſhed. Another point which muſt be attended to in the conducting of water is, that the motion ſhould not be ſubſultory, but continuous. When water is to be driven along a main by the ſtrokes of a reciprocating engine, it ſhould be forced into an air-box, the ſpring of which may preſerve it in motion along the whole ſubſequent main. If the water is brought to reſt at every ſucceſſive ſtroke of the piſton, the whole maſs muſt again be put in motion through the whole length of the main. This requires the ſame uſeleſs expenditure of power as to communicate this motion to as much dead matter; and this is over and above the force which may be neceſſary for raiſing the water to a certain height; which is the only circumſtance that enters into the calculation of the power of the pump-engine.

An air-box removes this imperfection, becauſe it keeps up the motion during the returning ſtroke of the piſton. The compreſſion of the air by the active ſtroke of the piſton muſt be ſuch as to continue the impulſe in oppoſition to the contrary preſſure of the water (if it is to be raiſed to ſome height), and in oppoſition to the friction or other reſiſtances which ariſe from the motion that the water really acquires. Indeed a very conſiderable force is employed here alſo in changing the motion of the water, which is forced out of the capacious air-box into the narrow pipe; and when this change of motion is not judiciouſly managed, the expenditure of power may be as great as if all were brought to reſt and again put into motion. It may even be greater, by cauſing the water to move in the oppoſite direction to its former motion. Of ſuch conſequence is it to have all theſe circumſtances ſcientifically conſidered. It is in ſuch particulars, unheeded by the ordinary herd of engineers or pump-makers, that the ſuperiority of an intelligent practitioner is to be ſeen.

Another material point in the conduit of water in pipes is the diſtribution of it to the different perſons who have occaſion for it. This is rarely done from the riſing main. It is uſual to ſend the whole into a ciſtern, from which it is afterwards conducted to different places in ſeparate pipes. Till the diſcovery of the general theorem by the chevalier Buat, this has been done with great inaccuracy. Engineers think that the different purchaſers from water-works receive in proportion to their reſpective bargains when they give them pipes whoſe areas are proportional to theſe payments. But we now ſee, that when theſe pipes are of any conſiderable length, the waters of a larger pipe run with a greater velocity than thoſe of a ſmaller pipe having the ſame ſlope. A pipe of two inches diameter will give much more water than four pipes of one inch diameter; it will give as much as five and a half ſuch pipes, or more; becauſe the ſquares of the diſcharges are very nearly as the fifth powers of the diameters. This point ought therefore to be carefully conſidered in the bargains made with the proprietors of water-works, and the payments made in this proportion. Perhaps the moſt unexceptionable method would be to make a double diſtribution. Let the water be firſt let off in its proper proportions into a ſecond ſeries of ſmall ciſterns, and let each have a pipe which will convey the whole water that is diſcharged into it. The firſt diſtribution may be made entirely by pipes of one inch in diameter; this would leave nothing to the calculation of the diſtributor, for every man would pay in proportion to the number of ſuch pipes which run into his own ciſtern.

Water-works.

In many caſes, however, water is diſtributed by pipes derived from a main. And here another circumſtance comes into action. When water is paſſing along a pipe, its preſſure on the ſides of the pipe is diminiſhed by its velocity; and if a pipe is now derived from it, the quantity drawn off is alſo diminiſhed in the ſubduplicate ratio of the preſſures. If the preſſure is reduced to $\frac{1}{4}$th, $\frac{1}{9}$th, $\frac{1}{16}$th, &c. the diſcharge from the lateral pipe is reduced to $\frac{1}{2}$, $\frac{1}{3}$d, $\frac{1}{4}$th, &c.

It is therefore of great importance to determine, what this diminution of preſſure is which ariſes from the motion along the main.

It is plain that if the water ſuffered no reſiſtance in the main, its velocity would be that with which it entered, and it would paſs along without exerting any preſſure. If the pipe were ſhut at the end, the preſſure on the ſides would be the full preſſure of the head of water. If the head of water remain the ſame, and the end of the tube be contracted, but not ſtopped entirely, the velocity in the pipe is diminiſhed. If we would have the velocity in the pipe with this contracted mouth augmented to what it was before the contraction was made, we muſt employ the preſſure of a piſton, or of a head of water. This is propagated through the fluid, and thus a preſſure is immediately excited on the ſides of the pipe. New obſtructions of any kind, ariſing from friction or any other cauſe, produce a diminution of velocity in the pipe. But when the natural velocity is checked, the particles react on what obſtructs their motion; and this action is uniformly propagated through a perfect fluid in every direction. The reſiſtance therefore which we thus aſcribe to friction, produces the ſame lateral preſſure which a contraction of the orifice, which equally diminiſhes the velocity in the pipe, would do. Indeed this is demonſtrable from any diſtinct notions that we can form of theſe obſtructions. They proceed from the want of perfect ſmoothneſs, which obliges the particles next the ſides to move in undulated lines. This excites tranſverſe forces in the ſame manner as any conſtrained curvilineal motion. A particle in its undulated path tends to eſcape from it, and acts on the lateral particles in the ſame manner that it, would do if moving ſingly in a capillary tube having the ſame undulations; it would preſs on the concave ſide of every ſuch undulation. Thus a preſſure is exerted among the particles, which is propagated to the ſides of the pipe; or the diminution of velocity may ariſe from a viſcidity or want of perfect fluidity. This obliges the particle immediately preſſed to drag along with it another particle which is withheld by adheſion to the ſides. This requires additional preſſure from a piſton, or an additional head of water; and this preſſure alſo is propagated to the ſides of the pipe.

Hence it ſhould follow, that the preſſure which water in motion exerts on the ſides of its conduit is equal to that which is competent to the head of water which impels it into the pipe, diminiſhed by the head of water competent to the actual velocity with which it moves along the pipe. Let H repreſent the head of water which impels it into the entry of the pipe, and h the head which would produce the actual velocity; then H—h is the column which would produce the preſſure exerted on its ſides.

This is abundantly verified by very ſimple experiments.

Water-works.

Let an upright pipe be inſerted into the ſide of the main pipe. When the water runs out by the mouth of the main, it will riſe in this branch till the weight of the column balances the preſſure that ſupports it; and if we then aſcertain the velocity of the iſſuing water by means of the quantity diſcharged, and compute the head or height neceſſary for producing this velocity, and ſubtract this from the height of water above the entry of the main, we ſhall find the height in the branch preciſely equal to their difference. Our readers may ſee this by examining the experiments related by Graveſande, and ſtill better by conſulting the experiments narrated by Boſſut, § 558, which are detailed with great minuteneſs; the reſults correſponded accurately with this propoſition. The experiments indeed were not heights of water ſupported by this preſſure, but water expelled by it through the ſame orifice. Indeed the truth of the propoſition appears in every way we can conſider the motion of water. And as it is of the firſt importance in the practice of conducting water (for reaſons which will preſently appear), it merits a particular attention. When an inclined tube is in train, the accelerating power of the water (or its weight diminiſhed in the proportion of the length of the oblique column to its vertical height, or its weight multiplied by the fraction $\frac{1}{s}$, which expreſſes the ſlope), is in equilibrio with the obſtructions; and therefore it exerts no preſſure on the pipe but what ariſes from its weight alone. Any part of it would continue to ſlide down the inclined plane with a conſtant velocity, though detached from what follows it. It therefore derives no preſſure from the head of water which impelled it into the pipe. The ſame muſt be ſaid of a horizontal pipe infinitely ſmooth, or oppoſing no reſiſtance. The water would move in this pipe with the full velocity due to the head of water which impels it into the entry. But when the pipe oppoſes an obſtruction, the head of water is greater than that which would impel it into the pipe with the velocity that it actually has in it; and this additional preſſure is propagated along the pipe, where it is balanced by the actual reſiſtance, and therefore excites a *quaqua verſum* preſſure on the pipe. In ſhort, whatever part of the head of water in the reſervoir, or of the preſſure which impels it along the tube, is not employed in producing velocity, is employed in acting againſt ſome obſtruction, and excites (by the reacton of this obſtruction) an equal preſſure on the tube. The rule therefore is general, but is ſubject to ſome modifications which deſerve our attention.

In the ſimply inclined pipe BC (fig. 4.), the preſſure on any point S is equal to that of the head AB of water which impels the water into the pipe wanting; or *minus* that of the head of water which would communicate to it the velocity with which it actually moves. This we ſhall call x, and conſider it as the weight of a column of water whoſe length alſo is x. In like manner H may be the column AB, which impels the water into the pipe, and would communicate a certain velocity; and h may repreſent the column which would communicate the actual velocity. We have therefore $x = H - h$.

In the pipe HIKL, the preſſure at the point I is AH $- h -$ IO, $=$ H $- h -$ IO; and the preſſure at K is H $- h +$ PK.

And in the pipe DEFG, the preſſure on E is $=$ AR $- h -$ EM, $=$ H $- h -$ EM; and the preſſure at F is H $- h +$ FN.

We muſt carefully diſtinguiſh this preſſure on any ſquare inch of the pipe from the obſtruction or reſiſtance which that inch actually exerts, and which is part of the cauſe of this preſſure. The preſſure is (by the laws of hydroſtatics) the ſame with that exerted on the water by a ſquare inch of the piſton or forcing head of water. This muſt balance the united obſtructions of the whole pipe, in as far as they are not balanced by the relative weight of the water in an incloſed pipe. Whatever be the inclination of a pipe, and the velocity of the water in it, there is a certain part of this reſiſtance which may not be balanced by the tendency which the water has to ſlide along it, provided the pipe be long enough; or if the pipe is too ſhort, the tendency down the pipe may more than balance all the reſiſtances that obtain below. In the firſt caſe, this overplus muſt be balanced by an additional head of water; and in the latter caſe the pipe is not in train, and the water will accelerate. There is ſomething in the mechaniſm of theſe motions which makes a certain length of pipe neceſſary for bringing it into train; a certain portion of the ſurface which acts in concert in obſtructing the motion. We do not completely underſtand this circumſtance, but we can form a pretty diſtinct notion of its mode of acting. The film of water contiguous to the pipe is withheld by the obſtruction, but glides along; the film immediately within this is withheld by the outer film, but glides through it: and thus all the concentric films glide within thoſe around them, ſomewhat like the ſliding tubes of a ſpy-glaſs, when we draw it out by taking hold of the end of the innermoſt. Thus the ſecond film paſſes beyond the firſt or outermoſt, and becomes the outermoſt, and rubs along the tube. The third does the ſame in its turn; and thus the central filaments come at laſt to the outſide, and all ſuſtain their greateſt poſſible obſtruction. When this is accompliſhed, the pipe is in train. This requires a certain length, which we cannot determine by theory. We ſee however that pipes of greater diameter muſt require a greater length, and this in a proportion which is probably that of the number of filaments, or the ſquare of the diameter. Buat found this ſuppoſition agree well enough with his experiments. A pipe of one inch in diameter ſuſtained no change of velocity by gradually ſhortening it till he reduced it to ſix feet, and then it diſcharged a little more water. A pipe of two inches diameter gave a ſenſible augmentation of velocity when ſhortened to 25 feet. He therefore ſays, that the ſquare of the diameter in inches, multiplied by 72, will expreſs (in inches) the length neceſſary for putting any pipe in train.

The reſiſtance exerted by a ſquare inch of the pipe makes but a ſmall part of the preſſure which the whole reſiſtances occaſion to be exerted there before they can be overcome. The reſiſtance may be repreſented by $\frac{d}{s}$, when d is the hydraulic depth ($\frac{1}{4}$th of the diameter), and s the length of a column whoſe vertical height is one inch, and it is the relative weight of a column of water whoſe baſe is a ſquare inch, and height is d. For the reſiſtance of any length s of pipe which is in train, is equal to the tendency of the water to ſlide down (being balanced by it); that is, is equal to the weight of this column multiplied by $\frac{1}{s}$. The magnitude of this column is had by multiplying its length by its ſection. The ſection is the product of the border b or circumference, multiplied by the mean depth d, or it is $b\,d$. This, multiplied by the length, is $b\,d\,s$; and this multiplied by the ſlope $\frac{1}{s}$ is $b\,d$, the relative weight of the column whoſe length is s. The relative weight of one inch is therefore $\frac{b\,d}{s}$; and this is in equilibrio with the reſiſtance of a ring of the pipe one inch broad. This, when unfolded, is a parallelogram b inches in length. One inch of this therefore

Water-works.

Water-works.

fore is $\frac{a}{s}$, the relative weight of a column of water having d for its height and a ſquare inch for its baſe. Suppoſe the pipe four inches in diameter, and the ſlope = 253, the reſiſtance is one grain; for an inch of water weighs 253 grains.

This knowledge of the preſſure of water in motion is of great importance. In the management of rivers and canals it inſtructs us concerning the damages which they produce in their beds by tearing up the ſoil; it informs us of the ſtrength which we muſt give to the banks: but it is of more conſequence in the management of cloſe conduits. By this we muſt regulate the ſtrength of our pipes; by this alſo we muſt aſcertain the quantities of water which may be drawn off by lateral branches from any main conduit.

With reſpect to the firſt of theſe objects, where ſecurity is our ſole concern, it is proper to conſider the preſſure in the moſt unfavourable circumſtances, viz. when the end of the main is ſhut. The caſe is not unfrequent. Nay, when the water is in motion, its velocity in a conduit ſeldom exceeds a very few feet in a ſecond. Eight feet *per* ſecond requires only one foot of water to produce it. We ſhould therefore eſtimate the ſtrain on all conduits by the whole height of the reſervoir.

In order to adjuſt the ſtrength of a pipe to the ſtrain, we may conceive it as conſiſting of two half cylinders of inſuperable ſtrength, joined along the two ſeams, where the ſtrength is the ſame with the ordinary ſtrength of the materials of which it is made. The inſide preſſure tends to burſt the pipe by tearing open theſe ſeams, and each of them ſuſtains half of the ſtrain. The ſtrain on an inch of theſe two ſeams is equal to the weight of a column of water whoſe height is the depth of the ſeam below the ſurface of the reſervoir, and whoſe baſe is an inch broad and a diameter of the pipe in length. This follows from the common principles of hydroſtatics.

Suppoſe the pipe to be of lead, one foot in diameter and 100 feet under the ſurface of the reſervoir. Water weighs $62\frac{1}{2}$ pounds *per* foot. The baſe of our column is therefore $\frac{1}{12}$th of a foot, and the tendency to burſt the pipe is $100 \times 62\frac{1}{2} \times \frac{1}{12}\text{th} = {}^{6}\frac{25}{12}{}^{0}$, = 521 pounds nearly. Therefore an inch of one ſeam is ſtrained by $260\frac{1}{2}$ pounds. A rod of lead one inch ſquare is pulled aſunder by 860 pounds (ſee *Strength of Materials*, n° 40). Therefore, if the thickneſs of the ſeam is = $\frac{260}{8000}$ inches, or $\frac{1}{31}$d of an inch, it will juſt withſtand this ſtrain. But we muſt make it much ſtronger than this, eſpecially if the pipe leads from an engine which ſends the water along it by ſtarts. Belidor and Deſaguiliers have given tables of the thickneſs and weights of pipes which experience has found ſufficient for the different materials and depths. Deſaguiliers ſays, that a leaden pipe of $\frac{1}{4}$ths of an inch in thickneſs is ſtrong enough for a height of 140 feet and diameter of 7 inches. From this we may calculate all others. Belidor ſays, that a leaden pipe 12 inches diameter and 60 feet deep ſhould be half an inch thick: but theſe things will be more properly computed by means of the liſt given in n° 40 of the article *Strength of Materials*.

The application which we are moſt anxious to make of the knowledge of the preſſure of moving waters is the derivation from a main conduit by lateral branches. This occurs very frequently in the diſtribution of waters among the inhabitants of towns; and it is ſo imperfectly underſtood by the greateſt part of thoſe who take the name of engineers, that individuals have no ſecurity that they ſhall get even one half of the water they bargain and pay for; yet this may be as accurately aſcertained as any other problem in hydraulics by means of our general theorem. The caſe therefore merits our particular attention.

It appears to be determined already, when we have aſcertained the preſſures by which the water is impelled into theſe lateral pipes, eſpecially after we have ſaid that the experiments of Boſſut on the actual diſcharges from a lateral pipe fully confirm the theoretical doctrine. But much remains to be conſidered. We have ſeen that there is a vaſt difference between the diſcharge made through a hole, or even through a ſhort pipe, and the diſcharge from the far end of a pipe derived from a main conduit. And even when this has been aſcertained by our new theory, the diſcharge thus modified will be found conſiderably different from the real ſtate of things: For when water is flowing along a main with a known velocity, and therefore exerting a known preſſure on the circle which we propoſe for the entry of a branch, if we inſert a branch there water will go along it; but this will generally make a conſiderable change in the motion along the main, and therefore in the preſſure which is to expel the water. It alſo makes a conſiderable change in the whole quantity which paſſes along the anterior part of the main, and a ſtill greater change on what moves along that part of it which lies beyond the branch: it therefore affects the quantity neceſſary for the whole ſupply, the force that is required for propelling it, and the quantity delivered by other branches. This part therefore of the management of water in conduits is of conſiderable importance and intricacy. We can propoſe in this place nothing more than a ſolution of ſuch leading queſtions as involve the chief circumſtances, recommending to our readers the peruſal of original works on this ſubject. M. Boſſut's experiments are fully competent to the eſtabliſhment of the fundamental principle. The hole through which the lateral diſcharges were made was but a few feet from the reſervoir. The pipe was ſucceſſively lengthened, by which the reſiſtances were increaſed, and the velocity diminiſhed. But this did not affect the lateral diſcharges, except by affecting the preſſures: and the diſcharges from the end of the main were ſuppoſed to be the ſame as when the lateral pipe was not inſerted. Although this was not ſtrictly true, the difference was inſenſible, becauſe the lateral pipe had but about the 18th part of the area of the main.

Suppoſe that the diſcharge from the reſervoir remains the ſame after the derivation of this branch, then the motion of the water all the way to the inſertion of the branch is the ſame as before; but, beyond this, the diſcharge is diminiſhed by all that is diſcharged by the branch, with the head x equivalent to the preſſure on the ſide. The diſcharge by the lower end of the main being diminiſhed, the velocity and reſiſtance in it are alſo diminiſhed. Therefore the difference between x and the head employed to overcome the friction in this ſecond caſe, would be a needleſs or inefficient part of the whole load at the entry, which is impoſſible; for every force produces an effect, or it is deſtroyed by ſome reaction. The effect of the forcing head of water is to produce the greateſt diſcharge correſponding to the obſtructions; and thus the diſcharge from the reſervoir, or the ſupply to the main, muſt be augmented by the inſertion of the branch, if the forcing head of water remains the ſame. A greater portion therefore of the forcing head was employed in producing a greater diſcharge at the entry of the main, and the remainder, leſs than x, produced the preſſure on the ſides. This head was the one competent to the obſtructions reſulting from the velocity beyond the inſertion of the branch; and this velocity, diminiſhed by the diſcharge already made, was leſs than that at the entry, and even than that of the main without a branch. This will appear more diſtinctly by putting the caſe into the form of an equation. Therefore let H—x be the height due to the velocity at the entry, of which the effect obtains only hori-

Water-works.

horizontally. The head x is the only one which acts on the sides of the tube, tending to produce the discharge by the branch, at the same time that it must overcome the obstructions beyond the branch. If the orifice did not exist and if the force producing the velocity on a short tube be represented by 2 G, and the section of the main by A, the supply at the entry of the main would be $A\sqrt{2G}\sqrt{H-x}$; and if the orifice had no influence on the value of x, the discharge by the orifice would be $D\sqrt{\frac{x}{H}}$, D being its discharge by means of the head H, when the end of the main is shut; for the discharges are in the subduplicate ratio of the heads of water by which they are expelled; and therefore $\sqrt{H} : \sqrt{x} = D : D\sqrt{\frac{x}{H}} (= \delta)$.

But we have seen that x must diminish; and we know that the obstructions are nearly as the square roots of the velocities, when these do not differ much among themselves. Therefore calling y the pressure or head which balances the resistances of the main without a branch, while x is the head necessary for the main with a branch, we may institute this proportion $y : H-y = x : \frac{x(H-y)}{y}$; and this 4th term will express the head producing the velocity in the main beyond the branch (as $H-y$ would have done in a main without a branch). This velocity beyond the branch will be $\sqrt{2G}\sqrt{\frac{x(H-y)}{y}}$, and the discharge at the end will be $A\sqrt{2G}\sqrt{\frac{x(H-y)}{y}}$. If to this we add the discharge of the branch, the sum will be the whole discharge, and therefore the whole supply. Therefore we have the following equation, $A\sqrt{2G}\sqrt{H-y} = A\sqrt{2G}\sqrt{\frac{x(H-y)}{y}} + D\sqrt{\frac{x}{H}}$. From this we deduce the value of $x = \frac{2GHA^2}{\left(A\sqrt{2G}\sqrt{\frac{H-y}{y}} + \frac{D}{\sqrt{H}}\right)^2 + 2GA^2}$. This value of x being substituted in the equation of the discharge δ of the branch, which was $= D\sqrt{\frac{x}{H}}$, will give the discharges required, and they will differ so much the more from the discharges calculated according to the simple theory, as the velocity in the main is greater. By the simple theory, we mean the supposition that the lateral discharges are such as would be produced by the head $H-h$, where H is the height of the reservoir, and h the head due to the actual velocity in the main.

And thus it appears that the proportion of the discharge by a lateral pipe from a main that is shut at the far end, and the discharge from a main that is open, depends not only on the pressures, but also on the size of the lateral pipe, and its distance from the reservoir. When it is large, it greatly alters the train of the main, under the same head, by altering the discharge at its extremity, and the velocity in it beyond the branch; and if it be near the reservoir, it greatly alters the train, because the diminished velocity takes place through a greater extent, and there is a greater diminution of the resistances.

When the branch is taken off at a considerable distance from the reservoir, the problem becomes more complicated, and the head x is resolved into two parts; one of which balances the resistance in the first part of the main, and the other balances the resistances beyond the lateral pipe, with a velocity diminished by the discharge from the branch.—A branch at the end of the main produces very little change in the train of the pipe.

When the lateral discharge is great, the train may be so altered, that the remaining part of the main will not run full, and then the branch will not yield the same quantity. The velocity in a very long horizontal tube may be so small (by a small head of water and great obstructions in a very long tube) that it will just run full. An orifice made in its upperside will yield nothing; and yet a small tube inserted into it will carry a column almost as high as the reservoir. So that we cannot judge in all cases of the pressures by the discharges, and *vice versa*.

If there be an inclined tube, having a head greater than what is competent to the velocity, we may bring it into train by an opening on its upper side near the reservoir. This will yield some water, and the velocity will diminish in the tube till it is in train. If we should now enlarge the hole, it will yield no more water than before.

And thus we have pointed out the chief circumstances which affect these lateral discharges. The discharges are afterwards modified by the conduits in which they are conveyed to their places of destination. These being generally of small dimensions, for the sake of economy, the velocity is much diminished. But, at the same time, it approaches nearer to that which the same conduit would bring directly from the reservoir, because its small velocity will produce a less change in the train of the main conduit.

We should now treat of jets of water, which still make an ornament in the magnificent pleasure grounds of the wealthy. Some of these are indeed grand objects, such as the two at Peterhoff in Russia, which spout about 60 feet high a column of nine inches diameter, which falls again, and shakes the ground with its blow. Even a spout of an inch or two inches diameter, lancing to the height of 150 feet, is a gay object, and greatly enlivens a pleasure-ground; especially when the changes of a gentle breeze bend the jet to one side. But we have no room left for treating this subject, which is of some nicety; and must conclude this article which a very short account of the management of water as an active power for impelling machinery.

II. *Of Machinery drawn by Water.*

This is a very comprehensive article, including almost every possible species of mill. It is no less important, and it is therefore matter of regret, that we cannot enter into the detail which it deserves. The mere description of the immense variety of mills which are in general use, would fill volumes; and a scientific description of their principles and maxims of construction would almost form a complete body of mechanical science. But this is far beyond the limits of a Work like ours. Many of these machines have been already described under their proper names, or under the articles which give an account of their manufactures; and for others we must refer our readers to the original works, where they are described in minute detail. The great academical collection *Des Arts et Metiers*, published at Paris in many folio volumes, contains a description of the peculiar machinery of many mills; and the volumes of the *Encyclopédie Methodique*, which particularly relate to the mechanic arts, already contain many more. All that we can do in this place is, to consider the chief circumstances that are common to all water-mills; and from which all must derive their efficacy. These circumstances are to be found in the manner of employing water as an acting power, and most of them

Water-works

them are comprehended in the conſtruction of water-wheels. When we have explained the principles and the maxims of conſtruction of a water-wheel, every reader converſant in mechanics knows, that the axis of this wheel may be employed to tranſmit the force impreſſed on it to any ſpecies of machinery. Therefore nothing ſubſequent to this can with propriety be conſidered as *water-works*.

Water-wheels are of two kinds, diſtinguiſhed by the manner in which water is made an impelling power, viz. by its weight, or by its impulſe. This requires a very different form and manner of adaptation; and this forms an oſtenſible diſtinction, ſufficiently obvious to give a name to each claſs. When water is made to act by its weight, it is delivered from the ſpout as high on the wheel as poſſible, that it may continue long to preſs it down: but when it is made to ſtrike the wheel, it is delivered as low as poſſible, that it may have previouſly acquired a great velocity. And thus the wheels are ſaid to be OVERSHOT or UNDERSHOT.

Of Overſhot Wheels.

THIS is nothing but a frame of open buckets, ſo diſpoſed round the rim of a wheel as to receive the water delivered from a ſpout; ſo that one ſide of the wheel is loaded with water, while the other is empty. The conſequence muſt be, that the loaded ſide muſt deſcend. By this motion the water runs out of the lower buckets, while the empty buckets of the riſing ſide of the wheel come under the ſpout in their turn, and are filled with water.

If it were poſſible to conſtruct the buckets in ſuch a manner as to remain completely filled with water till they come to the very bottom of the wheel, the preſſure with which the water urges the wheel round its axis would be the ſame as if the extremity of the horizontal radius were continually loaded with a quantity of water ſufficient to fill a ſquare pipe, whoſe ſection is equal to that of the bucket, and whoſe length is the diameter of the wheel. For let the buckets BD and EF (fig. 5.) be compared together, the arches DB and EF are equal. The mechanical energy of the water contained in the bucket EF, or the preſſure with which its weight urges the wheel, is the ſame as if all this water were hung on that point T of the horizontal arm CF, where it is cut by the vertical or plumb line BT. This is plain from the moſt elementary principles of mechanics. Therefore the effect of the bucket BD is to that of the bucket EF as CT to CF or CB. Draw the horizontal lines PB *b b*, QD *d d*. It is plain, that if BD is taken very ſmall, ſo that it may be conſidered as a ſtraight line, BD : BO = CB : BP, and EF : *b d* = CF : CT, and EF × CT = *b d* × CF. Therefore if the priſm of water, whoſe vertical ſection is *b b d d*, were hung on at F, its force to urge the wheel round would be the ſame as that of the water lying in the bucket BD. The ſame may be ſaid of every bucket; and the effective preſſure of the whole ring of water A *f* HKFI, in its natural ſituation, is the ſame with the pillar of water *a h h a* hung on at F. And the effect of any portion BF of this ring is the ſame with that of the correſponding portion *b* F *f b* of the vertical pillar. We do not take into account the ſmall difference which ariſes from the depth B or F *f*, becauſe we may ſuppoſe the circle deſcribed through the centres of gravity of the buckets. And in the farther proſecution of this ſubject, we ſhall take ſimilar liberties, with the view of ſimplifying the ſubject, and ſaving time to the reader.

But ſuch a ſtate of the wheel is impoſſible. The bucket at the very top of the wheel may be completely filled with water; but when it comes into the oblique poſition BD, a part of the water muſt run over the outer edge *d*, and the bucket will only retain the quantity ZBD *d*; and if the buckets are formed by partitions directed to the axis of the wheel, the whole water muſt be run out by the time that they deſcend to the level of the axis. To prevent this many contrivances have been adopted. The wheel has been ſurrounded with a hoop or ſweep, conſiſting of a circular board, which comes almoſt into contact with the rim of the wheel, and terminates at H, where the water is allowed to run off. But unleſs the work is executed with uncommon accuracy, the wheel made exactly round, and the ſweep exactly fitting it, a great quantity of water eſcapes between them; and there is a very ſenſible obſtruction to the motion of ſuch a wheel, from ſomething like friction between the water and the ſweep. Froſt alſo effectually ſtops the motion of ſuch a wheel. Sweeps have therefore been generally laid aſide, although there are ſituations where they might be uſed with good effect.

Mill-wrights have turned their whole attention to the giving a form to the buckets which ſhall enable them to retain the water along a great portion of the circumference of the wheel. It would be endleſs to deſcribe all theſe contrivances; and we ſhall therefore content ourſelves with one or two of the moſt approved. The intelligent reader will readily ſee that many of the circumſtances which concur in producing the ultimate effect (ſuch as the facility with which the water is received into the buckets, the place which it is to occupy during the progreſs of the bucket from the top to the bottom of the wheel, the readineſs with which they are evacuated, or the chance that the water has of being dragged beyond the bottom of the wheel by its adheſion, &c. &c.) are ſuch as do not admit of preciſe calculation or reaſoning about their merits; and that this or that form can ſeldom be evidently demonſtrated to be the very beſt poſſible. But, at the ſame time, he will ſee the general reaſons of preference, and his attention will be directed to circumſtances which muſt be attended to, in order to have a good bucketed wheel.

Fig. 6. is the outline of a wheel having 40 buckets. The ring of board contained between the concentric circles QDS and PAR, making the ends of the buckets, is called the SHROUDING, in the language of the art, and QP is called the *depth of ſhrouding*. The inner circle PAR is called the SOLE of the wheel, and uſually conſiſts of boards nailed to ſtrong wooden rings of compaſs timber of conſiderable ſcantling, firmly united with the ARMS or radii. The partitions, which determine the form of the buckets, conſiſt of three different planes or boards AB, BC, CD, which are variouſly named by different artiſts. We have heard them named the START or SHOULDER, the ARM, and the WRIST (probably for wriſt, on account of a reſemblance of the whole line to the human arm); B is alſo called the ELBOW. Fig. 7. repreſents a ſmall portion of the ſame bucketing on a larger ſcale, that the proportions of the parts may be more diſtinctly ſeen. AG, the ſole of one bucket, is made about $\frac{1}{7}$th more than the depth GH of the ſhrouding. The ſtart AB is $\frac{1}{2}$ of AI. The plane BC is ſo inclined to AB that it would paſs through H; but it is made to terminate in C, in ſuch a manner that FC is $\frac{5}{8}$ths of GH or AI. Then CD is ſo placed that HD is about $\frac{1}{7}$th of IH.

By this conſtruction, it follows that the area FABC is very nearly equal to DABC; ſo that the water which will fill the ſpace FABC will all be contained in the bucket when it ſhall come into ſuch a poſition that AD is a horizontal line; and the line AB will then make an angle of nearly 35° with the vertical, or the bucket will be 35° from the perpendicular. If the bucket deſcend ſo much lower that one half of the water runs out, the line AB will make an angle of 25°, or 24° nearly, with the vertical. Therefore

Water-works.

Water-works.

fore the wheel, filled to the degree now mentioned, will *begin* to loſe water at about $\frac{1}{8}$th of the diameter from the bottom, and *half of the water will be diſcharged* from the loweſt bucket, about $\frac{1}{12}$th of the diameter farther down. Theſe ſituations of the diſcharging bucket are marked at T and V in fig. 6. Had a greater proportion of the buckets been filled with water when they were under the ſpout, the diſcharge would have begun at a greater height from the bottom, and we ſhould loſe a greater portion of the whole fall of water. The loſs by the preſent conſtruction is leſs than $\frac{1}{10}$th (ſuppoſing the water to be delivered into the wheel at the very top), and may be eſtimated at about $\frac{1}{12}$; for the loſs is the verſed ſine of the angle which the radius of the bucket makes with the vertical. The verſed ſine of 35° is nearly $\frac{1}{9}$th of the radius (being 0,18085), or $\frac{1}{10}$th of the diameter. It is evident, that if only $\frac{1}{2}$ of this water were ſupplied to each bucket as it paſſes the ſpout, it would have been retained for 10° more of a revolution, and the loſs of fall would have been only about $\frac{1}{18}$th.

Theſe obſervations ſerve to ſhow, in general, that an advantage is gained by having the buckets ſo capacious that the quantity of water which each can receive as it paſſes the ſpout may not nearly fill it. This may be accompliſhed by making them of a ſufficient length, that is, by making the wheel ſufficiently broad between the two ſhroudings. Economy is the only objection to this practice, and it is generally very ill placed. When the work to be performed by the wheel is great, the addition of power gained by a greater breadth will ſoon compenſate for the additional expence.

The third plane CD is not very frequent; and millwrights generally content themſelves with continuing the board all the way from the elbow B to the outer edge of the wheel at H; and AB is generally no more than $\frac{1}{3}$d of the depth AI. But CD is a very evident improvement, cauſing the wheel to retain a very ſenſible addition to the water. Some indeed make this addition more conſiderable, by bringing BC more outward, ſo as to meet the rim of the wheel at H, for inſtance, and making HD coincide with the rim. But this makes the entry of the water ſomewhat more difficult during the very ſhort time that the opening of the bucket paſſes the ſpout. To facilitate this as much as poſſible, the water ſhould get a direction from the ſpout, ſuch as will ſend it into the buckets in the moſt perfect manner. This may be obtained by delivering the water through an aperture that is divided by thin plates of board or metal, placed in the proper poſition, as we have repreſented in fig. 6. The form of bucket laſt mentioned, having the wreſt concentric with the rim, is unfavourable to the ready admiſſion of the water; whereas an oblique wreſt conducts the water which has miſſed one bucket into the next below.

The mechanical conſideration of this ſubject alſo ſhows us, that a deep ſhrouding, in order to make a capacious bucket, is not a good method: it does not make the buckets retain their water any longer; and it diminiſhes the effective fall of water; for the water received at the top of the wheel immediately falls to the bottom of the bucket, and thus ſhortens the fictitious pillar of water, which we ſhowed to be the meaſure of the effective or uſeful preſſure on the wheel: and this concurs with our former reaſons for recommending as great a breadth of the wheel, and length of buckets, as economical conſiderations will permit.

A bucket wheel has been executed lately by Mr Robert Burns, at the cotton mills of Houſton, Burns, and Co. at Cartſide in Renfrewſhire, of a conſtruction entirely new, but founded on a good principle, which is ſuſceptible of great extenſion. It is repreſented in fig. 8. The bucket conſiſts of a ſtart AB, an arm BC, and a wreſt CD, concentric with the rim. But the bucket is alſo divided by a partition LM, concentric with the ſole and rim, and ſo placed as to make the inner and outer portions of nearly equal capacity. It is evident, without any farther reaſoning about it, that this partition will enable the bucket to retain its water much longer. When they are filled $\frac{1}{3}$d, they retain the whole water at 18° from the bottom; and they retain $\frac{1}{2}$ at 11°. They do not admit the water quite ſo freely as buckets of the common conſtruction; but by means of the contrivance mentioned a little ago for the ſpout (alſo the invention of Mr Burns, and furniſhed with a race-work, which raiſed or depreſſed it as the ſupply of water varied, ſo as at all times to employ the whole fall of the water), it is found, that a ſlow moving wheel allows one half of the water to get into the inner buckets, eſpecially if the partition do not altogether reach the radius drawn through the lip D of the outer bucket.

This is a very great improvement of the bucket-wheel; and when the wheel is made of a liberal breadth, ſo that the water may be very ſhallow in the buckets, it ſeems to carry the performance as far as it can go. Mr Burns made the firſt trial on a wheel of 24 feet diameter; and its performance is manifeſtly ſuperior to that of the wheel which it replaced, and which was a very good one. It has alſo another valuable property: When the ſupply of water is very ſcanty, a proper adjuſtment of the apparatus in the ſpout will direct almoſt the whole of the water into the outer buckets; which, by placing it at a greater diſtance from the axis, makes a very ſenſible addition to its mechanical energy.

We ſaid that this principle is ſuſceptible of conſiderable extenſion; and it is evident that two partitions will increaſe the effect, and that it will increaſe with the number of partitions: ſo that when the practice now begun, of making water-wheels of iron, ſhall become general, and therefore very thin partitions are uſed, their number may be greatly increaſed without any inconvenience: and it is obvious, that this ſeries of partitions muſt greatly contribute to the ſtiffneſs and general firmneſs of the whole wheel.

There frequently occurs a difficulty in the making of bucket-wheels, when the half-taught mill-wright attempts to retain the water a long time in the buckets. The water gets into them with a difficulty which he cannot account for, and ſpills all about, even when the buckets are not moving away from the ſpout. This ariſes from the air, which muſt find its way out to admit the water, but is obſtructed by the entering water, and occaſions a great ſputtering at the entry. This may be entirely prevented by making the ſpout conſiderably narrower than the wheel. This will leave room at the two ends of the buckets for the eſcape of the air. This obſtruction is vaſtly greater than one would imagine; for the water drags along with it a great quantity of air, as is evident in the *Water-blaſt* deſcribed by many authors.

There is another and very ſerious obſtruction to the motion of an overſhot or bucketed wheel. When it moves in back-water, it is not only reſiſted by the water, when it moves more ſlowly than the wheel, which is very frequently the caſe, but it lifts a great deal in the riſing buckets. In ſome particular ſtates of back-water, the deſcending bucket fills itſelf completely with water; and, in other caſes, it contains a very conſiderable quantity, and air of common denſity; while in ſome rarer caſes it contains leſs water, with air in a condenſed ſtate. In the firſt caſe, the riſing bucket muſt come up filled with water, which it cannot drop till its mouth get out of the water. In the ſecond

Water-works.

cond caſe, part of the water goes out before this; but the air rarefies, and therefore there is ſtill ſome water dragged or lifted up by the wheel, by ſuction as it is uſually called. In the laſt caſe there is no ſuch back load on the riſing ſide of the wheel, but (which is as detrimental to its performance) the deſcending ſide is employed in condenſing air; and although this air aids the aſcent of the riſing ſide, it does not aid it ſo much as it impedes the deſcending ſide, being (by the form of the bucket) nearer to the vertical line drawn thro' the axis.

All this may be completely prevented by a few holes made in the ſturt of each bucket. Air being at leaſt 800 times rarer than water, will eſcape through a hole almoſt 30 times faſter with the ſame preſſure. Very moderate holes will therefore ſuffice for this purpoſe: and the ſmall quantity of water which theſe holes diſcharge during the deſcent of the buckets, produces a loſs which is altogether inſignificant. The water which runs out of one runs into another, ſo that there is only the loſs of one bucket. We have ſeen a wheel of only 14 feet diameter working in nearly three feet of back water. It laboured prodigiouſly, and brought up a great load of water, which fell from it in abrupt daſhes, which rendered the motion very hobbling. When three holes of an inch diameter were made in each bucket (12 feet long), the wheel laboured no more, there was no more plunging of water from its riſing ſide, and its power on the machinery was increaſed more than $\frac{1}{4}$th.

