ENCYCLOPÆDIA;

OR, A

DICTIONARY

OF

ARTS, SCIENCES,

AND

MISCELLANEOUS LITERATURE;

Conſtructed on a PLAN,

BY WHICH

THE DIFFERENT SCIENCES AND ARTS

Are digeſted into the FORM of diſtinct

TREATISES OR SYSTEMS,

COMPREHENDING

THE HISTORY, THEORY, and PRACTICE, of each,

According to the Lateſt Diſcoveries and Improvements;

AND FULL EXPLANATIONS GIVEN OF THE

VARIOUS DETACHED PARTS OF KNOWLEDGE,

WHETHER RELATING TO

NATURAL and ARTIFICIAL Objects, or to Matters ECCLESIASTICAL, CIVIL, MILITARY, COMMERCIAL, *&c.*

Including ELUCIDATIONS of the moſt important Topics relative to RELIGION, MORALS, MANNERS, and the OECONOMY of LIFE.

TOGETHER WITH

A DESCRIPTION of all the Countries, Cities, principal Mountains, Seas, Rivers, *&c.* throughout the WORLD;

A General HISTORY, *Ancient* and *Modern*, of the different Empires, Kingdoms, and States;

AND

An Account of the LIVES of the moſt Eminent Perſons in every Nation, from the earlieſt ages down to the preſent times.

Compiled from the writings of the beſt authors in ſeveral languages; the moſt approved Dictionaries, as well of general ſcience as of its particular branches; the Tranſactions, Journals, and Memoirs, of various Learned Societies, the MS. Lectures of Eminent Profeſſors on different ſciences; and a variety of Original Materials, furniſhed by an Extenſive Correſpondence.

THE FIRST AMERICAN EDITION, IN EIGHTEEN VOLUMES, GREATLY IMPROVED.

ILLUSTRATED WITH FIVE HUNDRED AND FORTY-TWO COPPERPLATES.

VOL. XVIII. STR——ZYM

INDOCTI DISCANT, ET AMENT MEMINISSE PERITI.

PHILADELPHIA:

PRINTED BY THOMAS DOBSON, AT THE STONE-HOUSE, N° 41, SOUTH SECOND-STREET.

M.DCC.XCVIII.

ENCYCLOPÆDIA.

Strength of Materials.

STRENGTH OF MATERIALS, in mechanics, is a ſubject of ſo much importance, that in nations eminent for invention and ingenuity in all ſpecies of manufactures, and in particular diſtinguiſhed for their improvements in machinery of every kind, it is ſomewhat ſingular that no writer has treated it in the detail which its importance and difficulty demands. The man of ſcience who viſits great manufactures is delighted with the ingenuity which he obſerves in every part, the innumerable inventions which come even from individual artiſans, and the determined purpoſe of improvement and refinement which he ſees in every workſhop. Every cotton mill appears an academy of mechanical ſcience; and mechanical invention is ſpreading from theſe fountains over the whole country: But the philoſopher is mortified to ſee this ardent ſpirit ſo cramped by ignorance of principle, and many of theſe original and brilliant thoughts obſcured and clogged with needleſs and even hurtful additions, and a complication of machinery which checks improvement even by its appearance of ingenuity. There is nothing in which this want of ſcientific education, this ignorance of principle, is ſo frequently obſerved as in the injudicious proportion of the parts of machines and other mechanical ſtructures; proportions and forms of parts in which the ſtrength and poſition are nowiſe regulated by the ſtrains to which they are expoſed, and where repeated failures have been the only leſſons.

1 Importance of the ſubject.

It cannot be otherwiſe. We have no means of inſtruction, except two very ſhort and abſtracted treatiſes of the late Mr Emerſon on the ſtrength of materials. We do not recollect a performance in our language from which our artiſts can get information. Treatiſes written expreſsly on different branches of mechanical arts are totally ſilent on this, which is the baſis and *only principle* of their performances. Who would imagine that PRICE'S BRITISH CARPENTER, the work of the firſt reputation in this country, and of which the ſole aim is to teach the carpenter to erect ſolid and durable ſtructures, does not contain one propoſition or one reaſon by which one form of a thing can be ſhown to be ſtronger or weaker than another? We doubt very much if one carpenter in an hundred can give a reaſon to convince his own mind that a joiſt is ſtronger when laid on its edge than when laid on its broad ſide. We ſpeak in this ſtrong manner in hopes of exciting ſome man of ſcience to publiſh a ſyſtem of inſtruction on this ſubject. The limits of our Work will not admit of a detail: but we think it neceſſary to point out the leading principles, and to give the traces of that ſyſtematic connection by which all the knowledge already poſſeſſed of this ſubject may be brought together and properly arranged. This we ſhall now attempt in as brief a manner as we are able.

2 Strength of materials ariſes from coheſion.

THE ſtrength of materials ariſes immediately or ultimately from the coheſion of the parts of bodies. Our examination of this property of tangible matter has as yet been very partial and imperfect, and by no means enables us to apply mathematical calculations with preciſion and ſucceſs. The various modifications of coheſion, in its different appearances of perfect ſoftneſs, plaſticity, ductility, elaſticity, hardneſs, have a mighty influence on the ſtrength of bodies, but are hardly ſuſceptible of meaſurement. Their texture alſo, whether uniform like glaſs and ductile metals, cryſtallized or granulated like other metals and freeſtone, or fibrous like timber, is a circumſtance no leſs important; yet even here, although we derive ſome advantage from remarking to which of theſe forms of aggregation a ſubſtance belongs, the aid is but ſmall. All we can do in this want of general principles is to make experiments on every claſs of bodies. Accordingly philoſophers have endeavoured to inſtruct the public in this particular. The Royal Society of London at its very firſt inſtitution made many experiments at their meetings, as may be ſeen in the firſt regiſters of the Society†. Several individuals have added their experiments. The moſt numerous collection in detail is by Muſchenbroek, profeſſor of natural philoſophy at Leyden. Part of it was publiſhed by himſelf in his *Eſſais de Phyſique*, in 2 vols 4to; but the full collection is to be found in his Syſtem of Natural Philoſophy, publiſhed after his death by Lulofs, in 3 vols 4to. This was tranſlated from the Low Dutch into French by Sigaud de la Fond, and publiſhed at Paris in 1760, and is a prodigious collection of phyſical knowledge of all kinds, and may almoſt ſuffice for a library of natural philoſophy. But this collection of experiments on the coheſion of bodies is not of that value which one expects. We preſume that they were carefully made and faithfully narrated; but they were made on ſuch ſmall ſpecimens that the unavoidable natural inequalities of growth or texture produced irregularities in the reſults which bore too great a proportion to the whole quantities obſerved. We may make the ſame remark on the experiments of Couplet, Pitot, De la Hire, Du Hamel, and others of the French academy. In ſhort, if we except the experiments of Buffon on the ſtrength of timber, made at the public expence on a large ſcale, there is nothing to be met with from which we can obtain abſolute meaſures which may be employed with confidence; and there is nothing in the Engliſh language except a ſimple liſt by Emerſon, which is merely a ſet of affirmations, without any narration of circumſtances, to enable us to judge of the validity of his concluſions: but the character of Mr Emerſon, as a man of knowledge and of integrity gives even to theſe aſſertions a conſiderable value.

Strength of Materials.

3 Experiments to aſcertain it.

† See Birche's Hiſtory, and Hooke's Mathematical Collections.

But to make uſe of any experiments, there muſt be employed ſome general principle by which we can generalize their reſults. They will otherwiſe be only narrations of detached facts. We muſt have ſome notion of that intermedium, by the intervention of which an external force applied to one part of a lever, joiſt, or pillar, occaſions a ſtrain on a diſtant part. This can be nothing but the coheſion between the

4 Rendered uſeful by generalization.

Strength of Materials

parts. It is this connecting force which is brought into action, or, as we more ſhortly expreſs it, excited. This action is modified in every part by the laws of mechanics. It is this action which is what we call the *ſtrength* of that part, and its effect is the ſtrain on the adjoining parts; and thus it is the ſame force, differently viewed, that conſtitutes both the ſtrain and the ſtrength. When we conſider it in the light of a reſiſtance to fracture, we call it *ſtrength*.

5 Strength defined.

We call every thing a *force* which we obſerve to be ever accompanied by a change of motion; or, more ſtrictly ſpeaking, we infer the preſence and agency of a force wherever we obſerve the ſtate of things in reſpect of motion different from what we know to be the reſult of the action of all the forces which we know to act on the body. Thus when we obſerve a rope prevent a body from falling, we infer a moving force inherent in the rope with as much confidence as when we obſerve it drag the body along the ground. The *immediate* action of this force is undoubtedly exerted between the immediately adjoining parts of the rope. The immediate effect is the keeping the particles of the rope together. They ought to ſeparate by any external force drawing the ends of the rope contrarywiſe; and we aſcribe their not doing ſo to a mechanical force really oppoſing this external force. When deſired to give it a name, we name it from what we conceive to be its effect, and therefore its characteriſtic, and we call it COHESION. This is merely a name for the fact; but it is the ſame thing in all our denominations. We know nothing of the cauſes but in the effects; and our name for the cauſe is in fact the name of the effect, which is COHESION. We mean nothing elſe by gravitation or magnetiſm. What do we mean when we ſay that Newton underſtood thoroughly the nature of gravitation, of the force of gravitation; or that Franklin underſtood the nature of the electric force? Nothing but this: Newton conſidered with patient ſagacity the general facts of gravitation, and has deſcribed and claſſed them with the utmoſt preciſion. In like manner, we ſhall underſtand the nature of coheſion when we have diſcovered with equal generality the laws of coheſion, or general facts which are obſerved in the appearances, and when we have deſcribed and claſſed them with equal accuracy.

6 Cauſes known only from their effects.

Let us therefore attend to the more ſimple and obvious phenomena of coheſion, and mark with care every circumſtance of reſemblance by which they may be claſſed. Let us receive theſe as the laws of coheſion characteriſtic of its ſuppoſed cauſe, the force of coheſion. We cannot pretend to enter on this vaſt reſearch. The modifications are innumerable; and it would require the penetration of more than Newton to detect the circumſtance of ſimilarity amidſt millions of diſcriminating circumſtances. Yet this is the only way of diſcovering which are the primary facts characteriſtic of the force, and, which are the modifications. The ſtudy is immenſe, but is by no means deſperate; and we entertain great hopes that it will ere long be ſucceſsfully proſecuted: but, in our particular predicament, we muſt content ourſelves with ſelecting ſuch general laws as ſeem to give us the moſt immediate information of the circumſtances that muſt be attended to by the mechanician in his conſtructions, that he may unite ſtrength with ſimplicity, economy, and energy.

7 All bodies elaſtic.

1*ſt*, Then, it is a matter of fact that all bodies are in a certain degree perfectly elaſtic; that is, when their form or bulk is changed by certain moderate compreſſions or diſtractions, it requires the continuance of the changing force to continue the body in this new ſtate; and when the force is removed, the body recovers its original form. We limit the aſſertion to *certain moderate* changes: For inſtance, take a lead wire of $\frac{1}{15}$th of an inch in diameter and ten feet long; fix one end firmly to the ceiling, and let the wire hang perpendicular; affix to the lower end an index like the hand of a watch; on ſome ſtand immediately below let there be a circle divided into degrees, with its centre correſponding to the lower point of the wire: now turn this index twice round, and thus twiſt the wire. When the index is let go, it will turn backwards again, by the wire's untwiſting itſelf, and make almoſt four revolutions before it ſtops; after which it twiſts and untwiſts many times, the index going backwards and forwards round the circle, diminiſhing however its arch of twiſt each time, till at laſt it ſettles preciſely in its original poſition. This may be repeated for ever. Now, in this motion, every part of the wire partakes equally of the twiſt. The particles are ſtretched, require force to keep them in their ſtate of extenſion, and recover completely their original relative poſitions. Theſe are all the characters of what the mechanician calls *perfect* elaſticity. This is a quality quite familiar in many caſes; as in glaſs, tempered ſteel, &c. but was thought incompetent to lead, which is generally conſidered as having little or no elaſticity. But we make the aſſertion in the moſt general terms, with the limitation to moderate derangement of form. We have made the ſame experiment on a thread of pipe-clay, made by forcing ſoft clay through the ſmall hole of a ſyringe by means of a ſcrew; and we found it more elaſtic than the lead wire: for a thread of $\frac{1}{20}$th of an inch diameter and 7 feet long allowed the index to make two turns, and yet completely recovered its firſt poſition.

Strength of Marerials.

2*dly*, But if we turn the index of the lead wire four times round, and let it go again, it untwiſts again in the ſame manner, but it makes little more than four turns back again; and after many oſcillations it finally ſtops in a poſition almoſt two revolutions removed from its original poſition. It has now acquired a new arrangement of parts, and this new arrangement is permanent like the former; and, what is of particular moment, it is perfectly elaſtic. This change is familiarly known by the denomination of a SET. The wire is ſaid to have TAKEN A SET. When we attend minutely to the procedure of nature in this phenomenon, we find that the particles have as it were ſlid on each other, ſtill cohering, and have taken a new poſition, in which their connecting forces are in equilibrio: and in this change of relative ſituation, it appears that the connecting forces which maintained the particles in their firſt ſituations were not in equilibrio in ſome poſition intermediate between that of the firſt and that of the laſt form. The force required for changing this firſt form augmented with the change, but only to a certain degree; and during this proceſs the connecting forces always tended to the recovery of this firſt form. But after the change of mutual poſition has paſſed a certain magnitude, the union has been partly deſtroyed, and the particles have been brought into new ſituations; ſuch, that the forces which now connect each with its neighbour tend, not to the recovery of the firſt arrangement, but to puſh them farther from it, into a new ſitution, to which they now verge, and require force to prevent them from acquiring. The wire is now in fact again perfectly elaſtic; that is, the forces which now connect the particles with their new neighbours augment to a certain degree as the derangement from this new poſition augments. This is not reaſoning from any theory. It is narrating facts, on which a theory is to be founded. What we have been juſt now ſaying is evidently a deſcription of that ſenſible form of tangible matter which we call *ductility*. It has every gradation of variety, from the ſoftneſs of butter to the firmneſs of gold. All theſe bodies have ſome elaſticity; but we ſay they are not perfectly elaſtic, becauſe they do not completely recover their original form when it has been greatly

8 What is meant by a ſet.

9 Ductility.

Strength of Materials.

greatly deranged. The whole gradation may be moſt diſtinctly obſerved in a piece of glaſs or hard ſealing-wax. In the ordinary form glaſs is perhaps the moſt completely elaſtic body that we know, and may be bent till juſt ready to ſnap, and yet completely recovers its firſt form, and takes no ſet whatever; but when heated to ſuch a degree as juſt to be viſible in the dark, it loſes, its brittleneſs, and becomes ſo tough that it cannot be broken by any blow; but it is no longer elaſtic, takes any ſet, and keeps it. When more heated, it becomes as plaſtic as clay; but in this ſtate is remarkably diſtinguiſhed from clay by a quality which we may

10 Viſcidity

call VISCIDITY, which is ſomething like elaſticity, of which clay and other bodies purely plaſtic exhibit no appearance. This is the joint operation of ſtrong adheſion and ſoftneſs. When a rod of perfectly ſoft glaſs is ſuddenly ſtretched a little, it does not at once take the ſhape which it acquires after ſome little time. It is owing to this, that in taking the impreſſion of a ſeal, if we take off the ſeal while the wax is yet very hot, the ſharpneſs of the impreſſion is deſtroyed immediately. Each part drawing its neighbour, and each part yielding, the prominent parts are pulled down and blunted, and the ſharp hollows are pulled upwards and alſo blunted. The ſeal muſt be kept on till all has become not only ſtiff but hard.

11 Obſerved in all homogeneous plaſtic bodies.

This viſcidity is to be obſerved in all plaſtic bodies which are homogeneous. It is not obſerved in clay, becauſe it is not homogenous, but conſiſts of hard particles of the argillaceous earth ſticking together by their attraction for water. Something like it might be made of finely powdered glaſs and a clammy fluid ſuch as turpentine. Viſcidity has all degrees of ſoftneſs till it degenerates to ropy fluidity like that of olive oil. Perhaps ſomething of it may be found even in the moſt perfect fluid that we are acquainted with, as we obſerved in the experiments for aſcertaining ſpecific gravity.

There is in a late volume of the Philoſophical Tranſactions a narration of experiments, by which it appears that the thread of the ſpider is an exception to our firſt general law, and that it is perfectly ductile. It is there aſſerted, that a long thread of goſſamer, furniſhed with an index, takes any poſition whatever; and that though the index be turned round any number of times (even many hundreds), it has no tendency to recover its firſt form. The thread takes completely any ſet whatever. We have not had an opportunity of repeating this experiment, but we have diſtinctly obſerved a phenomenon totally inconſiſtent with it. If a fibre of goſſamer about an inch long be held by the end horizontally, it bends downward in a curve like a ſlender ſlip of whalebone or a hair. If totally devoid of elaſticity, and perfectly indifferent to any ſet, it would hang down perpendicularly without any curvature.

When ductility and elaſticity are combined in different proportions, an immenſe variety of ſenſible modes of aggregation may be produced. Some degree of both are probably to be obſerved in all bodies of complex conſtitution; that is, which conſiſt of particles made up of many different kinds of atoms. Such a conſtitution of a body muſt afford many ſituations permanent, but eaſily deranged.

In all theſe changes of diſpoſition which take place among the particles of a ductile body, the particles are at ſuch diſtance that they ſtill cohere. The body may be ſtretched a little; and on removing the extending force, the body ſhrinks into its firſt form. It alſo reſiſts moderate compreſſions; and when the compreſſing force is removed, the body ſwells out again. Now the corpuſcular *fact* here is that the particles are acted on by attractions and repulſions, which balance each other when no external force is acting on the body, and which augment as the particles are made, by any external cauſe, to recede from this ſituation of mutual inactivity; for ſince force is requiſite to produce either the dilatation or the compreſſion, and to maintain it, we are obliged, by the conſtitution of our minds, to infer that it is oppoſed by a force accompanying or inherent in every particle of dilatable or compreſſible matter: and as this neceſſity of employing force to produce a change indicates the agency of theſe corpuſcular forces, and marks their kind, according as the tendencies of the particles appear to be toward each other in dilatation, or from each other in compreſſion; ſo it alſo meaſures the degrees of their intenſity. Should it require three times the force to produce a double compreſſion, we muſt reckon the mutual repulſions triple when the compreſſion is doubled; and ſo in other inſtances. We ſee from all this that the phenomena of coheſion indicate ſome relation between the intenſity of the force of coheſion and the diſtance between the centres of the particles. To diſcover this relation is the great problem in corpuſcular mechaniſm, as it was in the Newtonian inveſtigation of the force of gravitation. Could we diſcover this law of action between the corpuſcles with the ſame certainty and diſtinctneſs, we might with equal confidence ſay what will be the reſult of any poſition which we give to the particles of bodies; but this is beyond our hopes. The law of gravitation is ſo ſimple that the diſcovery or detection of it amid the variety of celeſtial phenomena required but one ſtep; and in its own nature its poſſible combinations ſtill do not greatly exceed the powers of human reſearch. One is almoſt diſpoſed to ſay that the Supreme Being has exhibited it to our reaſoning powers as ſufficient to employ with ſucceſs our utmoſt efforts, but not ſo abſtruſe as to diſcourage us from the noble attempt. It ſeems to be otherwiſe with reſpect to coheſion. Mathematics informs us, that if it deviates ſenſibly from the law of gravitation, the ſimpleſt combinations will make the joint action of ſeveral particles an almoſt impenetrable myſtery. We muſt therefore content ourſelves, for a long while to come, with a careful obſervation of the ſimpleſt caſes that we can propoſe, and with the diſcovery of ſecondary laws of action, in which many particles combine their influence. In purſuance of this plan, we obſerve,

Strength of Materials.

12 Particles acted on by attractions and repulſions.

13 The great problem in corpuſcular mechaniſm.

14 Particles kept in their places by a balance of forces.

3*dly*, That whatever is the ſituation of the particles of a body with reſpect to each other, when in a quieſcent ſtate, they are kept in theſe ſituations by the balance of oppoſite forces. This cannot be refuſed, nor can we form to ourſelves any other notion of the ſtate of the particles of a body. Whether we ſuppoſe the ultimate particles to be of certain magnitudes and ſhapes, touching each other in ſingle points of coheſion; or whether we (with Boſcovich) conſider them as at a diſtance from each other, and acting on each other by attractions and repulſions—we muſt acknowledge, in the firſt place, that the centres of the particles (by whoſe mutual diſtances we muſt eſtimate the diſtance of the particles) may and do vary their diſtances from each other. What elſe can we ſay when we obſerve a body increaſe in length, in breadth, and in thickneſs, by heating it, or when we ſee it diminiſh in all theſe dimenſions by an external compreſſion? A particle, therefore, ſituated in the midſt of many others, and remaining in that ſituation, muſt be conceived as maintained in it by the mutual balancing of all the forces which connect it with its neighbours. It is like a ball kept in its place by the oppoſite action of two ſprings. This illuſtration merits a more particular application. Suppoſe a number of balls ranged on the table in the angles of equilateral triangles, and that each ball is connected with the ſix which lie around it by means of an elaſtic wire curled like a cork-ſcrew; ſuppoſe ſuch another ſtratum of balls above this, and parallel to it, and ſo placed that

15 Illuſtration of this propoſition

Strength of Materials.

each ball of the upper ſtratum is perpendicularly over the centre of the equilateral triangle below, and let theſe be connected with the balls of the under ſtratum by ſimilar ſpiral wires. Let there be a third and a fourth, and any number of ſuch ſtrata, all connected in the ſame manner. It is plain, that this may extend to any ſize and fill any ſpace.—Now let this aſſemblage of balls be firmly contemplated by the imagination, and be ſuppoſed to ſhrink continually in all its dimenſions, till the balls, and their diſtances from each other, and the connecting wires, all vaniſh from the ſight as diſcrete individual objects. All this is very conceivable. It will now appear like a ſolid body, having length, breadth, and thickneſs; it may be compreſſed, and will again reſume its dimenſions; it may be ſtretched, and will again ſhrink; it will move away when ſtruck; in ſhort, it will not differ in its ſenſible appearance from a ſolid elaſtic body. Now when this body is in a ſtate of compreſſion, for inſtance, it is evident that any one of the balls is at reſt, in conſequence of the mutual balancing of the actions of all the ſpiral wires which connect it with thoſe around it. It will greatly conduce to the full underſtanding of all that follows to recur to this illuſtration. The analogy or reſemblance between the effects of this conſtitution of things and the effects of the corpuſcular forces is very great; and wherever it obtains, we may ſafely draw concluſions from what we know would be the condition of the balls in particular circumſtances to what will be the condition of a body of common tangible matter. We ſhall juſt give one inſtructive example, and then have done with this hypothetical body. We can ſuppoſe it of a long ſhape, reſting on one point; we can ſuppoſe two weights A, B, ſuſpended at the extremities, and the whole in equilibrio. We commonly expreſs this ſtate of things by ſaying that A and B are in equilibrio. This is very inaccurate. A is in fact in equilibrio with the united action of all the ſprings which connect the ball to which it is applied with the adjoining balls. Theſe ſprings are brought into action, and each is in equilibrio with the joint action of all the reſt. Thus through the whole extent of the hypothetical body, the ſprings are brought into action in a way and in a degree which mathematics can eaſily inveſtigate. We need not do this: it is enough for our purpoſe that our imagination readily diſcovers that ſome ſprings are ſtretched, others are compreſſed, and that a preſſure is excited on the middle point of ſupport, and the ſupport exerts a reaction which preciſely balances it; and the other weight is, in like manner, in immediate equilibrio with the equivalent of the actions of all the ſprings which connect the laſt ball with its neighbours. Now take the analogical or reſembling caſe, an oblong piece of ſolid matter, reſting on a fulcrum, and loaded with two weights in equilibrio. For the actions of the connecting ſprings ſubſtitute the corpuſcular forces, and the reſult will reſemble that of the hypotheſis.

1 By example.

Now as there is ſomething that is at leaſt analogous to a change of diſtance of the particles, and a concomitant change of the intenſity of the connecting forces, we may expreſs this in the ſame way that we are accuſtomed to do in ſimilar caſes. Let A and B (fig. 1) repreſent the centres of two particles of a coherent elaſtic body in their quieſcent inactive ſtate, and let us conſider only the mechanical condition of B. The body may be ſtretched. In this caſe the diſtance A B of the particles may become A C. In this ſtate there is ſomething which makes it neceſſary to employ a force to keep the particles at this diſtance. C has a tendency towards A, or we may ſay that A attracts C. We may repreſent the magnitude of this tendency of C *towards* A, or this attraction of A, by a line C *c* perpendicular to A C. Again, the body may be compreſſed, and the diſtance A B may become A D. Something obliges us to employ force to continue this compreſſion; and D tends *from* A, or A appears to *repel* D. The intenſity of this tendency or repulſion may be repreſented by another perpendicular D *d*; and, to repreſent the different directions of theſe tendencies, or the different nature of theſe actions, we may ſet D *d* on the oppoſite ſide of A B. It is in this manner that the Abbé Boſcovich has repreſented the actions of corpuſcular forces in his celebrated Theory of Natural Philoſophy. Newton had ſaid, that, as the great movements of the ſolar ſyſtem were regulated by forces operating at a diſtance and varying with the diſtance, ſo he ſtrongly ſuſpected (*valdi ſuſpicor*) that all the phenomena of coheſion, with all its modifications in the different ſenſible forms of aggregation, and in the phenomena of chemiſtry and phyſiology, reſulted from the ſimilar agency of forces varying with the diſtance of the particles. The learned Jeſuit purſued this thought; and has ſhown, that if we ſuppoſe an ultimate atom of matter endowed with powers of attraction and repulſion, varying, both in kind and degree, with the diſtance, and if this force be the ſame in every atom, it may be regulated by ſuch a relation to the diſtance from the neighbouring atom, that a collection of ſuch atoms may have all the ſenſible appearances of bodies in their different forms of ſolids, liquids, and vapours, elaſtic or unelaſtic, and endowed with all the properties which we perceive, by whoſe immediate operation the phenomena of motion by impulſe, and all the phenomena of chemiſtry, and of animal and vegetable economy, may be produced. He ſhows, that notwithſtanding a perfect ſameneſs, and even a great ſimplicity in this atomical conſtitution, there will reſult from this union all that unſpeakable variety of form and property which diverſify and embelliſh the face of nature. We ſhall take another opportunity of giving ſuch an account of this celebrated work as it deſerves. We mention it only, by the by, as far as a general notion of it will be of ſome ſervice on the preſent occaſion. For this purpoſe, we juſt obſerve that Boſcovich conceives a particle of any individual ſpecies of matter to conſiſt of an unknown number of particles of ſimpler conſtitution; each of which particles, in their turn, is compounded of particles ſtill more ſimply conſtituted, and ſo on through an unknown number of orders, till we arrive at the ſimpleſt poſſible conſtitution of a particle of tangible matter, ſuſceptible of length, breadth, and thickneſs, and neceſſarily conſiſting of four atoms of matter. And he ſhows that the more complex we ſuppoſe the conſtitution of a particle, the more muſt the ſenſible qualities of the aggregate reſemble the obſerved qualities of tangible bodies. In particular, he ſhows how a particle may be ſo conſtituted, that although it act on one other particle of the ſame kind through a conſiderable interval, the interpoſition of a third particle of the ſame kind may render it totally, or almoſt totally, inactive; and therefore an aſſemblage of ſuch particles would form ſuch a fluid as air. All theſe curious inferences are made with uncontrovertible evidence; and the greateſt encouragement is thus given to the mathematical philoſopher to hope, that by cautious and patient proceeding in this way, we may gradually approach to a knowledge of the laws of coheſion, that will not ſhun a compariſon even with the *Principia* of Newton. No ſtep can be made in this inveſtigation, but by obſerving with care, and generalizing with judgment, the phenomena, which are abundantly numerous, and much more at our command than thoſe of the great and ſenſible motions of bodies. Following this plan, we obſerve,

Plate ccccLxxxiv.

17 How Boſcovich repreſents the action of corpuſcular forces.

18 Every body compreſſible and dilatable.

4thly, It is matter of fact, that every body has ſome degree of compreſſibility and dilatability; and when the changes of dimenſion are ſo moderate that the body completely recovers its

Strength of Materials.

its original dimenſions on the ceſſation of the changing force, the extenſions or compreſſions are ſenſibly proportional to the extending or compreſſing forces; and therefore *the connecting forces are proportional to the diſtances of the particles from their quieſcent, natural, or inactive poſitions.* This ſeems to have been firſt viewed as a law of nature by the penetrating eye of Dr Robert Hooke, one of the moſt eminent philoſophers of the laſt century. He publiſhed a cipher, which he ſaid contained the theory of ſpringineſs and of the motions of bodies by the action of ſprings. It was this, *c c i i i n o s s s t t u u.*—When explained in his diſſertation, publiſhed ſome years after, it was *ut tenſio ſic vis.* This is preciſely the propoſition juſt now aſſerted as a general fact, a law of nature. This diſſertation is full of curious obſervations of facts in ſupport of his aſſertion. In his application to the motion of bodies he gives his noble diſcovery of the balance-ſpring of a watch, which is founded on this law. The ſpring, as it is more and more coiled up, or unwound, by the motion of the balance, acts on it with a force proportional to the diſtance of the balance from its quieſcent poſition. The balance therefore is acted on by an accelerating force, which varies in the ſame manner as the force of gravity acting on a pendulum ſwinging in a cycloid. Its vibrations therefore muſt be performed in equal time, whether they are wide or narrow. In the ſame diſſertation Hooke mentions all the facts which John Bernoulli afterwards adduced in ſupport of Leibnitz's whimſical doctrine of the force of bodies in motion, or the doctrine of the *vires vivæ*; a doctrine which Hooke might juſtly have claimed as his own, had he not ſeen its futility.

19 Law of nature diſcovered by Dr Hooke,

20 And confirmed by the experiments of others.

Experiments made ſince the time of Hooke ſhow that this law is ſtrictly true in the extent to which we have limited it, viz. in all the changes of form which will be completely undone by the elaſticity of the body. It is nearly true to a much greater extent. James Bernoulli, in his diſſertation on the elaſtic curve, relates ſome experiments of his own, which ſeem to deviate conſiderably from it; but on cloſe examination they do not. The fineſt experiments are thoſe of Coulomb, publiſhed in ſome late volumes of the memoirs of the Academy of Paris. He ſuſpended balls by wires, and obſerved their motions of oſcillation, which he found accurately correſponding with this law.

This we ſhall find to be a very important fact in the doctrine of the ſtrength of bodies, and we deſire the reader to make it familiar to his mind. If we apply to this our manner of expreſſing theſe forces by perpendicular ordinates C *c*, D *d* (fig. 1.), we muſt take other ſituations E, F, of the particle B, and draw E *e*, F *f*; and we muſt have D*d* : F *f* = BD : BF, or C *c* : E *e* = BC : BE. In ſuch a ſuppoſition F *d* B *c e* muſt be a ſtraight line. But we ſhall have abundant evidence by and by that this cannot be ſtrictly true, and that the line B *c e* which limits the ordinates expreſſing the attractive forces becomes concave towards the line ABE, and that the part B *d f* is convex towards it. All that can be ſafely concluded from the experiments hitherto made is, that *to a certain extent* the forces, both attractive and repulſive, are *ſenſibly* proportional to the dilatations and compreſſions. For,

21 When a body is much dilated, a ſmall addition of force will increaſe its dilatation.

5thly, It is univerſally obſerved, that when the dilatations have proceeded a certain length, a leſs addition of force is ſufficient to increaſe the dilatation in the ſame degree. This is always obſerved when the body has been ſo far ſtretched that it takes a ſet, and does not completely recover its form. The like may be generally obſerved in compreſſions. Moſt perſons will recollect, that in violently ſtretching an elaſtic cord, it becomes ſuddenly weaker, or more eaſily ſtretched. But theſe phenomena do not poſitively prove a diminution of the corpuſcular force acting on one particle. It more probably ariſes from the diſunion of ſome particles, whoſe action contributed to the whole or ſenſible effect. And in compreſſions we may ſuppoſe ſomething of the ſame kind; for when we compreſs a body in one direction, it commonly bulges out in another; and in caſes of every violent action ſome particles may be diſunited, whoſe tranſverſe action had formerly balanced *part* of the compreſſing force. For the reader will ſee on reflection, that ſince the compreſſion, in one direction cauſes the body to bulge out in the tranſverſe direction; and ſince this bulging out is in oppoſition to the tranſverſe forces of attraction, it muſt employ ſome part of the compreſſing force. And the common appearances are in perfect uniformity with this conception of things. When we preſs a bit of dryiſh clay, it ſwells out and cracks tranſverſely. When a pillar of wood is overloaded, it ſwells out, and ſmall crevices appear in the direction of the fibres. After this it will not bear half of the load. This the carpenters call CRIPPLING; and a knowledge of the circumſtances which modify it is of great importance, and enables us to underſtand ſome very paradoxical appearances, as will be ſhown by and by.

Strength of Materials.

This partial diſuniting of particles formerly cohering is, we imagine, the chief reaſon why the totality of the forces which really oppoſe an external ſtrain does not increaſe in the proportion of the extenſions and compreſſions. But ſufficient evidence will alſo be given that the forces which would connect one particle with one other particle do not augment in the accurate proportion of the change of diſtance; that in extenſions they increaſe more ſlowly, and in compreſſions more rapidly.

22 Ductility another cauſe of deviation.

But there is another cauſe of this deviation perhaps equally effectual with the former. Moſt bodies manifeſt ſome degree of ductility. Now what is this? The fact is, that the parts have taken a new arrangement, in which they again cohere. Therefore, in the paſſage to this new arrangement, the ſenſible forces, which are the joint reſult of many corpuſcular forces, begin to reſpect this new arrangement inſtead of the former. This muſt change the ſimple law of corpuſcular force, characteriſtic of the particular ſpecies of matter under examination. It does not require much reflection to convince us that the poſſible arrangements which the particles of a body may acquire, without appearing to change their nature, muſt be more numerous according as the particles are of a more complex conſtitution; and it is reaſonable to ſuppoſe that the conſtitution even of the moſt ſimple kind of matter that we are acquainted with is exceedingly complex. Our microſcopes ſhow us animals ſo minute, that a heap of them muſt appear to the naked eye an uniform maſs with a grain finer that that of the fineſt marble or razor hone; and yet each of theſe has not only limbs, but bones, muſcular fibres, blood-veſſels, fibres, and a blood conſiſting, in all probability, of globules organiſed and complex like our own. The imagination is here loſt in wonder; and nothing is left us but to adore inconceivable art and wiſdom, and to exult in the thought that we are the only ſpectators of this beautiful ſcene who can derive pleaſure from the view. What is trodden under foot with indifference, even by the half-reaſoning elephant, may be made by us the ſource of the pureſt and moſt unmixed pleaſure. But let us proceed to obſerve,

23 The forces which connect the particles of tangible bodies change by a change of diſtance.

6thly, That the forces which connect the particles of tangible bodies change by a change of diſtance, not only in degree, but alſo in kind. The particle B (fig. 1.) is attracted by A when in the ſituation C or E. It is repelled by it when at D or F. It is not affected by it when in the ſituation B. The reader is requeſted carefully to remark, that this is not an inference founded on the authority of our mathematical figure. The figure is an expreſſion (to aſſiſt the imagination) of fact in nature. It requires no force to keep the particles of a body in

Strength of Materials.

in their quiescent situations: but if they are separated by stretching the body, they endeavour (pardon the figurative expression) to come together again. If they are brought nearer by compression, they endeavour to recede. This endeavour is manifest by the necessity of employing force to maintain the extension or condensation; and we represent this by the different position of our lines. But this is not all: the particle B, which is repelled by A when in the situation F or D, is neutral when at B, and is attracted when at C or E, may be placed at such a distance AG from A greater than AB that it shall be again repelled, or at such a distance AH that it shall again be attracted; and these alterations may be repeated again and again. This is curious and important, and requires something more than a bare assertion for its proof.

24 Light alternately attracted and repelled.

In the article Optics we mentioned the most curious and valuable observations of Sir Isaac Newton, by which it appears that light is thus alternately attracted and repelled by bodies. The rings of colour which appear between the object glasses of long telescopes showed, that in the small interval of $\frac{1}{1000}$th of an inch, there are at least an hundred such changes observable, and that it is highly probable that these alterations extend to a much greater distance. At one of these distances the light actually converges towards the solid matter of the glass, which we express shortly, by saying that it is attracted by it, and that at the next distance it declines from the glass, or is repelled by it. The same thing is more simply inferred from the phenomena of light passing by the edges of knives and other opaque bodies. We refer the reader to the experiments themselves, the detail being too long for this place; and we request the reader to consider them minutely and attentively, and to form distinct notions of the inferences drawn from them. And we desire it to be remarked, that although Sir Isaac, in his discussion, always considers light as a set of corpuscles moving in free space, and obeying the actions of external forces like any other matter, the particular conclusion in which we are just now interested does not at all depend on this notion of the nature of light. Should we, with Des Cartes or Huygens, suppose light to be the undulation of an elastic medium, the conclusion will be the same. The undulations at certain distances are disturbed by forces directed towards the body, and at a greater distance, the disturbing forces tend *from* the body.

25 The same alternations of attraction and repulsion observable in the particles of other bodies, as glass.

But the same alternations of attraction and repulsion may be observed between the particles of common matter. If we take a piece of very flat and well polished glass, such as are made for the horizon glasses of a good Hadley's quadrant, and if we wrap round it a fibre of silk as it comes from the cocoon, taking care that the fibre nowhere cross another, and then press this pretty hard on such another piece of glass, it will lift it up and keep it suspended. The particles therefore of the one do most certainly attract those of the other, and this at a distance equal to the thickness of the silk fibre. This is nearly the limit; and it sometimes requires a considerable pressure to produce the effect. The pressure is effectual only by compressing the silk fibre, and thus diminishing the distance between the glass plates. This adhesion cannot be attributed to the pressure of the atmosphere, because there is nothing to hinder the air from insinuating itself between the plates, since they are separated by the silk. Besides, the experiment succeeds equally well under the receiver of an air-pump. This most valuable experiment was first made by Huygens, who reported it to the Royal Society. It is narrated in the Philosophical Transactions, n° 86.

Here then is an attraction acting, like gravity, at a distance. But take away the silk fibre, and try to make the glasses touch each other, and we shall find a very great force necessary. By Newton's experiments it appears, that unless the prismatic colours begin to appear between the glasses, they are at least $\frac{1}{800}$th of an inch asunder or more. Now we know that a very considerable force is necessary for producing these colours, and that the more we press the glasses together the more rings of colours appear. It also appears from Newton's measures, that the difference of distance between the glasses where each of these colours appear is about the 89,000th part of an inch. We know farther, that when we have produced the least appearance of a greasy or pearly colour, and then augment the pressure, making it about a thousand pounds on the square inch, all colours vanish, and the two pieces of glass seem to make one transparent undistinguishable mass. They appear now to have no air between them, or to be in mathematical contact. But another fact shows this conclusion to be premature. The same circles of colours appear in the top of a soap bubble; and as it grows thinner at top, there appears an unreflecting spot in the middle. We have the greatest probability therefore that the perfect transparency in the middle of the two glasses does nor arise from their being in contact, but because the thickness of air between them is too small in that place for the reflection of light. Nay, Newton expressly found no reflection where the thickness was $\frac{2}{5}$ths or more of the $\frac{1}{89000}$th part of an inch.

Strength of Materials.

All this while the glasses are strongly repelling each other, for great pressure is necessary for continuing the apearance of those colours, and they vanish in succession as the pressure is diminished. This vanishing of the colours is a proof that the glasses are moving off from each other, or repelling each other. But we can put an end to this repulsion by very strong pressure, and at the same time sliding the glasses on each other. We do not pretend to account for this effect of the sliding motion; but the fact is, that by so doing, the glasses will cohere with very great force, so that we shall break them by any attempt to pull them asunder. It commonly happens (at least it did so with us), that in this sliding compression of two smooth flat plates of glass they scratch and mutually destroy each other's surface. It is also worth remarking, that different kinds of glass exhibit different properties in this respect. Flint glass will attract even though a silk fibre lies double between them, and they much more readily cohere by this sliding pressure.

Here then are two distances at which the plates of glass attract each other; namely, when the silk fibre is interposed, and when they are forced together with this sliding motion. And in any intermediate situation they repel each other. We see the same thing in other solid bodies. Two pieces of lead made perfectly clean, may be made to cohere by grinding them together in the same manner. It is in this way that pretty ornaments of silver are united to iron. The piece is scraped clean, and a small bit of silver like a fish scale is laid on. The die which is to strike it into a flower or other ornament is then set on it, and we give it a smart blow, which forces the metals into contact as firm as if they were soldered together. It sometimes happens that the die adheres to the coin so that they cannot be separated: and it is found that this frequently happens, when the engraving is such, that the raised figure is not completely surrounded with a smooth flat ground. The probable cause of this is curious. When the coin has a flat surface all around, this is produced by the most prominent part of the die. This applies to the metal, and completely confines the air which filled the hollow of the die. As the pressure goes on, the metal is squeezed up into the hollow of the die; but there is still air compressed between them, which cannot escape by any passage. It is therefore prodigiously condensed,

20 Lead and iron.

27 Probable cause why the die adheres to the coin.

Strength of Materials.

condenſed, and exerts an elaſticity proportioned to the condenſation. This ſerves to ſeparate the die from the metal when the ſtroke is over. The hollow part of the die has not touched the metal all the while, and we may ſay that the impreſſion was made by air. If this air eſcape by any engraving reaching through the border, they cohere inſeparably.

We have admitted that the glaſs plates are in contact when they cohere thus firmly. But we are not certain of this: for if we take theſe cohering glaſſes, and touch them with water, it quickly inſinuates itſelf between them. Yet they ſtill cohere, but can now be pretty eaſily ſeparated.

28 Repulſion the cauſe of ſome bodies ſwimming in a fluid ſpecifically lighter than themſelves.

It is owing to this repulſion, exerted through its proper ſphere, that certain powders ſwim on the ſurface of water, and are wetted with great difficulty. Certain inſects can run about on the ſurface of water. They have bruſhy feet, which occupy a conſiderable ſurface; and if their ſteps are viewed with a magniſying glaſs, the ſurface of the water is ſeen depreſſed all around, reſembling the footſteps of a man walking on feather-beds. This is owing to a repulſion between the bruſh and the water. A common fly cannot walk in this manner on water. Its feet are wetted, becauſe they attract the water inſtead of repelling it. A ſteel needle wiped very clean will lie on the ſurface of water, making an impreſſion as a great bar would make on a feather bed; and its weight is leſs than that of the diſplaced water. A dew drop lies on the leaves of plants without touching them mathematically, as is plain from the extreme brilliancy of the reflection at the poſterior ſurface; nay, it may be ſometimes obſerved that the drops of rain lie on the ſurface of water, and roll about on it like balls on a table. Yet all theſe ſubſtances can be wetted; that is, water can be applied to them at ſuch diſtances that they attract it.

What we ſaid a little ago of water inſinuating itſelf between the glaſs plates without altogether deſtroying their coheſion, ſhows that this coheſion is not the ſame that obtains between the particles of one of the plates, that is, the two plates are not in the ſtate of one continued maſs. It is highly probable, therefore, that between theſe two ſtates there is an intermediate ſtate of repulſion, nay, perhaps many ſuch, alternated with attractive ſtates.

A piece of ice is elaſtic, for it rebounds and it rings. Its particles, therefore, when compreſſed, reſile; and when ſtretched, contract again. The particles are therefore in the ſtate repreſented by B in figure 1. acted on by repulſive forces, if brought nearer; and by attractive forces, if drawn further aſunder. Ice expands, like all other bodies, by heat. It abſorbs a vaſt quantity of fire; which, by combining its attractions and repulſions with thoſe of the particles of ice, changes completely the law of action, without making any ſenſible change in the diſtance of the particles, and the ice becomes water. In this new ſtate the particles are again in limits between attractive and repulſive forces; for water has been ſhown, by the experiments of Canton and Zimmerman, to be elaſtic or compreſſible. It again expands by heat. It again abſorbs a prodigious quantity of heat, and becomes elaſtic vapour; its particles repelling each other at all diſtances yet obſerved. The diſtance between the particles of one plate of glaſs and thoſe of another which lies on it, and is carried by it, is a diſtance of repulſion; for the force which ſupports the upper piece is acting in oppoſition to its weight. This diſtance is leſs than that at which it would *ſuſpend* it below it with a ſilk fibre interpoſed; for no priſmatic colours appear between them when the ſilk fibre is interpoſed. But the diſtance at which glaſs attracts water is much leſs than this, for no colours appear when glaſs is wetted with water. This diſtance is leſs, and not greater, than the other; for when the glaſſes have water interpoſed between them inſtead of air, it is found, that when any particular colour appears, the thickneſs of the plate of water is to that of the plate of air which would produce the ſame colour nearly as 3 to 4. Now, if a piece of glaſs be wetted, and exhibit no colour, and another piece of glaſs be ſimply laid on it, no colour will appear; but if they are ſtrongly preſſed, the colours appear in the ſame manner as if the glaſſes had air between. Alſo, when glaſs is ſimply wetted, and the film of water is allowed to evaporate, when it is thus reduced to a proper thickneſs, the colours ſhow themſelves in great beauty.

Strength of Materials.

29 Particles of matter connected by forces acting at a diſtance.

Theſe are a few of many thouſand facts, by which it is unqueſtionably proved that the particles of tangible matter are connected by forces acting at a diſtance, varying with the diſtance, and alternately attractive and repulſive. If we repreſent theſe forces as we have already done in fig 1. by the ordinates C c, D d, E e, F f, &c. of a curve, it is evident that this curve muſt croſs the axis at all thoſe diſtances where the forces change from attractive to repulſive, and the curve muſt have branches alternately above and below the axis.

All theſe alternations of attraction and repulſion take place at ſmall and inſenſible diſtances. At all ſenſible diſtances the particles are influenced by the attraction of gravitation; and therefore this part of the curve muſt be a hyperbola whoſe equation is $y = \frac{a^3}{x^2}$. What is the form of the curve correſponding to the ſmalleſt diſtance of the particles? that is, what is the mutual action between the particles juſt before their coming into abſolute contact? Analogy ſhould lead as to ſuppoſe it to be repulſion: for ſolidity is the laſt and ſimpleſt form of bodies with which we are acquainted.—Fluids are more compounded, containing fire as an eſſential ingredient. We ſhould conclude that this ultimate repulſion is inſuperable, for the hardeſt bodies are the moſt elaſtic. We are fully entitled to ſay, that this repelling force exceeds all that we have ever yet applied to overcome it; nay, there are good reaſons for ſaying that this ultimate repulſion, by which the particles are kept from mathematical contact, is really inſuperable in its own nature, and that it is impoſſible to produce mathematical contact.

30 Mathematical contact impoſſible.

We ſhall juſt mention one of theſe, which we conſider as unanſwerable. Suppoſe two atoms, or ultimate particles of matter A and B. Let A be at reſt, and B move up to it with the velocity 2; and let us ſuppoſe that it comes into mathematical contact, and impels it (according to the common acception of the word). Both move with the velocity 1. This is granted by all to be the final reſult of the colliſion. Now the inſtant of time in which this communication happens is no part either of the duration of the ſolitary motion of A, nor of the joint motion of A and B: It is the ſeparation or boundary between them. It is at once the end of the firſt, and the beginning of the ſecond, belonging equally to both. A was moving with the velocity 2. The diſtinguiſhing circumſtance therefore of its mechanical ſtate is, that it has a determination (however incomprehenſible) by which it would move for ever with the velocity 2, if nothing changed it. This it has during the whole of its ſolitary motion, and therefore in the laſt inſtant of this motion. In like manner, during the whole of the joint motion, and therefore in the firſt inſtant of this motion, the atom A has a determination by which it would move for ever with the velocity 1. In one and the ſame inſtant, therefore, the atom A has two incompatible determinations. Whatever notion we can form of this ſtate,

Strength of Materials.

which we call velocity, as a diſtinction of condition, the ſame impoſſibility of conception or the ſame abſurdity occurs. Nor can it be avoided in any other way than by ſaying, that this change of A's motion is brought about by inſenſible gradations; that is, that A and B influence each other preciſely as they would do if a ſlender ſpring were interpoſed. The reader is deſired to look at what we have ſaid in the article PHYSICS, § 82.