Theſe practical obſervations may contain information that is new even to ſeveral experienced mill-wrights. To perſons leſs informed they cannot fail of being uſeful. We now proceed to conſider the action of water thus lying in the buckets of a wheel: and to aſcertain its energy as it may be modified by different circumſtances of fall, velocity, &c.

With reſpect to variations in the fall, there can be little room for diſcuſſion. Since the active preſſure is meaſured by the pillar of water reaching from the horizontal plane where it is delivered on the wheel, to the horizontal plane where it is ſpilled by the wheel, it is evident that it muſt be proportional to this pillar, and therefore we muſt deliver it as high and retain it as long as poſſible.

This maxim obliges us, in the firſt place, to uſe a wheel whoſe diameter is equal to the whole fall. We ſhall not gain any thing by employing a larger wheel; for although we ſhould gain by uſing only that part of the circumference where the weight will act more perpendicularly to the radius, we ſhall loſe more by the neceſſity of diſcharging the water at a greater height from the bottom: For we muſt ſuppoſe the buckets of both the wheels equally well conſtructed; in which caſe, the heights above the bottom, where they will diſcharge the water, will increaſe in the proportion of the diameter of the wheel. Now, that we ſhall loſe more by this than we gain by a more direct application of the weight, is plain, without any further reaſoning, by taking the extreme caſe, and ſuppoſing our wheel enlarged to ſuch a ſize, that the uſeleſs part below is equal to our whole fall. In this caſe the water will be ſpilled from the buckets as ſoon as it is delivered into them. All intermediate caſes, therefore, partake of the imperfection of this.

When our fall is exceedingly great, a wheel of an equal diameter becomes enormouſly big and expenſive, and is of itſelf an unmanageable load. We have ſeen wheels of 58 feet diameter, however, which worked extremely well; but they are of very difficult conſtruction, and extremely apt to warp and go out of ſhape by their weight. In caſes like this, where we are unwilling to loſe any part of the force of a ſmall ſtream, the beſt form of a bucket-wheel is an inverted chain-pump. Inſtead of employing a chain-pump of the beſt conſtruction, ABCDEA (fig. 9.) to raiſe water through the upright pipe CB, by means of a force applied to the upper wheel A, let the water be delivered from a ſpout F, into the upper part of the pipe BC, and it will preſs down the plugs in the lower and narrower bored part of it with the full weight of the column, and eſcape at the dead level of C. This weight will urge round the wheel A without any defalcation; and this is the moſt powerful manner that any fall of water whatever can be applied, and exceeds the moſt perfect overſhot wheel. But though it excels all chains of buckets in economy and in effect, it has all the other imperfections of this kind of machinery. Though the chain of plugs be of great ſtrength, it has ſo much motion in its joints that it needs frequent repairs; and when it breaks, it is generally in the neighbourhood of A, on the loaded ſide, and all comes down with a great craſh. There is alſo a loſs of power by the immerſion of ſo many plugs and chains in the water; for there can be no doubt but that if the plugs were big enough and little enough, they would buoy and even draw up the plugs in the narrow part at C. They muſt therefore diminiſh, in all other caſes, the force with which this plug is preſſed down.

The velocity of an overſhot wheel is a matter of very great nicety; and authors, both ſpeculative and practical, have entertained different, nay oppoſite, opinions on the ſubject. Mr Belidor, whom the engineers of Europe have long been accuſtomed to regard as ſacred authority, maintains, that there is a certain velocity related to that obtainable by the whole fall, which will procure to an overſhot wheel the greateſt performance. Deſaguilliers, Smeaton, Lambert, Des Parceux, and others, maintain, that there is no ſuch relation, and that the performance of an overſhot-wheel will be the greater, as it moves more ſlowly by an increaſe of its load of work. Belidor maintains, that the active power of water lying in a bucket-wheel of any diameter is equal to that of the impulſe of the ſame water on the floats of an underſhot wheel, when the water iſſues from a ſluice in the bottom of the dam. The other writers whom we have named aſſert, that the energy of an underſhot-wheel is but one-half of that of an overſhot, actuated by the ſame quantity of water falling from the ſame height.

To a manufacturing country like Britain, which derives the aſtoniſhing ſuperiority, by which it more than compenſates for the impediments of heavy taxes and luxurious living chiefly from its machinery, in which it leaves all Europe far behind, the deciſion of this queſtion, in ſuch a manner as ſhall leave no doubt or miſconception in the mind even of an unlettered artiſt, muſt be conſidered as a material ſervice; and we think that this is eaſily attainable.

When any machine moves uniformly, the accelerating force or preſſure actually exerted on the impelled point of the machine is in equilibrio with all the reſiſtances which are exerted at the working point with thoſe ariſing from friction, and thoſe that are excited in different parts of the machine by their mutual actions. This is an inconteſtable truth; and though little attended to by the mechanicians, is the foundation of all practical knowledge of machines. Therefore, when an overſhot-wheel moves uniformly, with *any velocity whatever*, the water is acting with its whole weight: for gravity would accelerate its deſcent, if not completely balanced by ſome reaction; and in this balance gravity and the reacting part of the machine exert equal and oppoſite preſſures, and thus produce the uniform motion of the machine. We are thus particular on this point, becauſe we obſerve mechanicians of the firſt

Water-works

name employing a mode of reasoning on the question now before us which is specious, and appears to prove the conclusion which they draw; but is nevertheless contrary to true mechanical principles. They assert, that the slower a heavy body is descending (suppose in a scale suspended from an axis in peritrochea), the more does it press on the scale, and the more does it urge the machine round; and therefore the slower an overshot wheel turns, the greater is the force with which the water urges it round, and the more work will be done. It is very true that the machine is more forcibly impelled, and that more work is done: but this is not because a pound of water presses more strongly, but because there is more water pressing on the wheel; for the spout supplies at the same rate, and each bucket receives more water as it passes by it.

Let us therefore examine this question by the unquestionable principles of mechanics.

Let the overshot-wheel A *f* H (fig. 5.) receive the water from a spout at the very top of the wheel; and, in order that the wheel may not be retarded by dragging into motion the water simply laid into the uppermost bucket at A, let it be received at B, with the velocity (directed in a tangent to the wheel) acquired by the head of water AP. This velocity, therefore, must be equal to that of the rim of the wheel. Let this be *v*, or let the wheel and the water move over *v* inches in a second. Let the buckets be of such dimensions, that all the water which each receives as it passes the spout is retained till it comes to the position R, where it is discharged at once. It is plain that, in place of the separate quantities of water lying in each bucket, we may substitute a continued ring of water, equal to their sum, and uniformly distributed in the space BER *β f β*. This constitutes a ring of uniform thickness. Let the area of its cross section *β* B or F *f* be called *a*. We have already demonstrated, that the mechanical energy with which this water on the circumference of the wheel urges it round, is the same with what would be exerted by the pillar *b r r b* pressing on F *f*, or acting by the lever CF. The weight of this pillar may be expressed by *a* × *b r*, or *a* × PS; and if we call the radius CF of the wheel R, the momentum or mechanical energy of this weight will be represented by *a* × PS × R.

Now, let us suppose that this wheel is employed to raise a weight W, which is suspended by a rope wound round the axis of the wheel. Let *r* be the radius of this axle. Then W × *r* is the momentum of the work. Let the weight rise with the velocity *u* when the rim of the wheel turns with the velocity *v*, that is, let it rise *u* inches in a second.

Since a perfect equilibrium obtains between the power and the work when the motion is uniform, we must have W × *r* = *a* × PS × R. But it is evident that R : *r* = *v* : *u* Therefore W × *u* = *a* × *v* × PS.

Now the performance of the machine is undoubtedly measured by the weight and the height to which it is raised in a second, or by W × *u*. Therefore the machine is in its best possible state when *a* × *v* × P S is a maximum. But it is plain that *a* × *v* is an invariable quantity; for it is the cubic inches of water which the spout supplies in a second. If the wheel moves fast, little water lies in each bucket, and *a* is small. When *v* is small, *a* is great, for the opposite reason; but *a* × *v* remains the same. Therefore we must make PS a maximum, that is, we must deliver the water as high up as possible. But this diminishes AP, and this diminishes the velocity of the wheel: and as this has no limit, the proposition is demonstrated; and an overshot-wheel does the more work as it moves slowest.

Convincing as this discussion must be to any mechanician, we are anxious to impress the same maxim on the minds of practical men, unaccustomed to mathematical reasoning of any kind. We therefore beg indulgence for adding a popular view of the question, which requires no such investigation. Water-works.

We may reason in this way: Suppose a wheel having 30 buckets; and that six cubic feet of water are delivered in a second on the top of the wheel, and discharged without any loss by the way at a certain height from the bottom of the wheel. Let this be the case, whatever is the rate of the wheel's motion; the buckets being of a sufficient capacity to hold all the water which falls into them. Let this wheel be employed to raise a weight of any kind, suppose water in a chain of 30 buckets, to the same height, and with the same velocity. Suppose, farther, that when the load on the rising side of the machine is one-half of that on the wheel, the wheel makes four turns in a minute, or one turn in 15 seconds. During this time 90 cubic feet of water have flowed into the 30 buckets, and each has received three cubic feet. Then each of the rising buckets contains $1\frac{1}{2}$ feet; and 45 cubic feet are delivered into the upper cistern during one turn of the wheel, and 180 cubic feet in one minute.

Now, suppose the machine so loaded, by making the rising buckets more capacious, that it makes only two turns in a minute, or one turn in 30 seconds. Then each descending bucket must contain six cubic feet of water. If each bucket of the rising side contained three cubic feet, the motion of the machine would be the same as before. This is a point which no mechanician will controvert. When two pounds are suspended to one end of a string which passes over a pulley, and one pound to the other end, the descent of the two pound will be the same with that of a four pounds weight, which is employed in the same manner to draw up two pounds. Our machine would therefore continue to make four turns in the minute, and would deliver 90 cubic feet during each turn, and 360 in a minute. But, by supposition, it is making but two turns in a minute: this must proceed from a greater load than three cubic feet of water in each rising bucket. The machine must therefore be raising *more* than 90 feet of water during one turn of the wheel, and *more* than 180 in the minute.

Thus it appears, that if the machine is turning twice as slow as before, there is *more than twice the former quantity* in the rising buckets, and more will be raised in a minute by the same expenditure of power. In like manner, if the machine go three times as slow, there must be *more than three times* the former quantity of water in the rising buckets, and more work will be done.

But we may go farther, and assert, that the *more* we retard the machine, by loading it with more work of a similar kind, the greater will be its performance. This does not immediately appear from the present discussion: But let us call the first quantity of water in the rising bucket A; the water raised by four turns in a minute will be 4 × 30 × A, = 120 A. The quantity in this bucket, when the machine goes twice as slow, has been shown to be greater than 2 A (call it 2 A × *x*); the water raised by two turns in a minute will be $2 \times 30 \times \overline{2\,A + x}$, = 120 A + 60 *x*. Now, let the machine go four times as slow, making but one turn in a minute, the rising bucket must now contain more than twice 2 A + *x*, or more than 4 A + 2 *x*; call it 4 A + 2 *x* + *y*. The work done by one turn in a minute will now be $30 \times \overline{4\,A + 2x + y}$ = 120 A + 60 *x* + 30 *y*.

By such an induction of the work, done with any rates of motion we choose, it is evident that the performance of the

Water-works.

the machine increaſes with every diminution of its velocity that is produced by the mere addition of a ſimilar load of work, or that it does the more work the ſlower it goes.

We have ſuppoſed the machine to be in its ſtate of permanent uniform motion. If we conſider it only in the beginning of its motion, the reſult is ſtill more in favour of ſlow motion: For, at the firſt action of the moving power, the inertia of the machine itſelf conſumes part of it, and it acquires its permanent ſpeed by degrees; during which, the reſiſtances ariſing from the work, friction, &c. increaſe, till they exactly balance the preſſure of the water; and after this the machine accelerates no more. Now the greater the power and the reſiſtance ariſing from the work are, in proportion to the inertia of the machine, the ſooner will all arrive at its ſtate of permanent velocity.

There is another circumſtance which impairs the performance of an overſhot-wheel moving with a great velocity, *viz.* the effects of the centrifugal force on the water in the buckets. Our mill-wrights know well enough, that too great velocity will throw the water out of the buckets; but few, if any, know exactly the diminution of power produced by this cauſe. The following very ſimple conſtruction will determine this: Let AOB (fig. 10.) be an overſhot wheel, of which AB is the upright diameter, and C is the centre. Make CF the length of a pendulum, which will make two vibrations during one turn of the wheel. Draw FE to the elbow of any of the buckets. The water in this bucket, inſtead of having its ſurface horizontal, as NO, will have it in the direction *n* O perpendicular to FE very nearly.

For the time of falling along half of FC is to that of two vibrations of this pendulum, or to the time of a revolution of the wheel as the radius of a circle is to its circumference: and it is well known, that the time of moving along half of AC, by the uniform action of the centrifugal force, is to that of a revolution as the radius of a circle to its circumference. Therefore the time of deſcribing $\frac{1}{2}$ of AC by the centrifugal force, is equal to the time of deſcribing $\frac{1}{2}$ of FC by gravity. Theſe ſpaces, being ſimilarly deſcribed in equal times, are proportional to the accelerating forces. Therefore $\frac{1}{2}$ FC : $\frac{1}{2}$ AC, or FC : AC = gravity : centrifugal force. Complete the parallelogram FCEK. A particle at E is urged by its weight in the direction KE, with a force which may be expreſſed by FC or KE; and it is urged by the centrifugal force in the direction CE, with a force = AC or CE. By their combined action it is urged in the direction FE. Therefore, as the ſurface of ſtanding water is always at right angles to the action of gravity, that is, to the plum-line, ſo the ſurface of the water in the revolving bucket is perpendicular to the action of the combined force FE.

Let NEO be the poſition of the bucket, which juſt holds all the water which it received as it paſſed the ſpout when not affected by the centrifugal force; and let NDO be its poſition when it would be empty. Let the vertical lines through D and E cut the circle deſcribed round C with the radius CF in the points H and I. Draw HC, IC, cutting the circle AOB in L and M. Make the arch *d'ſ* equal to AL, and the arch *e's* equal to AM: Then C*ſ* and C*s* will be the poſitions of the bucket on the revolving wheel, correſponding to CDO and CEO on the wheel at reſt. Water will begin to run out at *s*, and it will be all gone at *ſ*.—The demonſtration is evident.

The force which now urges the wheel is ſtill the weight *really* in the buckets: For though the water is urged in the direction and with the force FE, one of its conſtituents, CE, has no tendency to impel the wheel; and KE is the only impelling force.

It is but of late years that mills have been conſtructed or attended to with that accuracy and ſcientific ſkill which are neceſſary for deducing confidential concluſions from any experiments that can be made with them; and it is therefore no matter of wonder that the opinions of mill-wrights have been ſo different on this ſubject. There is a natural wiſh to ſee a machine moving briſkly; it has the appearance of activity: but a very ſlow motion always looks as if the machine were overloaded. For this reaſon mill-wrights have always yielded ſlowly and with ſome reluctance, to the repeated advices of the mathematicians: but they have yielded; and we ſee them adopting maxims of conſtruction more agreeable to ſound theory; making their wheels of great breadth, and loading them with a great deal of work. Mr Euler ſays, that the performance of the beſt mill cannot exceed that of the worſt above $\frac{1}{3}$th: but we have ſeen a ſtream of water completely expended in driving a ſmall flax mill, which now drives a cotton mill of 4000 ſpindles, with all its carding, roving, and drawing machinery, beſides the lathes and other engines of the ſmith and carpenters workſhops, exerting a force not leſs than ten times what ſufficed for the flax-mill.

The above diſcuſſion only demonſtrates in general the advantage of ſlow motion; but does not point out in any degree the relation between the rate of motion and the work performed, nor even the principles on which it depends. Yet this is a ſubject fit for mathematical inveſtigation; and we would proſecute it in this place, if it were neceſſary for the improvement of practical mechanics. But we have ſeen that there is not, in the nature of things, a maximum of performance attached to any particular rate of motion which ſhould therefore be preferred. For this reaſon we omit this diſcuſſion of mere ſpeculative curioſity. It is very intricate: For we muſt not now expreſs the preſſure on the wheel by a *conſtant* pillar of water incumbent on the extremity of the horizontal arm, as we did before when we ſuppoſed the buckets completely filled; nor by a ſmaller *conſtant* pillar, correſponding to a ſmaller but equal quantity lying in every bucket. Each different velocity puts a different quantity of water into the bucket as it paſſes the ſpout; and this occaſions a difference in the place where the diſcharge is begun and completed. This circumſtance is ſome obſtacle to the advantages of very ſlow motions, becauſe it brings on the diſcharge ſooner. All this may indeed be expreſſed by a ſimple equation of eaſy management; but the whole proceſs of the mechanical diſcuſſion is both intricate and tedious, and the reſults are ſo much diverſified by the forms of the buckets, that they do not afford any rule of ſufficient generality to reward our trouble. The curious reader may ſee a very full inveſtigation of this ſubject in two diſſertations by Elvius in the Swediſh Tranſactions, and in the *Hydrodynamique* of Profeſſor Karſtner of Gottingen; who has abridged theſe Diſſertations of Elvius, and conſiderably improved the whole inveſtigation, and has added ſome compariſons of his deductions with the actual performance of ſome great works. Theſe compariſons, however, are not very ſatisfactory. There is alſo a valuable paper on this ſubject by Mr Lambert, in the Memoirs of the Academy of Berlin for the year 1775. From theſe diſſertations, and from the *Hydrodynamique* of the Abbé Boſſut, the reader will get all that theory can teach of the relation between the preſſures of the power and work on the machine and the rates of its motion. The practical reader may reſt with confidence on the ſimple demonſtration we have given, that the performance is improved by diminiſhing the velocity.

All we have to do, therefore, is to load the machine, and thus to diminiſh its ſpeed, unleſs other phyſical circumſtances throw obſtacles in the way: but there are ſuch ob-

Water-works.

ſtacles. In all machines there are little inequalities of action that are unavoidable. In the action of a wheel and pinion, though made with the utmoſt judgment and care, there are ſuch inequalities. Theſe increaſe by the changes of form occaſioned by the wearing of the machine—much greater irregularities ariſe from the ſubſultory motions of cranks, ſtampers, and other parts which move unequally or reciprocally. A machine may be ſo loaded as juſt to be in equilibrio with its work, in the favourable poſition of its parts. When this changes into one leſs favourable, the machine may ſtop; if not, it at leaſt ſtaggers, hobbles, or works unequally. The rubbing parts bear long on each other, with enormous preſſures, and cut deep, and increaſe friction. Such ſlow motions muſt therefore be avoided. A little more velocity enables the machine to get over thoſe increaſed reſiſtances by its inertia, or the great quantity of motion inherent in it. Great machines poſſeſs this advantage in a ſuperior degree, and will therefore work ſteadily with a ſmaller velocity. Theſe circumſtances are hardly ſuſceptible of mathematical diſcuſſion, and our beſt reliance is on well directed experience.

For this purpoſe, the reader will do well to peruſe with care the excellent paper by Mr Smeaton in the Philoſophical Tranſactions for 1759. This diſſertation contains a numerous liſt of experiments, moſt judiciouſly contrived by him, and executed with the accuracy and attention, to the moſt important circumſtances, which is to be obſerved in all that gentleman's performances.

It is true, theſe experiments were made with ſmall models; and we muſt not, without great caution, transfer the reſults of ſuch experiments to large works. But we may ſafely transfer the *laws* of variation which reſult from a variation of circumſtances, although we muſt not adopt the abſolute quantities of the variations themſelves. Mr Smeaton was fully aware of the limitations to which concluſions drawn from experiments on models are ſubject, and has made the applications with his uſual ſagacity.

His general inference is, that, in ſmaller works, the rim of the overſhot-wheel ſhould not have a greater velocity than three feet in a ſecond; but that larger mills may be allowed a greater velocity than this. When every thing is executed in the beſt manner, he ſays that the work performed will amount to fully two-thirds of the power expended; that is, that three cubic feet of water deſcending from any height will raiſe two to the ſame height. See ſome farther account of this diſſertation under the word MECHANICS, ſect. 5.

It is not very eaſy to compare theſe deductions with obſervations on larger works; becauſe there are few caſes where we have good meaſures of the reſiſtances oppoſed by the work performed by the machine. Mills employed for pumping water afford the beſt opportunities. But the inertia of their working gear diminiſhes their uſeful performance very ſenſibly; becauſe their great beams, pump-rods, &c. have a reciprocating motion, which muſt be deſtroyed, and produced anew in every ſtroke. We have examined ſome machines of this kind which are eſteemed good ones; and we find few of them whoſe performance exceeds one half of the power expended.

By comparing other mills with theſe, we get the beſt information of their reſiſtances. The compariſon with mills worked by Watt and Boulton's ſteam-engines is perhaps a better meaſure of the reſiſtances oppoſed by different kinds of work, becauſe their power is very diſtinctly known. We have been informed by one of the moſt eminent engineers, that a ton and half of water *per* minute falling one foot will grind and dreſs one buſhel of wheat *per* hour. This is equivalent to 9 tons falling 10 feet.

If an overſhot-wheel oppoſed no reſiſtance, and only one bucket were filled, the wheel would acquire the velocity due to a fall through the whole height. But when it is in this ſtate of accelerated motion, if another bucket of water is delivered into it, its motion muſt be checked at the firſt, by the neceſſity of dragging forward this water. If the buckets fill in ſucceſſion as they paſs the ſpout the velocity acquired by an unreſiſting wheel is but half of that which one bucket would give. In all caſes, therefore, the velocity is diminiſhed by the inertia of the entering water when it is ſimply laid into the upper buckets. The performance will therefore be improved by delivering the water on the wheel with that velocity with which the wheel is really moving. And as we cannot give the direction of a tangent to the wheel, the velocity with which it is delivered on the wheel muſt be ſo much greater than the intended velocity of the rim, that it ſhall be preciſely equal to it when it is eſtimated in the direction of the tangent. Three or four inches of fall are ſufficient for this purpoſe: and it ſhould never be neglected, for it has a very ſenſible influence on the performance. But it is highly improper to give it more than this, with the view of impelling the wheel by its ſtroke. For even although it were proper to employ part of the fall in this way (which we ſhall preſently ſee to be very improper), we cannot procure this impulſe; becauſe the water falls among other water, or it ſtrikes the boards of the wheel with ſuch obliquity that it cannot produce any ſenſible effect.

It is a much debated queſtion among mill-wrights, Whether the diameter of the wheel ſhould be ſuch as that the water will be delivered at the top of the wheel? or larger, ſo that the water is received at ſome diſtance from the top, where it will act more perpendicularly to the arm? We apprehend that the obſervations formerly made will decide in favour of the firſt practice. The ſpace below, where the water is diſcharged from the wheel, being proportional to the diameter of the wheel, there is an undoubted loſs of fall attending a large wheel; and this is not compenſated by delivering the water at a greater diſtance from the perpendicular. We ſhould therefore recommend the uſe of the whole deſcending ſide, and make the diameter of the wheel no greater than the fall, till it is ſo much reduced that the centrifugal force begins to produce a ſenſible effect. Since the rim can hardly have a ſmaller velocity than three feet *per* ſecond, it is evident that a ſmall wheel muſt revolve more rapidly. This made it proper to inſert the determination that we have given, of the loſs of power produced by the centrifugal force. But even with this in view, we ſhould employ much ſmaller wheels than are generally done on ſmall falls. Indeed the loſs of water at the bottom may be diminiſhed, by nicely fitting the arch which ſurrounds the wheel, ſo as not to allow the water to eſcape by the ſides or bottom. While this improvement remains in good order, and the wheel entire, it produces a very ſenſible effect; but the paſſage widens continually by the wearing of the wheel. A bit of ſtick or ſtone falling in about the wheel tears off part of the ſhrouding or bucket, and froſty weather frequently binds all faſt. It therefore ſeldom anſwers expectations. We have nothing to add on this caſe to what we have already extracted from Mr Smeaton's Diſſertation on the Subject of Breaſt or half Overſhot Wheels.

There is another form of wheel by which water is made to act on a machine by its weight, which merits conſideration. This is known in Britain by the name of *Barker's mill*, and has been deſcribed by Deſaguilliers, vol. ii. p. 460. It conſiſts of an upright pipe or trunk AB (fig. 11), communicating with two horizontal branches BC, B*c*, which have a hole C *c* near their ends, opening in oppoſite direc-

Water-works.

directions, at right angles to their lengths. Suppoſe water to be poured in at the top from the ſpout F, it will run out by the holes C and *c* with the velocity correſponding to the depth of theſe holes under the ſurface. The conſequence of this muſt be, that the arms will be preſſed backwards; for there is no ſolid ſurface at the hole C, on which the lateral preſſure of the water can be exerted, while it acts with its full force on the oppoſite ſide of the arm. This unbalanced preſſure is equal to the weight of a column having the orifice for its baſe, and twice the depth under the ſurface of the water in the trunk for its height. This meaſure of the height may ſeem odd, becauſe if the orifice were ſhut, the preſſure on it is the weight of a column reaching from the ſurface. But when it is open, the water iſſues with nearly the velocity acquired by falling from the ſurface, and the quantity of motion produced is that of a column of twice this length, moving with this velocity. This is actually produced by the preſſure of the fluid, and muſt therefore be accompanied by an equal reaction.

Now ſuppoſe this apparatus ſet on the pivot E, and to have a ſpindle AD above the trunk, furniſhed with a cylindrical bobbin D, having a rope wound round it, and paſſing over a pulley G. A weight W may be ſuſpended there, which may balance this backward preſſure. If the weight be too ſmall for this purpoſe, the retrograde motion of the arms will wind up the cord, and raiſe the weight; and thus we obtain an acting machine, employing the preſſure of the water, and applicable to any purpoſe. A runner millſtone may be put on the top of the ſpindle; and we ſhould then produce a flour mill of the utmoſt ſimplicity, having neither wheel nor pinion, and ſubject to hardly any wear. It is ſomewhat ſurpriſing, that although this was invented at the beginning of this century, and appears to have ſuch advantage in point of ſimplicity, it has not come into uſe. So little has Dr Deſaguilliers's account been attended to (although it is mentioned by him as an excellent machine, and as highly inſtructive to the hydrauliſt), that the ſame invention was again brought forward by a German profeſſor (Segner) as his own, and has been honoured by a ſeries of elaborate diſquiſitions concerning its theory and performance by Euler and by John Bernoulli. Euler's Diſſertations are to be found in the Memoirs of the Academy of Berlin, 1751, &c. and in the *Nov. Comment. Petropol.* tom. vi. Bernoulli's are at the end of his Hydraulics. Both theſe authors agree in ſaying, that this machine excels all other methods of employing the force of water. Simple as it appears, its true theory, and the beſt form of conſtruction, are moſt abſtruſe and delicate ſubjects; and it is not eaſy to give ſuch an account of its principles as will be underſtood by an ordinary reader.

We ſee, in general, that the machine muſt preſs backwards; and little inveſtigation ſuffices for underſtanding the intenſity of this preſſure, when the machine is at reſt. But when it is allowed to run backwards, withdrawing itſelf from the preſſure, the intenſity of it is diminiſhed; and if no other circumſtances intervened, it might not be difficult to ſay what particular preſſure correſponded to any rate of motion. Accordingly, Deſaguilliers, preſuming on the ſimplicity of the machine, affirms the preſſure to be the weight of a column, which would produce a velocity of efflux equal to the difference of the velocity of the fluid and of the machine; and hence he deduces, that its performance will be the greateſt poſſible, when its retrograde velocity is one-third of the velocity acquired by falling from the ſurface, in which caſe, it will raiſe $\frac{8}{27}$ths of the water expended to the ſame height, which is double of the performance of a mill acted on by the impulſe of water.

But this is a very imperfect account of the operation. When the machine (conſtructed exactly as we have deſcribed) moves round, the water which iſſues deſcends in the vertical trunk, and then, moving along the horizontal arms, partakes of this circular motion. This excites a centrifugal force, which is exerted againſt the ends of the arms by the intervention of the fluid. The whole fluid is ſubjected to this preſſure (increaſing for every ſection acroſs the arm in the proportion of its diſtance from the axis), and every particle is preſſed with the accumulated centrifugal forces of all the ſections that are nearer to the axis. Every ſection therefore ſuſtains an actual preſſure proportional to the ſquare of its diſtance from the axis. This increaſes the velocity of efflux, and this increaſes the velocity of revolution; and this mutual co-operation would ſeem to terminate in an infinite velocity of both motions. But, on the other hand, the circular motion muſt be given anew to every particle of water as it enters the horizontal arm. This can be done only by the motion already in the arm, and at its expence. Thus there muſt be a velocity which cannot be overpaſſed even by an unloaded machine. But it is alſo plain, that by making the horizontal arm very capacious, the motion of the water from the axis to the jet may be made very ſlow, and much of this diminution of circular motion prevented. Accordingly, Euler has recommended a form by which this is done in the moſt eminent degree. His machine conſiſts of a hollow conoidal ring, of which fig. 12. is a ſection. Plate DXLII. The part AH *h a* is a ſort of funnel baſon, which receives the water from the ſpout F; not in the direction pointing towards the axis, but in the direction, and with the preciſe velocity of its motion. This prevents any retardation by dragging forward the water. The water then paſſes down between the outer conoid AC *c a* and the inner conoid HG *g h* along ſpiral channels formed by partitions ſoldered to both conoids. The curves of theſe channels are determined by a theory which aims at the annihilation of all unneceſſary and improper motions of the water, but which is too abſtruſe to find a place here. The water thus conducted arrives at the bottom CG, *c g*. On the outer circumference of this bottom are arranged a number of ſpouts (one for each channel), which are all directed one way in tangents to the circumference.

Adopting the common theory of the reaction of fluids, this ſhould be a very powerful machine, and ſhould raiſe $\frac{8}{27}$ths of the water expended. But if we admit the reaction to be equal to the force of the iſſuing fluid (and we do not ſee how this can be refuſed), the machine muſt be nearly twice as powerful. We therefore repeat our wonder, that it has not been brought into uſe. But it appears that no trial has been made even of a model; ſo that we have no experiments to encourage an engineer to repeat the trial. Even the late author Profeſſor Segner has not related any thing of this kind in his *Exercitationes Hydraulicæ*, where he particularly deſcribes the machine. This remiſſneſs probably has proceeded from fixing the attention on Euler's improved conſtruction. It is plain that this muſt be a moſt cumbrous maſs, even in a ſmall ſize, requiring a prodigious veſſel, and carrying an unwieldy load. If we examine the theory which recommends this conſtruction, we find that the advantages, tho' real and ſenſible, bear but a ſmall proportion to the whole performance of the ſimple machine as invented by Dr Barker. It is therefore to be regretted, that engineers have not attempted to realiſe the firſt project. We beg leave to recommend it, with an additional argument taken from an addition made to it by Mr Mathon de la Cour, in Rozier's *Journal de Phyſique*, January and Auguſt 1775. This gentleman brings down a large pipe FEH (fig. 13.) from a reſervoir, bends it upward at H, and introduces it into two horizontal arms DA, DB, which have an upright ſpindle DK, carrying

ing

Water-works.

ing a millſtone in the ſtyle of Dr Barker's mill. The ingenious mechanician will have no difficulty of contriving a method of joining theſe pipes, ſo as to permit a free circular motion without loſing much water. The operation of the machine in this form is evident. The water, preſſed by the column FG, flows out at the holes A and B, and the unbalanced preſſure on the oppoſite ſides of the arms forces them round. The compendiouſneſs and other advantages of this conſtruction are moſt ſtriking, allowing us to make uſe of the greateſt fall without any increaſe of the ſize of the machine. It undoubtedly enables us to employ a ſtream of water too ſcanty to be employed in any other form. The author gives the dimenſions of an engine which he had ſeen at Bourg Argental. AB is 92 inches, and its diameter 3 inches; the diameter of each orifice is $1\frac{1}{6}$; FG is 21 feet; the pipe D was fitted into C by grinding; and the internal diameter of D is 2 inches.

When the machine was performing no work, or was unloaded, and emitted water by one hole only, it made 115 turns in a minute. This gives a velocity of 46 feet *per* ſecond for the hole. This is a curious fact: For the water would iſſue from this hole at reſt with the velocity of $37\frac{1}{6}$. This great velocity (which was much leſs than the velocity with which the water actually quitted the pipe) was undoubtedly produced by the prodigious centrifugal force, which was nearly 17 times the weight of the water in the orifice.

The empty machine weighed 80 pounds, and its weight was half ſupported by the upper preſſure of the water, ſo that the friction of the pivots was much diminiſhed. It is a pity that the author has given no account of any work done by the machine. Indeed it was only working ventilators for a large hall. His theory by no means embraces all its principles, nor is it well-founded.

We think that the free motion round the neck of the feeding pipe, without any loſs of water or any conſiderable friction, may be obtained in the following manner: AB (fig. 14.) repreſents a portion of the revolving horizontal pipe, and CE*e c* part of the feeding pipe. The neck of the firſt is turned truly cylindrical, ſo as to turn eaſily, but without ſhake, in the collar C*c* of the feeding-pipe, and each has a ſhoulder which may ſupport the other. That the friction of this joint may not be great, and the pipes deſtroy each other by wearing, the horizontal pipe has an iron ſpindle EF, fixed exactly in the axis of the joint, and reſting with its pivot F in a ſtep of hard ſteel, fixed to the iron bar GH, which goes acroſs the feeding-pipe, and is firmly ſupported in it. This pipe is made bell-ſhaped, widening below. A collar or hoſe of thin leather is fitted to the inſide of this pipe, and is repreſented (in ſection) by LKM *m k l*. This is kept in its place by means of a metal or wooden ring N *n*, thin at the upper edge, and taper ſhaped. This is drawn in above the leather, and ſtretches it, and cauſes it to apply to the ſide of the pipe all around. There can be no leakage at this joint, becauſe the water will preſs the leather to the ſmooth metal pipe; nor can there be any ſenſible friction, becauſe the water gets at the edge of the leather, and the whole unbalanced preſſure is at the ſmall crevice, between the two metal ſhoulders. Theſe ſhoulders need not touch, ſo that the friction muſt be inſenſible. We imagine that this method of tightening a turning joint may be uſed with great advantage in many caſes.

We have only farther to obſerve on this engine, that any imperfection by which the paſſage of the water is diminiſhed or obſtructed produces a ſaving of water which is in exact proportion to the diminution of effect. The only inaccuracy that is not thus compenſated is when the jets are not at right angles to the arms.

Water-works.

We repeat our wiſhes, that engineers would endeavour to bring this machine into uſe, ſeeing many ſituations where it may be employed to great advantage. Suppoſe, for inſtance, a ſmall ſupply of water from a great height applied in this manner to a centrifugal pump, or to a hair belt paſſing over a pulley, and dipping in the water of a deep well. This would be a hydraulic machine exceeding all others in ſimplicity and durability, though inferior in effect to ſome other conſtructions.

2. *Of Underſhot Wheels.*

All wheels go by this name where the motion of the water is quicker than that of the partitions or boards of the wheel, and it therefore impels them. Theſe are called the *float-boards*, or *floats*, of an underſhot wheel. The water, running in a mill-row, with a velocity derived from a head of water, or from a declivity of channel, ſtrikes on theſe floats, and occaſions, by its deflections ſidewiſe and upwards, a preſſure on the floats ſufficient for impelling the wheel.

There are few points of practical mechanics that have been more conſidered than the action of water on the floats of a wheel; hardly a book of mechanics being ſilent on the ſubject. But the generality of them, at leaſt ſuch as are intelligible to perſons who are not very much converſant in dynamical and mathematical diſcuſſion, have hardly done any thing more than copied the earlieſt deductions from the ſimple theory of the reſiſtance of fluids. The conſequence has been, that our practical knowledge is very imperfect; and it is ſtill chiefly from experience that we muſt learn the performance of underſhot wheels. Unfortunately this ſtops their improvement; becauſe thoſe who have the only opportunities of making the experiments are not ſufficiently acquainted with the principles of hydraulics, and are apt to aſcribe differences in their performance to trifling noſtrums in their conſtruction, or in the manner of applying the impulſe of the water.

We have ſaid ſo much on the imperfection of our theories of the impulſe of fluids in the article *Resistance of Fluids*, that we need not repeat here the defects of the common explanations of the motions of underſhot wheels. The part of this theory of the impulſe of fluids which agrees beſt with obſervation is, *that the impulſe is in the duplicate proportion of the velocity with which the water ſtrikes the float.* That is, if v be the velocity of the ſtream, and u the velocity of the float, we ſhall have F, the impulſe on the float when held faſt to its impulſe f on the float moving with the velocity u, as v^2 to $\overline{v-u^2}$, and $f = F \times \frac{\overline{v-u^2}}{v^2}$.

This is the preſſure acting on the float, and urging the wheel round its axis. The wheel muſt yield to this motion, if the reſiſtance of the work does not exert a ſuperior preſſure on the float in the oppoſite direction. By yielding, the float withdraws from the impulſe, and this is therefore diminiſhed. The wheel accelerates, the reſiſtances increaſe, and the impulſes diminiſh, till they become an exact balance for the reſiſtances. The motion now remains uniform, and the momentum of impulſe is equal to that of reſiſtance. The performance of the mill therefore is determined by this; and, whatever be the conſtruction of the mill, its performance is beſt when the momentum of impulſe is greateſt. This is had by multiplying the preſſure on the float by its velocity. Therefore the momentum will be expreſſed by $F \times \frac{\overline{v-u^2}}{v^2} \times u$. But ſince F and v^2 are conſtant quanti-

ties,

Water-works.

ties, the momentum will be proportional to $u \times \overline{v-u}^2$. Let x repreſent the relative velocity. Then $v-x$ will be $= u$, and the momentum will be proportional to $v-x \times x^2$, and will be a maximum when $v-x \times x^2$ is a maximum, or when $v x^2 - x^3$ is a maximum. This will be diſcovered by making its fluxion $= o$. That is,

$$2 v x x - 3 x^2 x = o.$$

and $2 v x - 3 x^2 = o$

or $2 v - 3 x = o$

and $2 v = 3 x$, and $x = \frac{2}{3} v$; and therefore $v-x$, or u, $= \frac{1}{3} v$. That is, the velocity of the float muſt be one third of the velocity of the ſtream. It only remains to ſay what is the abſolute preſſure on the float thus circumſtanced. Let the velocity v be ſuppoſed to ariſe from the preſſure of a head of water h. The common theory teaches that the impulſe on a given ſurface S at reſt is equal to the weight of a column h S; put this in place of F, and $\frac{4}{9} v^2$ in place of $\overline{v-u}^2$ and $\frac{1}{3} v$ for u. This gives us S $h \times \frac{4}{27} v$ for the momentum. Now the power expended is S h v, or the column S h moving with the velocity v. Therefore the greateſt performance of an underſhot wheel is equivalent to raiſing $\frac{4}{27}$ of the water that drives it to the ſame height.

But this is too ſmall an eſtimation; for the preſſure exerted on a plane ſurface, ſituated as the float of a mill-wheel, is conſiderably greater than the weight of the column S h. This is nearly the preſſure on a ſurface wholly immerſed in the fluid. But when a ſmall vein ſtrikes a larger plane, ſo as to be deflected on all ſides in a thin ſheet, the impulſe is almoſt double of this. This is in ſome meaſure the caſe in a mill wheel. When the ſtream ſtrikes it, it is heaped up along its face, and falls back again—and during this motion it is acting with a hydroſtatic preſſure on it. When the wheel dips into an open river, this accumulation is leſs remarkable, becauſe much eſcapes laterally. But in a mill courſe it may be conſiderable.

We have conſidered only the action on one float, but ſeveral generally act at once. The impulſe on moſt of them muſt be oblique, and is therefore leſs than when the ſame ſtream impinges perpendicularly; and this diminution of impulſe is, by the common theory, in the proportion of the ſine of the obliquity. For this reaſon it is maintained, that the impulſe of the whole ſtream on the loweſt float board, which is perpendicular to the ſtream, is equal to the ſum of the impulſes made on all the floats which then dip into the water; or that the impulſe on any oblique float is preciſely equal to the impulſe which that part of the ſtream would have made on the loweſt float board had it not been interrupted. Therefore it has been recommended to make ſuch a number of floatboards, that when one of them is at the bottom of the wheel, and perpendicular to the ſtream, the next in ſucceſſion ſhould be juſt entering into the water. But ſince the impulſe on a float by no means annihilates all the motion of the water, and it bends round it and hits the one behind with its remaining force, there muſt be ſome advantage gained by employing a greater number of floats than this rule will permit. This is abundantly confirmed by the experiments of Smeaton and Boſſut. Mr Boſſut formed three or four ſuppoſitions of the number of floats, and calculated the impulſe on each; according to the obſervations made in a courſe of experiments made by the Academy of Sciences, and inſerted by us in the article *Resistance of Fluids*; and when he ſummed them up and compared the reſults with his exriments, he found the agreement very ſatisfactory. He deduces a general rule, that if the velocity of the wheel is $\frac{1}{3}$d of that of the ſtream, and if 72 degrees of the circumference are immerſed in the ſtream, the wheel ſhould have 36 floats. Each will dip $\frac{1}{5}$th of the radius. The velocity being ſtill ſuppoſed the ſame, there ſhould be more or fewer floats according as the arch is leſs or greater than 72 degrees.

Water-work.

Such is the theory, and ſuch are the circumſtances which it leaves undetermined. The accumulation of the water on a floatboard, and the force with which it may ſtill ſtrike another, are too intricate to be aſſigned with any tolerable preciſion; For ſuch reaſons we muſt acknowledge that the theory of underſhot wheels is ſtill very imperfect, and that recourſe muſt be had to experience for their improvement. We therefore ſtrongly recommend the peruſal of Mr Smeaton's experiments on underſhot-wheels, contained in the ſame diſſertation with thoſe we have quoted on over-ſhot-wheels. We have only to obſerve, that to an ordinary reader the experiments will appear too much in favour of underſhot-wheels. His aim is partly to eſtabliſh a theory, which will ſtate the relation between their performance and the velocity of the ſtream, and partly to ſtate the relation between the power expended and the work done. The velocity in his experiments is always conſiderably below that which a body would acquire by falling from the ſurface of the head of water; or it is the velocity acquired by a ſhorter fall. Therefore if we eſtimate the power expended by the quantity of water multiplied by this diminiſhed fall, we ſhall make it too ſmall; and the difference in ſome caſes is very great: yet, even with theſe conceſſions, it appears that the utmoſt performance of an underſhot wheel does not ſurpaſs the raiſing $\frac{1}{3}$d of the expended water to the place from which it came. It is therefore far inferior to an overſhot wheel expending the ſame power; and Mr Belidor has led engineers into very miſtaken maxims of conſtruction, by ſaying that overſhot wheels ſhould be given up, even in the caſe of great falls, and that we ſhould always bring on the water from a ſluice in the very bottom of the dam, and bring it to the wheel with as great velocity as poſſible. Mr Smeaton alſo ſays, that the maximum takes place when the velocity of the wheel is $\frac{2}{5}$ths of that of the ſtream, inſtead of $\frac{2}{6}$ths according to the theory; and this agrees with the experiments of Boſſut. But he meaſured the velocity by means of the quantity of water which run paſt. This muſt give a velocity ſomewhat too ſmall; as will appear by attending to Buat's obſervations on the ſuperficial, the mean, and the bottom velocities.

The reſt of his obſervations, of which we have given an abſtract in Mechanics, Sect. V. are moſt judicious, and well adapted to the inſtruction of practitioners. We have only to add to them the obſervations of Deparceux and Boſſut, who have evinced, by very good experiments, that there is a very ſenſible advantage gained by inclining the floatboards to the radius of the wheel about 20 degrees, ſo that the loweſt floatboard ſhall not be perpendicular, but have its point turned up the ſtream about 20 degrees. This inclination cauſes the water to heap up along the floatboard, and act by its weight. The floats ſhould therefore be made much broader than the vein of water interrupted by them is deep.

Some engineers, obſerving the great ſuperiority of overſhot wheels above underſhot wheels driven by the ſame expence of power, have propoſed to bring the water home to the bottom of the wheel on an even bottom, and to make the floatboard no deeper than the aperture of the ſluice, which would permit the water to run out. The wheel is to be fitted with a cloſe ſole and ſides, exactly fitted to the end of this trough, ſo that if the wheel is at reſt, the water may be dammed up by the ſole and floatboard. It will therefore preſs forward the floatboard with the whole force of the head of water. But this cannot anſwer; for if we ſuppoſe no floatboards, the water will flow out at the bottom, propelled in the manner thoſe perſons ſuppoſe; and it will be ſupplied from behind,

Water-works.

hind, the water coming *ſlowly* from all parts of the trough to the hole below the wheel. But now add the floats, and ſuppoſe the wheel in motion with the velocity that is expected. The other floats muſt drag into motion all the water which lies between them, giving to the greateſt part of it a motion vaſtly greater then it would have taken in conſequence of the preſſure of the water behind it; and the water out of the reach of the floats will remain ſtill, which it would not have done independent of the floatboards above it, becauſe it would have contributed to the expence of the hole. The motion therefore which the wheel will acquire by this conſtruction muſt be ſo different from what is expected, that we can hardly ſay what it will be.

We are therefore perſuaded, that the beſt way of delivering the water on an underſhot-wheel in a cloſe mill-courſe is, to let it ſlide down a very ſmooth channel, without touching the wheel till near the bottom, where the wheel ſhould be exactly fitted to the courſe; or, to make the floats exceedingly broader than the depth of the vein of water which glides down the courſe, and allow it to be partly intercepted by the firſt floats, and heap up along them, acting by its weight, after its impulſe has been expended. If the bottom of the courſe be an arch of a circle deſcribed with a radius much greater than that of the wheel, the water which ſlides down will be thus gradually intercepted by the floats.

Attempts have been made to conſtruct water-wheels which receive the impulſe obliquely, like the ſails of a common wind-mill. This would, in many ſituations, be a very great acquiſition. A very ſlow but deep river could in this manner be made to drive our mills; and although much power is loſt by the obliquity of the impulſe, the remainder may be very great. It is to be regretted, theſe attempts have not been more zealouſly proſecuted; for we have no doubt of their ſucceſs in a very ſerviceable degree. Engineers have been deterred, becauſe when ſuch wheels are plunged in an open ſtream, their lateral motion is too much impeded by the motion of the ſtream. We have ſeen one, however, which was very powerful: It was a long cylindrical frame, having a plate ſtanding out from it about a foot broad, and ſurrounding it with a very oblique ſpiral like a cork-ſcrew. This was plunged about $\frac{1}{4}$th of its diameter (which was about 12 feet), having its axis in the direction of the ſtream. By the work which it was performing, it ſeemed more powerful than a common wheel which occupied the ſame *breadth* of the river. Its length was not leſs than 20 feet: it might have been twice as much, which would have doubled its power, without occupying more of the water-way. Perhaps ſuch a ſpiral, continued to the very axis, and moving in a hollow canal wholly filled by the ſtream, might be a very advantageous way of employing a deep and ſlow ſtream.

But mills with oblique floats are moſt uſeful for employing ſmall ſtreams, which can be delivered from a ſpout with a great velocity. Mr Boſſut has conſidered theſe with due attention, and aſcertained the beſt modes of conſtruction. There are two which have nearly equal performances: 1. The vanes being placed like thoſe of a wind-mill, round the rim of a horizontal or vertical wheel, and being made much broader than the vein of water which is to ſtrike them, let the ſpout be ſo directed that the vein may ſtrike them perpendicularly. By this meaſure it will be ſpread about on the vane in a thin ſheet, and exert a preſſure nearly equal to twice the weight of a column whoſe baſe is the orifice of the ſpout, and whoſe height is the fall producing the velocity.

Mills of this kind are much in uſe in the ſouth of Europe. The wheel is horizontal, and the vertical axis carries the millſtone; ſo that the mill is of the utmoſt ſimplicity: and this is its chief recommendation; for its power is greatly inferior to that of a wheel conſtructed in the uſual manner. Water-works.

2. The vanes may be arranged round the rim of the wheel, not like the ſails of a wind-mill, but in planes inclined to the radii, but parallel to the axis, or to the planes paſſing through the axis. They may either ſtand on a ſole, like the oblique floats recommended by De Parceux, as above mentioned; or they may ſtand on the ſide of the rim, not pointing to the axis, but aſide from it.

This diſpoſition will admit the ſpout to be more conveniently diſpoſed either for a horizontal or a vertical wheel.

We ſhall conclude this article by deſcribing a contrivance of Mr Burns, the inventor of the double bucketed wheel, for fixing the arms of a water-wheel. It is well known to mill-wrights that the method of fixing them by making them to paſs through the axle, weakens it exceedingly, and by lodging water in the joint, ſoon cauſes it to rot and fail. They have, therefore, of late years put caſt-iron flanches on the axis, to which each arm is bolted: or the flanches are ſo faſhioned as to form boxes, ſerving as mortiſes to receive the ends of the arms. Theſe anſwer the purpoſe completely, but are very expenſive; and it is found that arms of fir, bolted into branches of iron, are apt to work looſe. Mr Burns has made wooden flanches of a very curious conſtruction, which are equally firm, and coſt much leſs than the iron ones.

This flanch conſiſts of eight pieces, four of which compoſe the ring repreſented in fig. 15. meeting in the joints *a b*, *a b*, *a b*, *a b*, directed to the centre O. The other four are covered by theſe, and their joints are repreſented by the doted lines $\alpha\beta$, $\alpha\beta$, $\alpha\beta$, $\alpha\beta$. Theſe two rings break joint in ſuch a manner that an arm MN is contained between the two neareſt joints $a'\ b'$ of the one, and $\alpha'\ \beta'$ of the other. The tenon formed on the end of the arm A, &c. is of a particular ſhape: one ſide, GF, is directed to the centre O; the other ſide, BCDE, has a ſmall ſhoulder BC; then a long ſide CD directed to the centre O; and then a third part DE parallel to GF, or rather diverging a little from it, ſo as to make up at E the thickneſs of the ſhoulder BC; that is, a line from B to E would be parallel to CD. This ſide of the tenon fits exactly to the correſponding ſide of the mortiſe; but the mortiſe is wider on the other ſide, leaving a ſpace GFK *h* a little narrower at FK than at G *h*. Theſe tenons and mortiſes are made extremely true to the ſquare; the pieces are put round the axle, with a few blocks or wedges of ſoft wood put between them and the axle, leaving the ſpace empty oppoſite to the place of each arm, and firmly bolted together by bolts between the arm-mortiſes. The arms are then put in, and each is preſſed home to the ſide CDE, and a wedge HF of hard wood is then put into the empty part of the mortiſe and driven home. When it comes through the flanch and touches the axle, the part which has come through is cut off with a thin chiſel, and the wedge is driven better home. The ſpaces under the ends of the arms are now filled with wedges, which are driven home from oppoſite ſides, till the circle of the arms ſtands quite perpendicular on the axle, and all is faſt. It needs no hoops to keep it together, for the wedging it up round the axle makes the two half rings draw cloſe on the arms, and it cannot ſtart at its own joints till it cruſhes the arms. Hoops, however, can do no harm, when all is once wedged up, but it would be improper to put them on before this be done. For the account of another very curious hydraulic machine, ſee ZURICH.

WORLD, the aſſemblage of parts which compoſe the globe of the earth. See GEOGRAPHY and ASTRONOMY.

WORM, in gunnery, a ſcrew of iron, to be fixed on the end of a rammer, to pull out the wad of a firelock, carabine, or piſtol, being the ſame with the wad-hook, only the one

WORMS, an ancient, large, and famous city of Germany, in the palatinate of the Rhine, with a biſhop's ſee, whoſe biſhop is a ſovereign and prince of the empire. It is a free and imperial city, and the inhabitants are Proteſtants. In the war of 1689 it was taken by the French, who almoſt reduced it to aſhes.—The biſhop afterwards built a new palace in it; and it is famous for a diet held here in 1521, at which Luther aſſiſted in perſon. The Proteſtants have lately built a handſome church, where Luther is repreſented as appearing at the diet. It is noted for the excellent wine that grows in the neighbourhood, which they call *our Lady's milk*. In the campaign of 1743, king Geo. II. took up his quarters in this city, and lodged at the biſhop's palace after the battle of Dettingen. It is ſeated on the weſtern bank of the Rhine, 14 miles north-weſt of Heidelburg, 20 ſouth-eaſt of Mentz, and 32 ſouth-weſt of Francfort. E. Long. 8. 29. N. Lat. 49. 32.

WORMING OF DOGS. All ſpaniels have certain ſtrings under their tongues, by moſt called *a worm*; this muſt be taken out when they are about two months old, with the help of a ſharp knife to ſlit it, and a ſhoemaker's awl to raiſe it up: you muſt be careful to take all out, or elſe your pains are to little purpoſe; for till then he will be hardly ever fat and right, in regard the worm or ſtring will grow foul and troubleſome, and hinder his reſt and eating. This operation is generally recommended as a preventative of madneſs in dogs, or at leaſt as diſabling them, if mad, from biting in that condition.

WORMIUS (Olaus), a learned Daniſh phyſician, born in 1588 at Arhuſen in Jutland. After beginning his ſtudies at home, he ſtudied at ſeveral foreign univerſities, and travelled to various parts of Europe for improvement. He returned to his native country in 1613, and was made profeſſor of the belles lettres in the univerſity of Copenhagen. In 1615, he was tranſlated to the chair of the Greek profeſſor; and in 1624 to the profeſſorſhip of phyſic, which he held to his death. Theſe occupations did not hinder him from practiſing in his profeſſion, and from being the faſhionable phyſician: the king and court of Denmark always employed him; and Chriſtian IV. as a recompenſe for his ſervices, conferred on him a canonry of Lunden. He publiſhed ſome pieces on ſubjects relating to his profeſſion, ſeveral works in defence of Ariſtotle's philoſophy, and ſeveral concerning the antiquities of Denmark and Norway; for which latter he is principally regarded, as they are very learned, and contain many curious particulars. He died in 1654.

WORMWOOD, in botany. See ARTEMISIA.

WORSHIP OF GOD *(cultus Dei)*, amounts to the ſame with what we otherwiſe call *religion*. This worſhip conſiſts in paying a due reſpect, veneration, and homage to the Deity, under a certain expectation of reward. And this internal reſpect, &c. is to be ſhown and teſtified by external acts; as prayers, ſacrifices, thankſgivings, &c.

Worſhip.

The Quietiſts, and ſome other myſtic divines, ſet aſide not only all uſe of external worſhip, but even the conſideration of rewards and puniſhments. Yet even the heathens had a notion that God did not require us to ſerve him for nought: "Dii quamobrem colendi ſint (ſays Cicero), non intelligo, nullo nec accepto ab illis nec ſperato bono."

The ſchool-divines divide worſhip into divers kinds, *viz. latria*, that rendered to God; and *idololatria*, that rendered to idols or images. To which the Romaniſts add, *dulia*, that rendered to ſaints; and *hyperdulia*, that to the Virgin. Some theological writers have obſerved, that the Greek word, προσκυνεω, *to worſhip*, is not deſcriptive only of the honour which is appropriated to God, but is indifferently uſed to ſignify the honour and reſpect which are paid to ſuperiors of all kinds in heaven or on earth. Accordingly, they have diſtinguiſhed between civil and religious worſhip.

That it is the duty of man to worſhip his Maker, has been ſufficiently proved under other articles (ſee PRAYER; and THEOLOGY, n° 40—45.). It is not indeed eaſily to be conceived how any one who has tolerably juſt notions of the attributes and providence of God, can poſſibly neglect the duty of *private* worſhip; and though we have admitted in the laſt of the two articles referred to, that *public* worſhip does not ſeem to be enjoined in that ſyſtem which is called the religion of *nature*, yet it is moſt expreſsly commanded by the religion of CHRIST, and will be regularly performed by every one who reflects on its great utility.

As the illiterate vulgar cannot form to themſelves correct notions of the divine providence and attributes, it is obvious, that without the inſtitution of public worſhip, they would never think of worſhipping God at all, unleſs perhaps occaſionally, when under the preſſure of ſome ſevere calamity; but occaſional worſhip, the offspring of compulſion, could have little of the reſigned ſpirit of true devotion. Ignorant, however, as the loweſt of the vulgar are, and neceſſarily muſt be, it cannot be denied, that in moſt Chriſtian countries, perhaps in all, they are more accurately acquainted with the firſt principles of religion, and the laws of morality, than even the leaders of barbarous nations. This ſuperiority is doubtleſs owing in ſome meaſure to their acceſs to the Sacred Scriptures, but much more, we are perſuaded, to the inſtruction which they receive in the aſſemblies which they frequent for public worſhip. If this be admitted, public worſhip may be eaſily proved to be the duty of every individual of the community: For were thoſe, who may be ſuppoſed to ſtand in no need either of the influence and example of ſociety to kindle their own devotion, or of the preaching of a clergyman to inſtruct them in the doctrines and precepts of the goſpel, to "forſake, on theſe accounts, the aſſembling themſelves together, as the manner of ſome is," religious aſſemblies and public worſhip would very quickly fall into univerſal diſuſe. Man is an animal prone to imitation; and every order in ſociety is ambitious of treading in the footſteps of the order immediately above it. Were the wiſe and the good, therefore, permitted to abſent themſelves from the aſſemblies inſtituted for the public worſhip of the Creator and Redeemer of the world, others would quickly follow their example; impelled to it not only by this univerſal propenſity, but by the additional motive of wiſhing to appear both to the world and to themſelves as wiſe and as good as their privileged neighbours. The conſequence is obvious: one man would ſtay from church with the ſerious intention perhaps of employing the Lord's-day in private devotion and religious ſtudy; another, following his example, would abſent himſelf upon the ſame pretence, but would in reality

Worſhip
Wotton.

waſte the day in dozing indolence or in ſecret ſenſuality. For theſe and other reaſons which might be eaſily aſſigned, no ſincere Chriſtian will think himſelf at liberty to diſpute a practice enjoined by the inſpired preachers of his religion, coeval with the inſtitution, and retained by every ſect into which it has ſince been unhappily divided.

As Chriſtian worſhip conſiſts of prayers and praiſes, it has been a matter of ſome debate whether it is moſt properly performed by preconcerted forms or liturgies, or by extemporaneous addreſſes to the Almighty. Both theſe modes have their advantages and diſadvantages; and by the ſacred writers neither of them is preſcribed in oppoſition to the other.

The advantages of a liturgy are, that it prevents abſurd, extravagant, or impious addreſſes to God, which the folly or enthuſiaſm of individuals muſt always be in danger of producing; it gives the congregation an opportunity of *joining* in the prayers which are put up for them, which they cannot poſſibly do in a ſeries of extemporaneous petitions, ſince before they can aſſent to any one of theſe and make it their own, their attention is neceſſarily called away to that which ſucceeds it; and it relieves the clergyman from the labour of compoſition, which ſeems incompatible with that fervour which conſtitutes the ſpirit of devotion.

The diſadvantages of a fixed liturgy, which are the recommendations of extemporary prayer, are principally two. The forms compoſed in one age muſt, by the unavoidable change of language, circumſtances, and opinions, become in ſome degree unfit for another; and the perpetual repetition of the ſame form of words is very apt to produce inattentive laſſitude in the congregation. Would the clergy of the church of England take that liberty which is allowed them in the bidding prayer before ſermon, perhaps the ſervice of that church would unite in itſelf all the advantages both of liturgic and extemporary worſhip. We have only to add on this ſubject, that public prayers, whether precompoſed or not, ought to be compendious; that they ought to expreſs juſt conceptions of the Divine attributes; recite ſuch wants as the congregation are likely to feel and no other; that they ought to contain as few controverted propoſitions as poſſible; and that, if it can be done without offence, the pompous ſtyle of *the ſtate* ſhould be laid aſide in our prayers for the king and all that are in authority; becauſe in every act which carries the mind to God, human greatneſs muſt be annihilated.

WORT, the infuſion of malt, of which beer is made. The uſes of this infuſion in common affairs are well known. By Dr M'Bride it has lately been found to have a ſtrong antiſeptic virtue, and to be uſeful in preventing the ſcurvy and other diſeaſes to which ſailors are liable; which was confirmed by captain Cook in his late voyages. See *Means of Preſerving the Health of* SEAMEN.

WOTTON (Sir Henry), an eminent writer, was the ſon of Thomas Wotton, Eſq; and was born in 1568. He ſtudied for ſome time at New-college, Oxford, whence he removed to Queen's college, where he made a great progreſs in logic and philoſophy; wrote a tragedy for the uſe of that college, called *Tancredo*; and afterwards received the degree of maſter of arts. After this, leaving the univerſity, he travelled into France, Germany, and Italy; and having ſpent about nine years abroad, he returned to England, and became ſecretary to Robert earl of Eſſex, with whom he continued till that earl was apprehended for high-treaſon. He then retired to Florence, where he became known to the grand duke of Tuſcany, who ſent him privately with letters to James VI. king of Scotland, under the name of *Octavio Baldi*, to inform that king of a deſign againſt his life. Some months after he went back to Florence; but king James coming to the poſſeſſion of the crown of England, Mr Wotton returned home, was knighted by his majeſty, and ſent ambaſſador to the republic of Venice; and afterwards was employed in many other embaſſies to that and other courts; but the only reward he obtained for theſe ſervices was his having the provoſtſhip of Eaton conferred upon him about the year 1623, which he kept till his death, which happened in 1639. After his deceaſe ſome of his manuſcripts and printed tracts were publiſhed together in a volume, intitled, *Reliquiæ Wottonianæ*.

Wotton
Wreath.

WOTTON (Dr William), a very learned divine and writer, was the ſon of Mr Henry Wotton, B. D. rector of Wrentham, in Suffolk, where he was born in 1666. He was educated by his father, a gentleman well ſkilled in the learned languages; under whom he made ſuch amazing proficiency, that at five years of age it is ſaid he could render ſeveral chapters in the goſpels out of Latin and Greek, and many pſalms in Hebrew, into his mother tongue. When he was very young, he remembered the whole of almoſt every diſcourſe he had heard, and often ſurpriſed a preacher by repeating his ſermon to him. He was admitted into Catharine-hall in Cambridge ſome months before he was ten years old; when the progreſs he made in learning in that univerſity engaged Dr Duport, then maſter of Magdalen college, and dean of Peterborough, to write an elegant copy of Latin verſes in his praiſe. In 1679 he took the degree of bachelor of arts when he was but twelve years and five months old; and the winter following he was invited to London by Dr Gilbert Burnet, then preacher at the Rolls, who introduced him to moſt of the learned men in that city, and particularly to Dr William Lloyd, biſhop of St Aſaph; to whom he recommended himſelf by repeating to him one of his ſermons, as Dr Burnet had engaged he ſhould. In 1691 he commenced bachelor of divinity. The ſame year biſhop Lloyd gave him the ſinecure of Llandrillo, in Denbighſhire. He was afterwards made chaplain to the earl of Nottingham, then ſecretary of ſtate, who preſented him to the rectory of Middleton Keynes, in Bucks, and to whom he dedicated his Reflections upon Ancient and Modern Learning. In 1705, biſhop Burnet gave him a prebend in the church of Saliſbury; and in 1707, archbiſhop Teniſon preſented him with the degree of doctor of divinity: but in 1714, the difficulties he laboured under with reſpect to his private fortune, obliged him to retire into South Wales, where he was treated with great kindneſs and humanity by the gentlemen of that country; and wrote there the "Memoirs of the Cathedral Churches of St David's and Landaff," and his "Miſcellaneous Diſcourſes, relating to the Traditions and Uſages of the Scribes and Phariſees;" which were afterwards printed. He died in 1726. This great man was remarkable for his humanity and friendlineſs of temper; the narrowneſs of a party ſpirit never broke in upon any of his friendſhips; and his time and abilities were at the ſervice of any perſon who was making advances in real learning. He wrote, beſides the above works, 1. A Hiſtory of Rome. 2. A defence of his Reflections upon Ancient and Modern Learning. 3. A Diſcourſe concerning the Languages of Babel. 4. Advice to a young Student, with a Method of Study for the firſt four Years; and other learned pieces.

WREATH, in heraldry, a roll of fine linen or ſilk (like that of a Turkiſh turban), conſiſting of the colours borne in the eſcutcheon, placed in an atchievement between the

Wreck. the helmet and the creſt, and immediately ſupporting the creſt.

WRECK, or SHIPWRECK, the deſtruction of a ſhip by rocks or ſhallows at ſea.

By the ancient common law, where any ſhip was loſt at ſea, and the goods or cargo were thrown upon the land, theſe goods, ſo wrecked, were judged to belong to the king: for it was held, that, by the loſs of the ſhip, all property was gone out of the original owner. But this was undoubtedly adding ſorrow to ſorrow, and was conſonant neither to reaſon nor humanity. Wherefore it was firſt ordained by king Henry I. that if any perſon eſcaped alive out of the ſhip, it ſhould be no wreck; and afterwards king Henry II. by his charter, declared, that if on the coaſts of either England, Poictou, Oleron, or Gaſcony, any ſhip ſhould be diſtreſſed, and either man or beaſt ſhould eſcape or be found therein alive, the goods ſhould remain to the owners, if they claimed them within three months; but otherwiſe ſhould be eſteemed a wreck, and ſhould belong to the king, or other lord of the franchiſe. This was again confirmed with improvements by king Richard I.; who, in the ſecond year of his reign, not only eſtabliſhed theſe conceſſions, by ordaining that the owner, if he was ſhipwrecked and eſcaped, *omnes res ſuas liberas, et quietas haberet*, but alſo, that if he periſhed, his children, or in default of them, his brethren and ſiſters, ſhould retain the property; and in default of brother or ſiſter, then the goods ſhould remain to the king (A). And the law, as laid down by Bracton in the reign of Henry III. ſeems ſtill to have improved in its equity. For then, if not only a dog (for inſtance) eſcaped, by which the owner might be diſcovered, but if any certain mark were ſet on the goods, by which they might be known again, it was held to be no wreck. And this is certainly moſt agreeable to reaſon; the rational claim of the king being only founded upon this, that the true owner cannot be aſcertained. Afterwards, in the firſt ſtatute of Weſtminſter, the time of limitation of claims, given by the charter of Henry II. is extended to a year and a day, according to the uſage of Normandy: and it enacts, that if any man, a dog, or a cat, eſcape alive, the veſſel ſhall not be adjudged a wreck. Theſe animals, as in Bracton, are only put for examples; for it is now held, that not only if any live thing eſcape, but if proof can be made of the property of any of the goods or lading which come to ſhore, they ſhall not be forfeited as wreck. The ſtatute further ordains, that the ſheriff of the county ſhall be bound to keep the goods a year and a day (as in France for one year, agreeable to the maritime laws of Oleron, and in Holland for a year and a half), that if any man can prove a property in them, either in his own right or by right of repreſentation, they ſhall be reſtored to him without delay; but if no ſuch property be proved within that time, they then ſhall be the king's. If the goods are of a periſhable nature, the ſheriff may ſell them, and the money ſhall be liable in their ſtead. This revenue of wrecks is frequently granted out to lords of manors as a royal franchiſe; and if any one be thus intitled to wrecks in his own land, and the king's goods are wrecked thereon, the king may claim them at any time, even after the year and day.

It is to be obſerved, that, in order to conſtitute a legal wreck, the goods muſt come to land. If they continue at ſea, the law diſtinguiſhes them by the barbarous and uncouth appellations of *jetſam*, *flotſam*, and *ligan*. Jetſam is where goods are caſt into the ſea, and there ſink and remain under water: flotſam is where they continue ſwimming on the ſurface of the waves: ligan is where they are ſunk in the ſea, but tied to a cork or buoy, in order to be found again. Theſe are alſo the king's, if no owner appears to claim them; but if any owner appears, he is intitled to recover the poſſeſſion. For even if they be caſt overboard, without any mark or buoy, in order to lighten the ſhip, the owner is not by this act of neceſſity conſtrued to have renounced his property: much leſs can things ligan be ſuppoſed to be abandoned, ſince the owner has done all in his power to aſſert and retain his property. Theſe three are therefore accounted ſo far a diſtinct thing from the former, that by the king's grant to a man of wrecks, things jetſam, flotſam, and ligan, will not paſs. Wreck.

Wrecks, in their legal acceptation, are at preſent not very frequent: for if any goods come to land, it rarely happens, ſince the improvement of commerce, navigation, and correſpondence, that the owner is not able to aſſert his property within the year and day limited by law. And in order to preſerve this property entire for him, and if poſſible to prevent wrecks at all, our laws have made many very humane regulations; in a ſpirit quite oppoſite to thoſe ſavage laws which formerly prevailed in all the northern regions of Europe, and a few years ago were ſtill ſaid to ſubſiſt on the coaſts of the Baltic Sea, permitting the inhabitants to ſeize on whatever they could get as lawful prize; or, as an author of their own expreſſes it, "*in naufragorum miſeria et calamitate tanquam vultures ad prædam currere.*" For by the ſtatute 27 Edw. III. c. 13. if any ſhip be loſt on the ſhore, and the goods come to land (which cannot, ſays the ſtatute, be called *wreck*), they ſhall be preſently delivered to the merchants, paying only a reaſonable reward to thoſe that ſaved and preſerved them, which is intitled *ſalvage*. Alſo by the common law, if any perſons (others than the ſheriff) take any goods ſo caſt on ſhore, which are not legal wreck, the owners might have a commiſſion to inquire and find them out, and compel them to make reſtitution. And by 12 Ann. ſt. 2. c. 18. confirmed by 4 Geo. I. c. 12. in order to aſſiſt the diſtreſſed, and prevent the ſcandalous illegal practices on ſome of our ſea coaſts (too ſimilar to thoſe on the Baltic), it is enacted, that all head-officers and others of towns near the ſea, ſhall, upon application made to them, ſummon as many hands as are neceſſary, and ſend them to the relief of any ſhip in diſtreſs, on forfeiture of L. 100; and in caſe of aſſiſtance given, ſalvage ſhall be paid by the owners, to be aſſeſſed by three neighbouring juſtices. All perſons that ſecrete any goods ſhall forfeit their treble value: and if they wilfully do any act whereby the ſhip is loſt or deſtroyed, by making holes in her, ſtealing her pumps, or otherwiſe, they are guilty of felony without benefit of clergy. Laſtly, by the ſtatute 26 Geo. II. c. 19. plundering any veſſel, either in diſtreſs or wrecked, and whether any living creature be on board or not (for whether wreck or otherwiſe, it is clearly not the property of the populace), ſuch plundering or preventing the eſcape of any perſon that endeavours to ſave his life, or wounding him with intent to deſtroy him, or putting out falſe lights in order to bring any veſſel into danger, are all declared to be capital felonies; in like manner as the deſtroying of trees, ſteeples,

(A) In like manner Conſtantine the Great, finding that by the imperial law the revenue of wrecks was given to the prince's treaſury or fiſcus, reſtrained it by an edict (Cod. 11. 5. 1.) and ordered them to remain to the owners; adding this humane expoſtulation: "Quod enim jus habet fiſcus in alienâ calamitate, ut de re tam luctuoſâ compendium ſectetur?"

or other ſtated ſea-marks, is puniſhed by the ſtatute 8 Eliz. c. 13. with a forfeiture of L. 100 or outlawry. Moreover, by the ſtatute of Geo. II. pilfering any goods caſt aſhore is declared to be petty larceny; and many other ſalutary regulations are made, for the more effectually preſerving ſhips of any nation in diſtreſs.

By the civil law, to deſtroy perſons ſhipwrecked, or prevent their ſaving the ſhip, is capital. And to ſteal even a plank from a veſſel in diſtreſs or wrecked, makes the party liable to anſwer for the whole ſhip and cargo. The laws alſo of the Wiſigoths, and the moſt early Neapolitan conſtitutions, puniſhed with the utmoſt ſeverity all thoſe who neglected to aſſiſt any ſhip in diſtreſs, or plundered any goods caſt on ſhore.

WREN, in ornithology. See MOTACILLA.

WREN (Sir Chriſtopher), a great philoſopher, and one of the moſt learned and moſt eminent architects of his age, was the ſon of Chriſtopher Wren dean of Windſor, and was born in 1632. He ſtudied at Wadham college in Oxford; where he took the degree of maſter of arts in 1653, and was choſen fellow of All Souls college. When very young he diſcovered a ſurpriſing genius for the mathematics; in which ſcience he made great advances before he was ſixteen years old. In 1657, he was made profeſſor of aſtronomy at Greſham college, London; which he reſigned in 1660, on his being choſen to the Savilian profeſſorſhip of aſtronomy in Oxford: he was the next year created doctor of laws, and in 1663 was elected fellow of the Royal Society. He was one of the commiſſioners for the reparation of St Paul's; and in 1665 travelled into France, to examine the moſt beautiful edifices there, when he made many curious obſervations. At his return to England, he drew a noble plan for rebuilding the city of London after the fire, which he preſented to parliament; and upon the deceaſe of Sir John Denham in 1668, was made ſurveyor-general of his majeſty's works; and from that time had the direction of a great number of public edifices, by which he acquired the higheſt reputation. He built the magnificent theatre at Oxford, St Paul's cathedral, the churches of St Stephen Walbrook, and St Mary-le-Bow, the Monument, the modern part of the palace of Hampton Court, Chelſea College, one of the wings of Greenwich Hoſpital, and many other beautiful edifices. He was preſident of the Royal Society, one of the commiſſioners of Chelſea College, and twice member of parliament; firſt for Plymouth in Devonſhire, and then for Melcomb Regis in the ſame county; but in 1718 was removed from his place of ſurveyor-general. He died in 1723, and was interred in the vault under St Paul's.

This great man alſo diſtinguiſhed himſelf by many curious inventions and diſcoveries in natural philoſophy; and, among many others, contrived an inſtrument for meaſuring the quantity of rain that falls on any ſpace of land for a year; he invented many ways of making aſtronomical obſervations more accurate and eaſy; and was the firſt author of the anatomical experiment of injecting liquors into the veins of animals, &c. He tranſlated into Latin Mr Oughtred's *Horologiographica Geometrica;* and wrote a Survey of the cathedral church of Saliſbury, and other pieces. After his death his poſthumous works and draughts were publiſhed by his ſon.

WRESTLING, a kind of combat or engagement between two perſons unarmed, body to body, to prove their ſtrength and dexterity, and try which can throw his opponent to the ground.

Wreſtling is an exerciſe of very great antiquity and fame. It was in uſe in the heroic age; witneſs Hercules, who wreſtled with Antæus.

It continued a long time in the higheſt repute, and had conſiderable rewards and honours aſſigned to it at the Olympic games. It was the cuſtom for the Athletæ to anoint their bodies with oil, to give the leſs hold to their antagoniſts.

Lycurgus ordered the Spartan maids to wreſtle in public quite naked, in order, as it is obſerved, to break them of their too much delicacy and niceneſs, to make them appear more robuſt, and to familiarize the people, &c. to ſuch nudities.

WRIST, in ANATOMY. See there, n° 53.

WRIT, in law, ſignifies, in general, the king's precept in writing under ſeal, iſſuing out of ſome court, directed to the ſheriff or other officer, and commanding ſomething to be done in relation to a ſuit or action, or giving commiſſion to have the ſame done. And, according to Fitzherbert, a writ is ſaid to be a formal letter of the king in parchment, ſealed with his ſeal, and directed to ſome judge, officer, or miniſter, &c. at the ſuit of a ſubject, for the cauſe briefly expreſſed, which is to be determined in the proper court according to law.

WRITS, in civil actions, are either original or judicial: original, are ſuch as are iſſued out of the court of chancery for the ſummoning of a defendant to appear, and are granted before the ſuit is commenced, in order to begin the ſame; and judicial writs iſſue out of the court where the original is returned, after the ſuit is begun. See PROCESS.

The original writ is the foundation of the ſuit. See SUIT.

When a perſon hath received an injury, and thinks it worth his while to demand a ſatisfaction for it, he is to conſider with himſelf, or take advice, what redreſs the law has given for that injury; and thereupon is to make application or ſuit to the crown, the fountain of all juſtice, for that particular ſpecific remedy which he is determined or adviſed to purſue. As for money due on bond, an action of debt; for goods detained without force, an action of *detinue* or *trover;* or, if taken with force, an action of *treſpaſs vi et armis;* or, to try the title of lands, a writ of entry or action of treſpaſs in ejectment: or for any conſequential injury received, a ſpecial action on the caſe. To this end he is to ſue out, or purchaſe by paying the ſtated fees, an *original* or original writ, from the court of chancery, which is the *officina juſtitiæ*, the ſhop or mint of juſtice, wherein all the king's writs are framed. It is a mandatory letter from the king in parchment, ſealed with his great ſeal, and directed to the ſheriff of the county wherein the injury is committed, or ſuppoſed ſo to be, requiring him to command the wrongdoer or party accuſed, either to do juſtice to the complainant, or elſe to appear in court, and anſwer the accuſation againſt him. Whatever the ſheriff does in purſuance of this writ, he muſt return or certify to the court of common-pleas, together with the writ itſelf: which is the foundation of the juriſdiction of that court, being the king's warrant for the judges to proceed to the determination of the cauſe. For it was a maxim introduced by the Normans, that there ſhould be no proceedings in common-pleas before the king's juſtices without his original writ; becauſe they held it unfit that thoſe juſtices, being only the ſubſtitutes of the crown, ſhould take cognizance of any thing but what was thus expreſsly referred to their judgment. However, in ſmall actions, below the value of forty ſhillings, which are brought in the court-baron or county-court, no royal writ is neceſſary; but the foundation of ſuch ſuits continue to be (as in the times of the Saxons), not by original writ, but by plaint; that is, by a private memorial tendered in open court to the judge, wherein the party injured ſets forth his cauſe of action: and the judge is bound of common right to adminiſter juſtice therein, without any ſpecial mandate from the king. Now indeed even the royal writs are held to be demandable of common right, on paying the uſual fees: for

any

Writs, Writing.

any delay in the granting them, or ſetting an unuſual or exorbitant price upon them, would be a breach of magna charta, c. 29. "nulli vendemus, nulli negabimus, aut differemus juſtitiam vel rectum."