The two magnets there ſpoken of are good repreſentatives of two atoms endowed with mutual powers of repulſion; and the communication of motion is accompliſhed in both caſes in preciſely the ſame manner.

If, therefore, we ſhall ever be ſo fortunate as to diſcover the law of variation of that force which connects one ATOM of matter with another atom, and which is therefore characteriſtic of matter, and the ultimate ſource of all its ſenſible qualities, the curve whoſe ordinates repreſent the kind and the intenſity of this atomical force will be ſomething like that ſketched in fig. 2. The firſt branch *a n* B will have AK (perpendicular to the axis AH) for its aſſymptote, and the laſt branch *l m o* will be to all ſenſe a hyperbola, having AO for its aſſymptote; and the ordinates *l* L, *m* M, &c. will be proportional to $\frac{1}{AL^2}$, $\frac{1}{AM^2}$, &c. expreſſing the univerſal gravitation of matter. It will have many branches B *b* C, D *d* E, F *f* G, &c. expreſſing attractions, and alternate repulſive branches C *c* D, E *e* F, G *g* H, &c. All theſe will be contained within a diſtance A H, which does not exceed a very minute fraction of an inch.

31 The ſimpleſt extended particle conſiſts of four atoms.

The ſimpleſt particle which can be a conſtituent of a body having length, breadth, and thickneſs, muſt conſiſt of four ſuch atoms, all of which combine their influence on each attom of another ſuch particle. It is evident that the curve which expreſſes the forces that connect two ſuch particles muſt be totally different from this original curve, this hylarchic principle. Suppoſing the laſt known, our mathematical knowledge is quite able to diſcover the firſt; but when we proceed to compoſe a body of particles, each of which conſiſts of four ſuch particles, we may venture to ſay, that the compound force which connects them is almoſt beyond our ſearch, and that the diſcovery of the primary force from an *accurate* knowledge of the corpuſcular forces of *this* particular matter is abſolutely out of our power.

All that we can learn is, the poſſibility, nay the certainty, of an innumerable variety of external ſenſible forms and qualities, by which different kinds of matter will be diſtinguiſhed, ariſing from the number, the order of compoſition, and the arrangement of the ſubordinate particles of which a particle of this or that kind of matter is compoſed. All theſe varieties will take place at thoſe ſmall and inſenſible diſtances which are between A and H, and may produce all that variety which we obſerve in the tangible or mechanical forms of bodies, ſuch as elaſticity, ductility, hardneſs, ſoftneſs, fluidity, vapour, and all thoſe unſeen motions or actions which we obſerve in fuſion and congelation, evaporation and condenſation, ſolution and precipitation, cryſtallization, vegetable and animal aſſimilation and ſecretion, &c. &c. &c. while all bodies muſt be, in a certain degree, elaſtic, all muſt gravitate, and all muſt be incompenetrable.

This general and ſatisfactory reſemblance between the appearances of tangible matter and the legitimate conſequence of this general hypothetical property of an atom of matter, affords a conſiderable probability that ſuch is the origin of all the phenomena. We earneſtly recommend to our readers a *careful* peruſal of Boſcovich's celebrated treatiſe. A careful peruſal is neceſſary for ſeeing its value; and nothing will be got by a haſty look at it. The reader will be particularly pleaſed with the facility and evidence with which the ingenious author has deduced all the ordinary principles of mechanics, and with the explanation which he has given of fluidity, and his deduction from thence of the laws of hydroſtatics. No part of the treatiſe is more valuable than the doctrine of the propagation of preſſure through ſolid bodies. This, however, is but juſt touched on in the courſe of the inveſtigation of the principles of mechanics. We ſhall borrow as much as will ſuffice for our preſent inquiry into the ſtrength of materials; and we truſt that our readers are not diſpleaſed with this general ſketch of the doctrine (if it may be ſo called) of the coheſion of bodies. It is curious and important in itſelf, and is the foundation of all the knowledge we can acquire of the preſent article. We are ſorry to ſay that it is as yet a new ſubject of ſtudy; but it is a very promiſing one, and we by no means deſpair of ſeeing the whole of chemiſtry brought by its means within the pale of mechanical ſcience. The great and diſtinguiſhing agent in chemiſtry is heat, or fire the cauſe of heat; and one of its moſt ſingular effects is the converſion of bodies into elaſtic vapour. We have the cleareſt evidence that this is brought about by mechanical forces: for it can be oppoſed or prevented by external preſſure, a very familiar mechanical force. We may perhaps find another mechanical force which will prevent fuſion.

Strength of Materials.

32 The doctrine of coheſion yet a new ſubject.

HAVING now made our readers familiar with the mode of action in which coheſion operates in giving ſtrength to ſolid bodies, we proceed to conſider the ſtrains to which the ſtrength is oppoſed.

A piece of ſolid matter is expoſed to four kinds of ſtrain, pretty different in the manner of their operation.

33 Strains to which ſtrength is oppoſed.

1. It may be torn aſunder, as in the caſe of ropes, ſtretchers, king-poſts, tye-beams, &c.

2. It may be cruſhed, as in the caſe of pillars, poſts, and truſs-beams.

3. It may be broken acroſs, as happens to a joiſt or lever of any kind.

4 It may be wrenched or twiſted, as in the caſe of the axle of a wheel, the nail of a preſs, &c.

I. IT MAY BE PULLED ASUNDER.

34 Matter may be pulled aſunder.

This is the ſimpleſt of all ſtrains, and the others are indeed modifications of it. To this the force of coheſion is *directly* oppoſed, with very little modification of its action by any particular circumſtances.

When a long cylindrical or priſmatic body, ſuch as a rod of wood or metal, or a rope, is drawn by one end, it muſt be reſiſted at the other, in order to bring its coheſion into action. When it is faſtened at one end, we cannot conceive it any other way than as equally ſtretched in all its parts; for all our obſervations and experiments on natural bodies concur in ſhowing us that the forces which connect their particles, in any way whatever, are equal and oppoſite. This is called the *third law of motion*; and we admit its univerſality, while we affirm that it is purely experimental (ſee PHYSICS). Yet we have met with diſſertations by perſons of eminent knowledge, where propoſitions are maintained inconſiſtant with this. During the diſpute about the communication of motion, ſome of the ableſt writers have ſaid, that a ſpring compreſſed or ſtretched at the two ends was gradually leſs and leſs compreſſed or ſtretched from the extremities towards the middle: but the ſame writers acknowledge the univerſal equality of action and reaction, which is quite incompatible with this ſtate of the ſpring. No ſuch inequality of compreſſion or dilatation has ever been obſerved;

Strength of Materials.

ved; and a little reflection will show it to be impossible, in consistency with the equality of action and reaction.

Since all parts are thus equally stretched, it follows, that the strain in any transverse section is the same, as also in every point of that section. If therefore the body be supposed of a homogeneous texture, the cohesion of the parts is equable; and since every part is equally stretched, the particles are drawn to equal distances from their quiescent positions, and the forces which are thus excited, and now exerted in opposition to the straining force, are equal. This external force may be increased by degrees, which will gradually separate the part of the body more and more from each other, and the connecting forces increase with this increase of distance, till at last the cohesion of some particles is overcome. This must be immediately followed by a rupture, because the remaining forces are now weaker than before.

It is the united force of cohesion, immediately before the disunion of the first particles, that we call the STRENGTH of the section. It may also be properly called its ABSOLUTE STRENGTH, being exerted in the simplest form, and not modified by any relation to other circumstances.

35 A circumstance to be attended to in every construction requiring strength.

If the external force has not produced any permanent change on the body, and it therefore recovers its former dimensions when the force is withdrawn, it is plain that this strain may be repeated as often as we please, and the body which withstands it once will always withstand it. It is evident that this should be attended to in all constructions, and that in all our investigations on this subject this should be kept strictly in view. When we treat a piece of soft clay in this manner, and with this precaution, the force employed must be very small. If we exceed this, we produce a permanent change. The rod of clay is not indeed torn asunder; but it has become somewhat more slender: the number of particles in a cross section is now smaller; and therefore, although it will again, in this new form, suffer, or allow an endless repetition of a *certain* strain without any farther permanent change, this strain is smaller than the former.

Something of the same kind happens to all bodies which receive a SETT by the strain to which they are exposed. All ductile bodies are of this kind. But there are many bodies which are not ductile. Such bodies break completely whenever they are stretched beyond the limit of their perfect elasticity. Bodies of a fibrous structure exhibit very great varieties in their cohesion. In some the fibres have no lateral cohesion, as in the case of a rope. The only way in which all the fibres can be made to unite their strength is, to twist them together. This causes them to bind each other so fast, that any one of them will break before it can be drawn out of the bundle. In other fibrous bodies, such as timber, the fibres are held together by some cement or gluten. This is seldom as strong as the fibre. Accordingly timber is much easier pulled asunder in a direction transverse to the fibres. There is, however, every possible variety in this particular.

35 Great varieties in cohesion, but

In stretching and breaking fibrous bodies, the visible extension is frequently very considerable. This is not solely the increasing of the distance of the particles of the cohering fibres: the greatest part chiefly arises from drawing the crooked fibre straight. In this, too, there is great diversity; and it is accompanied with important differences in their power of withstanding a strain. In some woods, such as fir, the fibres on which the strength most depends are very straight. Such woods are commonly very elastic, do not take a set, and break abruptly when overstrained: others, such as oak and birch, have their resisting fibres very undulating and crooked, and stretch very sensibly by a strain. They are very liable to take a set, and they do not break so suddenly, but give warning by *complaining*, as the carpenters call it; that is, by giving visible signs of a derangement of texture. Hard bodies of an uniform glassy structure, granulated like stones, are elastic through the whole extent of their cohesion, and take no set, but break at once when overloaded.

Notwithstanding the immense variety which nature exhibits in the structure and cohesion of bodies, there are certain general facts of which we may now avail ourselves with advantage. In particular,

37 The absolute cohesion or strength proportional to the area of the section perpendicular to the extending force.

The absolute cohesion is proportional to the area of the section. This must be the case where the texture is perfectly uniform, as we have reason to think it is in glass and the ductile metals. The cohesion of each particle being alike, the whole cohesion must be proportional to their number, that is, to the area of the section. The same must be admitted with respect to bodies of a granulated texture, where the granulation is regular and uniform. The same must be admitted of fibrous bodies, if we suppose their fibres equally strong, equally dense, and similarly disposed through the whole section; and this we must either suppose, or must state the diversity, and measure the cohesion accordingly.

We may therefore assert, as a general proposition on this subject, that the absolute strength in any part of a body by which it resists being pulled asunder, or the force which must be employed to tear it asunder *in that part*, is proportional to the area of the section perpendicular to the extending force.

Therefore all cylindrical or prismatical rods are equally strong in every part, and will break alike in any part; and bodies which have unequal sections will always break in the slenderest part. The length of the cylinder or prism has no effect on the strength; and the vulgar notion, that it is easier to break a very long rope than a short one, is a very great mistake. Also the absolute strengths of bodies which have similar sections are proportional to the squares of their diameters or homologous sides of the section.

The weight of the body itself may be employed to strain it and to break it. It is evident, that a rope may be so long as to break by its own weight. When the rope is hanging perpendicularly, although it is equally strong in every part, it will break towards the upper end, because the strain on any part is the weight of all that is below it. Its RELATIVE STRENGTH in any part, or power of withstanding the strain which is actually laid on it, is inversely as the quantity below that part.

38 Relative strength.

When the rope is stretched horizontally, as in towing a ship, the strain arising from its weight often bears a very sensible proportion to its whole strength.

Let AEB (fig. 3.) be any portion of such a rope, and AC, BC be tangents to the curve into which its gravity bends it. Complete the parallelogram ACBD. It is well known that the curve is a catenaria, and that DC is perpendicular to the horizon; and that DC is to AC as the weight of the rope AEB to the strain at A.

In order that a suspended heavy body may be equally able in every part to carry its own weight, the section in that part must be proportional to the solid contents of all that is below it. Suppose it a conoidal spindle, formed by the revolution of the curve A *a e* (fig. 4.) round the axis CE. We must have $AC^2 : ac^2 = AEB$ sol. : *a E b* sol. This condition requires the logarithmic curve for A *a e*, of which C *c* is the axis.

These are the chief general rules which can be safely deduced from our clearest notions of the cohesion of bodies. In order to make any practical use of them, it is proper to have some measures of the cohesion of such bodies as are com-

Strength of Materials.

commonly employed in our mechanics, and other ſtructures where they are expoſed to this kind of ſtrain. Theſe muſt be deduced ſolely from experiment. Therefore they muſt be conſidered as no more than general values, or as the averages of many particular trials. The irregularities are very great, becauſe none of the ſubſtances are conſtant in their texture and firmneſs. Metals differ by a thouſand circumſtances unknown to us, according to their purity, to the heat with which they were melted, to the moulds in which they were caſt, and the treatment they have afterwards received, by forging, wire-drawing, tempering, &c.

39 The cohefion of metals depends on various circumſtances.

It is a very curious and inexplicable fact, that by forging a metal, or by frequently drawing it through a ſmooth hole in a ſteel plate, its coheſion is greatly increaſed. This operation undoubtedly deranges the natural ſituation of the particles. They are ſqueezed cloſer together in one direction; but it is not in the direction in which they reſiſt the fracture. In this direction they are rather ſeparated to a greater diſtance. The general denſity, however, is augmented in all of them except lead, which grows rather rarer by wire-drawing: but its coheſion may be more than tripled by this operation. Gold, ſilver, and braſs, have their coheſion nearly tripled; copper and iron have it more than doubled. In this operation they alſo grow much harder. It is proper to heat them to redneſs after drawing a little. This is called *nealing* or *annealing*. It ſoftens the metal again, and renders it ſuſceptible of another drawing without the riſk of cracking in the operation.

We do not pretend to give any explanation of this remarkable and very important fact, which has ſomething reſembling it in woods and other fibrous bodies, as will be mentioned afterwards.

The varieties in the coheſion of ſtones and other minerals, and of vegetables and animal ſubſtances, are hardly ſuſceptible of any deſcription or claſſification.

40 Cohefion and ſtrength of different metals.

We ſhall take for the meaſure of coheſion the number of pounds avoirdupois which are juſt ſufficient to tear aſunder a rod or bundle of one inch ſquare. From this it will be eaſy to compute the ſtrength correſponding to any other dimenſion.

1*ſt*, Metals.

		lbs.
Gold, caſt		20,000 to 24,000
Silver, caſt		40,000 to 43,000
Copper, caſt	Japan	19,500
	Barbary	22,000
	Hungary	31,000
	Angleſea	34,000
	Sweden	37,000
Iron, caſt		42,000 to 59,000
Iron, bar	Ordinary	68,000
	Stirian	75,000
	Beſt Swediſh and Ruſſian	84,000
	Horſe-nails	71,000 (A)
Steel, bar	Soft	120,000
	Razor temper	150,000
Tin, caſt	Malacca	3,100
	Banca	3,600
	Block	3,800
	Engliſh block	5,200
	—— grain	6,500
Lead, caſt		860
Regulus of antimony		1,000
Zinc		2,600
Biſmuth		2,900

Strength of Materials.

41 Tenacity of metals increaſed by mixture.

It is very remarkable that almoſt all the mixtures of metals are more tenacious than the metals themſelves. The change of tenacity depends much on the proportion of the ingredients, and the proportion which produces the moſt tenacious mixture is different in the different metals. We have ſelected the following from the experiments of Muſchenbroek. The proportion of ingredients here ſelected is that which produces the greateſt ſtrength.

Two parts of gold with one of ſilver	28,000
Five parts of gold with one of copper	50,000
Five parts of ſilver with one of copper	48,500
Four parts of ſilver with one of tin	41,000
Six parts of copper with one of tin	41,000
Five parts of Japan copper with one of Banca tin	57,000
Six parts of Chili copper with one of Malacca tin	60,000
Six parts of Swediſh copper with one of Malacca tin	64,000
Braſs conſiſts of copper and zinc in an unknown proportion; its ſtrength is	51,000
Three parts of block-tin with one part of lead	10,200
Eight parts of block-tin with one part of zinc	10,000
Four parts of Malacca tin with one part of regulus of antimony	12,000
Eight parts of lead with one of zinc	4,500
Four parts of tin with one of lead and one of zinc	13,000

Theſe numbers are of conſiderable uſe in the arts. The mixtures of copper and tin are particularly intereſting in the fabric of great guns. We ſee that, by mixing copper whoſe greateſt ſtrength does not exceed 37,000 with tin which does not exceed 6,000, we produce a metal whoſe tenacity is almoſt double, at the ſame time that it is harder and more eaſily wrought. It is, however, more fuſible, which is a great inconvenience. We alſo ſee that a very ſmall addition of zinc almoſt doubles the tenacity of tin, and increaſes the tenacity of lead five times; and a ſmall addition of lead doubles the tenacity of tin. Theſe are economical mixtures. This is a very valuable information to the plumbers for augmenting the ſtrength of water-pipes.

By having recourſe to theſe tables, the engineer can proportion the thickneſs of his pipes (of whatever metal) to the preſſures to which they are expoſed.

2*d*, Woods.

We may premiſe to this part of the table the following general obſervations:

42 Tenacity or ſtrength of wood.

1. The wood immediately ſurrounding the pith or heart of the tree is the weakeſt, and its inferiority is ſo much more remarkable as the tree is older. In this aſſertion, however, we ſpeak with ſome heſitation. Muſchenbroek's *detail* of experiments is decidedly in the affirmative. Mr Buffon, on the other hand, ſays, that his experience has taught him that the heart of a ſound tree is the ſtrongeſt; but he gives no inſtances. We are certain, from many obſervations

(A) This was an experiment by Muſchenbroek, to examine the vulgar notion that iron forged from old horſe-nails was ſtronger than all others, and ſhows its falſity

Strength of Materials.

servations of our own on *very large* oaks and firs, that the heart is much weaker than the exterior parts.

2. The wood next the bark, commonly called the *white* or *blea*, is alſo weaker than the reſt; and the wood gradually increaſes in ſtrength as we recede from the centre to the blea.

3. The wood is ſtronger in the middle of the trunk than at the ſpringing of the branches or at the root; and the wood of the branches is weaker than that of the trunk.

4. The wood of the north ſide of all trees which grow in the European climates is the weakeſt, and that of the ſouth-eaſt ſide is the ſtrongeſt; and the difference is moſt remarkable in hedge row trees, and ſuch as grow ſingly. The heart of a tree is never in its centre, but always nearer to the north ſide, and the annual coats of wood are thinner on that ſide. In conformity with this, it is a general opinion of carpenters that timber is ſtronger whoſe annual plates are thicker. The trachea or air-veſſels are weaker than the ſimple ligneous fibres. Theſe air-veſſels are the ſame in diameter and number of rows in the trees of the ſame ſpecies, and they make the viſible ſeparation between the annual plates. Therefore when theſe are thicker, they contain a greater proportion of the ſimple ligneous fibres.

5. All woods are more tenacious while green, and loſe very conſiderably by drying after the trees are felled.

The only author who has put it in our power to judge of the propriety of his experiments is Muſchenbroek. He has deſcribed his method of trial minutely, and it ſeems unexceptionable. The woods were all formed into ſlips fit for his apparatus, and part of the ſlip was cut away to a parallelopiped of $\frac{1}{5}$th of an inch ſquare and therefore $\frac{1}{25}$th of a ſquare inch in ſection. The abſolute ſtrengths of a ſquare inch were as follow:

43 Abſolute ſtrength of different kinds of wood,

	lib.		lib.
Locuſt tree	20,100	Pomegranate	9,750
Jujeb	18,500	Lemon	9,250
Beech, oak	17,300	Tamarind	8,750
Orange	15,500	Fir	8,330
Alder	13,900	Walnut	8,130
Elm	13,200	Pitch pine	7,650
Mulberry	12,500	Quince	6,750
Willow	12,500	Cypreſs	6,000
Aſh	12,000	Poplar	5,500
Plum	11,800	Cedar	4,880
Elder	10,000		

Mr. Muſchenbroek has given a very minute detail of the experiments on the aſh and the walnut, ſtating the weights which were required to tear aſunder ſlips taken from the four ſides of the tree, and on each ſide in a regular progreſſion from the centre to the circumference. The numbers of this table correſponding to theſe two timbers may therefore be conſidered as the average of more than 50 trials made of each; and he ſays that all the others were made with the ſame care. We cannot therefore ſee any reaſon for not confiding in the reſults; yet they are conſiderably higher than thoſe given by ſome other writers. Mr Pitot ſays, on the authority of his own experiments, and of thoſe of Mr Parent, that 60 pounds will juſt tear aſunder a ſquare line of ſound oak, and that it will bear 50 with ſafety. This gives 8640 for the utmoſt ſtrength of a ſquare inch, which is much inferior to Muſchenbroek's valuation.

We may add to theſe,

44 And of other ſubſtances.

Ivory	16,270
Bone	5,250
Horn	8,750
Whalebone	7,500
Tooth of ſea-calf	4,075

The reader will ſurely obſerve, that theſe numbers expreſs ſomething more than the utmoſt coheſion; for the weights are ſuch as will very quickly, that is, in a minute or two, tear the rods aſunder. It may be ſaid in general, that two-thirds of theſe weights will ſenſibly impair the ſtrength after a conſiderable while, and that one half is the utmoſt that can remain ſuſpended at them without riſk for ever; and it is this laſt allotment that the engineer ſhould reckon upon in his conſtructions. There is, however, conſiderable difference in this reſpect. Woods of a very ſtraight fibre, ſuch as fir, will be leſs impaired by any load which is not ſufficient to break them immediately.

Strength of Materials.

45 No ſubſtance to be ſtrained in architecture above one half its ſtrength.

According to Mr Emerſon, the load which may be ſafely ſuſpended to an inch ſquare is as follows:

Iron	76,400
Braſs	35,600
Hempen rope	19,600
Ivory	15,700
Oak, box, yew, plum-tree	7,850
Elm, aſh, beech	6,070
Walnut, plum	5,360
Red fir, holly, elder, plane, crab	5,000
Cherry, hazle	4,760
Alder, aſp, birch, willow	4,290
Lead	430
Freeſtone	914

He gives us a practical rule, that a cylinder whoſe diameter is *d* inches, loaded to one-fourth of its abſolute ſtrength, will carry as follows:

Iron	135	Cwt.
Good rope	22	
Oak	14	
Fir	9	

The rank which the different woods hold in this liſt of Mr Emerſon's is very different from what we find in Muſchenbroek's. But preciſe meaſures muſt not be expected in this matter. It is wonderful that in a matter of ſuch unqueſtionable importance the public has not enabled ſome perſons of judgment to make proper trials. They are beyond the abilities of private perſons.

II. Bodies may be crushed.

46 It is of importance to know what will cruſh bodies.

It is of equal, perhaps greater, importance to know the ſtrain which may be laid on ſolid bodies without danger of cruſhing them. Pillars and poſts of all kinds are expoſed to this ſtrain in its ſimpleſt form; and there are caſes where the ſtrain is enormous, viz. where it ariſes from the oblique poſition of the parts; as in the ſtuts, braces, and truſſes, which occur very frequently in our great works.

It is therefore moſt deſirable to have ſome general knowledge of the principle which determines the ſtrength of bodies in oppoſition to this kind of ſtrain. But unfortunately we are much more at a loſs in this than in the laſt caſe. The mechaniſm of nature is much more complicated in the preſent caſe. It muſt be in ſome circuitous way that compreſſion can have any tendency to tear aſunder the parts of a ſolid body, and it is very difficult to trace the ſteps.

If we ſuppoſe the particles inſuperably hard and in contact, and diſpoſed in lines which are in the direction of the external preſſures, it does not appear how any preſſure can diſunite the particles; but this is a gratuitous ſuppoſition. There are infinite odds againſt this preciſe arrangement of the lines of particles; and the compreſſibility of all kinds of matter in ſome degree ſhows that the particles are in a ſituation equivalent to diſtance. This being the caſe, and the particles, with their intervals, or what is equivalent to in-

Strength of Materials.

tervals, being in ſituations that are oblique with reſpect to the preſſures, it muſt follow, that by ſqueezing them together in one direction, they are made to bulge out or ſeparate in other directions. This may proceed ſo far that ſome may be thus puſhed laterally beyond their limits of coheſion. The moment that this happens the reſiſtance to compreſſion is diminiſhed, and the body will now be cruſhed together. We may form ſome notion of this by ſuppoſing a number of ſpherules, like ſmall ſhot, ſticking together by means of a cement. Compreſſing this in ſome particular direction cauſes the ſpherules to act among each other like ſo many wedges, each tending to penetrate through between the three which lie below it: and this is the ſimpleſt, and perhaps the only diſtinct, notion we can have of the matter. We have reaſon to think that the conſtitution of very homogeneous bodies, ſuch as glaſs, is not very different from this. The particles are certainly arranged ſymmetrically in the angles of ſome regular ſolids. It is only ſuch an arrangement that is conſiſtent with tranſparency, and with the free paſſage of light in *every* direction.

47 Their ſtrength or power of reſiſtance to ſuch a force

If this be the conſtitution of bodies, it appears probable that the ſtrength, or the reſiſtance which they are capable of making to an attempt to cruſh them to pieces, is proportional to the area of the ſection whoſe plane is perpendicular to the external force; for each particle being ſimilarly and equally acted on and reſiſted, the whole reſiſtance muſt be as their number; that is, as the extent of the ſection.

Accordingly this principle is aſſumed by the few writers who have conſidered this ſubject; but we confeſs that it appears to us very doubtful. Suppoſe a number of brittle or friable balls lying on a table uniformly arranged, but not cohering nor in contact, and that a board is laid over them and loaded with a weight; we have no heſitation in ſaying, that the weight neceſſary to cruſh the whole collection is proportional to their number or to the area of the ſection. But when they are in contact (and ſtill more if they cohere), we imagine that the caſe is materially altered. Any individual ball is cruſhed only in conſequence of its being bulged outwards in the direction perpendicular to the preſſure employed. If this could be prevented by a hoop put round the ball like an equator, we cannot ſee how any force can cruſh it. Any thing therefore which makes this bulging outwards more difficult, makes a greater force neceſſary. Now this effect will be produced by the mere contact of the balls before the preſſure is applied; for the central ball cannot ſwell outward laterally without puſhing away the balls on all ſides of it. This is prevented by the friction on the table and upper board, which is at leaſt equal to one third of the preſſure. Thus any interior ball becomes ſtronger by the mere vicinity of the others; and if we farther ſuppoſe them to cohere laterally, we think that its ſtrength will be ſtill more increaſed.

The analogy between theſe balls and the cohering particles of a friable body is very perfect. We ſhould therefore expect that the ſtrength by which it reſiſts being cruſhed will increaſe in a greater ratio than that of the ſection, or the ſquare of the diameter of ſimilar ſections; and that a ſquare inch of any matter will bear a greater weight in proportion as it makes a part of a greater ſection. Accordingly this appears in many experiments, as will be noticed afterwards. Muſchenbroek, Euler, and ſome others, have ſuppoſed the ſtrength of columns to be as the biquadrates of their diameters. But Euler deduced this from formulæ which occurred to him in the courſe of his algebraic analyſis; and he boldly adopts it as a principle, without looking for its foundation in the phyſical aſſumptions which he had made in the beginning of his inveſtigation. But ſome of his original aſſumptions were as paradoxical, or at leaſt as gratuitous, as theſe reſults: and thoſe, in particular, from which this proportion of the ſtrength of columns was deduced, were almoſt foreign to the caſe; and therefore the inference was of no value. Yet it was received as a principle by Muſchenbroek and by the academicians of St. Peterſburgh. We make theſe very few obſervations, becauſe the ſubject is of great practical importance; and it is a great obſtacle to improvements when deference to a great name, joined to incapacity or indolence, cauſes authors to adopt his careleſs reveries as principles from which they are afterwards to draw important conſequences. It muſt be acknowledged that we have not as yet eſtabliſhed the relation between the dimenſions and the ſtrength of a pillar on ſolid mechanical principles. Experience plainly contradicts the general opinion, that the ſtrength is proportional to the area of the ſection; but it is ſtill more inconſiſtent with the opinion, that it is in the quadruplicate ratio of the diameters of ſimilar ſections. It would ſeem that the ratio depends much on the internal ſtructure of the body; and experiment ſeems the only method for aſcertaining its general laws.

48 To be aſcertained only by experiment.

If we ſuppoſe the body to be of a fibrous texture, having the fibres ſituated in the direction of the preſſure, and ſlightly adhering to each other by ſome kind of cement, ſuch a body will fail only by the bending of the fibres, by which they will break the cement and be detached from each other. Something like this may be ſuppoſed in wooden pillars. In ſuch caſes, too, it would appear that the reſiſtance muſt be as the number of equally reſiſting fibres, and as their mutual ſupport, jointly; and, therefore, as ſome function of the area of the ſection. The ſame thing muſt happen if the fibres are naturally crooked or undulated, as is obſerved in many woods, &c. provided we ſuppoſe ſome ſimilarity in their form. Similarity of ſome kind muſt always be ſuppoſed, otherwiſe we need never aim at any general inferences.

In all caſes therefore we can hardly refuſe admitting that the ſtrength in oppoſition to compreſſion is proportional to a function of the area of the ſection.

As the whole length of a cylinder or priſm is equally preſſed, it does not appear that the ſtrength of a pillar is at all affected by its length. If indeed it be ſuppoſed to bend under the preſſure, the caſe is greatly changed, becauſe it is then expoſed to a tranſverſe ſtrain; and this increaſes with the length of the pillar. But this will be conſidered with due attention under the next claſs of ſtrains.

Few experiments have been made on this ſpecies of ſtrength and ſtrain. Mr Petit ſays, that his experiments, and thoſe of Mr Parent, ſhow that the force neceſſary for cruſhing a body is nearly equal to that which will tear it aſunder. He ſays that it requires ſomething more than 60 pounds on every ſquare line to cruſh a piece of ſound oak. But the rule is by no means general: Glaſs, for inſtance, will carry a hundred times as much as oak in this way, that is, reſting on it; but will not *ſuſpend* above four or five times as much. Oak will ſuſpend a great deal more than fir; but fir will carry twice as much as a pillar. Woods of a ſoft texture, although conſiſting of very tenacious fibres, are more eaſily cruſhed by their load. This ſoftneſs of texture is chiefly owing to their fibres not being ſtraight but undulated, and there being conſiderable vacuities between them, ſo that they are eaſily bent laterally and cruſhed. When a poſt is overſtrained by its load, it is obſerved to ſwell ſenſibly in diameter. Increaſing the load cauſes longitudinal cracks or ſhivers to appear, and it preſently after gives way. This is called *crippling*.

In all caſes where the fibres lie oblique to the ſtrain the ſtrength is greatly diminiſhed, becauſe the parts can then be made

Strength of Materials.

made to slide on each other, when the cohesion of the cementing matter is overcome.

Muschenbroek has given some experiments on this subject; but they are cases of long pillars, and therefore do not belong to this place. They will be considered afterwards.

The only experiments of which we have seen any detail (and it is useless to insert mere assertions) are those of Mr Gauthey, in the 4th volume of Rozier's *Journal de Physique*. This engineer exposed to great pressures small rectangular parallelopipeds, cut from a great variety of stones, and noted the weights which crushed them. The following table exhibits the medium results of many trials on two very uniform kinds of freestone, one of them among the hardest and the other among the softest used in building.

49 Experiments for this purpose made on freestone

Column 1st expresses the length AB of the section in French lines or 12ths of an inch; column 2d expresses the breadth BC; column 3d is the area of the section in square lines; column 4th is the number of ounces required to crush the piece; column 5th is the weight which was then borne by each square line of the section; and column 6th is the round numbers to which Mr Gauthey imagines that those in column 5th approximate.

	AB	BC	AB×BC	Weight	Force	
			Hard Stone.			
1	8	8	64	736	11,5	12
2	8	12	96	2625	27,3	24
3	8	16	128	4496	35,1	36
			Soft Stone.			
4	9	16	144	560	3,9	4
5	9	18	162	848	5,3	4,5
6	18	18	324	2928	9	9
7	18	24	432	5296	12,2	12

Little can be deduced from these experiments: The 1st and 3d, compared with the 5th and 6th, should furnish similar results; for the 1st and 5th are respectively half of the 3d and 6th: but the 3d is three times stronger (that is, a line of the 3d) than the first, whereas the 6th is only twice as strong as the 5th.

It is evident, however, that the strength increases much faster than the area of the section, and that a square line can carry more and more weight, according as it makes a part of a larger and larger section. In the series of experiments on the soft stone, the individual strength of a square line seems to increase nearly in the proportion of the section of which it makes a part.

Mr Gauthey deduces, from the whole of his numerous experiments, that a pillar of hard stone of Givry, whose section is a square foot, will bear with perfect safety 664,000 pounds, and that its extreme strength is 871,000, and the smallest strength observed in any of his experiments was 460,000. The soft bed of Givry stone had for its smallest strength 187,000, for its greatest 311,000, and for its safe load 249,000. Good brick will carry with safety 320,000; chalk will carry only 9000. The boldest piece of architecture in this respect which he has seen is a pillar in the church of All-Saints at Angers. It is 24 feet long and 11 inches square, and is loaded with 60,000, which is not $\frac{1}{7}$th of what is necessary for crushing it.

We may observe here by the way, that Mr Gauthey's measure of the suspending strength of stone is vastly small in proportion to its power of supporting a load laid above it. He finds that a prism of the hard bed of Givry, of a foot section, is torn asunder by 4600 pounds; and if it be firmly fixed horizontally in a wall, it will be broken by a weight of 56,000 suspended a foot from the wall. If it rest on two props at a foot distance, it will be broken by 206,000 laid on its middle. These experiments agree so ill with each other, that little use can be made of them. The subject is of great importance, and well deserves the attention of the patriotic philosopher.

50 Not satisfactory.

Strength of Materials.

51 Good experiments much wanted.

A set of good experiments would be very valuable, because it is against this kind of strain that we must guard by judicious construction in the most delicate and difficult problems which come through the hands of the civil and military engineer. The construction of stone arches, and the construction of great wooden bridges, and particularly the construction of the frames of carpentry called *centres* in the erection of stone bridges, are the most difficult jobs that occur. In the centres on which the arches of the bridge of Orleans were built some of the pieces of oak were carrying upwards of two tons on every square inch of their scantling. All who saw it said that it was not able to carry the fourth part of the intended load. But the engineer understood the principles of his art, and ran the risk: and the result completely justified his confidence; for the centre did not complain in any part, only it was found too supple; so that it went out of shape while the haunches only of the arch were laid on it. The engineer corrected this by loading it at the crown, and thus kept it completely in shape during the progress of the work.

In the Memoirs (old) of the Academy of Petersburgh for 1778, there is a dissertation by Euler on this subject, but particularly limited to the strain on columns, in which the bending is taken into the account. Mr Fuss has treated the same subject with relation to carpentry in a subsequent volume. But there is little in these papers besides a dry mathematical disquisition, proceeding on assumptions which (to speak favourably) are extremely gratuitous. The most important consequence of the compression is wholly overlooked, as we shall presently see. Our knowledge of the mechanism of cohesion is as yet far too imperfect to entitle us to a confident application of mathematics. Experiments should be multiplied.

52 How they are to be made useful.

The only way we can hope to make these experiments useful is to pay a careful attention to the *manner* in which the fracture is produced. By discovering the general resemblances in this particular, we advance a step in our power of introducing mathematical measurement. Thus, when a cubical piece of chalk is slowly crushed between the chaps of a vice, we see it uniformly split in a surface oblique to the pressure, and the two parts then slide along the surface of fracture. This should lead us to examine mathematically what relation there is between this surface of fracture and the necessary force; then we should endeavour to determine experimentally the position of this surface. Having discovered some general law or resemblance in this circumstance, we should try what mathematical hypothesis will agree with this. Having found one, we may then apply our simplest notions of cohesion, and compare the result of our computations with experiment. We are authorised to say, that a series of experiments have been made in this way, and that their results have been very uniform, and therefore satisfactory, and that they will soon be laid before the public as the foundations of successful practice in the construction of arches.

III. A Body may be broken across.

53 It is of importance to know what strain will break a body transversely.

The most usual, and the greatest strain, to which materials are exposed, is that which tends to break them transversely. It is seldom, however, that this is done in a manner perfectly simple; for when a beam projects horizontally from a wall, and a weight is suspended from its extremity, the beam is commonly broken near the wall, and the intermediate part has performed the functions of a lever. It sometimes, though rarely, happens that the pin in the joint of a pair of pincers or scissars is cut through by the strain;

Strength of Materials.

ſtrain; and this is almoſt the only caſe of a ſimple tranſverſe fracture. Being ſo rare, we may content ourſelves with ſaying, that in this caſe the ſtrength of the piece is proportional to the area of the ſection.

54 Experiments made to aſcertain

Experiments were made for diſcovering the reſiſtances made by bodies to this kind of ſtrain in the following manner: Two iron bars were diſpoſed horizontally at an inch diſtance; a third hung perpendicularly between them, being ſupported by a pin made of the ſubſtance to be examined. This pin was made of a priſmatic form, ſo as to fit exactly the holes in the three bars, which were made very exact, and of the ſame ſize and ſhape. A ſcale was ſuſpended at the lower end of the perpendicular bar, and loaded till it tore out that part of the pin which filled the middle hole. This weight was evidently the meaſure of the lateral coheſion of two ſections. The ſide-bars were made to graſp the middle bar pretty ſtrongly between them, that there might be no diſtance impoſed between the oppoſite preſſures. This would have combined the energy of a lever with the purely tranſverſe preſſure. For the ſame reaſon it was neceſſary that the internal parts of the holes ſhould be no ſmaller than the edges. Great irregularities occurred in our firſt experiments from this cauſe, becauſe the pins were ſomewhat tighter within than at the edges; but when this was corrected they were extremely regular. We employed three ſets of holes, viz. a circle, a ſquare (which was occaſionally made a rectangle whoſe length was twice its breadth), and an equilateral triangle. We found in all our experiments the ſtrength exactly proportional to the area of the ſection, and quite independant of its figure or poſition, and we found it conſiderably above the direct coheſion; that is, it took conſiderably more than twice the force to tear out this middle piece than to tear the pin aſunder by a direct pull. A piece of fine freeſtone required 205 pounds to pull it directly aſunder, and 575 to break it in this way. The difference was very conſtant in any one ſubſtance, but varied from $\frac{4}{3}$ds to $\frac{6}{3}$ds in different kinds of matter, being ſmalleſt in bodies of a fibrous texture. But indeed we could not make the trial on any bodies of conſiderable coheſion, becauſe they required ſuch forces as our apparatus could not ſupport. Chalk, clay baked in the ſun, baked ſugar, brick, and freeſtone, were the ſtrongeſt that we could examine.

55 Their reſult.

But the more common caſe, where the energy of a lever intervenes, demands a minute examination.

Let DABC (fig. 5. n° 1.) be a vertical ſection of a priſmatic ſolid (that is, of equal ſize throughout), projecting horizontally from a wall in which it is firmly fixed; and let a weight P be hung on it at B, or let any power P act at B in a direction perpendicular to AB. Suppoſe the body of inſuperable ſtrength in every part except in the vertical ſection DA, perpendicular to its length. It muſt break in this ſection only. Let the coheſion be uniform over the whole of this ſection; that is, let each of the adjoining particles of the two parts cohere with an equal force f.

56 The ſtrength of a lever.

There are two ways in which it may break. The part ABCD may ſimply ſlide down along the ſurface of fracture, provided that the power acting at B is equal to the accumulated force which is exerted by every particle of the ſection in the direction AD.

But ſuppoſe this effectually prevented by ſomething that ſupports the point A. The action at P tends to make the body turn round A (or round a horizontal line paſſing thro' A at right angles to AB) as round a joint. This it cannot do without ſeparating at the line DA. In this caſe the adjoining particles at D or at E will be ſeparated horizontally. But their coheſion reſiſts this ſeparation. In order, therefore, that the fracture may happen, the energy or momentum of the power P, acting by means of the lever AB, muſt be ſuperior to the accumulated energies of the particles. The energy of each depends not only on its coheſive force, but alſo on its ſituation: for the ſuppoſed inſuperable firmneſs of the reſt of the body makes it a lever turning round the fulcrum A, and the coheſion of each particle, ſuch as D or E, acts by means of the arm DA or EA. The energy of each particle will therefore be had by multiplying the force exerted by it in the inſtant of fracture by the arm of the lever by which it acts.

Strength of Materials.

Let us therefore firſt ſuppoſe, that in the inſtant of fracture every particle is exerting an equal force f. The energy of D will be $f \times DA$, and that of E will be $f \times EA$, and that of the whole will be the ſum of all theſe products. Let the depth DA of the ſection be called d, and let any undetermined part of it EA be called x, and then the ſpace occupied by any particle will be $\dot{x}$. The coheſion of this ſpace may be repreſented by $f\dot{x}$, and that of the whole by fd. The energy by which each element $\dot{x}$ of the line DA, or d, reſiſts the fracture, will be $f\dot{x}x$, and the whole accumulated energies will be $f \times f\dot{x}x$. This we know to be $f \times \frac{1}{2}d^2$, or $fd \times \frac{1}{2}d$. It is the ſame therefore as if the coheſion fd of the whole ſection had been acting at the point G, which is in the middle of DA.

The reader who is not familiarly acquainted with this fluxionary calculus may arrive at the ſame concluſion in another way. Suppoſe the beam, inſtead of projecting horizontally from a wall, to be hanging from the ceiling, in which it is firmly fixed. Let us conſider how the equal coheſion of every part operates in hindering the lower part from ſeparating from the upper by opening round the joint A. The equal coheſion operates juſt as equal gravity would do, but in the oppoſite direction. Now we know, by the moſt elementary mechanics, that the effect of this will be the ſame as if the whole weight were concentrated in the centre of gravity G of the line DA, and that this point G is in the middle of DA. Now the number of fibres being as the length d of the line, and the coheſion of each fibre being $= f$, the coheſion of the whole line is $f \times d$ or fd.

The accumulated energy therefore of the coheſion in the inſtant of fracture is $fd \times \frac{1}{2}d$. Now this muſt be equal or juſt inferior to the energy of the power employed to break it. Let the length AB be called l; then $P \times l$ is the correſponding energy of the power. This gives us $fd\frac{1}{2}d = pl$ for the equation of equilibrium correſponding to the vertical ſection ADCB.

Suppoſe now that the fracture is not permitted at DA, but at another ſection $d\alpha$ more remote from B. The body being priſmatic, all the vertical ſections are equal; and therefore $fd\frac{1}{2}d$ is the ſame as before. But the energy of the power is by this means increaſed, being now $= P \times B\alpha$, inſtead of $P \times BA$: Hence we ſee that when the priſmatic body is not inſuperably ſtrong in all its parts, but equally ſtrong throughout, it muſt break cloſe at the wall, where the ſtrain or energy of the power is greateſt. We ſee, too, that a power which is juſt able to break it at the wall is unable to break it anywhere elſe; alſo an abſolute coheſion fd, which can withſtand the power p in the ſection DA, will not withſtand it in the ſection $d\alpha$, and will withſtand more in the ſection $d'\alpha'$.

This teaches us to diſtinguiſh between abſolute and relative ſtrength. The relative ſtrength of a ſection has a reference to the ſtrain actually exerted on that ſection. This relative ſtrength is properly meaſured by the power which is juſt able to balance or overcome it, when applied at its proper

Strength of Materials.

proper place. Now since we had $f d \frac{1}{2} d = p l$, we have $p = \frac{f d \frac{1}{2} d}{l}$ for the measure of the strength of the section DA, in relation to the power applied at B.

If the solid is a rectangular beam, whose breadth is b, it is plain that all the vertical sections are equal, and that AG or $\frac{1}{2}d$ is the same in all. Therefore the equation expressing the equilibrium between the momentum of the external force and the accumulated momenta of cohesion will be $p l = f d b \times \frac{1}{2} d$.

The product $d b$ evidently expresses the area of the section of fracture, which we may call s, and we may express the equilibrium thus, $p l = f s \frac{1}{2} d$, and $2 l : d = f s : p$.

Now $f s$ is a proper expression of the absolute cohesion of the section of fracture, and p is a proper measure of its strength in relation to a power applied at B. We may therefore say, that *twice the length of a rectangular beam is to the depth as the absolute cohesion to the relative strength.*

Since the action of equable cohesion is similar to the action of equal gravity, it follows, that whatever is the figure of the section, the relative strength will be the same as if the absolute cohesion of all the fibres were acting at the centre of gravity of the section. Let g be the distance between the centres of gravity of the section and the axis of fracture, we shall have $p l = f s g$, and $l : g = f s : p$. It will be very useful to recollect this analogy in words: "*The length of a prismatic beam of any shape is to the height of the centre of gravity above the lower side, as the absolute cohesion to the strength relative to this length.*"

Because the relative strength of a rectangular beam is $\frac{f b d \frac{1}{2} d}{l}$ or $\frac{f b d^2}{2 l}$, it follows, that the relative strengths of different beams are proportional to the absolute cohesion of the particles, to the breadth, and to the square of the depth directly, and to the length inversely; also in prisms whose sections are similar, the strengths are as the cubes of the diameters.

57 Ascertained on the hypothesis of equal cohesion;

Such are the more general results of the mechanism of this transverse strain, in the hypothesis that all the particles are exerting equal forces in the instant of fracture. We are indebted for this doctrine to the celebrated Galileo; and it was one of the first specimens of the application of mathematics to the science of nature.

We have not included in the preceding investigation that action of the external force by which the solid is drawn sidewise, or tends to slide along the surface of fracture. We have supposed a particle E to be pulled only in the direction E e, perpendicular to the section of fracture, by the action of the crooked lever BAE. But it is also pulled in the direction EA; and its reaction is in some direction ϵE, compounded of ϵf, by which it resists being pulled outwards; and ϵe, by which it resists being pulled downwards. We are but imperfectly acquainted with the force ϵe, and only know that their accumulated sum is equal to the force p: but in all important cases which occur in practice, it is unnecessary to attend to this force; because it is so small in comparison of the forces in the direction E e, as we easily conclude from the usual smallness of AD in comparison of AB.

58 But that hypothesis not conformable to nature.

The hypothesis of equal cohesion, exerted by all the particles in the instant of fracture, is not conformable to nature: for we know, that when a force is applied transversely at B, the beam is bent downwards, becoming convex on the upper side; that side is therefore on the stretch. The particles at D are farther removed from each other than those at E, and are therefore *actually exerting* greater cohesive forces. We cannot say with certainty and precision in what proportion each fibre is extended. It seems most probable that the extensions are proportional to the distances from A. We shall suppose this to be really the case. Now recollect the general law which we formerly said was *observed* in all moderate extensions, *viz.* that the attractive forces exerted by the dilated particles were proportional to their dilatations. Suppose now that the beam is so much bent that the particles at D are exerting their utmost force, and that this fibre is just ready to break or actually breaks. It is plain that a total fracture must immediately ensue; because the force which was superior to the full cohesion of the particle at D, and a certain portion of the cohesion of all the rest, will be more than superior to the full cohesion of the particle next within D, and a smaller portion of the cohesion of the remainder.

Strength of Materials.