Original writs are either optional or peremptory; or, in the language of our law, they are either a *præcipe*, or a *ſi te fecerit ſecurum*. The *præcipe* is in the alternative, commanding the defendant to do the thing required, or ſhow the reaſon wherefore he hath not done it. The uſe of this writ is where ſomething certain is demanded by the plaintiff, which is in the power of the defendant himſelf to perform; as, to reſtore the poſſeſſion of land, to pay a certain liquidated debt, to perform a ſpecific covenant, to render an account, and the like; in all which caſes the writ is drawn up in the form of a *præcipe* or command, to do thus, or ſhow cauſe to the contrary; giving the defendant his choice to redreſs the injury or ſtand the ſuit. The other ſpecies of original writs is called a *ſi fecerit te ſecurum*, from the words of the writ; which directs the ſheriff to cauſe the defendant to appear in court, without any option given him, provided the plaintiff gives the ſheriff ſecurity effectually to proſecute his claim. This writ is in uſe where nothing is ſpecifically demanded, but only a ſatisfaction in general; to obtain which, and miniſter complete redreſs, the intervention of ſome judicature is neceſſary. Such are writs of treſpaſs, or on the caſe, wherein no debt or other ſpecific thing is ſued for in certain, but only damages to be aſſeſſed by a jury. For this end the defendant is immediately called upon to appear in court, provided the plaintiff gives good ſecurity of proſecuting his claim. Both ſpecies of writs are teſted, or witneſſed, in the king's own name; "witneſs ourſelf at Weſtminſter," or wherever the chancery may be held.

The ſecurity here ſpoken of, to be given by the plaintiff for proſecuting his claim, is common to both writs, though it gives denomination only to the latter. The whole of it is at preſent become a mere matter of form; and John Doe and Richard Roe are always returned as the ſtanding pledges for this purpoſe.—The ancient uſe of them was to anſwer for the plaintiff, who in caſe he brought an action without cauſe, or failed in the proſecution of it when brought, was liable to an amercement from the crown for raiſing a falſe accuſation; and ſo the form of the judgment ſtill is. In like manner, as by the Gothic conſtitutions no perſon was permitted to lay a complaint againſt another, *niſi ſub ſcriptura aut ſpecificatione trium teſtium, quod actionem vellet perſequi*: and, as by the laws of Sancho I. king of Portugal, damages were given againſt a plaintiff who proſecuted a groundleſs action.

The day on which the defendant is ordered to appear in court, and on which the ſheriff is to bring in the writ, and report how far he has obeyed it, is called the *return of the writ*; it being then returned by him to the king's juſtices at Weſtminſter. And it is always made returnable at the diſtance of leaſt 15 days from the date or teſt, that the defendant may have time to come up to Weſtminſter, even from the moſt remote parts of the kingdom; and upon ſome day in one of the four terms, in which the court ſits for the diſpatch of buſineſs.

WRITING, the art or act of ſignifying and conveying our ideas to others, by letters or characters viſible to the eye. See COMPOSITION, GRAMMAR, and LANGUAGE.

The moſt ancient remains of writing, which have been tranſmitted to us, are upon hard ſubſtances, ſuch as ſtones and metals, which were uſed by the ancients for edicts and matters of public notoriety; the decalogue was written on two tables of ſtone; but this practice was not peculiar to the Jews, for it was uſed by moſt of the eaſtern nations, as well as by the Greeks and Romans; and therefore the ridicule which Voltaire attempts to caſt upon that part of the book of Geneſis, where the people are commanded to write the law on ſtones, is abſurd; for what is there ſaid by no means implies, that other materials might not be uſed on common occaſions. The laws penal, civil, and ceremonial, among the Greeks, were engraven on tables of braſs which were called *Cyrbes*. Writing.

We find that wood was alſo uſed for writing on in different countries. In the Sloanian library (N° 4852.) are ſix ſpecimens of Kufic writing, on boards about two feet in length, and ſix inches in depth. The Chineſe, before the invention of paper, wrote or engraved with an iron tool upon thin boards or on bamboo. Pliny ſays, that table books of wood were in uſe before the time of Homer. Theſe table books were called by the Romans *pugillares*. The wood was cut into thin ſlices, and finely plained and poliſhed. The writing was at firſt upon the bare wood, with an iron inſtrument called a *ſtyle*. In later times theſe tables were uſually waxed over, and written upon with that inſtrument. The matter written upon the tables which were thus waxed over was eaſily effaced, and by ſmoothing the wax new matter might be ſubſtituted in the place of what had been written before. The Greeks and Romans continued the uſe of waxed table-books long after the uſe of papyrus, leaves, and ſkins, became common, becauſe they were ſo convenient for correcting extemporary compoſitions.

Table books of ivory are ſtill uſed for memorandums, but they are commonly written upon with black lead pencils. The practice of writing on table-books covered with wax was not entirely laid aſide till the commencement of the 14th century.

The bark of trees was alſo uſed for writing by the ancients, and is ſo ſtill in ſeveral parts of Aſia. The ſame thing may be ſaid of the leaves of trees. It is needleſs to obſerve the uſe of parchment and vellum, papyrus and paper, for writing; it is too well known. The method of fabricating theſe ſubſtances has been already deſcribed as they occurred in the order of the alphabet.

It is obvious, that when men wrote, or rather engraved, on hard ſubſtances, inſtruments of metal were neceſſary, ſuch as the chiſel and the ſtylus; but the latter was chiefly uſed for writing upon boards, waxed tablets, or on bark.

When the ancients wrote on ſofter materials than wood or metal, other inſtruments were uſed for writing with, of which reeds and canes ſeem to have been the firſt. Reeds and canes are ſtill uſed as inſtruments for writing with by the Tartars, the Indians, the Perſians, the Turks, and the Greeks. Pencils made of hair are uſed by the Chineſe for their writing: they firſt liquify their ink, and dip their pencils into it. Hair-pencils have likewiſe been uſed for writing in Europe. Large capital letters were made with them from the time of the Roman emperors till the 16th century. After the invention of printing they were drawn by the illuminators. Quills of geeſe, ſwans, peacocks, crows, and other birds, have been uſed in theſe weſtern parts for writing with, but how long is not eaſy to aſcertain. St Iſidore of Seville, who lived about the middle of the 7th century, deſcribes a pen made of a quill as uſed in his time.

Method of reſtoring decayed WRITINGS. In the 77th vol. of the Phil. Tranſ. there is a paper on this ſubject by Sir Charles Blagden. One of the beſt methods he found upon experiment to be, covering the letters with phlogiſticated or pruſſic alkali, with the addition of a diluted mineral acid; upon the application of which, the letters changed very ſpeedily to a deep blue colour, of great beauty and intenſity. To prevent the ſpreading of the colour, which, by blotting the parchment, detracts greatly from the legibility, the alkali ſhould be put on firſt, and the diluted acid added upon it.

The

Writings || Wurtemberg.

The method found to anſwer beſt has been, to ſpread the alkali thin with a feather over the traces of the letters, and then to touch it gently, as nearly upon or over the letters as can be done with the diluted acid, by means of a feather or a bit of ſtick cut to a blunt point. Though the alkali ſhould occaſion no ſenſible change of colour, yet the moment the acid comes upon it, every trace of a letter turns at once to a fine blue, which ſoon acquires its full intenſity, and is beyond compariſon ſtronger than the colour of the original trace had been. If, then, the corner of a bit of blotting paper be carefully and dexterouſly applied near the letters, ſo as to imbibe the ſuperfluous liquor, the ſtaining of the parchment may be in a great meaſure avoided; for it is this ſuperfluous liquor which, abſorbing part of the colouring matter from the letters, becomes a dye to whatever it touches. Care muſt be taken not to bring the blotting paper in contact with the letters, becauſe the colouring matter is ſoft whilſt wet, and may eaſily be rubbed off. The acid chiefly employed was the marine; but both the vitriolic and nitrous ſucceed very well. They ſhould be ſo far diluted as not to be in danger of corroding the parchment, after which the degree of ſtrength does not ſeem to be a matter of much nicety.

Method of Copying Writings. The ingenious Mr Watt, about 16 years ago, invented a method of copying writings very ſpeedily, and without the poſſibility of committing miſtakes. A piece of thin unſized paper is to be taken exactly of the ſize of the paper to be copied; it is to be moiſtened with water, or, what is better, with the following liquid: Take of diſtilled vinegar two pounds weight, diſſolve it in one ounce of boracic acid; then take four ounces of oyſter-ſhells calcined to whiteneſs, and carefully freed from their brown cruſt; put them into the vinegar, ſhake the mixture frequently for 24 hours, then let it ſtand until it depoſits its ſediment; filter the clear part through unſized paper into a glaſs veſſel; then add two ounces of the beſt blue Aleppo galls bruiſed, and place the liquor in a warm place, ſhaking it frequently for 24 hours; then filter the liquor again through unſized paper, and add to it after filtration one quart, ale meaſure, of pure water. It muſt then ſtand 24 hours, and be filtered again if it ſhows a diſpoſition to depoſit any ſediment, which it generally does. When the paper has been wet with this liquid, put it between two thick unſized papers to abſorb the ſuperfluous moiſture; then lay it over the writing to be copied, and put a piece of clean writing paper above it. Put the whole on the board of a rolling-preſs, and preſs them thro' the rolls, as is done in printing copperplates, and a copy of the writing ſhall appear on both ſides of the thin moiſtened paper; on one ſide in a reverſed order and direction, but on the other ſide in the natural order and direction of the lines.

WRITTEN MOUNTAINS. See MOUNTAINS.

WRY-NECK, in ornithology. See JYNX.

WURTEMBURG, or WIRTENBURG, a ſovereign duchy of Germany, in Suabia; bounded on the north by Franconia, the archbiſhopric of Mentz, and the palatinate of the Rhine; on the eaſt by the county of Oeting, the marquiſate of Burgau, and the territory of Ulm; on the ſouth by the principality of Hoen Zollern, Furſtenburg, and the marquiſate of Hohenburg; and on the weſt by the palatinate of the Rhine, the marquiſate of Baden, and the Black Foreſt. It is 65 miles in length, and as much in breadth, and the river Neckar runs almoſt through the middle of it from ſouth to north. Though there are many mountains and woods, yet it is one of the moſt populous and fertile countries in Germany, producing plenty of graſs, corn, fruits, and a great deal of wine towards the confines of the palatinate. There are alſo mines, and ſalt ſprings, with plenty of game and fiſh. It contains 645 villages, 88 towns, and 26 cities, of which Stutgard is the capital. Wurtſburg, Wycherley.

WURTSBURG, a large biſhopric in Germany, comprehending the principal part of Franconia. It is bounded by the county of Henneburg, the duchy of Coburg, the abbey of Fuld, the archbiſhopric of Mentz, the marquiſate of Anſpach, the biſhopric of Bamberg, and the county of Wertheim; being about 65 miles in length, and 50 in breadth, and divided into 50 bailiwicks. The ſoil is very fertile, and produces more corn and wine than the inhabitants conſume. The territories of the biſhop comprehend above 400 towns and villages, of which he is ſovereign, being one of the greateſt eccleſiaſtical princes of the empire.

WURTZBURG, a large and handſome city of Germany, and one of the principal in the circle of Franconia. It is defended with good fortifications, and has a magnificent palace. There is a handſome hoſpital, in which are generally 400 poor men and women. The caſtle is at a ſmall diſtance from the city, and commands it, as it ſtands upon an eminence. It communicates with the city by a ſtone-bridge, on which are 12 ſtatues, repreſenting as many ſaints. The arſenal and the cellars of the biſhop deſerve the attention of the curious. There is alſo an univerſity, founded in 1403. It is ſeated on the river Maine, in E. Long. 10. 2. N. Lat. 49. 46.

WYCHERLEY (William), an eminent Engliſh comic poet, was born about 1640. A little before the reſtoration of King Charles II. he became a gentleman commoner of Queen's college Oxford, where he was reconciled by Dr Barlow to the Proteſtant religion, which he had a little before abandoned in his travels. He afterward entered himſelf in the Middle-temple, but ſoon quitted the ſtudy of the law for purſuits more agreeable to his own genius, as well as to the taſte of the age. Upon writing his firſt play, intitled, Love in a Wood, or St James's Park, which was acted in 1672, he became acquainted with ſeveral of the celebrated wits both of the court and town, and likewiſe with the ducheſs of Cleveland. Some time after appeared his comedies, called The Gentleman-Dancing-Maſter, the Plain Dealer, and the Country Wife; all which were acted with applauſe. George duke of Buckingham had a very high eſteem for him, and beſtowed on him ſeveral advantageous poſts. King Charles alſo ſhowed him ſignal marks of favour; and once gave him a proof of his eſteem, which perhaps never any ſovereign prince before had given to a private gentleman. Mr Wycherley being ill of a fever, at his lodgings in Bow-ſtreet, the king did him the honour of a viſit. Finding him extremely weakened, he commanded him to take a journey to the ſouth of France, and aſſured him, at the ſame time, that he would order him 500 l. to defray the charges of the journey. Mr Wycherley accordingly went into France; and having ſpent the winter there, returned to England entirely reſtored to his former vigour. The king, ſhortly after his arrival, told him, that he had a ſon, who he was reſolved ſhould be educated like the ſon of a king, and that he could not chooſe a more proper man for his governor than Mr Wycherley; for which ſervice 1500 l. *per annum* ſhould be ſettled upon him.

Immediately after this offer he went down to Tunbridge, where walking one day upon the Well's-walk with his friend Mr Fairbeard of Gray's-Inn, juſt as he came up to the bookſeller's ſhop, the counteſs of Drogheda, a young widow, rich, noble, and beautiful came there to enquire for the Plain Dealer; "Madam," ſays Mr Fairbeard, "ſince you are for the Plain Dealer, there he is for you;" puſhing Mr Wycherley towards her. "Yes," ſays Mr Wycherley,

Wycherly. Wycherley, "this lady can bear plain dealing; for she appears to be so accomplished, that what would be a compliment to others, would be plain dealing to her." "No, truly, Sir," said the countess, "I am not without my faults, any more than the rest of my sex; and yet, notwithstanding, I love plain-dealing, and am never more fond of it than when it tells me of them." "Then, madam," says Mr Fairbeard, "you and the Plain-Dealer seem designed by Heaven for each other."—In short, Mr Wycherley walked a turn or two with the countess, waited upon her home, visited her daily while she staid at Tunbridge, and married her soon after without acquainting the king. By this step, which was looked upon as a contempt of his majesty's orders, he forfeited the royal favour. The countess of Drogheda settled her whole fortune upon him; but his title being disputed after her death, he was so reduced by the expences of the law and other incumbrances, as to be unable to satisfy the impatience of his creditors, who threw him into prison; and the bookseller who printed his Plain-Dealer, by which he got almost as much money as the other gained reputation, was so ungrateful as to refuse to lend him 20l. in his extreme necessity. In that confinement he languished seven years; but at length king James going to see the above play, was so charmed with it, that he gave immediate orders for the payment of his debts, and even granted him a pension of 200l. *per annum*. But that prince's bountiful intentions were in a great measure defeated merely through Mr Wycherley's modesty; he being ashamed to tell the earl of Mulgrave, whom the king had sent to demand it, a true state of his debts. He laboured under the weight of these difficulties till his father died, who left him 600 l. a year. But this estate was under uneasy limitations, he being only a tenant for life, and not being allowed to raise any money for the payment of his debts. However, he took a method of doing it which few suspected to be his choice; and this was making a jointure. He had often declared, that he was resolved to die married, though he could not bear the thoughts of living in that state again: accordingly, just at the eve of his death, he married a young gentlewoman with 1500l. fortune, part of which he applied to the uses he wanted it for. Eleven days after the celebration of these nuptials, in December 1715, he died, and was interred in the vault of Covent-garden church.

Wynd ham Wye.

Besides his plays above-mentioned, he published a volume of poems in folio. In 1728 his posthumous works in prose and verse were published by Mr Theobald.

WYNDHAM (Sir William), descended of an ancient family, was born about the year 1687, and succeeded young to the title and estate of his father. On his return from his travels, he was chosen member for the county of Somerset; in which station he served in the three last parliaments of Queen Anne, and as long as he lived: after the change of the ministry in 1710, he was appointed secretary at war; and in 1713 was raised to be chancellor of the exchequer. Upon the breach between the earl of Oxford and lord Bolingbroke, he adhered to the interests of the latter. He was removed from his employment on the accession of George I. and falling under suspicion on the breaking out of the rebellion in 1715, was apprehended. He made his escape; a reward was published for apprehending him; he surrendered, was committed to the Tower, but never brought to a trial. After he regained his liberty, he continued in opposition to the several administrations under which he lived; and died in 1740.

WYKEHAM (William of). See WILLIAM.

WYE, a river of Wales, which rising on the confines of Cardiganshire, and running south-east, divides the counties of Radnor and Brecknock: then crossing Herefordshire, it runs south and falls into the mouth of the Severn at Chepstow.

X.

Xanthium. X or *x*, is the 22d letter of our alphabet, and a double consonant. It was not used by the Hebrews or ancient Greeks; for as it is a compound letter, the ancients, who used great simplicity in their writings, expressed this letter by its component letters *c s*. Neither have the Italians this letter, but express it by *ss*. X begins no word in our language but such as are of Greek original; and is in few others but what are of Latin derivation; as *perplex*, *reflexion*, *defluxion*, &c. We often express this sound by single letters, as *cks*, in *backs*, *necks*; by *ks*, in *books*, *breaks*; by *cc*, in *access*, *accident*; by *ct*, in *action*, *unction*, &c. The English and French pronounce it like *cs* or *ks*; the Spaniards like *c* before *a*, viz. *Alexandro*, as if it were *Alecandro* In numerals it expresseth 10, whence in old Roman manuscripts it is used for *denarius*; and as such seems to be made of two V's placed one over the other. When a dash is added over it, thus $\bar{X}$, it signifies 10,000.

XANTHIUM, in botany; a genus of plants of the class *monœcia*, order *pentandria*, and arranged in the natural classification under the 49th order, *compositæ*. The male flowers are compositе, common calyx imbricated; corollulæ monopetalous, tubular, quinquefid. Female: calyx involucrum of two leaves, containing two flowers; corolla 0; drupa, dry, prickly; nucleus bilocular. There are five species, only one of which is a native of Britain, the *strumarium* or less burdock. The stem of this plant is a foot and a half high, thick, often spotted; leaves heart-shaped, lobed, on long foot-stalks. Flowers, male and female, many together, in the alæ of the leaves. The leaves are bitter and astringent. A decoction of the whole plant affords a showy yellow colour, but it is better if only the flowers are used. Horses and goats eat it; cows, sheep, and swine refuse it.

Xanthoxylum, Xebec.

XANTHOXYLUM. See ZANTHOXYLUM.

XEBEC, or ZEBEC a small three-masted vessel, navigated in the Mediterranean Sea, and on the coasts of Spain, Portugal, and Barbary. See Plate CCCCLII, fig. 10.

The sails of the xebec are in general similar to those of the polacre, but the hull is extremely different from that and almost every other vessel. It is furnished with a strong prow: and the extremity of the stern, which is nothing more than a sort of railed platform or gallery, projects farther behind the counter and buttock than that of any European ship.

Being generally equipped as a corsair, the xebec is constructed with a narrow floor, to be more swift in pursuit of the enemy; and of a great breadth, to enable her to carry

Xenocrates.

a great force of ſail for this purpoſe without danger of overturning. As theſe veſſels are uſually very low built, their decks are formed with a great convexity from the middle of their breadth towards the ſides, in order to carry off the water which falls aboard more readily by their ſcuppers. But as this extreme convexity would render it very difficult to walk thereon at ſea, particularly when the veſſel rocks by the agitation of the waves, there is a platform of grating extending along the deck from the ſides of the veſſel towards the middle, whereon the crew may walk dry-footed whilſt the water is conveyed through the grating to the ſcuppers.

The xebecs, which are generally armed as veſſels of war by the Algerines, mount from 16 to 24 cannon, and carry from 300 to 450 men, two-thirds of whom are generally ſoldiers.

By the very complicated and inconvenient method of working theſe veſſels, what one of their captains of Algiers told Mr Falconer will be readily believed, viz. that every xebec requires at leaſt the labour of three ſquare-rigged ſhips, wherein the ſtanding ſails are calculated to anſwer every ſituation of the wind.

XENOCRATES, a celebrated ancient Grecian philoſopher, was born at Chalcedon in the 95th Olympiad. At firſt he attached himſelf to Æſchines, but afterwards became a diſciple of Plato, who took much pains in cultivating his genius, which was naturally heavy. His temper was gloomy, his aſpect ſevere, and his manners little tinctured with urbanity. Theſe material defects his maſter took great pains to correct; frequently adviſing him to ſacrifice to the Graces, and the pupil was patient of inſtruction, and knew how to value the kindneſs of his preceptor. As long as Plato lived, Xenocrates was one of his moſt eſteemed diſciples; after his death he cloſely adhered to his doctrine; and, in the ſecond year of the 110th Olympiad, he took the chair in the academy, as the ſucceſſor of Speuſippus.

Xenocrates was celebrated among the Athenians, not only for his wiſdom, but for his virtues. So eminent was his reputation for integrity, that when he was called upon to give evidence in a judicial tranſaction, in which an oath was uſually required, the judges unanimouſly agreed, that his ſimple aſſeveration ſhould be taken, as a public teſtimony to his merit. Even Philip of Macedon found it impoſſible to corrupt him. So abſtemious was he with reſpect to food, that his proviſion was frequently ſpoiled before it was conſumed. His chaſtity was invincible. Phryne, a celebrated Athenian courtezan, attempted without ſucceſs to ſeduce him. Of his humanity the following pathetic incident is a ſufficient proof: A ſparrow, which was purſued by a hawk, flew in his boſom; he afforded it protection till its enemy was out of ſight, and then let it go, ſaying, that he would never betray a ſuppliant. He was fond of retirement, and was ſeldom ſeen in the city. He was diſcreet in the uſe of his time, and carefully allotted a certain portion of each day to its proper buſineſs. One of theſe he employed in ſilent meditation. He was an admirer of the mathematical ſciences; and was ſo fully convinced of their utility, that when a young man, who was unacquainted with geometry and aſtronomy, deſired admiſſion into the academy, he refuſed his requeſt, ſaying, that he was not yet poſſeſſed of the handles of philoſophy. In fine, Xenocrates was eminent both for the purity of his morals and for his acquaintance with ſcience, and ſupported the credit of the Platonic ſchool, by his lectures, his writings, and his conduct. He lived to the firſt year of the 116th Olympiad, or the 82 of his age, when he loſt his life by accidentally falling, in the dark, into a reſervoir of water.

Enfield's Hiſt of Philoſophy, vol. ii.

Xenophanes, Xenophon.

XENOPHANES, the founder of the Eleaic ſect of philoſophy among the Greeks, was born at Colophon probably about the 65th Olympiad. From ſome cauſe or other he left his country early, and took refuge in Sicily, where he ſupported himſelf by reciting, in the court of Hiero, elegiac and iambic verſes, which he had written in reprehenſion of the theogonies of Heſiod and Homer. From Sicily he paſſed over into Magna Græcia, where he took up the profeſſion of philoſophy, and became a celebrated preceptor in the Pythagorean ſchool. Indulging, however, a greater freedom of thought than was uſual among the diſciples of Pythagoras, he ventured to introduce new opinions of his own, and in many particulars to oppoſe the doctrines of Epimenides, Thales, and Pythagoras. Xenophanes poſſeſſed the Pythagorean chair of philoſophy about ſeventy years, and lived to the extreme age of an hundred years, that is, according to Euſebius, till the 81ſt Olympiad. The doctrine of Xenophanes concerning nature is ſo imperfectly preſerved, and obſcurely expreſſed, that it is no wonder that it has been differently repreſented by different writers. Perhaps the truth is, that he held the univerſe to be one in nature and ſubſtance, but diſtinguiſhed in his conception between the matter of which all things conſiſt, and that latent divine force which, though not a diſtinct ſubſtance but an attribute, is neceſſarily inherent in the univerſe, and is the cauſe of all its perfection.

XENOPHON, an illuſtrious philoſopher, general, and hiſtorian, was born at Athens in the 3d year of the 82d Olympiad. When he was a youth, Socrates, ſtruck with his external appearance, determined to admit him into the number of his pupils. Meeting him by accident in a narrow paſſage, the philoſopher put his ſtaff acroſs the path, and ſtopping him, aſked, where thoſe things were to be purchaſed which are neceſſary to human life? Xenophon appearing at a loſs for a reply to this unexpected ſalutation, Socrates proceeded to aſk him, where honeſt and good men were to be found? Xenophon ſtill heſitating, Socrates ſaid to him, "Follow me, and learn." From that time Xenophon became a diſciple of Socrates, and made a rapid progreſs in that moral wiſdom for which his maſter was ſo eminent. Xenophon accompanied Socrates in the Peloponneſian war, and fought courageouſly in defence of his country. He afterwards entered into the army of Cyrus as a private volunteer in his expedition againſt his brother. This enterprize proving unfortunate, Xenophon, after the death of Cyrus, adviſed his fellow ſoldiers to attempt a retreat into their own country. They liſtened to his advice; and having had many proofs of his wiſdom as well as courage, they gave him the command of the army, in the room of Proxenus who had fallen in battle. In this command he acquired great glory by the prudence and firmneſs with which he conducted them back, through the midſt of innumerable dangers, into their own country. The particulars of this memorable adventure are related by Xenophon himſelf in his Retreat of the Ten Thouſand. After his return into Greece, he joined Ageſilaus, king of Sparta, and fought with him againſt the Thebans in the celebrated battle of Chæronea. The Athenians, diſpleaſed at this alliance, brought a public accuſation againſt him for his former conduct in engaging in the ſervice of Cyrus, and condemned him to exile. The Spartans, upon this, took Xenophon, as an injured man, under their protection, and provided him a comfortable retreat at Scilluntes in Elea. Here, with his wife and two children, he remained ſeveral years, and paſſed his time in the ſociety of his friends, and

in

Xenophon || Ximenes.

in writing these historical works which have rendered his name immortal. A war at length arose between the Spartans and Eleans; and Xenophon was obliged to retire to Lepreus, where his eldest son had settled. He afterwards removed, with his whole family, to Corinth, where, in the first year of the hundred and fifth Olympiad, he finished his days.

Xenophon the *Younger*, a Greek writer, so called to distinguish him from the celebrated Xenophon, was born at Ephesus, and lived, according to some authors, before Heliodorus, that is, about the beginning of the 4th century. He is only known by his *Ephesiaca*, a Greek romance in five books, which is esteemed, and contains the amours or adventures of Abracomes and Anthia. This romance was printed at London, in Greek and Latin, in 1724, 4to.

XERXES I. the fifth king of Persia, memorable for the vast army he is said to have carried into the field against Leonidas king of Sparta; consisting, according to some historians, of 800,000 men, while others make it amount to 3,000,000, exclusive of attendants. The fleet that attended this prodigious land force is likewise made to consist of 2000 sail; and all the success they met with was the taking and burning the city of Athens; for the army was shamefully repulsed near the straits of Thermopylæ by Leonidas, and the fleet was dispersed and partly destroyed by Themistocles at the straits of Salamis, who had only 380 sail under his command. Xerxes was assassinated by Artabanes, chief captain of his guards, and his distinguished favourite. See SPARTA.

XIMENES (Francis), a justly celebrated cardinal, bishop of Toledo, and prime minister of Spain, was born at Torrelaguna, in Old Castile, in 1437, and studied at Alcala and Salamanca. He then went to Rome; and being robbed on the road, brought nothing back but a bull for obtaining the first vacant prebend: but the archbishop of Toledo refused it him, and threw him in prison. Being at length restored to liberty, he obtained a benefice in the diocese of Siguenca, where cardinal Gonzales de Mendoza, who was the bishop, made him his grand vicar. Ximenes some time after entered among the Franciscans of Toledo; but being there troubled with visits, he retired to a solitude named *Castanel*, and applied himself to the study of divinity and the oriental tongues. At his return to Toledo, queen Isabella of Castile chose him for her confessor, and afterwards nominated him archbishop of Toledo; which, next to the papacy, is the richest dignity in the church of Rome. "This honour (says Dr Robertson) he declined with a firmness which nothing but the authoritative injunction of the pope was able to overcome. Nor did this height of promotion change his manners. Though obliged to display in public that magnificence which became his station, he himself retained his monastic severity. Under his pontifical robes he constantly wore the coarse frock of St Francis, the rents of which he used to patch with his own hands. He at no time used linen, but was commonly clad in hair-cloth. He slept always in his habit; most frequently on the floor or on boards, and rarely in a bed. He did not taste any of the delicacies which appeared at his table, but satisfied himself with that simple diet which the rule of his order prescribed. Notwithstanding these peculiarities, so opposite to the manners of the world, he possessed a thorough knowledge of its affairs, and discovered talents for business which rendered the fame of his wisdom equal to that of his sanctity." His first care was to provide for the necessities of the poor; to visit the churches and hospitals; to purge his diocese of usurers and places of debauchery; to degrade corrupt judges, and place in their room persons whom he knew to be distinguished by their probity and disinterestedness. He erected a famous university at Alcala; and in 1499 founded the college of St Ildephonso. Three years after he undertook the Polyglot Bible; and for that purpose sent for many learned men to come to him at Toledo, purchased seven copies in Hebrew for 4000 crowns, and gave a great price for Latin and Greek manuscripts. At this Bible they laboured above 12 years. It contains the Hebrew text of the Bible; the version of the Septuagint, with a literal translation; that of St Jerom, and the Chaldee paraphrases of Onkelos; and Ximenes added to it a dictionary of the Hebrew and Chaldee words contained in the Bible. This work is called *Ximenes's Polyglot*. In 1507 pope Julius II. gave him the cardinal's hat, and king Ferdinand the Catholic entrusted him with the administration of affairs. Cardinal Ximenes was from this moment the soul of every thing that passed in Spain. He distinguished himself at the beginning of his ministry by discharging the people from the burdensome tax called *acavale*, which had been continued on account of the war against Granada; and laboured with such zeal and success in the conversion of the Mahometans, that he made 3000 converts, among whom was a prince of the blood of the kings of Granada. In 1509 cardinal Ximenes extended the dominions of Ferdinand, by taking the city of Oran in the kingdom of Algiers. He undertook this conquest at his own expence, and marched in person at the head of the Spanish army cloathed in his pontifical ornaments, and accompanied by a great number of ecclesiastics and monks. Some time after, foreseeing an extraordinary scarcity, he erected public granaries at Toledo, Alcala, and Torrelaguna, and had them filled with corn at his own expence; which gained the people's hearts to such a degree, that to preserve the memory of this noble action they had an eulogium upon it cut on marble, in the hall of the senate-house at Toledo, and in the market-place. King Ferdinand dying in 1516, left cardinal Ximenes regent of his dominions; and the archduke Charles, who was afterwards the emperor Charles V. confirmed that nomination. The cardinal immediately made a reform of the officers of the supreme council and of the court, and put a stop to the oppression of the grandees. He vindicated the rights of the people against the nobility; and as by the feudal constitution the military power was lodged in the hands of the nobles, and men of inferior condition were called into the field only as their vassals, a king with scanty revenues depended on them in all his operations. From this state Ximenes resolved to deliver the crown; and issued a proclamation, commanding every city in Castile to inrol a certain number of its burgesses, and teach them military discipline; he himself engaging to provide officers to command them at the public expence. This was vigorously opposed by the nobles; but by his intrepidity and superior address he carried his point. He then endeavoured to diminish the possessions of the nobility, by reclaiming all the crown-lands, and putting a stop to the pensions granted by the late king Ferdinand. This addition made to the revenues enabled him to discharge all the debts of Ferdinand, and to establish magazines of warlike stores. The nobles, alarmed at these repeated attacks, uttered loud complaints; but before they proceeded to extremities, appointed some grandees of the first rank to examine the powers in consequence of which he exercised acts of such high authority. Ximenes received them with cold civility; produced the testament of Ferdinand, by which he was appointed regent, together with the ratification of that deed by Charles. To both these they objected; and he endeavoured to establish their validity. As the conversation grew warm, he led them insensibly to a balcony, from which they had a view of a large body of troops under arms, and of a formidable train of artillery.

Ximenes.

Ximenes, Xiphias.

"Behold (says he, pointing to these, and raising his voice) the powers which I have received from his Catholic majesty! With these I govern Castile; and with these I will govern it, till the king, your master and mine, takes possession of his kingdom!" A declaration so bold and haughty silenced them, and astonished their associates. They saw that he was prepared for his defence, and laid aside all thoughts of a general confederacy against his administration. At length, from the repeated intreaties of Ximenes, and the impatient murmurs of the Spanish ministry, Charles V. embarked, and landed in Spain, accompanied by his favourites. Ximenes was advancing to the coast to meet him, but at Bos Equillos was seized with a violent disorder, which his followers considered as the effects of poison. This accident obliging Ximenes to stop, he wrote to the king, and with his usual boldness advised him to dismiss all the strangers in his train, whose number and credit already gave offence to the Spaniards, and earnestly desired to have an interview with him, that he might inform him of the state of the nation, and the temper of his subjects. To prevent this, not only the Flemings, but the Spanish grandees, employed all their address to keep Charles at a distance from Aranda, the place to which the cardinal had removed. His advice was now slighted and despised. Ximenes, conscious of his own integrity and merit, expected a more grateful return from a prince to whom he delivered a kingdom more flourishing than it had been in any former age, and a more extensive authority than the most illustrious of his ancestors had ever possessed; and lamented the fate of his country, about to be ruined by the rapaciousness and insolence of foreign favourites. While his mind was agitated by these passions, he received a letter from the king; in which, after a few cold and formal expressions of regard, he was allowed to retire to his diocese; and he expired a few hours after reading it in 1517, in the 81st year of his age.

This famous cardinal ought not to be confounded with *Roderick* XIMENES, archbishop of Toledo, in the 13th century, who wrote a History of Spain in nine books; nor with several other Spanish writers of the name of *Ximenes*.

XIPHIAS, in zoology, the SWORD-FISH; a genus of fishes belonging to the order of *apodes*. The upper jaw terminates in a long sword-shaped rostrum, from which it is called the *sword-fish*: there are no teeth in the mouth; the gill-membrane has eight rays; and the body is somewhat cylindrical. There is but one species, *viz.* the *gladius*, found in the European ocean. This fish sometimes frequents our coasts, but is much more common in the Mediterranean Sea, especially in the part that separates Italy from Sicily, which has been long celebrated for it: the promontory Pelorus, now Capo di Faro, was a place noted for the resort of the xiphias, and possibly the station of the speculatores, or the persons who watched and gave notice of the approach of the fish.

The ancient method of taking them is particularly described by Strabo, and agrees exactly with that practised by the moderns. A man ascends one of the cliffs that overhangs the sea: as soon as he spies the fish, he gives notice, either by his voice or by signs, of the course it takes. Another, that is stationed in a boat, climbs up the mast, and on seeing the sword-fish, directs the rowers towards it. As soon as he thinks they are got within reach, he descends, and taking a spear in his hand, strikes it into the fish; which, after wearying itself with its agitation, is seized and drawn into the boat. It is much esteemed by the Sicilians, who buy it up eagerly, and at its first coming into season give about sixpence English *per* pound. The season lasts from May till August. The ancients used to cut this fish into pieces and salt it; whence it was called *Tomus Thurianus*, from Thurii, a town in the bay of Tarentum, where it was taken and cured. Xylo-aloes.

The sword-fish is said to be very voracious, and that it is a great enemy to the tunny, who (according to Belon) are as much terrified at it as sheep are at the sight of a wolf. It is a great enemy to the whales, and frequently destroys them. See BALÆNA.

XYLO-ALOES, or ALOE-WOOD, in the materia medica, is the product of a tree growing in China and some of the Indian islands. See EXCÆCARIA.

This drug is distinguished into three sorts: the calambac or tambac, the common lignum aloes, and calambour.

The calamback, or finest aloes-wood, called by authors *lignum aloes præstantissimum*, and by the Chinese *sukhiang*, is the most resinous of all the woods we are acquainted with: it is of a light spongy texture, very porous, and its pores so filled up with a soft and fragrant resin, that the whole may be pressed and dented by the fingers like wax, or moulded about by chewing in the mouth, in the manner of mastich. This kind, laid on the fire, melts in great parts like resin, and burns away in a few moments with a bright flame and perfumed smell. Its scent, while in the mass, is very fragrant and agreeable; and its taste acrid and bitterish, but very aromatic and agreeable. It is so variable in its colour, that some have divided it into three kinds; the one variegated with black and purple; the second, with the same black, but with yellowish instead of purple; and the third, yellow alone like the yolk of an egg; this last is the least scented of the three. The variation, however, is owing to the trunk of the tree being itself of three different colours; and the heart of it is the valuable sort first described. The two following are supposed to be the other parts of the trunk; though this seems doubtful, especially in regard to the last sort, from the circumstances mentioned of its being found in large logs entire, and sometimes only the *heart*, which, as above noticed, constitutes the calambac.

The lignum aloes vulgare is the second in value. This is of a more dense and compact texture, and consequently less resinous than the other; there is some of it, however, that is spongy, and has the holes filled up with the right resinous matter; and all of it, when good, has veins of the same resin in it. We meet with it in small fragments, which have been cut and split from larger: these are of a tolerably dense texture in the more solid pieces, and of a dusky brown colour, variegated with resinous black veins. It is in this state very heavy, and less fragrant than in those pieces which show a multitude of little holes, filled up with the same blackish matter that forms the veins in others. The woody part of these last pieces is somewhat darker than the other, and is not unfrequently purplish, or even blackish. The smell of the common aloe-wood is very agreeable, but not so strongly perfumed as the former. Its taste is somewhat bitter and acrid, but very aromatic.

The calambour, called also *agallochum sylvestre*, and *lignum aloes mexicanum*, is light and friable, of a dusky and often mottled colour, between a dusky green black and a deep brown. Its smell is fragrant and agreeable, but much less sweet than that of either of the others; and its taste bitterish, but not so much acrid or aromatic as either of the two former. This is said to be met with very frequently, and in large logs: and these sometimes entire, sometimes only the heart of the tree. This is the aloe-wood used by the cabinet-makers and inlayers.

This drug is esteemed a cordial taken inwardly; and is sometimes given in disorders of the stomach and bowels, and to destroy the worms. A very fragrant oil may be procured from it by distillation; which is recommended in paralytic cases from five to fifteen drops. It is at present, however,

Xynoecia, Xyſtarcha.

however, but little uſed; and would ſcarce be met with anywhere in the ſhops, but that it is an ingredient in ſome of the old compoſitions.