Now let F represent, as before, the full force of the exterior fibre D, which is exerted by it in the instant of its breaking, and then the force exerted at the same instant by the fibre E will be had by this analogy AD : AE, or $d : x = f : \frac{f x}{d}$, and the force really exerted by the fibre E is $f \times \frac{x}{d}$.

The force exerted by a fibre whose thickness is $\dot{x}$ is therefore $\frac{f x \dot{x}}{d}$; but this force resists the strain by acting by means of the lever EA or x. Its energy or momentum is therefore $\frac{f x^2 \dot{x}}{d}$, and the accumulated momenta of all the fibres in the line AE will be $f \times$ sum of $\frac{x^2 \dot{x}}{d}$. This, when x is taken equal to d, will express the momentum of the whole fibres in the line AD. This, therefore, is $f \frac{\frac{1}{3} d^3}{d}$, or $f \frac{1}{3} d^2$, or $f d \times \frac{1}{3} d$. Now $f d$ expresses the absolute cohesion of the whole line AD. The accumulated momentum is therefore the same as if the absolute cohesion of the whole line were exerted at $\frac{1}{3}$d of AD from A.

59 The strength ascertained on other principles.

From these premises it follows that the equation expressing the equilibrium of the strain and cohesion is $p l = f d \times \frac{1}{3} d$; and hence we deduce the analogy, "*As thrice the length is to the depth, so is the absolute cohesion to the relative strength.*"

This equation and this proportion will equally apply to rectangular beams whose breadth is b; for we shall then have $p l = f b d \times \frac{1}{3} d$.

We also see that the relative strength is proportional to the absolute cohesion of the particles, to the breadth, and to the square of the depth directly, and to the length inversely: for p is the measure of the force with which it is resisted, and $p = \frac{f b d \frac{1}{3} d}{l} = \frac{f b d^2}{3 l}$. In this respect therefore this hypothesis agrees with the Galilean; but it assigns to every beam a smaller proportion of the absolute cohesion of the section of fracture, in the proportion of 3 to 2. In the Galilean hypothesis this section has a momentum equal to $\frac{1}{2}$ of its absolute strength, but in the other hypothesis it is only $\frac{1}{3}$d. In beams of a different form the proportion may be different.

As this is a most important proposition, and the foundation of many practical maxims, we are anxious to have it clearly comprehended, and its evidence perceived by all. Our better informed readers will therefore indulge us while we endeavour to present it in another point of view, where it will be better seen by those who are not familiarly acquainted with the fluxionary calculus.

Fig.

Strength of Materials.

60

The same proposition presented in another point of view.

Fig. 5. n° 2. A is a perspective view of a three sided beam projecting horizontally from a wall, and loaded with a weight at B just sufficient to break it. DABC is a vertical plane through its highest point D, in the direction of its length. a D a is another vertical section perpendicular to AB. The piece being supposed of insuperable strength everywhere except in the section a D a, and the cohesion being also supposed insuperable along the line a A a, it can break nowhere but in this section, and by turning round a A a as round a hinge. Make D d equal to AD, and let D d represent the absolute cohesion of the fibre at D, which absolute cohesion we expressed by the symbol f. Let a plane $a\,d\,a$ be made to pass through $a\,a$ and d, and let $d\,a'\,a'$ be another cross section. It is plain that the prismatic solid contained between the two sections a D a and $a'\,d\,a'$ will represent the full cohesion of the whole section of fracture; for we may conceive this prism as made up of lines such as F f, equal and parallel to D d, representing the absolute cohesion of each particle such as F. The pyramidal solid d D $a\,a$, cut off by the plane $d\,a\,a$, will represent the cohesions *actually exerted* by the different fibres in the instant of fracture. For take any point E in the surface of fracture, and draw E e parallel to AB, meeting the plane $a\,d\,a$ in e, and let e A E be a vertical plane. It is evident that D d is to E e as AD to AE; and therefore (since the forces exerted by the different fibres are as their extension, and their extension as their distances from the axis of fracture) E e will represent the force actually exerted by the fibre in E, while D is exerting its full force D d. In like manner, the plane F F $f\,f$ expresses the cohesion exerted by all the fibres in the line F F, and so on through the whole surface. Therefore the pyramid $d\,a\,a$ D expresses the accumulated exertion of the whole surface of fracture.

Farther, suppose the beam to be held perpendicular to the horizon with the end B uppermost, and that the weight of the prism contained between the two sections a D a and $a'\,d\,a'$ (now horizontal) is just able to overcome the full cohesion of the section of fracture. The weight of the pyramid d D $a\,a$ will also be just able to overcome the cohesions *actually exerted* by the different fibres in the instant of fracture, because the weight of each fibre, such as E e, is just superior to the cohesion actually exerted at E.

Let o be the centre of gravity of the pyramidal solid, and draw o O perpendicular to the plane a D a. The whole weight of the solid d D $a\,a$ may be conceived as accumulated in the point o, and as acting on the point O, and it will have the same tendency to separate the two cohering surfaces as when each fibre is hanging by its respective point. For this reason the point O may be called the *centre of actual effort* of the unequal forces of cohesion. The momentum therefore, or energy by which the cohering surfaces are separated, will be properly measured by the weight of the solid d D $a\,a$ multiplied by OA; and this product is equal to the product of the weight p multipled by BA, or by l. Thus suppose that the cohesion along the line AD only is considered. The whole cohesion will be represented by a triangle A D d. D d represents f, and AD is d, and AD is x. Therefore A D d is $\frac{1}{2}fd$. The centre of gravity o of the triangle A D d is in the intersection of a line drawn from A to the middle of D d with a line drawn from d to the middle of AD; and therefore the line o O will make AO $= \frac{2}{3}$ of A D. Therefore the actual momentum of cohesion is $f \times \frac{1}{2}d \times \frac{2}{3}d$, $= f \times d \times \frac{1}{3}d$, $= fd \times \frac{1}{3}d$, or equal to the absolute cohesion acting by means of the lever $\frac{d}{3}$. If the section of fracture is a rectangle, as in a common joist, whose breadth $a\,a$ is $= b$, it is plain that all the vertical lines will be equal to AD, and their cohesions will be represented by triangles like A D d; and the whole actual cohesion will be represented by a wedge whose bases are vertical planes, and which is equal to half of the parallelopiped AD $\times$ D $d \times a\,a$, and will therefore be $= \frac{1}{2}f\,b\,d$; and the distance A O of its centre of gravity from the horizontal line A A' will be $\frac{2}{3}$ of A D. The momentum of cohesion of a joist will therefore be $\frac{1}{2}f\,b\,d \times \frac{2}{3}d$, or $f\,b\,d\,\frac{1}{3}d$, as we have determined in the other way.

Strength of Materials.

The beam represented in the figure is a triangular prism. The pyramid D $a\,a\,d$ is $\frac{1}{3}$ of the prism $a\,a$ D $d\,a'\,a'$. If we make s represent the surface of the triangle a D a, the pyramid is $\frac{1}{3}$ of fs. The distance AO of its centre of gravity from the horizontal line A A' is $\frac{1}{2}$ of A D, or $\frac{1}{2}d$. Therefore the momentum of actual cohesion is $\frac{1}{3}fs \times \frac{1}{2}d$, $= fs\,\frac{1}{6}d$; that is, it is the same as if the full cohesion of all the fibres were accumulated at a point I whose distance from A is $\frac{1}{6}$th of AD or d; or (that we may see its value in every point of view) it is $\frac{1}{6}$th of the momentum of the full cohesion of all the fibres when accumulated at the point D, or acting at the distance $d =$ A D.

This is a very convenient way of conceiving the momentum of actual cohesion, by comparing it with the momentum of absolute cohesion applied at the distance AD from the axis of fracture. The momentum of the absolute cohesion applied at D is to the momentum of actual cohesion in the instant of fracture as AD to AI. Therefore the length of AI, or its proportion to AD, is a sort of index of the strength of the beam. We shall call it the INDEX, and express it by the symbol i.

Its value is easily obtained. The product of the absolute cohesion by AI must be equal to that of the actual cohesion by AO. Therefore say, "as the prismatic solid $a\,a$ D $d\,a'\,a'$ is to the pyramidal solid $a\,a$ D d, so is AO to AI." We are assisted in this determination by a very convenient circumstance. In this hypothesis of the actual cohesions being as the distances of the fibres from A, the point O is the centre of oscillation or percussion of the surface D $a\,a$ turning round the axis $a\,a$: for the momentum of cohesion of the line F F is F F $\times$ F $f \times$ EA $=$ F F $\times$ EA^2, because F f is equal to E A. Now A O, by the nature of the centre of gravity, is equal to the sum of all these momenta divided by the pyramid $a\,a$ D d; that is, by the sum of all the F F $\times$ F f; that is, by the sum of all the FF $\times$ EA.

Therefore $AO = \frac{\text{sum of F F} \times \text{E A}^2}{\text{sum of F F} \times \text{E A}}$, which is just the value of the distance of the centre of percussion of the triangle $a\,a$ D from A: (See ROTATION). Moreover, if G be the centre of gravity of the triangle a D a, we shall have D A to G A as the absolute cohesion to the sum of the cohesions actually exerted in the instant of fracture; for, by the nature of this centre of gravity, A G is equal to $\frac{\text{sum of F F} \times \text{E A}}{\text{sum of F F}}$, and the sum of F F $\times$ A G is equal to the sum of F F $\times$ E A. But the sum of all the lines F F is the triangle a D a, and the sum of all the F F $\times$ E A is the sum of all the rectangles F F $f\,f$; that is, the pyramid d D $a\,a$. Therefore a prism whose base is the triangle a D a, and whose height is AG, is equal to the pyramid, or will express the sum of the actual cohesions; and a prism, whose base is the same triangle, and whose height is D d or D a, expresses the absolute cohesion. Therefore D A is to G A as the absolute cohesion to the sum of the actual cohesions.

Therefore we have DA : GA $=$ OA : IA.

Therefore, whatever be the form of the beam, that is, whatever be the figure of its section, find the centre of oscillation O, and the centre of gravity G of this section.

Strength of Materials.

Call their distances from the axis of fracture o and g. Then A I or $i = \frac{o g}{d}$, and the momentum of cohesion is $f s \times \frac{o g}{d}$, where s is the area of fracture.

This index is easily determined in all the cases which generally occur in practice. In a rectangular beam A I is $\frac{1}{3}$d of AD; in a cylinder (circular or elliptic) AI is $\frac{5}{16}$ths of AD, &c. &c.

In this hypothesis, that the cohesion actually exerted by each fibre is as its extension, and that the extensions of the fibres are as their distances from A (fig. 5. n° 1.), it is plain that the forces exerted by the fibres D, E, &c. will be represented by the ordinates D d, E e, &c. to a straight line A d. And we learn from the principles of ROTATION that the centre of percussion O is in the ordinate which passes through the centre of gravity of the triangle A D d, or (if we consider the whole section having breadth as well as depth) through the centre of gravity of the solid bounded by the planes DA, dA; and we found that this point O was the centre of effort of the cohesions *actually* exerted in the instant of fracture, and that I was the centre of an *equal* momentum, which would be produced if all the fibres were accumulated there and exerted their *full* cohesion.

This consideration enables us to determine, with equal facility and neatness, the strength of a beam in any hypothesis of forces. The above hypothesis was introduced with a cautious limitation to moderate strains, which produced no permanent change of form, or no set as the artists call it: and this suffices for all purposes of practice, seeing that it would be imprudent to expose materials to more violent strains. But when we compare this theory with experiments in which the pieces are really broken, considerable deviations may be expected, because it is very probable that in the vicinity of rupture the forces are no longer proportional to the extensions.

61 How the relative strength may be determined by any other hypothesis.

That no doubt may remain as to the justness and completeness of the theory, we must show how the relative strength may be determined in any other hypothesis. Therefore suppose that it has been established by experiment on any kind of solid matter, that the forces actually exerted in the instant of fracture by the fibres at D, E, &c. are as the ordinates D d', E e, &c. of any curve line A e' d'. We are supposed to know the form of this curve, and that of the solid which is bounded by the vertical plane through AD, and by the surface which passes through this curve A e' d' perpendicularly to the length of the beam. We know the place of the centre of gravity of this curve surface or solid, and can draw a line through it parallel to A B, and cutting the surface of fracture in some point O. This point is also the centre of effort of all the cohesions actually exerted; and the product of A O and of the solid which expresses the actual cohesions will give the momentum of cohesion equivalent to the former $f s \frac{o g}{d}$. Or we may find an index A I, by making A I a fourth proportional to the full cohesion of the surface of fracture, to the accumulated actual cohesions, and to AO; and then $f s \times i$ (= A I) will be the momentum of cohesion; and we shall still have I for the point in which all the fibres may be supposed to exert their full cohesion f, and to produce a momentum of cohesion equal to the real momentum of the cohesions actually exerted, and the relative strength of the beam will still be $p = \frac{f s i}{l}$ or $\frac{f s g o}{d l}$. Thus, if the forces be as the squares of the extensions (still supposed to be as the distances from A), the curve A e' d' will be a common parabola, having A B for its axis and A D for the tangent at its vertex. The area A D d' will be $\frac{1}{3}$d A D × D d; and in the case of a rectangular beam, A O will be $\frac{1}{4}$ths A D, and A I will be $\frac{1}{4}$th of A D.

Strength of Materials.

We may observe here in general, that if the forces actually exerted in the instant of fracture be as any power q of the distance from A, the index A I will be $= \frac{A D}{q+2}$ for a rectangular beam, and the momentum of cohesion will always be (*cæteris paribus*) as the breadth and as the square of the depth; nay, this will be the case whenever the action of the fibres D and E is expressed by any *similar functions* of d and x. This is evident to every reader acquainted with the fluxionary calculus.

As far as we can judge from experience, no simple algebraic power of the distance will express the actual cohesions of the fibres. No curve which has either AD or AB for its tangent will suit. The observations which we made in the beginning show, that although the curve of fig. 2. must be sensibly straight in the vicinity of the points of intersection with the axis, in order to agree with our observations which show the moderate extensions to be as the extending forces, the curve *must* be concave towards the axis in all its attractive branches, because it cuts it again. Therefore the curve A e' d' of fig. 5. (n° 1.) must make a finite angle with AD or A B, and it must, in all probability, be also concave towards AD in the neighbourhood of d'. It may however be convex in some part of the intermediate arch. We have made experiments on the extensions of different bodies, and find great diversities in this respect: But in all, the moderate extensions were as the forces, and this with great accuracy till the body took a set, and remained longer than formerly when the extending force was removed.

We must now remark, that this correction of the Galilean hypothesis of equal forces was suggested by the bending which is observed in all bodies which are strained transversely. Because they are bent, the fibres on the convex side have been extended. We cannot say in what proportion this obtains in the different fibres. Our most distinct notions of the internal equilibrium between the particles render it highly probable that their extension is proportional to their distance from the fibre which retains its former dimensions. But by whatever law this is regulated, we see plainly that the actions of the stretched fibres must follow the proportions of some function of this distance, and that therefore the relative strength of a beam is in all cases susceptible of mathematical determination.

62 Bernoulli's problem of the elastic curve.

We also see an intimate connection between the strain and the curvature. This suggested to the celebrated James Bernoulli the problem of the ELASTIC CURVE, *i. e.* the curve into which an extensible rigid body will be bent by a transverse strain. His solution in the *Acta Lipsiæ* 1694 and 1695 is a very beautiful specimen of mathematical discussion; and we recommend it to the perusal of the curious reader. He will find it very perspicuously treated in the first volume of his works, published after his death, where the wide steps which he had taken in his investigation are explained so as to be easily comprehended. His nephew Dan. Bernoulli has given an elegant abridgment in the Petersburg Memoirs for 1729. The problem is too intricate to be fully discussed in a work like ours; but it is also too intimately connected with our present subject to be entirely omitted. We must content ourselves with showing the leading mechanical property of this curve, from which the mathematician may deduce all its geometrical properties.

When a bar of uniform depth and breadth, and of a given length, is bent into an arch of a circle, the extension of the

Strength of Materials.

outer fibres is proportional to the curvature; for, because the curves formed by the inner and outer sides of the beam are similar, the circumferences are as the radii, and the radius of the inner circle is to the difference of the radii as the length of the inner circumference is to the difference of the circumferences. The difference of the radii is the depth of the beam, the difference of the circumferences is the extension of the outer fibres, and the inner circumference is supposed to be the primitive length of the beam. Now the second and third quantities of the above analogy, viz. the depth and length of the beam, are constant quantities, as is also their product. Therefore the product of the inner radius and the extension of the outer fibre is also a constant quantity, and the whole extension of the outer fibre is inversely as the radius of curvature, or is directly as the curvature of the beam.

63 Its leading mechanical property described.

The mathematical reader will readily see, that into whatever curve the elastic bar is bent, the whole extension of the outer fibre is equal to the length of a similar curve, having the same proportion to the thickness of the beam that the length of the beam has to the radius of curvature.

Now let ADCB (fig. 5. n° 3) be such a rod, of uniform breadth and thickness, firmly fixed in a vertical position, and bent into a curve AEFB by a weight W suspended at B, and of such magnitude that the extremity B has its tangent perpendicular to the action of the weight, or parallel to the horizon. Suppose too that the extensions are proportional to the extending forces. From any two points E and F draw the horizontal ordinates EG, FH. It is evident that the exterior fibres of the sections E *e* and F *f* are stretched by forces which are in the proportion of EG to FH (these being the long arms of the levers, and the equal thicknesses E *e*, F *f* being the short arms). Therefore (by the hypothesis) their extensions are in the same proportion. But because the extensions are proportional to some similar functions of the distance from the axes of fracture E and F, the extension of any fibre in the section E *e* is to the contemporaneous extension of the similarly situated fibre in the section F *f*, as the extension of the exterior fibre in the section E *e* is to the extension of the exterior fibre in the section F *f*: therefore the whole extension of E *e* is to the whole extension of F *f* as EG to FH, and EG is to FH as the curvature in E to the curvature in F.

Here let it be remarked, that this proportionality of the curvature to the extension of the fibres is not limited to the hypothesis of the proportionality of the extensions to the extending forces. It follows from the extension in the different sections being as some similar function of the distance from the axis of fracture; an assumption which cannot be refused.

This then is the fundamental property of the elastic curve, from which its equation, or relation between the abscissa and ordinate, may be deduced in the usual forms, and all its other geometrical properties. These are foreign to our purpose; and we shall notice only such properties as have an immediate relation to the strain and strength of the different parts of a flexible body, and which in particular serve to explain some difficulties in the valuable experiments of Mr Buffon on the Strength of Beams.

64 It is not a circle.

We observe, in the first place, that the elastic curve cannot be a circle, but is gradually more incurvated as it recedes from the point of application B of the straining forces. At B it has no curvature; and if the bar were extended beyond B there would be no curvature there. In like manner, when a beam is supported at the ends and loaded in the middle, the curvature is greatest in the middle; but at the props, or beyond them, if the beam extend farther, there is no curvature. Therefore when a beam projecting 20 feet from a wall is bent to a certain curvature at the wall by a weight suspended at the end, and a beam of the same size projecting 20 feet is bent to the very same curvature at the wall by a greater weight at 10 feet distance, the figure and the mechanical state of the beam in the vicinity of the wall is different in these two cases, though the curvature at the very wall is the same in both. In the first case every part of the beam is incurvated; in the second, all beyond the 10 feet is without curvature. In the first experiment the curvature at the distance of five feet from the wall is $\frac{3}{4}$ths of the curvature at the wall; in the second, the curvature at the same place is but $\frac{1}{2}$ of that at the wall. This must weaken the long beam in this whole interval of five feet, because the greater curvature is the result of a greater extension of the fibres.

Strength of Materials.

65 Every beam has a certain determinate curvature.

In the next place, we may remark, that there is a certain determinate curvature for every beam which cannot be exceeded without breaking it; for there is a certain separation of two adjoining particles that puts an end to their cohesion. A fibre can therefore be extended only a certain proportion of its length. The ultimate extension of the outer fibres must bear a certain determinate proportion to its length, and this proportion is the same with that of the thickness (or what we have hitherto called the depth) to the radius of ultimate curvature, which is therefore determinate.

66 And when of uniform breadth and depth is most incurvated where the strain is greatest.

A beam of uniform breadth and depth is therefore most incurvated where the strain is greatest, and will break in the most incurvated part. But by changing its form, so as to make the strength of its different sections in the ratio of the strain, it is evident that the curvature may be the same throughout, or may be made to vary according to any law. This is a remark worthy of the attention of the watchmaker. The most delicate problem in practical mechanics is so to taper the balance-spring of a watch that its wide and narrow vibrations may be isochronous. Hooke's principle *ut tensio sic vis* is not sufficient when we take the *inertia* and motion of the spring itself into the account. The figure into which it bends and unbends has also an influence. Our readers will take notice that the artist aims at an accuracy which will not admit an error of $\frac{1}{86400}$th, and that Harrison and Arnold have actually attained it in several instances. The taper of a spring is at present a nostrum in the hands of each artist, and he is careful not to impart his secret.

Again, since the depth of the beam is thus proportional to the radius of ultimate curvature, this ultimate or breaking curvature is inversely as the depth. It may be expressed by $\frac{1}{d}$.

67 To what the curvature is proportional.

When a weight is hung on the end of a prismatic beam, the curvature is nearly as the weight and the length directly, and as the breadth and the cube of the depth inversely; for the strength is $= f\frac{b\,d^2}{3\,l}$. Let us suppose that this produces the ultimate curvature $\frac{1}{d}$. Now let the beam be loaded with a smaller weight w, and let the curvature produced be C, we have this analogy $f\frac{b\,d^2}{3\,l} : w = \frac{1}{d} : C$, and $C = \frac{3\,l\,w}{f\,b\,d^3}$. It is evident that this is also true of a beam supported at the ends and loaded between the props; and we see how to determine the curvature in its different parts, whether arising from the load, or from its own weight, or from both.

When a beam is thus loaded at the end or middle, the loaded

Strength of Materials.

68 Deflection.

loaded point is pulled down, and the ſpace through which it is drawn may be called the DEFLECTION. This may be conſidered as the ſub-tenſe of the angle of contact, or as the verſed ſine of the arch into which the beam is bent, and is therefore as the curvature when the length of the arches is given (the flexure being moderate), and as the ſquare of the length of the arch when the curvature is given. The deflection therefore is as the curvature and as the ſquare of the length of the arch jointly; that is, as $\frac{3\,l\,w}{f\,b\,d^3} \times l^2$, or as $\frac{3\,l^3\,w}{f\,b\,d^3}$. The deflection from the primitive ſhape is therefore as the bending weight and the cube of the length directly, and as the breadth and cube of the depth inverſely.

In beams juſt ready to break, the curvature is as the depth inverſely, and the deflection is as the ſquare of the length divided by the depth; for the ultimate curvature at the breaking part is the ſame whatever is the length; and in this caſe the deflection is as the ſquare of the length.

69 The theorems reſulting from this ſubject afford the fineſt methods of examining the laws of corpuſcular action.

We have been the more particular in our conſideration of this ſubject, becauſe the reſulting theorems afford us the fineſt methods of examining the laws of corpuſcular action, that is, for diſcovering the variation of the force of coheſion by a change of diſtance. It is true it is not the atomical law, or HYLARCHIC PRINCIPLE as it may juſtly be called, which is thus made acceſſible, but the ſpecific law of the particles of the ſubſtance or kind of matter under examination. But even this is a very great point; and coincidences in this reſpect among the different kinds of matter are of great moment. We may thus learn the nature of the corpuſcular action of different ſubſtances, and perhaps approach to a diſcovery of the *mechaniſm* of chemical affinities. For that chemical actions are inſenſible cauſes of local motion is undeniable, and local motion is the province of mechanical diſcuſſion; nay, we ſee that theſe hidden changes are produced by mechanical forces in many important caſes, for we ſee them promoted or prevented by means purely mechanical. The converſion of bodies into elaſtic vapour by heat can at all times be prevented by a *ſufficient* external preſſure. A ſtrong ſolution of Glauber's ſalt will congeal in an inſtant by agitation, giving out its latent heat; and it will remain fluid for ever, and return its latent heat in a cloſe veſſel which it completely fills. Even water will by ſuch treatment freeze in an inſtant by agitation, or remain fluid for ever by confinement. We know that heat is produced or extricated by friction, that certain compounds of gold or ſilver with ſaline matters explode with irreſiſtible violence by the ſmalleſt preſſure or agitation. Such facts ſhould rouſe the mathematical philoſopher, and excite him to follow out the conjectures of the illuſtrious Newton, encouraged by the ingenious attempts of Boſcovich; and the proper beginning of this ſtudy is to attend to the laws of attraction and repulſion exerted by the particles of cohering bodies, diſcoverable by experiments made on their actual extenſions and compreſſions. The experiments of ſimple extenſions and compreſſions are quite inſufficient, becauſe the total ſtretching of a wire is ſo ſmall a quantity, that the miſtake of the 1000th part of an inch occaſions an irregularity which deranges any progreſſion ſo as to make it uſeleſs. But by the bending of bodies, a diſtenſion of $\frac{1}{100}$th of an inch may be eaſily magnified in the deflection of the ſpring ten thouſand times. We know that the inveſtigation is intricate and difficult, but not beyond the reach of our preſent mathematical attainments; and it will give very fine opportunities of employing all the addreſs of analyſis. In the laſt century and the beginning of the preſent this was a ſufficient excitement to the firſt geniuſes of Europe. The cycloid, the catenaria, the elaſtic curve, the velaria, the cauſtics, were reckoned an abundant recompence for much ſtudy; and James Bernoulli requeſted, as an honourable monument, that the logarithmic ſpiral might be inſcribed on his tombſtone. The reward for the ſtudy to which we now preſume to incite the mathematicians is the almoſt unlimited extenſion of natural ſcience, important in every particular branch. To go no further than our preſent ſubject, a great deal of important practical knowledge reſpecting the ſtrength of bodies is derived from the ſingle obſervation, that in the moderate extenſions which happen before the parts are overſtrained the forces are nearly in the proportion of the extenſions or ſeparations of the particles. To return to our ſubject.

Strength of Materials.

70 Bernoulli calls in queſtion this law.

James Bernoulli in his ſecond diſſertation on the elaſtic curve, calls in queſtion this law, and accommodates his inveſtigation to any hypotheſis concerning the relation of the forces and extenſions. He relates ſome experiments of lute ſtrings where the relation was conſiderably different. Strings of three feet long,

Stretched by	2,	4,	6,	8,	10 pds.
Were lengthened	9,	17,	23,	27,	30 lines.

But this is a moſt exceptionable form of the experiment. The ſtrings were twiſted, and the mechaniſm of the extenſions is here exceedingly complicated, combined with compreſſions and with tranſverſe twiſts, &c. We made experiments on fine ſlips of the gum caoutchouc, and on the juice of the berries of the white bryony, of which a ſingle grain will draw to a thread of two feet long, and again return into a perfectly round ſphere. We meaſured the diameter of the thread by a microſcope, with a micrometer, and thus could tell in every ſtate of extenſion the proportional number of particles in the ſections. We found, that though the whole range in which the diſtance of the particles was changed in the proportion of 13 to 1, the extenſions did not *ſenſibly* deviate from the proportion of the forces. The ſame thing was obſerved in the caoutchouc as long as it perfectly recovered its firſt dimenſions. And it is on the authority of theſe experiments that we preſume to announce this as a law of nature.

71 Which was firſt aſſumed by Dr Hooke.

Dr Robert Hooke was undoubtedly the firſt who attended to this ſubject, and aſſumed this as a law of nature. Mariotte indeed was the firſt who expreſsly uſed it for determining the ſtrength of beams: this he did about the year 1679, correcting the ſimple theory of Galileo. Leibnitz indeed, in his diſſertation in the *Acta Eruditorum* 1684 *de Reſiſtentia Solidorum*, introduces this conſideration, and wiſhes to be conſidered as the diſcoverer; and he is always acknowledged as ſuch by the Bernoullis and others who adhered to his peculiar doctrines. But Marriotte had publiſhed the doctrine in the moſt expreſs terms long before; and Pulfinger, in the *Comment. Petropol.* 1729, completely vindicates his claim. But Hooke was unqueſtionably the diſcoverer of this law. It made the foundation of his theory of ſprings, announced to the Royal Society about the year 1661, and read in 1666. On this occaſion he mentions many things on the ſtrength of bodies as quite familiar to his thoughts, which are immediate deductions from this principle; and among theſe *all* the facts which John Bernoulli ſo vauntingly adduces in ſupport of Leibnitz's finical dogmas about the force of bodies in motion; a doctrine which Hooke might have claimed as his own, had he not perceived its frivolous inanity.

72 Though corrected by Mariotte it does not properly explain the mechaniſm of tranſverſe ſtrain,

But even with this firſt correction of Marriotte, the mechaniſm of tranſverſe ſtrain is not fully nor juſtly explained. The force acting in the direction BP (fig. 5. n° 1.), and bending the body ABCD, not only ſtretches the fibres on the ſide oppoſite to the axis of fracture, but compreſſes the ſide AB, which becomes concave by the ſtrain. Indeed it cannot do the one without doing the other: For in order

Strength of Materials.

to ſtretch the fibres at D, there muſt be ſome fulcrum, ſome ſupport, on which the virtual lever BAD may preſs, that it may tear aſunder the ſtretched fibres. This fulcrum muſt ſuſtain both the preſſure ariſing from the coheſion of the diſtended fibres, and alſo the action of the external force, which immediately tends to cauſe the prominent part of the beam to ſlide along the ſection D A. Let BAD (fig. 5. n° 1.) be conſidered as a crooked lever, of which A is the fulcrum. Let an external force be applied at B in the direction B P, and let a force equal to the accumulated coheſion of A D be applied at O in the direction oppoſite to A B, that is, perpendicular to A O; and let theſe two forces be ſuppoſed to balance each other by the intervention of the lever. In the firſt place, the force at O muſt be to the force at B as AB to AO: Therefore, if we make AK equal and oppoſite to AO, and AL equal and oppoſite to AB, the common principles of mechanics inform us that the fulcrum A is affected in the ſame manner as if the two forces AK and AL were immediately applied to it, the force AK being equal to the weight P, and AL equal to the accumulated coheſion actually exerted in the inſtant of fracture. The fulcrum is therefore really preſſed in the direction AM, the diagonal of the parallelogram, and it muſt reſiſt in the direction and with the force MA; and this power of reſiſtance, this ſupport, muſt be furniſhed by the repulſive forces exerted by *thoſe particles only* which are in a ſtate of actual compreſſion. The force AK, which is equal to the external force P, muſt be reſiſted in the direction KA by the lateral coheſion of the whole particles between D and A (the particle D is not only drawn forward but downward). This prevents the part CDAB from ſliding down along the ſection DA.

73 As is fully verified by experiment.

This is fully verified by experiment. If we attempt to break a long ſlip of cork, or any ſuch very compreſſible body, we always obſerve it to bulge out on the concave ſide before it cracks on the other ſide. If it is a body of fibrous or foliated texture, it ſeldom fails ſplintering off on the concave ſide; and in many caſes this ſplintering is very deep, even reaching half way through the piece. In hard and granulated bodies, ſuch as a piece of freeſtone, chalk, dry clay, ſugar, and the like, we generally ſee a conſiderable ſplinter or ſhiver fly off from the hollow ſide. If the fracture be ſlowly made by a force at B gradually augmented, the formation of the ſplinter is very diſtinctly ſeen. It forms a triangular piece like *a* I *b*, which generally breaks in the middle. We doubt not but that attentive obſervation would ſhow that the direction of the crack on each ſide of I is not very different from the direction AM and its correſpondent on the other ſide. This is by no means a circumſtance of idle curioſity, but intimately connected with the mechaniſm of coheſion.

74 Conſequences reſulting from the ſtate of the caſe.

Let us ſee what conſequences reſult from this ſtate of the caſe reſpecting the ſtrength of bodies. Let D Δ K C (fig. 6.) repreſent a vertical ſection of a priſm of compreſſible materials, ſuch as a piece of timber. Suppoſe it loaded with a weight P hung at its extremity. Suppoſe it of ſuch a conſtitution that all the fibres in AD are in a ſtate of dilatation, while thoſe in A Δ are in a ſtate of compreſſion. In the inſtant of fracture the particles at D and E are with-held by forces D *d*, E *e*, and the particles at Δ and E repel, reſiſt, or ſupport, with forces Δ *δ*, E ε.

Some line, ſuch as *d e* A ε *δ*, will limit all theſe ordinates, which repreſent the forces actually exerted in the inſtant of fracture. If the forces are as the extenſions and compreſſions, as we have great reaſon to believe, *d e* A and A ε *δ* will be two ſtraight lines. They will form *one* ſtraight line *d* A *δ*, if the forces which reſiſt a certain dilatation are equal to the forces which reſiſt an equal compreſſion. But this is quite accidental, and is not ſtrictly true in any body. In moſt bodies which have any conſiderable firmneſs, the compreſſions made by any external force are not ſo great as the dilatations which the ſame force would produce; that is, the repulſions which are excited by any ſuppoſed degree of compreſſion are greater than the attractions excited by the ſame degree of dilatation. Hence it will generally follow, that the angle *d* AD is leſs than the angle *δ* A Δ, and the ordinates D *d*, E *e*, &c. are leſs than the correſponding ordinates Δ *δ*, E ε, &c.

Strength of Materials.

But whatever be the nature of the line *d* A *δ*, we are certain of this, that the whole area AD *d* is equal to the whole area A Δ *δ*: for as the force at B is gradually increaſed, and the parts between A and D are more extended, and greater coheſive forces are excited, there is always ſuch a degree of repulſive forces excited in the particles between A and Δ that the one ſet preciſely balances the other. The force at B, acting perpendicularly to AB, has no tendency to puſh the whole piece cloſer on the part next the wall or to pull it away. The ſum of the attractive and repulſive force, actually excited muſt therefore be equal. Theſe ſums are repreſented by the two triangular areas, which are therefore equal.

The greater we ſuppoſe the repulſive forces correſponding to any degree of compreſſion, in compariſon with the attractive forces correſponding to the ſame degree of extenſion, the ſmaller will A Δ be in the compariſon of AD. In a piece of cork or ſponge, A Δ may chance to be equal to AD, or even to exceed it; but in a piece of marble, A Δ will perhaps be very ſmall in compariſon of AD.

75 An important conſequence of the compreſſibility of body fully proved.

Now it is evident that the repulſive forces excited between A and Δ have no ſhare in preventing the fracture. They rather contribute to it, by furniſhing a fulcrum to the lever, by whoſe energy the coheſion of the particles in AD is overcome. Hence we ſee an important conſequence of the compreſſibility of the body. Its power of reſiſting this tranſverſe ſtrain is diminiſhed by it, and ſo much the more diminiſhed as the ſtuff is more compreſſible.

This is fully verified by ſome very curious experiments made by Du Hamel. He took 16 bars of willow 2 feet long and ½ an inch ſquare, and ſupporting them by props under the ends, he broke them by weights hung on the middle. He broke 4 of them by weights of 40, 41, 47, and 52 pounds: the mean is 45. He then cut 4 of them ⅓d through on the upper ſide, and filled up the cut with a thin piece of harder wood ſtuck in pretty tight. Theſe were broken by 48, 54, 50, and 52 pouuds; the mean of which is 51. He cut other four ½ through, and they were broken by 47, 49, 50, 46; the mean of which is 48. The remaining four were cut ⅔ds; and their mean ſtrength was 42.

Another ſet of his experiments is ſtill more remarkable.

Six battens of willow 36 inches long and 1½ ſquare were broken by 525 pounds at a medium.

Six bars were cut ⅓d through, and the cut filled with a wedge of hard wood ſtuck in with a little force: theſe broke with 551

Six bars were cut half through, and the cut was filled in the ſame manner: they broke with 542.

Six bars were cut ¾ths through: theſe broke with 530.

A batten cut ¾ths through, and loaded till nearly broken, was unloaded, and the wedge taken out of the cut. A thicker wedge was put in tight, ſo as to make the batten ſtraight again by filling up the ſpace left by the compreſſion of the wood: this batten broke with 577 pounds.

From this it is plain that more than ⅔ds of the thickneſs (perhaps nearly ¾ths) contributed nothing to the ſtrength.

The point A is the centre of fracture in this caſe; and in order to eſtimate the ſtrength of the piece, we may ſuppoſe

Strength of Materials.

pose that the crooked lever virtually concerned in the strain is DAB. We must find the point I, which is the centre of effort of all the attractive forces, or that point where the full cohesion of AD must be applied, so as to have a momentum equal to the accumulated momenta of all the variable forces. We must in like manner find the centre of effort *i* of the repulsive or supporting forces exerted by the fibres lying between A and Δ.

It is plain, and the remark is important, that this last centre of effort is the real fulcrum of the lever although A is the point where there is neither extension nor contraction; for the lever is supported in the same manner as if the repulsions of the whole line A Δ were exerted at that point. Therefore let S represent the surface of fracture from A to D, and *f* represent the absolute cohesion of a fibre at D in the instant of fracture. We shall have $fS \times \overline{I + i} = p\,l$, or $l : I + i = fS : p$; that is, the length AB is to the distance between the two centres of effort I and *i*, as the absolute cohesion of the section between A and D is to the relative strength of the section.

It would be perhaps more accurate to make A I and A *i* equal to the distances of A from the horizontal lines passing through the centres of gravity of the triangles *d* A D and *δ* A Δ. It is only in this construction that the points I and *i* are the centres of real effort of the accumulated attractions and repulsions. But I and *i*, determined as we have done, are the points where the full, equal, actions may be all applied, so as to produce the same momenta. The final results are the same in both cases. The attentive and duly informed reader will see that Mr Bulfinger, in a very elaborate dissertation on the strength of beams in the *Comment. Petropolitan.* 1729, has committed several mistakes in his estimation of the actions of the fibres. We mention this because his reasonings are quoted and appealed to as authorities by Muschenbroek and other authors of note. The subject has been considered by many authors on the continent. We recommend to the reader's perusal the very minute discussions in the Memoirs of the Academy of Paris for 1702 by Varignon, the Memoirs for 1708 by Parent, and particularly that of Coulomb in the *Mem. par les Sçavans Etrangers*, tom. vii.

It is evident, from what has been said above, that if S and *s* represent the surfaces of the sections above and below A, and if G and *g* are the distances of their centres of gravity from A, and O and *o* the distances of their centres of oscillation, and D and *d* their whole depths, the momentum of cohesion will be $\frac{fS \cdot G \cdot O}{D} + \frac{f\,s.g.o}{d} = p\,l$.

If (as is most likely) the forces are proportional to the extensions and compressions, the distances AI and A*i*, which are respectively $= \frac{G \cdot O}{D}$ and $\frac{g.o}{d}$, are respectively $= \frac{1}{3}$ D A, and $\frac{1}{3}$ Δ A; and when taken together are $= \frac{1}{3}$ D Δ. If, moreover, the extensions are equal to the compressions in the instant of fracture, and the body is a rectangular prism like a common joist or beam, then D A and Δ A are also equal; and therefore the momentum of cohesion is $f\,b \times \frac{1}{2}d \times \frac{1}{3}d, = \frac{f\,b\,d^2}{6}, = f\,b\,d \times \frac{1}{6}\,d = p\,l$. Hence we obtain this analogy, "Six times the length is to the depth as the absolute cohesion of the section is to its relative strength."

76 This consequence farther explained.

Thus we see that the compressibility of bodies has a very great influence on their power of withstanding a transverse strain. We see that in this most favourable supposition of equal dilatations and compressions, the strength is reduced to one half of the value of what it would have been had the body been incompressible. This is by no means obvious; for it does not readily appear how compressibility, which does not diminish the cohesion of a single fibre, should impair the strength of the whole. The reason, however, is sufficiently convincing when pointed out. In the instant of fracture a smaller portion of the section is actually exerting cohesive forces, while a part of it is only serving as a fulcrum to the lever, by whose means the strain on the section is produced. We see too that this diminution of strength does not so much depend on the sensible compressibility, as on its proportion to the dilatability by equal forces. When this proportion is small, A Δ is small in comparison of AD, and a greater portion of the whole fibre is exerting attractive forces. The experiments already mentioned of Du Hamel de Monceau on battens of willow show that its compressibility is nearly equal to its dilatability. But the case is not very different in tempered steel. The famous Harrison, in the delicate experiments which he made while occupied in making his longitude watch, discovered that a rod of tempered steel was nearly as much diminished in its length as it was augmented by the same external force. But it is not by any means certain that this is the proportion of dilatation and compression which obtains in the very instant of fracture. We rather imagine that it is not. The forces are nearly as the dilatations till very near breaking; but we think that they diminish when the body is just going to break. But it seems certain that the forces which resist compression increase faster than the compressions, even before fracture. We know incontestably that the ultimate resistances to compression are insuperable by any force which we can employ. The repulsive forces therefore (in their whole extent) increase faster than the compressions, and are expressed by an asymptotic branch of the Boscovician curve formerly explained. It is therefore probable, especially in the more simple substances, that they increase faster, even in such compressions as frequently obtain in the breaking of hard bodies. We are disposed to think that this is always the case in such bodies as do not fly off in splinters on the concave side; but this must be understood with the exception of the permanent changes which may be made by compression, when the bodies are crippled by it. This always increases the compression itself, and causes the neutral point to shift still more towards D. The effect of this is sometimes very great and fatal.

Experiment alone can help us to discover the proportion between the dilatability and compressibility of bodies. The strain now under consideration seems the best calculated for this research. Thus if we find that a piece of wood an inch square requires 12,000 pounds to tear it asunder by a direct pull, and that 200 pounds will break it transversely by acting 10 inches from the section of fracture, we must conclude that the neutral point A is in the middle of the depth, and that the attractive and repulsive forces are equal. Any notions that we can form of the constitution of such fibrous bodies as timber, make us imagine that the *sensible* compressions, including what arises from the bending up of the compressed fibres, is much greater than the real corpuscular extensions. One may get a general conviction of this unexpected proposition by reflecting on what must happen during the fracture. An undulated fibre can only be drawn straight, and then the corpuscular extension begins; but it may be bent up by compression to any degree, the corpuscular compression being little affected all the while. This observation is very important; and though the forces of corpuscular repulsion may be almost insuperable by any compression that we can employ, a *sensible* compression may be produced by forces not enormous, sufficient to cripple the beam. Of this we shall see very important instances afterwards.

It

Strength of Materials.

It deſerves to be noticed, that although the relative ſtrength of a priſmatic ſolid is extremely different in the three hypotheſes now conſidered, yet the proportional ſtrengths of different pieces follow the ſame ratio; namely, the direct ratio of the breadth, the direct ratio of the ſquare of the depth, and the inverſe ratio of the length. In the firſt hypotheſis (of equal forces) the ſtrength of a rectangular beam was $\frac{f b d^2}{2 l}$; in the ſecond (of attractive forces proportional to the extenſions) it was $\frac{f b d^2}{3 l}$; and in the third (equal attractions and repulſions proportional to the extenſions and compreſſions) it was $\frac{f b d^2}{6 l}$, or more generally $\frac{f b d^2}{m l}$, where m expreſſes the unknown proportion between the attractions and repulſions correſponding to an equal extenſion and compreſſion.

77 The proportional ſtrengths of different pieces follow the ſame ratio.

78 The ſtrength of a piece depends chiefly on its depth,

Hence we derive a piece of uſeful information, which is confirmed by unexcepted experience, that the ſtrength of a piece depends chiefly on its depth, that is, on that dimenſion which is in the direction of the ſtrain. A bar of timber of one inch in breadth and two inches in depth is four times as ſtrong as a bar of only one inch deep, and it is twice as ſtrong as a bar two inches broad and one deep; that is, a joiſt or lever is always ſtrongeſt when laid on its edge.

79 And therefore a choice in the manner in which the coheſion is oppoſed to the ſtrain.

There is therefore a choice in the manner in which the coheſion is oppoſed to the ſtrain. The general aim muſt be to put the centre of effort I as far from the fulcrum or the neutral point A as poſſible, ſo as to give the greateſt energy or momentum to the coheſion. Thus if a triangular bar projecting from a wall is loaded with a weight at its extremity, it will bear thrice as much when one of the ſides is uppermoſt as when it is undermoſt. The bar of fig. 5. n° 2. would be three times as ſtrong if the ſide AB were uppermoſt and the edge DC undermoſt.

80 The ſtrongeſt joiſt has not the greateſt quantity of timber.

Hence it follows that the ſtrongeſt joiſt that can be cut out of a round tree is not the one which has the greateſt quantity of timber in it, but ſuch that the product of its breadth by the ſquare of its depth ſhall be the greateſt poſſible. Let ABCD (fig. 7.) be the ſection of this joiſt inſcribed in the circle, AB being the breadth and AD the depth. Since it is a rectangular ſection, the diagonal BD is a diameter of the circle, and BAD is a right angled triangle. Let BD be called a, and BA be called x; then AD is $= \sqrt{a^2 - x^2}$. Now we muſt have $AB \times AD^2$, or $x \times a^2 - x^2$, or $a^2 x - x^3$, a maximum. Its fluxion $a^2 \dot{x} - 3x^2 \dot{x}$ muſt be made $= 0$, or $a^2 = 3x^2$, or $x^2 = \frac{a^2}{3}$. If therefore we make $DE = \frac{1}{3} DB$, and draw EC perpendicular to BD, it will cut the circumference in the point C, which determines the depth BC and the breadth CD.

Becauſe BD : BC = CD : CE, we have the area of the ſection BC·CD = BD·CE. Therefore the different ſections having the ſame diagonal BD are proportional to their heights CE. Therefore the ſection BCDA is leſs than the ſection B c D a, whoſe four ſides are equal. The joiſt ſo ſhaped, therefore, is both ſtronger, lighter, and cheaper.

81 A hollow tube ſtronger than a ſolid rod containing the ſame quantity of matter,

The ſtrength of ABCD is to that of a B c D as 10,000 to 9186, and the weight and expence as 10,000 to 10,607; ſo that ABCD is preferable to a B c D in the proportion of 10,607 to 9186, or nearly 115 to 100.

From the ſame principles it follows that a hollow tube is ſtronger than a ſolid rod containing the ſame quantity of matter. Let fig. 8. repreſent the ſection of a cylindric tube, of which AF and BE are the exterior and interior diameters and C the centre. Draw BD perpendicular to BC, and join DC. Then, becauſe $BD^2 = CD^2 - CB^2$, BD is the radius of a circle containing the ſame quantity of matter with the ring. If we eſtimate the ſtrength by the firſt hypotheſis, it is evident that the ſtrength of the tube will be to that of the ſolid cylinder, whoſe radius is BD, as $BD^2 \times AC$ to $BD^2 \times BD$; that is, as AC to BD: for BD^2 expreſſes the coheſion of the ring or the circle, and AC and DB are equal to the diſtances of the centres of effort (the ſame with the centres of gravity) of the ring and circle from the axis of fracture.

Strength of Materials.

The proportion of theſe ſtrengths will be different in the other hypotheſes, and it is not eaſily expreſſed by a general formula; but in both it is ſtill more in favour of the ring or hollow tube.

The following very ſimple ſolution will be readily underſtood by the intelligent reader. Let O be the centre of oſcillation of the exterior circle, o the centre of oſcillation of the inner circle, and w the centre of oſcillation of the ring included between them. Let M be the quantity of ſurface of the exterior circle, m that of the inner circle, and μ that of the ring.

We have $F w = \frac{M \cdot FO - m \cdot F o}{\mu} = \frac{5FC^2 + EC^2}{4FC}$, and the ſtrength of the ring $= \frac{f \mu \times F w}{2}$, and the ſtrength of the ſame quantity of matter in the form of a ſolid cylinder is $f \mu \times \frac{5}{8}$ BD; ſo that the ſtrength of the ring is to that of the ſolid rod of equal weight as F w to $\frac{5}{4}$ B D, or nearly as FC to BD. This will eaſily appear by recollecting that FO is $= \frac{\text{ſum of } p \cdot r^2}{m \cdot FC}$ (ſee ROTATION), and that the momentum of coheſion is $\frac{f m \cdot FC \cdot F a}{2FC} = \frac{f m \cdot F o}{2}$ for the inner circle, &c.

Emerſon has given a very inaccurate approximation to this value in his *Mechanics*, 4to.

82 And more ſtiff.

This property of hollow tubes is accompanied alſo with greater ſtiffneſs; and the ſuperiority in ſtrength and ſtiffneſs is ſo much the greater as the ſurrounding ſhell is thinner in proportion to its diameter.

83 Hence the wiſdom of God in forming the bones, &c. hollow.

Here we ſee the admirable wiſdom of the Author of nature in forming the bones of animal limbs hollow. The bones of the arms and legs have to perform the office of levers, and are thus oppoſed to very great tranſverſe ſtrains. By this form they become incomparably ſtronger and ſtiffer, and give more room for the inſertion of muſcles, while they are lighter and therefore more agile; and the ſame Wiſdom has made uſe of this hollow for other valuable purpoſes of the animal economy. In like manner the quills in the wings of birds acquire by their thinneſs the very great ſtrength which is neceſſary, while they are ſo light as to give ſufficient buoyancy to the animal in the rare medium in which it muſt live and fly about. The ſtalks of many plants, ſuch as all the graſſes, and many reeds, are in like manner hollow, and thus poſſeſs an extraordinary ſtrength. Our beſt engineers now begin to imitate nature by making many parts of their machines hollow, ſuch as their axles of caſt iron, &c.; and the ingenious Mr Ramſden now makes the axes and framings of his great aſtronomical inſtruments in the ſame manner.

In the ſuppoſition of homogeneous texture, it is plain that the fracture happens as ſoon as the particles at D are ſeparated beyond their utmoſt limit of coheſion. This is a determined quantity, and the piece bends till this degree of extenſion is produced in the outermoſt fibre. It follows, that the ſmaller we ſuppoſe the diſtance between A and D,

the

Strength of Materials.

the greater will be the curvature which the beam will acquire before it breaks. Greater depth therefore makes a beam not only ſtronger but alſo ſtiffer. But if the parallel fibres can ſlide on each other, both the ſtrength and the ſtiffneſs will be diminiſhed. Therefore if, inſtead of one beam D ▵ KC, we ſuppoſe two, DABC and A ▵ KB, not cohering, each of them will bend, and the extenſion of the fibres AB of the under beam will not hinder the compreſſion of the adjoining fibres AB of the upper beam. The two together therefore will not be more than twice as ſtrong as one of them (ſuppoſing DA = A ▵) inſtead of being four times as ſtrong; and they will bend as much as either of them alone would bend by half the load. This may be prevented, if it were poſſible to unite the two beams all along the ſeam AB, ſo that the one ſhall not ſlide on the other. This may be done in ſmall works, by gluing them together with a cement as ſtrong as the natural lateral coheſion of the fibres. If this cannot be done (as it cannot in large works), the ſliding is prevented by JOGGLING the beams together; that is, by cutting down ſeveral rectangular notches in the upper ſide of the lower beam, and making ſimilar notches in the under ſide of the upper beam, and filling up the ſquare ſpaces with pieces of very hard wood firmly driven in, as repreſented in fig. 9. Some employ iron bolts by way of joggles. But when the joggle is much harder than the wood into which it is driven, it is very apt to work looſe, by widening the hole into which it is lodged. The ſame thing is ſometimes done by ſcarfing the one upon the other, as repreſented in fig. 9. (n° 2.); but this waſtes more timber, and is not ſo ſtrong, becauſe the mutual hooks which this method forms on each beam are very apt to tear each other up. By one or other of theſe methods, or ſomething ſimilar, may a compound beam be formed, of any depth, which will be almoſt as ſtiff and ſtrong as an entire piece.

Fig. 6.

84 How a ſtrong compound beam may be formed.

85 How ſtrength may be combined with pliableneſs.

On the other hand, we may combine ſtrength with pliableneſs, by compoſing our beam of ſeveral thin planks laid on each other, till they make a proper depth, and leaving them at full liberty to ſlide on each other. It is in this manner that coach-ſprings are formed, as is repreſented in fig. 10. In this aſſemblage there muſt be no joggles nor bolts of any kind put through the planks or plates; for this would hinder their mutual ſliding. They muſt be kept together by ſtraps which ſurround them, or by ſomething equivalent.

86 Maxims of conſtruction.

The preceding obſervations ſhow the propriety of ſome maxims of conſtruction, which the artiſts have derived from long experience.

Thus, if a mortiſe is to be cut out of a piece which is expoſed to a croſs ſtrain, it ſhould be cut out from that ſide which becomes concave by the ſtrain, as in fig. 11. but by no means as in fig. 12.

If a piece is to be ſtrengthened by the addition of another, the added piece muſt be joined to the ſide which grows convex by the ſtrain, as in fig. 13. and 14.

Before we go any farther, it will be convenient to recal the reader's attention to the analogy between the ſtrain on a beam projecting from a wall and loaded at the extremity, and a beam ſupported at both ends and loaded in ſome intermediate point. It is ſufficient on this occaſion to read attentively what is delivered in the article ROOF, n° 19.—We learn there that the ſtrain on the middle point C (fig. 14. of the preſent article) of a rectangular beam AB, ſupported on props at A and B, is the ſame as if the part CA projected from a wall, and were loaded with the half of the weight W ſuſpended at A. The momentum of the ſtrain is therefore $\frac{1}{2}$ W × $\frac{1}{2}$ AB, = W × $\frac{1}{4}$ AB = $p \frac{1}{4} l$, or $\frac{pl}{4}$.

The momentum of coheſion muſt be equal to this in every hypotheſis.

Strength of Materials.

Having now conſidered in ſufficient detail the circumſtances which affect the ſtrength of any ſection of a ſolid body that is ſtrained tranſverſely, it is neceſſary to take notice of ſome of the chief modifications of the ſtrain itſelf. We ſhall conſider only thoſe that occur moſt frequently in our conſtructions.

The ſtrain depends on the external force, and alſo on the lever by which it acts.

87 The ſtrain depends on the external force.

It is evidently of importance, that ſince the ſtrain is exerted in any ſection by means of the coheſion of the parts intervening between the ſection under conſideration and the point of application of the external force, the body muſt be able in all theſe intervening parts to propagate or excite the ſtrain in the remote ſection. In every part it muſt be able to reſiſt the ſtrain excited in that part. It ſhould therefore be equally ſtrong; and it is uſeleſs to have any part ſtronger, becauſe the piece will nevertheleſs break where it is not ſtronger throughout; and it is uſeleſs to make it ſtronger (relatively to its ſtrain) in any part, for it will nevertheleſs equally fail in the part that is too weak.

Suppoſe then, in the firſt place, that the ſtrain ariſes from a weight ſuſpended at one extremity, while the other end is firmly fixed in a wall. Suppoſing alſo the croſs ſections to be all rectangular, there are ſeveral ways of ſhaping the beam ſo that it ſhall be equally ſtrong throughout. Thus it may be equally deep in every part, the upper and under ſurfaces being horizontal planes. The condition will be fulfilled by making all the horizontal ſections triangles, as in fig. 15. The two ſides are vertical planes meeting in an edge at the extremity L. For the equation expreſſing the balance of ſtrain and ſtrength is $p l = f b d^2$. Therefore ſince d^2 is the ſame throughout, and alſo p, we muſt have $f b = l$, and b (the breadth AD of any ſection ABCD) muſt be proportional to l (or AL), which it evidently is.

Or, if the beam be of uniform breadth, we muſt have d^2 everywhere proportional to l. This will be obtained by making the depths the ordinates of a common parabola, of which L is the vertex and the length is the axis. The upper or under ſide may be a ſtraight line, as in fig. 16. or the middle line may be ſtraight, and then both upper and under ſurfaces will be curved. It is almoſt indifferent what is the ſhape of the upper and under ſurfaces, provided the diſtances between them in every part be as the ordinates of a common parabola.

Or, if the ſections are all ſimilar, ſuch as circles, ſquares, or any other ſimilar polygons, we muſt have d^3 or b^3 proportional to l, and the depths or breadths muſt be as the ordinates of a cubical parabola.

88 And on the form of the levers by which it acts.

It is evident that theſe are alſo the proper forms for a lever moveable round a fulcrum, and acted on by a force at the extremity. The force comes in the place of the weight ſuſpended in the caſes already conſidered; and as ſuch levers always are connected with another arm, we readily ſee that both arms ſhould be faſhioned in the ſame manner. Thus in fig. 15. the piece of timber may be ſuppoſed a kind of ſteelyard, moveable round a horizontal axis OP, in the front of the wall, and having the two weights P and π in equilibrio. The ſtrain occaſioned by each at the ſection in which the axis OP is placed muſt be the ſame, and each arm OL and Oλ muſt be equally ſtrong in all its parts. The longitudinal ſections of each arm muſt be a triangle, a common parabola, or a cubic parabola, according to the conditions previouſly given.

And, moreover, all theſe forms are equally ſtrong: For any one of them is equally ſtrong in all its parts, and they are all ſuppoſed to have the ſame ſection at the front of the

Strength of Materials.

wall or at the fulcrum. They are not, however, equally ſtiff. The firſt, repreſented in fig. 15. will bend leaſt upon the whole, and the one formed by the cubic parabola will bend moſt. But their curvature at the very fulcrum will be the ſame in all.

It is alſo plain, that if the lever is of the ſecond or third kind, that is, having the fulcrum at one extremity, it muſt ſtill be of the ſame ſhape; for in abſtract mechanics it is indifferent which of the three points is conſidered as the axis of motion. In every lever the two forces at the extremities act in one direction, and the force in the middle acts in the oppoſite direction, and the great ſtrain is always at that point. Therefore a lever ſuch as fig. 15. moveable round an axis paſſing horizontally through λ, and acting againſt an obſtacle at OP, is equally able in all its parts to reſiſt the ſtrains excited in thoſe parts.

The ſame principles and the ſame conſtruction will apply to beams, ſuch as joiſts, ſupported at the ends L and λ (fig. 15.), and loaded at ſome intermediate part OP. This will appear evident by merely inverting the directions of the forces at theſe three points, or by recurring to the article ROOFS, n° 19.

89 The external ſtraining force may be diſtributed over the beam.

Hitherto we have ſuppoſed the external ſtraining force as acting only in one point of the beam. But it may be uniformly diſtributed all over the beam. To make a beam in ſuch circumſtances equally ſtrong in all its parts, the ſhape muſt be conſiderably different from the former.

Thus ſuppoſe the beam to project from a wall.

90 To make a beam ſtrong which projects from a wall.

If it be equal breadth throughout, its ſides being vertical planes parallel to each other and to the length, the vertical ſection in the direction of its length muſt be a triangle inſtead of a common parabola; for the weight uniformly diſtributed over the part lying beyond any ſection, is as the length beyond that ſection: and ſince it may all be conceived as collected at its centre of gravity, which is the middle of that length, the lever by which this load acts or ſtrains the ſection is alſo proportional to the ſame length. The ſtrain on the ſection (or momentum of the load) is as the ſquare of that length. The ſection muſt have ſtrength in the ſame proportion. Its ſtrength being as the breadth and the ſquare of the depth, and the breadth being conſtant, the ſquare of the depth of any ſection muſt be as the ſquare of its diſtance from the end, and the depth muſt be as that diſtance; and therefore the longitudinal vertical ſection muſt be a triangle.

But if all the tranſverſe ſections are circles, ſquares, or any other ſimilar figures, the ſtrength of every ſection, or the cube of the diameter, muſt be as the ſquare of the lengths beyond that ſection, or the ſquare of its diſtance from the end; and the ſides of the beam muſt be a ſemicubical parabola.

If the upper and under ſurfaces are horizontal planes, it is evident that the breadth muſt be as the ſquare of the diſtance from the end, and the horizontal ſections may be formed by arches of the common parabola, having the length for their tangent at the vertex.

By recurring to the analogy ſo often quoted between a projecting beam and a joiſt, we may determine the proper form of joiſts which are uniformly loaded through their whole length.

91 The ſtran upon a beam ſupported at both ends.

This is a frequent and important caſe, being the office of joiſts, rafters, &c. and there are ſome circumſtances which muſt be particularly noticed, becauſe they are not ſo obvious, and have been miſunderſtood. When a beam AB (fig. 17.) is ſupported at the ends, and a weight is laid on any point P, a ſtrain is excited in every part of the beam. The load on P cauſes the beam to preſs on A and B, and the props react with forces equal and oppoſite to theſe preſſures. The load at P is to the preſſures at A and B as AB to PB and PA, and the preſſures at A is to that at B as PB to PA; the beam therefore is in the ſame ſtate, with reſpect to ſtrain in every part of it, as if it were reſting on a prop at P, and were loaded at the ends with weights equal to the two preſſures on the props: and obſerve, theſe preſſures are ſuch as will balance each other, being inverſely as their diſtances from P. Let P repreſent the weight or load at P. The preſſure on the prop P muſt be $P \times \frac{PA}{AB}$. This is therefore the reaction of the prop B, and is the weight which we may ſuppoſe ſuſpended at B, when we conceive the beam reſting on a prop at P, and carrying the balancing weights at A and B.

Strength of Materials.

The ſtrain occaſioned at any other point C, by the load P at P, is the ſame with the ſtrain at C, by the weight $P \times \frac{PA}{B}$ hanging at B, when the beam reſts on P, in the manner now ſuppoſed; and it is the ſame if the beam, inſtead of being balanced on a prop at P, had its part AP fixed in a wall. This is evident. Now we have ſhown at length that the ſtrain at C, by the weight $P \times \frac{PA}{AB}$ hanging at B, is $P \times \frac{PA}{AB} \times BC$. We deſire it to be particularly remarked that the preſſure at A has no influence on the ſtrain at C, ariſing from the action of any load between A and C; for it is indifferent how the part AP of the projecting beam PB is ſupported. The weight at A juſt performs the ſame office with the wall in which we ſuppoſe the beam to be fixed. We are thus particular, becauſe we have ſeen even perſons not unaccuſtomed to diſcuſſions of this kind puzzled in their conceptions of this ſtrain.

Now let the load P be laid on ſome point p between C and B. The ſame reaſoning ſhows us that the point is (with reſpect to ſtrain) in the ſame ſtate as if the beam were fixed in a wall, embracing the part p B, and a weight $= P \times \frac{p\,B}{AB}$ were hung on at A, and the ſtrain at C is $P \times \frac{p\,B}{AB} \times AC$.

92 A general propoſition.

In general, therefore, the ſtrain on any point C, ariſing from a load P laid on another point P, is proportional to the rectangle of the diſtances of P and C from the ends neareſt to each. It is $P \times \frac{PA \times CB}{AB}$, or $P \times \frac{p\,B \times CA}{AB}$, according as the load lies between C and A or between C and B.

Cor. 1. The ſtrains which a load on any point P occaſions on the points C, c, lying on the ſame ſide of P, are as the diſtances of theſe points from the end B. In like manner the ſtrains on E and e are as EA and e A.

Cor. 2. The ſtrain which a load occaſions in the part on which it reſts is as the rectangle of the parts on each ſide. Thus the ſtrain occaſioned at C by a load is to that at D by the ſame load as AC × CB to AD × DB. It is therefore greateſt in the middle.

93 The ſtrain ariſing from a load diſtributed along the beam.

Let us now conſider the ſtrain on any point C ariſing from a load uniformly diſtributed along the beam. Let AP be repreſented by x, and Pp by $\dot{x}$, and the whole weight on the beam by a. Then

The weight on Pp is $= a \frac{\dot{x}}{AB}$,

Preſſure on B by the weight on Pp $= a \frac{\dot{x}}{AB} \times \frac{x}{AB}$.

Or

Strength of Materials.

Or $= \frac{a \times x}{AB^2}$

Pref. on B by the whole wt. on $AC = a\frac{\frac{1}{2}AC^2}{AB^2} = a\frac{AC^2}{2AB^2}$.

Strain at C by the weight on $AC = a\frac{AC^2 \times BC}{2AB^2}$.

Strain at C by the weight on $BC = a\frac{BC^2 \times AC}{2AB^2}$.

Do. by the whole weight on $AB = a\frac{AC^2 \times BC + BC^2 \times AC}{2AB^2}$

$= a\frac{AC \times BC \times \overline{AC + CB}}{2AB^2}$, $= a\frac{AC + BC}{2AB}$.

Thus we see that the ſtrain is proportional to the rectangle of the parts, in the ſame manner as if the load *a* had been laid directly on the point C, and is indeed equal to one-half of the ſtrain which would be produced at C by the load *a* laid on there.

94 Miſtakes in this ſubject committed by authors of reputation.

It was neceſſary to be thus particular, becauſe we ſee in ſome elementary treatiſes of mechanics, publiſhed by authors of reputation, miſtakes which are very plauſible, and miſlead the learner. It is there ſaid, that the preſſure at B from a weight uniformly diffuſed along AB is the ſame as if it were collected at its centre of gravity, which would be the middle of AB; and then the ſtrain at C is ſaid to be this preſſure at B multiplied by BC. But ſurely it is not difficult to ſee the difference of theſe ſtrains. It is plain that the preſſure of gravity downwards on any point between the end A and the point C has no tendency to diminiſh the ſtrain at C, ariſing from the upward reaction of the prop B; whereas the preſſure of gravity between C and B is almoſt in direct oppoſition to it, and muſt diminiſh it. We may however avoid the fluxionary calculus with ſafety by the conſideration of the centre of gravity, by ſuppoſing the weights of AC and BC to be collected at their reſpective centres of gravity; and the reſult of this computation will be the ſame as above: and we may uſe either method, although the weight is not uniformly diſtributed, provided only that we know in what manner it is diſtributed.

This inveſtigation is evidently of importance in the practice of the engineer and architect, informing them what ſupport is neceſſary in the different parts of their conſtructions. We conſidered ſome caſes of this kind in the article Roofs.

95 To form a joiſt which may have the ſame relative ſtrength in all its parts.

It is now eaſy to form a joiſt, ſo that it ſhall have the ſame relative ſtrength in all its parts.

I. To make it equally able in all its parts to carry a given weight laid on any point C taken at random or uniformly diffuſed over the whole length, the ſtrength of the ſection at the point C muſt be as $AC \times CB$. Therefore

1. If the ſides are parallel vertical planes, the ſquare of the depth (which is the only variable dimenſion) or CD^2, muſt be as $AC \times CB$, and the depths muſt be ordinates of an ellipſe,

2. If the tranſverſe ſections are ſimilar, we muſt make CD^3 as $AC \times CB$.

3. If the upper and under ſurfaces are parallel, the breadth muſt be as $AC \times CB$.

II. If the beam is neceſſarily loaded at ſome given point C, and we would have the beam equally able in all its parts to reſiſt the ſtrain ariſing from the weight at C, we muſt make the ſtrength of every tranſverſe ſection between C and either end as its diſtance from that end. Therefore

1. If the ſides are parallel vertical planes, we muſt make $CD^2 : EF^2 = AC : AE$.

2. If the ſections are ſimilar, then $CD^3 : EF^3 = AC : AE$.

3. If the upper and under ſurfaces are parallel, then, breadth at C : breadth at E = AC : AE. Strength of Materials.

96 The ſtrain and ſtrength of ſquare or circular plates of different extent, but of equal thickneſs, may be determined from the ſame principles.

The ſame principles enable us to determine the ſtrain and ſtrength of ſquare or circular plates, of different extent, but equal thickneſs. This may be comprehended in this general propoſition.

Similar plates of equal thickneſs ſupported all round will carry the ſame abſolute weight, uniformly diſtributed, or reſting on ſimilar points, whatever is their extent.

Suppoſe two ſimilar oblong plates of equal thickneſs, and let their lengths and breadths be L, *l*, and B, *b*. Let their ſtrength or momentum of coheſion be C, *c*, and the ſtrains from the weights W, *w*, be S, *s*.

Suppoſe the plates ſupported at the ends only, and reſiſting fracture tranſverſely. The ſtrains, being as the weights and lengths, are as WL and *w l*, but their coheſion are as the breadths; and ſince they are of equal relative ſtrength, we have $WL : wl = B : b$, and $WLb = wlB$ and $L : l = wB : Wb$: but ſince they are of ſimilar ſhapes $L : l = B : b$, and therefore $w = W$.

The ſame reaſoning holds again when they are alſo ſupported along the ſides, and therefore holds when they are ſupported all round (in which caſe the ſtrength is doubled).

And if the plates are of any other figure, ſuch as circles or ellipſes, we need only conceive ſimilar rectangles inſcribed in them. Theſe are ſupported all round by the continuity of the plates, and therefore will ſuſtain equal weights; and the ſame may be ſaid of the ſegments which lie without them, becauſe the ſtrengths of any ſimilar ſegments are equal, their lengths being as their breadths.

Therefore the thickneſs of the bottoms of veſſels holding heavy liquors or grains ſhould be as their diameters, and as the ſquare root of their depths jointly.

Alſo the weight which a ſquare plate will bear is to that which a bar of the ſame matter and thickneſs will bear as twice the length of the bar to its breadth.

97 The ſtrain of a beam ariſing from its own weight.

There is yet another modification of the ſtrain which tends to break a body tranſverſely, which is of very frequent occurrence, and in ſome caſes muſt be very carefully attended to, viz. the ſtrain ariſing from its own weight.

When a beam projects from a wall, every ſection is ſtrained by the weight of all that projects beyond it. This may be conſidered as all collected at its centre of gravity. Therefore the ſtrain on any ſection is in the joint ratio of the weight of what projects beyond it, and the diſtance of its centre of gravity from the ſection.

The determination of this ſtrain and of the ſtrength neceſſary for withſtanding it muſt be more complicated than the former, becauſe the form of the piece which reſults from this adjuſtment of ſtrain and ſtrength influences the ſtrain. The general principle muſt evidently be, that the ſtrength or momentum of coheſion of every ſection muſt be as the product of the weight beyond it multiplied by the diſtance of its centre of gravity. For example:

98 General principle reſpecting it.

Plate CCCCLXXXVI.

Suppoſe the beam DLA (fig. 18.) to project from the wall, and that its ſides are parallel vertical planes, ſo that the depth is the only variable dimenſion. Let $LB = x$ and $Bb = y$. The element BbcC is $= yx$. Let G be the centre of gravity of the part lying without Bb, and *g* be its diſtance from the extremity L. Then $x - g$ is the arm of the lever by which the ſtrain is excited in the ſection Bb. Let Bb or *y* be as ſome power *m* of LB; that is, let $y = x^m$. Then the contents of LBb is $\frac{x^{m+1}}{m+1}$. The momentum of gravity round a horizontal axis at L is $yx \times x = x^{m+1}x$, and the whole momentum round the axis is $\frac{x^{m+2}}{m+2}$. The diſtance of

Strength of Materials.

the centre of gravity from L is had by dividing this momentum by the whole weight, which is $\frac{x^{m+1}}{m+1}$. The quotient or g is $\frac{x \times \overline{m+1}}{m+2}$. And the distance of the centre of gravity from the section B b is $x - \frac{x \times m+1}{m+2}$, $= \frac{x \times \overline{m+2} - x \times \overline{m+1}}{m+2}$, $= \frac{x}{m+2}$. Therefore the strain on the section B b is had by multiplying $\frac{x^{m+1}}{m+1}$ by $\frac{x}{m+2}$. The product is $\frac{x^{m+2}}{m+2 \times m+1}$. This must be as the square of the depth, or as y^2. But y is as x^m, and y^2 as x^{2m}. Therefore we have $m+2 = 2m$, and $m = 2$; that is, the depth must be as the square of the distance from the extremity, and the curve L b A is a parabola touching the horizontal line in L.

99 A conoid equally able in every section to bear its own weight.

It is easy to see that a conoid formed by the rotation of this figure round D L will also be equally able in every section to bear its own weight.

We need not prosecute this farther. When the figure of the piece is given, there is no difficulty in finding the strain; and the circumstance of equal strength to resist the strain is chiefly a matter of curiosity.

100 The more a beam projects, the less able it is to bear its own weight.

It is evident, from what has been already said, that a projecting beam becomes less able to bear its own weight, as it projects farther. Whatever may be the strength of the section DA, the length may be such that it will break by its own weight. If we suppose two beams A and B of the same substance and similar shapes, that is, having their lengths and diameters in the same proportion; and farther suppose that the shorter can just bear its own weight; then the longer beam will not be able to do the same: For the strengths of the sections are as the cubes of the diameters, while the strains are as the biquadrates of the diameters; because the weights are as the cubes, and the levers by which these weights act in producing the strain are as the lengths or as the diameters.

101 Small bodies more able to withstand the strain produced by the weight of the machine than great bodies.

These considerations show us, that in all cases where the strain is affected by the weight of the parts of the machine or structure of any kind, the smaller bodies are more able to withstand it than the greater; and there seems to be bounds set by nature to the size of machines constructed of any given materials. Even when the weight of the parts of the machine is not taken into the account, we cannot enlarge them in the same proportion in all their parts. Thus a steam-engine cannot be doubled in all its parts, so as to be still efficient. The pressure on the piston is quadrupled. If the lift of the pump be also doubled in height while it is doubled in diameter, the load will be increased eight times, and will therefore exceed the power. The depth of lift, therefore, must remain unchanged; and in this case the machine will be of the same relative strength as before, independent of its own weight. For the beam being doubled in all its dimensions, its momentum of cohesion is eight times greater, which is again a balance for a quadruple load acting by a double lever.—But if we now consider the increase of the weight of the machine itself, which must be supported, and which must be put in motion by the intervention of its cohesion, we see that the large machine is weaker and less efficient than the small one.

There is a similar limit set by nature to the size of plants and animals formed of the same matter. The cohesion of an herb could not support it if it were increased to the size of a tree, nor could an oak support itself if 40 or 50 times bigger, nor could an animal of the make of a long-legged spider be increased to the size of a man; the articulations of its legs could not support it.

Strength of Materials.

102 Even small animals are remarkable for strength and agility.

Hence may be understood the prodigious superiority of the small animals both in strength and agility. A man by falling twice his own height may break his firmest bones. A mouse may fall 20 times its height without risk; and even the tender mite or wood-louse may fall unhurt from the top of a steeple. But their greatest superiority is in respect of nimbleness and agility. A flea can leap above 500 times its own length, while the strength of the human muscles could not raise the trunk from the ground on limbs of the same construction.

The angular motions of small animals (in which consists their nimbleness or agility) must be greater than those of large animals, supposing the force of the muscular fibre to be the same in both. For supposing them similar, the number of equal fibres will be as the square of their linear dimensions; and the levers by which they act are as their linear dimensions. The energy therefore of the moving force is the cube of these dimensions. But the momentum of inertia, or $\int p \cdot r^2$, is as the 4th power: Therefore the angular velocity of the greater animals is smaller. The number of strokes which a fly makes with its wings in a second is astonishingly great; yet, being voluntary, they are the effects of its agility.

We have hitherto confined our attention to the simplest form in which this transverse strain can be produced. This was quite sufficient for showing us the mechanism of nature by which the strain is resisted; and a very slight attention is sufficient for enabling us to reduce to this every other way in which the strain can be produced. We shall not take up the reader's time with the application of the same principles to other cases of this strain, but refer him to what has been said in the article Roofs. In that article we have shown the analogy between the strain on the section of a beam projecting from a wall and loaded at the extremity, and the strain on the same section of a beam simply resting on supports at the ends, and loaded at some intermediate point or points. The strain on the middle C of a beam AB (fig. 19.) so supported, arising from a weight laid on there, is the same with the strain which half that weight hanging at B would produce on the same section C if the other end of the beam were fixed in a wall. If therefore 1000 pounds hung on the end of the beam projecting 10 feet from a wall will just break it at the wall, it will require 4000 pounds on its middle to break the same beam resting on two props 10 feet asunder. We have also shown in that article the additional strength which will be given to this beam by extending both ends beyond the props, and there framing it firmly into other pillars or supports. We can hardly add any thing to what has been said in that article, except a few observations on the effect of the obliquity of the external force. We have hitherto supposed it to act in the direction BP (fig. 6.) perpendicular to the length of the beam. Suppose it to act in the direction B P', oblique to BA. In the article Roof we supposed the strain to be the same as if the force p acted at the distance AB', but still perpendicular to AB: so it is. But the strength of the section AA is not the same in both cases; for by the obliquity of the action the piece DCKA is pressed to the other. We are not sufficiently acquainted with the corpuscular forces to say precisely what will be the effect of the pressure arising from this obliquity; but we can clearly see, in general, that the point A, which in the instant of fracture is neither stretched nor compressed, must now be farther up, or nearer

103 Effects of the obliquity of the external force.

Strength of Materials.

to D; and therefore the number of particles which are exerting coheſive forces is ſmaller, and therefore the ſtrength is diminiſhed. Therefore, when we endeavour to proportion the ſtrength of a beam to the ſtrain ariſing from an external force acting obliquely, we make too liberal allowance by increaſing this external force in the ratio of AB to AB. We acknowledge our inability to aſſign the proper correction. But this circumſtance is of very great influence. In many machines, and many framings of carpentry, this oblique action of the ſtraining force is unavoidable; and the moſt enormous ſtrains to which materials are expoſed are generally of this kind. In the frames ſet up for carrying the ring-ſtones of arches, it is hardly poſſible to avoid them: for although the judicious engineer diſpoſes his beams ſo as to ſuſtain only preſſures in the direction of their lengths, tending either to cruſh them or to tear them aſunder, it frequently happens that, by the ſettling of the work, the pieces come to check and bear on each other tranſverſely, tending to break each other acroſs. This we have remarked upon in the article ROOFS, with reſpect to a truſs by Mr Price (ſee ROOFS, n° 40, 41, 45). Now when a croſs ſtrain is thus combined with an enormous preſſure in the direction of the length of the beam, it is in the utmoſt danger of ſnapping ſuddenly acroſs. This is one great cauſe of the carrying away of maſts. They are compreſſed in the direction of their length by the united force of the ſhrouds, and in this ſtate the tranſverſe action of the wind ſoon completes the fracture.

104 The ſtrain on columns.

When conſidering the compreſſing ſtrains to which materials are expoſed, we deferred the diſcuſſion of the ſtrain on columns, obſerving that it was not, in the caſes which uſually occur, a ſimple compreſſion, but was combined with a tranſverſe ſtrain, ariſing from the bending of the column. When the column ACB (fig. 20.) reſting on the ground at B, and loaded at top with a weight A, acting in the vertical direction AB, is bent into a curve ACB, ſo that the tangent at C is perpendicular to the horizon, its condition ſomewhat reſembles that of a beam firmly fixed between B and C, and ſtrongly pulled by the end A, ſo as to bend it between C and A. Although we cannot conceive how a force acting on a ſtraight column AB in the direction AB can bend it, we may ſuppoſe that the force acted firſt in the horizontal direction A *b*, till it was bent to this degree, and that the rope was then gradually removed from the direction A *b* to the direction AB, increaſing the force as much as is neceſſary for preſerving the ſame quantity of flexure.

105 Obſervations on Euler's theory of the ſtrength of columns.

The firſt author (we believe) who conſidered this important ſubject with ſcrupulous attention was the celebrated Euler, who publiſhed in the Berlin Memoirs for 1757 his Theory of the Strength of Columns. The general propoſition eſtabliſhed by this theory is, that the ſtrength of priſmatical columns is in the direct quadruplicate ratio of their diameters and the inverſe duplicate ratio of their lengths. He proſecuted this ſubject in the Peterſburg Commentaries for 1778, confirming his former theory. We do not find that any other author has beſtowed much attention on it, all ſeeming to acquieſce in the determinations of Euler, and to conſider the ſubject as of very great difficulty, requiring the application of the moſt refined mathematics. Muſchenbroek has compared the theory with experiment; but the compariſon has been very unſatisfactory, the difference from the theory being ſo enormous as to afford no argument for its juſtneſs. But the experiments do not contradict it, for they are ſo anomalous as to afford no concluſion or general rule whatever.

To ſay the truth, the theory can be conſidered in no other light than as a ſpecimen of ingenious and very artful algebraic analyſis. Euler was unqueſtionably the firſt analyſt in Europe for reſource and addreſs. He knew this, and enjoyed his ſuperiority, and without ſcruple admitted any phyſical aſſumptions which gave him an opportunity of diſplaying his ſkill. The inconſiſtency of his aſſumptions with the known laws of mechaniſm gave him no concern; and when his algebraic proceſſes led him to any concluſion which would make his readers ſtare, being contrary to all our uſual notions, he frankly owned the paradox, but went on in his analyſis, ſaying, "*Sed analyſi magis fidendum.*" Mr. Robins has given ſome very riſible inſtances of this confidence in his analyſis, or rather of his confidence in the indolent ſubmiſſion of his readers. Nay, ſo fond was he of this kind of amuſement, that after having publiſhed an untenable Theory of Light and Colours, he publiſhed ſeveral Memoirs, explaining the aberration of the heavenly bodies, and deducing ſome very wonderful conſequences, fully confirmed by experience, from the Newtonian principles, which were oppoſite and totally inconſiſtent with his own theory, merely becauſe the Newtonian theory gave him "*occaſionem analyſeos promovendæ.*" We are thus ſevere in our obſervations, becauſe his theory of the ſtrength of columns is one of the ſtrongeſt inſtances of this wanton kind of proceeding, and becauſe his followers in the Academy of St. Peterſburg, ſuch as Mr Fuſs, Lexill, and others, adopt his concluſions, and merely echo his words. Since the death of Dan. Bernoulli no member of that academy has controverted any thing advanced by their *Profeſſor ſublimis geometriæ*, to whom they had been indebted for their places and for all their knowledge, having been (moſt of them) his amanuenſes, employed by this wonderful man during his blindneſs to make his computations and carry on his algebraic inveſtigations. We are not a little ſupriſed to ſee Mr Emerſon, a conſiderable mathematician, and a man of very independent ſpirit, haſtily adopting the ſame theory, of which we doubt not but our readers will eaſily ſee the falſity.

Euler conſiders the column ACB as in a condition preciſely ſimilar to that of an elaſtic rod bent into the curve by a cord AB connecting its extremities.—In this he is not miſtaken.—But he then draws CD perpendicular to AB, and conſiders the ſtrain on the ſection C as equal to the momentum or mechanical energy of the weight A acting in the direction DB upon the lever κc D, moveable round the fulcrum *c*, and tending to tear aſunder the particles which cohere along the ſection *c* C κ. This is the ſame principle (as Euler admits) employed by James Bernoulli in his inveſtigation of the elaſtic curve ACB. Euler conſiders the ſtrain on the ſection $c \kappa$ as the ſame with what it would ſuſtain if the ſame power acted in the horizontal direction EF on a point E as far removed from C as the point D is. We reaſoned in the ſame manner (as has been obſerved) in the article ROOFS, where the obliquity of action was inconſiderable. But in the preſent caſe, this ſubſtitution leads to the greateſt miſtakes, and has rendered the whole of this theory falſe and uſeleſs. It would be juſt if the column were of materials which are incompreſſible. But it is evident, by what has been ſaid above, that by the compreſſion of the parts the real fulcrum of the lever ſhifts away from the point *c*, ſo much the more as the compreſſion is greater. In the great compreſſions of loaded columns, and the almoſt unmeaſurable compreſſions of the truſs beams in the centres of bridges, and other caſes of chief importance, the fulcrum is ſhifted far over towards κ, ſo that very few fibres reſiſt the fracture by their coheſion; and theſe few have a very feeble energy or momentum, on account of the ſhort arm of the lever by which they act. This is a moſt important conſideration in carpentry, yet makes no element of Euler's theory. The conſequence of this is, that a very ſmall degree of curvature is ſufficient to cauſe the co-

Strength of Materials.

lumn or ſtuff to ſnap in an inſtant, as is well known to every experienced carpenter. The experiment by Muſchenbroek, which Euler makes uſe of in order to obtain a meaſure of ſtrength in a particular inſtance, from which he might deduce all others by his theorem, is an inconteſtible proof of this. The force which broke the column is not the twentieth part of what is neceſſary for breaking it by acting at E in the direction EF. Euler takes no notice of this immenſe diſcrepancy, becauſe it muſt have cauſed him to abandon the ſpeculation with which he was then amuſing himſelf.

106 This theory falſe and uſeleſs.

The limits of this Work do not afford room to enter minutely upon the refutation of this theory; but we can eaſily ſhow its uſeleſſneſs, by its total inconſiſtency with common obſervation. It reſults legitimately from this theory, that if CD have no magnitude, the weight A can have no momentum, and the column cannot be broken—True,—it cannot be broken in this way, ſnapped by a tranſverſe fracture, if it do not bend; but we know very well that it can be cruſhed or crippled, and we ſee this frequently happen. This circumſtance or event does not enter into Euler's inveſtigation, and therefore the theory is imperfect at leaſt and uſeleſs. Had this crippling been introduced in the form of a phyſical aſſumption, every topic of reaſoning employed in the proceſs muſt have been laid aſide, as the intelligent reader will eaſily ſee. But the theory is not only imperfect, but falſe. The ordinary reader will be convinced of this by another legitimate conſequence of it. Fig. 20. n° 2. is the ſame with fig. 106 of *Emerſon's Mechanics*, where this ſubject is treated on Euler's principles, and repreſents a crooked piece of matter reſting on the ground at F, and loaded at A with a weight acting in the vertical direction AF. It reſults from Euler's theory that the ſtrains at *b*, B, D, E, &c. are as *bc*, BC, DI, EK, &c. Therefore the ſtrains at G and H are nothing; and this is aſſerted by Emerſon and Euler as a ſerious truth; and the piece may be thinned *ad infinitum* in theſe two places, or even cut through, without any diminution of its ſtrength. The abſurdity of this aſſertion ſtrikes at firſt hearing. Euler aſſerts the ſame thing with reſpect to a point of contrary flexure. Farther diſcuſſion is (we apprehend) needleſs.

107 Yet Euler's diſſertations deſerve a peruſal.

This theory muſt therefore be given up. Yet theſe diſſertations of Euler in the Peterſburg Commentaries deſerve a peruſal, both as very ingenious ſpecimens of analyſis, and becauſe they contain maxims of practice which are important. Although they give an erroneous meaſure of the comparative ſtrength of columns, they ſhow the immenſe importance of preventing all bendings, and point out with accuracy where the tendencies to bend are greateſt, and how this may be prevented by very ſmall forces, and what a prodigious acceſſion of force this gives the column. There is a valuable paper in the ſame volume by Fuſs *on the Strains on framed Carpentry*, which may alſo be read with advantage.

108 A new theory cannot be ſubſtituted in place of Euler's, till many experiments be made.

It will now be aſked, What ſhall be ſubſtituted in place of this erroneous theory? What is the true proportion of the ſtrength of columns? We acknowledge our inability to give a ſatisfactory anſwer. Such can be obtained only by a previous knowledge of the proportion between the extenſions and compreſſions produced by equal forces, by the knowledge of the abſolute compreſſions producible by a given force, and by a knowledge of the degree of that derangement of parts which is termed crippling. Theſe circumſtances are but imperfectly known to us, and there lies before us a wide field of experimental inquiry. Fortunately the force requiſite for crippling a beam is prodigious, and a very ſmall lateral ſupport is ſufficient to prevent that bending which puts the beam in imminent danger. A judicious engineer will always employ tranſverſe bridles, as they are called, to ſtay the middle of long beams, which are employed as pillars, ſtrutts, or truſs beams, and are expoſed, by their poſition, to enormous preſſures in the direction of their lengths. Such ſtays may be obſerved, diſpoſed with great judgment and economy, in the centries employed by Mr Perronet in the erection of his great ſtone arches. He was obliged to correct this omiſſion made by his ingenious predeceſſor in the beautiful centres of the bridge of Orleans, which we have no heſitation in affirming to be the fineſt piece of carpentry in the world.

Strength of Materials.

It only remains on this head to compare theſe theoretical deductions with experiment.

Experiments on the tranſverſe ſtrength of bodies are eaſily made, and accordingly are very numerous, eſpecially thoſe made on timber, which is the caſe moſt common and moſt intereſting. But in this great number of experiments there are very few from which we can draw much practical information. The experiments have in general been made on ſuch ſmall ſcantlings, that the unavoidable natural inequalities bear too great a proportion to the ſtrength of the whole piece. Accordingly, when we compare the experiments of different authors, we find them differ enormouſly, and even the experiments by the ſame author are very anomalous.

109 Table of experiments made by Belidor.

The completeſt ſeries that we have yet ſeen is that detailed by Belidor in his *Science des Ingenieurs*. They are contained in the following table. The pieces were found, even-grained oak. The column *b* contains the breadths of the pieces in inches; the column *d* contains their depths; the column *l* contains their lengths; column *p* contains the weights (in pounds) which broke them when hung on their middles; and *m* is the column of averages or mediums.

N	*b*	*d*	*l*	*p*	*m*	
1	1	1	18	400 415 405	406	The ends lying looſe.
2	1	1	18	600 600 624	608	The ends firmly fixed.
3	2	1	18	810 795 812	805	Looſe.

6	1	1	36	285 280 285	283	Fixed.
7	2	2	36	1550 1620 1585	1585	Looſe.
8	1⅔	2⅓	36	1665 1675 1640	1660	Looſe.

By

Strength of Materials.

By comparing Experiments 1ſt and 3d, the ſtrength appears proportional to the breadth.

110 Corollaries deduced from them.

Experiments 3d and 4th ſhew the ſtrength proportional to the ſquare of the depth.

Experiments 1ſt and 5th ſhew the ſtrength nearly in the inverſe proportions of the lengths, but with a ſenſible deficiency in the longer pieces.

Experiments 5th and 7th ſhew the ſtrengths proportional to the breadths and the ſquare of the depth.

Experiments 1ſt and 7th ſhew the ſame thing, compounded with the inverſe proportion of the length: the deficiency relative to the length is not ſo remarkable here.

Experiments 1ſt and 2d and experiments 5th and 6th ſhew the increaſe of ſtrength, by faſtening the ends, to be in the proportion of 2 to 3. The theory gives the proportion of 2 to 4. But a difference in the manner of fixing may produce this deviation from the theory, which only ſuppoſed them to be held down at places beyond the props, as when a joiſt is held in the walls, and alſo reſts on two pillars between the walls. (See what is ſaid on this ſubject in the article ROOF, § 19.); where note, that there is a miſtake, when it is ſaid that a beam ſupported at both ends and loaded in the middle will carry twice as much as if one end were fixed in the wall and the weight ſuſpended at the other end. The reaſoning employed there ſhows that it will carry four times as much.

The chief ſource of irregularity in ſuch experiments is the fibrous, or rather plated texture of timber. It conſiſts of annual additions, whoſe coheſion with each other is vaſtly weaker than that of their own fibres. Let fig. 21. repreſent the ſection of a tree, and ABCD, *a b c d* the ſection of two battens that are to be cut out of it for experiment, and let AD and *a d* be the depths, and DC, *d c* the breadths. The batten ABCD will be the ſtrongeſt, for the ſame reaſon that an aſſemblage of planks ſet edgewiſe will form a ſtronger joiſt than planks laid above each other like the plates of a coach ſpring. Mr Buffon found by many trials that the ſtrength of ABCD was to that of *a b c d* (in oak) nearly as 8 to 7. The authors of the different experiments were not careful that their battens had their plates all diſpoſed ſimilarly with reſpect to the ſtrain. But even with this precaution they would not have afforded ſure grounds of computation for large works; for great beams occupy much, if not the whole, of the ſection of the tree; and from this it has happened that their ſtrength is leſs than in proportion to that of a ſmall lath or batten. In ſhort, we can truſt no experiments but ſuch as have been made on large beams. Theſe muſt be very rare, for they are moſt expenſive and laborious, and exceed the abilities of moſt of thoſe who are diſpoſed to ſtudy this matter.

But we are not wholly without ſuch authority. Mr Buffon and Mr Du Hamel, two of the firſt philoſophers and mechanicians of the age, were directed by government to make experiments on this ſubject, and were ſupplied with ample funds and apparatus. The relation of their experiments is to be found in the Memoirs of the French Academy for 1740, 1741, 1742, 1768; as alſo in Du Hamel's valuable performances *ſur l'Exploitation des Arbres, et ſur la Conſervation et le Tranſport de Bois*. We earneſtly recommend theſe diſſertations to the peruſal of our readers, as containing much uſeful information relative to the ſtrength of timber, and the beſt methods of employing it. We ſhall here give an abſtract of Mr Buffon's experiments.

111 Mr Buffon's experiments on bars of found oak.

He relates a great number which he had proſecuted during two years on ſmall battens. He found that the odds of a ſingle layer, or part of a layer, more or leſs, or even a different diſpoſition of them, had ſuch influence that he was obliged to abandon this method, and to have recourſe to the largeſt beams that he was able to break. The following table exhibits one ſeries of experiments on bars of found oak, clear of knots, and four inches ſquare. This is a ſpecimen of all the reſt.

Column 1ſt is the length of the bar in feet clear between the ſupports.

Column 2d is the weight of the bar (the 2d day after it was felled) in pounds. Two bars were tried of each length. Each of the firſt three pairs conſiſted of two cuts of the ſame tree. The one next the root was always found the heavieſt, ſtiffeſt, and ſtrongeſt. Indeed Mr Buffon ſays that this was invariably true, that the heavieſt was always the ſtrongeſt; and he recommends it as a certain (or ſure) rule for the choice of timber. He finds that this is always the caſe when the timber has grown vigorouſly, forming very thick annual layers. But he alſo obſerves that this is only during the advances of the tree to maturity; for the ſtrength of the different circles approaches gradually to equality during the tree's healthy growth, and then it decays in theſe parts in a contrary order. Our tool-makers aſſert the ſame thing with reſpect to beech: yet a contrary opinion is very prevalent; and wood with a fine, that is, a ſmall grain, is frequently preferred. Perhaps no perſon has ever made the trial with ſuch minuteneſs as Mr Buffon, and we think that much deference is due to his opinion.

Column 3d is the number of pounds neceſſary for breaking the tree in the courſe of a few minutes.

Column 4th is the inches which it bent down before breaking.

Column 5th is the time at which it broke.

1	2	3	4	5
7	60	5350	3,5	29
	56	5275	4,5	22
8	68	4600	3,75	15
	63	4500	4,7	13
9	77	4100	4,85	14
	71	3950	5,5	12
10	84	3625	5,83	15
	82	3600	6,5	15
12	100	3050	7,	
	98	2925	8,	

The experiments on other ſizes were made in the ſame way. A pair at leaſt of each length and ſize was taken. The mean reſults are contained in the following table. The beams were all ſquare, and their ſizes in inches are placed at the head of the columns, and their lengths in feet are in the firſt column.

Strength of Materials.

	4	5	6	7	8	A
7	5312	11525	18950	32200	47649	11525

22		2975				3667
24		2162				3362
28		1775				2881

Mr Buffon had found by numerous trials that oak-timber loſt much of its ſtrength in the courſe of drying or ſeaſoning; and therefore, in order to ſecure uniformity, his trees were all felled in the ſame ſeaſon of the year, were ſquared the day after, and tried the third day. Trying them in this green ſtate gave him an opportunity of obſerving a very curious and unaccountable phenomenon. When the weights were laid briſkly on, nearly ſufficient to break the log, a very ſenſible ſmoke was obſerved to iſſue from the two ends with a ſharp hiſſing noiſe. This continued all the while the tree was bending and cracking. This ſhows that the log is affected or ſtrained through its whole length; indeed this muſt be inferred from its bending through its whole length. It alſo ſhows us the great effects of the compreſſion. It is a pity Mr Buffon did not take notice whether this ſmoke iſſued from the upper or compreſſed half of the ſection only, or whether it came from the whole.

112 Obſervations on Mr Buffon's experiments.

We muſt now make ſome obſervations on theſe experiments, in order to compare them with the theory which we have endeavoured to eſtabliſh.

Mr Buffon conſiders the experiments with the 5-inch bars as the ſtandard of compariſon, having both extended theſe to greater lengths, and having tried more pieces of each length.