XYNOECIA, in Grecian antiquity, an anniverſary feaſt obſerved by the Athenians in honour of Minerva, upon the ſixteenth of Hecatombæon, to commemorate their leaving, by the perſuaſion of Theſus, their country-ſeats, in which they lay diſperſed here and there in Attica, and uniting together in one body.

XYSTARCHA, in antiquity, the maſter or director of the xyſtus. In the Greek gymnaſium, the xyſtarcha was the ſecond officer, and the gymnaſiarcha the firſt; the former was his lieutenant, and preſided over the two xyſti, and all the exerciſes of the athletæ therein. Xyſtus.

XYSTUS, among the Greeks, was a long portico, open or covered at the top, where the athletæ practiſed wreſtling and running: the gladiators, who practiſed therein, were called *xyſtici*. Among the Romans, the xyſtus was only an alley, or double row of trees, meeting like an arbour, and forming a ſhade to walk under.

Y.

Y ‖ Yard.

Y, or y, the 23d letter of our alphabet: its ſound is formed by expreſſing the breath with a ſudden expanſion of the lips from that configuration by which we expreſs the vowel *u*. It is one of the ambigenial letters, being a conſonant in the beginning of words, and placed before all vowels, as in *yard, yield, young*, &c. but before no conſonant. At the end of words it is a vowel, and is ſubſtituted for the ſound of *i*, as in *try, deſcry*, &c. In the middle of words it is not uſed ſo frequently as *i* is, unleſs in words derived from the Greek, as in *chyle, empyreal*, &c. though it is admitted into the middle of ſome pure Engliſh words, as in *dying, flying*, &c. The Romans had no capital of this letter, but uſed the ſmall one in the middle and laſt ſyllables of words, as in *coryambus, onyx, martyr*. Y is alſo a numeral, ſignifying 150, or according to Baronius 159; and with a daſh a-top, as $\overline{Y}$, it ſignified 150,000.

YACHT, or YATCH, a veſſel of ſtate, uſually employed to convey princes, ambaſſadors, or other great perſonages, from one kingdom to another.

As the principal deſign of a yacht is to accommodate the paſſengers, it is uſually fitted with a variety of convenient apartments, with ſuitable furniture, according to the quality or number of the perſons contained therein.

The royal yachts are commonly rigged as ketches, except the principal one reſerved for the ſovereign, which is equipped with three maſts like a ſhip. They are in general elegantly furniſhed, and richly ornamented with ſculpture; and always commanded by captains in his majeſty's navy.

Beſides theſe, there are many other yachts of a ſmaller kind, employed by the commiſſioners of the exciſe, navy and cuſtoms; or uſed as pleaſure boats by private gentlemen.

YAMS. See DISCOREA.

YAMBOO. See EUGENIA.

YARD *of a* SHIP, a long piece of timber ſuſpended upon the maſts of a ſhip, to extend the ſails to the wind. See MAST and SAIL.

All yards are either ſquare or lateen; the former of which are ſuſpended acroſs the maſts at right angles, and the latter obliquely. See Plate CCCCXLIV, fig. 1.

The ſquare yards are nearly of a cylindrical ſurface. They taper from the middle, which is called the *ſlings*, towards the extremities, which are termed the *yard arms*; and the diſtance between the ſlings and the yard-arms on each ſide is by the artificers divided into quarters, which are diſtinguiſhed into the firſt, ſecond, third quarters, and yard-arms. The middle quarters are formed into eight ſquares, and each of the end parts is figured like the fruſtum of a cone. All the yards of a ſhip are ſquare except that of the mizen. Yard.

The proportions for the length of yards, according to the different claſſes of ſhips in the Britiſh navy, are as follows:

			Guns.
1000 : gun-deck : :	560 : 559 : 570 : 576 : 575 : 561 :	main-yard fig. 1. Pl. CCCLXIV.—Note, the figure repreſents the yard and ſails of a ſhip of 74 guns.	100 / 90 80 / 70 / 60 / 50 / 44
1000 : main-yard : :	880 : 874 :	fore-yard.	100 90 80 all the reſt.

To apply this rule to practice, ſuppoſe the gun-deck 144 feet. The proportion for this length is as 1000 is to 575, ſo is 144 to 83; which will be the length of the main-yard in feet, and ſo of all the reſt.

			Guns.
1000 main-yard : :	820 : 847 : 840 :	mizen-yard	100 90 80 60 44 / 70 / 24
1000 : main-yard : :	726 : 720 :	main topſail-yard	24 / all the reſt.
1000 : fore-yard : :	719 : 726 : 715 :	fore topſail-yard	70 / 24 / all the reſt.
1000 : main topſail-yard : :	main top gail. yard all the rates.		
1000 fore topſail-yard : :	696 : 690 :	fore top-gallant-yard.	70 / all the reſt.
1000 : fore topſail yard : :	768 : 750 :	mizen topſail-yard	70 / all the reſt.

Croſs-jack and ſprit-ſail yard equal to the fore topſail-yard.

Sprit-topſail-yard equal to the fore top-gallant-yard.

The diameters of yards are in the following proportions to their length.

The main and fore yards five-ſevenths of an inch to one yard. The topſail, croſs-jack, and ſprit-ſail yards, nine-fourteenths of an inch to one yard. The top-gallant, mizen top-ſail, and ſprit-ſail topſail yards, eight-thirteenths of an inch to one yard.

The mizen-yard five-ninths of an inch to one yard.

All ſtudding-ſail booms and yards half an inch to one yard in length.

The lifts of the main-yard are exhibited in the above figure by *gg*; the horſes and their ſtirrups by *h, i*; the reef-tackles and their pendents by *k, l*; and the braces and brace pendents by *m, n*.

The lateen-yards evidently derive their names from ha-

Yard ‖ Yawning.

ving been peculiar to the ancient Romans. They are uſually compoſed of ſeveral pieces faſtened together by woolds-ings, which alſo ſerve as ſteps whereby the ſailors climb to the peek or upper extremity, in order to furl or caſt looſe the ſail.

The mizen-yard of a ſhip, and the main-yard of a bilander, are hung obliquely on the maſt, almoſt in the ſame manner as the lateen-yard of a xebec, ſettee, or polacre.

YARD, a meaſure of length uſed in Britain and Spain, conſiſting of three feet, chiefly to meaſure cloth, ſtuffs, &c.

YARD-Arm is that half of the yard that is on either ſide of the maſt, when it lies athwart the ſhip.

YARDS alſo denote places belonging to the navy, where the ſhips of war, &c. are laid up in harbour.—There are belonging to his majeſty's navy ſix great yards, *viz.* Chatham, Deptford, Woolwich, Portſmouth, Sheerneſs, and Plymouth; theſe yards are fitted with ſeveral docks, wharfs, lanches, and graving places, for the building, repairing, and cleaning of his majeſty's ſhips; and therein are lodged great quantities of timber, maſts, planks, anchors, and other materials: there are alſo convenient ſtore-houſes in each yard, in which are laid up vaſt quantities of cables, rigging, ſails, blocks, and all other ſorts of ſtores needful for the royal navy.

YARE, among ſailors, implies ready or quick: as, be yare at the helm; that is, be quick, ready, and expeditious at the helm. It is ſometimes alſo uſed for bright by ſeamen: as, to keep his arms yare; that is, to keep them clean and bright.

YARE, a river of Norfolk, which runs from weſt to eaſt through that county, paſſing by Norwich, and falling into the German ſea at Yarmouth.

YARMOUTH, a ſea-port town of Norfolk, with a market on Wedneſdays and Saturdays, and a fair on Friday and Saturday in Eaſter-week for petty chapmen. It is ſeated on the river Yare, where it falls into the ſea; and is a place of great ſtrength, both by art and nature, being almoſt ſurrounded with water; and there is a draw-bridge over the river. It is eſteemed the key of this coaſt, and is a clean handſome place, whoſe houſes are well built, it being a conſiderable town for trade. It has one large church, and a neat chapel, and the ſteeple of St Nicholas's is ſo high that it ſerves for a ſea-mark. It is governed by a mayor. The harbour is a very fine one, though it is very dangerous for ſtrangers in windy weather; and it has for its ſecurity a pretty ſtrong fort. It is 27 miles eaſt of Norwich, and 112 north-eaſt of London. E. Long. 1. 55. N. Lat. 52. 45.

YARMOUTH, a town of the Iſle of Wight, in Hampſhire, with a market on Fridays, and one fair on July 25th for toys. It is ſeated on the weſtern part of the iſland, on the ſea-ſhore, and is encompaſſed with water; for, not many years ago a channel was cut through the peninſula, over which there is a draw-bridge, and it is defended by a ſtrong caſtle on the quay. It is a handſome place, whoſe houſes are chiefly built with ſtone, and covered with ſlate; and it ſends two members to parliament. The market is now diſuſed. W. Long. 1. 28. N. Lat. 50. 40.

YARN, wool or flax ſpun into thread, of which they weave cloth. See CLOTH.

YARROW, in botany. See ACHILLÆA.

YAWNING, an involuntary opening of the mouth, generally produced by wearineſs or an inclination to ſleep. Yawning, according to Boerhaave, is performed by expanding at one and the ſame time all the muſcles capable of ſpontaneous motion; by greatly extending the lungs; by drawing in gradually and ſlowly a large quantity of air; and gradually and ſlowly breathing it out, after it has been retained for ſome time and rarefied; and then reſtoring the muſcles to their natural ſtate. Hence the effect of yawning is to move, accelerate, and equally diſtribute all the humours through all the veſſels of the body, and conſequently to qualify the muſcles and organs of ſenſation for their various functions. Year.

Sanctorius obſerves, that a great deal is inſenſibly diſcharged, when nature endeavours to get rid of the retained perſpirable matter, by yawning and ſtretching of the limbs. To theſe a perſon is moſt inclined juſt after ſleep, becauſe a greater quantity going off by the pores of the ſkin than at other times, whenſoever a perſon wakes, the increaſing contraction that then happens cloſes a great deal of the perſpirable matter in the cutaneous paſſages, which will continually give ſuch irritations as excite yawning and ſtretching; and ſuch motions, by ſhaking the membranes of the whole body, and ſhifting the contacts of their fibres, and the incloſed matter, by degrees throw it off. Hence we ſee the reaſon why healthful ſtrong people are moſt inclined to ſuch motions, becauſe they perſpire moſt in time of ſleep, and therefore have more of the perſpirable matter to lodge in the pores, and greater irritations thereunto. The advantages of ſome little exerciſe juſt after waking in a morning are conſiderable, as it throws off all the perſpirable matter that is ready for its exit out of the body. When yawning is troubleſome, Hippocrates ſays that long deep reſpiration or drawing in the air at long intervals cures it.

YEAR, in aſtronomy and chronology. See ASTRONOMY, n° 347. p. 520. and KALENDAR.

The ancient Roman year was the lunar year, which, as firſt ſettled by Romulus, conſiſted only of ten months; *viz.* 1. March, containing 31 days. 2. April, 30. 3. May, 31. 4. June, 30. 5. Quintilis, 31. 6. Sextilis, 30. 7. September, 30. 8. October, 31. 9. November, 30. 10. December, 30.—in all 304 days; which came ſhort of the true lunar year by 50 days, and of the ſolar, by 61 days. Numa Pompilius corrected this irregular conſtitution of the year, and compoſed two new months, January and February, of the days that were uſed to be added to the former year.

The ancient Egyptian year, called alſo the *year of Nabonaſſar*, on account of the epocha of Nabonaſſar, is the ſolar year of 365 days, divided into 12 months, of 30 days each, beſides five intercalary days added at the end. The names, &c. of the months are as follows: 1. Thoth. 2. Paophi. 3. Athyr. 4. Chojac. 5. Tybi. 6. Mecheir. 7. Phamenoth. 8. Pharmuthi. 9. Pachon. 10. Pauni. 11. Epiphi. 12. Meſori; beſide the ἡμέραι ἐπαγόμεναι.

The ancient Greek year was lunar; conſiſting of 12 months, which at firſt had 30 days apiece, then alternately 30 and 29 days, computed from the firſt appearance of the new moon; with the addition of an emboliſmic month of 30 days every 3d, 5th, 8th, 11th, 14th, 16th, and 19th year of a cycle of 19 years; in order to keep the new and full moons to the ſame terms or ſeaſons of the year. Their year commenced with that new moon, the full moon of which comes next after the ſummer ſolſtice. The order, &c. of their months was thus: 1. Ἑκατομβαιών, containing 29 days. 2. Μεταγειτνιών 30. 3. Βοηδρομιών, 29. 4. Μαιμακτηριών, 30. 5. Πυανεψιών, 29. 6. Ποσειδεών, 30. 7. Γαμηλιών, 29. 8. Ανθεστηριών, 30. 9. Ελαφηβολιών, 30. 10. Μουνυχιών, 30. 11. Θαργηλιών, 29. 12. Σκιροφοριών, 30.

The ancient Jewiſh year is a lunar year, conſiſting commonly of 11 months, which alternately contain 30 and 29 days. It was made to agree with the ſolar year, either by the adding of 11, and ſometimes 12 days, at the end of the year, or by an emboliſmic month. The names and quanti-

ties

Year. ties of the months ſtand thus: 1. Niſan, or Abib, 30 days. 2. Jiar, or Zius, 29. 3. Siban, or Siwan, 30. 4. Thammuz, or Tammuz, 29. 5. Ab, 30. 6. Elul, 29. 7. Tiſri, or Ethanim, 30. 8. Marcheſvam, or Bul, 29. 9. Ciſleu, 30. 10. Tebeth, 29. 11. Sabat, or Schebeth, 30. 12. Adar, in the emboliſmic year, 30. Adar, in the common year, was but 29. Note, in the defective year, Ciſleu was only 29 days; and in the redundant year, Marcheſvam was 30.

The Perſian year is a ſolar year of about 365 days; conſiſting of 12 months of 30 days each, with 5 intercalary days added at the end.

The Arabic, Mahometan, and Turkiſh years, called alſo the *year of the Hegira*, is a lunar year, equal to 354 days 8 hours and 48 minutes, and conſiſts of 12 months, which contain alternately 30 and 29 days.

The Hindoo year differs from all theſe, and is indeed different in different provinces of India. The beſt account that we have of it is by Mr Cavendiſh, in the Phil. Tranſ. of the Royal Society of London for the year 1792. "Before I ſpeak of the civil year of the Hindoos (ſays this eminent philoſopher), it will be proper to ſay a few words of the aſtronomical year, by which it is regulated.

"The aſtronomical year begins at the inſtant when the ſun comes to the firſt point of the Hindoo zodiac. In the year 1792, it began on April 9th, at 22h. 14′ after midnight of their firſt meridian, which is about 41′ of time weſt of Calcutta; but, according to Mr Gentil's account of the Indian aſtronomy, it began 3 h. 24′ earlier. As this year, however, is longer than ours, its commencement falls continually later, in reſpect of the Julian year, by 50′ 26″ in four years. This year is divided into 12 months, each of which correſponds to the time of the ſun's ſtay in ſome ſign; ſo that they are of different lengths, and ſeldom begin at the beginning of a day.

"The civil day in all parts of India begins at ſunriſe, and is divided into 60 parts called *dandas*, which are again divided into 60 palas. In thoſe parts of India in which the Benares almanac, or as it is there called *patras*, is uſed, the civil year is luniſolar, conſiſting of 12 lunar months, with an intercalary month inſerted between them occaſionally. It begins at the day after the new moon next before the beginning of the ſolar year. The lunar month is divided into 30 parts called *teethees*; theſe are not ſtrictly of the ſame length, but are equal to the time in which the moon's true motion from the ſun is 12°. From the new moon till the moon arrives at 12° diſtance from the ſun is called the firſt *teethee*; from thence till it comes to 24°, is called the ſecond *teethee*; and ſo on till the full moon, after which the teethees return in the ſame order as before.

"The civil day is conſtantly called by the number of that teethee which expires during the courſe of the day; and as the teethee is ſometimes longer than one day, a day ſometimes occurs in which no teethee ends. When this is the caſe, the day is called by the ſame number as the following day; ſo that two ſucceſſive days go by the ſame name. It oftener happens, however, that two teethees end on the ſame day; in which caſe the number of the firſt of them gives name to the day, and there is no day called by the number of the laſt, ſo that a gap is made in the order of the days. In the latter part of the month the days are counted from the full moon, in the ſame manner as in the former part they are counted from the new moon; only the laſt day, or that on which the new moon happens, is called the *30th*, inſtead of the *15th*. It appears, therefore, that each half of the month conſtantly begins on the day after that on which the new or full moon falls; only ſometimes the half month begins with the ſecond day, the firſt being wanting.

"This manner of counting the days is ſufficiently intricate; but that of counting the months is ſtill more ſo. Year, Yeaſt.

"The civil year, as was before ſaid, begins at the day after the new moon; and, moreover, in the years which have an intercalary month, this month begins at the day after the new moon; but notwithſtanding this, the ordinary civil month begins at the day after the full moon. To make their method more intelligible, we will call the time from new moon to new moon the natural month. The civil month Viſākha, the firſt in the Hindoo kalender, which extends from the 9th of our April to the 10th of May, begins at the day after that full moon which is neareſt to the inſtant at which the ſun enters Meſha, the firſt in order of the Indian ſigns, whether before or after; however, it is not always accurately the neareſt.

"A conſequence of this way of counting the months is, that the firſt half of Chitra, the laſt month in the Indian kalender, extending from March the 10th to April the 9th, falls in one year, and the latter half in the following year; and whenever the ſun enters no ſign during a natural month, this month is intercalary. The number of days in the month varies from 29 to 32. Indeed the Hindoo months, both ſolar and lunar, conſiſt neither of a determinate number of days, nor are regulated by any cycle, but depend ſolely on the motions of the ſun and moon; ſo that a Hindoo has no way of knowing what day of the month it is but by conſulting his almanac; and what is more, the month ought ſometimes to begin on different days, in different places, on account of the difference in latitude and longitude, not to mention the difference which may ariſe from errors in computation. This mode of computing time muſt be attended with many inconveniences; but in the tranſactions of civil life the Hindoos do not much regard it. A diſagreement, however, in the computation of the teethee, which ſometimes alſo happens, occaſions no ſmall perplexity; becauſe by the teethees or lunar days are regulated moſt of their religious feſtivals. Every Brahmin in charge of a temple, or whoſe duty is to announce the times for the obſervance of religious ceremonies, is therefore furniſhed with one of their almanacs; and if he be an aſtronomer, he makes ſuch corrections in it as the difference of latitude and longitude render neceſſary."

New Year's Gift. See Gift.

YEAST, or YEST, a head or ſcum riſing upon beer or ale while working or fermenting in the vat. See BREWING.

It is uſed for a leaven or ferment in the baking of bread, as ſerving to ſwell or puff it up very conſiderably in a little time, and to make it much lighter, ſofter, and more delicate. See BAKING, BARM, and BREAD.

Mr Henry has publiſhed a method of preparing *artificial yeaſt*, by which good bread may be made without the aſſiſtance of any other ferment. The method is this: Boil flour and water together to the conſiſtence of treacle, and when the mixture is cold ſaturate it with fixed air. Pour the mixture thus ſaturated into one or more large bottles or narrow-mouthed jars: cover it over looſely with paper, and upon that lay a ſlate or board with a weight to keep it ſteady. Place the veſſel in a ſituation where the thermometer will ſtand from 70° to 80°, and ſtir up the mixture two or three times in 24 hours. In about two days ſuch a degree of fermentation will have taken place, as to give the mixture the appearance of yeaſt. With the yeaſt in this ſtate, and before it has acquired a thoroughly vinous ſmell, mix the quantity of flour intended for bread, in the proportion of ſix pounds of flour to a quart of the yeaſt, and a ſufficient portion of warm water. Knead them well together

in

Yeaſt ‖ Yellow.

in a proper veſſel, and covering it with a cloth, let the dough ſtand for 12 hours, or till it appears to be ſufficiently fermented in the fore-mentioned degree of warmth. It is then to be formed into loaves and baked. Mr Henry adds, that perhaps the yeaſt would be more perfect, if a decoction of malt were uſed inſtead of ſimple water.

It has lately been diſcovered, that a decoction of malt alone, without any addition, will produce a yeaſt proper enough for the purpoſe of brewing. This diſcovery was made by Joſeph Senyor, ſervant of the reverend Mr Maſon of Aſton near Rotheram; and he received for it a reward of L. 20 from the Society for promoting Arts, Manufactures, and Commerce. The proceſs is as follows: Procure three earthen or wooden veſſels of different ſizes and apertures, one capable of holding two quarts, the other three or four, and the third five or ſix: boil a quarter of a peck of malt for about eight or ten minutes in three pints of water; and when a quart is poured off from the grains, let it ſtand in the firſt or ſmaller veſſel in a cool place till not quite cold, but retaining that degree of heat which the brewers uſually find to be proper when they begin to work their liquor. Then remove the veſſel into ſome warm ſituation near a fire, where the thermometer ſtands between 70 and 80 degrees Fahrenheit, and there let it remain till the fermentation begins, which will be plainly perceived within 30 hours: add then two quarts more of a like decoction of malt, when cool, as the firſt was; and mix the whole in the ſecond or larger veſſel, and ſtir it well in, which muſt be repeated in the uſual way, as it riſes in a common vat; then add a ſtill greater quantity of the ſame decoction, to be worked in the largeſt veſſel, which will produce yeaſt enough for a brewing of 40 gallons.

Common ale yeaſt may be kept freſh and fit for uſe ſeveral months by the following method: Put a quantity of it into a cloſe canvas bag, and gently ſqueeze out the moiſture in a ſcrew-preſs till the remaining matter be as firm and ſtiff as clay. In this ſtate it may be cloſe packed up in a tight caſk for ſecuring it from the air; and will keep freſh, ſound, and fit for uſe, for a long time. This is a ſecret that might be of great uſe to the brewers and diſtillers, who, though they employ very large quantities of yeaſt, ſeem to know no method of preſerving it, or raiſing nurſeries of it; for want of which they ſuſtain a very conſiderable loſs; whereas the brewers in Flanders make a very great advantage of ſupplying the malt-diſtillers of Holland with yeaſt, which is rendered laſting and fit for carriage by this eaſy expedient.

YELL, one of the iſlands of Shetland, lying north-eaſt from the main land, and divided from it by an arm of the ſea, called *Yell-Sound*. By ſome it is thought to have been the *Thule* of the ancients. In the old deſcriptions it is ſaid to be 20 miles long and 8 broad. It is very mountainous and full of moſs; but there are pretty conſiderable paſtures in which they feed a great many ſheep; and it alſo affords plenty of peat. It has eight large harbours, which would not be thought deſpicable in other countries. Anciently it ſeems to have been pretty populous, ſince there are in it three churches, twenty chapels, and many brughs or Pictiſh forts.

YELLOW, one of the original colours of light.

Yellow-Colour for Houſe-painting. See CHEMISTRY, n° 699.

Naples Yellow, a beautiful colour much uſed by painters, formerly thought to be prepared from arſenic, but now diſcovered to have lead for its baſis.

Yellow-Hammer, in ornithology. See FRINGILLA.

Yellow-Fever. See MEDICINE, n° 168.

YEMEN, a province of Arabia, ſtretching along the Red Sea and Indian Ocean, and forming a part of the country once known by the name of Arabia Felix.

Yemen ‖ York.

YEOMAN, the firſt or higheſt degree among the plebeians of England, next in order to the gentry.

The yeomen are properly freeholders, who having land of their own, live on good huſbandry.

YEOMEN is alſo a title of office in the king's houſehold, of a middle place or rank between an uſher and a groom.

Yeomen of the Guard were anciently 250 men of the beſt rank under gentry, and of larger ſtature than ordinary, each being required to be ſix feet high. At preſent there are but 100 yeomen in conſtant duty, and 70 more not in duty; and as any of the 100 dies, his place is ſupplied out of the 70. They go dreſſed after the manner of King Hen. VIII.'s time. They formerly had diet as well as wages when in waiting; but this was taken off in the reign of Queen Anne.

YEST, or YEAST. See YEAST.

YEW, in botany. See TAXUS.

YNCA, an appellation anciently given to the kings of Peru, and the princes of their blood; the word literally ſignifying, lord, king, emperor, and royal blood.

YOAK, or YOKE, in agriculture, a frame of wood fitted over the necks of oxen, whereby they are coupled together, and harneſſed to the plough.

Yoak of Land, in our ancient cuſtoms, was the ſpace which a yoke of oxen, that is, two oxen, may plow in one day.

YOLK, the yellow part in the middle of an egg (ſee EGG). It contains a lymphatic ſubſtance mixed with a certain quantity of mild oil, which, on account of this mixture, is ſoluble in water. When expoſed to heat, it aſſumes a conſiſtence not ſo hard as the white of the egg; and when bruiſed gives out the oil which it contains. This oil has been uſed externally as a liniment.

YONNE, a river in France, which riſing in Burgundy, and running north through Nivernois and Champaign, falls into the Seyne at Monterau ſur Yonne.

YORK, in Latin *Eboracum*, the capital of Yorkſhire in England. This city is ſo ancient that the origin of it is uncertain. In the time of the Romans a legion was ſtationed here, it being then the capital of the Brigantes; and here died the emperor Severus, and Flavius Valerius Conſtantius Chlorus, father of Conſtantine the Great. There was then alſo a temple of Bellona here, and no leſs than three military ways went from hence. In the time of the Saxons it was erected into an archbiſhopric by Pope Honorius, to which are now ſubject the biſhoprics of Cheſter, Durham, Carliſle, and the Iſle of Man; though anciently 12 biſhoprics in England, and all Scotland, were. A horn is ſtill kept in the miniſter, by which Ulphius, one of the Saxon princes, beſtowed all his lands and revenues upon the church.

This city ſuffered very much during the ravages of the Danes; but, after the conqueſt, it began to flouriſh again. The cathedral, which coſt a long time and a great deal of money in building, is a moſt ſtately Gothic pile. Its chapter-houſe is particularly admired for its painted glaſs, its fine marble ſtalls, its pillars of alabaſter, and curious contrivance. In it is the following line in gold letters:

Ut Roſa, flos florum, ſic eſt Domus iſta Domorum.

The choir is remarkable for its fine carvings, particularly the ſtatues of all the Engliſh monarchs; and the windows are exquiſitely painted with the hiſtory of the Bible. The lanthorn ſteeple is 70 feet ſquare, and 188 high, and the windows are 45. At the ſouth end is a circular light, called

York. Yorkſhire.

ed the *marigold window* from the colour of its glaſs; and at the north end is a very large one, whoſe painting repreſents embroidery.

This city is generally reckoned the ſecond city in England; but though it ſtands upon more ground, it is inferior in trade, wealth, and number of people, to Briſtol. The inhabitants are reckoned at 12,784. It is ſituate in a fine plain, in the middle of the ſhire, on both ſides the Ouſe, walled and divided into four wards, containing 28 pariſhes. It enjoys large privileges and immunities, conferred upon it by a ſucceſſion of kings from Henry II. and its chief magiſtrate has the title of *lord mayor*, which is an honour peculiar to it and London. Richard II. made it a county of itſelf. The conſervancy of moſt of the rivers of the county, within certain limits, belongs to the lord mayor and aldermen. The middle arch of the bridge here over the Ouſe is thought to equal the Rialto at Venice in architecture, height, and breadth, the diameter being 81 feet, and the height 51. Though this city is 60 miles diſtant from the ſea, yet ſhips of 70 tons burden come up the river to it. The town-houſe or Guild-hall ſtands upon the bridge, and is ſuperior in all reſpects to that of London. In the Popiſh times there were nine abbeys here, and a vaſt number of churches; but of the latter there are only 17 now. The ſteeple of that of Allhallows is reckoned the fineſt in England. The archbiſhop has a fine palace; and the aſſembly-room, deſigned by the earl of Burlington, is very noble. Here are plays, aſſemblies, concerts, and the like entertainments, at ſome houſe or other, almoſt every night in the week. In the old caſtle, built originally by William the Conqueror, and repaired in 1701, the aſſizes are kept. It ſerves alſo for the county-goal, which is the neateſt and pleaſanteſt in England, with an area larger than that of the King's-bench, and it has a handſome chapel in it, with a good allowance for a preacher. This city has long given the title of *duke* to ſome branch of the royal family.

The plenty and cheapneſs of proviſions induces many perſons of ſmall fortune, or that would live frugally, to take up their abode here; and the venerable remains of Roman antiquities, and thoſe of a later date, as abbeys, churches, and caſtles, procure this city a viſit from every curious traveller. Many Roman altars, urns, coins, inſcriptions, &c. have been found; and Saxon coins are ſtill extant that have been ſtruck here. The members for this city have precedence of all others, except thoſe of London, in the houſe of commons. An infirmary, after the manner of thoſe of Bath, Briſtol, &c. hath been erected in it; and a cotton manufacture eſtabliſhed and brought to great perfection. Beſides four weekly markets, it has a great many fairs; one, in particular, every other Thurſday for cattle and ſheep. W. Long. 1. 1. N. Lat. 53. 59.

YORKSHIRE, the largeſt county of England, bounded on the ſouth by Derbyſhire, Nottinghamſhire, and Lincolnſhire; on the north by Durham and Weſtmoreland; on the eaſt by the German Ocean; and on the weſt by Lancaſhire and a part of Cheſhire.—It is upwards of 80 miles in length from eaſt to weſt, nearly as much in breadth, and about 360 in circumference, containing, in the whole, 26 hundreds or wapentakes, 49 market-towns, 563 pariſhes, 242 vicarages, with many chapels of eaſe, and 2330 villages. Its area is computed by ſome at 4684 ſquare miles, by others at 3,770,000 acres, and its inhabitants at upwards of 530,000. It is divided into three parts or ridings, viz. the Weſt, Eaſt, and North; ſo denominated from their ſituation, in reſpect of the city of York. Each of theſe is as large, if not larger than any ordinary county. There are other diviſions, as Richmondſhire, Allertonſhire, Howdenſhire, Hallamſhire, Craven, Cleveland, Marſhland, Holderneſs, &c.

As the ſoil and face of the country vary greatly, ſo does the air. In the hilly parts the air is good, but the ſoil very indifferent; of the lower ſome are marſhy, others drier, and the ſoil of both rich; but the air of the former is more foggy and unhealthy than that of the latter. The manufactures of this country are cutlery and hard-wares; particularly knives, bits, and ſpurs; but the principal are ſtockings and woollen cloth, with which it ſupplies in a great meaſure Germany and the North. As to the produce, it abounds in corn, cattle, horſes, lead, and iron, coal, wood, lime, liquorice, alum, jet, &c. It lies wholly in the northern circuit, and much the greater part of it in the dioceſe of York; that only which is called *Richmondſhire* belonging to the dioceſe of Cheſter. The members it ſends to parliament are 30; of which two are for the ſhire and 28 for the towns.

New-York.

New-York, one of the United States of America, is bounded towards the ſouth-eaſt by the Atlantic Ocean; eaſt by Connecticut, Maſſachuſets, and Vermont; north by the 45th degree of latitude, which divides it from Canada; northweſtwardly by the river Iroquois or St Lawrence, and the lakes Ontario and Erie; ſouthweſt and ſouth by Pennſylvania and New Jerſey. The whole ſtate contains about 44,000 ſquare miles, equal to 28,160,000 acres.

The ſettlements already made in this ſtate are chiefly upon two narrow oblongs, extending from the city of New York eaſt and north. The one eaſt is Long Iſland, which is 140 miles long, and narrow, and ſurrounded by the ſea. The one extending north is about 40 miles in breadth, and biſected by Hudſon's river. And ſuch is the interſection of the whole ſtate by the branches of the Hudſon, the Delaware, the Suſquehannah, and other large rivers, that there are few places throughout its whole extent which are more than 15 or 20 miles from ſome navigable ſtream. There are few fiſh in the rivers, but in the brooks are plenty of trout; and on the lakes yellow perch, ſun-fiſh, ſalmon-trout, catfiſh, and a variety of others.

The State, to ſpeak generally, abounds with lakes, ſome of ſalt and others of freſh water. It is interſected by ridges of mountains running in a north-eaſt and ſouth-weſt direction. Beyond the Allegany mountains, however, the country is a dead level, of a fine rich ſoil, covered, in its natural ſtate, with maple, beach, birch, cherry, black-walnut, locuſt, hickory, and ſome mulberry trees. On the banks of lake Erie are a few cheſnut and oak ridges. Hemlock ſwamps are interſperſed thinly through the country. All the creeks that empty into lake Erie have falls, which afford many excellent mill ſeats. Eaſt of the Allegany mountains, the country is broken into hills with rich intervening valleys. The hills are clothed thick with timber, and when cleared afford fine paſture; the valleys, when cultivated, produce wheat, hemp, flax, peaſe, graſs, oats, Indian corn. Of the commodities produced from culture, wheat is the ſtaple; of which immenſe quantities are raiſed and exported. Indian corn and peaſe are likewiſe raiſed for exportation; and rye, oats, barley, &c. for home conſumption. In ſome parts of the State excellent dairies are kept, which furniſh for the market butter and cheeſe.

The ſituation of New York, with reſpect to foreign markets, has decidedly the preference to any other of the United States. It has at all ſeaſons of the year a ſhort and eaſy acceſs to the ocean. Its exports to the Weſt Indies are, biſcuit, peaſe, Indian corn, apples, onions, boards, ſtaves, horſes, ſheep, butter, cheeſe, pickled oyſters, beef, and pork. But wheat is the ſtaple commodity of the State, of which

no

New-York. no less than 677,700 bushels were exported in the year 1775, besides 2555 tons of bread and 2828 tons of flour. Inspectors of flour are appointed to prevent impositions, and to see that none is exported but that which is deemed by them merchantable. Besides the above-mentioned articles, are exported flax-seed, cotton, wool, sarsaparilla, coffee, indigo, rice, pig-iron, bar-iron, pot-ash, pearl-ash, furs, deer-skins, logwood, fustick, mahogany, bees-wax, oil, Madeira wine, rum, tar, pitch, turpentine, whale-fins, fish, sugars, molasses, salt, tobacco, lard, &c. but most of these articles are imported for re-exportation. In the year 1774, there were employed, in the trade of this State, 1075 vessels, whose tonnage amounted to 40,812.

Since the revolution the literature of the State has engaged the attention of the legislature. In one of their earliest sessions an act passed, constituting 21 gentlemen (of whom the governor and lieutenant-governor for the time being are members *ex officiis*) a body corporate and politic, by the name and style of "The regents of the university of the State of New-York." They are intrusted with the care of literature in general in the State, and have power to grant charters of incorporation for erecting colleges and academies throughout the state—are to visit these institutions as often as they shall think proper, and report their state to the legislature once a year. All degrees above that of master of arts are to be conferred by the regents. A universal toleration is granted in religion.

The supreme legislative powers of the State are vested in two branches, a senate and assembly. The members of the senate are elected by the freeholders of the State, who possess freehold estates to the value of L. 100 clear of debts. For the purpose of electing senators, the State is divided into four great districts, each of which chooses a certain number.

The assembly of the State is composed of representatives from the several counties, chosen annually in May. Every male inhabitant of full age, who has resided in the State six months preceding the day of election, and possessing a freehold to the value of L. 20, in the county where he is to give his vote; or has rented a tenement therein of the yearly value of forty shillings, and has been rated and actually paid taxes—is intitled to vote for representatives in assembly. The number of representatives is limited to 300.

The supreme executive power of the State is vested in a governor chosen once in three years by the freemen of the State. The lieutenant governor is, by his office, president of the senate; and, upon an equal division of voices, has a casting vote; but has no voice on other occasions. The governor has not a seat in the legislature; but as a member of the council of revision and council of appointment, he has a vast influence in the State. The council of revision is composed of the chancellor, the judges of the supreme court, or any of them, and the governor. In the year 1790 the number of inhabitants in this State was 340,120, of whom 21,324 were negroes.

New-York, a city of North America, capital of the State of the same name. It is situated at the south-west point of an island, at the confluence of Hudson and East rivers, and is about four miles in circumference. The situation is both healthy and pleasant. Surrounded on all sides by water, it is refreshed by cool breezes in summer, and the air in winter is more temperate than in other places under the same parallel. York Island is 15 miles in length, and hardly one in breadth. It is joined to the main by a bridge called King's Bridge. The channels between Long and Staten Islands, and between Long and York Islands, are so narrow as to occasion an unusual rapidity of the tides, which is increased by the confluence of the waters of Hudson and East rivers. This rapidity, in general, prevents the obstruction of the channel by ice. There is no bason or bay for the reception of ships, but the road where they lie in East river is defended from the violence of the sea by the islands which interlock with each other; so that, except that of Rhode Island, the harbour of New-York, which admits ships of any burden, is the best of the United States. The number of inhabitants in 1790 was 33,131. New-York is 97 miles north-east of Philadelphia. W. Long. 74. 5. N. Lat. 40. 43.

Young. YOUNG (Dr Edward), was the son of a clergyman of the same name, and was born about the year 1679. When sufficiently qualified, he was matriculated into All-Souls college, Oxford; and designing to follow the civil law, he took a degree in that profession. In this situation he wrote his poems called *The Last Day*, published in 1704; which coming from a layman gave universal satisfaction: this was soon after followed by another, intitled *The Force of Religion*, or *Vanquished Love*. These productions gained him a respectable acquaintance; he was intimate with Addison, and thus became one of the writers of the Spectator: but the turn of his mind leading him to the church, he took orders, was made one of the king's chaplains, and obtained the living of Welwyn in Hartfordshire, worth about L. 500 *per annum*, but he never rose to higher preferment. For some years before the death of the late prince of Wales, Dr Young attended his court pretty constantly; but upon his decease all his hopes of church preferment vanished; however, upon the death of Dr Hales, he was taken into the service of the princess-dowager of Wales, and succeeded him as her privy chaplain. When pretty far advanced in life, he married the lady Elizabeth Lee, daughter of the late earl of Litchfield. This lady was a widow, and had an amiable son and daughter, who both died young. What he felt for their loss, as well as for that of his wife, is finely expressed in his Night Thoughts, in which the young lady is characterised under the name of Narcissa; her brother by that of Philander; and his wife, though nameless, is frequently mentioned; and he thus, in an apostrophe to death, deplores the loss of all the three.

Insatiate archer, could not once suffice!
Thy shaft flew thrice, and thrice my peace was slain,
And thrice ere thrice yon moon renew'd her horn.