Our theory determines the relative ſtrength of bars of the ſame ſection to be inverſely as their lengths. But (if we except the five experiments in the firſt column) we find a very great deviation from this rule. Thus the 5-inch bar of 28 feet long ſhould have half the ſtrength of that of 14 feet, or 2650; whereas it is but 1775. The bar of 14 feet ſhould have half the ſtrength of that of 7 feet, or 5762; whereas it is but 5300. In like manner, the fourth of 11525 is 2881; but the real ſtrength of the 28 feet bar is 1775. We have added a column A, which exhibits the ſtrength which each of the 5-inch bars ought to have by the theory. This deviation is moſt diſtinctly ſeen in fig. 22. where BK is the ſcale of lengths, B being at the point 7 of the ſcale and K at 28. The ordinate CB is = 11525, and the other ordinates DE, GK, &c. are reſpectively = $\frac{7\,CB}{Length}$. The lines DF, GH, &c. are made = 4350, 1775, &c. expreſſing the ſtrengths given by experiment. The 10-feet bar and the 24-feet bar are remarkably anomalous. But all are deficient, and the defect has an evident progreſſion from the firſt to the laſt. The ſame thing may be ſhown of the other columns, and even of the firſt, though it is very ſmall in that column. It may alſo be obſerved in the experiments of Belidor, and in all that we have ſeen. We cannot doubt therefore of its being a law of nature, depending on the true principles of coheſion and the laws of mechanics.

But it is very puzzling, and we cannot pretend to give a ſatisfactory explanation of the difficulty. The only effect which we can conceive the length of a beam to have, is to increaſe the ſtrain at the ſection of fracture by employing the intervening beam as a lever. But we do not diſtinctly ſee what change this can produce in the mode of action of the fibres in this ſection, ſo as either to change their coheſion or the place of its centre of effort: yet ſomething of this kind muſt happen.

Strength of Material.

We ſee indeed ſome circumſtances which muſt contribute to make a ſmaller weight ſufficient, in Mr Buffon's experiments, to break a long beam than in the exact inverſe proportion of its length.

In the firſt place, the weight of the beam itſelf augments the ſtrain as much as if half of it were added in form of a weight. Mr Buffon has given the weights of every beam on which he made experiments, which is very nearly 74 pounds *per* cubic foot. But they are much too ſmall to account for the deviation from the theory. The half weights of the 5-inch beams of 7, 14, and 28 feet length are only 45, 92, and 182 pounds; which makes the real ſtrains in the experiments 11560, 5390, and 1956; which are far from having the proportions of 4, 2, and 1.

Buffon ſays that healthy trees are univerſally ſtrongeſt at the root end; therefore, when we uſe a longer beam, its middle point, where it is broken in the experiment, is in a weaker part of the tree. But the trials of the 4-inch beams ſhow that the difference from this cauſe is almoſt inſenſible.

The length muſt have ſome mechanical influence which the theory we have adopted has not yet explained. It may not however be inadequate to the taſk. The very ingenious inveſtigation of the elaſtic curve by James Bernoulli and other celebrated mathematicians is perhaps as refined an application of mathematical analyſis as we know. Yet in this inveſtigation it was neceſſary, in order to avoid almoſt inſuperable difficulties, to take the ſimpleſt poſſible caſe, viz. where the thickneſs is exceedingly ſmall in compariſon with the length. If the thickneſs be conſiderable, the quantities neglected in the calculus are too great to permit the concluſion to be accurate, or very nearly ſo. Without being able to define the form into which an elaſtic body of conſiderable thickneſs will be bent, we can ſay with confidence, that in an extreme caſe, where the compreſſion in the concave ſide is very great, the curvature differs conſiderably from the Bernoullian curve. But as our inveſtigation is incomplete and very long, we do not offer it to the reader. The following more familiar conſiderations will, we apprehend, render it highly probable that the relative ſtrength of beams decreaſes faſter than in the inverſe ratio of their length. The curious obſervation by Mr Buffon of the vapour which iſſued with a hiſſing noiſe from the ends of a beam of green oak, while it was breaking by the load on its middle, ſhows that the whole length of the piece was affected: indeed it muſt be, ſince it is bent throughout. We have ſhown above, that a certain definite curvature of a beam of a given form is always accompanied by rupture. Now ſuppoſe the beam A of 10 feet long, and the beam B of 20 feet long, bent to the ſame degree, at the place of their fixture in the wall; the weight which hangs on A is nearly double of that which muſt hang on B. The form of any portion, ſuppoſe 5 feet, of theſe two beams, immediately adjoining to the wall is conſiderably different. At the diſtance of 5 feet the curvature of A is $\frac{1}{2}$ of its curvature at the wall. The curvature of B in the correſponding point is $\frac{3}{4}$ths of the ſame curvature at the wall. Through the whole of the intermediate 5 feet, therefore, the curvature of B is greater than that of A. This muſt make it weaker throughout. It muſt occaſion the fibres to ſlide more on each other (that it may acquire *this* greater curvature), and thus affect their lateral union;

113 Probable that the relative ſtrength of beams decreaſes faſter than in the inverſe ratio of their length.

Strength of Materials.

union; and therefore those which are stronger will not assist their weaker neighbours. To this we must add, that in the shorter beams the force with which the fibres are pressed laterally on each other is double. This must impede the mutual sliding of the fibres which we mentioned a little ago; nay, this lateral compression may change the law of longitudinal cohesion (as will readily appear to the reader who is acquainted with Boscovich's doctrines), and increase the strength of the very surface of fracture, in the same way (however inexplicable) as it does in metals when they are hammered or drawn into wire.

The reader must judge how far these remarks are worthy of his attention. The engineer will carefully keep in mind the important fact, that a beam of quadruple length, instead of having $\frac{1}{4}$th of the strength, has only about $\frac{1}{6}$th; and the philosopher should endeavour to discover the cause of this diminution, that he may give the artist a more accurate rule of computation.

114 We cannot discover the precise relation between the curvature and the momentum of cohesion.

Our ignorance of the law by which the cohesion of the particles changes by a change of distance, hinders us from discovering the precise relation between the curvature and the momentum of cohesion; and all we can do is to multiply experiments, upon which we may establish some *empirical* rules for calculating the strength of solids. Those from which we must reason at present are too few and too anomalous to be the foundation of such an empirical formula. We may, however, observe, that Mr Buffon's experiments give us considerable assistance in this particular: For if to each of the numbers of the column for the 5 inch beams, corrected by adding half the weight of the beam, we add the constant number 1245, we shall have a set of numbers which are very nearly reciprocals of the lengths. Let 1245 be called c, and let the weight which is known by experiment to be necessary for breaking the 5-inch beam of the length a be called P. We shall have $\frac{\overline{P+c} \times a}{l} - c = p$. Thus the weight necessary for breaking the 7-foot bar is 11560. This added to 1245, and the sum multiplied by 7, gives $\overline{P+c} \times a = 89635$. Let l be 18; then $\frac{89635}{18} - 1245 = 3725, = p$, which differs not more than $\frac{1}{70}$th from what experiment gives us. This rule holds equally well in all the other lengths except the 10 and 24 foot beams, which are very anomalous. Such a formula is abundantly exact for practice, and will answer through a much greater variety of length, though it cannot be admitted as a true one; because, in a certain very great length, the strength will be nothing. For other sizes the constant number must change in the proportion of d^3, or perhaps of f.

115 Relation between the strength and the square of the depth of the section.

The next comparison which we have to make with the theory is the relation between the strength and the square of the depth of the section. This is made by comparing with each other the numbers in any horizontal line of the table. In making this comparison we find the numbers of the five-inch bars uniformly greater than the rest. We imagine that there is something peculiar to these bars: They are in general heavier than in the proportion of their section, but not so much so as to account for all their superiority. We imagine that this set of experiments, intended as a standard for the rest, has been made at one time, and that the season has had a considerable influence. The fact however is, that if this column be kept out, or uniformly diminished about $\frac{1}{70}$th in their strength, the different sizes will deviate very little from the ratio of the square of the depth, as determined by theory. There is however a small deficiency in the bigger beams.

Strength of Materials.

We have been thus anxious in the examination of these experiments, because they are the only ones which have been related in sufficient detail, and made on a proper scale for giving us data from which we can deduce confidential maxims for practice. They are so troublesome and expensive that we have little hopes of seeing their number greatly increased; yet surely the navy board would do an unspeakable service to the public by appropriating a fund for such experiments under the management of some man of science.

116 Proportion between the absolute cohesion and the relative strength.

There remains another comparison which is of chief importance, namely, the proportion between the ABSOLUTE COHESION and the RELATIVE STRENGTH. It may be guessed, from the very nature of the thing, that this must be very uncertain. Experiments on the absolute strength must be confined to very small pieces, by reason of the very great forces which are required for tearing them asunder. The values therefore deduced from them must be subject to great inequalities. Unfortunately we have got no detail of any experiments; all that we have to depend on is two passages of Muschenbroek's *Essais de Physique*; in one of which he says that a piece of sound oak $\frac{27}{100}$ths of an inch square is torn asunder by 1150 pounds; and in the other, that an oak plank 12 inches broad and 1 thick will just suspend 189163 pounds. These give for the cohesion of an inch square 15,755 and 15,763 pounds. Bouguer, in his *Traité du Navire*, says that it is very well known that a rod of sound oak $\frac{1}{4}$th of an inch square will be torn asunder by 1000 pounds. This gives 16000 for the cohesion of a square inch. We shall take this as a round number, easily used in our computations. Let us compare this with Mr Buffon's trials of beams four inches square.

The absolute cohesion of this section is 16,000 × 16 = 256,000. Did every fibre exert its whole force in the instant of fracture, the momentum of cohesion would be the same as if it had all acted at the centre of gravity of the section at 2 inches from the axis of fracture, and is therefore 512000. The 4-inch beam, 7 feet long, was broken by 5312 pounds hung on its middle. The half of this, or 2656 pounds, would have broken it, if suspended at its extremity, projecting $3\frac{1}{2}$ feet or 42 inches from a wall. The momentum of this strain is therefore 2656 × 42, = 111552. Now this is in equilibrio with the actual momentum of cohesion, which is therefore 111552, instead of 512000. The strength is therefore diminished in the proportion of 512000 to 111552, or very nearly of 4,59 to 1.

As we are quite uncertain as to the place of the centre of effort, it is needless to consider the full cohesion as acting at the centre of gravity, and producing the momentum 512,000; and we may convert the whole into a simple multiplier m of the length, and say, *as m times the length is to the depth, so is the absolute cohesion of the section to the relative strength.* Therefore let the absolute cohesion of a square inch be called f, the breadth b, the depth d, and the length l (all in inches), the relative strength, or the external force p, which balances it, is $\frac{fbd^2}{9,18l}$, or in round numbers $\frac{fbd^2}{9l}$; for $m = 2 \times 4,59$.

This great diminution of strength cannot be wholly accounted for by the inequality of the cohesive forces exerted in the instant of fracture; for in this case we know that the centre of effort is at $\frac{1}{3}$d of the height in a rectangular section (because the forces really exerted are as the extensions of the fibres). The relative strength would be $\frac{fbd^2}{3l}$, and p would have been 8127 instead of 2656.

We must ascribe this diminution (which is three times greater than that produced by the inequality of the cohe-

sive

Strength of Materials.

five forces) to the compreſſion of the under part of the beam; and we muſt endeavour to explain in what manner this compreſſion produces an effect which ſeems ſo little explicable by ſuch means.

As we have repeatedly obſerved, it is a matter of nearly univerſal experience that the forces *actually* exerted by the particles of bodies, when ſtretched or compreſſed, are very nearly in the proportion of the diſtances to which the particles are drawn from their natural poſitions. Now, altho' we are certain that, in enormous compreſſions, the forces increaſe faſter than in this proportion, this makes no ſenſible change in the preſent queſtion, becauſe the body is broken before the compreſſions have gone ſo far; nay, we imagine that the compreſſed parts are crippled in moſt caſes even before the extended parts are torn aſunder. Muſchenbroek aſſerts this with great confidence with reſpect to oak, on the authority of his own experiments. He ſays, that although oak will ſuſpend half as much again as fir, it will not ſupport, as a pillar, two thirds of the load which fir will ſupport in that form.

We imagine therefore that the mechaniſm in the *preſent* caſe is nearly as follows:

Let the beam DCK Δ (fig. 23.) be loaded at its extremity with the weight P, acting in the direction KP perpendicular to DC. Let D Δ be the ſection of fracture. Let DA be about $\frac{1}{3}$d of D Δ. A will be the particle or fibre which is neither extended nor compreſſed. Make $\Delta\delta : Dd = DA : A\Delta$. The triangles DA *d*, Δ A δ, will repreſent the accumulated attracting and repelling forces. Make AI and A $i = \frac{1}{3}$DA and $\frac{1}{3}$ Δ A. The point I will be that to which the full coheſion D *d* or *f* of the particles in AD muſt be applied, ſo as to produce the ſame momentum which the variable forces at I, D, &c. really produce at their ſeveral points of application. In like manner, *i* is the centre of ſimilar effort of the repulſive forces excited by the compreſſion between A and Δ, and it is the real fulcrum of a bended lever I *i* K, by which, the whole effect is produced. The effect is the ſame as if the full coheſion of the ſtretched fibres in AD were accumulated in I, and the full repulſion of all the compreſſed fibres in AΔ were accumulated in *i*. The forces which are balanced in the operation are the weight P, acting by the arm *k i*, and the full coheſion of AD acting by the arm I *i*. The forces exerted by the compreſſed fibres between A and Δ only ſerve to give ſupport to the lever, that it may exert its ſtrain.

We imagine that this does not differ much from the real procedure of nature. The poſition of the point A may be different from what we have deduced from Mr Buffon's experiments, compared with Muſchenbroek's value of the abſolute coheſion of a ſquare inch. If this laſt ſhould be only 12000, DA muſt be greater than we have here made it, in the proportion of 12000 to 16000. For I *i* muſt ſtill be made = $\frac{1}{3}$ A Δ, ſuppoſing the forces to be proportional to the extenſions and compreſſions. There can be no doubt that a part only of the coheſion of D Δ operates in reſiſting the fracture in all ſubſtances which have any compreſſibility; and it is confirmed by the experiments of Mr Du Hamel on willow, and the inferences are by no means confined to that ſpecies of timber. We ſay therefore, that when the beam is broken, the coheſion of AD alone is exerted, and that each fibre exerts a force proportional to its extenſion; and the accumulated momentum is the ſame as if the full coheſion of AD were acting by the lever I *i* = $\frac{1}{3}$d of D Δ.

It may be ſaid, that if only $\frac{1}{3}$ of the coheſion of oak be exerted, it may be cut $\frac{1}{3}$ds through without weakening it. But this cannot be, becauſe the coheſion of the whole is employed in preventing the lateral ſlide ſo often mentioned. We have no experiments to determine that it *may not* be cut through $\frac{1}{3}$d without loſs of its ſtrength.

Strength of Materials.

This muſt not be conſidered as a ſubject of mere ſpeculative curioſity: It is intimately connected with all the practical uſes which we can make of this knowledge; for it is almoſt the only way that we can learn the compreſſibility of timber. Experiments on the direct coheſion are indeed difficult, and exceedingly expenſive if we attempt them in large pieces. But experiments on compreſſion are almoſt impracticable. The moſt inſtructive experiments would be, firſt to eſtabliſh, by a great number of trials, the tranſverſe force of a modern batten; and then to make a great number of trials of the diminution of its ſtrength, by cutting it through on the concave ſide. This would very nearly give us the proportion of the coheſion which really operates in reſiſting fractures. Thus if it be found that one-half of the beam may be cut on the under ſide without diminution of its ſtrength (taking care to drive in a ſlice of harder wood), we may conclude that the point A is at the middle, or ſomewhat above it.

Much lies before the curious mechanician, and we are as yet very far from a ſcientific knowledge of the ſtrength of timber.

117 A uſeful practical rule may be deduced from Mr Buffon's experiments.

In the mean time, we may derive from theſe experiments of Buffon a very uſeful practical rule, without relying on any value of the abſolute coheſion of oak. We ſee that the ſtrength is nearly as the breadth, as the ſquare of the depth, and as the inverſe of the length. It is moſt convenient to meaſure the breadth and depth of the beam in inches, and its length in feet. Since, then, a beam four inches ſquare and ſeven feet between the ſupports is broken by 5312 pounds, we muſt conclude that a batten one inch ſquare and one foot between the ſupports will be broken by 581 pounds. Then the ſtrength of any other beam of oak, or the weight which will juſt break it when hung on its middle, is $581\frac{d^2}{l}$.

But we have ſeen that there is a very conſiderable deviation from the inverſe proportion of the lengths, and we muſt endeavour to accommodate our rule to this deviation. We found, that by adding 1245 to each of the ordinates or numbers in the column of the five-inch bars, we had a ſet of numbers very nearly reciprocal of the lengths; and if we make a ſimilar addition to the other columns in the proportion of the cubes of the fixes, we have nearly the ſame reſult. The greateſt error (except in the caſe of experiments which are very irregular) does not exceed $\frac{1}{17}$th of the whole. Therefore, for a radical number, add to the 5312 the number 640, which is to 1245 very nearly as 4^3 to 5^3. This gives 5952. The 64th of this is 93, which correſponds to a bar of one inch ſquare and ſeven feet long. Therefore 93×7 will be the reciprocal correſponding to a bar of one foot. This is 651. Take from this the preſent empirical correction, which is $\frac{b\,40}{b\,4}$, or 10, and there remains 641 for the ſtrength of the bar. This gives us for a general rule $p = 651\frac{b\,d^2}{l} - 10\,b\,d^2$.

Example. Required the weight neceſſary to break an oak beam eight inches ſquare and 20 feet between the props, $p = 651 \times \frac{8\times 8^2}{20} - 10 \times 8 \times 8^2$. This is 11545, whereas the experiment gives 11487. The error is very ſmall indeed. The rule is moſt deficient in compariſon with the five-inch bars, which we have already ſaid appear ſtronger than the reſt.

Strength of Materials.

The following process is easily remembered by such as are not algebraists.

Multiply the breadth in inches twice by the depth, and call this product f. Multiply f by 651, and divide by the length in feet. From the quotient take 10 times f. The remainder is the number of pounds which will break the beam.

We are not sufficiently sensible of our principles to be confident that the correction 10 f should be in the proportion of the section, although we think it most probable. It is quite empirical, founded on Buffon's experiments. Therefore the safe way of using this rule is to suppose the beam square, by increasing or diminishing its breadth till equal to the depth. Then find the strength by this rule, and diminish or increase it for the change which has been made in its breadth. Thus, there can be no doubt that the strength of the beam given as an example is double of that of a beam of the same depth and half the breadth.

The reader cannot but observe that all this calculation relates to the very greatest weight which a beam will bear for a very few minutes. Mr Buffon uniformly found that two-thirds of this weight sensibly impaired its strength, and frequently broke it at the end of two or three months. One-half of this weight brought the beam to a certain bend, which did not increase after the first minute or two, and may be borne by the beam for any length of time. But the beam contracted a bend, of which it did not recover any considerable portion. One-third seemed to have no permanent effect on the beam; but it recovered its rectilineal shape completely, even after having been loaded several months, provided that the timber was seasoned when first loaded; that is to say, one-third of the weight which would quickly break a seasoned beam, or one-fourth of what would break one just felled, may lie on it for ever without giving the beam a set.

We have no detail of experiments on the strength of other kinds of timber: only Mr Buffon says, that fir has about $\frac{6}{10}$ths of the strength of oak; Mr Parent makes it $\frac{5}{12}$ths; Emerson, $\frac{2}{3}$ds, &c.

We have been thus minute in our examination of the mechanism of this transverse strain, because it is the greatest to which the parts of our machines are exposed. We wish to impress on the minds of artists the necessity of avoiding this as much as possible. They are improving in this respect, as may be seen by comparing the centres on which stone arches of great span are now turned with those of former times. They were formerly a load of mere joists resting on a multitude of posts, which obstructed the navigation, and were frequently losing their shape by some of the posts sinking into the ground. Now they are more generally trusses, where the beams abutt on each other, and are relieved from transverse strains. But many performances of eminent artists are still very injudiciously exposed to cross strains. We may instance one which is considered as a fine work, viz. the bridge at Walton on Thames. Here every beam of the great arch is a joist, and it hangs together by framing. The finest piece of carpentry that we have seen is the centre employed in turning the arches of the bridge at Orleans, described by Perronet. In the whole there is not one cross strain. The beam, too, of Hornblower's steam-engine, described in that article, is very scientifically constructed.

118 Strain produced by twisting.

IV. The last species of strain which we are to examine is that produced by twisting. This takes place in all axles which connect the working parts of machines.

Although we cannot pretend to have a very distinct conception of that modification of the cohesion of a body by which it resists this kind of strain, we can have no doubt that, when all the particles act alike, the resistance must be proportional to the number. Therefore if we suppose that two parts ABCD, ABFE (fig. 24.), of the body EFCD to be of insuperable strength, but cohering more weakly in the common surface AB and that one part ABCD is pushed laterally in the direction AB, there can be no doubt that it will yield only there, and that the resistance will be proportional to the surface.

Strength of Materials.

119 The resistance must be proportional to the number of particles.

In like manner, we can conceive a thin cylindrical tube, of which KAH (fig. 25.) is the section, as cohering more weakly in that section than any where else. Suppose it to be grasped in both hands, and the two parts twisted round the axis in opposite directions, as we would twist the two joints of a flute, it is plain that it will first fail in this section, which is the circumference of a circle, and the particles of the two parts which are contiguous to this circumference will be drawn from each other laterally. The total resistance will be as the number of equally resisting particles, that is, as the circumference (for the tube being supposed very thin, there can be no sensible difference between the dilatation of the external and internal particles). We can now suppose another tube within this, and a third within the second, and so on till we reach the centre. If the particles of each ring exerted the same force (by suffering the same dilatation in the direction of the circumference), the resistance of each ring of the section would be as its circumference and its breadth (supposed indefinitely small), and the whole resistance would be as the surface; and this would represent the resistance of a solid cylinder. But when a cylinder is twisted in this manner by an external force applied to its circumference, the external parts will suffer a greater circular extension than the internal; and it appears that this extension (like the extension of a beam strained transversely) will be proportional to the distance of the particles from the axis. We cannot say that this is demonstrable, but we can assign no proportion that is more probable. This being the case, the forces simultaneously exerted by each particle will be as its distance from the axis. Therefore the whole force exerted by each ring will be as the square of its radius, and the accumulated force actually exerted will be as the cube of its radius; that is, the accumulated force exerted by the whole cylinder, whose radius is CA, is to the accumulated force exerted *at the same time* by the part whose radius is CE, as CA^3 to CE^3.

The whole cohesion now exerted is just two-thirds of what it would be if all the particles were exerting the same attractive forces which are just now exerted by the particles in the external circumference. This is plain to any person in the least familiar with the fluxionary calculus. But such as are not may easily see it in this way.

Let the rectangle A C c a be set upright on the surface of the circle along the line CA, and revolve round the axis C c. It will generate a cylinder whose height is C c or A a, and having the circle KAH for its base. If the diagonal C a be supposed also to revolve, it is plain that the triangle c C a will generate a cone of the same height, and having for its base the circle described by the revolution of c a, and the point C for its apex. The cylindrical surface generated by A a will express the whole cohesion exerted by the circumference AHK, and the cylindrical surface generated by E e will represent the cohesion exerted by the circumference ELM, and the solid generated by the triangle C A a will represent the cohesion exerted by the whole circle AHK, and the cylinder generated by the rectangle A C c a will represent the cohesion exerted by the same surface if each particle had suffered the extension A a.

Now it is plain, in the first place, that the solid generated by the triangle e E C is to that generated by a A C as EC^3 to AC^3. In the next place, the solid generated by

Strength of Materials.

a AC is two-thirds of the cylinder, becauſe the cone generated by c C a is one-third of it.

We may now ſuppoſe the cylinder twiſted till the particles in the external circumference loſe their coheſion. There can be no doubt that it will now be wrenched aſunder, all the inner circles yielding in ſucceſſion. Thus we obtain one uſeful information, viz. that a body of homogeneous texture reſiſts a *ſimple twiſt* with two-thirds of the force with which it reſiſts an attempt to force one part laterally from the other, or with one-third part of the force which will cut it aſunder by a ſquare-edged tool. For to drive a ſquare-edged tool through a piece of lead, for inſtance, is the ſame as forcing a piece of the lead as thick as the tool laterally away from the two pieces on each ſide of the tool. Experiments of this kind do not ſeem difficult, and they would give us very uſeful information.

120 With what force a body of a homogeneous texture reſiſts a ſimple twiſt.

121 The forces exerted in breaking two cylinders are as the ſquares of the diameters.

When two cylinders AHK and BNO are wrenched aſunder, we muſt conclude that the external particles of each are juſt put beyond their limits of coheſion, are equally extended, and are exerting equal forces. Hence it follows, that in the inſtant of fracture the ſum total of the forces actually exerted are as the ſquares of the diameters.

For drawing the diagonal C e, it is plain that E e, = A a, expreſſes the diſtenſion of the circumference ELM, and that the ſolid generated by the triangle CE e expreſſes the coheſion exerted by the ſurface of the circle ELM, when the particles in the circumference ſuffer the extenſion E e equal to A a. Now the ſolids generated by CA a and CE e being reſpectively two-thirds of the correſponding cylinders, are as the ſquares of the diameters.

122 Relative ſtrength of the ſection to the external force employed to break it.

Having thus aſcertained the real ſtrength of the ſection, and its relation to its abſolute lateral ſtrength, let us examine its ſtrength relative to the external force employed to break it. This examination is very ſimple in the caſe under conſideration. The ſtraining force muſt act by ſome lever, and the coheſion muſt oppoſe it by acting on ſome other lever. The centre of the ſection may be the neutral point, whoſe poſition is not diſturbed.

Let F be the force exerted laterally by an exterior particle. Let a be the radius of the cylinder, and x the indeterminate diſtance of any circumference, and $\dot{x}$ the indefinitely ſmall interval between the concentric arches; that is, let $\dot{x}$ be the breadth of a ring and x its radius. The forces being as the extenſions, and the extenſions as the diſtances from the axis, the coheſion actually exerted at any part of any ring will be $f\frac{x\dot{x}}{a}$. The force exerted by the whole ring (being as the circumference or as the radius) will be $f\frac{x^2\dot{x}}{a}$. The momentum of coheſion of a ring, being as the force mutiplied by its lever, will be $f\frac{x^3\dot{x}}{a}$. The accumulated momentum will be the ſum or fluent of $f\frac{x^3\dot{x}}{a}$; that is, when $x = a$, it will be $\frac{1}{4}f\frac{a^4}{a}$, $= \frac{1}{4}fa^3$.

123 The reſiſtance of the axle is as the cube of its diameter.

Hence we learn that the ſtrength of an axle, by which it reſiſts being wrenched aſunder by a force acting at a given diſtance from the axis, is as the cube of its diameter.

But farther, $\frac{1}{4}fa^3$ is $= fa^2 \times \frac{1}{4}a$. Now fa^2 repreſents the full lateral coheſion of the ſection. The momentum therefore is the ſame as if the full lateral coheſion were accumulated at a point diſtant from the axis by $\frac{1}{4}$th of the radius or $\frac{1}{8}$th of the diameter of the cylinder.

Therefore let F be the number of pounds which meaſures the lateral coheſion of a circular inch, d the diameter of the cylinder in inches, and l the length of the lever by which the ſtraining force p is ſuppoſed to act, we ſhall have $F \times \frac{1}{8}d^3 = pl$, and $F\frac{d^3}{8l} = p$.

Strength of Materials.

We ſee in general that the ſtrength of an axle, by which it reſiſts being wrenched aſunder by twiſting, is as the cube of its diameter.

We ſee alſo that the internal parts are not acting ſo powerfully as the external. If a hole be bored out of the axle of half its diameter, the ſtrength is diminiſhed only $\frac{1}{8}$th, while the quantity of matter is diminiſhed $\frac{1}{4}$th. Therefore hollow axles are ſtronger than ſolid ones containing the ſame quantity of matter. Thus let the diameter be 5 and that of the hollow 4: then the diameter of another ſolid cylinder having the ſame quantity of matter with the tube is 3. The ſtrength of the ſolid cylinder of the diameter 5 may be expreſſed by 5^3 or 125. Of this the internal part (of the diameter 4) exerts 64; therefore the ſtrength of the tube is $125 - 64 = 61$. But the ſtrength of the ſolid axle of the ſame quantity of matter and diameter 3 is 3^3, or 27, which is not half that of the tube.

124 Hollow axles more proper than ſolid ones.

Engineers, therefore, have of late introduced this improvement in their machines, and the axles of caſt iron are all made hollow when their ſize will admit it. They have the additional advantage of being much ſtiffer, and of affording much better fixure for the ſtanches, which are uſed for connecting them with the wheels or levers by which they are turned and ſtrained. The ſuperiority of ſtrength of hollow tubes over ſolid cylinders is much greater in this kind of ſtrain than in the former or tranſverſe. In this laſt caſe the ſtrength of this tube would be to that of the ſolid cylinder of equal weight as 61 to $32\frac{1}{2}$ nearly.

125 And now generally uſed.

The apparatus which we mentioned on a former occaſion for trying the lateral ſtrength of a ſquare inch of ſolid matter, enabled us to try this theory of twiſt with all deſirable accuracy. The bar which hung down from the pin in the former trials was now placed in a horizontal poſition, and loaded with a weight at the extremity. Thus it acted as a powerful lever, and enabled us to wrench aſunder ſpecimens of the ſtrongeſt materials. We found the reſults perfectly conformable to the theory, in as far as it determined the proportional ſtrength of different ſizes and forms: but we found the ratio of the reſiſtance to twiſting to the ſimple lateral reſiſtance conſiderably different; and it was ſome time before we diſcovered the cauſe.

126 The ratio of reſiſtance to twiſting to the ſimple lateral reſiſtance appears different.

We had here taken the ſimpleſt view that is poſſible of the action of coheſion in reſiſting a twiſt. It is frequently exerted in a very different way. When, for inſtance, an iron axle is joined to a wooden one by being driven into one end of it, the extenſions of the different circles of particles are in a very different proportion. A little conſideration will ſhow that the particles in immediate contact with the iron axle are in a ſtate of violent extenſion; ſo are the particles of the exterior ſurface of the wooden part, and the intermediate parts are leſs ſtrained. It is almoſt impoſſible to aſſign the exact proportion of the coheſive forces exerted in the different parts. Numberleſs caſes can be pointed out where parts of the axle are in a ſtate of compreſſion, and where it is ſtill more difficult to determine the ſtate of the other particles. We muſt content ourſelves with the deductions made from this ſimple caſe, which is fortunately the moſt common. In the experiments juſt now mentioned the centre of the circle is by no means the neutral point, and it is very difficult to aſcertain its place. but when this conſideration occurred to us, we eaſily freed the experiments from this uncertainty, by extending the lever to both ſides, and by means of a pulley applied equal force to each arm, acting in oppoſite directions. Thus the centre

127 But when the experiment was altered, it was exactly the ſame.

became

Strength of Materials ‖ Stretto.

became the neutral point, and the reſiſtance to twiſt was found to be $\frac{1}{3}$ds of the ſimple lateral ſtrength.

128 Experiments on chalk, clay, and wax, ſatisfactory; but thoſe on timber irregular.

We beg leave to mention here that our ſucceſs in theſe experiments encouraged us to extend them much farther. We hoped by theſe means to diſcover the abſolute coheſion of many ſubſtances, which would have required an enormous apparatus and a moſt unmanageable force to tear them aſunder directly. But we could reaſon with confidence from the reſiſtance to twiſt (which we could eaſily meaſure), provided that we could aſcertain the proportion of the direct and the lateral ſtrengths. Our experiments on chalk, finely prepared clay, and white bees-wax (of one melting and one temperature), were very conſiſtent and ſatisfactory. But we have hitherto found great irregularities in this proportion in bodies of a fibrous texture like timber. Theſe are the moſt important caſes, and we ſtill hope to be able to accompliſh our project, and to give the public ſome valuable information. This being our ſole object, it was our duty to mention the method which promiſes ſucceſs, and thus excite others to the taſk; and it will be no mortification to us to be deprived of the honour of being the firſt who thus add to the ſtock of experimental knowledge.

When the matter of the axle is of the moſt ſimple texture, ſuch as that of metals, we do not conceive that the length of the axle has any influence on the fracture. It is otherwiſe if it be of a fibrous texture like timber: the fibres are bent before breaking, being twiſted into ſpirals like a cork-ſcrew. The length of the axle has ſomewhat of the influence of a lever in this caſe, and it is eaſier wrenched aſunder if long. Accordingly we have found it ſo; but we have not been able to reduce this influence to calculation.

122 Concluding remarks.

Our readers are requeſted to accept of theſe endeavours to communicate information on this important and difficult ſubject. We are duly ſenſible of their imperfection, but flatter ourſelves that we have in many inſtances pointed out the method which muſt be purſued for improving our knowledge on this ſubject; and we have given the Engliſh reader a more copious liſt of experiments on the ſtrength of materials than he will meet with in our language. Many uſeful deductions might be made from theſe premiſes reſpecting the manner of diſpoſing and combining the ſtrength of materials in our ſtructures. The beſt form of joints, mortiſes, tenons, ſcarphs; the rules for jogging, tabling, faying, fiſhing, &c. practiſed in the delicate art of maſt-making, are all founded on this doctrine: but the diſcuſſion of theſe would be equivalent to writing a complete treatiſe of carpentry. We hope that this will be executed by ſome intelligent mechanician, for there is nothing in our language on this ſubject but what is almoſt contemptible; yet there is no mechanic art that is more ſuſceptible of ſcientific treatment. Such a treatiſe, if well executed, could not fail of being well received by the public in this age of mechanical improvement.

STRENGTHENERS, or CORROBORANTS, ſuch medicines as add to the bulk and firmneſs of the ſolids; and ſuch are all agglutinant and aſtringent medicines. See MATERIA MEDICA, p. 649. art. 6.

STRETCHING, in navigation, is generally underſtood to imply the progreſſion of a ſhip under a great ſurface of ſail, when cloſe-hauled. The difference between this term and *ſtanding*, conſiſts apparently in the quantity of ſail; which in the latter may be very moderate; but ſtretching generally ſignifies exceſs: as, we ſaw the enemy at day break ſtretching to the ſouthward under a croud of ſail, &c. *Falconer.*

STRETTO, in Italian muſic, is ſometimes uſed to ſignify that the meaſure is to be ſhort and conciſe, and conſequently quick. In this ſenſe it ſtands oppoſed to LARGO.

STRIATED LEAF, among botaniſts, one that has a number of longitudinal furrows on its ſurface. Striated ‖ Strix.

STRIKE, a meaſure of capacity, containing four buſhels. Alſo an inſtrument uſed in meaſuring corn.

STRIX, the OWL, in ornithology, a genus belonging to the order of *accipitres*. The bill is hooked, but has no cere or wax; the noſtrils are covered with ſetaceous feathers; the head is very large, as are alſo the ears and eyes; and the tongue is bifid. There are 46 ſpecies; the moſt remarkable are,

1. The *bubo*, or great-eared owl, in ſize is almoſt equal to an eagle. Irides bright yellow; head and whole body finely varied with lines, ſpots, and ſpecks of black, brown, cinereous, and ferruginous. Wings long; tail ſhort, marked with duſky bars. Legs thick, covered to the very end of the toes with a cloſe and full down of a teſtaceous colour. Claws great, much hooked, and duſky.—It has been ſhot in Scotland and in Yorkſhire. It inhabits inacceſſible rocks and deſert places; and preys on hares and feathered game. Its appearance in cities was deemed an unlucky omen. Rome itſelf once underwent, a luſtration becauſe one of them ſtrayed into the capitol. The ancients had them in the utmoſt abhorrence; and thought them, like the ſcreech-owls, the meſſengers of death. Pliny ſtyles it *bubo funebris*, and *noctis monſtrum*.

Solaque culminibus ferali *carmine* bubo
Sæpe queri et longas in fletum ducere voces. VIRGIL.

Perch'd on the roof, the bird of night complains,
In lengthen'd ſhrieks and dire funereal ſtrains.

2. The *otus*, or long-eared owl, is found, though not frequently, in the north of England, in Cheſhire, and in Wales. Mr Haſſelquiſt ſaw it alive in Cairo, and it is not unfrequent all over Egypt. Its weight, according to Dr Latham, is nine ounces; the length 14 inches and a half; the breadth 34; the irides are of a bright yellow; the bill black; the breaſt and belly are of a dull yellow, marked with ſlender brown ſtrokes pointing downwards; the thighs and vent-feathers of the ſame colour, but unſpotted. The back and coverts of the wings are varied with deep brown and yellow; the quill-feathers of the ſame colour, but near the ends of the outmoſt is a broad bar of red; the tail is marked with duſky and reddiſh bars, but beneath appears aſh-coloured; the horns or ears are about an inch long, and conſiſt of ſix feathers variegated with yellow and black; the feet are feathered down to the claws.

3. The *brachyotos*, or ſhort-eared owl, is 14 inches long; three feet broad; the head is ſmall and hawk-like; the bill is duſky; weight 14 ounces; the circle of feathers that immediately ſurrounds the eyes is black; the larger circle white, terminated with tawny and black; the feathers on the head, back, and coverts of the wings, are brown, edged with pale dull yellow; the breaſt and belly are of the ſame colour marked with a few long narrow ſtreaks of brown pointing downwards; the quill-feathers, are duſky, barred with red; the tail is of a very deep brown, adorned on each ſide of the ſhaft of the four middle feathers with a yellow circle which contains a brown ſpot; the tip of the tail is white. The horns of this ſpecies are very ſmall, and each conſiſts of only a ſingle feather; theſe it can raiſe or depreſs at pleaſure; and in a dead bird are with difficulty diſcovered. This kind is ſcarcer than the former; both are ſolitary birds, avoiding inhabited places. Theſe ſpecies may be called *long-winged owls*; the wings when cloſed reaching beyond the end of the tail; whereas in the common kinds they fall ſhort of it.—This is a bird of paſſage, and has been obſerveſt to viſit Lincolnſhire in the beginning of October, and

Strix. to retire early in the ſpring; ſo probably, as it performs its migrations with the woodcock, its ſummer-retreat is Norway. During day it lies hid in long old glaſs; when diſturbed, it ſeldom flies far, but will light, and ſit looking at one, at which time the horns may be ſeen very diſtinctly. It has not been obſerved to perch on trees like other owls; it uſually flies in ſearch of prey in cloudy hazy weather. Farmers are fond of ſeeing theſe birds in the fields, as they clear them from mice. It is found frequently on the hill of Hoy in the Orkneys, where it flies about and preys by day like a hawk. It is found alſo, as we mentioned before, in Lancaſhire, which is a hilly and woody country; and in New England and Fewfoundland.

4. The *flammea*, or common white owl. The elegant plumage of this bird makes amends for the uncouthneſs of its form: a circle of ſoft white feathers ſurround the eyes. The upper part of the body, the coverts, and ſecondary feathers of the wings, are of a fine pale yellow: on each ſide of the ſhafts are two grey and two white ſpots placed alternate: the exterior ſides of the quill-feathers are yellow; the interior white, marked on each ſide with four black ſpots: the lower ſide of the body is wholly white; the interior ſides of the feathers of the tail are white; the exterior marked with ſome obſcure duſky bars; the legs are feathered to the feet: the feet are covered with ſhort hairs: the edge of the middle claw is ſerrated. The uſual weight is 11 ounces; its length 14 inches; its breadth 3 feet.—This ſpecies is almoſt domeſtic; inhabiting, for the greateſt part of the year, barns, hay-lofts, and other out houſes; and is as uſeful in clearing thoſe places from mice as the congenial cat: towards twilight it quits its perch, and takes a regular circuit round the fields, ſkimming along the ground in queſt of field-mice, and then returns to its uſual reſidence: in the breeding-ſeaſon it takes to the eaves of churches, holes in lofty buildings, or hollows of trees. During the time the young are in the neſt, the male and female alternately ſally out in queſt of food, make their circuit, beat the fields with the regularity of a ſpaniel, and drop inſtantly on their prey in the graſs. They very ſeldom ſtay out above five minutes; return with their prey in their claws; but as it is neceſſary to ſhift it into their bill, they always alight for that purpoſe on the roof, before they attempt to enter their neſt. This ſpecies does not hoot; but ſnores and hiſſes in a violent manner; and while it flies along will often ſcream moſt tremendouſly. Its only food is mice. As the young of theſe birds keep their neſt for a great length of time, and are fed even long after they can fly, many hundreds of mice will ſcarcely ſuffice to ſupply them with food. Owls caſt up the bones, fur, or feathers of their prey, in form of ſmall pellets, after they have devoured it, in the ſame manner as hawks do. A gentleman, on grubbing up an old pollard aſh that had been the habitation of owls for many generations, found at the bottom many buſhels of this rejected ſtuff. Some owls, when they are ſatisfied, hide the remainder of their meat like dogs.

5. The *ſtridula*, or tawny owl. The female of this ſpecies weighs 19 ounces; the length in 15 inches; the breadth 2 feet 8 inches; the irides are duſky; the ears in this, as in all owls, very large; and their ſenſe of hearing very exquiſite. The colour of this kind is ſufficient to diſtinguiſh it from every other: that of the back, head, coverts of the wings, and on the ſcapular feathers, being a fine tawny red, elegantly ſpotted and powdered with the black or duſky ſpots of various ſizes: on the coverts of the wings and on the ſcapulars are ſeveral large white ſpots: the coverts of the tail are tawny, and quite free from any marks: the tail is variouſly blotched, barred and ſpotted with pale red and black; in the two middle feathers the red predominates: the breaſt and belly are yellowiſh, mixed with white, and marked with narrow black ſtrokes pointing downwards: the legs are covered with feathers down to the toes.—This is a hardier ſpecies than the former; and the young will feed on any dead thing, whereas thoſe of the white owl muſt have a conſtant ſupply of freſh meat. It is the ſtrix of Aldrovandus, and what we call the *ſcreech-owl*; to which the folly of ſuperſtition had given the power of preſaging death by its cries. The ancients believed that it ſucked the blood of young children: a fact ſome think not incredible: for Haſſelquiſt deſcribes a ſpecies found in Syria, which frequently in the evening flies in at the windows, and deſtroys the helpleſs infant. Strix.

Nocte volant, pueroſque petunt nutricis egentes
Et vitiant cuneis corpora rapta ſuis.
Carpere dicuntur lactentia viſcera roſtris,
Et plenum poto ſanguine guttur habent.
Eſt illis ſtrigibus nomen, ſed nominis hujus
Cauſa quod horrenda ſtridere nocte ſoient. Ovid Faſt. vi. 135.

6. The *ulula*, or brown owl, agrees with the former in its marks; differing only in the colours: in this, the head, wings, and back, are of a deep brown, ſpotted with black in the ſame manner as the former: the coverts of the wings and the ſcapulars are adorned with ſimilar white ſpots: the exterior edges of the four firſt quill-feathers in both are ſerrated: the breaſt in this is of a very pale aſh-colour mixed with tawny, and marked with oblong jagged ſpots: the feet too are feathered down to the very claws: the circle round the face is aſh-coloured, ſpotted with brown.—Both theſe ſpecies inhabit woods, where they reſide the whole day: in the night they are very clamorous; and when they hoot, their throats are inflated to the ſize of an hen's egg. In the duſk they approach our dwellings; and will frequently enter pigeon-houſes, and make great havoc in them. They deſtroy numbers of little leverets, as appears by the legs frequently found in their neſts. They alſo kill abundance of moles, and ſkin them with as much dexterity as a cook does a rabbit. They build in hollow trees or ruined edifices; lay four eggs, of an elliptic form, and of a whitiſh colour.

7. The *paſſerina*, or little owl, is very rare in England; it is ſometimes found in Yorkſhire, Flintſhire, and alſo near London: in ſize it ſcarcely exceeds a thruſh, though the fulneſs of its plumage makes it appear larger: the irides are of a light yellow; the bill of a paper-colour; the feathers that encircle the face are white tipt with black; the head brown, ſpotted with white; on the breaſt is a mixture of white and brown; the belly is white, marked with a few brown ſpots; the tail of the ſame colour with the back; in each feather barred with white; in each adorned with circular white ſpots, placed oppoſite to one another on both ſides of the ſhaft; the legs and feet are covered with feathers down to the claws.—The Italians make uſe of this owl to decoy ſmall birds to the limed twig; the method of which is exhibited in Olina's *Uccelliera*, p. 65. Mr Steuart, author of the Antiquities of Athens, informed Mr Pennant, that this ſpecies of owl was very common in Attica; that they were birds of paſſage, and appeared there in the beginning of April in great numbers; that they bred there; and that they retired at the ſame time as the ſtorks, whoſe arrival they a little preceded.

8. The ſpectacle owl of Cayenne, which is accurately deſcribed by Dr Latham, is 21 inches in length: the upper parts of the body are of a reddiſh colour; the lower parts of Lath. Syn. vol. vii. p. 50.

Strobilus, Stroking.

of a rufous white: the head and neck are white, and not ſo full of feathers as thoſe of owls generally are, and from this circumſtance it appears not unlike a hawk: a large patch of dark brown ſurrounds each eye, giving the bird much the appearance of wearing ſpectacles; the legs are covered with feathers quite to the toes, and are or a yelloviſh colour. A ſpecimen of this curious bird may be ſeen in the Leverian muſeum.

STROBILUS, in botany, a pericarp formed from an amentum by the hardening of the ſcales.

STROKING, or rubbing gently with the hand, a method which has been employed by ſome perſons for curing diſeaſes.

Mr Greatrakes or Greatrix, the famous Iriſh ſtroker, is ſaid to have performed many wonderful cures. He gives the following account of his diſcovery of this art, and of the ſucceſs with which he practiſed it. "About 1662 I had an impulſe (ſays he), or a ſtrange perſuaſion in my own mind (of which I am not able to give any rational account to another), which did very frequently ſuggeſt to me, that there was beſtowed on me the gift of curing the king's evil; which, for the extraordinarineſs of it, I thought fit to conceal for ſome time; but at length I communicated this to my wife, and told her, that I did verily believe that God had given me the bleſſing of curing the king's evil; for whether I were in private or public, ſleeping or waking, ſtill I had the ſame impulſe. But her reply to me was, that ſhe conceived this was a ſtrange imagination; yet, to prove the contrary, a few days after there was one William Mather of Salterbridge in the pariſh of Liſmore, who brought his ſon William to my houſe, deſiring my wife to cure him, who was a perſon ready to afford her charity to her neighbours, according to her ſmall ſkill in chirurgery. On which my wife told me, there was one that had the king's evil very grievouſly in the eyes, cheek, and throat; whereupon I told her, that ſhe ſhould now ſee whether this were a bare fancy or imagination, as ſhe thought it, or the dictates of God's Spirit on my heart. Then I laid my hands on the places affected, and prayed to God for Jeſus' ſake to heal him; and bid the parent two or three days afterwards to bring the child to me again, which accordingly he did; and I then ſaw the eye was almoſt quite whole; and the node, which was almoſt as big as a pullet's egg, was ſuppurated; and the throat ſtrangely amended; and, to be brief (to God's glory I ſpeak it) within a month diſcharged itſelf quite, and was perfectly healed, and ſo continues, God be praiſed."

See Brief Account of Mr Valentine Greatrakes, London, 1666, 4to.

Then there came to him one Margaret Macſhane of Ballinecly, in the pariſh of Liſmore, who had been afflicted with the evil above ſeven years, in a much more violent degree; and ſoon after, his fame increaſing, he cured the ſame diſeaſe in many other perſons for three years. He did not meddle all this time with any other diſtemper; till about the end of theſe three years, the ague growing epidemical, he found, as formerly, that there was beſtowed on him the gift of curing that diſeaſe. He cured Colonel Phaire, of Cahirmony in the county of Corke, of an ague, and afterwards many other perſons of different diſtempers, by ſtroking; ſo that his name was wonderfully cried up, as if ſome divine perſon had been ſent from above. January 1665-6, he came over to England, at the requeſt of the earl of Orrery; in order to cure the lady of the lord-viſcount Conway, of Ragley in Warwickſhire, who had for many years laboured under a moſt violent head-ache. He ſtaid at Ragley three weeks or a month; and though he failed in his endeavours to relieve that lady, he cured vaſt numbers of people in thoſe parts and at Worceſter.

Though we are no friends to the marvellous, nor believe it poſſible that either the king's evil or ague can be cured by ſtroking or friction of any kind, whether gentle or ſevere, we have no heſitation to acknowledge that many cures might be performed by Mr Greatrakes. Every reflecting perſon who reads the foregoing account which he gives of himſelf will ſee that he was an enthuſiaſt, and believed himſelf guided by a particular revelation; and ſuch is the credulity of mankind, that his pretenſions were readily admitted, and men crouded with eagerneſs to be relieved of their diſeaſes. But it is well known to phyſicians, that in many caſes the imagination has accompliſhed cures as wonderful as the force of medicine. It is owing chiefly to the influence of imagination that we have ſo many accounts from people of veracity of the wonderful effects of quack medicines. We are perfectly aſſured that theſe medicines, by their natural operation, can never produce the effects aſcribed to them; for there is no kind of proportion between the medicine and the effect produced, and often no connection between the medicine and the diſeaſe.

Stromateus ‖ Strongoli.

STROMATEUS, in ichthyology, a genus of fiſhes belonging to the order of *apodes*. The head is compreſſed; the teeth are placed in the jaws and palate; the body is oval and ſlippery; and the tail is forked. There are three ſpecies according to Gmelin, the fiatola, paru, and cumarca.

STROMBOLI, the moſt northern of the Lipari iſlands. It is a volcano, which conſtantly diſcharges much fire and ſmoke. It riſes in a conical form above the ſurface of the ſea. On the eaſt ſide it has three or four little craters ranged near each other, not at the ſummit, but on the declivity, nearly at two-thirds of its height. But as the ſurface of the volcano is very rugged, and interſected with hollow ways, it may be naturally concluded, that at the time of ſome great eruption, the ſummit and a part of this ſide fell in, as muſt have happened alſo to Veſuvius; conſequently, the common chimney is at this day on the declivity, although always in the centre of the whole baſe. It is inhabited notwithſtanding its fires; but care is taken to avoid the proximity of the crater, which is yet much to be feared. "I was aſſured (ſays M. de Luc) by an Engliſhman, who, like me, had the curioſity to viſit theſe iſles, that the fine weather having invited him and his company to land at Stromboli, they aſcended a volcano, whoſe craters at that time threw out nothing; but that while they were attentively viewing them, unapprehenſive of any danger, they were ſuddenly ſaluted by ſuch a furious diſcharge, as to be obliged to retreat with precipitation, and not without one of the company being wounded by a piece of ſcoria." Of all the volcanoes recorded in hiſtory, Stromboli ſeems to be the only one that burns without ceaſing. Etna and Veſuvius often lie quiet for many months, and even years, without the leaſt appearance of fire; but Stromboli is ever at work, and for ages paſt has been looked upon as the great lighthouſe of theſe ſeas. E. Long. 15. 45. N. Lat. 30. 0.

STROMBUS, in natural hiſtory, a genus of *vermes*, belonging to the order of *teſtacea*. The animal is a limax; the ſhell is univalve and ſpiral; the opening is much dilated, and ends in a canal which turns to the left. Gmelin enumerates 53 ſpecies; of which only one is peculiar to Britain, the pes pelecani. The ſpires are ten; the lip is fingered; the point very ſharp; the length two inches.

STRONGOLI, a town of the kingdom of Naples, with a biſhop's ſee. It is ſituated on a rugged mountain, is about three miles from the ſea, and ſeven north from St Severino. It is ſuppoſed to be the ancient *Petelia*, which made a conſpicuous figure in the ſecond Punic war by its obſtinate reſiſtance againſt Hannibal. Near its walls Marcellus the ri-

Strontites. val of Hannibal was ſlain in a ſkirmiſh. E. Long. 17. 26. N. Lat. 39. 20.

STRONTITES, or STRONTIAN EARTH, a new ſpecies of earth lately diſcovered at Strontian in Scotland.

Who the diſcoverer of this earth was we have not learned; but Dr Kirwan ſays, the firſt information he received of it was from Dr Crawford in the year 1790. In the Miners' Journal for February 1791 a good deſcription of its external appearance, with ſome account of its chemical properties, was publiſhed from the obſervations of Mr Sulzer. Dr Kirwan examined it in October 1793, and found it to be a new earth between the barytic and common limeſtone. Dr Hope, who is now joint profeſſor of chemiſtry with Dr Black in the univerſity of Edinburgh, read a paper on the 4th November 1793 before the Royal Society of Edinburgh, intitled "An Account of a Mineral from Strontian, and of a peculiar Species of Earth which it contains;" an abridgment of which is publiſhed in the third volume of the Edinburgh Philoſophical Tranſactions. Mr Schmeiſſer read a paper on the ſame ſubject before the Royal Society of London in May 1794, which is publiſhed in their Tranſactions for that year, p. 418, &c.

Tranſactions of the Iriſh Academy, vol. v.

Its external characters are theſe: Its colour is whitiſh or light green; its luſtre common; its tranſparency intermediate between the ſemitranſparent and opaque; its fracture ſtriated, preſenting oblong diſtinct concretions, ſomewhat uneven and bent; its hardneſs moderate, being eaſily ſcratched, but not ſcraped. It is very brittle; and its ſpecific gravity from 3,4 to 3,644.

For a full account of its chemical qualities we muſt refer to the books already mentioned, as all the accounts of it which we have ſeen are too long to inſert here, and as we do not conſider the circumſtance of its being a newly diſcovered earth a ſufficient reaſon for running into a tedious detail till its utility be aſcertained. We ſhall, however, mention ſome of its moſt remarkable qualities. It requires 180 times its weight of water at a low temperature to diſſolve it. When diſſolved in boiling water, and allowed to cool, it depoſits tranſparent cryſtals, which when expoſed to the air become white and powdery. It is not affected by the ſulphuric acid; but when diluted, 10,000 parts of it will diſſolve one of ſtrontites. Diluted nitric acid diſſolves it rapidly. The muriatic acid, whether diluted or oxygenated, diſſolves it in a ſimilar manner.

Strontites has a ſtrong reſemblance to barytes, but eſſentially differs from it. Its ſpecific gravity is leſs; it parts with its carbonic acid when urged by heat ſomewhat more readily, and without ſuffering fuſion; when calcined, it imbibes moiſture with vaſtly greater avidity, ſwelling and cracking with more heat and noiſe. Strontites diſſolves much more abundantly in hot water than barytes; and the form of the cryſtals of theſe pure earths is very diſſimilar. The compounds generated by ſtrontites differ from thoſe of barytes. It will ſuffice to mention the nitrate and muriate. This earth, united to nitric and muriatic acid, forms ſalts that ſuffer changes from expoſure to air, which do not happen to the nitrate and muriate of barytes. They are likewiſe much more ſoluble in water, and have cryſtals of a peculiar figure. The combinations of ſtrontites with acids are not, like thoſe of barytes, decompoſed by pruſſiate of lime or of potaſh. Strontites and its compounds tinge flame, which barytes does not. Laſtly, theſe earths diſagree in the order of their attractions. From theſe conſiderations it is concluded, that the mineral is not aerated barytes.

Tranſactions of the Royal Society of Edinburgh, vol. iii.

It alſo is diſtinguiſhed from calcareous ſpar or limeſtone: for it is much heavier, and retains its fixed air with more obſtinacy in the fire. The incomparably greater ſolubility of the pure earth in hot than in cold water, and the cryſtalline form it aſſumes, ſufficiently diſtinguiſh it from lime, which the diſpoſition of the nitrate and muriate to cryſtallize no leſs tends to do.

Strophe ‖ Struthio.

The moſt remarkable quality of ſtrontites is that of tinging flame of a red colour. The muriate has it in the moſt eminent degree, and its effects are well exhibited by putting a portion of the ſalt on the wick of a candle, which is thereby made to burn with a very beautiful blood-red flame. The nitrate ſtands next, then cryſtallized ſtrontites, and after it the acetate. A hundred parts of ſtrontites are compoſed of 61.21 of earth, 30.20 of carbonic acid, and 8.59 of water.

STROPHE, in ancient poetry, a certain number of verſes, including a perfect ſenſe, and making the firſt part of an ode. See POETRY, n° 130.

STRUMÆ, ſcrophulous tumors ariſing on the neck and throat, conſtituting what is commonly called the *king's evil*. See MEDICINE, n° 349.

STRUMPFIA, in botany; a genus of plants belonging to the claſs of *ſyngeneſia*, and to the order of *monogamia*. The calyx is quinquedentate and ſuperior; the corolla is pentapetalous; and the berry monoſpermous. There is only one ſpecies, the maritima.

STRUTHIO, in natural hiſtory; a genus of birds belonging to the order of *grallæ* of Linnæus; but, according to the new claſſification of Dr Latham, it forms, along with the dodo, caſſuarius, and rhea, a ſeparate order under the name of *ſtruthius*. As the dodo or didus, and rhea, have been already deſcribed in their proper place, we will now give ſome account of the oſtrich and caſſowary.

I. The OSTRICH (the *Camelus* of Linnæus) has a bill ſomewhat conical; the wings are ſo ſhort as to be unfit for flying; the thighs and ſides of the body are naked; the feet are formed for running, having two toes, one only of which is furniſhed with a nail. In this reſpect it differs entirely from the caſſowary, which has three toes complete. The oſtrich is without doubt the largeſt of all birds: it is nearly eight feet in length, and when ſtanding upright from ſix to eight feet in height. We are told in the Gentleman's Magazine *, that two oſtriches were ſhown in London in the year 1750, and that the male was 10 feet in height, and weighed three hundred weight and a quarter. The head and bill ſomewhat reſemble thoſe of a duck; and the neck may be likened to that of a ſwan, but that it is much longer; the legs and thighs reſemble thoſe of an hen; though the whole appearance bears a ſtrong reſemblance to that of a camel. But though uſually ſeven feet high from the top of the head to the ground, from the back it is only four; ſo that the head and neck are above three feet long. From the top of the head to the rump, when the neck is ſtretched out in a right line, it is ſix feet long, and the tail is about a foot more. One of the wings, without the feathers, is a foot and an half; and being ſtretched out, with the feathers, is three feet.

Plate CCCCLXXXVI.

* Vol. xx. p. 536.

The plumage is much alike in all; that is, generally black and white; though ſome of them are ſaid to be grey. There are no feathers on the ſides, nor yet on the thighs, nor under the wings. The lower part of the neck, about half way, is covered with ſtill ſmaller feathers than thoſe on the belly and back; and thoſe alſo are of different colours.

All theſe feathers are of the ſame kind, and peculiar to the oſtrich; for other birds have ſeveral ſorts, ſome of which are ſoft and downy, and others hard and ſtrong. Oſtrich-feathers are almoſt all as ſoft as down, being utterly unfit to ſerve the animal for flying, and ſtill leſs adapted to be a proper defence againſt external injury. The feathers

of

Struthio. of other birds have the webs broader on one ſide than the other, but thoſe of the oſtrich have their ſhaft exactly in the middle. The upper part of the head and neck are covered with a very fine clear white hair, that ſhines like the briſtles of a hog; and in ſome places there are ſmall tufts of it, conſiſting of about 12 hairs, which grow from a ſingle ſhaft about the thickneſs of a pin. Struthio.

At the end of each wing there is a kind of ſpur almoſt like the quill of a porcupine. It is an inch long, being hollow and of an horny ſubſtance. There are two of theſe on each wing; the largeſt of which is at the extremity of the bone of the wing, and the other a foot lower. The neck ſeems to be more ſlender in proportion to that of other birds, from its not being furniſhed with feathers. The ſkin in this part is of a livid fleſh-colour, which ſome, improperly, would have to be blue. The bill is ſhort and pointed, and two inches and an half at the beginning. The external form of the eye is like that of a man, the upper eye-lid being adorned with eye-laſhes which are longer than thoſe on the lid below. The tongue is ſmall, very ſhort and compoſed of cartilages, ligaments, and membranes, intermixed with fleſhy fibres. In ſome it is about an inch long, and very thick at the bottom; in others it is but half an inch, being a little forked at the end.

The thighs are very fleſhy and large, being covered with a white ſkin inclining to redneſs, and wrinkled in the manner of a net, whoſe meſhes will admit the end of the finger. Some have very ſmall feathers here and there on the thighs; and others again have neither feathers nor wrinkles. What are called the legs of birds, in this are covered before with large ſcales. The end of the foot is cloven, and has two very large toes, which, like the leg, are covered with ſcales. Theſe toes are of unequal ſizes. The largeſt, which is on the inſide, is ſeven inches long, including the claw, which is near three-fourths of an inch in length, and almoſt as broad. The other toe is but four inches long, and is without a claw.

The internal parts of this animal are formed with no leſs ſurpriſing peculiarity. At the top of the breaſt, under the ſkin, the fat is two inches thick; and on the fore part of the belly it is as hard as ſuet, and about two inches and an half thick in ſome places. It has two diſtinct ſtomachs. The firſt, which is lowermoſt, in its natural ſituation ſomewhat reſembles the crop in other birds; but it is conſiderably larger than the other ſtomach, and is furniſhed with ſtrong muſcular fibres, as well circular as longitudinal. The ſecond ſtomach or gizzard has outwardly the ſhape of the ſtomach of a man; and upon opening is always found filled with a variety of diſcordant ſubſtances; hay, graſs, barley, beans, bones, and ſtones, ſome of which exceed in ſize a pullet's egg. The kidneys are eight inches long and two broad, and differ from thoſe of other birds in not being divided into lobes. The heart and lungs are ſeparated by a midriff as in quadrupeds; and the parts of generation alſo bear a very ſtrong reſemblance and analogy.

The oſtrich is a native only of the torrid regions of Africa, and has long been celebrated by thoſe who have had occaſion to mention the animals of that region. Its fleſh is proſcribed in Scripture as unfit to be eaten; and moſt of the ancient writers deſcribe it as well known in their times. Like the race of the elephant, it is tranſmitted down without mixture; and has never been known to breed out of that country which firſt produced it. It ſeems formed to live among the ſandy and burning deſerts of the torrid zone; and, as in ſome meaſure it owes its birth to their genial influence, ſo it ſeldom migrates into tracts more mild or more fertile. The Arabians aſſert that the oſtrich never drinks; and the place of its habitation ſeems to confirm the aſſertion. In theſe formidable regions oſtriches are ſeen in large flocks, which to the diſtant ſpectator appear like a regiment of cavalry, and have often alarmed a whole caravan. There is no deſert, how barren ſoever, but what is capable of ſupplying theſe animals with proviſion; they eat almoſt every thing; and theſe barren tracts are thus doubly grateful, as they afford both food and ſecurity. The oſtrich is of all other animals the moſt voracious. It will devour leather, graſs, hair, iron, ſtones, or any thing that is given. Thoſe ſubſtances which the coats of the ſtomach cannot ſoften, paſs whole; ſo that glaſs, ſtones, or iron, are excluded in the form in which they were devoured. In an oſtrich diſſected by Ranby, there appeared ſuch a quantity of heterogeneous ſubſtances, that it was wonderful how any animal could digeſt ſuch an overcharge of nourithment. Valiſnieri alſo found the firſt ſtomach filled with a quantity of incongruous ſubſtances; graſs, nuts, cords, ſtones, glaſs, braſs, copper, iron, tin, lead, and wood; a piece of ſtone was found among the reſt that weighed more than a pound. He ſaw one of theſe animals that was killed by devouring a quantity of quicklime. It would ſeem that the oſtrich is obliged to fill up the great capacity of its ſtomach in order to be at eaſe; but that nutritious ſubſtances not occurring, it pours in whatever offers to ſupply the void.

In their native deſerts, however, it is probable they live chiefly upon vegetables, where they lead an inoffenſive and ſocial life; the male, as Thevenot aſſures us, aſſorting with the female with connubial fidelity. They are ſaid to be very much inclined to venery; and the make of the parts in both ſexes ſeem to confirm the report. It is probable alſo they copulate like other birds, by compreſſion. They lay very large eggs, ſome of them being above five inches in diameter, and weighing above fifteen pounds. Theſe eggs have a very hard ſhell, ſomewhat reſembling thoſe of the crocodile, except that thoſe of the latter are leſs and rounder.

The ſeaſon for laying depends on the climate where the animal is bred. In the northern parts of Africa, this ſeaſon is about the beginning of July; in the ſouth, it is about the latter end of December. Theſe birds are very prolific, and lay generally from 40 to 50 eggs at one clutch, which are as big as a child's head. It has been commonly reported, that the female depoſits them in the ſand, and covering them up, leaves them to be hatched by the heat of the climate, and then permits the young to ſhift for themſelves. Very little of this, however, is true: no bird has a ſtronger affection for her young than the oſtrich, nor none watches her eggs with greater aſſiduity. It happens, indeed, in thoſe hot climates, that there is leſs neceſſity for the continual incubation of the female; and ſhe more frequently leaves her eggs, which are in no danger of being chilled by the weather: but though ſhe ſometimes forſakes them by day, ſhe always carefully broods over them by night; and Kolben, who has ſeen great numbers of them at the Cape of Good Hope, affirms, that they ſit on their eggs like other birds, and that the male and the female take this office by turns, as he had frequent opportunities of obſerving. Nor is it more true what is ſaid of their forſaking their young after they are excluded the ſhell. On the contrary, the young ones are not even able to walk for ſeveral days after they are hatched. During this time the old ones are very aſſiduous in ſupplying them with graſs, and very careful to defend them from danger; nay, they encounter every danger in their defence. The young, when brought forth, are of an aſh-colour the firſt year, and are covered with feathers all over. But in time theſe feathers drop; and thoſe parts

which

Struthio. which are covered aſſume a different and more becoming plumage.

The beauty of a part of this plumage, particularly the long feathers that compoſe the wings and tail, is the chief reaſon that man has been ſo active in purſuing this harmleſs bird to its deſerts, and hunting it with no ſmall degree of expence and labour. The ancients uſed thoſe plumes in their helmets; our military wear them in their hats; and the ladies make them an ornament in their dreſs. Thoſe feathers which are plucked from the animal while alive are much more valued than thoſe taken when dead, the latter being dry, light, and ſubject to be worm-eaten.

Beſide the value of their plumage, ſome of the ſavage nations of Africa hunt them alſo for their fleſh; which they conſider as a dainty. They ſometimes alſo breed theſe birds tame, to eat the young ones, of which the females are ſaid to be the greateſt delicacy. Some nations have obtained the name of *Struthophagi*, or *oſtrich eaters*, from their peculiar fondneſs for this food; and even the Romans themſelves were not averſe to it. Even among the Europeans now, the eggs of the oſtrich are ſaid to the well taſted, and extremely nouriſhing; but they are too ſcarce to be fed upon, although a ſingle egg be a ſufficient entertainment for eight men.

As the ſpoils of the oſtrich are thus valuable, it is not to be wondered at that man has become their moſt aſſiduous purſuer. For this purpoſe, the Arabians train up their beſt and fleeteſt horſes, and hunt the oſtrich ſtill in view. Perhaps, of all other varieties of the chaſe, this, though the moſt laborious, is yet the moſt entertaining. As ſoon as the hunter comes within ſight of his prey, he puts on his horſe with a gentle gallop, ſo as to keep the oſtrich ſtill in ſight; yet not ſo as to terrify him from the plain into the mountains. Of all known animals, the oſtrich is by far the ſwifteſt in running; upon obſerving himſelf, therefore, purſued at a diſtance, he begins to run at firſt but gently; either inſenſible of his danger, or ſure of eſcaping. In this ſituation, he ſomewhat reſembles a man at full ſpeed; his wings, like two arms, keep working with a motion correſpondent to that of his legs; and his ſpeed would very ſoon ſnatch him from the view of his purſuers; but, unfortunately for the ſilly creature, inſtead of going off in a direct line, he takes his courſe in circles; while the hunters ſtill make a ſmall courſe within, relieve each other, meet him at unexpected turns, and keep him thus ſtill employed, ſtill followed, for two or three days together. At laſt, ſpent with fatigue and famine, and finding all power of eſcape impoſſible, he endeavours to hide himſelf from thoſe enemies he cannot avoid, and covers his head in the ſand or the firſt thicket he meets. Sometimes, however, he attempts to face his purſuers; and though in general the moſt gentle animal in nature, when driven to deſperation he defends himſelf with his beak, his wings, and his feet. Such is the force of his motion, that a man would be utterly unable to withſtand him in the ſhock.

The Struthophagi have another method of taking this bird: they cover themſelves with an oſtrich's ſkin, and paſſing up an arm though the neck, thus counterfeit all the motions of this animal. By this artifice they approach the oſtrich, which becomes an eaſy prey. He is ſometimes alſo taken by dogs and nets; but the moſt uſual way is that mentioned above.

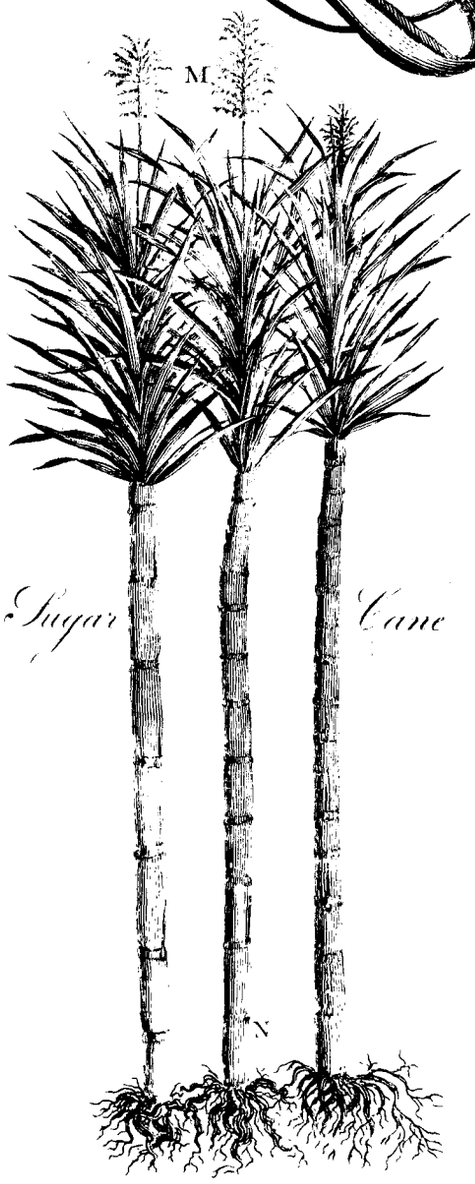
When the Arabians have thus taken an oſtrich, they cut its throat; and making a ligament below the opening, they ſhake the bird as one would rinſe a barrel; then taking off the ligature, there runs out from the wound in the throat a conſiderable quantity of blood mixed with the fat of the animal; and this is conſidered as one of their greateſt dainties. They next flea the bird; and of the ſkin, which is ſtrong and thick, ſometimes make a kind of veſt, which anſwers the purpoſes of a cuiraſs and a buckler. Struthio.

There are others who, more compaſſionate or more provident, do not kill their captive, but endeavour to tame it, for the purpoſes of ſupplying thoſe feathers which are in ſo great requeſt. The inhabitants of Dara and Lybia breed up whole flocks of them, and they are tamed with very little trouble. But it is not for their feathers alone that they are prized in this domeſtic ſtate; they are often ridden upon and uſed as horſes. Moore aſſures us, that at Joar he ſaw a man travelling upon an oſtrich; and Adanſon aſſerts, that at the factory of Podore he had two oſtriches, which were then young, the ſtrongeſt of which ran ſwifter than the beſt Engliſh racer, although he carried two negroes on his back. As ſoon as the animal perceived that it was thus loaded, it ſet off running with all its force, and made ſeveral circuits round the village; till at length the people were obliged to ſtop it by barring up the way. How far this ſtrength and ſwiftneſs may be uſeful to mankind, even in a poliſhed ſtate, is a matter that perhaps deſerves inquiry.

II. The CASSOWARY (the *Caſuarius* of Linnæus, and *Galeated Caſſowary* of Dr Latham) was firſt brought into Europe from Java by the Dutch about the year 1597. It is nearly equal in ſize to the oſtrich, but its legs are much thicker and ſtronger in proportion. This conformation gives it an air of ſtrength and force, which the fierceneſs and ſingularity of its countenance conſpire to render formidable. It is five feet and an half long from the point of the bill to the extremity of the claws. The legs are two feet and an half high from the belly to the end of the claws. The head and neck together are a foot and an half; and the largeſt toe, including the claw, is five inches long. The claw alone of the leaſt toe is three inches and a half in length. The wing is ſo ſmall that it does not appear, it being hid under the feathers of the back. In other birds, a part of the feathers ſerve for flight, and are different from thoſe that ſerve merely for covering; but in the caſſowary all the feathers are of the ſame kind, and outwardly of the ſame colour. They are generally double, having two long ſhafts, which grow out of a ſhort one, which is fixed in the ſkin. Thoſe that are double are always of an unequal length; for ſome are 14 inches long, particularly on the rump, while others are not above three. The beards that adorn the ſtem or ſhaft are about half-way to the end, very long, and as thick as an horſe-hair, without being ſubdivided into fibres. The ſtem or ſhaft is flat, ſhining, black, and knotted below; and from each knot there proceeds a beard; likewiſe the beards at the end of the large feathers are perfectly black, and towards the root of a grey tawny colour; ſhorter, more ſoft, and throwing out fine fibres like down; ſo that nothing appears except the ends, which are hard and black; becauſe the other part, compoſed of down, is quite covered. There are feathers on the head and neck; but they are ſo ſhort and thinly ſown, that the bird's ſkin appears naked, except towards the hidder part of the head, where they are a little longer. The feathers which adorn the rump are extremely thick; but do not differ in other reſpects from the reſt, excepting their being longer. The wings, when they are deprived of their feathers, are but three inches long; and the feathers are like thoſe on other parts of the body. The ends of the wings are adorned with five prickles, of different lengths and thickneſs, which bend like a bow: theſe are hollow from the roots to the very points, having only that ſlight ſubſtance within which all quills are known to have. The longeſt of theſe prickles is 11 inches; and it is a quarter of an inch in diameter at the root, being thicker there than towards the extremity; the point ſeems broken off.

Stylephorus chordatus

Styrax Benzoin



Sugar Cane

Struthio (Ostrich)

Grav'd by James Akin

Struthio. The part, however, which moſt diſtinguiſhes this animal is the head; which, though ſmall, like that of an oſtrich, does not fail to inſpire ſome degree of terror. It is bare of feathers, and is in a manner armed with an helmet of horny ſubſtance, that covers it from the root of the bill to near half the head backwards. This helmet is black before and yellow behind. Its ſubſtance is very hard, being formed by the elevation of the bone of the ſkull; and it conſiſts of ſeveral plates, one over another, like the horn of an ox. Some have ſuppoſed that this was ſhed every year with the feathers; but the moſt probable opinion is, that it only exfoliates ſlowly like the beak. To the peculiar oddity of this natural armour may be added the colour of the eye in this animal, which is a bright yellow; and the globe being above an inch and a half in diameter, give it an air equally fierce and extraordinary. The hole of the ear is very large and open, being only covered with ſmall black feathers. The ſides of the head, about the eye and ear, being deſtitute of any covering, are blue, except the middle of the lower eyelid, which is white. The part of the bill which anſwers to the upper jaw in other animals is very hard at the edges above, and the extremity of it is like that of a turkey-cock. The end of the lower mandible is ſlightly notched, and the whole is of a greyiſh brown, except a green ſpot on each ſide. As the beak admits a very wide opening, this contributes not a little to the bird's menacing appearance. The neck is of a violet colour, inclining to that of ſlate; and it is red behind in ſeveral places, but chiefly in the middle. About the middle of the neck before, at the riſe of the large feathers, there are two proceſſes formed by the ſkin, which reſemble ſomewhat the gills of a cock, but that they are blue as well as red. The ſkin which covers the forepart of the breaſt, on which this bird leans and reſts, is hard, callous, and without feathers. The thighs and legs are covered with feathers, and are extremely thick, ſtrong, ſtraight, and covered with ſcales of ſeveral ſhapes; but the legs are thicker a little above the foot than in any other place. The toes are likewiſe covered with ſcales, and are but three in number; for that which ſhould be behind is wanting. The claws are of a hard ſolid ſubſtance, black without and white within.

The internal parts are equally remarkable. The caſſowary unites with the double ſtomach of animals that live upon vegetables the ſhort inteſtines of thoſe that live upon fleſh. The inteſtines of the caſſowary are 13 times ſhorter than thoſe of the oſtrich. The heart is very ſmall, being but an inch and an half long, and an inch broad at the baſe. Upon the whole, it has the head of a warrior, the eye of a lion, the defence of a porcupine, and the ſwiftneſs of a courſer.

Thus formed for a life of hoſtility, for terrifying others, and for its own defence, it might be expected that the caſſowary was one of the moſt fierce and terrible animals of the creation. But nothing is ſo oppoſite to its natural character: it never attacks others; and inſtead of the bill, when attacked, it rather makes uſe of its legs, and kicks like a horſe, or runs againſt its purſuer, beats him down, and treads him to the ground.

The manner in which this animal moves is not leſs extraordinary than its appearance. Inſtead of going directly forward, it ſeems to kick up behind with one leg; and then making a bound onward with the other, it goes with ſuch prodigious velocity, that the ſwifteſt racer would be left far behind.

The ſame degree of voraciouſneſs which we perceived in the oſtrich obtains as ſtrongly here. The caſſowary ſwallows every thing that comes within the capacity of its gullet. The Dutch aſſert, that it can devour not only glaſs, iron, and ſtones, but even live and burning coals, without teſtifying the ſmalleſt fear or feeling the leaſt injury. It is ſaid, that the paſſage of the food through its gullet is performed ſo ſpeedily, that even the very eggs which it has ſwallowed whole paſs through it unbroken in the ſame form they went down. In fact, the alimentary canal of this animal, as was obſerved above, is extremely ſhort; and it may happen, that many kinds of food are indigeſtible in its ſtomach, as wheat or currants are to man, when ſwallowed whole. Struthio ‖ Strymon.

The caſſowary's eggs are of a grey-aſh colour, inclining to green. They are not ſo large nor ſo round as thoſe of the oſtrich. They are marked with a number of little tubercles of a deep green, and the ſhell is not very thick. The largeſt of theſe is found to be 15 inches round one way, and about 12 the other.

The ſouthern parts of the moſt eaſtern Indies ſeem to be the natural climate of the caſſowary. His domain, if we may ſo call it, begins where that of the oſtrich terminates. The latter has never been found beyond the Ganges; while the caſſowary is never ſeen nearer than the iſlands of Banda, Sumatra, Java, the Molucca iſlands, and the correſponding parts of the continent. Yet even here this animal ſeems not to have multiplied in any conſiderable degree, as we find one of the kings of Java making a preſent of one of theſe birds to the captain of a Dutch ſhip, conſidering it as a very great rarity.

2. The *Caſuarius Novæ Hollandiæ*, or New Holland caſſowary, differs conſiderably from the common caſſowary. It is a much larger bird, ſtanding higher on its legs, and having the neck longer than in the common one. Total length ſeven feet two inches. The bill is not greatly different from that of the common caſſowary; but the horny appendage or helmet on the top of the head in this ſpecies is totally wanting: the whole of the head and neck is alſo covered with feathers, except the throat and fore part of the neck about half way, which are not ſo well feathered as the reſt; whereas in the common caſſowary the head and neck are bare and carunculated as in the turkey. Governor Phillip's Voyage to Botany Bay.

The plumage in general conſiſts of a mixture of brown and grey, and the feathers are ſomewhat curled or bent at the ends in the natural ſtate: the wings are ſo very ſhort as to be totally uſeleſs for flight, and indeed are ſcarcely to be diſtinguiſhed from the reſt of the plumage, were it not for their ſtanding out a little. The long ſpines which are ſeen in the wings of the common ſort are in this not obſervable, nor is there any appearance of a tail. The legs are ſtout, formed much as in the galeated caſſowary, with the addition of their being jagged or ſawed the whole of their length at the back part.

This bird is not uncommon in New Holland, as ſeveral of them have been ſeen about Botany Bay and other parts. Although it cannot fly, it runs ſo ſwiftly, that a greyhound can ſcarcely overtake it. The fleſh is ſaid to be in taſte not unlike beef.

STRUTHIOLA, in botany; a genus of plants belonging to the claſs of *tetrandria*, and order of *monogynia*. The corolla is wanting; the calyx is tubulous, with eight glandules at its mouth; the berry is without juice, and monoſpermous. The ſpecies are three, the virgata, erecta, and nana, all of foreign extraction.

STRYCHNOS, in botany: A genus of plants belonging to the claſs of *pentandria*, and order of *monogynia*; and in the natural ſyſtem ranging under the 28th order, *Luridæ*. The corolla is quinquefid; the berry is unilocular, with a woody bark. The ſpecies are three, the nux vomica, colubrina, and potatorum, natives of foreign countries.

STRYMON (anc. geog.), formerly *Conozus*; a river conſtituting

Strype, Stuart.

ſtituting the ancient limits of Macedonia and Thrace; riſing in mount Scombrus (Ariſtotle). Authors differ as to the modern name of this river.

STRYPE (John), was deſcended from a German family, born at London, and educated at Cambridge. He was vicar of Low Layton in Eſſex, and diſtinguiſhed himſelf by his compilations of Lives and Memoirs; in which, as Dr Birch remarks, his fidelity and induſtry will always give a value to his writings, however deſtitute they may be of the graces of ſtyle. He died in 1737, after having enjoyed his vicarage near 68 years.

STUART (Dr Gilbert), was born at Edinburgh in the year 1742. His father Mr George Stuart was profeſſor of humanity in the univerſity, and a man of conſiderable eminence for his claſſical taſte and literature. For theſe accompliſhments he was probably indebted in no ſmall degree to his relation the celebrated Ruddiman, with whom both he and his ſon converſed familiarly though they afterwards united to injure his fame.

Gilbert having finiſhed his claſſical and philoſophical ſtudies in the grammar ſchool and univerſity, applied himſelf to juriſprudence, without following or probably intending to follow the profeſſion of the law. For that profeſſion he has been repreſented as unqualified by indolence; by a paſſion which at a very early period of life he diſplayed for general literature; or by boundleſs diſſipation:—and all theſe circumſtances may have contributed to make him relinquiſh purſuits in which he could hope to ſucceed only by patient perſeverance and ſtrict decorum of manners. That he did not waſte his youth in idleneſs, is, however, evident from An Hiſtorical Diſſertation concerning the Antiquity of the Britiſh Conſtitution, which he publiſhed before he had completed his twenty-ſecond year, and which had ſo much merit as to induce the univerſity of Edinburgh to confer upon the author, though ſo young a man, the degree of LL.D.

After a ſtudious interval of ſome years, he produced a valuable work, under the title of A View of Society in Europe, in its Progreſs from Rudeneſs to Refinement; or, Inquiries concerning the Hiſtory of Laws, Government, and Manners. He had read and meditated with patience on the moſt important monuments of the middle ages; and in this volume (which ſpeedily reached a ſecond edition) he aimed chiefly at the praiſe of originality and invention, and diſcovered an induſtry that is ſeldom connected with ability and diſcernment. About the time of the publication of the firſt edition of this performance, having turned his thoughts to an academical life, he aſked for the profeſſorſhip of public law in the univerſity of Edinburgh. According to his own account he had been promiſed that place by the miniſter, but had the mortification to ſee the profeſſorſhip beſtowed on another, and all his hopes blaſted by the influence of Dr Robertſon, whom he repreſented as under obligations to him.

To the writer of this article, who was a ſtranger to theſe rival candidates for hiſtorical fame, this part of the ſtory ſeems very incredible; as it is not eaſy to conceive how it ever could be in the power of Dr Stuart to render to the learned Principal any eſſential ſervice. It was believed indeed by the earl of Buchan, and by others, who obſerved that the illiberal jealouſy not unfrequent in the world of letters, was probably the ſource of this oppoſition; which entirely broke the intimacy of two perſons who, before that time, were underſtood to be on the moſt friendly footing with each other. Ingratitude, however, is as likely to have been the vice of Dr Stuart as of Dr Robertſon; for we have been told by a writer,* who, at leaſt in one inſtance, has completely proved what he affirms, that "ſuch was Gilbert Stuart's laxity of principle as a man, that he conſidered ingratitude as one of the moſt venial ſins; ſuch was his conceit as a writer, that he regarded no one's merits but his own; ſuch were his diſappointments, both as a writer and a man, that he allowed his peeviſhneſs to ſour into malice, and indulged his malevolence till it ſettled in corruption."

* Chalmers in his life of Ruddiman.

Stuart, Stucco.

Soon after this diſappointment Dr Stuart went to London, where he became from 1768 to 1774 one of the writers of the Monthly Review. In 1772 Dr Adam, rector of the high ſchool at Edinburgh, publiſhed a Latin Grammar, which he intended as an improvement of the famous Ruddiman's. Stuart attacked him in a pamphlet under the name of *Buſhby*, and treated him with much ſeverity. In doing this, he was probably actuated more by ſome perſonal diſlike of Dr Adam than by regard for the memory of his learned relation; for on other occaſions he ſhowed ſufficiently that he had no regard to Ruddiman's honour as a grammarian, editor, or critic.

In 1774 he returned to his native city, and began the Edinburgh Magazine and Review, in which he diſcuſſed the liberty and conſtitution of England, and diſtinguiſhed himſelf by an inquiry into the character of John Knox the reformer, whoſe principles he reprobated in the ſevereſt terms. About this time he reviſed and publiſhed Sullivan's Lectures on the Conſtitution of England. Soon after he turned his thoughts to the hiſtory of Scotland, and publiſhed Obſervations concerning its Public Law and Conſtitutional Hiſtory; in which he examined with a critical care the preliminary book to Dr Robertſon's Hiſtory. His next work was The Hiſtory of the Reformation; a book which deſerves praiſe for the eaſy dignity of the narrative, and for ſtrict impartiality. His laſt great work, The Hiſtory of Scotland from the Eſtabliſhment of the Reformation to the Death of Queen Mary, which appeared in 1782, has been very generally read and admired. His purpoſe was to vindicate the character of the injured queen, and expoſe the weakneſs of the arguments by which Dr Robertſon had endeavoured to prove her guilty: but though the ſtyle of this work is his own, it contains very little matter which was not furniſhed by Goodall and Tytler; and it is with the arms which theſe two writers put into his hands that Dr Stuart vanquiſhed his great antagoniſt.

In 1782 he once more viſited London, and engaged in the Political Herald and Engliſh Review; but the jaundice and dropſy increaſing on him, he returned by ſea to his native country, where he died in the houſe of his father on the 13th of Auguſt 1786.

In his perſon Dr Stuart was about the middle ſize and juſtly proportioned. His countenance was modeſt and expreſſive, ſometimes glowing with ſentiments of friendſhip, of which he was truly ſuſceptible, and at others darting that ſatire and indignation at folly and vice which appear in ſome of his writings. He was a boon companion; and, with a conſtitution that might have ſtood the ſhock of ages, he fell a premature martyr to intemperance. His talents were certainly great, and his writings are uſeful; but he ſeems to have been influenced more by paſſion than prejudice, and in his character there was not much to be imitated.

STUCCO, in building a compoſition of white marble pulveriſed, and mixed with plaſter of lime; and the whole being ſifted and wrought up with water, is to be uſed like common plaſter: this is called by Pliny *marmoratum opus* and *albarium opus*.

A patent has been granted to Mr B. Higgins for inventing a new kind of ſtucco, or water-cement, more firm and durable than any heretofore. Its compoſition, as extracted

Stucco. tracted from the ſpecification ſigned by himſelf, is as follows: "Drift-ſand, or quarry (A) ſand, which conſiſts chiefly of hard quartoſe flat-faced grains with ſharp angles; which is the freeſt, or may be moſt eaſily freed by waſhing, from clay, ſalts, and calcareous, gypſeous, or other grains leſs hard and durable than quartz; which contains the ſmalleſt quantity of pyrites or heavy metallic matter inſeparable by waſhing; and which ſuffers the ſmalleſt diminution of its bulk in waſhing in the following manner—is to be preferred before any other. And where a coarſe and a fine ſand of this kind, and correſponding in the ſize of their grains with the coarſe and fine ſands hereafter deſcribed, cannot be eaſily procured, let ſuch ſand of the foregoing quality be choſen as may be ſorted and cleanſed in the following manner:

"Let the ſand be ſifted in ſtreaming clear water, thro' a ſieve which ſhall give paſſage to all ſuch grains as do not exceed one-ſixteenth of an inch in diameter; and let the ſtream of water and the ſifting be regulated ſo that all the ſand, which is much finer than the Lynn-ſand commonly uſed in the London glaſs-houſes, together with clay and every other matter ſpecifically lighter than ſand, may be waſhed away with the ſtream, whilſt the purer and coarſer ſand, which paſſes through the ſieve, ſubſides in a convenient receptacle, and whilſt the coarſe rubbiſh and rubble remain on the ſieve to be rejected.

"Let the ſand which thus ſubſides in the receptacle be waſhed in clean ſtreaming water through a finer ſieve, ſo as to be further cleanſed and ſorted into two parcels; a coarſer, which will remain in the ſieve which is to give paſſage to ſuch grains of ſand only as are leſs than one-thirtieth of an inch in diameter, and which is to be ſaved apart under the name of *coarſe ſand*; and a finer, which will paſs thro' the ſieve and ſubſide in the water, and which is to be ſaved apart under the name of *fine ſand*.—Let the coarſe and the fine ſand be dried ſeparately, either in the ſun or on a clean iron-plate, ſet on a convenient ſurface, in the manner of a ſand-heat (B). Stucco.

"Let lime be choſen (C) which is ſtone-lime, which heats the moſt in ſlaking, and ſlakes the quickeſt when duly watered; which is the freſheſt made and cloſeſt kept; which diſſolves in diſtilled vinegar with the leaſt effervescence, and leaves the ſmalleſt reſidue inſoluble, and in this reſidue the ſmalleſt quantity of clay, gypſum, or martial matter.

"Let the lime choſen according to theſe important rules be put in a braſs-wired ſieve to the quantity of 14 pounds. Let the ſieve be finer than either of the foregoing; the finer, the better it will be: let the lime be ſlaked (D) by plunging it in a butt filled with ſoft water, and raiſing it out quickly and ſuffering it to heat and fume, and by repeating this plunging and raiſing alternately, and agitating the lime, until it be made to paſs through the ſieve into the water; and let the part of the lime which does not eaſily paſs through the ſieve be rejected: and let freſh portions of the lime be thus uſed, until as many (E) ounces of lime have paſſed through the ſieve as there are quarts of water in the butt. Let the water thus impregnated ſtand in the butt cloſely covered (F) until it becomes clear; and through wooden (G) cocks placed at different heights in the butt, let the clear liquor be drawn off as faſt (H) and as low as the lime ſubſides, for uſe. This clear liquor I call the *cementing liquor* (I). The freer the water is from ſaline matter, the better will be the cementing liquor made with it.

(A) "This is commonly called *pit-ſand*.

(B) "The ſand ought to be ſtirred up continually until it is dried, and is then to be taken off; for otherwiſe the evaporation will be very ſlow, and the ſand which lies next the iron plate, by being overheated, will be diſcoloured.

(C) "The perference given to ſtone-lime is founded on the preſent practice in the burning of lime, and on the cloſer texture of it, which prevents it from being ſo ſoon injured by expoſure to the air as the more ſpongy chalk-lime is; not on the popular notion that ſtone-lime has ſomething in it whereby it excels the beſt chalk in the cementing properties. The gypſum contained in lime-ſtone remains unaltered, or very little altered, in the lime, after the burning; but it is not to be expected that clay or martial matter ſhould be found in their native ſtate in well-burned lime; for they concrete or vitrify with a part of the calcareous earth, and conſtitute the hard grains or lumps which remain undiſſolved in weak acids, or are ſeparable from the ſlaked lime by ſifting it immediately through a ſieve.

(D) "This method of impregnating the water with lime is not the only one which may be adopted. It is, however, preferred before others, becauſe the water clears the ſooner in conſequence of its being warmed by the ſlaking lime; and the gypſeous part of the lime does not diffuſe itſelf in the water ſo freely in this way as it does when the lime is ſlaked to fine powder in the common method, and is then blended with the water; for the gypſeous part of the lime ſlakes at firſt into grains rather than into fine powder, and will remain on the ſieve after the pure lime has paſſed through, long enough to admit of the intended ſeparation; but when the lime is otherwiſe ſlaked, the gypſeous grains have time to ſlake to a finer powder, and paſſing through the ſieve, diſſolve in the water along with the lime. I have imagined that other advantages attended this method of preparing the lime-water, but I cannot yet ſpeak of them with preciſion.

(E) "If the water contains no more acidulous gas than is uſually found in river or rain water, a fourth part of this quantity of lime, or leſs, will be ſufficient.

(F) "The calcareous cruſt which forms on the ſurface of the water ought not to be broke, for it aſſiſts in excluding the air, and preventing the abſorption of acidulous gas whereby the lime-water is ſpoiled.

(G) "Braſs-cocks are apt to colour a part of the liquor.

(H) "Lime-water cannot be kept many days unimpaired, in any veſſels that are not perfectly air-tight. If the liquor be drawn off before it clears, it will contain whiting, which is injurious; and if it be not inſtantly uſed after it is drawn limpid from the butt into open veſſels, it will grow turbid again, and depoſite the lime changed to whiting by the gas abſorbed from the air. The calcareous matter which ſubſides in the butt reſembles whiting the more nearly as the lime has been more ſparingly employed; in the contrary circumſtances, it approaches to the nature of lime; and in the intermediate ſtate, it is fit for the common compoſition of the plaſterers for inſide ſtucco.

(I) "At the time of writing this ſpecification, I preferred this term before that of lime-water, on grounds which I had not ſufficiently examined.

Stucco. "Let 56 pounds of the aforeſaid choſen lime be ſlaked, by gradually ſprinkling on it, and eſpecially on the unſlaked pieces, the cementing liquor, in a cloſe (K) clean place. Let the ſlaked part be immediately (L) ſifted through the laſt-mentioned fine braſs-wired ſieve: Let the lime which paſſes be uſed inſtantly, or kept in air-tight veſſels, and let the part of the lime which does not paſs through the ſieve be rejected (M).—This finer richer part of the lime which paſſes through the ſieve I call *purified lime*.

"Let bone-aſh be prepared in the uſual manner, by grinding the whiteſt burnt bones, but let it be ſifted, to be much finer than the bone-aſh commonly ſold for making cupels.

"The moſt eligible materials for making my cement being thus prepared, take 56 pounds of the coarſe ſand and 42 pounds of the fine ſand; mix them on a large plank of hard wood placed horizontally; then ſpread the ſand ſo that it may ſtand to the height of ſix inches, with a flat ſurface on the plank; wet it with the cementing liquor; and let any ſuperfluous quantity of the liquor, which the ſand in the condition deſcribed cannot retain, flow away off the plank. To the wetted ſand add 14 pounds of the purified lime in ſeveral ſucceſſive portions, mixing and beating them up together in the mean time with the inſtruments generally uſed in making fine mortar: then add 14 pounds of the bone-aſh in ſucceſſive portions, mixing and beating all together. The quicker and the more perfectly theſe materials are mixed and beaten together, and the ſooner the cement thus formed is uſed, the better (N) it will be. This I call the *water-cement coarſe-grained*, which is to be applied in building, pointing, plaſtering, ſtuccoing, or other work, as mortar and ſtucco now are; with this difference chiefly, that as this cement is ſhorter than mortar or common ſtucco, and dries ſooner, it ought to be worked expeditiouſly in all caſes; and in ſtuccoing, it ought to be laid on by ſliding the trowel upwards on it; that the materials uſed along with this cement in building, or the ground on which it is to be laid in ſtuccoing, ought to be well wetted with the cementing liquor in the inſtant of laying on the cement; and that the cementing liquor is to be uſed when it is neceſſary to moiſten the cement, or when a liquid is required to facilitate the floating of the cement.