He wrote three tragedies, *The Revenge*, *Busiris*, and *The Brothers*. His satires, called *Love of Fame the universal Passion*, are by many esteemed his principal performance; though Swift said the poet should have been either more angry or more merry: they have been characterised as a string of epigrams written on one subject, that tire the reader before he gets through them. His *Complaint*, or *Night Thoughts*, exhibit him as a moral and melancholy poet, and are esteemed his masterpiece. They form a species of poetry peculiarly his own, and in which he has been unrivalled by all those who attempted to write in this manner. They were written under the recent pressure of his sorrow for the loss of his wife, daughter, and son-in-law; they are addressed to Lorenzo, a man of pleasure and the world, and who, as it is insinuated by some, is his own son, but then labouring under his father's displeasure. As a prose-writer, he arraigned the prevailing manners of his time, in a work called *The Centaur not Fabulous*; and when he was above 80 years of age, published *Conjectures on Original Composition*. He published some other pieces; and the whole of his works are collected in 4 and 5 vols 12mo. Dr Young's turn of mind was naturally solemn; and he usually, when

Young. when at home in the country, ſpent many hours of the day walking in his own church-yard among the tombs. His converſation, his writings, had all a reference to the life after this; and this turn of diſpoſition mixed itſelf even with his improvements in gardening. He had, for inſtance, an alcove with a bench, ſo painted near his houſe, that at a diſtance it looked as a real one which the ſpectator was then approaching. Upon coming up near it, however, the deception was perceived, and this motto appeared, *Inviſibilia non decipiunt*, "The things unſeen do not deceive us." Yet, notwithſtanding this gloomineſs of temper, he was fond of innocent ſports and amuſement; he inſtituted an aſſembly and a bowling-green in the pariſh of which he was rector, and often promoted the gaiety of the company in perſon. His wit was generally poignant, and ever levelled at thoſe who teſtified any contempt for decency and religion. His epigram, ſpoken extempore upon Voltaire, is well known; who happening in his company to ridicule Milton, and the allegorical perſonages of Death and Sin, Young thus addreſſed him:

Thou art ſo witty, profligate, and thin,
You ſeem a Milton with his Death and Sin.

One Sunday preaching in office at St James's, he found, that though he ſtrove to make his audience attentive he could not prevail. Upon which his pity for their folly got the better of all decorums, and he ſat back in the pulpit and burſt into a flood of tears. Towards the latter part of his life he knew his own infirmities, and ſuffered himſelf to be in pupilage to his houſe-keeper; for he conſidered that, at a certain time of life, the ſecond childhood of age demanded its wonted protection. His ſon, whoſe boyiſh follies were long obnoxious to paternal ſeverity, was at laſt forgiven in his will; and our poet died regretted by all, having performed all that man could do to fill his poſt with dignity. His death happened in 1765. Youth ‖ Yunx.

YOUTH, that ſtate of man in which he approaches towards his greateſt perfection of body.

YPRES, a handſome, large, and populous town of the Auſtrian Netherlands, with a biſhop's ſee. It has a conſiderable manufactory in cloth and ſerges, and every year in Lent there is a conſiderable fair. It is one of the barrier towns, but was beſieged and taken by the French in 1744. It is ſeated on a fertile plain on the river Ypre, in E. Long. 2. 48. N. Lat. 50. 51.

YUCCA, Adam's Needle, in botany; a genus of plants of the claſs *hexandria* and order *monogynia*. The corolla is campanulate and patent, there is no ſtyle, the capſule is trilocular. There are four ſpecies, none of which are natives of Britain. All of them are exceedingly curious in their growth, and are therefore much cultivated in gardens. The Indians make a kind of bread from the roots of this plant.

YULE, Yool, or *Iul*. See Iul.

YUNX, in zoology, a genus of birds of the order *picæ*. The bill is ſhort, roundiſh, and pointed; the noſtrils concave and naked; the tongue very long and cylindrical; there are two fore and two hind claws. There is only one ſpecies, the *torquilla*, wry-neck, which is a native of Europe, Aſia, and Africa, and is often ſeen in Britain. It is aſh-coloured above, with light black and brown ſtrokes. Beneath light brown, with black ſpots. Tail aſh-colour, with four black bars. Weight 1¼ oz. Irides hazel. Length 7 inches. Migrates.

Z.

Z, Zaara. Z, or z, the 24th and laſt letter, and the 19th conſonant of our alphabet; the ſound of which is formed by a motion of the tongue from the palate downwards and upwards to it again, with a ſhutting and opening of the teeth at the ſame time. This letter has been reputed a double conſonant, having the ſound *ds*; but ſome think with very little reaſon: and, as if we thought otherwiſe, we often double it, as in *puzzle*, *muzzle*, &c. Among the ancients, Z was a numeral letter, ſignifying 2000; and with a daſh added a-top, $\overline{Z}$ ſignified 2000 times 2000, or 4,000,000.

In abbreviation this letter formerly ſtood as a mark for ſeveral ſorts of weights; ſometimes it ſignified an ounce and a half; and very frequently it ſtood for half an ounce; ſometimes for the eighth part of an ounce, or a dram Troy weight: and it has in earlier times been uſed to expreſs the third part of an ounce or eight ſcruples. ZZ were uſed by ſome of the ancient phyſicians to expreſs myrrh, and at preſent they are often uſed to ſignify zinziber or ginger.

ZAARA, zapara, sahara, or *the Deſert*, a vaſt country of Africa, bounded on the north by Barbary, on the eaſt by Fezzan and Caſhna, on the ſouth by Tombuctoo, and on the weſt by the Atlantic Ocean. Zaara contains a variety of wandering nations, all proceeding from Arabs, Moors, and fugitive Portugueſe, who took refuge there when the family of the Sherifs made themſelves maſters of the three kingdoms of Barbary. All theſe people bear indiſcriminately the names of *Mars*, *Moors*, or *Arabs*. They are ſubdivided into various nations, of which the moſt conſiderable are the Mongearts, Traſars, and Bracnars. The Mongearts lead a wandering life, and live chiefly on the milk of their flocks, with a little barley-meal, and ſome dates. The poorer ſort go naked, except the females, who commonly wrap a clout about their middle, and wear a kind of bonnet on their head; but the wealthier ſort have a kind of looſe gown, made of blue callicoe, with large ſleeves, that is brought them from Negro-land. When they move from one place to another for freſh paſture, water, or prey, moſt of them ride on camels, which have generally a ſort of ſaddle between the bunch and the neck, with a ſtring or ſtrap run through their noſtrils, which ſerves for a bridle; and inſtead of ſpurs they uſe a ſharp bodkin. Their tents or huts are covered with a coarſe ſtuff, made of camel's hair, and a kind of wool or moſs that grows on the palm trees. Theſe Arabs live here under the government of their ſheiks or cheyks; as in Arabia, Egypt, and other places. The other two tribes are rather more civiliſed. They are all Mahometans. Zaara, Zabulon.

ZABULON (anc. geog.), one of the twelve tribes; bounded on the north by the tribes of Aſher and Naphthali; on the eaſt by the ſea of Galilee; on the ſouth by the tribe of Iſſachar or the brook Ciſon, which ran between both; on the weſt by the Mediterranean; ſo that it touched two ſeas, or was bimarous.

Zabulon (anc. geog.), a very ſtrong town in the tribe

Zacynthus
Zaleucus.

of that name, on the Mediterranean, ſirnamed *of men*, near Ptolemais: its vicinity to which makes it probable that it was alſo Chabulon, unleſs either name is a faulty reading in Joſephus; diſtant about 60 ſtadia from Ptolemais.

ZACYNTHUS (anc. geog.), an iſland to the ſouth of Cephalonia 60 ſtadia, but nearer to Peloponneſus, in the Ionian Sea, formerly ſubject to Ulyſſes, in compaſs above 160 ſtadia, woody and fruitful, with a conſiderable cognominal town and port. The iſland lies over againſt Elis, having a colony of Achæans from Peloponneſus, over againſt the Corinthian Gulf. Both iſland and town are now called *Zante*.

ZAFFRE, is the oxyd of cobalt, employed for painting pottery ware and porcelain of a blue colour. The method of preparing it is as follows: The cobalt taken out of the mine is broken with hammers into pieces about the ſize of an hen's egg; and the ſtony involucrum, with ſuch other heterogeneous matters as are diſtinguiſhable by the eye, are ſeparated as much as poſſible. The choſen mineral is then pounded in ſtamping mills, and ſifted through braſs wire ſieves. The lighter parts are waſhed off by water, and it is afterwards put into a large flat-bottomed arched furnace, reſembling a baking oven, where the flame of the wood reverberates upon the ore; which is occaſionally ſtirred and turned with long handled iron hooks or rakes; and the proceſs is continued till it ceaſes to emit any fumes. The oven or furnace is terminated by a long horizontal gallery, which ſerves for a chimney; in which the arſenic, naturally mixed with the ore, ſublimes. If the ore contains a little biſmuth, as this ſemimetal is very fuſible, it is collected at the bottom of the furnace The cobalt remains in the ſtate of a dark grey oxyd, and is called *zaffre*. One hundred pounds of the cobalt ore loſe 20 and even 30 *per cent.* during this operation, which is continued 4 or even 9 hours, according to the quality of the ore. The roaſted ore being taken out from the furnace, ſuch parts as are concreted into lumps are pounded and ſifted afreſh. Zaffre, in commerce, is never pure, being mixed with two or rather three parts of powdered flints. A proper quantity of the beſt ſort of theſe, after being ignited in a furnace, are thrown into water to render them friable, and more eaſily reduced to powder; which, being ſifted, is mixed with the zaffre, according to the before mentioned doſe; and the mixture is put into caſks, after being moiſtened with water. This oxyd, fuſed with three parts of ſand and one of pot-aſh, forms a blue glaſs; which, when pounded, ſifted, and afterwards ground in mills, included in large caſks, forms *ſmalt*.

Magellan's Cronſtedt's Mineralogy.

The blue of zaffre is the moſt ſolid and fixed of all the colours that can be employed in vitrification. It ſuffers no change from the moſt violent fire. It is ſucceſsfully employed to give ſhades of blue to enamels, and to the cryſtal-glaſſes made in imitation of ſome opaque and tranſparent precious ſtones, as the lapis lazuli, the turquois, the ſapphire, and others of this kind.

ZALEUCUS, a famous legiſlator of the Locrians, and the diſciple of Pythagoras, flouriſhed 500 years B. C. He made a law, by which he puniſhed adulterers with the loſs of both their eyes; and his ſon offending, was not abſolved from this puniſhment: yet, to ſhow the father as well as the juſt lawgiver, he put out his own right, and his ſon's left eye. This example of juſtice and ſeverity made ſo ſtrong an impreſſion on the minds of his ſubjects, that no inſtance was found of the commiſſion of that vice during the reign of that legiſlator. It is added, that Zaleucus forbad any wine being given to the ſick on pain of death, unleſs it was preſcribed by the phyſicians; and that he was ſo jealous of his laws, that he ordered, that whoever was deſirous of changing them, ſhould be obliged, when he made the propoſal, to have a cord about his neck, in order that he might be immediately ſtrangled, if thoſe alterations were eſteemed no better than the laws already eſtabliſhed. Diodorus Siculus attributes the ſame thing to Charondas legiſlator of the Sybarites.

Zama.

ZAMA (anc. geog.), a town of Chamane, a diſtrict of Cappadocia, of unknown ſituation.—Another Zama, of Meſopotamia, on the Saocoras, to the ſouth of Niſibis.—A third, of Numidia, diſtant five days journey to the weſt of Carthage; it was the other royal reſidence of the Kings of Numidia, hence called *Zama Regia*. It ſtood in a plain; was ſtronger by art than nature; richly ſupplied with every neceſſary; and abounding in men, and every weapon both of defence and annoyance.

The laſt of theſe is remarkable for the deciſive battle fought between the two greateſt commanders in the world, Hannibal the Carthaginian and Scipio Africanus. Of this engagement, the moſt important perhaps that ever was fought, Mr Hooke gives us the following account.

"Scipio drew up his army after the Roman manner, except that he placed the cohorts of the Principes directly behind thoſe of the Haſtati, ſo as to leave ſufficient ſpace for the enemy's elephants to paſs through from front to rear. C. Lælius was poſted on the left wing with the Italian horſe, and Maſiniſſa with his Numidians on the right. The intervals of the firſt line Scipio filled up with his Velites, or light armed troops, ordering them, upon a ſignal given, to begin the battle; and in caſe they were repulſed, or broke by the elephants, to run back through the lanes before mentioned, and continue on their flight till they were got behind the Triarii. Thoſe that were wounded, or in danger of being overtaken, were to turn off to the right and left through the ſpaces between the lines, and that way eſcape to the rear.

"The army thus drawn up, Scipio went from rank to rank, urging his ſoldiers to conſider the conſequences of a defeat and the rewards of victory: on the one hand, certain death or ſlavery (for they had no town in Africa ſtrong enough to protect them); on the other, not only a laſting ſuperiority over Carthage, but the empire of the reſt of the world.

"Hannibal ranged all his elephants, to the number of above 80, in one front. Behind theſe he placed his mercenaries, conſiſting of 12,000 men, Ligurians, Gauls, Baleares, and Mauritanians.

"The new levies of Carthaginians and other Africans, together with 4000 Macedonians, under a general named *Sopater*, compoſed the ſecond line. And in the rear of all, at the diſtance of about a furlong, he poſted his Italian troops, in whom he chiefly confided. The Carthaginian horſe formed his right wing, the Numidians his left.

"He ordered their ſeveral leaders to exhort their troops not to be diſcouraged by their own weakneſs, but to place the hope of victory in him and his Italian army; and particularly directed the captains of the Carthaginians to repreſent to them what would be the fate of their wives and children if the event of this battle ſhould not prove ſucceſsful. The general himſelf, walking through the ranks of his Italian troops, called upon them to be mindful of the 17 campaigns in which they had been fellow-ſoldiers with him; and of that conſtant ſeries of victories by which they had extinguiſhed in the Romans all hope of ever being conquerors. He urged them to remember, above all, the battles of Trebia, Thraſymenus, and Cannæ; with any of which the approaching battle was in no wiſe to be compared, either with reſpect to the bravery or the number of the enemy. 'The Romans were yet unfoiled, and in the height of their ſtrength, when you firſt met them in the field; nevertheleſs

you

Zama. you vanquiſhed them. The ſoldiers now before us are either the children of the vanquiſhed, or the remains of thoſe whom you have often put to flight in Italy. Maintain therefore your general's glory and your own, and eſtabliſh to yourſelves the name of invincible, by which you are become famous throughout the world.'

"When the Numidians of the two armies had ſkirmiſhed a while, Hannibal ordered the managers of the elephants to drive them upon the enemy. Some of the beaſts, frightened at the noiſe of the trumpets and other inſtruments of war which ſounded on all ſides, immediately ran back among the Numidians of the Carthaginian left wing, and put them into confuſion; which Maſiniſſa taking advantage of, entirely routed them. Great deſtruction was made of the Velites by the reſt of the elephants, till theſe alſo being terrified, ſome of them ran through the void ſpaces of the Roman army which Scipio had left for that purpoſe; others falling in among the cavalry of the enemy's right wing, gave Lælius the ſame opportunity againſt the Carthaginian horſe as had been given to Maſiniſſa againſt the Numidian, and of which the Roman did not fail to make the ſame uſe. After this the infantry of the foremoſt lines joined battle. Hannibal's mercenaries had the advantage in the beginning of the conflict; but the Roman Haſtati, followed and encouraged by the principes, who exhorted them to fight manfully, and ſhowed themſelves ready to aſſiſt them, bravely ſuſtained the attack, and at length gained ground upon the enemy. The mercenaries not being ſeaſonably ſupported by their ſecond line, and therefore thinking themſelves betrayed, they in their retreat fell furiouſly upon the Africans; ſo that theſe, the Haſtati coming up, were obliged to fight for ſome time both againſt their own mercenaries and the enemy. When the two Carthaginian lines had ceaſed their mutual rage, they joined their ſtrength; and though now but a mere throng of men, broke the Haſtati: but then the Principes advancing to the aſſiſtance of the latter, reſtored the battle; and moſt of the Africans and mercenaries were here cut off. Hannibal did not advance to their relief, the Roman Triarii not having yet engaged, and the Principes being ſtill in good order; and leſt the routed Africans and mercenaries ſhould break the ranks of his Italian ſoldiers, he commanded theſe to preſent their ſpears at thoſe who fled to them for protection, which obliged the runaways to move off to the right and left.

"The ground over which the Romans muſt march before they could attack Hannibal being ſtrewed with heaps of dead bodies and weapons, and being ſlippery with blood, Scipio feared that the order of his battalions would be broke, ſhould he paſs it haſtily. To avoid this miſchief, he commanded the Haſtati to give over the purſuit, and halt where they were, oppoſite to the enemy's centre: after which, having ſent all his wounded to the rear, he advanced leiſurely with the Principes and Triarii, and placed them on the wings of the Haſtati. Then followed a ſharp engagement, in which victory was long and eagerly diſputed. It would ſeem that the Romans, though ſuperior in number, were once upon the point of loſing the day; for Polybius tells us, that Maſiniſſa and Lælius came very ſeaſonably, and as if ſent from heaven, to their aſſiſtance. Theſe generals being returned from the purſuit of the cavalry, fell ſuddenly upon the rear of Hannibal's men, moſt of whom were cut off in their ranks; and of thoſe that fled, very few eſcaped the horſe, the country all around being a plain.

"There died of the Carthaginians in the fight above 20,000, and almoſt the like number were taken priſoners. The loſs on the ſide of the Romans amounted to about 2000 men. Hannibal eſcaped with a few horſe to Adrumetum, having performed every thing in the engagement which could be expected from a great general. His army (ſays Polybius) could not have been more ſkilfully drawn up. For as the order of the Roman battalions makes it extremely difficult to break them, the Carthaginian wiſely placed his elephants in the front, that they might put the enemy in confuſion before the armies ſhould engage. In his firſt line he placed the mercenaries; men bold and active, but not well diſciplined, that by their impetuoſity he might give a check to the ardour of the Romans. The Africans and Carthaginians, whoſe courage he doubted, he poſted in the middle between the mercenaries and his Italian ſoldiers, that they might be forced to fight, or at leaſt that the Romans, by ſlaughtering them, might fatigue themſelves and blunt their weapons. Laſt of all, he drew up the troops he had diſciplined himſelf, and in whom he chiefly confided, at a good diſtance from the ſecond line, that they might not be broken by the route of the Africans and mercenaries, and kept them in reſerve for a vigorous attack upon a tired and weakened enemy."

Zanguebar Zante.

ZANGUEBAR, a country in Africa, lying on the eaſtern coaſt, between three degrees of north latitude, and 18 ſouth. It includes ſeveral petty kingdoms, in which the Portugueſe have various ſettlements. The inhabitants, except thoſe converted by the Portugueſe, are all Mahometans or idolaters; and the latter much the more numerous. The names of the principal territories are *Mombaza*, *Lamon*, *Melinda*, *Quiola*, and *Moſambique*. The Portugueſe have built ſeveral forts in Mombaza and Moſambique, and have ſettled ſeveral colonies there. They trade with the negroes for ſlaves, ivory, gold, oſtrich-feathers, wax, and drugs. The productions are much the ſame as in other parts of Africa between the tropics.

ZANONIA, in botany; the name of a genus of plants of the order *diœcia*, claſs *pentandria*. The characters are theſe: it produces ſeparate male and female flowers; in the male flower the cup is a perianthium, compoſed of three leaves of an oval figure, expanding every way, and ſhorter than the flower; the flower is monopetalous, but divided into five ſegments, and has an open mouth; the ſegments are jagged, and are equal in ſize, and bend backwards; the ſtamina are five filaments of the length of the cup, ſtanding open at their ends, and terminated by ſimple apices; the female flowers grow on ſeparate plants, and have the cup and flower the ſame as in the male, only that the cup ſtands upon the germen of the piſtil; this germen is oblong, and from it are propagated three reflex conic ſtyles; the ſtigmata are bifid and curled; the fruit is a long and very large berry, truncated at the end, and very ſmall at the baſe; it contains three cells, and has a curled future near the apex; the ſeeds are two; they are of an oblong figure, and flat. There is one ſpecies, the *indica*.

ZANTE, an iſland of the Mediterranean, near the coaſt of the Morea, 19 miles ſouth-eaſt of the iſland of Cephalonia, belonging to the Venetians. It is about 24 miles in length and 12 in breadth, and very pleaſant and fertile; but its principal riches conſiſt in currants, with which it greatly abounds. They are cultivated in a very large plain, under the ſhelter of mountains on the ſhore of this iſland; for which reaſon the ſun has greater power to bring them to perfect maturity. The town called *Zante* may contain near 20,000 inhabitants; the whole iſland contains about 40,000. The houſes are low, on account of the frequent earthquakes, for ſcarce a year paſſes without one; however, they do no great damage. The natives ſpeak both Greek and Italian. There are very few Roman Catholics among them; but they have a biſhop as well as the Greeks. This place has no fortifications, but there is a fortreſs upon an eminece

Zanthoxylum ‖ Zea.

planted with cannon. In one part of this iſland is a place which ſhakes when trod upon like a quagmire; and a ſpring which throws out a great deal of bitumen, eſpecially at the time of an earthquake. It ſerves inſtead of pitch to pay the bottoms of the ſhips, and about 100 barrels in a year are uſed for this purpoſe. There are about 50 villages in the iſland; but no other large town beſide Zante. It is ſeated on the eaſtern ſide of the iſland, and has a good harbour. The Engliſh and Dutch have each a factory and conſul here. E. Long. 21. 3. N. Lat. 37. 53.

ZANTHOXYLUM, the TOOTHACH-TREE, in botany; a genus of plants of the claſs of *diœcia*, and order of *pentandria*; and in the natural ſyſtem arranged under the 46th order, *Hederaceæ*. The calyx is quinquepartite, there is no corolla; the female flower has five piſtils and as many monoſpermous capſules. There are two ſpecies, the clava *herculis*, and the *trifoliatum*; neither of which are natives of Britain.

ZAPATA, a kind of feaſt or ceremony held in Italy, in the courts of certain princes, on St Nicholas's day; wherein people hide preſents in the ſhoes or ſlippers of thoſe they would do honour to, in ſuch a manner as may ſurpriſe them on the morrow when they come to dreſs; being done in imitation of the practice of St Nicholas, who uſed in the night-time to throw purſes of money in at the windows to marry poor maids withal.

ZEA, INDIAN CORN, in botany; a genus of plants of the claſs *monœcia*, order *triandria*. The male-flowers are placed on diſtinct ſpikes; the calyx is a biflorous, beardleſs glume; the corolla a beardleſs glume; the female calyx is a bivalve glume, as is the corolla. There is one filiform, pendulous ſtyle; the ſeeds are ſolitary and buried in an oblong receptacle. There is only one ſpecies, the *Mays*, maize. The Indians in New England, and many other parts of America, had no other vegetable but maize or Indian corn for making their bread. They call it *weachin*; and in the United States of America there is much of the bread of the country made of this grain, not of the European corn. In Italy and Germany alſo there is a ſpecies of maize which is the food of the poor inhabitants.

The ear of the maize yields a much greater quantity of grain than any of our corn ears. There are commonly about eight rows of grain in the ear, often more, if the ground be good. Each of theſe rows contains at leaſt 30, grains, and each of theſe gives much more flour than a grain of any of our corn. The grains are uſually either white or yellowiſh; but ſometimes they are red, bluiſh, greeniſh, or olive-coloured, and ſometimes ſtriped and variegatied. This ſort of grain, though ſo eſſentially neceſſary to the natives of the place, is yet liable to many accidents. It does not ripen till the end of September; ſo that the rains often fall heavy upon it while on the ſtalk, and the birds in general peck it when it is ſoft and unripe. Nature has, to defend it from theſe accidents, covered it with a thick huſk, which keeps off ſlight rains very well; but the birds, if not frighted away, often eat through it, and devour great quantity of the grain.

There are three or four varieties of maize in different parts of America. That of Virginia is very tall and robuſt, growing to ſeven or eight feet high; that of New England is ſhorter and lower. And the Indians farther up in the country have a yet ſmaller kind in common uſe. The ſtalk of the maize is joined like the ſugar-cane; it is very ſoft and juicy, and the juice is ſo ſweet and ſaccharine, that a ſyrup, as ſweet as that of ſugar, has been often made of it; and things ſweetened with it have been found not diſtinguiſhable from thoſe done with ſugar. It has not been tried yet whether it will cryſtallize into ſugar; but in all probability it will.

Zea, Zeal.

The Americans plant this corn any time from the beginning of March to the beginning of June; but the beſt ſeaſon is the middle of April. The ſavage Indians, who knew nothing of our account of months, uſed to guide themſelves in the ſeed-time of this uſeful plant by the budding of ſome particular trees of that country, and by the coming up of a ſort of fiſh into their rivers which they call the *alooſe*. Theſe things were both ſo regular, that they were in no danger of miſtaking the time.

The manner of planting maize is in rows, at equal diſtances, every way about five or ſix feet. They open the earth with a hoe, taking away the ſurface to three or four inches deep, and of the breadth of the hoe; they then throw in a little of the finer earth, ſo as to leave the hole four inches deep or thereabouts, and in each of theſe holes they place four or five grains at a little diſtance from one another. If two or three of theſe grow up, it is very well; ſome of them are uſually deſtroyed either by the birds or other animals.

When the young plants appear, they hoe up the weeds from time to time; and when the ſtalk gathers ſome ſtrength, they raiſe the earth a little about it, and continue this at every hoeing till it begins to put forth the ears; then they enlarge the hill of earth, round the root, to the ſize of a hop-hill, and after this they leave it till the time of harveſt, without any farther care. When they gather the ears, they either immediately ſtrip off the corn, or elſe hang up the ears, tied in traces at diſtances from one another; for if they are laid near together, they will heat and rot or elſe ſprout and grow; but kept cool and ſeparate, they will remain good all the winter. The beſt method is to threſh out the corn as ſoon as the harveſt is over, to dry it well on mats in the ſun, and then lay it up in holes of the ground, well lined with mats, graſs, or the like, and afterwards covered at top with more earth. The moſt careful among the Indians uſe this method, and this ſort of ſubterranean granary always proves good.

The uſes of this plant among the Indians are very many. The great article is the making their bread of it; but beſides this, the ſtalks, when cut up before they are too much dried, are an excellent winter food for cattle; but they uſually leave them on the ground for the cattle to feed on. The huſks about the ear are uſually ſeparated from the reſt, and make a particular ſort of fodder, not inferior to our hay. The Indian women have a way of ſlitting them into narrow parts, and they then weave them artificially into baſkets and many other toys. The original way of eating the grain among the Indians was this: they boiled it whole in water till it ſwelled and became tender, and then they fed on it either alone or eat it with their fiſh and veniſon inſtead of bread. After this, they found the way of boiling it into a ſort of pudding, after bruiſing it in a mortar; but the way of reducing it to flour is the beſt of all. They do this by parching it carefully in the fire, without burning, and then beating it in mortars and ſifting it. This flour they lay up in bags as their conſtant proviſion, and take it out with them when they go to war, eating it either dry or with water. The Engliſh have contrived, by mixing it into a ſtiff paſte, either by itſelf or with rye or wheat-meal, fermenting it with leaven or yeaſt, and baking it in a hot oven, to make good bread of it. They have likewiſe found out a method of making good beer, either of the bread or by malting the grain.

ZEAL, paſſionate ardour for any perſon or cauſe. It is moſt frequently uſed to denote a ſtrong and warm attachment

Zealand
Zell.

ment to the diſtinguiſhing doctrines or worſhip of ſome particular ſect of Chriſtians. Thus we ſay, a zealous *Calviniſt*, *Arminian*, or *Papiſt*; though we may likewiſe with the greateſt propriety ſay of an upright and benevolent man, that he is zealous of *good works*.

ZEALAND, the chief of the Daniſh iſlands, is ſituated at the entrance of the Baltic Sea, bounded by the Schaggerrac Sea on the north; by the Sound, which ſeparates it from Schonen, on the eaſt; by the Baltic Sea on the ſouth; and by the ſtrait called the *Great Belt*, which ſeparates it from the iſland of Funen, on the weſt; being of a round figure, near 200 miles in circumference: the chief town is Copenhagen.

ZEALAND, is alſo a province of the United Netherlands, conſiſting of eight iſlands, which lie in the mouth of the river Scheld, bounded by the province of Holland, from which they are ſeparated by a narrow channel on the north; by Brabant on the eaſt; by Flanders, from which they are ſeparated by one of the branches of the Scheld, on the ſouth; and by the German Ocean on the weſt.

New ZEALAND, a country of Aſia, in the South Pacific Ocean, firſt diſcovered by Taſman, the Dutch navigator, in the year 1642, who gave it the name of *Staten Land*, though it has been generally diſtinguiſhed in our maps and charts by the name of *New Zealand*, and was ſuppoſed to be part of a ſouthern continent: but it is now known, from the late diſcoveries of Captain Cook who ſailed round it, to conſiſt of two large iſlands, divided from each other by a ſtrait four or five leagues broad. They are ſituated between the latitudes of 34 and 48 degrees ſouth, and between the longitudes of 166 and 180 degrees eaſt from Greenwich. One of theſe iſlands is for the moſt part mountainous, rather barren, and but thinly inhabited; but the other is much more fertile, and of a better appearance. In the opinion of Sir Joſeph Banks and Dr Solander, every kind of European fruits, grain, and plants, would flouriſh here in the utmoſt luxuriance. From the vegetables found here, it is ſuppoſed that the winters are milder than thoſe in England, and the ſummers not hotter, though more equally warm; ſo that it is imagined, that if this country were ſettled by people from Europe, they would, with moderate induſtry, be ſoon ſupplied, not only with the neceſſaries, but the luxuries of life, in great abundance. Here are foreſts of vaſt extent, filled with very large timber trees; and near 400 plants were found here that had not been deſcribed by the naturaliſts. The inhabitants of New Zealand are ſtout and robuſt, and equal in ſtature to the largeſt Europeans. Their colour in general is brown, but in few deeper than that of the Spaniard who has been expoſed to the ſun, and in many not ſo deep; and both ſexes have good features. Their dreſs is very uncouth, and they mark their bodies in a manner ſimilar to the inhabitants of Otaheite, and which is called *tattowing*. Their principal weapons are lances, darts, and a kind of battle-axes; and they have generally ſhown themſelves very hoſtile to the Europeans who have viſited them.

ZEALOTS, an ancient ſect of the Jews, ſo called from their pretended zeal for God's law and the honour of religion.

ZEBRA, in zoology. See EQUUS.

ZEBU, in zoology; a name given by M. de Buffon to the bos indicus of Linnæus. See BOS, vi.

ZECHIN, or ZECCHINO. See SEQUIN.

ZEDOARY, in the materia medica. See KÆMPFERIA.

ZELL, a city of Germany in the circle of Lower Saxony, capital of the duchies of Zell and Lunenburg, ſituated at the confluence of the rivers Aller and Fuhſe, 30 miles north of Hanover, and 40 ſouth of Lunenburg. E. Long. 10. 12. N. Lat. 52. 49.

Zenbla
Zend.

ZEMBLA NOVA, a very large iſland, lying in the Northern Ocean, to the north of Ruſſia, from which it is ſeparated by the ſtrait of Waigate. It has no inhabitants except wild beaſts, particularly white foxes and bears. In 1595 a Dutch veſſel was caſt away on the coaſt, and the ſhip's company were obliged to winter here; but they did not ſee the ſun from the fourth of November to the beginning of February, and had great difficulty to keep themſelves from being frozen to death.

ZEMINDAR. See HINDOSTAN, Vol. VIII. page 585.

ZEND, or ZENDAVESTA, a book aſcribed to Zoroaſter, and containing his pretended revelations; which the ancient Magicians and modern Perſees, called alſo *Gaurs*, obſerve and reverence in the ſame manner as the Chriſtians do the Bible, and the Mahometans the Koran, making it the ſole rule both of their faith and manners. The word, it is ſaid, originally ſignifies any inſtrument for kindling fire, and is applied to this book to denote its aptitude for kindling the flame of religion in the hearts of thoſe who read it.

The Zend contains a reformed ſyſtem of Magianiſm; teaching that there is a Supreme Being, eternal, ſelf-exiſtent, and independent, who created both light and darkneſs, out of which he made all other things; that theſe are in a ſtate of conflict, which will continue till the end of the world; that then there ſhall be a general reſurrection and judgment; and that juſt retribution ſhall be rendered unto men according to their works; that the angel of darkneſs with his followers ſhall be conſigned to a place of everlaſting darkneſs and puniſhment, and the angel of light with his diſciples introduced into a ſtate of everlaſting light and happineſs; after which light and darkneſs ſhall no more interfere with each other. The Zend alſo enjoins the conſtant maintenance of ſacred fires and fire-temples for religious worſhip; the diſtinction of clean and unclean beaſts; the payment of tithes to prieſts, which are to be of one family or tribe; a multitude of waſhings and purifications, reſembling thoſe of the Jewiſh law; and a variety of rules and exhortations for the exerciſe of benevolence and charity.

In this book there are many paſſages evidently taken out of the Scriptures of the Old Teſtament, particularly out of the Pſalms of David: The author repreſents Adam and Eve as the firſt parents of all mankind, gives in ſubſtance the ſame account of the creation and deluge with Moſes, differing indeed with regard to the former, by converting the ſix days of the Moſaic account into ſix times, comprehending in the whole 365 days; and ſpeaks alſo of Abraham, Joſeph, Moſes, and Solomon. Moreover, Dr Baumgarten aſſerts, that this work contains doctrines, opinions, and facts, actually borrowed from the Jews, Chriſtians, and Mahometans; whence, and from other circumſtances, he concludes that both the hiſtory and writings of this prophet were probably invented in the later ages, when the fire-worſhippers under the Mahometan government thought fit to vindicate their religion from the ſuſpicion of idolatry.

At whatever period the Zend may have been written, we are aſſured by Dr Hyde that it is in the pure old Perſian language, and in the character called *Pep'lavi*. Some parts of it contain the original text, and others Zoroaſter's ſecond thoughts ſubjoined, for explaining more fully his doctrine. Theſe were occaſioned by the oppoſition of adverſaries, and unforeſeen circumſtances which occurred during the fabrication of the impoſture. About 300 years

ago,

Zenith, Zeno

ago, when the old Perſian language had become antiquated and little underſtood, one of the deſtoura or high-prieſts among the Perſees compoſed the *Sadda*, which is a compendium in the vulgar or modern Perſic tongue, of thoſe parts of the Zend that relate to religion, or a kind of code of canons and precepts, drawn from the theological writings of Zoroaſter, ſerving as an authoritative rule of faith and practice for his followers. This Sadda is written in a low kind of Perſic verſe, and, as Dr Hyde informs us, it is *bonorum & malorum farrago*, having many good and pious things, and others very ſuperſtitious and trifling. See PERSEES and ZOROASTER.

ZENITH, in aſtronomy, the vertical point, or a point in the heavens directly over our heads.

ZENO ELEATES, an eminent Grecian philoſopher, was born at Elea about 504 years before Chriſt. He was a zealous friend of civil liberty, and is celebrated for his courageous and ſucceſsful oppoſition to tyrants; but the inconſiſtency of the ſtories related by different writers concerning him in a great meaſure deſtroys their credit. He choſe to reſide in his ſmall native city of Elea rather than at Athens, becauſe it afforded freer ſcope to his independent and generous ſpirit, which could not eaſily ſubmit to the reſtraints of authority. It is related, that he vindicated the warmth with which he reſented reproach, by ſaying, "If I were indifferent to cenſure, I ſhould alſo be indifferent to praiſe." The invention of the dialectic art has been improperly aſcribed to Zeno; but there can be no doubt that this philoſopher, and other metaphyſical diſputants in the Eleatic ſect, employed much ingenuity and ſubtlety in exhibiting examples of moſt of the logical arts, which were afterwards reduced to rule by Ariſtotle and others.

Enfield's Hiſtory of Philoſophy.

According to Ariſtotle, he taught, that nothing can be produced either from that which is ſimilar or diſſimilar; that there is only one being, God; who is eternal, homogeneous, and ſpherical, neither finite nor infinite, neither quieſcent nor moveable; that there are many worlds; that there is in nature no vacuum; that all bodies are compoſed of four elements, heat and moiſture, cold and dryneſs; and that the body of man is from the earth, and his ſoul an equal mixture of theſe four elements. He argued with great ſubtlety againſt the poſſibility of motion. If Seneca's account of this philoſopher deſerves credit, he reached the higheſt point of ſcepticiſm, and denied the real exiſtence of external objects. The truth is, that after all that has been advanced by different writers, it is impoſſible to determine whether Zeno underſtood the term *One*, metaphyſically, logically, or phyſically; or whether he admitted or denied a nature properly divine.

Zeno, the founder of the ſect of the Stoics, was born about 300 years before Chriſt, at Citium in the iſland of Cyprus. This place having been originally peopled by a colony of Phœnicians, Zeno is ſometimes called a Phœnician. His father was by profeſſion a merchant, but diſcovering in the youth a ſtrong propenſity towards learning, he early devoted him to philoſophy. In his mercantile capacity he had frequent occaſion to viſit Athens, where he purchaſed for his ſon ſeveral of the writings of the moſt eminent Socratic philoſophers. Theſe he read with great avidity; and when he was about 30 years of age, he determined to take a voyage to a city which was ſo celebrated both as a mart of trade and of ſcience. If it be true, as ſome writers relate, that he brought with him a valuable cargo of Phœnician purple, which was loſt by ſhipwreck upon the coaſt of Piræus, this circumſtance will account for the facility with which he at firſt attached himſelf to a ſect whoſe leading principle was the contempt of riches. Upon his firſt arrival in Athens, going accidentally into the ſhop of a bookſeller, he took up a volume of the commentaries of Xenophon; and after reading a few paſſages, was ſo much delighted with the work, and formed ſo high an idea of the author, that he aſked the bookſeller where he might meet with ſuch men. Crates the Cynic philoſopher happening at that inſtant to be paſſing by, the bookſeller pointed to him, and ſaid, "Follow that man." Zeno attended upon the inſtructions of Crates, and was ſo well pleaſed with his doctrine that he became one of his diſciples. But though he admired the general principles of the Cynic ſchool, he could not eaſily reconcile himſelf to their peculiar manners. Beſides, his inquiſitive turn of mind would not allow him to adopt that indifference to every ſcientific enquiry which was one of the characteriſtic diſtinctions of the ſect. He therefore attended upon other maſters, who profeſſed to inſtruct their diſciples in the nature and cauſes of things. When Crates, diſpleaſed at his following other philoſophers, attempted to drag him by force out of the ſchool of Stilpo, Zeno ſaid to him, "You may ſeize my body, but Stilpo has laid hold of my mind." After continuing to attend upon the lectures of Stilpo ſeveral years, he paſſed over to other ſchools, particularly to thoſe of Xenocrates and Diodorus Cronus. By the latter he was inſtructed in dialectics. He was ſo much delighted with this branch of ſtudy, that he preſented to his maſter a large pecuniary gratuity, in return for his free communication of ſome of his ingenious ſubtleties. At laſt, after attending almoſt every other maſter, he offered himſelf as a diſciple of Polemo. This philoſopher appears to have been aware, that Zeno's intention in thus removing from one ſchool to another, was to collect materials from various quarters for a new ſyſtem of his own; for, when he came into Polemo's ſchool, he ſaid to him, "I am no ſtranger, Zeno, to your Phœnician arts; I perceive that your deſign is to creep ſlyly into my garden, and ſteal away my fruit." Polemo was not miſtaken in his opinion. Having made himſelf maſter of the tenets of others, Zeno determined to become the founder of a new ſect. The place which he made choice of for his ſchool was a public portico, adorned with the pictures of Polygnotus, and other eminent painters. It was the moſt famous portico in Athens, and called, by way of eminence, Στοα, "the Porch." It was from this circumſtance that the followers of Zeno were called *Stoics*.