"When ſuch cement is required to be of a finer texture, take 98 pounds of the fine ſand, wet it with the cementing liquor, and mix it with the purified lime and the bone-aſh in the quantities and in the manner above deſcribed; with this difference only, that 15 pounds of lime, or (O) thereabouts, are to be uſed inſtead of 14 pounds, if the greater part of the ſand be as fine as Lynn ſand. This I call *water-cement fine-grained*. It is to be uſed in giving the laſt coating, or the finiſh to any work intended to imitate the finer-grained ſtones or ſtucco. But it may be applied to all the uſes of the water-cement coarſe-grained, and in the ſame manner. Stucco.

"When for any of the foregoing purpoſes of pointing, building, &c. ſuch a cement is required much cheaper and coarſer-grained, then much coarſer clean ſand than the foregoing coarſe ſand, or well waſhed fine rubble, is to be provided. Of this coarſe ſand or rubble take 56 pounds, of the foregoing coarſe ſand 28 pounds, and of the fine ſand 14 pounds; and after mixing theſe, and wetting them with the cementing liquor in the foregoing manner, add 14 pounds. or ſomewhat leſs, of the (P) purified lime, and then 14 pounds or ſomewhat leſs of the bone-aſh, mixing them together in the manner already deſcribed. When my cement is required to be white, white ſand, white lime, and the whiteſt bone-aſh are to be choſen. Grey ſand, and grey bone-aſh formed of half-burnt bones, are to be choſen to make the cement grey; and any other colour of the cement is obtained, either by chooſing coloured ſand, or by the admixture of the neceſſary quantity of coloured talc in powder, or of coloured, vitreous, or metallic powders, or other durable colouring ingredients commonly uſed in paint.

"To the end that ſuch a water-cement as I have deſcribed may be made as uſeful as it is poſſible in all circumſtances; and that no perſon may imagine that my claim and right under theſe letters-patent may be eluded by divers variations, which may be made in the foregoing proceſs without producing any notable defect in the cement; and to the end that the principles of this art, as well as the art itſelf, of making my cement, may be gathered from this ſpecification and perpetuated to the public; I ſhall add the following obſervations:

"This my water-cement, whether the coarſe or fine grained, is applicable in forming artificial ſtone, by making alternate layers of the cement and of flint, hard ſtone, or brick,

---

(K) "The vapour which ariſes in the ſlaking of lime contributes greatly to the ſlaking of theſe pieces which lie in its way; and an unneceſſary waſte of the liquor is prevented, by applying it to the lime heaped in a pit or in a veſſel, which may reſtrain the iſſue of the vapour, and direct it through the maſs. If more of the liquor be uſed than is neceſſary to ſlake the lime, it will create error in weighing the ſlaked powder, and will prevent a part of it from paſſing freely thro' the ſieve. The liquid is therefore to be uſed ſparingly, and the lime which has eſcaped its action is to be ſprinkled apart with freſh liquor.

(L) "When the aggregation of the lumps of lime is thus broken, it is impaired much ſooner than it is in the former ſtate, becauſe the air more freely pervades it.

(M) "Becauſe it conſiſts of heterogeneous matter or of ill-burnt lime; which laſt will ſlake and paſs through the ſieve, if the lime be not immediately ſifted after the ſlaking agreeable to the text.

(N) "Theſe proportions are intended for a cement made with ſharp ſand, for incruſtation in expoſed ſituations, where it is neceſſary to guard againſt the effects of hot weather and rain. In general, half this quantity of bone-aſhes will be found ſufficient; and although the incruſtation in this latter caſe will not harden deeply ſo ſoon, it will be ultimately ſtronger, provided the weather be favourable.

"The injuries which lime and mortar ſuſtain by expoſure to the air, before the cement is finally placed in a quieſcent ſtate, are great; and therefore our cement is the worſe for being long beaten, but the better as it is quickly beaten until the mixture is effected, and no longer.

(O) "The quantity of bone-aſhes is not to be increaſed with that of the lime; but it is to be leſſened as the expoſure and purpoſes of the work will admit.

(P) "Becauſe leſs lime is neceſſary, as the ſand is coarſer.

Stucco. brick, in moulds of the figure of the intended ſtone, and by expoſing the maſſes ſo formed to the open (Q) air to harden.

"When ſuch cement is required for water (R) fences, two thirds of the preſcribed quantity of bone-aſhes are to be omitted; and in the place thereof an equal meaſure of powdered terras is to be uſed; and if the ſand employed be not of the coarſeſt ſort, more terras muſt be added, ſo that the terras ſhall be by weight one-ſixth part of the weight of the ſand.

"When ſuch a cement is required of the fineſt grain (S) or in a fluid form, ſo that it may be applied with a bruſh, flint powder, or the powder of any quartoſe or hard earthy ſubſtance, may be uſed in the place of ſand; but in a quantity ſmaller, as the flint or other powder is finer; ſo that the flint-powder, or other ſuch powder, ſhall not be more than ſix times the weight of the lime, nor leſs than four times its weight. The greater the quantity of lime within theſe limits, the more will the cement be liable to crack by quick drying, and *vice verſa*.

"Where ſuch ſand as I prefer cannot be conveniently procured, or where the ſand cannot be conveniently waſhed and ſorted, that ſand which moſt reſembles the mixture of coarſe and fine ſand above preſcribed, may be uſed as I have directed, provided due attention is paid to the quantity of the lime, which is to be greater (T) as the quantity is finer, and *vice verſa*.

"Where ſand cannot be eaſily procured, any durable ſtony body, or baked earth groſsly powdered (U), and ſorted nearly to the ſizes above preſcribed for ſand, may be uſed in the place of ſand, meaſure for meaſure, but not weight for weight, unleſs ſuch groſs powder be as heavy ſpecifically as ſand.

"Sand may be cleanſed from every ſofter, lighter, and leſs durable matter, and from that part of the ſand which is too fine, by various methods preferable (X), in certain circumſtances, to that which I have deſcribed.

"Water may be found naturally free from fixable gas, ſelenite, or clay; ſuch water may, without any notable inconvenience, be uſed in the place of the cementing liquor; and water approaching this ſtate will not require ſo much lime as I have ordered to make the cementing liquor; and a cementing liquor ſufficiently uſeful may be made by various methods of mixing lime and water in the deſcribed proportions, or nearly ſo. Stucco.

"When ſtone-lime cannot be procured, chalk-lime, or ſhell-lime, which beſt reſembles ſtone-lime, in the characters above written of lime, may be uſed in the manner deſcribed, except that fourteen pounds and a half of chalk-lime will be required in the place of fourteen pounds of ſtone-lime. The proportion of lime which I have preſcribed above may be increaſed without inconvenience, when the cement or ſtucco is to be applied where it is not liable to dry quickly; and in the contrary circumſtance, this proportion may be diminiſhed; and the defect of lime in quantity or quality may be very advantageouſly ſupplied (Y), by cauſing a conſiderable quantity of the cementing liquor to ſoak into the work, in ſucceſſive portions, and at diſtant intervals of time, ſo that the calcareous matter of the cementing liquor, and the matter attracted from the open air, may fill and ſtrengthen the work.

"The powder of almoſt every well-dried or burnt animal ſubſtance may be uſed inſtead of bone-aſh; and ſeveral earthy powders, eſpecially the micaceous and the metallic; and the elixated aſhes of divers vegetables whoſe earth will not burn to lime; and the aſhes of mineral fuel, which are of the calcareous kind, but will not burn to lime, will anſwer the ends of bone-aſh in ſome degree.

"The quantity of bone-aſh deſcribed may be leſſened without injuring the cement, in thoſe circumſtances eſpecially which admit the quantity of lime to be leſſened, and in thoſe wherein the cement is not liable to dry quickly. And the art of remedying the defects of lime may be advantageouſly practiſed to ſupply the deficiency of bone-aſh, eſpecially in building, and in making artificial ſtone with this cement."

STUD,

(Q) "But they muſt not be expoſed to the rain until they are almoſt as ſtrong as freſh Portland ſtone; and even then they ought to be ſheltered from it as much as the circumſtances will admit. Theſe ſtones may be made very hard and beautiful, with a ſmall expence of bone-aſh, by ſoaking them, after they have dried thoroughly and hardened, in the lime liquor, and repeating this proceſs twice or thrice, at diſtant intervals of time. The like effect was experienced in incruſtations.

(R) "In my experiments, mortar made with terras-powder, in the uſual method, does not appear to form ſo ſtrong a cement for water-fences as that made, according to the ſpecification, with coarſe ſand; and I ſee no more reaſon for avoiding the uſe of ſand in terras-mortar, than there would be for rejecting ſtone from the embankment. The bone-aſhes meant in this place are the dark grey or black ſort. I am not yet fully ſatisfied about the operation of them in this inſtance.

(S) "The qualities and uſes of ſuch fine calcareous cement are recommended chiefly for the purpoſe of ſmoothing and finiſhing the ſtronger cruſtaceous works, or for waſhing walls to a lively and uniform colour. For this laſt intention, the mixture muſt be as thin as new cream, and laid on briſkly with a bruſh, in dry weather; and a thick and durable coat is to be made by repeated waſhing; but is not to be attempted by uſing a thicker liquor; for the coat made with this laſt is apt to ſcale, whilſt the former endures the weather much longer than any other thin calcareous covering that has been applied in this way. Fine yellow-ochre is the cheapeſt colouring ingredient for ſuch waſh, when it is required imitate Bath-ſtone, or the warm-white ſtones.

(T) "If ſea ſand be well waſhed in freſh water, it is as good as any other round ſand.

(U) "The cement made with theſe and the proper quantities of purified lime and lime-water, are inferior to the beſt, as the grains of theſe powders are more periſhable and brittle than thoſe of ſand. They will not therefore be employed, unleſs for the ſake of evaſion, or for want of ſand: in this latter caſe, the finer powder ought to be waſhed away.

(X) "This and the next paragraph is inſerted with a view to evaſions, as well as to ſuggeſt the eaſier and cheaper methods which may be adopted in certain circumſtances, by artiſts who underſtand the principles which I endeavoured to teach.

(Y) "This practice is noticed, as the remedy which may be uſed for the defects ariſing from evaſive meaſures, and as the method of giving ſpongy incruſtations containing bone-aſhes the greateſt degree of hardneſs."

Stud ‖ Sturmius.

STUD, in the manege, a collection of breeding horſes and mares.

STUDDING-SAILS, certain light ſails extended, in moderate and ſteady breezes, beyond the ſkirts of the principal ſails, where they appear as wings upon the yard-arms.

STUFF, in commerce, a general name for all kinds of fabrics of gold, ſilver, ſilk, wool, hair, cotton, or thread, manufactured on the loom; of which number are velvets, brocades, mohairs, ſatins, taffetas, cloths, ſerges, &c.

STUKELY (Dr William), a celebrated antiquarian, deſcended from an ancient family in Lincolnſhire, was born at Holbech in 1687, and educated in Bennet college, Cambridge. While an under-graduate, he often indulged a ſtrong propenſity to drawing and deſigning; but made phyſic his principal ſtudy, and firſt began to practiſe at Boſton in his native country. In 1717 he removed to London, where, on the recommendation of Dr Mead, he was ſoon after elected a fellow of the Royal Society; he was one of the firſt who revived that of the antiquarians in 1718, and was their ſecretary for many years during his reſidence in town. In 1729 he took holy orders by the encouragement of archbiſhop Wake; and was ſoon after preſented by lord-chancellor King with the living of All-Saints in Stamford. In 1741 he became one of the founders of the Egyptian ſociety, which brought him acquainted with the benevolent duke of Montague, one of the members: who prevailed on him to leave Stamford, and preſented him to the living of St George the Martyr, Queen Square. He died of a ſtroke of the palſy in 1765. In his phyſical capacity, his Diſſertation on the Spleen was well received; and his *Itinerarium Curioſum*, the firſt fruit of his juvenile excurſions, was a good ſpecimen of what was to be expected from his riper age. His great learning, and profound reſearches into the dark remains of antiquity, enabled him to publiſh many elaborate and curious works: his friends uſed to call him the *arch-druid* of his age. His diſcourſes, intitled *Palæographia Sacra*, on the vegetable creation, beſpeak him a botaniſt, philoſopher, and divine.

STUM, in the wine-trade, denotes the unfermented juice of the grape after it has been ſeveral times racked off and ſeparated from its ſediment. The caſks are for this purpoſe well matched or fumigated with brimſtone every time, to prevent the liquor from fermenting, as it would otherwiſe readily do, and become wine. See MUST.

STUPIDITY. The Greek word μωρότης correſponds moſt with our Engliſh word *ſtupidity* or *fooliſhneſs*, when uſed to expreſs that ſtate of mind in which the intellects are defective. The immediate cauſes are ſaid to be, a deficiency of vital heat, or a defect in the brain. Stupid children ſometimes become ſprightly youths; but if ſtupidity continues to the age of puberty, it is hardly ever removed. If ſtupidity follows upon a violent paſſion, an injury done to the head, or other evident cauſe, and if it continues long, it becomes incurable. But the ſtupidity which conſiſts in a loſs of memory, and ſucceeds a lethargy, ſpontaneouſly ceaſes when the lethargy is cured.

STUPOR, a numbneſs in any part of the body, whether occaſioned by ligatures obſtructing the blood's motion, by the palſy, or the like.

STUPPA, or STUPE, in medicine, is a piece of cloth dipped in ſome proper liquor, and applied to an affected part.

STURDY, a diſtemper to which cattle are ſubject, called alſo the *turning evil*. See FARRIERY.

STURGEON. See ACCIPENSER.

STURMIUS (John), a learned philologer and rhetorician, was born at Sleida in Eiſel near Cologne in 1507. He ſtudied at firſt in his native country with the ſons of count de Manderſcheld, whoſe receiver his father was. He afterwards purſued his ſtudy at Liege in the college of St Jerom, and then went to Louvain in 1524. Five years he ſpent there, three in learning and two in teaching. He ſet up a printing-preſs with Rudger Reſcius profeſſor of the Greek tongue, and printed ſeveral Greek authors. He went to Paris in 1529, where he was highly eſteemed, and read public lectures on the Greek and Latin writers, and on logic. He married there, and kept a great number of boarders: but as he liked what were called the *new opinions*, he was more than once in danger; and this undoubtedly was the reaſon why he removed to Straſburgh in 1537, in order to take poſſeſſion of the place offered him by the magiſtrates. The year following he opened a ſchool, which became famous, and by his means obtained of Maximilian II. the title of an univerſity in 1566. He was very well ſkilled in polite literature, wrote Latin with great purity, and was a good teacher. His talents were not confined to the ſchool; for he was frequently intruſted with deputations in Germany and foreign countries, and diſcharged theſe employments with great honour and diligence. He ſhowed extreme charity to the refugees on account of religion: He not only laboured to aſſiſt them by his advice and recommendations; but he even impoveriſhed himſelf for them. He died in his 82d year, after he had been for ſome time blind. He publiſhed many books; the principal of which are, 1. *Partitiones Dialecticæ*. 2. *De Educatione Principum*. 3. *De Nobilitate Anglicana*. 4. *Linguæ Latinae reſolvendæ Ratio*. 5. Excellent notes on Ariſtotle's and Hermogenes's Rhetoric, &c. Sturmius, Sturnus.

He ought not to be confounded with *John Sturmius*, a native of Mechlin, and phyſician and profeſſor of mathematics at Louvain, who alſo wrote ſeveral works.

STURNUS, the STARLING; a genus of birds belonging to the order of *paſſeres*. The beak is ſubulated, depreſſed, and ſomewhat blunt; the ſuperior mandible is entire, and ſomewhat open at the edges; the noſtrils are marginated above; and the tongue is ſharp and emarginated. There are 15 ſpecies according to Dr Latham; the vulgaris, capenſis, ludovicianus, militaris, cellaris, carunculatus, gallinaceus, ſericeus, viridis, olivaceus, mauritanicus, loyca, dauuricus, junceti, and mexicanus.

The *vulgaris*, or common ſtarling, is the only ſpecies of the ſturnus that is indigenous. The weight of the male of this ſpecies is about three ounces; that of the female rather leſs. The length is eight inches three quarters: the bill is brown or yellow, but in old birds generally yellow. The whole plumage is black, very reſplendant, with changeable blue, purple, and copper: each feather marked with a pale yellow ſpot. The leſſer coverts are edged with yellow, and ſlightly gloſſed with green. The quill-feathers and tail duſky: the former edged with yellow on the exterior ſide; the laſt with dirty white. The legs of a reddiſh brown. Latham's Synopſis, vol. iii.

The ſtare breeds in hollow trees, eaves of houſes, towers, ruins, cliffs, and often in high rocks over the ſea, ſuch as that of the iſle of Wight. It lays four or five eggs, of a pale-greeniſh aſh-colour; and makes its neſt of ſtraw, ſmall fibres of roots, and the like. In winter, ſtares aſſemble in vaſt flocks: they collect in myriads in the fens of Lincolnſhire, and do great damage to the fen-men, by rooſting on the reeds, and breaking them down by their weight; for reeds are the thatch of the country, and are laid up in harveſt with great care. Theſe birds feed on worms and inſects; and it is ſaid that they will get into pigeon-houſes, for the ſake of ſucking the eggs. Their fleſh is ſo bitter as to be ſcarce eatable. They are fond of following oxen and other large cattle as they feed in the meadows, attracted, it is ſaid, by the inſects which flutter round them, or by thoſe, perhaps, which

Stye, Style. Buffon's Nat Hiſtory of Birds. vol. iii.

which ſwarm in their dung, or in meadows in general. From this habit is derived the German name *Rinder Staren*. They are alſo accuſed of feeding on the carcaſes that are expoſed on gibbets; but it is probably in ſearch only of inſects. They live ſeven or eight years, or even longer, in the domeſtic ſtate. The wild ones cannot be decoyed by the call, becauſe they regard not the ſcream of the owl. A method has been diſcovered of taking entire families, by fixing to the walls and the trees where they lodge pots of earthen ware of a convenient form, which the birds often prefer to place their neſts in. Many are alſo caught by the gin and draw-net. In ſome parts of Italy it is common to employ tame weaſels to drag them out of their neſts, or rather their holes; for the artifice of man conſiſts in employing one enſlaved race to extend his dominion over the reſt.

The ſtare, it is ſaid, can be taught to ſpeak either French, German, Latin, Greek, &c. and to pronounce phraſes of ſome length. Its pliant throat accommodates itſelf to every inflection and every accent. It can readily articulate the letter R, and acquires a ſort of warbling which is much ſuperior to its native ſong. This bird is ſpread through an extenſive range in the ancient continent. It is found in Sweden, Germany, France, Italy, the Iſle of Malta, the Cape of Good Hope, and is everywhere nearly the ſame; whereas thoſe American birds which have been called ſtares, preſent a great diverſity of appearance.

STYE, or STYTHE, in the eye. See CRITHE.

STYLE, a word of various ſignifications, originally deduced from *ſtylos*, a kind of bodkin wherewith the ancients wrote on plates of lead, or on wax, &c. and which is ſtill uſed to write on ivory-leaves and paper prepared for that purpoſe, &c.

STYLE, in dialling, denotes the gnomon or cock of a dial raiſed on the plane thereof to project a ſhadow.

STYLE, in botany. See BOTANY, Sect. iv. p. 434.

STYLE, in language, is the peculiar manner in which a man expreſſes his conceptions. It is a picture of the ideas which riſe in his mind, and of the order in which they are there produced.

The qualities of a good ſtyle may be ranked under two heads; perſpicuity and ornament. It will readily be admitted, that perſpicuity ought to be eſſentially connected with every kind of writing; and to attain it, attention muſt be paid, firſt to ſingle words and phraſes, and then to the conſtruction of ſentences. When conſidered with reſpect to words and phraſes, it requires theſe three qualities; purity, propriety, and preciſion. When conſidered with regard to ſentences, it requires a clear arrangement of the words and unity in the ſenſe; to which, if ſtrength and harmony be added, the ſtyle will become ornamented.

One of the moſt important directions to be obſerved by him who wiſhes to form a good ſtyle, is to acquire clear and preciſe ideas on the ſubject concerning which he is to write or ſpeak. To this muſt be added frequency of compoſition, and an acquaintance with the ſtyle of the beſt authors. A ſervile imitation, however, of any author is carefully to be avoided; for he who copies, can hardly avoid copying faults as well as beauties. A ſtyle cannot be proper unleſs it be adapted to the ſubject, and likewiſe to the capacity of our hearers, if we are to ſpeak in public. A ſimple, clear, and unadorned ſtyle, ſuch as that of Swift, is fitteſt for intricate diſquiſition; a ſtyle elegant as Addiſon's, or impetuous like Johnſon's, is moſt proper for fixing the attention on truths; which, though known, are too much neglected. We muſt not be inattentive to the ornaments of ſtyle, if we wiſh that our labours ſhould be read and admired: but he is a contemptible writer, who looks not beyond the dreſs of language, who lays not the chief ſtreſs upon his matter, and who does not regard ornament as a ſecondary and inferior recommendation. For further obſervations on the different kinds of ſtyle, ſee ORATORY, n° 99, &c.

Style ‖ Stilites.

STYLE, in juriſprudence, the particular form or manner of proceeding in each court of juriſdiction, agreeable to the rules and orders eſtabliſhed therein: thus we ſay, the ſtyle of the court of Rome, of chancery, of parliament, of the privy-council, &c.

STYLE, in muſic, denotes a peculiar manner of ſinging, playing, or compoſing; being properly the manner that each perſon has of playing, ſinging, or teaching; which is very different both in reſpect of different geniuſes, of countries, nations, and of the different matters, places, times, ſubjects, paſſions, expreſſions, &c. Thus we ſay, the ſtyle of Paleſtrina, of Lully, of Corelli, of Handel, &c.; the ſtyle of the Italians, French, Spaniards, &c.

Old STYLE, the Julian method of computing time, as the *New* STYLE is the Gregorian method of computation. See KALENDAR.

STYLEPHORUS CHORDATUS, a genus of fiſhes belonging to the order of *apodes*. This very curious genus was diſcovered by Dr Shaw, who read a deſcription of it before the Linnæan Society in the year 1788. The eyes are fixed on cylindrical pillars which lie cloſe together. The roſtrum, or narrow part which is terminated by the mouth, is connected to the back part of the head by a flexible leathery duplicature, which permits it either to be extended in ſuch a manner that the mouth points directly upwards, or to fall back ſo as to be received into a ſort of caſe, formed by the upper part of the head. There are three pairs of branchiæ ſituate under the throat. The pectoral fins are ſmall; the dorſal fin runs from the head to within about an inch and a half of the tail; the caudal fin is ſhort, and is furniſhed with five remarkable ſpines. The body is extremely long, and compreſſed very much, and gradually diminiſhes as it approaches the tail, which terminates in a proceſs or ſtring of an enormous length, and finiſhes in a very fine point. This ſtring, or caudal proceſs, ſeems to be ſtrengthened throughout its whole length, or at leaſt as far as the eye can trace it, by a ſort of double fibre or internal part. The ſtylephorus chordatus is a native of the Weſt Indian Sea. It was taken between the iſlands of Cuba and Martinico, near a ſmall cluſter of little iſlands about nine leagues from ſhore, and was ſeen ſwimming near the ſurface. The whole length of this uncommon animal from the head to the extremity of the caudal proceſs is about thirty-two inches, of which the proceſs itſelf meaſures twenty-two.

Plate CCCCLXXXVI. Tranſactions of the Linnæan Society, vol. i.

STYLET, a ſmall dangerous kind of poniard which may be concealed in the hand, chiefly uſed in treacherous aſſaſſinations. The blade is uſually triangular, and ſo ſmall that the wound it makes is almoſt imperceptible.

STYLITES, PILLAR SAINTS, in eccleſiaſtical hiſtory, an appellation given to a kind of ſolitaries, who ſtood motionleſs upon the tops of pillars, raiſed for this exercile of their patience, and remained there for ſeveral years, amidſt the admiration and applauſe of the ſtupid populace. Of theſe we find ſeveral mentioned in ancient writers, and even as low as the twelfth century, when they were totally ſuppreſſed.

The founder of the order was St Simeon Stylites, a famous anchoret in the fifth century, who firſt took up his abode on a column ſix cubits high; then on a ſecond of twelve cubits, a third of twenty-two, a fourth of thirty-ſix, and on another of forty cubits, where he thus paſſed thirty-ſeven years of his life. The tops of theſe columns were only three feet in diameter, and were defended by a rail that reached almoſt to the girdle, ſomewhat reſembling a

pulpit

Styloceraloides ‖ Styrax.

pulpit. There was no lying down in it. The faquirs, or devout people of the Eaſt, imitate this extraordinary kind of life to this day.

STYLOCERALOIDES, STYLO GLOSSUS, *Stylo-Hyoidæus.* *Stylo-Pharyngæus,* STYLOIDES, } The names of different muſcles in the human body. See *Table of the Muſcles under* ANATOMY.

STYLOSANTHES, in botany: A genus of the *decandria* order, belonging to the *diadelphia* claſs of plants; and in the natural method ranking under the 32d order, *Papilionaceæ*. The calyx is tubulated, very long, having the corolla attached to it. The legumen or pod biarticulated and hooked. Of this there are two ſpecies, both natives of Jamaica, viz. 1. *Procumbens*, the *hedyſarum procumbens* of Linnæus; a figure of which may be ſeen in Sloane's Natural Hiſtory of Jamaica. 2. *Viſcoſa*, the *trifolium* 2. of Browne; a figure of which is alſo given by Sloane.

STYPTIC, in pharmacy, a medicine which by its aſtringency ſtops hæmorrhagies, &c. See PHARMACY, n° 547.

STYRAX, the STORAX-TREE, in botany: A genus of plants belonging to the claſs of *decandria*, and to the order of *monogynia*; and in the natural ſyſtem ranging under the 18th order, *bicornes*. Linnæus only mentions one ſpecies of this genus, the *ſtyrax-officinale*; but Aiton, in his *Hortus Kewenſis*, has added two more; namely, the *grande folium* and *lævigatum*; and we believe a fourth may now be added, the *ſtyrax benzoin*.

The *officinale* uſually riſes above twenty feet in height; it ſends off many ſtrong branches, which are covered with a roughiſh bark of a grey colour: the leaves are broad, elliptical, entire, ſomewhat pointed, on the upper ſurface ſmooth, and of a light green colour, on the under ſurface covered with a whitiſh down; they are placed alternately, and ſtand upon ſhort footſtalks: the flowers are large, white, and diſpoſed in cluſters upon ſhort peduncles, which terminate the branches: the corolla is monopetalous, funnel-ſhaped, and divided at the limb into five lance-ſhaped ſegments: the filaments are ten, placed in a regular circle, and ſeem to adhere towards the baſe: the antheræ are erect and oblong: the germen is oval, and ſupports a ſlender ſtyle, with a ſimple ſtigma: the fruit is a pulpy pericarpium, which contains one or two nuts of an oval compreſſed figure. Woodville's Medical Botany, vol. ii.

The reſinous drug called *ſtorax* iſſues in a fluid ſtate from inciſions made in the trunk or branches of the tree. Two ſorts of this reſin have been commonly diſtinguiſhed in the ſhops. 1. *Storax in the tear:* is ſcarcely, if ever, found in ſeparate tears, but in maſſes, ſometimes compoſed of whitiſh and pale reddiſh brown tears, and ſometimes of an uniform reddiſh yellow or bowniſh appearance; unctuous and ſoft like wax, and free from viſible impurities. This is ſuppoſed to be the ſort which the ancients received from Pamphylia in reeds or canes, and which was thence named *calamita*. Lewis's Materia Medica, vol. ii.

2. *Common ſtorax:* in large maſſes, conſiderably lighter and leſs compact that the former, and having a large admixture of woody matter like ſaw-duſt. This appears to be the kind intended by the London college, as they direct their ſtyrax calamita to be purified, for medicinal uſe, by ſoftening it with boiling water, and preſſing it out from the feces betwixt warm iron plates; a proceſs which the firſt ſort does not ſtand in need of. And indeed there is rarely any other than this impure ſtorax to be met with in the ſhops.

Storax, with ſome of the ancients, was a familiar remedy as a reſolvent, and particularly uſed in catarrhal complaints, coughs, aſthmas, menſtrual obſtructions, &c. and from its affinity to the balſams it was alſo preſcribed in ulcerations of the lungs, and other ſtates of pulmonary conſumption. And our pharmacopœias formerly directed the *pilulæ e ſtyrace*; but this odoriferous drug has now no place in any of the officinal compounds; and though a medicine which might ſeem to promiſe ſome efficacy in nervous debilities, yet by modern practitioners it is almoſt totally diſregarded. Styrax.

The *ſtyrax benzoin* is deſcribed by Dr Dryander in the Philoſophical Tranſactions for 1787, p. 308, &c. It has been characterized by oblong acuminated leaves, which are downy underneath, and nearly of the length of the racemi. The botanical character of this tree was miſtaken by modern botaniſts till Dr Dryander aſcertained it to be a ſtyrax. Benzoin was long ſuppoſed to be the produce of a ſpecies of *laurus*. Linnæus detected this error: but he committed another; for he tells us, that it is furniſhed by a ſhrub which, in the country where it grows, is called *croton bezoe*; and afterwards, in his *Supplementum Plantarum*, deſcribes the ſame plant a ſecond time, under the name of *terminalia benzoin*. Plate CCCCLXXXVI.

This tree, which is a native of Sumatra, is deemed in ſix years of ſufficient age for affording the benzoin, or when its trunk acquires about ſeven or eight inches in diameter; the bark is then cut through longitudinally, or ſomewhat obliquely, at the origin of the principal lower branches, from which the drug exudes in a liquid ſtate, and by expoſure to the ſun and air ſoon concretes, when it is ſcraped off from the bark with a knife or chiſel. The quantity of benzoin which one tree affords never exceeds three pounds, nor are the trees found to ſuſtain the effects of theſe annual inciſions longer than ten or twelve years. The benzoin which iſſues firſt from the wounded bark is the pureſt, being ſoft, extremely fragrant, and very white; that which is leſs eſteemed is of a browniſh colour, very hard, and mixed with various impurities, which it acquires during its long continuance upon the trees. Eſchelſkron diſtinguiſhes benzoin into three kinds, viz. *camayan poeti*, or white benjamin, which, upon being melted in a bladder by the heat of the ſun, appears marked with red ſtreaks or veins. *Camayan bamatta* is leſs white than the former, and often ſpotted with white circles, called eyes, from the number of which its goodneſs is eſtimated: it likewiſe melts by the heat of the ſun. *Camayan itam*, or black benjamin, which requires to be melted in hot water for its preſervation in bladders. In Arabia, Perſia, and other parts of the Eaſt, the coarſer kinds of benjamin are conſumed for fumigating and perfuming the temples, and for deſtroying inſects. Woodville's Medical Botany, vol. ii.

The benzoin which we find here in the ſhops is in large brittle maſſes, compoſed partly of white, partly of yellowiſh or light brown, and often alſo of darker coloured pieces: that which is cleareſt, and contains the moſt white matter, called by authors *benzoe amygdaloides*, is accounted the beſt. This reſin has very little taſte, impreſſing on the palate only a ſlight ſweetneſs: its ſmell, eſpecially when rubbed or heated, is extremely fragrant and agreeable. It totally diſſolves in rectified ſpirit, (the impurities excepted, which are generally in a very ſmall quantity), into a deep yellowiſh red liquor, and in this ſtate diſcovers a degree of warmth and pungency, as well as ſweetneſs. It imparts, by digeſtion, to water alſo a conſiderable ſhare of its fragrance, and a ſlight pungency: the filtered liquor, gently exhaled, leaves not a reſinous or mucilaginous extract, but a cryſtalline matter, ſeemingly of a ſaline nature, amounting to one-tenth or one-eighth of the weight of the benzoin. Expoſed to the fire in proper veſſels, it yields a quantity of a white ſaline concrete, called *flores benzoes*, of an acidulous taſte and grateful odour, ſoluble in rectified ſpirit, and in water by the aſſiſtance of heat.

Styrax, Styx.

The principal uſe of this fragrant reſin is in perfumes, and as a coſmetic; for which laſt purpoſe, a ſolution of it in ſpirit of wine is mixed with ſo much water as is ſufficient to render it milky, as twenty times its quantity or more. It promiſes, however, to be applicable to other uſes, and to approach in virtue, as in fragrance, to ſtorax and balſam of Tolu. It is ſaid to be of great ſervice in diſorders of the breaſt, for reſolving obſtructions of the pulmonary veſſels, and promoting expectoration: in which intentions the flowers are ſometimes given, from three or four grains to fifteen. The white powder, precipitated by water from ſolutions of the benzoin in ſpirit, has been employed by ſome as ſimilar and ſuperior to the flowers, but appears to be little other than the pure benzoin in ſubſtance: it is not the ſaline, but the reſinous matter of the benzoin, that is moſt diſpoſed to be precipitated from ſpirit by water. The flowers, ſnuffed up the noſe, are ſaid to be a powerful errhine.

Liquid ſtorax is a reſinous juice obtained from a tree called by Linnæus *liquidambar ſtyraciflua*, a native of Virginia and Mexico, and lately naturalized in Britain. The juice called liquidambar is ſaid to exude from inciſions made in the trunk of this tree, and the liquid ſtorax to be obtained by boiling the bark or branches in water. Two ſorts of liquid ſtorax are diſtinguiſhed by authors: one, the purer part of the reſinous matter that ariſes to the ſurface in boiling, ſeparated by a ſtrainer, of the conſiſtence of honey, tenacious like turpentine, of a reddiſh or aſh brown colour, moderately tranſparent, of an acrid unctuous taſte, and a fragrant ſmell, faintly reſembling that of the ſolid ſtorax, but ſomewhat diſagreeable: the other, the more impure part, which remains on the ſtrainer, is not tranſparent, in ſmell and taſte is much weaker, and contains a conſiderable proportion of the ſubſtance of the bark. What is moſt commonly met with under this name in the ſhops is of a weak ſmell and a grey colour, and is ſuppoſed to be an artificial compoſition.

Liquid ſtorax has been employed chiefly in external applications. Among us, it is at preſent almoſt wholly in diſuſe.

STYX (fab. hiſt.), a celebrated river of hell, round which it flows nine times. The gods held the waters of the Styx in ſuch veneration, that to ſwear by them was reckoned an oath altogether inviolable. If any of the gods had perjured themſelves, Jupiter obliged them to drink the waters of the Styx, which lulled them for one whole year into a ſenſeleſs ſtupidity, for the nine following years they were deprived of the ambroſia and the nectar of the gods, and after the expiration of the years of their puniſhment, they were reſtored to the aſſembly of the deities, and to all their original privileges. It is ſaid that this veneration was ſhewn to the Styx, becauſe it received its name from the nymph Styx, who with her three daughters aſſiſted Jupiter in his war againſt the Titans.

Styx was a river which it was neceſſary for departed ſhades to paſs before they could enter the infernal regions; and it was the office of Charon to ferry them over in a boat which was kept for that purpoſe. The ghoſts of thoſe who had not been honoured with the rites of ſepulture were obliged to wander an hundred years before Charon could admit them into his boat to convey them before the judges of Hades. What could have given riſe to this fable of Charon and his boat, it is not very material to inquire. Mythological writers have ſaid, that the Greeks learned it from the Egyptians, which is indeed probable enough; that the Egyptians framed both this, and ſome other fables relating to the dead, from certain cuſtoms peculiar to their country; that in particular there was, not far from Memphis, a famous burying-place, to which the dead bodies were conveyed in a boat acroſs the lake Acheruſia; and that Charon was a boatman who had long officiated in that ſervice. The learned Dr. Blackwell ſays, in his life of Homer, that, in the old Egyptian language, *Charoni* ſignified "ferryman."

Tranſ. of the R. Society of Edinburgh vol. ii.

Suabia ‖ Subclavian.

SUABIA, a circle of Germany, bounded on the north by the circle of Franconia and that of the Lower Rhine; on the weſt by the circle of the Lower Rhine and Alſace; on the ſouth by Switzerland; and on the eaſt by the circle of Bavaria. Of all the circles of the empire, Suabia is the moſt divided; it contains four eccleſiaſtical and thirteen lay principalities, nineteen independent prelacies and abbeys, twenty-ſix earldoms and lordſhips, and thirty-one free cities. The prime directors of the circle, as they are termed, are the biſhop of Conſtance and the duke of Wirtemberg. The duke has the ſole direction of all that relates to war.

The mixture of the various forms of government and religious ſects; the oppreſſion exerciſed by the great on the poor; the game conſtantly played by the emperor, who poſſeſſes many pieces of detached country in Suabia, which depend not on the circle, and can, in conſequence of his privileges as archduke of Auſtria, extend his poſſeſſions in it by various ways; are circumſtances (ſays baron Rieſbeck) which give the cultivation of the country, and the character of the inhabitants, a moſt extraordinary caſt. In ſeveral of the poſt towns where you ſtop, you ſee the higheſt degree of cultivation in the midſt of the moſt ſavage wildneſs; a great degree of knowledge and poliſh of manners, mixed with the groſſeſt ignorance and ſuperſtition; traces of liberty; under the deepeſt oppreſſion; national pride, together with the contempt and neglect of the native country; in ſhort, all the ſocial qualities in ſtriking contraſt and oppoſition to each other. Thoſe parts of Suabia which belong to the great potentates, ſuch as Wirtemberg, Auſtria, and Baden, are certainly the moſt improved. The whole of Suabia may comprehend about nine hundred German ſquare miles, and two millions of people. More than half of theſe are ſubjects of the three abovementioned princes, though they are not proprietors of near one half of the lands.

Baron Rieſbeck's Travels through Germany, vol. i.

SUARES (Francis), a Jeſuit, was born in Granada on the 5th of January 1548. He was a profeſſor of theology at Alcala, Salamanca, Rome, and Coimbra in Portugal. He died at Liſbon in 1617 with the greateſt reſignation; "I never thought (ſaid he) that it was ſo eaſy to die." His memory was aſtoniſhing, he could repeat the whole of his voluminous works by heart. His writings fill 23 folio volumes, and are moſtly on theological and moral ſubjects. His Treatiſe of Laws has been reprinted in Britain His Defence of the Catholic Faith againſt the Errors of England was written at the requeſt of pope Paul V. This book was publicly burnt at London by order of James I. When Suares heard it, he is ſaid to have exclaimed, "O that I too could ſeal with my blood, the truths which I have defended with my pen!"

SUBAH, the general name of the viceroyſhips, or greater governments, into which the Mogul empire was divided, conſiſting of ſeveral provinces. The juriſdiction of a ſubahdar, the ſame as ſubahſhip, ſubaedaree, or nizamut.

SUBAHDAR, the viceroy, lord-lieutenant, or governor, holding a ſubah; the ſame as nabob or nazim. Alſo the black commander of a company of Seapoys.

SUBALTERN, a ſubordinate officer, or one who diſcharges his poſt under the command and ſubject to the direction of another; ſuch are lieutenants, ſub-lieutenants, cornets, and enſigns, who ſerve under the captain.

SUBCLAVIAN, in anatomy, is applied to any thing under the arm-pit or ſhoulder, whether artery, nerve, vein, or muſcle.

Sub-deacon ‖ Submultiple.

SUB-DEACON, an inferior miniſter, who anciently attended at the altar, prepared the ſacred veſſels, delivered them to the deacons in time of divine ſervice, attended the doors of the church during communion ſervice, went on the biſhop's embaſſies with his letters or meſſages to foreign churches, and was inveſted with the firſt of the holy orders. They were ſo ſubordinate to the ſuperior rulers of the church, that, by a canon of the council of Laodicea, they were forbidden to ſit in the preſence of a deacon without his leave. According to the canons, a perſon muſt be twenty-two years of age to be promoted to the order of ſubdeacon. See DEACON.

SUBDOMINANT, in muſic a name given by M. Rameau to the fourth note of the tone, which of conſequence is the ſame interval from the tonic when deſcending as the dominant in riſing. This denomination ariſes from the affinity which this author finds by inverſion between the minor mode of the ſubordinant and the major mode of the tonic.

SUBDUPLE RATIO, is when any number or quantity is contained in another twice. Thus 3 is ſaid to be ſubduple of 6, as 6 is duple of 3. See RATIO.

SUBDUPLICATE RATIO of any two quantities, is the ratio of their ſquare roots.

SUBER, the CORK-TREE, in botany. See QUERCUS.

SUBJECT, a perſon under the rule and dominion of a ſovereign prince or ſtate.

SUBJECT is alſo uſed for the matter of an art or ſcience, or that which it conſiders, or whereon it is employed: thus the human body is the ſubject of medicine.

SUBINFEUDATION, was where the inferior lords, in imitation of their ſuperiors, began to carve out and grant to others minuter eſtates than their own, to be held of themſelves; and were ſo proceeding downwards *in infinitum*, till the ſuperior lords obſerved that by this method of ſubinfeudation they loſt all their feodal profits, or wardſhips, marriages, and eſcheats, which fell into the hands of theſe meſne or middle lords, who were the immediate ſuperiors of the terre-tenant, or him who occupied the land. This occaſioned the ſtat. of Weſtm. 3. or *quia emptores*, 18 Edw. I. to be made; which directs, that, upon all ſales or feoffments of lands, the feoffee ſhall hold the ſame, not of his immediate feoffer, but of the chief lord of the fee of whom ſuch feoffer himſelf held it. And from hence it is held, that all manors exiſting at this day muſt have exiſted by immemorial preſcription; or at leaſt ever ſince the 18 Edw. I. when the ſtatute of *quia emptores* was made.

Black-ſtone's Commentary, vol. ii.

SUBITO, in the Italian muſic, is uſed to ſignify that a thing is to be performed quickly and haſtily: thus we meet with *volti ſubito*, turn over the leaf quickly.

SUBJUNCTIVE, in grammar. See GRAMMAR.

SUBLIMATE, a chemical preparation, conſiſting of quickſilver united with the marine acid. See CHEMISTRY-*Index*.

SUBLIMATION, in chemiſtry, the condenſing and collecting, in a ſolid form, by means of veſſels aptly conſtructed, the fumes of bodies raiſed from them by the application of a proper heat. See CHEMISTRY, n° 581.

SUBLIME, or SUBLIMITY. See the article GRANDEUR and SUBLIMITY.

SUBLINGUAL ARTERY. See ANATOMY.

SUBLINGUAL Glands, in anatomy, two glands under the tongue, placed one on each ſide thereof.

SUBMULTIPLE, in geometry, &c. A ſubmultiple number, or quantity, is that which is contained a certain number of times in another, and which, therefore, repeated a certain number of times, becomes exactly equal thereto. Thus 3 is a ſubmultiple of 21. In which ſenſe a ſubmultiple coincides with an aliquot part. Submultiple ‖ Subſcription

SUBMULTIPLE Ratio, is that between the quantity contained and the quantity containing. Thus the ratio of 3 to 21 is ſubmultiple. In both caſes ſubmultiple is the reverſe of multiple: 21, *e. gr.* being a multiple of 3, and the ratio of 21 to 3 a multiple ratio.

SUBORDINARIES. See HERALDRY, Chap. III. Sect. II. page 454.

SUBORDINATION, a relative term, expreſſing an inferiority betwixt one perſon and another.

SUBORNATION, in law, a ſecret, underhand, preparing, inſtructing, or bringing in a falſe witneſs; and from hence *ſubornation of perjury* is the preparing or corrupt alluring to perjury. The puniſhment for this crime was formerly death, then baniſhment or cutting out the tongue, afterwards forfeiture of goods; and it is now a fine and impriſonment, and never more to be received as evidence. The ſtatute 2 Geo. II. c. 25. ſuperadded a power for the court to order the offender to be ſent to the houſe of correction for a term not exceeding ſeven years, or to be tranſported for the ſame period.

SUBPŒNA, in law, a writ whereby common perſons are called into chancery, in ſuch caſes where the common law hath provided no ordinary remedy; and the name of it proceeds from the words therein, which charge the party called to appear at the day and place aſſigned, *ſub pœna centum librarum*, &c. The ſubpœna is the leading proceſs in the courts of equity; and by ſtatute, when a bill is filed againſt any perſon, proceſs of ſubpœna ſhall be taken out to oblige the defendant to appear and anſwer the bill, &c.

SUBPŒNA ad teſtificandum, a writ or proceſs to bring in witneſſes to give their teſtimony. If a witneſs on being ſerved with this proceſs does not appear, the court will iſſue an attachment againſt him; or a party, plaintiff or defendant, injured by his non-attendance, may maintain an action againſt the witneſs. See *Blackſt. Com.* Vol. III. p. 369.

SUBPŒNA in Equity, "a proceſs in equity, calling on a defendant to appear and anſwer to the complainant's bill. See ſtatute 5th Geo. II. c. 25. which enacts, that where the party cannot be found to be ſerved with a ſubpœna, and abſconds (as believed) to avoid being ſerved, a day ſhall be appointed him to appear to the bill of the plaintiff; which is to be inſerted in the London Gazette, read in the pariſh-church where the defendant laſt lived, and fixed up at the Royal Exchange: and if the defendant doth not appear upon that day, the bill ſhall be taken *pro confeſſo*."

SUBREPTITIOUS, a term applied to a letter, licence, patent, or other act, fraudulently obtained of a ſuperior, by concealing ſome truth which, had it been known, would have prevented the conceſſion or grant.

SUBROGATION, or SURROGATION, in the Civil Law, the act of ſubſtituting a perſon in the place, and intitling him to the rights, of another. In its general ſenſe, ſubrogation implies a ſucceſſion of any kind, whether of a perſon to a perſon, or of a perſon to a thing.

There are two kinds of ſubrogation: the one *conventional*, the other *legal*. *Conventional* ſubrogation is a contract whereby a creditor tranſfers his debt, with all appurtenances thereof, to the profit of a third perſon. *Legal* ſubrogation is that which the law makes in favour of a perſon who diſcharges an antecedent creditor; in which caſe there is a legal tranſlation of all rights of the ancient creditor to the perſon of the new one.

SUBSCRIPTION, in general, ſignifies the ſignature put at the bottom of a letter, writing, or inſtrument.

In commerce, it is uſed for the ſhare or intereſt which particular perſons take in a public ſtock or a trading company,

Subſcription ‖ Subularia.

pany, by writing their names, and the ſhares they require, in the books or regiſter thereof.

SUBSCRIPTION to articles of faith is required of the clergy of every eſtabliſhed church, and of ſome churches not eſtabliſhed. Whether ſuch ſubſcription ſerves any good purpoſe, in a religious or theological view, is a very doubtful queſtion. It may be neceſſary in an eſtabliſhment, as a teſt of loyalty to the prince, and of attachment to the conſtitution, civil and eccleſiaſtical, but it cannot produce uniformity of opinion. As all language is more or leſs ambiguous, it becomes difficult, if not impoſſible, to determine in what ſenſe the words of long eſtabliſhed creeds are to be interpreted; and we believe that the clergy of the churches of England and Scotland ſeldom conſider themſelves as fettered by the thirty-nine Articles, or the Confeſſion of Faith, when compoſing inſtructions either for their reſpective pariſhes or for the public at large. See INDEPENDENTS.

SUBSCRIPTION, in the commerce of books, ſignifies an engagement to take a certain number of copies of a book intended to be printed, and a reciprocal obligation of the bookſeller or publiſher to deliver the ſaid copies, on certain terms.—Theſe ſubſcriptions, which had their riſe in England about the middle of the laſt century, were lately very frequent in France and Holland, and are now very common among ourſelves.