Zeno.

In his perſon Zeno was tall and ſlender; his aſpect was ſevere, and his brow contracted. His conſtitution was feeble, but he preſerved his health by great abſtemiouſneſs. The ſupplies of his table conſiſted of figs, bread, and honey; notwithſtanding which, he was frequently honoured with the company of great men. In public company, to avoid every appearance of an aſſuming temper, he commonly took the loweſt place. Indeed ſo great was his modeſty, that he ſeldom choſe to mingle with a crowd, or wiſhed for the company of more than two or three friends at once. He paid more attention to neatneſs and decorum in external appearance than the Cynic philoſophers. In his dreſs indeed he was plain, and in all his expences frugal; but this is not to be imputed to avarice, but a contempt of external magnificence. He ſhowed as much reſpect to the poor as to the rich; and converſed freely with perſons of the meaneſt occupations. He had only one ſervant, or, according to Seneca, none.

Zeno lived to the extreme age of 98; and at laſt, in conſequence of an accident, voluntarily put an end to his life. As he was walking out of his ſchool he fell down, and in the fall broke one of his fingers; upon which he was ſo affected with the conſciouſneſs of infirmity, that, ſtriking the earth, he ſaid, "Why am I thus importuned? I obey thy ſummons;" and immediately went home and ſtrangled himſelf.

Zeno || Zeus.

self. He died in the first year of the 129th Olympiad. The Athenians, at the request of Antigonus, erected a monument to his memory in the Ceramicum.

We ought not to confound the two Zenos already mentioned with

ZENO, a celebrated Epicurean philosopher, born at Sidon, who had Cicero and Pomponius Atticus for his disciples, and who wrote a book against the mathematics, which, as well as that of Possidonius's refutation of it, is lost; nor with several other *Zenos* mentioned in history.

ZENOBIA, queen of Palmyra. See PALMYRA.

ZEOLITE. See CLAY, Vol. V. page 49. and MINERALOGY, Vol. XII. page 88.

ZEPHANIAH, a canonical book of the Old Testament. See SCRIPTURE, n° 79.

ZEPHYR, the *West-Wind*, or that which blows from the cardinal point of the horizon opposite to the east.

ZEPHYRUS, one of the Pagan deities, was represented as the son of Aurora, and the lover of the nymph Chloris, according to the Greeks, or of Flora according to the Romans; and as presiding over the growth of fruits and flowers. He is described as giving a refreshing coolness to the air by his soft and agreeable breath, and as moderating the heat of summer by fanning the air with his silken wings. He is depictured under the form of a youth, with a very tender air, with wings resembling those of the butterfly, and with his head crowned with a variety of flowers. As the poets of Greece and Rome lived in a warm climate, they are lavish in their praise of this beneficent deity, and under his name describe the pleasure and advantage they received from the western breezes.

ZERDA. See CANIS, Sp. xiv.

ZERTA, the ZERTE, a fish caught in the rivers of Italy and some other places, of the figure of the chub, and called by authors *capito anodromus*, and the *blike*. It seldom grows to more than two pounds weight, and at times lives in rivers, at times in the sea; and is esteemed a very well tasted fish, especially a little before the season of its spawning. The zerte is that species of cyprinus described by Gesner, and others under the name of *capito anodromus*.

ZEST, the woody thick skin quartering the kernel of a walnut; prescribed by some physicians, when dried and taken with white-wine, as a remedy against the gravel.

Zest is also used for a chip of orange or lemon peel; such as is usually squeezed into ale, wine, &c. to give it a flavour; or the fine oil which spurts out of that peel on squeezing it.

ZEUGMA, a figure in grammar, whereby an adjective or verb which agrees with a nearer word, is also, by way of supplement, referred to another more remote.

ZEUS, in ichthyology, a genus of fishes of the order of *thoracici*. The head is compressed, and declines, the upper lip being vaulted over by a transverse membrane; the tongue is subulated; there are seven rays in the gill membrane; and the body is compressed.—The species are eight; of which the most remarkable is the *faber* or *doree*. It is of a hideous form, its body is oval, and greatly compressed on the sides; the head large; the snout vastly projecting; the mouth very wide; the teeth very small; the eyes great, the irides yellow; the lateral line oddly distorted, sinking at each end, and rising near the back in the middle; beneath it on each side is a round black spot. The tail is round at the end, and consists of 15 yellow rays. The colour of the sides is olive, varied with light blue and white, and while living is very resplendent, and as if gilt; for which reason it is called the *doree*. The largest fish we have heard of weighed 12 pounds.

Superstition hath made the doree rival to the haddock, for the honour of having been the fish out of whose mouth St Peter took the tribute-money, leaving on its sides those inconteſtible proofs of the identity of the fish, the marks of his finger and thumb. It is rather difficult at this time to determine on which part to decide the dispute; for the doree likewise asserts an origin of its spots of a similar nature, but of a later date than the former. St Christopher, in wading through an arm of the sea, having caught a fish of this kind *en passant*, as an eternal memorial of the fact, left the impressions on its sides to be transmitted to all posterity. In our own country it was very long before this fish attracted our notice, at least as an edible one. We are indebted to the late Mr Quin for adding a most delicious fish to our table, who, overcoming all the vulgar prejudices on account of its deformity, has effectually established its reputation. This fish was supposed to be found only in the southern seas of this kingdom, but it has been discovered likewise on the coast of Anglesey. Those of the greatest size are taken in the Bay of Biscay, off the French coasts; they are also very common in the Mediterranean: Ovid must therefore have styled it *rarus faber*, on account of its excellency, not its scarcity.

Zeuxis.

ZEUXIS, a celebrated painter of antiquity, flourished about 400 years before Christ. He was born at Heraclea; but as there have been many cities of that name, it cannot be certainly determined which of them had the honour of his birth. Some learned men, however, conjecture, that it was the Heraclea near Crotona in Italy. He carried painting to a much higher degree of perfection than Apollodorus had left it; discovered the art of properly disposing of lights and shades, and particularly excelled in colouring. He amassed immense riches; and then resolved to sell no more of his pictures, but gave them away; saying very frankly, "That he could not set a price on them equal to their value." Before this time he made people pay for seeing them; and nobody was admitted to see his Helena without ready money, which occasioned the wags calling his picture *Helen the Courtezan*. It is not known whether this Helen of Zeuxis was the same with that which was at Rome in Pliny's time, or that which he painted for the inhabitants of Crotona to be hung up in the temple of Juno: this last he painted from five beautiful girls of that city, copying from each her greatest excellencies. Pliny observes, that this admirable painter, disputing for the prize of painting with Parrhasius, painted some grapes so naturally, that the birds flew down to peck them. Parrhasius, on the other hand, painted a curtain so very artfully, that Zeuxis mistaking it for a real one that hid his rival's work, ordered the curtain to be drawn aside, to show what Parrhasius had done; but having found his mistake, he ingenuously confessed himself vanquished, since he had only imposed upon birds, while Parrhasius had deceived even a master of the art. Another time he painted a boy loaded with grapes; when the birds also flew to this picture, at which he was vexed; and confessed, that this work was not sufficiently finished, since had he painted the boy as perfectly as the grapes, the birds would have been afraid of him. Archelaus, king of Macedon, made use of Zeuxis's pencil for the embellishment of his palace. One of this painter's finest pieces was a Hercules strangling some serpents in his cradle, in the presence of his affrighted mother: but he himself chiefly esteemed his Athleta, or Champion, under which he placed a Greek verse that afterwards became very famous, and in which he says, "That it was easier to criticise than to imitate the picture." He made a present of his Alcmena to the Agrigentines. Zeuxis did not value himself on speedily finishing his pictures; but knowing that Agathurchus gloried in his being able to paint with ease and in a little

Ziklag ‖ Zinc.

little time, he ſaid, "That for his part he, on the contrary, gloried in his ſlowneſs; and if he was long in painting, it was becauſe he painted for eternity. Verrius Flaccus ſays, that Zeuxis having painted an old woman, he laughed ſo very heartily at the ſight of this picture, that he died: but as no other of the ancients have mentioned this particular, there is the greateſt reaſon to believe it fabulous. Carlo Dati has compoſed in Italian the Life of Zeuxis, with thoſe of Parrhaſius, Apelles, and Protogenes. This work was printed at Florence in 1667.

ZICLAG, or ZIKLAG (anc. geog.), a town of the tribe of Simeon, on the borders of the Philiſtines (Joſhua xv. and xix.), but in the hands of the Philiſtines till David's time. (1 Sam. xxvii, and xxx.)

ZIMB, in natural hiſtory. See ETHIOPIA, n° 11.

ZIMENT-WATER, COPPER-WATER, in natural hiſtory, the name by which ſome have called water found in places where there are copper-mines, and lightly impregnated with particles of that metal.

The moſt famous ſpring of this kind is about a mile diſtant from Newſol in Hungary, in the great copper-mine called by the Germans *herrn-grundt*. The water in this mine is found at different depths, and is received into baſons, for the purpoſe of ſeparating the copper from it: in ſome of theſe it is much more ſated with this metal than in others, and will make the ſuppoſed change of iron into that metal much ſooner. The moſt common pieces of iron uſed in the experiments are horſe-ſhoes, nails, and the like; and they are found very little altered in ſhape, after the operation, except that their ſurfaces are more raiſed. The water appears greeniſh in the baſon, where it ſtands; but if a glaſs of it be taken up, it looks clear as cryſtal: it has no ſmell, but a ſtrong vitriolic aſtringent taſte, inſomuch that the lips and tongue are bliſtered and ſcorched upon taſting it.

ZIN (anc. geog.), a wilderneſs encompaſſing Idumea, at leaſt on the ſouth and weſt, as far as Paleſtine or Canaan; but according to Wells, on the eaſt of Edom, to the north of Ezion-gaber.

ZINC, a ſemimetal. For a deſcription of the ores of this metal, the method of extracting it from theſe ores, and for its properties, ſee CALAMINE; CHEMISTRY-*Index*; MINERALOGY, Vol. XII. page 128; METALLURGY, Part II. ſect. xii.

Zinc, beſides its medical qualities (for which ſee PHARMACY-*Index*), is of great uſe in the arts: united with copper in different proportions, it forms braſs and pinchbeck; and united with tin, it forms a kind of pewter.

Braſs is formed by mixing two parts of copper with one of zinc; pinchbeck by mixing three or four parts of copper to one of zinc: when the metals are mixed in equal quantities they form a very exact imitation of gold. Its inflammable property renders zinc a uſeful ingredient in fire-works.

It has been propoſed to ſubſtitute this ſemimetal inſtead of tin in the lining of copper veſſels; the latter being thought inſufficient to prevent the dangerous effects of the copper. Mr Malouin, who has made many experiments on the lining of veſſels in this manner, aſſerts that it ſpreads more evenly on the copper than tin itſelf; that it is much harder and leſs fuſible, and conſequently more durable than tin. Mr Macquer owns theſe advantages; but thinks it dangerous to be uſed in culinary veſſels, as it is ſoluble in vegetable acids, and the combination of it with the vitriolic acid is known to be a ſtrong emetic. Gaubius alſo mentions a celebrated remedy for convulſive diſorders, named *luna fixeta ludemannic* which Macquer affirms to be ſtrongly emetic in very ſmall doſes. "But, may it not be preſumed (ſays Foucroy), that properties which are applicable only to the vitriol and flower zinc, cannot be applied to the ſemimetal itſelf, nor even, without farther experiments, to the ſalts formed by its combination with the vegetable acids." Mr de la Plandie, doctor in medicine of the faculty of Paris, has changed this preſumption into certainty by experiments made with great care on himſelf. He took the ſalts of zinc, formed by its combination with vegetable acids, in a much ſtronger doſe than the aliments prepared in copper covered with zinc can poſſibly contain them, and found no dangerous effects to follow. However, ſince objects which relate to the health and lives of mankind cannot be treated with too much circumſpection, it appears to be prudent, and even neceſſary, not to decide on the ſubject till after a great number of experiments, and that the action of zinc combined with the vegetable acids uſed in cookery have been fully aſcertained. The flowers of zinc have been uſed as an antiſpaſmodic, and are an article of our preſent materia medica; but it does not clearly appear what ſucceſs may be expected from them.

Zinnia ‖ Zion.

ZINNIA, in botany; a genus of plants of the claſs *ſyngeneſia*, order *polygamia ſuperflua*; and in the natural ſyſtem arranged under the 49th order, *Compoſita*. The receptacle is paleaceous, the pappus conſiſts of two erect awns, the calyx is ovato-cylindrical and imbricated; the rays conſiſt of five perſiſting entire florets. There are two ſpecies, the *pauciflora* and *multiflora*, neither of which is a native of Britain.

ZINZENDORFF (Nicholas Lewis), count, was the noted founder of the German religious ſect called *Moravians*, or *Herrnhuters*, or, as they pretend, the reſtorer of that ſociety. From his own narrative it appears, that when he came of age in 1721, his thoughts were wholly bent on gathering together a little ſociety of believers, among whom he might live, and who ſhould entirely employ themſelves in exerciſes of devotion under him. He accordingly purchaſed an eſtate at Bertholſdorff in Upper Luſatia, where being joined by ſome followers, he gave the curacy of the village to a man of his own complexion; and Bertholſdorff ſoon became talked of for a new mode of piety. One Chriſtian David, a carpenter, brought a few proſelytes from Moravia: they began a new town about half a league from the village, where count Zinzendorff fixed his reſidence among them, and where great numbers of Moravians flocked and eſtabliſhed themſelves under his protection: ſo that in 1732 their number amounted to 600. An adjacent hill, called the *Huthberg*, gave occaſion to theſe coloniſts to call their new ſettlement *Huth des Herrn*, and afterward *Herrnhuth*; which may be interpreted "The guard or protection of the Lord:" and from this the whole ſect have taken their name. The count ſpared neither pains nor art to propagate his opinions; he went himſelf all over Europe, and at leaſt twice to America; and ſent his miſſionaries throughout the world. Count Zinzendorff died in 1760. Thoſe who wiſh to know more of the Moravian tenets may conſult Rimius's account of them, tranſlated in 1753. See UNITED BRETHREN.

ZINZIBER, or ZINGIBER, in botany. See AMOMUM and GINGER.

ZION, or SION (anc. geog.), a very famous mountain, ſtanding on the north ſide of the city of Jeruſalem, (Pſal. xlvii. 2.); containing the upper city, built by King David: and where ſtood the royal palace, (Joſephus). A part of Zion, ſituated at its extremity, was called *Millo*, of, or in the city of David (2 Chron. xxxii. 5.) Modern travellers, who have been upon the ſpot, ſay, that Zion is the whole of the mountain, on which Jeruſalem ſtands at this day, though not to the extent in which it anciently ſtood on the ſame mountain, as appears Pſal. ix. 12. 15. lxv. 1. lxxxvii. 2. 3. Iſ. lxii. 1. It is ſwelled into ſeveral eminences or tops; as Moriah,

Acra

Zion ‖ Zirchnitzer-ſee.

Acra, Bezetha, and Zion a particular eminence of mount and Zion Proper, &c. encompaſſed on three ſides, eaſt, weſt, and ſouth, with one continued very deep and ſteep valley; by means of which it was impregnable on theſe three ſides, and always attacked and taken, according to Joſephus, by the enemy on the north ſide, where mount Zion becomes level, and the vales of Gihon and Jehoſophat gradually loſe themſelves. This deep and ſteep valley inconteſtibly conſtitutes the compaſs of the old Jeruſalem on thoſe three ſides, as plainly appears to any perſon who has been upon the ſpot. On that particular top of the mount called *Zion* ſtood the fortreſs of the Jebuſites; which being afterwards taken by David, came to be called the *City of David*, where he had his royal reſidence and kept his court. That part of the valley which lay to the eaſt was called *Jehoſophat's*, having mount Olivet lying beyond it; that to the ſouth, *Gehinnon*; and that to the weſt, *Gihon*, from cognominal mountains lying beyond them. At the weſt end of Gihon, without the city, ſtood Golgotha or Calvary. The pretended Golgotha, ſhown at this day within the walls, is the ſpurious brat of intereſted and fraudulent monks, (Korte). There is another *Zion*, the ſame with HERMON.

ZION, or *Sion College*. See LONDON, n° 76.

ZIPH, or SIPH (anc. geog.), the name of a wilderneſs or deſert in the tribe of Judah, where David was a fugitive; lying to the ſouth-eaſt of Hebron; ſo called from Ziph or Siph, a twofold town in this tribe; the one more to the ſouth towards Idumea, on the confines of Eleutheropolis, (Jerome); the other eight miles to the eaſt of Hebron, towards the Dead Sea, inclining ſouthwards, becauſe near mount Carmel. Here was a mountain, mentioned 1 Sam. xxiii. 14. in which David abode, ſaid by Jerome to be rugged, diſmal, and always overcaſt. *Ziphim*, *Ziphæi*, or *Ziphenſes*, the inhabitants of Ziph, ver. 19.

ZIRCHNITZER-SEE, otherwiſe called the *Lake of Czirknitz*, in Carniola, is about one German or four Engliſh miles in length, and half as much in breadth, contains three beautiful iſlands, and is encompaſſed at ſome diſtance with mountains and foreſts. But what is moſt remarkable is, that it diſappears generally once a-year, about St John's or St James's day, running off through holes or pits in the bottom; ſometimes it will diſappear twice or thrice a-year, and ſometimes even in winter if the weather be dry. On the other hand, it has been known to continue two or three years without running off. Of the holes or pits, there are five much larger than the reſt, each of which ſucceſſively, when the water runs off, ſtands empty five days; ſo that the whole lake becomes dry in 25. As ſoon as the beginning of the ebb is obſerved, the fiſhing in the pits begins, which belongs to five ſeigniories. The fiſh, which are carp, tench, pike, eels, and two other ſorts called *ſchleien* and *ruten*, are caught by laying nets over the holes. Mr Keyſler tells us, that upon the ringing of a bell at Zirknitz, when the waters begin to fall, the peaſants, both men and women, run to the pools quite naked, notwithſtanding both the clergy and magiſtrates have uſed their utmoſt endeavours to ſuppreſs ſo indecent a cuſtom. When the water runs off early in the year, in about three weeks after it is gone there is good graſs on the bottom, which is mowed down, and the bottom afterwards ploughed and ſowed with millet. If the water runs not off early, nothing can be ſown; and if it returns ſoon, the ſeed is loſt. With reſpect to its return, the water at firſt burſts out of ſome pits on the ſouth ſide with great violence, a little rain always falling at the ſame time; but afterwards (when the rain falls heavier, and it thunders at the ſame time ſo loud as to ſhake the earth) it breaks out through all the apertures with great force, inſomuch that the lake is filled in 18 or 24 hours, at which time it is in a manner covered with wild fowl; ſuch as geeſe, ducks, &c. After the millet-harveſt, all manner of game is hunted, caught, or killed in it. On the ſouth ſide are two caverns, out of which, when it thunders, water iſſues with aſtoniſhing violence; and if it happens in harveſt, a great many naked, black, and blind, but fat ducklings, are brought up with the water, which in 14 days receive their ſight, and are covered with feathers.

Ziſca ‖ Zodiac.

ZISCA (John), a famous general of the forces of the Huſſites, in the 15th century, was a gentleman educated at the court of Bohemia, in the reign of Wenceſlaus. He entered very young into the army, and after diſtinguiſhing himſelf on ſeveral occaſions, loſt an eye in a battle, whence he was called *Ziſca* or *One-eyed*. At length the Reformation, begun by John Huſs, ſpreading through almoſt all Bohemia, Ziſca placed himſelf at the head of the Huſſites, and had ſoon under his command a body of 40,000 men. With this army he gained ſeveral victories over thoſe of the Romiſh religion, who carried on a kind of cruſade againſt them, and built a town in an advantageous ſituation, to which he gave the name of *Tabor*; whence the Huſſites were afterwards called *Taborites*. Ziſca loſt his other eye by an arrow at the ſiege of the city of Rubi; but this did not prevent his continuing the war, his fighting battles, and gaining ſeveral great victories, among which was that of Auſig on the Elbe, in which 9000 of the enemy were left dead on the field. The emperor Sigiſmund, alarmed at his progreſs, cauſed very advantageous propoſals to be offered to him; which he readily accepted, and ſet out to meet Sigiſmund, but died on the road. He ordered that his body ſhould be left a prey to the birds and wild beaſts; and that a drum ſhould be made of his ſkin, being perſuaded that the enemy would fly as ſoon as they heard the ſound. It is added, that the Huſſites executed his will; and that the news of this order made ſuch an impreſſion on the diſturbed imaginations of the German Papiſts, that in many battles they actually fled at the beat of the drum with the utmoſt precipitation, leaving their baggage and artillery behind them.

ZIZANIA, in botany; a genus of plants of the claſs *monœcia*, order *hexandria*; and in the natural ſyſtem arranged under the 4th order, *Gramina*. There is no male calyx; the corolla is a bivalved, beardleſs glume, intermixed with the female flowers; there is no female calyx, the corolla is an univalved, cucullated, and ariſtated glume; the ſtyle is bipartite, and there is one ſeed covered with the plaited corolla. There are three ſpecies; the aquatica, the paluſtris, and terreſtris, none of which are natives of Britain.

ZODIAC, in aſtronomy, a broad circle, whoſe middle is the ecliptic, and its extremes two circles parallel thereto, at ſuch a diſtance from it as to bound or comprehend the excurſions of the ſun and planets, (ſee ASTRONOMY). It is a curious enough fact, that the ſolar diviſion of the Indian zodiac is the ſame in ſubſtance with that of the Greeks, and yet that it has not been borrowed either from the Greeks or the Arabians. The identity, or at leaſt ſtriking ſimilarity, of the diviſion, is univerſally known; and M. Montucla has endeavoured to prove, that the Bramins received it from the Arabs. His opinion, we believe, has been very generally admitted; but in the ſecond volume of the Aſiatic Reſearches, the accompliſhed preſident Sir William Jones has proved unanſwerably, that neither of thoſe nations borrowed that diviſion from the other; that it has been known among the Hindoos from time immemorial; and that it was probably invented by the firſt progenitors of that race, whom he conſiders as the moſt ancient of mankind, before their diſperſion. The queſtion is not of importance ſufficiently general, ſtraitened as we are by the limits preſcribed us, for our entering into the diſpute; but we think it

Zoegea, Zone.

our duty to mention it, that our aſtronomical readers, if they think it worth their while, may have recourſe to the original writers for further information.

ZOEGEA, in botany; a genus of plants of the claſs *ſyngeneſia*, and order *polygamia fruſtranea*. The receptacle is briſtly; the pappus ſetaceous; the corollulæ of the radius ligulated; the calyx imbricated. There are two ſpecies, the capenſis and the leptaurea, neither of which are natives of Britain.

ZONE, in geography and aſtronomy, a diviſion of the terraqueous globe with reſpect to the different degrees of heat found in the different parts thereof. The zones are denominated torrid, frigid, and temperate. The torrid zone is a band, ſurrounding the terraqueous globe, and terminated by the two tropics. Its breadth is 46°. 58′. The equator, running through the middle of it, divides it into two equal parts, each containing 23°. 29′. The ancients imagined the torrid zone uninhabitable. The temperate zones are contained between the tropics and the polar circles. The breadth of each is 43. 2. The frigid zones are ſegments of the ſurface of the earth, terminated, one by the antarctic, and the other by the arctic circle. The breadth of each is 46. 58.

Zone.

ZOOLOGY.

Mammalia

IS that part of Natural Hiſtory which relates to *Animals*.

In order to abridge the ſtudy of zoology, many methods of reducing animals to claſſes, genera, and ſpecies, have been invented: But as that of Linnæus is undoubtedly the beſt, the moſt extenſive, and the moſt generally adopted, we ſhall give a brief account of it.

Linnæus divides the whole animal kingdom into ſix claſſes. The characters of theſe ſix claſſes are taken from the internal ſtructure of animals, in the following manner:

CLASS I. MAMMALIA, includes all animals that ſuckle their young. The characters of this claſs are theſe:—The *heart* has two ventricles and two auricles; the *blood* is red and warm; and the animals belonging to it are *viviparous*.

CLASS II. AVES, or BIRDS. The characters are the ſame with thoſe of Claſs I. excepting that the animals belonging to it are *oviparous*. See BIRD, and ORNITHOLOGY.

CLASS III. AMPHIBIA, or AMPHIBIOUS ANIMALS. The *heart* has but *one ventricle* and one *auricle*; the *blood* is red and cold; and the animals belonging to this claſs have the command of their *lungs*, ſo that the intervals between *inſpiration* and *expiration* are in ſome meaſure *voluntary*. See AMPHIBIOUS.

CLASS IV. PISCES, or FISHES. The *heart* has the ſame ſtructure, and the *blood* the ſame qualities, with thoſe of the *Amphibia*; but the animals belonging to this claſs are eaſily diſtinguiſhed from the Amphibia, by having no ſuch voluntary command of their *lungs*, and by having external *branchiæ* or *gills*. See FISH, and ICHTHYOLOGY.

CLASS V. INSECTA, or INSECTS. The *heart* has *one ventricle*, but no *auricle*; the *blood* is cold and white; and the animals are furniſhed with *antennæ* or *feelers*. See INSECT.

CLASS VI. VERMES, or WORMS. The characters are the ſame with thoſe of Claſs V. only the animals have no antennæ, and are furniſhed with *tentacula*.

The *Firſt Claſs*, MAMMALIA, is ſubdivided into ſeven ORDERS; the characters of which are taken from the number, ſtructure, and ſituation of the TEETH.

ORDER I. The PRIMATES have four inciſores, or *fore-teeth*, in each jaw, and one *dog-tooth*. N. B. By *one* dog-tooth, Linnæus means one on each ſide of the fore teeth in both jaws.—This order includes four genera, *viz.* Homo, Simia, Lemur, Veſpertilio.

ORDER II. The BRUTA have no *fore-teeth* in either jaw. This order includes ſeven genera, *viz.* Rhinoceros, Elephas, Trichechus, Bradypus, Myrmecophaga, Manis, Daſypus.

Mammalia Avos.

ORDER III. The FERÆ have, for the moſt part, ſix *conical fore-teeth* in each jaw. This order includes 10 genera, *viz.* Phoca, Canis, Felis, Viverra, Muſtela, Urſus, Didelphis, Talpa, Sorex, Erinaceus.

ORDER IV. The GLIRES have two fore-teeth in each jaw, and no *dog-teeth*.—This order includes 10 genera, *viz.* Hyſtrix, Lepus, Caſtor, Mus, Sciurus, Myoxus, Cavia, Arotomys, Dypus, Hyrox.

ORDER V. The PECORA, have no *fore-teeth* in the upper jaw, but 6 or 8 in the under-jaw.—This order includes 8 genera, *viz.* Camelus, Moſchus, Giraffa, Cervus, Antilope, Capra, Ovis, Bos.

ORDER VI. The BELLUÆ, have *obtuſe-fore-teeth* in each jaw.—This order includes 4 genera, *viz.* Equus, Hippopotamus, Sus, Tapir.

ORDER VII. The CETE, or *whale kind*, have no uniform character in their teeth, being very different in the different genera; but are ſufficiently diſtinguiſhed from the other orders of Mammalia, by living in the ocean, having pectoral fins, and a fiſtula or ſpiraculum upon the head.—This order includes 4 genera, *viz.* Monodon, Balæna, Phyſeter, Delphinus. See CETACEOUS.

The *generic* characters of the Mammalia are, like thoſe of the orders, almoſt entirely taken from the TEETH, excepting the Veſpertilio, which, beſides the character of the order derived from the teeth, has this farther mark, that there is a membrane attached to the feet and ſides, by means of which the creature is enabled to fly:—the Hyſtrix whoſe body is covered with ſharp ſpines:—and the whole order of Pecora, whoſe genera, beſides the characters taken from the teeth, are diſtinguiſhed into thoſe which have *horns*, thoſe which have *no horns*, and by peculiarities in the horns themſelves.

The *ſpecific* characters are very various, being taken from any part of the body which poſſeſſes a peculiar uniform mark of diſtinction. As examples of theſe characters are to be found under the proper name of each genus, it is unneceſſary to ſay any thing further concerning them in this place.

The *Second Claſs*, AVES, is ſubdivided into ſix ORDERS; the characters of which are taken chiefly from the ſtructure of the BILL.

ORDER I. The ACCIPITRES, have a HOOKED BILL, the ſuperior mandible, near the baſe, being extended on each ſide beyond the inferior; and in ſome it is armed

Aves, Amphibia.

armed with *teeth*.—This order includes four ſpecies, *viz.* Vultur, Falco, Strix, Lanius.

ORDER II. The PICÆ, have a convex, compreſſed BILL, reſembling a knife.—This order contains 23 genera, *viz.* Trochilus, Certhia, Upupa, Glaucopis, Buphaga, Sitta, Oriolus, Coracias, Gracula, Corvus, Paradiſea, Ramphaſtos, Trogon, Pſittacus, Crotophaga, Picus, Yunx, Cuculus, Bucco, Boceros, Alcedo, Merops, Todus.

ORDER III. The ANSERES, have a ſmooth BILL, broadeſt at the point, covered with a ſmooth ſkin, and furniſhed with teeth: The *tongue* is fleſhy; and the toes are palmated or webbed.—This order includes 13 genera, *viz.* Anas, Mergus, Phaeton, Plotus, Rhyncops, Diomedea, Aptenodyta, Alca, Procellaria, Pelecanus, Larus, Sterna, Colymbus.

ORDER IV. The GRALLÆ, have a ſomewhat cylindrical BILL: The tail is ſhort, and the thighs are naked. This order contains 20 genera, *viz.* Phœnicopterus, Platalea, Palamedea, Myctéria, Tantalus, Ardea, Corrira, Recurviroſtra, Scolopax, Tringa, Fulica, Parra, Rallus, Vaginalis, Pſophia, Cancroma, Scopus, Glareola, Hæmatopus, Charadrius.

ORDER V. The GALLINÆ, have a convex BILL; the ſuperior mandible is vaulted over the inferior: The *noſtrils* are half covered with a convex cartilaginous membrane; and the *feet* are divided, but connected, at the inmoſt joint.—This order contains 10 genera, *viz.* Otis, Struthio, Didus, Pavo, Meleagris, Penelope, Crax, Phaſianus, Numida, Tetrao.

ORDER VI. The PASSERES, have a conical ſharp-pointed BILL; and the *noſtrils* are oval, wide, and naked.—This order contains 17 genera, *viz.* Loxia, Colius, Fringilla, Phytotoma, Emberiza, Caprimulgus, Hirundo, Pipra, Turdus, Ampelis, Tanagra, Mucicapa, Parus, Motacilla, Alauda, Sturnus, Columba.

The *generic* characters of this claſs are taken from peculiarities in the *bill*, the *noſtrils*, the *tongue*, the *feet*, the *feathers*, the *face*, the *figure* of the *body*, &c.

The characters which ſerve to diſtinguiſh the *ſpecies* are very various: For example, the *colour* of the particular *feathers* or parts of *feathers*; *creſts* of feathers on the head, diſpoſed in different manners; the colour of the *cere* or *wax*; the colour of the *feet*; the ſhape and length of the *tail*; the number, ſituation, &c. of the *toes*; the colour and figure of the *bill*, &c.

The *Third Claſs*, AMPHIBIA, is divided into two ORDERS.

ORDER I. The REPTILES, have four *feet*, and breathe by the *mouth*.—This order contains four genera, *viz.* Teſtudo, Draco, Lacerta, Rana.

ORDER II. The SERPENTES, have no *legs*, and breathe by the *mouth*.—This order contains ſix genera, *viz.* Crotalus, Boa, Coluber, Anguis, Amphiſbæna, Cœcilia.

The *generic* characters of this claſs are taken from the general figure of the *body*; from their having *tails* or *no tails*; being covered with a *ſhell*; having *teeth* or *no teeth*, in the *mouth*; being furniſhed with *lungs*; having *covered* or *naked* bodies; from the number, ſituation, and figure of the *ſcuta* and *ſcales*; from the number and ſituation of the *ſpiracula*: from the ſituation of the *mouth*, &c.

The *ſpecific* characters are ſo very various, that it would be ſuperfluous to enumerate them.

The *Fourth Claſs*, PISCES, is ſubdivided into ſix ORDERS, the characters of which are taken from the ſituation of the *belly fins*.

Piſces, Inſecta.

ORDER I. The APODES, have no *belly-fins*.—This order contains eight genera, *viz.* Muræna, Gymnotus, Trichiurus, Anarchichas, Ammodytes, Ophidium, Stromateus, Xiphias, Sternoptyx, Leptocephalus.

ORDER II. The JUGULARES, have the *belly-fins* placed before the *pectoral fins*.—This order includes five genera, *viz.* Callionymus, Uranoſcopus, Trachinus, Gadus, Blennius, Kurtus.

ORDER III. The THORACICI, have the *belly-fins* placed *under* the *pectoral fins*.—This order comprehends 19 genera, *viz.* Cepola, Echeneis, Coryphæna, Gobius, Cottus, Scorphæna, Zeus, Pleuronectes, Chætodon, Sparus, Scarus, Labrus, Sciæna, Perca, Gaſteroſteus, Scomber, Centrogaſter, Mullus, Trigla.

ORDER IV. The ABDOMINALES, have the *belly-fins* placed *behind* the *pectoral fins*.—This order contains 16 genera, *viz.* Cobitis, Amia, Silurus, Teuthis, Loricaria, Salmo, Fiſtularia, Eſox, Elops, Argentina, Atherina, Mugil, Exocætus, Polynemus, Clupea, Cyprinus.

ORDER V. The BRANCHIOSTEGI, have the *gills* deſtitute of bony rays.—This order contains 10 genera, *viz.* Mormyrus, Oſtracion, Tetrodon, Diodon, Syngnathus, Pegaſus, Centricus, Baliſtes, Cyclopterus, Lophius.

ORDER VI. The CHONDROPTERYGII, have cartilaginous *gills*.—This order contains five genera, *viz.* Acipenſer, Chimæra, Squalus, Raia, Petromyzon.

The *generic* characters of this claſs are taken from peculiarities in the *head*, the *mouth*, the *teeth*, the *noſtrils*, the *rays* in the *membrane* of the *gills*, the *eyes*, the general *figure* of the *body*, the figure of the *tail*, the ſituation of the *ſpiracula*, &c.

The *ſpecific* characters are taken from peculiarities in all the parts above enumerated, and many others.

See further the articles FISH and ICHTHYOLOGY.

The *Fifth Claſs*, INSECTA, is ſubdivided into ſeven ORDERS, the characters of which are taken from the wings. See the article INSECT.

ORDER I. The COLEOPTERA, have *four wings*, the two ſuperior ones being cruſtaceous, and furniſhed with a *ſtraight ſuture*.—This order comprehends 47 genera, *viz.* Scarabæus, Lucanus, Dermeſtes, Melyris, Byrrhus, Silpha, Tritoma, Hydrophilus, Hiſter, Pauſus, Boſtrichus, Anthrenus, Nitidula, Coccinella, Curculio, Brentus, Attelabus, Erodius, Staphylinus, Scaurus, Zygia, Meloe, Tenebrio, Caſſida, Opatrum, Mordella, Chryſomela, Horia, Apalus, Manticora, Pimelia, Gyrinus, Cucujus, Cryptocephalus, Bruchus, Ptinus, Hiſpa, Bupreſtis, Necydalis, Lampyris, Cantharis, Notoxus, Elater, Calopus, Alurnus, Carabus, Lytta, Serropalpus, Cerambyx, Leptura, Rhinomacer, Zonitis, Cicindela, Dyticus, Forficula.

ORDER II. The HEMIPTERA, have *four wings*, the two ſuperior ones being *ſemicruſtaceous*, and *incumbent*, *i. e.* the *interior edges* lie above one another.—This order includes 14 genera, *viz.* Blatta, Pneumora, Mantis, Gryllus, Fulgora, Cicada, Notonecta, Nepa, Cimex, Macrocephalus, Aphis, Chermes, Coccus, Thrips.

Inſecta, Vermes

ORDER III. The LEPIDOPTERA, have *four wings*, all of them imbricated with *ſcales*.—This order contains three genera, *viz.* Papilio, Sphinx, Phalæna.

ORDER IV. The NEUROPTERA, have *four wings*, interwoven with veins, like a peice of *network*, and no *ſting* in the *anus*.—This order includes ſeven genera, *viz.* Libella, Ephemera, Hemerobius, Myrmelion, Phryganea, Panorpa, Rophidia.

ORDER V. The HYMENOPTERA, have the ſame characters with the former, only the *anus* is armed with a *ſting*. But this mark is peculiar to the *females* and *neuters*; for the males have no *ſting*.—This order comprehends 15 genera, *viz.* Cynips, Tentredo, Sirex, Ichneumon, Sphex, Scolia, Thynnus, Leucoſpis, Tiphia, Chalcis, Chryſis, Veſpa, Apis, Formica, Mutilla.

ORDER VI. The DIPTERA, have *two wings*, and two *clavated halteres* or *balances* behind each wing.—This order contains 12 genera, *viz.* Diopſis, Tipula, Muſca, Tabanus, Empis, Conops, Oeſtrus, Aſilus, Stomoxys, Culex, Bombylius, Hippoboſca.

ORDER VII. The APTERA, have *no wings*.—This order contains 15 ſpecies, *viz.* Lepiſma, Podura, Termes, Pediculus, Pulex, Acarus, Hydrachna, Aranea, Phalangium, Scorpio, Cancer, Monoculus, Oniſcus, Scolopendra, Julus. See farther the articles ENTOMOLOGY and INSECT.

The *Sixth Claſs*, VERMES, is divided into five ORDERS.

ORDER I. The INTESTINA, are the moſt *ſimple animals*, being perfectly *naked*, and without *limbs* of any kind.—This order contains 21 genera, *viz.* Aſcaris, Trichocephalus, Uncinaria, Tilaria, Scolex, Ligula, Linguatula, Strongylus, Echinorhynchus, Hæruca, Cucullanus, Caryophyllæus, Faſciola, Tænia, Furia, Myxine, Gordius, Hirudo, Lumbricus, Sipunculus, Planaria.

ORDER II. The MOLLUSCA, are likewiſe *ſimple naked animals*, without any *ſhell*; but they are *brachiated*, or furniſhed with a kind of *limbs*.—This order comprehends 31 genera, *viz.* Actiania, Clava, Mammaria, Pedicellaria, Aſcidia, Salpa, Dagyſa, Pterotrachea, Limax, Aplyſia, Doris, Tethis, Holothuria, Terebella, Triton, Sepia, Clio, Lobaria, Lernæa, Scyllæa, Glaucus, Aphrodita, Amphitrite, Spio, Nereis, Nais, Phyſſophora, Meduſa, Lucernaria, Aſterias, Echinus. Vermes

ORDER III. The TESTACEA, have the ſame characters with thoſe of Order II. but are covered with a *ſhell*.—This order includes 36 genera, *viz.* Chiton, Lepas, Pholas, Mya, Solen, Tellina, Cardium, Mactra, Donax, Venus, Spondylus, Chama, Arca, Oſtrea, Anomia, Mytilus, Pinna, Argonauta, Nautilus, Conus, Cypræa, Bulla, Voluta, Buccinum, Strombus, Murex, Trochus, Turbo, Helix, Nerita, Haliotis, Patella, Dentalium, Serpula, Teredo, Sabella.

ORDER IV. The ZOOPHYTA, are *compound animals*, furniſhed with a kind of *flowers*, and having a vegetating *root* and *ſtem*.—This order contains 15 genera, *viz*, Tubipora, Madrepora, Millepora, Celleporа, Iſis, Antipathes, Gorgonia, Alcyonium, Spongia, Fluſtra, Tubularia, Corralina, Sertularia, Pennatula, Hydra. See *ANIMAL Flower*.

ORDER V. The INFUSORIA, conſiſts of very ſmall *ſimple animals*.—This order contains 15 genera, *viz.* Brachionus, Vorticella, Trichoda, Cercaria, Leucopera, Gonium, Colpoda, Paramecium, Cyclidium, Burſaria, Vibrio, Enchelis, Bacillaria, Volvox, Monas.

For more particular information concerning the ſeveral branches and ſubjects of zoology, the reader may conſult the various articles above referred to, and he will find moſt of the genera deſcribed in their order in the alphabet.

Zoophite ‖ Zoroaſter.

ZOOPHYTE, in natural hiſtory, the 4th order of the claſs of *Vermes*. See ZOOLOGY.

ZOOTOMY, the art of diſſecting animals or living creatures, being the ſame with anatomy. See ANATOMY, and *COMPARATIVE Anatomy*.

ZORILLE, in zoology, a ſpecies of weaſel, having the back and ſides marked with ſhort ſtripes of black and white, the laſt tinged with yellow; the tail long and buſhy, partly white and partly black; the legs and belly black. This animal inhabits Peru, and other parts of South America: its peſtilential vapour overcomes even the panther of America, and ſtupefies that formidable enemy.

ZOROASTER, or ZERDUSHT, a celebrated ancient Philoſopher, ſaid to have been the reformer or the founder of the religon of the magi. It is wholly uncertain to how many eminent men the name of Zoroaſter belonged. Some have maintained that there was but one Zoroaſter, and that he was a Perſian; others have ſaid that there were ſix eminent founders of philoſophy of this name. Ham the ſon of Noah, Moſes, Oſiris, Mithras, and others, both gods and men, have by different writers been aſſerted to have been the ſame with Zoroaſter. Many different opinions have alſo been advanced concerning the time in which he flouriſhed. Ariſtotle and Pliny fix his date at ſo remote a period as 6000 years before the death of Plato. According to Laertius, he flouriſhed 600 years before the Trojan war; according to Suidas, 500. If, in the midſt of ſo much uncertainty, any thing can be advanced with the appearance of probability, it ſeems to be this; that there was a Zoroaſter, a Perſo-Median, who flouriſhed about the time of Darius Hyſtaſpes; and that beſides him there was another Zoroaſter, who lived in a much more remote period among the Babylonians, and taught them aſtronomy. The Greek and Arabian writers are agreed concerning the exiſtence of the Perſian Zoroaſter; and the ancients unanimouſly aſcribe to a philoſopher, whom they call *Zoroaſter*, the origin of the Chaldean aſtronomy, which is certainly of much earlier date than the time of Hyſtaſpes: it ſeems, therefore, neceſſary to ſuppoſe a Chaldean Zoroaſter diſtinct from the Perſian. Concerning this Zoroaſter, however, nothing more is known, than that he flouriſhed towards the beginning of the Babyloniſh empire, and was the father of the Chaldean aſtrology and magic. All the writings that have been aſcribed to Zoroaſter are unqueſtionably ſpurious. Zoroaſter, Zoſtera.

Z O S

ZOSTERA, in botany; a genus of plants of the claſs *gynandria*, order *polyandria*; and in the natural ſyſtem arranged under the ſecond order, *Piperitæ*. The ſpadix is linear, and fertile only on one ſide; there is no calyx nor corolla; the ſtamina are alternate; the ſeeds ſolitary and alternate. There are two ſpecies, the marina and oceanica; neither of which is a native of Britain.

Zoſimus || Zuinglius.

ZOSIMUS, an ancient hiſtorian who lived at the end of the fourth and beginning of the fifth centuries. There are ſix books of his hiſtory extant; in the firſt of which he runs over the Roman affairs in a very ſuccinct manner from Auguſtus to Diocleſian; the other five are written more diffuſely. Zoſimus was a zealous Pagan; whence we find him frequently inveighing with great bitterneſs againſt the Chriſtian princes, particularly againſt Conſtantine the Great, and the elder Theodoſius. His hiſtory has been publiſhed with the Latin verſion of Leunclavius at Frankfort, 1590, with the other minor hiſtorians of Rome, in folio; and at Oxford in 8vo, 1679.

ZUG, a canton of Switzerland, bounded on the eaſt and north by that of Zurich, on the ſouth by Schweiz and Lucern, and on the weſt by the canton of Lucern and the Freye-Amt or Free Provinces. It is not above 12 miles either way; but very populous and fruitful, yielding wine, wheat, cheſnuts, and other fruits, in its vales, and excellent paſture on its mountains. The inhabitants of this canton are ſtaunch Roman Catholics. It lies in the dioceſe of Conſtance, and its government is democratical. There are two lakes in it abounding in fiſh, particularly large carps, pikes, and a ſpecies of trouts called *rotels*; as well as ſeveral woods full of game. Zug, which gives name to it, and is its capital, ſtands on the eaſt ſide of a lake of the ſame name, about ſeven miles long, and is a ſtrong neat town, containing a priory and two convents.

ZUINGLIUS (Ulricus), an able and zealous reformer, who laid the foundation of a ſeparation from Rome in Switzerland, at the ſame time that Luther did the like in Saxony, was born at Wildehauſen in 1487. While he officiated as preacher at Zurich, a Franciſcan ſent by Leo X. came to publiſh indulgences there; againſt which Zuinglius after the example of Luther, declaimed powerfully. In the courſe of this oppoſition he ſtarted a new doctrine, which he called *Evangelical Truth*; and from the beginning of 1519, to 1523, he preached not only againſt indulgences, but againſt other articles of the Romiſh church. But though Zuinglius made no leſs progreſs than Luther, he yet conducted himſelf with more moderation and prudence; and wiſhing to have the concurrence of the civil powers, procured two aſſemblies to be called at Zurich: by the firſt, he was authoriſed to proceed as he had begun; and by the ſecond, the outward worſhip and ceremonies of the church of Rome were aboliſhed. During theſe tranſactions, Zuinglius publiſhed ſeveral books in defence of his doctrines; but treating of the euchariſt, and preſcribing a form of celebrating the Lord's Supper different from Luther, he was involved in violent diſputes with the reſt of his reforming brethren. Interpreting the words *hoc eſt corpus meum*, by *hoc ſignificat corpus meum*, he maintained, that the body and blood of Chriſt are not *really* preſent in the euchariſt; and that the bread and wine are nothing more than external *ſigns* or *ſymbols*, deſigned to excite in the minds of Chriſtians the remembrance of the ſufferings of the Divine Saviour, and of the benefits which ariſe from them. This opinion, which was afterwards ſo plauſibly ſupported by the celebrated Hoadley (ſee *Supper of the Lord*), gave offence to Calvin as well as to Luther; but the doctrines of Zuinglius, which were moſt obnoxious to that eminent reformer, were thoſe which deny *election* and *reprobation*, and make the church as a ſociety wholly dependent on the ſtate. Reſpecting the divine DECREES, the opinion of Zuinglius and his followers differed very little from that of the PELAGIANS: for he maintained that heaven is open to all who live according to the dictates of right reaſon; and he ſeems to have denied the doctrine of original ſin. Inſtead of declaring with Calvin, that the church is a ſeparate independent body, veſted with the right of legiſlation for itſelf, Zuinglius aſcribed to the civil magiſtrate an abſolute and unbounded power in religious matters, allowing at the ſame time a certain ſubordination among the miniſters of the church. This was abundantly agreeable to the magiſtrates of Zurich; but the reſt of the Swiſs cantons diſallowing of their proceedings, other aſſemblies were called, and things tending to tumult, both ſides had recourſe to arms; when Zuinglius, who began as a preacher, died in arms as a ſoldier, in 1531. His works amount to four vols folio. Zurich.

ZURICH, a canton of Switzerland, bounded to the north by Swabia and the canton of Schaffhauſen; to the ſouth by the town and territory of Rapperſchweil and the cantons of Switz and Zug; to the eaſt by the Thurgau, Toggenburg, and Utznach; and to the weſt by the free bailiages and county of Baden. It is about 60 miles from north to ſouth, and 48 from eaſt to weſt. With reſpect to its face, air, and ſoil, it is ſaid to be an epitome of all Switzerland, as containing in it hills, valleys, plains, cornlands, vineyards, lakes, and rivers. Their wines have a tartneſs at firſt, but the longer they are kept the more agreeable they are. The other products are excellent fruits, corn, paſture, fine clay, chalk, ſeveral coloured earths, pit-coal, turf, and ſulphur. There are alſo ſome mineral ſprings in the canton; and of the lakes, that of Zurich is the moſt conſiderable. The reformation was introduced here by Zuinglius in the year 1517. This canton is the firſt in rank, and inferior only to that of Bern in extent, power, and wealth; in conſequence of which, its repreſentatives preſide in the general diets, when held in any place belonging in common to the cantons; and the affairs relating to the whole confederacy are tranſacted in its offices. Its quota, for the defence of the ſeveral members of the confederacy, is 1400 men. Of one of the two armies raiſed on theſe occaſions, it nominates one of the commanders in chief, as Lucern does the other. Its revenue is ſaid to be about 150,000 crowns a-year; of which, one year with another, two-thirds are expended in the charges of government, and the reſt laid up in the treaſury. It can bring 50,000 fighting men into the field at a very ſhort warning.

ZURICH, the capital of a canton of the ſame name in Switzerland, ſtands in a pleaſant country, near where the river Aa iſſues from the lake that takes its name from the town, 23 miles from Schaffhauſen, and 114 from Geneva. After having been ruined by Attila the Hun, it is ſaid to have been reſtored by Thuricus, ſon of Theodoric king of the Goths, from whom it took the name of *Thuricum*, corrupted afterwards into that of *Zurich*. It is fortified in the modern way, and has wide ditches, faced with free ſtone. There are five arſenals in it, well ſtored with arms and artillery; an academy or college, having 15 profeſſors; a muſeum, or chamber of rarities; a ſtately town-houſe, the pillars in the front of which are of black marble, ſtreaked with white; and a town library. The ſovereignty and adminiſtration of all affairs are lodged in the greater and leſſer council, out of which are choſen the city-officers, as the councils are out of the 13 companies of burghers. There are ſeveral other councils or colleges, each of which has its particular department. Here are a great variety of ſilk, woollen, linen, cotton, and other manufactures; this being the place of the greateſt trade in all Switzerland. The town is well ſupplied with proviſions by and from its lake. The ſtreets are neat, and houſes well built, but not magnificent. In the town library are ſeveral letters to Bullinger from lady Jane Gray daughter to the duke of Suffolk. In one of the arſenals is the figure of William Tell, dreſſed and armed

Zurich. armed in the ancient Swiſs manner, with the croſs-bow whence he ſhot the arrow that ſtruck the apple off his child's head.

Both men and women are ſo fond of muſic, that there are few of them that cannot play on ſome inſtrument. If a burgher goes out of town, or a peaſant enters it, without a ſword, they are liable to be fined. No perſons, whatever their rank or office may be, are exempted from the ſumptuary laws. The burgomaſters, who are the ſame as the advoyers at Bern, have the title of excellence. The hoſpitals here are very neat and well endowed; but they do not affect the ridiculous vanity of lodging the poor in palaces. Not only in this town and canton, and other parts of Switzerland, but alſo among the Griſons, the miniſters all preach covered. The country about the town is very pleaſant and fruitful; for both which it is not a little indebted to the lake, that extends 24 miles in length, and about two or three in breadth. The water is of a green colour, ſuppoſed to be owing to the melted ſnow that falls into it from the adjacent mountains. That part of it next Zurich is called the *Lower Lake*, and the other end the *Upper*. The cathedral, or great church here, is collegiate. The preſent city is ſaid to owe its origin to a nunnery, founded by the emperor Lewis I. near where the ancient Tigurum ſtood. E. Long. 8. 30. N. Lat. 47. 20.

What may be reckoned one of the greateſt curioſities of Zurich is the pump invented and erected here by H. Andreas Wirtz, a tinplate worker of this place. The invention ſhows him to be a perſon of very uncommon mechanical knowledge and ſagacity. As it is a machine which operates on a principle widely different from all other hydraulic machines, and is really excellent in its kind, we preſume that our readers will not be diſpleaſed with ſome account of it, although it be rather out of place here, and ſhould have appeared in the article *Water Works*.

Pl. DXLII. Fig. 16. is a ſketch of the ſection of the machine, as it was firſt erected by Wirtz at a dye-houſe in Limmat, in the ſuburbs or vicinity of Zurich. It conſiſts of a hollow cylinder, like a very large grindſtone, turning on a horizontal axis, and partly plunged in a ciſtern of water. The axis is hollow at one end, and communicates with a perpendicular pipe CBZ′, part of which is hid by the cylinder. This cylinder or drum is formed into a ſpiral canal by a plate coiled up within it like the main ſpring of a watch in its box; only the ſpires are at a diſtance from each other, ſo as to form a conduit for the water of uniform width. This ſpiral partition is well joined to the two ends of the cylinder, and no water eſcapes between them. The outermoſt turn of the ſpiral begins to widen about $\frac{1}{4}$ths of a circumference from the end, and this gradual enlargement continues from Q to S nearly a ſemicircle: this part may be called the Horn. It then widens ſuddenly, forming a Scoop or ſhovel SS′. The cylinder is ſupported ſo as to dip ſeveral inches into the water, whoſe ſurface is repreſented by VV′.

When this cylinder is turned round its axis in the direction ABEO, as expreſſed by the two darts, the ſcoop SS′ dips at V′, and takes up a certain quantity of water before it emerges again at V. This quantity is ſufficient to fill the taper part SQ, which we have called the Horn; and this is nearly equal in capacity to the outermoſt uniform ſpiral round.

After the ſcoop has emerged, the water paſſes along the ſpiral by the motion of it round the axis, and drives the air before it into the riſing-pipe, where it eſcapes.—In the mean time, air comes in at the mouth of the ſcoop; and when the ſcoop again dips into the water, it again takes in ſome. Thus there is now a part filled with water and a part filled with air. Continuing this motion, we ſhall receive a ſecond round of water and another of air. The water in any turn of the ſpiral will have its two ends on a level; and the air between the ſucceſſive columns of water will be in its natural ſtate; for ſince the paſſage into the riſing-pipe or Main is open, there is nothing to force the water and air into any other poſition. But ſince the ſpires gradually diminiſh in their length, it is plain that the column of water will gradually occupy more and more of the circumference of each. At laſt it will occupy a complete turn of ſome ſpiral that is near the centre; and when ſent farther in, by the continuance of the motion, ſome of it will run back over the top of the ſucceeding ſpiral. Thus it will run over at K 4 into the right hand ſide of the third ſpiral. Therefore it will puſh the water of this ſpire backwards, and raiſe its other end, ſo that it alſo will run over backwards *before* the next turn be completed. And this change of diſpoſition will at laſt reach the firſt or outermoſt ſpiral, and ſome water will run over into the horn and ſcoop, and finally into the ciſtern.

Zurich.

But as ſoon as water gets into the riſing-pipe, and riſes a little in it, it ſtops the eſcape of the air when the next ſcoop of water is taken in. Here are now two columns of water acting againſt each other by hydroſtatic preſſure and the intervening column of air. They muſt compreſs the air between them, and the water and air columns will now be unequal. This will have a general tendency to keep the whole water back, and cauſe it to be higher on the left or riſing ſide of each ſpire than on the right deſcending ſide. The exceſs of height will be juſt ſuch as produces the compreſſion of the air between that and the preceding column of water. This will go on increaſing as the water mounts in the riſing-pipe; for the air next to the riſing-pipe is compreſſed at its inner end with the weight of the whole column in the main. It muſt be as much compreſſed at its outer end. This muſt be done by the water column without it; and this column exerts this preſſure partly by reaſon that *its* outer end is higher than its inner end, and party by the tranſmiſſion of the preſſure on its outer end by air, which is ſimilarly compreſſed from without. And thus it will happen that each column of water, being higher at its outer than at its inner end, compreſſes the air on the water-column beyond or within it, which tranſmits this preſſure to the air beyond it, adding to it the preſſure ariſing from its own want of level at the ends. Therefore the greateſt compreſſion, viz. that of the air next the main, is produced by *the ſum of all the tranſmitted preſſures*; and theſe are the ſum of all the differences between the elevations of the inner ends of the water columns above their outer ends: and the height to which the water will riſe in the main will be juſt equal to this ſum.

Draw the horizontal lines K′K 1, K′K2, K′K3, &c. and *m n*, *m n*, *m n*, &c. Suppoſe the left hand ſpaces to be filled with water, and the right hand ſpaces to be filled with air. There is a certain gradation of compreſſion which will keep things in this poſition. The ſpaces evidently decreaſe in arithmetical progreſſion; ſo do the hydroſtatic heights and preſſures of the water columns. If therefore the air be denſe in the ſame progreſſion, all will be in hydroſtatical equilibrium. Now this is evidently producible by the mere motion of the machine; for ſince the denſity and compreſſion in each air column is ſuppoſed inverſely as the bulk of the column, the abſolute quantity of air is the ſame in all; therefore the column firſt taken in will paſs gradually inwards, and the increaſing compreſſion will cauſe it to occupy preciſely the whole right hand ſide of every ſpire. The gradual diminution of the water columns will be produced during the motion by the water running over backwards at the

Zurich. the top, from ſpire to ſpire, and at laſt coming out by the ſcoop.

It is evident that this diſpoſition of the air and water will raiſe the water to the greateſt height, becauſe the hydroſtatic height of each water column is the greateſt poſſible, *viz.* the diameter of the ſpire. This diſpoſition may be obtained in the following manner: Take CL to CB as the denſity of the external air to its denſity in the laſt column next the riſing-pipe or main; that is, make CL to CB as 33 feet (the height of the column of water which balances the atmoſphere), to the ſum of 33 feet and the height of the riſing-pipe. Then divide BL into ſuch a number of turns, that the ſum of their diameters ſhall be equal to the height of the main; then bring a pipe ſtraight from L to the centre C. The reaſon of all this is very evident.

But when the main is very high, this conſtruction will require a very great diameter of the drum, or many turns of a very narrow pipe. In ſuch caſes it will be much better to make the ſpiral in the form of a cork-ſcrew, as in fig. 17. inſtead of this flat form like a watch-ſpring. The pipe which forms the ſpiral may be lapped round the fruſtrum of a cone, whoſe greateſt diameter is to the leaſt (which is next to the riſing pipe) in the ſame proportion that we aſſigned to CB and CL. By this conſtruction the water will ſtand in every round ſo as to have its upper and lower ſurfaces tangents to the top and bottom of the ſpiral, and the water columns will occupy the whole aſcending ſide of the machine, while the air occupies the deſcending ſide.

This form is vaſtly preferable to the flat: it will allow us to employ many turns of a large pipe, and therefore produce a great elevation of a large quantity of water.

The ſame thing will be ſtill better done by lapping the pipe on a cylinder, and making it taper to the end, in ſuch a proportion that the contents of each round may be the ſame as when it is lapped round the cone. It will raiſe the water to a greater height (but with an increaſe of the impelling power) by the ſame number of turns, becauſe the vertical or preſſing height of each column is greater.

Nay, the ſame thing may be done in a more ſimple manner, by lapping a pipe of uniform bore round a cylinder. But this will require more turns, becauſe the water columns will have leſs differences between the heights of their two ends. It requires a very minute inveſtigation to ſhow the progreſs of the columns of air and water in this conſtruction, and the various changes of their arrangement, before one is attained which will continue during the working of the machine.

We have choſen for the deſcription of the machine that conſtruction which made its principles and manner of working moſt evident, namely, which contained the ſame material quantity of air in each turn of the ſpiral, more and more compreſſed as it approaches to the riſing-pipe. We ſhould otherwiſe have been obliged to inveſtigate in great detail the gradual progreſs of the water, and the frequent changes of its arrangement, before we could ſee that one arrangement would be produced which would remain conſtant during the working of the machine. But this is not the beſt conſtruction. We ſee that, in order to raiſe water to the height of a column of 34 feet, which balances the atmoſphere, the air in the laſt ſpire is compreſſed into half its bulk; and the quantity of water delivered into the main at each turn is but half of what was received into the firſt ſpire, the reſt flowing back from ſpire to ſpire, and being diſcharged at the ſpout.

But it may be conſtructed ſo as that the quantity of water in each ſpire may be the ſame that was received into the firſt; by which means a greater quantity (double in the inſtance now given) will be delivered into the main, and raiſed to the ſame height by very nearly the ſame force.— This may be done by another proportion of the capacity of the ſpires, whether by a change of their caliber or of their diameters. Suppoſe the bore to be the ſame, the diameter muſt be made ſuch that the conſtant column of water, and the column of air, compreſſed to the proper degree, may occupy the whole circumference. Let A be the column of water which balances the atmoſphere, and h the height to which the water is to be raiſed. Let A be to A + h as 1 to m. Zurich.

It is plain that m will repreſent the denſity of the air in the laſt ſpire, if its natural denſity be 1, becauſe it is preſſed by the column A + h, while the common air is preſſed by A. Let 1 repreſent the conſtant water column, and therefore nearly equal to the air column in the firſt ſpire. The whole circumference of the laſt ſpire muſt be $1 + \frac{1}{m}$, in order to hold the water 1, and the air compreſſed into the ſpace $\frac{1}{m}$ or $\frac{A}{A+h}$.

The circumference of the firſt ſpire is 1 + 1 or 2. Let D and d be the diameters of the firſt and laſt ſpires; we have $2 : 1 + \frac{1}{m} = D : d$, or $2m : m + 1 = D : d$. Therefore if a pipe of uniform bore be lapped round a cone, of which D and d are the end diameters, the ſpirals will be very nearly ſuch as will anſwer the purpoſe. It will not be quite exact, for the intermediate ſpirals will be ſomewhat too large. The conoidal fruſtum ſhould be formed by the revolution of a curve of the logarithmic kind. But the error is very trifling.

With ſuch a ſpiral, the full quantity of water which was confined in the firſt ſpiral will find room in the laſt, and will be ſent into the main at every turn. This is a very great advantage, eſpecially when the water is to be much raiſed. The ſaving of power by this change of conſtruction is always in proportion of the greateſt compreſſion of the air.

The great difficulty in the conſtruction of any of theſe forms is in determining the form and poſition of the horn and the ſcoop; and on this greatly depends the performance of the machine. The following inſtructions will make it pretty eaſy.

Let ABEO (fig. 18.) repreſent the firſt or outermoſt round of the ſpiral, of which the axis is C. Suppoſe it immerged up to the axis in the water VV′, we have ſeen that the machine is moſt effective when the ſurfaces KB and O n, of the water columns are diſtant the whole diameter BO of the ſpiral. Therefore let the pipe be firſt ſuppoſed of equal caliber to the very mouth E e, which we ſuppoſe to be juſt about to dip into the water. The ſurface O n is kept there, in oppoſition to the preſſure of the water column BAO, by the compreſſed air contained in the quadrant OE, and in the quadrant which lies behind EB. And this compreſſion is ſupported by the columns behind, between this ſpire and the riſing pipe. But the air in the outermoſt quadrant EB is in its natural ſtate, communicating as yet with the external air. When, however, the mouth E e has come round to A, it will not have the water ſtanding in it in the ſame manner, leaving the half ſpace BEO filled with compreſſed air; for it took in and confined only what filled the quadrant BE. It is plain, therefore, that the quadrant BE muſt be ſo ſhaped as to take in and confine a much greater quantity of air; ſo that when it has come to A, the ſpace BEO may contain air ſufficiently denſe to ſupport the column AO. But this is not enough: For when the wide mouth, now at A α, riſes up to the top, the ſurface of the water in it riſes alſo, becauſe the part AO $o\,a$ is more capa-

cious

Zurich. cious than the cylindric part OE *e o* which ſucceeds it, and which cannot contain all the water that it does. Since, then, the water in the ſpire riſes above A, it will preſs the water back from O *n* to ſome other poſition *m' n'*, and the preſſing height of the water-column will be diminiſhed by this riſing on the other ſide of O. In ſhort, the horn muſt begin to widen, not from B, but from A, and muſt occupy the whole ſemicircle ABE; and its capacity muſt be to the capacity of the oppoſite cylindrical ſide as the ſum of BO, and the height of a column of water which balances the atmoſphere to the height of that column. For then the air which filled it, when of the common denſity, will fill the uniform ſide BEO, when compreſſed ſo as to balance the vertical column BO. But even this is not enough; for it has not taken in enough of water. When it dipped into the ciſtern at E, it carried air down with it, and the preſſure of the water in the ciſtern cauſed the water to riſe into it a little way; and ſome water muſt have come over at B from the other ſide, which was drawing narrower. Therefore when the horn is in the poſition EOA, it is not full of water. Therefore when it comes into the ſituation OAB, it cannot be full nor balance the air on the oppoſite ſide. Some will therefore come out at O, and riſe up thro' the water. The horn muſt therefore *1ſt*, Extend at leaſt from O to B, or occupy half the circumference; and, *2dly*, It muſt contain at leaſt twice as much water as would fill the ſide BEO. It will do little harm though it be much larger; becauſe the ſurplus of air which it takes in at E will be diſcharged, as the end E *e* of the horn riſes from O to B, and it will leave the preciſe quantity that is wanted. The overplus water will be diſcharged as the horn comes round to dip again into the ciſtern. It is poſſible, but requires a diſcuſſion too intricate for this place, to make it of ſuch a ſize and ſhape, that while the mouth moves from E to B, paſſing through O and A, the ſurface of the water in it ſhall advance from E *e* to O *n*, and be exactly at O when the beginning or narrow end of the horn arrives there.

We muſt alſo ſecure the proper quantity of water. When the machine is ſo much immerſed as to be up to the axis in water, the capacity which thus ſecures the proper quantity of air will alſo take in the proper quantity of water. But it may be erected ſo as that the ſpirals ſhall not even reach the water. In this caſe it will anſwer our purpoſe if we join to the end of the horn a ſcoop or ſhovel QRSB (fig. 19.), which is ſo formed as to take in at leaſt as much water as will fill the horn. This is all that is wanted in the beginning of the motion along the ſpiral, and more than is neceſſary when the water has advanced to the ſucceeding ſpire; but the overplus is diſcharged in the way we have mentioned. At the ſame time, it is needleſs to load the machine with more water than is neceſſary, merely to throw it out again. We think that if the horn occupies fully more than one-half of the circumference, and contains as much as will fill the whole round, and if the ſcoop lifts as much as will certainly fill the horn, it will do very well.

N. B. The ſcoop muſt be very open on the ſide next the axis, that it may not confine the air as ſoon as it enters the water. This would hinder it from receiving water enough.

The following dimenſions of a machine erected at Florence, and whoſe performance correſponded extremely well with the theory, may ſerve as an example.

The ſpiral is formed on a cylinder of 10 feet diameter, and the diameter of the pipe is 6 inches. The ſmaller end of the horn is of the ſame diameter; and it occupies $\frac{3}{4}$ths of the circumference, and it is $7\frac{8}{10}$ths inches wide at the outer end. Here it joins the ſcoop, which lifts as much water as fills the horn, which contains 4340 Swediſh cubic inches, each = 1,577 Engliſh. The machine makes 6 turns in a minute, and raiſes 1354 pounds of water, or 22 cubic feet, 10 feet high in a minute. Zurich.

The above account will, we hope, ſufficiently explain the manner on which this ſingular hydraulic machine produces its effect. When every thing is executed by the maxims which we have deduced from its principles, we are confident that its performance will correſpond to the theory; and we have the Florentine machine as a proof of this. It raiſes more than $\frac{19}{11}$ths of what the theory promiſes, and it is not perfect. The ſpiral is of equal caliber, and is formed on a cylinder. The friction is ſo inconſiderable in this machine, that it need not be minded: but the great excellency is, that whatever imperfection there may be in the arrangement of the air and water columns, this only affects the elegance of the execution, cauſing the water to make a few more turns in the ſpiral before it can mount to the height required; but waſtes no power, becauſe the power employed is always in proportion to the ſum of the vertical columns of water in the riſing ſide of the machine; and the height to which the water is raiſed by it is in the very ſame proportion. It ſhould be made to move very ſlow, that the water be not always dragged up by the pipes, which would cauſe more to run over from each column, and diminiſh the preſſure of the remainder.

If the riſing-pipe be made wide, and thus room be made for the air to eſcape freely up through the water, it will riſe to the height aſſigned; but if it be narrow, ſo that the air cannot get up, it riſes almoſt as ſlow as the water, and by this circumſtance the water is raiſed to a much greater height mixed with air, and this with hardly any more power. It is in this way that we can account for the great performance of the Florentine machine, which is almoſt triple of what a man can do with the fineſt pump that ever was made: indeed the performance is ſo great that one is apt to ſuſpect ſome inaccuracy in the accounts. The entry into the riſing-pipe ſhould be no wider than the laſt part of the ſpiral; and it would be adviſable to divide it into four channels by a thin partition, and then to make the riſing-pipe very wide, and to put into it a number of ſlender rods, which would divide it into ſlender channels that would completely entangle the air among the water. This will greatly increaſe the height of the heterogeneous column. It is ſurpriſing that a machine that is ſo very promiſing ſhould have attracted ſo little notice. We do not know of any being erected out of Switzerland except at Florence in 1778. The account of its performance was in conſequence of a very public trial in 1779, and honourable declaration of its merit, by Sig. Lorenzo Ginori, who erected another, which fully equalled it. It is ſhortly mentioned by Profeſſor Sulzer of Berlin in the *Sammlungen Vermiſchten Schriften* for 1754. A deſcription of it is publiſhed by the Philoſophical Society at Zurich in 1766, and in the deſcriptions publiſhed by the Society in London for the encouragement of Arts in 1776. The celebrated Daniel Bernouilli has publiſhed a very accurate theory of it in the Peterſburg Commentaries for 1772, and the machines at Florence were erected according to his inſtructions. Baron Alſtromer in Sweden cauſed a glaſs model of it to be made, to exhibit the internal motions for the inſtruction of artiſts, and alſo ordered an operative engine to be erected; but we have not ſeen any account of its performance. It is a very intricate machine in its principles; and an ignorant engineer, nay the moſt intelligent, may erect one which ſhall hardly do any thing; and yet, by a very trifling change, may become very powerful. We preſume that failures of this kind have turned the attention of engineers from it; but we are perſuaded that it may be made very effective, and we are certain that it muſt be very durable. Fig. 20. is a ſection of the manner in which the author Zurich.

Zurich ‖ Zuyder-zee.

author has formed the communication between the ſpiral and the riſing pipe. P is the end of the hollow axis which is united with the ſolid iron axis. Adjoining to P, on the under ſide, is the entry from the laſt turn of the ſpiral. At Q is the collar which reſts on the ſupports, and turns round in a hole of bell-metal. *f f* is a broad flanch caſt in one piece with the hollow part. Beyond this the pipe is turned ſomewhat ſmaller, very round and ſmooth, ſo as to fit into the mouth of the riſing-pipe, like the key of a cock. This mouth has a plate *e e* attached to it. There is another plate *d d*, which is broader than *e e*, and is not fixed to the cylindrical part, but moves eaſily round it. In this plate are four ſcrews, ſuch as *g*, *g*, which go into holes in the plate *f f*, and thus draw the two plates *f f* and *d d* together, with the plate *e e* between them. Pieces of thin leather are put on each ſide of *e e*; and thus all eſcape of water is effectually prevented, with a very moderate compreſſion and friction.

ZUTPHEN, a ſtrong and conſiderable town of the United Provinces in Guelderland, and capital of a county of the ſame name. It has a magnificent church, and is ſurrounded with walls. It was taken by the French in 1672, who in 1674 delivered it up to the States-General. It is ſeated at the confluence of the rivers Berkel and Yeſſel, nine miles ſouth-eaſt of Deventer, and 55 eaſt by ſouth of Amſterdam. E Long. 6. 0. N. Lat. 52 10.

ZUYDER-ZEE, a great gulph or bay of the German Ocean, which extends from ſouth to north in the United Provinces, between Frieſland, Over-Yeſſel, Guelderland, and Holland. It is ſo called from its ſituation towards the ſouth. It is ſaid that the Zuyder-zee was formerly a lake, and that the land is ſwallowed up which united North-Holland with Frieſland.

Zygoma ‖ Zymoſimeter.

ZYGOMA, in anatomy, a bone of the head, or rather an union or aſſemblage of two proceſſes or eminences of bones; the one from the os temporis, the other from the os malæ: theſe proceſſes are hence termed the *zygomatic proceſſes*, and the ſuture that joins them together is denominated the *zygomatic ſuture*.

ZYGOMATICUS, in anatomy, a muſcle of the head, ariſing from the *Os Zygoma*, whence its name, and terminating at the angle of the lips.

ZYGOPHYLLUM, BEAN CAPER, in botany; a genus of plants of the claſs of decandria and order monogynia, and in the natural ſyſtem arranged under the 14th order, *Gruinales*. There are 11 ſpecies, partly ſhrubby and partly herbaceous plants, all natives of warm climates, though ſome of them are hardy enough to endure the open air in this country.

ZYMOSIMETER (formed from ζυμωσις *fermentation*, and μετρον *meaſure*), an inſtrument propoſed by Swammerdam in his book *De Reſpiratione*, wherewith to meaſure the degree of fermentation occaſioned by the mixture of different matters, and the degree of heat which thoſe matters acquire in fermenting, as alſo the heat or temperament of the blood of animals.

FINIS.

ERRATA not pointed out at the end of any preceding Volume.

N. B. *b* added to the number of the line ſignifies "from the bottom of the page."

Vol.	*page.*	*col.*	*line.*	
I.	368	2	Marg.	After "Index," add "at *Spirit of wine.*"
II.	216	2	31 *b.*	For "ARCHIMIDES," read "ARCHIMEDES."
	250	2	22	For "ſloping," read "ſtopping."
	770	2	7 *b.*	For "n° 79." read "578."
III.	258	1	20	For "50th," read "57th."
	283	1	marg.	For "See *Index*, &c." read "See MEDICINE, n° 359, &c."
	342	2	25	Dele "MEDICINE and."
	805	2		After the laſt line read "cauſed the ſoldiers and all the inhabitants to be put to."
IV.	86	2	11 *b.*	For "MEDICINE." read "SURGERY."
	374	2	12 *b.*	For "tar," read "water."
	392	1	23 *b.*	For "vapour," read "heat."
	392	1	1 *b.*	For "807 degrees," read "811."
V.	137	1	31	For "MEDICINE-*Index*," read "*Catarrh*, MEDICINE-*Index*."
	606	1	23	For "the only oſtenſible," read "only the oſtenſible."
VI.	181	1	19 *b.*	For "Elvet," read "Wear."
VIII.	170	2	4 *b.*	For "See *Index*," read "See MEDICINE, n° 396, 397, 400."
	124	1	39	For "*Ornithyology*," read "*Ichthyology*."
	191	2	18	For "*Ichthology*," read "*Ornithology*."
	293	1	11	For "queen's palace at Weſtminſter," read "Windſor caſtle."
	311	1	11	For "*venery*," read "*venary*."
	390	2	16 *b.*	For "*Polydectes*," read "*Philoctetes*."
	497	2	27 *b.*	For "Cumberland," read "Northumberland."
	521	2	19 *b.*	For "155," read "355."
	743	2	16	For "dibblers," read "droppers."
IX.	6	1	4	At "AMLB," read "Plate CCXL. fig. 1."
X.	114	2	3 *b.*	For "1694," read "1664."
	731	2	16 *b.*	For "from E to B, and from B to C," read "from B to E, and from C to E." inſerting an E in the fig. where AD and CB croſs each other.
XI.	475	1	12 *b.*	For "n° 50." read "n° 54."
	482	2	19	For "loquacity," read "logomachy."
	631	2	5	For "μετφια," read "μετρια," or "μετρον."
				In the article METHODISTS, *paſſim*. For "Hanſon," read "Hampſon."
XII	273	Note		For "Low," read "LAW."
	409	2	25 *b.* / 22 *b.*	For "BC," read "AC."
XIII	204	2	18	For "364th," read "304th."
	577	2	5 *b.*	For "γινομαι," read "γινομαι."
	709	2	25	For "9," read "*g*."
XIV.	141	1		Before the article "PERCHE" inſert "PERCH, in ichthyology. See PERCA."
	178	2	33	For "PERSICANA," read "PERSICARIA."
	196	2	27	For "Teith," read "Tay."
	196	2	29	For "D'air of Drummond," read "Stob-hall."
	214	1	28 *b.*	For "bottom," read "top."
	669	2	18 *b.*	For "667," read "669."
	671	2	16	For "rive," read "pine."
XV.	373	1	6 *b.*	For "Wenderdon," read "Wenderborn."
XVI.	9	2	25	For "1697," read "1679."
	533	1	10 *b.*	For "Emelia," read "Emelius."
	591	2	6 *b.*	For "ſacrifices," read "ſcriptures."
	592	1	26	For "demand," read "demeanor."
XVII.	99	Note	5 *b.*	For "it is abſurd," read "is it abſurd."
	512	2	7	Add "See MURÆNA."
	610	2	22	For "an Engliſh gallon," read "half an Engliſh gallon."
	782	2	22	For "Dorſetſhire," read "Hampſhire."
XVIII.	129	1	27 *b.*	For "(fig. 26. *l*)," read "(fig. 26. *b*)."
	143	1	marg.	For "338," read "238."
	187	2	20	For "337," read "237."
	187	2	22, 23, 25,	For "352," read "238."

ERRATA not pointed out at the end of any preceding Volume.

Vol.	*page.*	*col.*	*line.*	
XVIII.	297	2	32 *b.*	Read " For almoſt every ſpecies of quadrupeds has a ſpecies of tænia peculiar to itſelf."
	419	Note 6	*b.*	For " layman," read " clergyman likewiſe, but."
	453	2	39	Read " ἰμασθαν."
	455	1	6 *b.*	For " this," read " his."
	455	Note 1	*b.*	Read " *Harmonia*."
	480	1	15	Dele " ;"
	490	2	22	Dele " the" before the word " interceſſion."
	497	1	2 *b.*	For " phyſicians," read " philoſophers."
Plate CCCXCVIII.			fig. 1.	For what appears to be " E *c* D," read E *f* D.
			3.	For " IM ;" read " CM."
CCCCLXXXVIII.				The crooked pipe on the right of fig. 38. ſhould be marked " 38 *a*."