SUBSEQUENT, ſomething that comes after another, particularly with regard to the order of time.

SUBSIDY, in law, "ſignifies an aid or tax granted to the king by parliament, for the neceſſary occaſions of the kingdom; and is to be levied on every ſubject of ability, according to the rate or value of his lands or goods: but this word, in ſome of our ſtatutes, is confounded with that of cuſtoms." See TAX.

SUBSTANCE, the ſubject to which we ſuppoſe qualities belong. Thus gold is the ſubſtance to which the quaties of ductility, yellowneſs, denſity, &c. belong. See METAPHYSICS, n° 145.

SUBSTANTIAL, in the ſchools, ſomething belonging to the nature of ſubſtance.

SUBSTANTIVE, in grammar. See GRAMMAR.

SUBSTITUTE, a perſon who officiates for another in his abſence.

SUBSTITUTION, in the civil law, a diſpoſition of a teſtament, whereby the teſtator ſubſtitutes one heir for another, who has only the uſufruit, and not the property, of the thing left him.

SUBSTRACTION, or SUBTRACTION, in arithmetic, the ſecond rule, or rather operation, in arithmetic, whereby we deduct a leſs number from a greater, to learn their preciſe difference. See ARITHMETIC and ALGEBRA.

SUBTANGENT OF A CURVE, the line that determines the interſection of a tangent with the axis; or that determines the point wherein the tangent cuts the axis prolonged.

SUBTENSE, formed from *ſub* "under," and *tendo* "I ſtretch." in geometry, a right line which is oppoſite to an angle, and drawn between the two extremities of the arch which meaſures that angle.

SUBTERRANEOUS, whatever is under ground: thus naturaliſts ſpeak of ſubterraneous fires, ſubterraneous damps, &c.

SUBTERRANEOUS Cavern. See QUARRIES.

SUBTILE, in phyſics, an appellation given to whatever is extremely ſmall, fine, and delicate; ſuch as the animal-ſpirits, the effluvia of orderous bodies, &c. are ſuppoſed to be.

SUBULARIA, ROUGH-LEAVED ALYSSON, or *Awl-wort*, in botany: A genus of plants belonging to the claſs of *tetradynamia*, and order of *ſiliculoſa*; and in the natural order ranging under the 39th order, *ſiliquoſæ*. The ſilicula its entire and ovate; the valves are ovate, concave, and contrary to the partitions. The ſtyle is ſhorter than the ſilicula. There is only one ſpecies, the *aquatica*, which is a native of Britain. It is about an inch high. The leaves are awl-ſhaped, and grow in cluſters round the root. The ſtalk is naked, and produces four or five ſmall white flowers growing alternately on ſhort footſtalks. It flowers under water, whereas moſt aquatic plants emerge above water at the time of flowering. The Author of Nature has, however, carefully prevented the tender flower from receiving any injury from the water, by making the petals cloſe, and form themſelves into a kind of arch. This plant grows on the borders of the Highland lakes, in Loch Tay, in Scotland, alſo in Wales and Ireland.

Subulated ‖ Succeſſion.

SUBULATED, ſomething ſhaped like an awl.

SUCCEDANEUM, in pharmacy, denotes a drug ſubſtituted in the place of another.

SUCCESSION, in metaphyſics, the idea which we get by reflecting on the ideas that follow one another in our mind; and from the ſucceſſion of ideas we get the idea of *time*. See METAPHYSICS, n° 93. and 209.

SUCCESSION, in law. See DESCENT.

SUCCESSION to the Crown. See *HEREDITARY Right.*—"From the days of Egbert, the firſt ſole monarch of England, even to the preſent, the four cardinal maxims mentioned in that article have ever been held conſtitutional canons of ſucceſſion. It is true, as Sir William Blackſtone obſerves, this ſucceſſion, through fraud or force, or ſometimes through neceſſity, when in hoſtile times the crown deſcended on a minor or the like, has been very frequently ſuſpended; but has generally at laſt returned back into the old hereditary channel, though ſometimes a very conſiderable period has intervened. And even in thoſe inſtances where this ſucceſſion has been violated, the crown has ever been looked upon as hereditary in the wearer of it. Of which the uſurpers themſelves were ſo ſenſible, that they for the moſt part endeavoured to vamp up ſome feeble ſhow of a title by deſcent, in order to amuſe the people, while they gained the poſſeſſion of the kingdom. And, when poſſeſſion was once gained, they conſidered it as the purchaſe or acquiſition of a new eſtate of inheritance, and tranſmitted, or endeavoured to tranſmit it, to their own poſterity by a kind of hereditary right of uſurpation. (See *Black. Com.* v. i. 197—217.) From the hiſtorical view there given, it appears, that the title to the crown is at preſent hereditary, though not quite ſo abſolutely hereditary as formerly: and the common ſtock, or anceſtor, from whom the deſcent muſt be derived, is alſo different. Formerly, the common ſtock was King Egbert; then William the Conqueror; afterwards, in James I.'s time, the two common ſtocks united; and ſo continued till the vacancy of the throne in 1688: now it is the Princeſs Sophia, in whom the inheritance was veſted by the new king and parliament. Formerly, the deſcent was abſolute, and the crown went to the next heir without any reſtriction: but now, upon the new ſettlement, the inheritance is conditional; being limited to ſuch heirs only, of the body of the Princeſs Sophia, as are Proteſtant members of the church of England, and are married to none but Proteſtants.

"And in this due medium conſiſts the true conſtitutional notion of the right of ſucceſſion to the imperial crown of theſe kingdoms. The extremes between which it ſteers are each of them equally deſtructive of thoſe ends for which ſocieties were formed and are kept on foot. Where the magiſtrate, upon every ſucceſſion, is elected by the people, and

Succeſſion ‖ Succinum.

may by the expreſs proviſion of the laws be depoſed (if not puniſhed) by his ſubjects, this may ſound like the perfection of liberty, and look well enough when delineated on paper; but in practice will be ever productive of tumult, contention, and anarchy. And, on the other hand, divine indefeaſible hereditary right, when coupled with the doctrine of unlimited paſſive obedience, is ſurely of all conſtitutions the moſt thoroughly ſlaviſh and dreadful. But when ſuch an hereditary right as our laws have created and veſted in the royal ſtock, is cloſely interwoven with thoſe liberties which are equally the inheritance of the ſubject; this union will form a conſtitution, in theory the moſt beautiful of any, in practice the moſt approved, and, we truſt, in duration the moſt permanent.

"In France the ſucceſſion to the monarchy was limited to heirs male (See SALIC); but in Navarre the crown was inherited by the heir of line, whether male or female. The caſe ſtands thus: Philip the Fourth, king of France, ſurnamed *the Fair*, in the year 1285 eſpouſed Jane queen of Navarre in her own right; and as king conſort of this latter kingdom added the title of Navarre to his former one of France. Louis X. ſon and heir of Philip and Jane (ſurnamed *Hutin*, or the *Boiſterous*), ſucceeded to both crowns. By Margaret his firſt wife, who had been crowned queen of Navarre, he left one daughter Joan or Jane. His ſecond wife Clementia was pregnant at the time of his deceaſe, and was delivered of a poſthumous ſon, whom moſt of the French annaliſts recognize as John I. of France, though he lived no longer than three weeks. On his death the kingdom of France paſſed to Philip V. (ſurnamed the *Long*), and that of Navarre (to which the Salic law could by no conſtruction extend) to Joanna the only child and heir of Louis and Margaret. From Joanna, in lineal ſucceſſion, the kingdom of Navarre paſſed to Jane d'Albret, mother of Henry IV. of France, and wife of Anthony of Vendoſme, who as king conſort wore the crown of Navarre. On the acceſſion of Henry to the kingdom of France, the two monarchies were united, and the four ſucceeding princes aſſumed the joint titles. But if ever the monarchy be reſtored in France, Mary, princeſs royal and daughter of Louis XVI. will have the ſame right to the throne of NAVARRE that her uncle has to the throne of France; for ſhe is the undoubted heir of line of the great and illuſtrious Henry IV."

SUCCINIC ACID, an acid extracted from amber by ſublimation in a gentle heat, and riſes in a concrete form into the neck of the ſubliming veſſel. The operation muſt not be puſhed too far, or by too ſtrong a fire, otherwiſe the oil of the amber riſes along with the acid. The ſalt is dried upon blotting paper, and purified by repeated ſolution and cryſtallization.

Lavoiſier's Elements of Chemiſtry.

The acid is ſoluble in 24 times its weight of cold water, and in a much ſmaller quantity of hot water. It poſſeſſes the qualities of an acid in a very ſmall degree, and only affects the blue vegetable colours very lightly. The affinities of this acid with the ſalifiable baſes were determined by Mr de Morveau, who is the firſt chemiſt that has endeavoured to aſcertain them.

SUCCINUM, AMBER, in mineralogy, a ſpecies of bitumen claſſed under the inflammable ſubſtances. As a full account of this mineral was given under the word AMBER, nothing remains but to mention a few things which recent experiments enable us to add. According to Dr Kirwan, 100 grains of amber afford about 72 of petroleum, 4.5 of ſuccinic acid, and a reſidue of fixed matter and water. Mr Scheele ſays, that, when diſtilled, it yields an aqueous acid reſembling vinegar in its qualities. This would induce us to believe it to be of vegetable origin. But its origin is a point not yet aſcertained. Its ſpecific gravity is from 1,065 to 1,100, and melts at 550° of Fahrenheit. Wallerius affirms, that mirrors, priſms, &c. may be made of amber.

Succop ‖ Sueſſiones.

SUCCORY, in botany. See CICHORIUM.

SUCCOTH (anc. geog.), a town which lay between the brook Jabbok and the river Jordon, where Jacob fixed his tents. There was another Succoth where the Iſraelites firſt encamped after their departure from Rameſes towards the Red Sea. Succoth ſignifies *tents*.

SUCCUBUS, a term uſed by ſome writers for a dæmon who aſſumes the ſhape of a woman, and as ſuch lies with a man; in which ſenſe it ſtands oppoſed to *incubus*, which was a dæmon in form of a man, that lies with a woman. But the truth is, the ſuccubus is only a ſpecies of the nightmare. See MEDICINE, n° 329.

SUCCULA, in mechanics, an axis or cylinder, with ſtaves in it to move it round; but without any tympanum or peritrochium.

SUCCULENT PLANTS, among botaniſts, ſuch whoſe leaves are thick and full of juice.

SUCKER, in ichthyology. See CYCLOPTERUS.

SUCKERS, in gardening, the ſame with OFFSETS.

SUCKING-FISH. See ECHENEIS.

SUCKLING (Sir John), an Engliſh poet and dramatic writer, was the ſon of Sir John Suckling, comptroller of the houſehold to king Chales I. and born at Witham in Eſſex in 1613. He diſcovered an uncommon propenſity to the acquiring of languages, inſomuch that he is reported to have ſpoken Latin at five years of age, and to have written it at nine. When he was grown up, he travelled; but ſeems to have affected nothing more than the character of a courtier and fine gentleman; which he ſo far attained, that he was allowed to have the peculiar happineſs of making every thing he did become him. In his travels he made a campaign under the great Guſtavus Adolphus; and his loyalty, if not his valour, appeared in the beginning of the civil wars, for, after his return to England, he raiſed a troop of horſe for the king's ſervice entirely at his own charge; and mounted them ſo completely and richly, that they are ſaid to have coſt him 12,000 l. This troop, with Sir John at its head, behaved ſo ill in the engagement with the Scots, upon the Engliſh borders, in 1639, as to occaſion the famous lampoon compoſed by Sir John Mennis; "Sir John he got him an ambling nag," &c. This ballad, which was ſet to a briſk tune, was much ſung by the parliamentarians, and continues to be ſung to this day. This diſaſtrous expedition, and the ridicule that attended it, was ſuppoſed to have haſtened his death; being ſeized by a fever, of which he died, at 28 years of age. He was a ſprightly wit, and an eaſy verſifier, but no great poet. His works, conſiſting of a few poems, letters, and plays, have nevertheleſs gone through ſeveral editions.

SUCTION, the act of ſucking or drawing up a fluid, as air, water, milk, or the like, by means of the mouth and lungs; or, in a ſimilar manner, by artificial means. See PNEUMATICS and HYDROSTATICS.

SUDATORY, a name given by the ancient Romans to their hot or ſweating rooms; ſometimes alſo called *Laconica*.

SUDEROE. See *Ferro-Iſlands*.

SUDORIFIC, an appellation given to any medicine that cauſes or promotes ſweat.

SUESSIONES, a branch of the Remi, a people of Gallia Belgica (Pliny); called ſometimes *Sueſſones*, in the lower age *Sueſſi*; ſituated between the Remi to the eaſt, the Nervii to the north, the Veromandui to the weſt, and the Meldæ to the ſouth, in the tract now called *le Soiſſonois*.—*Sueſſiones*, *Sueſſones*, and *Sueſſonæ*, the name of their city in the

Suet ‖ Suez.

the lower age; thought to have been formerly called *Noviodunum* (Cæsar), is now called *Soissons*.

SUET, Sevum, or *Sebum*, in anatomy, the solid fat found in several animals, as sheep, oxen, &c. but not in the human species. See the article Fat.—It is of the sevum that tallow is made.

SUETONIUS tranquillus (Caius), a famous Latin historian, was born at Rome, and became secretary to the emperor Adrian, about the 118th year of the Christian era; but that post was taken from him three years after, when several persons fell under that prince's displeasure for not showing the empress Sabina all the respect she deserved. During his disgrace he composed many works, which are lost. Those now extant are his History of the XII first Emperors, and a part of his Treatise of the Illustrious Grammarians and Rhetoricians. Pliny the Younger was his intimate friend, and persuaded him to publish his books. His History of the XII Roman Emperors has been much commended by most of our polite scholars. He represents, in a continued series of curious and interesting particulars, without any digressions or reflections, the actions of the emperors, without omitting their vices, which he exposes with all their deformity, and with the same freedom mentions the good qualities of the very same persons; but the horrid dissoluteness and obscene actions he relates of Tiberius, Caligula, Nero, &c. have made some say, that he wrote the lives of the emperors with the same licentiousness with which they lived. The edition of this history procured by Grævius at Utrecht in 1672, with the excellent Commentaries of Torrentius and Casaubon, and the notes of some other learned critics, is much esteemed. Burman also published an edition in two vols. 4to with notes.

SUEVI, the Catti or Chatti of Cæsar (Strabo), placed on the Rhine: the reason of Cæsar's calling them thus does not appear, though considerably distant from the proper Suevi or Alemanni.

Suevi (Tacitus), a common name of the people situated between the Elbe and the Vistula, distinguished otherwise by particular names; as in Ptolemy, *Suevi Angili*, *Suevi Semnones*.

SUEVUS (anc. geog.), a river of Germany, thought to be the same with the Viadrus or Oder, emptying itself at three mouths into the Baltic, the middlemost of which is called *Swine* or *Swene*; which last comes nearer the name *Suevus*.

SUEZ, a small sea-port town, situated near the northern extremity of the Red Sea, and about 30 hours journey east from Cairo. The country around it is a sandy plain, without the smallest spot of verdure. The only water which can be drunk is brought from El-Naba, or the spring, at the distance of three hours journey; and it is so brackish, that without a mixture of rum it is insupportable to Europeans. The town itself is a collection of miserable ruins, the khans being the only solid buildings; yet from March till June, the season when the Jidda and Yambo fleet arrives, the town becomes crowded; but after its departure nobody remains except the governor, who is a Mamlouk, 12 or 14 persons who form his household, and the garrison. The fortress is a defenceless heap of ruins, which the Arabs consider as a citadel, because it contains six brass four pounders, and two Greek gunners, who turn their heads aside when they fire. The harbour is a wretched quay, where the smallest boats are unable to reach the shore, except at the highest tides. There, however, the merchandise is embarked, to convey it over the banks of sand to the vessels which anchor in the road. This road, situated a league from the town, is separated from it by a shore which is left dry at low water; it has no works for its defence, so that the vessels which M. Volney tells us he has seen there, to the number of 28 at a time, might be attacked without opposition; for the ships themselves are incapable of resistance, none having any other artillery than four rusty swivels. Suez

Volney's Travels, vol. i.

Suez has always been, notwithstanding its local disadvantages, a place of great trade, on account of its geographical situation. It was by the gulph of Suez that the commodities of India were formerly conveyed to Europe, till the discovery of the passage by the Cape of Good Hope converted that trade into a new channel. As the isthmus of Suez, which separates the Red Sea from the Mediterranean, is not more than 57 miles, it has been frequently proposed to join these two seas together by a canal. As there are no mountains nor remarkable inequalities of surface, this plan would at first view appear easy to be executed. But though the difference of levels would not prevent a junction, the great difficulty arises from the nature of the corresponding coasts of the Mediterranean and the Red Sea, which are of a low and sandy soil, where the waters form lakes, shoals, and morasses, so that vessels cannot approach within a considerable distance. It will therefore be found scarcely possible to dig a permanent canal amid these shifting sands: not to mention, that the shore is destitute of harbours, which must be entirely the work of art. The country besides has not a drop of fresh water, and to supply the inhabitants, it must be brought as far as from the Nile.

The best and only method therefore of effecting this junction, is that which has been already successfully practised at different times; which is, by making the river itself the medium of communication, for which the ground is perfectly well calculated; for Mount Mokattam suddenly terminating in the latitude of Cairo, forms only a low and semicircular mound, round which is a continued plain from the banks of the Nile as far as the point of the Red Sea. The ancients, who early understood the advantage to be derived from this situation, adopted the idea of joining the two seas by a canal connected with the river. Strabo * observes, that this was first executed under Sesostris, who reigned about the time of the Trojan war; and this work was so considerable as to occasion it to be remarked, "that it was 100 cubits (or 170 feet) wide, and deep enough for large vessels." After the Greeks conquered the country, it was restored by the Ptolemies, and again renewed by Trajan. In short, even the Arabs themselves followed these examples. "In the time of Omar ebn-el-Kattab (says the historian El Makin), the cities of Mecca and Medina suffering from famine, the Calif ordered Amrou governor of Egypt to cut a canal from the Nile to Kolzoum, that the contributions of corn and barley appointed for Arabia might be conveyed that way."

* Lib. xvii.

This canal is the same which runs at present to Cairo, and loses itself in the country to the north-east of Berket-el-Hadj, or the Lake of the Pilgrims.

The place on the west coast of the gulph of Suez, where the children of Israel are supposed to have entered it, is called *Badea*, about six miles to the north of Cape Korondel, on the other side of the gulph, as we are informed in a letter from the ingenious Edward Wortley Montague, F. R. S. to Dr Watson, containing an account of his journey from Cairo to the Written Mountains in the desert of Sinai. Opposite to Badea is a strong current which sets to the opposite shore, about south-east, with a whirlpool called *Birque Pharoane*, the *well* or *pool of Pharoah*, being the place where his host is said to have been destroyed. We are told by the same gentleman, that the Egyptian shore from Suez to Badea is so rocky and steep, that there was no entering upon the gulph but at one of these two places.

The

Suez ‖ Suffolk.

The British nation, we believe, never attempted to carry on commerce with any of the ports of the Red Sea beyond Jidda, till, on the ſuggeſtion of Mr Bruce, in 1776, ſome Britiſh merchants at Bengal equipped two or three veſſels for Suez, laden with piece-goods of Bengal and coaſt manufactures. The command of the veſſels was committed to Captain Greig, a meritorious ſeaman; and the management of the goods was entruſted to Mr Straw, a gentleman diſtinguiſhed for his mercantile knowledge. The ſale turned out to advantage; but ſuch great expences were incurred in making preſents to the bey of Cairo and Suez, as to conſume the whole profits gained by the ſale of the cargo. The great purpoſe of the expedition was, however, accompliſhed, as a firman was obtained from the government of Cairo to trade by the way of Suez. In conſequence of this, three ſhips went to Suez the following year, and as many in 1778. The opening of this trade alarmed the jealouſy of the Eaſt India Company; they applied to government, and orders were given to relinquiſh this promiſing commerce. Theſe orders reached Egypt ſooner than Bengal, and the conſequence was fatal to the unfortunate adventurers who viſited Suez that year (1779). By a plan concerted between the beys, a large body of Bedouin Arabs attacked the caravan paſſing from Suez to Cairo with goods valued at 12 lacks of rupees. The goods were plundered, the Europeans were ſtripped and left naked in the deſert, expoſed to the burning rays of the ſun, without a drop of water to quench their thirſt, or food to ſupport life. Moſt of them died, and ſome of their bodies were afterwards found mangled and diſfigured by wolves. We have been favoured with a particular account of the ſufferings of theſe unfortunate men by a correſpondent, which, we are ſorry, we have not room to inſert. Thoſe who wiſh to obtain a more full account may conſult the Annual Regiſter for 1781 or 1782.

SUFFETULA (anc. geog.), a town of Africa, in the dominions of Carthage; probably ſo called from Suffetes, the title of the magiſtrates of that city. It is now called *Spaitla*, in the kingdom of Tunis, and has many elegant remains of antiquity. There are three temples in a great meaſure entire; one of them of the Compoſite order, the other two Corinthian. "A beautiful and perfect capital of the Compoſite order (ſays Mr Bruce), the only perfect one that now exiſts, is deſigned in all its parts in a very large ſize; and with the detail of the reſt of the ruin, is a precious monument of what that order was, now in the collection of the king." The town itſelf (he ſays) is ſituated in the moſt beautiful ſpot in Barbary, ſurrounded by great numbers of juniper-trees, and watered by a pleaſant ſtream, which ſinks under the earth at that place, without appearing any more.

SUFFOCATION, in medicine, the privation of reſpiration or breathing. See the articles DROWNING, HANGING, &c.

SUFFOLK, a county of England. Its name is contracted from *Southfolk*, ſo called from its ſituation in regard to Norfolk. It is bounded on the weſt by Cambridgeſhire; on the ſouth by Eſſex, from which it is parted by the river Stour; on the eaſt by the German Ocean; and on the north by Norfolk, ſeparated from it by the Leſſer Ouſe and the Waveney. From weſt to eaſt it is 52 miles in length, about 20 at a medium in breadth, and 196 in circumference. It contains 22 hundreds, 29 market-towns, 575 pariſhes, upwards of 34,000 houſes, and more than 200,000 inhabitants. The whole is divided into two parts, viz. the Liberty of St Edmund, and the Geldable; the former of which contains the weſt parts of the county, and the other the eaſt; and there is a grand jury for each at the aſſizes. The air is reckoned as wholeſome and pleaſant as any in the kingdom, nor is it otherwiſe upon the ſea coaſt, which is dry and ſandy, and free from ſalt marſhes. The ſoil, except to the weſt and upon the ſea-coaſt, is very rich, being a compound of clay and marle. Towards the ſea there are large heaths and tracts of ſand; but theſe produce hemp, rye, and peaſe, and feed great flocks of ſheep. About Newmarket the ſoil is much the ſame; but in high Suffolk or the woodlands, beſides wood, there are very rich paſtures, where abundance of cattle are fed. In other parts of the country, as about Bury, there is plenty of corn. As this county is noted for the richneſs of its paſtures, ſo is it for butter and cheeſe, eſpecially the former, which is ſaid to be remarkably good; ſo that being packed up in firkins, it is ſold for all uſes both by ſea and land, and conveyed to many parts of England, eſpecially to London. The inland parts of the county are well ſupplied with wood for fuel, and thoſe upon the ſea-coaſt with coals from Newcaſtle. The manufactures of the county are chiefly woollen and linen cloth. It lies in the dioceſe of Norwich, has two archdeacons, viz. of Sedbury and Suffolk; gives title of earl to a branch of the Howards; ſends two members to parliament for the county, and two for each of the following places, Ipſwich, Dunwich, Orford, Aldborough, Sudbury, Eye, and St Edmund's-Bury. The county is extremely well watered by the following rivers, which either traverſe its borders, or run acroſs into the German Ocean, viz. the Leſſer Ouſe, the Waveney, the Blithe, the Deben, the Orwell or Gipping, and the Stour.

Gough's edition of Camden's Britannia.

Suffragan ‖ Sugar.

SUFFRAGAN, an appellation given to ſimple biſhops with regard to archbiſhops, on whom they depend, and to whom appeals lie from the biſhops' courts.

Suffragan is likewiſe the appellation given to a biſhop, who is occaſionally appointed to reſide in a town or village, and aſſiſt the dioceſan.

SUFFRAGE, denotes a vote given in an aſſembly, where ſomething is deliberated on, or where a perſon is elected to an office or benefice.

SUFFRUTEX, among botaniſts, denotes an underſhrub, or the loweſt kind of woody plants, as lavender.

SUGAR, a ſolid ſweet ſubſtance obtained from the juice of the ſugar-cane; or, according to chemiſts, an eſſential ſalt, capable of cryſtallization, of a ſweet and agreeable flavour, and contained in a greater or leſs quantity in almoſt every ſpecies of vegetables, but moſt abundant in the ſugar-cane.

Value of ſugar.

As the ſugar-cane is the principal production of the Weſt Indies, and the great ſource of their riches; as it is ſo important in a commercial view, from the employment which it gives to ſeamen, and the wealth which it opens for merchants; and beſides is now become a neceſſary of life—it may juſtly be eſteemed one of the moſt valuable plants in the world. The quantity conſumed in Europe is eſtimated at nine millions Sterling, and the demand would probably be greater if it could be ſold at a reduced price. Since ſugar then is reckoned ſo precious a commodity, it muſt be an object of deſire to all perſons of curioſity and reſearch, to obtain ſome general knowledge of the hiſtory and nature of the plant by which it is produced, as well as to underſtand the proceſs by which the juice is extracted and refined. We will therefore firſt inquire in what countries it originally flouriſhed, and when it was brought into general uſe, and became an article of commerce.

From the few remains of the Grecian and Roman authors which have ſurvived the ravages of time, we can find no proofs that the juice of the ſugar-cane was known at a very early period. There can be no doubt, however, that in thoſe countries where it was indigenous its value was not long con-

Sugar.

concealed. It is not improbable that it was known to the ancient Jews; for there is some reason to suppose, that the Hebrew word קנה, which occurs frequently in the Old Testament, and is by our translators rendered sometimes *calamus* and sometimes *sweet-cane*, does in fact mean the sugar-cane. The first passage in which we have observed it mentioned is Exod. xxx. 23. where Moses is commanded to make an ointment with myrrh, cinnamon, kené, and cassia. Now the kené does not appear to have been a native of Egypt nor of Judea; for in Jeremiah vi. 20. it is mentioned as coming from a far country. "To what purpose cometh there to me incense from Sheba and the sweet-cane from a far country?" This is not true of the calamus aromaticus, which grows spontaneously in the Levant, as well as in many parts of Europe. If the cinnamon mentioned in the passage of Exodus quoted above was true cinnamon, it must have come from the East Indies, the only country in the world from which cinnamon is obtained. There is no difficulty therefore in supposing, that the sugar-cane was exported from the same country. If any credit be due to etymology, it confirms the opinion that kené denotes the sugar-cane; for the Latin word *canna* and the English word *cane* are evidently derived from it. It is also a curious fact, that *sachar* or *shekar* ‡, in Hebrew, signifies *inebriation*, from which the Greek word σακχαρ "sugar" is undoubtedly to be traced.

2 Was probably known to the ancient Jews.

3 Account of it by Greek and Roman authors.

‡ שכר.

The sugar-cane was first made known to the western parts of the world by the conquests of Alexander the Great. Strabo * relates that Nearchus his admiral found it in the East Indies in the year before Christ 325. It is evidently alluded to in a fragment of Theophrastus, preserved in Photius. Varro, who lived A. C. 68, describes it in a fragment quoted by Isidorus § as a fluid pressed from reeds of a large size, which was sweeter than honey ‖. Dioscorides, about the year 35 before Christ, says "that there is a kind of honey called *saccharon*, which is found in India and Arabia Felix. It has the appearance of salt, and is brittle when chewed. If dissolved in water, it is beneficial to the bowels and stomach, is useful in diseases of the bladder and kidneys, and, when sprinkled on the eye, removes those substances that obscure the sight." This is the first account we have of its medical qualities. Galen often prescribed it as a medicine. Lucan relates, that an oriental nation in alliance with Pompey used the juice of the cane as a common drink.

* Lib. xv.

§ Lib. xvii. cap. 7.

‖ Matthioli Dios cap. lxxv.

Quique libunt tenera dulces ab arundine succos.
Lib. iii. 237.

Pliny says it was produced in Arabia and India, but that the best came from the latter country. It is also mentioned by Arrian, in the Periplus of the Red Sea, by the name of Σακχαρ (*sachar*) as an article of commerce from India to the Red Sea. Ælian ¶, Tertullian ‡, and Alexander Aphrodiseus †, mention it as a species of honey procured from canes (A).

¶ Nat. Hist.

‡ De Judicio Dei.

† Lib. ii. Prob. 79.

That the sugar-cane is an indigenous plant in some parts of the East Indies, we have the strongest reason to believe; for Thunberg found it in Japan, and has accordingly mentioned it as a native of that country in his *Flora Japonica*, published in 1784. Osbeck also found it in China in 1751. It may indeed have been transplanted from some other country; but as it does not appear from history that the inhabitants of Japan or China ever carried on any commerce with remote nations, it could only be conveyed from some neighbouring country. Marco Polo, a noble Venetian, who travelled into the East about the year 1250, found sugar in abundance in Bengal. Vasco de Gama, who doubled the Cape of Good Hope in 1497, relates, that a considerable trade in sugar was then carried on in the kingdom of Calicut. On the authority of Dioscorides and Pliny, too, we should be disposed to admit, that it is a native of Arabia, did we not find, on consulting Niebuhr's Travels, that that botanist has omitted it when enumerating the most valuable plants of that country. If it be a spontaneous production of Arabia, it must still flourish in its native soil. Mr Bruce found it in Upper Egypt. If we may believe the relation of Giovan Lioni, a considerable trade was carried on in sugar in Nubia in 1500: it abounded also at Thebes, on the Nile, and in the northern parts of Africa, about the same period.

4 Is a native of the East Indies.

Sugar.

There is reason to believe that the sugar-cane was introduced into Europe during the crusades; expeditions which however romantic in their plan, and unsuccessful in their execution, were certainly productive of many advantages to the nations of Europe. Albertus Aquensis, a monkish writer, observes, that the Christian soldiers in the Holy Land frequently derived refreshment and support during a scarcity of provisions by sucking the canes. This plant flourished also in the Morea, and in the islands of Rhodes and Malta; from which it was transported into Sicily. The date of this transaction it is not easy to ascertain; but we are sure that sugar was cultivated in that island previous to the year 1166; for Lafitau the Jesuit, who wrote a history of the Portuguese discoveries, mentions a donation made that year to the monastery of St Bennet, by William the second king of Sicily, of a mill for grinding sugar-canes, with all its rights, members, and appurtenances.

5 Introduced into Europe probably during the crusades.

From Sicily, where the sugar-cane still flourishes on the sides of mount Hybla, it was conveyed to Spain, Madeira, the Canary and Cape de Verd islands, soon after they were discovered in the 15th century.

D'Orville's Travels.

An opinion has prevailed, that the sugar-cane is not a native of the western continent, or its adjacent islands the West Indies, but was conveyed thither by the Spaniards or Portuguese soon after the discovery of America by Columbus. From the testimony of Peter Martyr, in the third book of his first decade, composed during Columbus's second voyage, which commenced in 1493 and ended in 1495, it appears, that the sugar-cane was known at that time in Hispaniola. It may be said, that it was brought thither by Columbus; but for this assertion we have found no direct evidence; and though we had direct evidence, this would not prove that the sugar cane was not an indigenous plant of the West Indies. There are authors of learning who, after investigating this subject with attention, do not hesitate to maintain, that it is a native both of the islands and of the continent of America.

6 Supposed by some not a native of America or the West Indies.

P. Labat has supported this opinion with much appearance of truth ‡; and, in particular, he appeals to the testimony of Thomas Gage, an Englishman, who visited New Spain in 1625. Gage enumerates sugar-canes among the provisions with which the Charaibes of Guadaloupe supplied his ship. "Now (says Labat) it is a fact that the Spaniards had never cultivated an inch of ground in the Smaller Antilles. Their ships commonly touched at those islands indeed for wood and water; and they left twine in the view of supplying with fresh provisions such of their countrymen as might call there in future; but it would be absurd in the highest

‡ Tom. iii. c. xv.

7 This opinion opposed by Labat.

(A) For a more minute account of the history of sugar in the early and middle ages, a paper of the Manchester Transactions, in Volume IV. by Dr Falconer, may be consulted.

Sugar. highest degree to suppose, that they would plant sugar-canes, and at the same time put hogs ashore to destroy them.

"Neither had the Spaniards any motive for bestowing this plant on islands which they considered as of no kind of importance, except for the purpose that has been mentioned; and to suppose that the Charaibes might have cultivated, after their departure, a production of which they knew nothing, betrays a total ignorance of the Indian disposition and character.

8 From testimony.

"But (continues Labat) we have surer testimony, and such as proves, beyond all contradiction, that the sugar-cane is the natural production of America. For, besides the evidence of Francis Ximines, who, in a Treatise on American Plants, printed at Mexico, asserts, that the sugar-cane grows without cultivation, and to an extraordinary size, on the banks of the river Plate, we are assured by Jean de Lery, a Protestant minister, who was chaplain in 1556 to the Dutch garrison in the fort of Coligny, on the river Janeiro, that he himself found sugar-canes in great abundance in many places on the banks of that river, and in situations never visited by the Portuguese. Father Hennepen and other voyagers bear testimony in like manner to the growth of the cane near the mouth of the Mississippi; and Jean de Laet to its spontaneous production in the island of St Vincent. It is not for the plant itself, therefore, but for the secret of making sugar from it, that the West Indies are indebted to the Spaniards and Portuguese; and these to the nations of the east."

Such is the reasoning of Labat, which the learned Lasitau has pronounced incontrovertible; and it is greatly strengthened by recent discoveries, the sugar-cane having been found in many of the islands of the Pacific Ocean by the late illustrious navigator Captain Cook.

9 Description of the sugar-cane.

The sugar-cane, or saccharum officinarum of botanists, is a jointed reed, commonly measuring (the flag part not included) from three feet and a half to seven feet in height, but sometimes rising to 12 feet. When ripe it is of a fine straw colour inclining to yellow, producing leaves or blades, the edges of which are finely and sharply serrated, and terminating in an arrow decorated with a panicle. The joints in one stalk are from 40 to 60 in number, and the stalks rising from one root are sometimes very numerous. The young shoot ascends from the earth like the point of an arrow; the shaft of which soon breaks, and the two first leaves, which had been inclosed within a quadruple sheath of seminal leaves, rise to a considerable height (B). See Plate CCCCLXXXVI. M is the arrow and N the lower part with the root.

10 Soil most favourable to its growth.

As the cane is a rank succulent plant, it must require a strong deep soil to bring it to perfection, perhaps indeed no soil can be too rich for this purpose. The soil which experience has found to be most favourable to the cultivation of it in the West Indies is the dark grey loam of St Christopher's, which is so light and porous as to be penetrable by the slightest application of the hoe. The under stratum is gravel from 8 to 12 inches deep. Canes planted in particular spots in this island have been known to yield 8000 pounds of Muscovado sugar from a single acre. The average produce of the island for a series of years has been 16,000 hogsheads of 16 cwt. which is one-half only of the whole cane-land, or 8500 acres. When annually cut, it gives nearly two hogsheads of 16 cwt. per acre for the whole of the land in ripe canes. Sugar.

Next to the ashy loam of St Christopher's is the soil which in Jamaica is called *brick-mold;* not as resembling a brick in colour, but as containing such a due mixture of clay and sand as is supposed to render it well adapted for the use of the kiln. It is a deep, warm, and mellow, hazel earth, easily worked; and though its surface soon grows dry after rain, the under stratum retains a considerable degree of moisture in the driest weather; with this advantage too, that even in the wettest season it seldom requires trenching. Plant-canes, by which is meant canes of the first growth, have been known in very fine seasons to yield two tons and a half of sugar per acre. After this may be reckoned the black mold of several varieties. The best is the deep black earth of Barbadoes, Antigua, and some other of the windward islands; but there is a species of this mold in Jamaica that is but little, if any thing inferior to it, which abounds with limestone and flint on a substratum of soapy marle. Black mold on clay is more common; but as the mold is generally shallow, and the clay stiff and retentive of water, this last sort of land requires great labour, both in ploughing and trenching, to render it profitable. When manured and properly pulverized, it becomes very productive. It is unnecessary to attempt a minute description of all the other soils which are found in these islands. There is, however, a peculiar sort of land on the north side of Jamaica, chiefly in the parish of Trelawney, that cannot be passed over unnoticed, not only on account of its scarcity but its value; few soils producing finer sugars, or such *as answer so well in the pan;* an expression signifying a greater return of refined sugar than common. The land alluded to is generally of a red colour; the shades of which, however, vary considerably from a deep chocolate to a rich scarlet; in some places it approaches to a bright yellow, but it is everywhere remarkable, when first turned up, for a glossy or shining surface, and if wetted stains the fingers like paint. Edwards's History of the West Indies, vol. ii.

11 Proper season for planting it.

And in every climate there is a season more favourable for vegetation than others, it is of great importance that plants for seed be committed to the ground at the commencement of this season. As the cane requires a great deal of moisture to bring it to maturity, the properest season for planting it is in the months of September and October, when the autumnal rains commence, that it may be sufficiently luxuriant to shade the ground before the dry weather sets in. Thus the root is kept moist, and the crop is ripe for the mill in the beginning of the ensuing year. Canes planted in the month of November, or later in the season, lose the advantage of the autumnal rains; and it often happens that dry weather in the beginning of the ensuing year retards their vegetation until the vernal or May rains set in, when they sprout both at the roots and the joints; so that

(B) "A field of canes, when standing, in the month of November, when it is in arrow or full blossom (says Mr Beckford in his descriptive Account of the Island of Jamaica), is one of the most beautiful productions that the pen or pencil can possibly describe. It in common rises from three to eight feet or more in height; a difference of growth that very strongly marks the difference of soil or the varieties of culture. It is when ripe of a bright and golden yellow; and where obvious to the sun, is in many parts very beautifully streaked with red: the top is of a darkish green; but the more dry it becomes, from either an excess of ripeness or a continuance of drought, of a russet yellow, with long and narrow leaves depending; from the centre of which shoots up an arrow like a silver wand from two to six feet in height; and from the summits of which grows out a plume of white feathers, which are delicately fringed with a lilac dye; and indeed is, in its appearance, not much unlike the tuft that adorns this particular and elegant tree."

Sugar.

by the time they are cut the field is loaded with unripe ſuckers inſtead of ſugar-canes. A January plant, however, commonly turns out well; but canes planted very late in the ſpring, though they have the benefit of the May rains, ſeldom anſwer expectation; for they generally come in unſeaſonably, and throw the enſuing crops out of regular rotation. They are therefore frequently cut before they are ripe; or if the autumnal ſeaſons ſet in early, are cut in wet weather, which has probably occaſioned them to ſpring afreſh; in either caſe the effect is the ſame: The juice is unconcocted, and all the ſap being in motion, the root is deprived of its natural nouriſhment, to the great injury of the ratoon. The chief objection to a fall plant is this, that the canes become rank and top heavy, at a period when violent rains and high winds are expected, and are therefore frequently lodged before they are fit to be cut.

12 Method of planting

The ſugar-cane is propagated by the top-ſhoots, which are cut from the tops of the old canes. The uſual method of planting in the Weſt Indies is this: The quantity of land intended to be planted, being cleared of weeds and other incumbrances, is firſt divided into ſeveral plats of certain dimenſions, commonly from 15 to 20 acres each; the ſpaces between each plat or diviſion are left wide enough for roads, for the coveniency of carting, and are called *intervals*. Each plat is then ſubdivided, by means of a line and wooden pegs, into ſmall ſquares of about three feet and a half. Sometimes indeed the ſquares are a foot larger; but this circumſtance makes but little difference. The negroes are then placed in a row in the firſt line, one to a ſquare, and directed to dig out with their hoes the ſeveral ſquares, commonly to the depth of five or ſix inches. The mold which is dug up being formed into a bank at the lower ſide, the excavation or cane-hole ſeldom exceeds 15 inches in width at the bottom, and two feet and a half at the top. The negroes then fall back to the next line, and proceed as before. Thus the ſeveral ſquares between each line are formed into a trench of much the ſame dimenſions with that which is made by the plough. An able negro will dig from 100 to 120 of theſe holes for his day's work of ten hours; but if the land has been previouſly ploughed and lain fallow, the ſame negro will dig nearly double the number in the ſame time (c).

The cane-holes or trench being now completed, whether by the plough or by the hoe, and the cuttings ſelected for planting, which are commonly the tops of the canes that have been ground for ſugar (each cutting containing five or ſix gems), two of them are ſufficient for a cane hole of the dimenſions deſcribed. Theſe, being placed longitudinally in the bottom of the hole, are covered with mold about two inches deep; the reſt of the bank being intended for future uſe. In 12 or 14 days the young ſprouts begin to appear; and as ſoon as they riſe a few inches above the ground,

13 And cleaning it.

they are, or ought to be, carefully cleared of weeds, and furniſhed with an addition of mold from the banks. This is uſually performed by the hand. At the end of four or five months the banks are wholly levelled, and the ſpaces between the rows carefully hoe-ploughed. Frequent cleanings, while the canes are young, are indeed ſo eſſentially neceſſary, that no other merit in an overſeer can compenſate for the want of attention in this particular. A careful manager will remove at the ſame time all the lateral ſhoots or ſuckers that ſpring up after the canes begin to joint, as they ſeldom come to maturity, and draw nouriſhment from the original plants.

Sugar.

14 The plough might be uſed with advantage.

"In the cultivation of other lands, in Jamaica eſpecially (ſays Mr Edwards, the elegant hiſtorian of the Weſt Indies, whoſe ſuperior excellence has induced us frequently to refer to him in the courſe of this article), the plough has been introduced of late years, and in ſome few caſes to great advantage; but it is not every ſoil or ſituation that will admit the uſe of the plough; ſome lands being much too ſtony, and others too ſteep; and I am ſorry I have occaſion to remark, that a practice commonly prevails in Jamaica, on properties where this auxiliary is uſed, which would exhauſt the fineſt lands in the world. It is that of ploughing, then croſs-ploughing, round-ridging, and harrowing the ſame lands from year to year, or at leaſt every other year, without affording manure: accordingly it is found that this method is utterly deſtructive of the ratoon or ſecond growth, and altogether ruinous. It is indeed aſtoniſhing that any planter of common reading or obſervation ſhould be paſſive under ſo pernicious a ſyſtem. Some gentlemen, however, of late manage better: their practice is to break up ſtiff and clayey land, by one or two ploughings, early in the ſpring, and give it a ſummer's fallow. In the autumn following, being then mellow and more eaſily worked, it is holed and planted by manual labour after the old method, which has been already deſcribed. But in truth, the only advantageous ſyſtem of ploughing in the Weſt Indies is to confine it to the ſimple operation of holing, which may certainly be performed with much greater facility and diſpatch by the plough than by the hoe; and the relief which, in the caſe of ſtiff and dry ſoils, is thus given to the negroes, exceeds all eſtimation, in the mind of a humane and provident owner. On this ſubject I ſpeak from practical knowledge. At a plantation of my own, the greateſt part of the land which is annually planted is neatly and ſufficiently laid into cane-holes, by the labour of one able man, three boys, and eight oxen, with the common ſingle-wheeled plough. The ploughſhare indeed is ſomewhat wider than uſual; but this is the only difference, and the method of ploughing is the ſimpleſt poſſible. By returning the plough back along the furrow, the turf is alternately thrown to the right and to the left, forming a trench ſeven inches deep, about two feet and a half wide at the top, and one foot wide at the bottom. A ſpace of 18 or 20 inches is left between each trench, on which the mold being thrown by the ſhare, the banks are properly formed, and the holing is complete. Thus the land is not exhauſted by being too much expoſed to the ſun; and in this manner a field of 20 acres is holed with one plough, and with great eaſe, in 13 days. The plants are afterwards placed in the trench as in the common method, where manual labour alone is employed."

Edwards's Hiſtory of the Weſt Indies, vol. ii.

In moſt parts of the Weſt Indies it is uſual to hole and plant a certain proportion of the cane-land, commonly one-third in annual rotation. Canes of the firſt year's growth are called *plant canes*, as has been already obſerved. The ſprouts that ſpring from the roots of the canes that have been

15 Canes named according to the age of their roots.

(c) As the negroes work at this buſineſs very unequally, according to their different degrees of bodily ſtrength, it is ſometimes the practice to put two negroes to a ſingle ſquare; but if the land has not had the previous aſſiſtance of the plough, it commonly requires the labour of 50 able negroes for 13 days to hole 20 acres. In Jamaica, ſome gentlemen, to eaſe their own ſlaves, have this laborious part of the planting-buſineſs performed by job-work. The uſual price for holing and planting is L. 6 currency *per* acre (equal to L. 4, 7s. Sterling). The coſt of falling and clearing heavy woodland is commonly as much more.

Sugar.

been previouſly cut for ſugar are called *ratoons*; the firſt yearly returns from their roots are called *firſt ratoons*; the ſecond year's growth *ſecond ratoons*.

16 Manures employed.

Mr Edwards informs us, that the manure generally uſed is a compoſt formed, 1ſt, Of the vegetable aſhes, drawn from the fires of the boiling and ſtill houſes. 2dly, Feculencies diſcharged from the ſtill-houſe, mixed up with rubbiſh of buildings, white-lime, &c. 3dly, Refuſe, or field-traſh (*i. e.*), the decayed leaves and ſtems of the canes; ſo called in contradiſtinction to cane-traſh, reſerved for fuel. 4thly, Dung, obtained from the horſe and mule ſtables, and from moveable pens, or ſmall incloſures made by poſts and rails, occaſionally ſhifted upon the lands intended to be planted, and into which the cattle are turned at night. 5thly, Good mold, collected from gullies and other waſte places, and thrown into the cattle pens.

17 The ſugar-cane deſtroyed by monkeys.

The ſugar-cane is liable to be deſtroyed by monkeys, rats, and inſects. The upland plantations ſuffer greatly from monkeys; theſe creatures, which now abound in the mountainous parts of St Chriſtopher's, were firſt brought thither by the French, when they poſſeſſed half that iſland; they come down from the rocks in ſilent parties by night, and having poſted centinels to give the alarm if any thing approaches, they deſtroy incredible quantities of the cane, by their gambols as well as their greedineſs. It is in vain to ſet traps for theſe creatures, however baited; and the only way to protect the plantation, and deſtroy them, is to ſet a numerous watch, well armed with fowling-pieces, and furniſhed with dogs. The negroes will perform this ſervice cheerfully, for they are very fond of monkeys as food. The celebrated Father Labat ſays, they are very delicious, but the white inhabitants of St Kitt's never eat them.

Grainger's Hiſtory of the Sugar-cane.

18 Rats.

The low-land plantations ſuffer as much by rats as thoſe on the mountains do from monkeys; but the rats, no more than the monkeys, are natives of the place; they came with the ſhipping from Europe, and breed in the ground under looſe rocks and buſhes: the field negroes eat them greedily, and they are ſaid to be publicly ſold in the markets at Jamaica. To free the plantations from theſe vermin, the breed of wild cats ſhould be encouraged, and ſnakes ſuffered to multiply unmoleſted; they may alſo be poiſoned with arſenic, and the raſped root of the caſſava made into pellets, and plentifully ſcattered over the grounds. This practice, however, is dangerous; for as the rats when thus poiſoned become exceeding thirſty, they run in droves to the neighbouring ſtreams, which they poiſon as they drink, and the cattle grazing on the banks of theſe polluted waters have frequently periſhed by drinking after them: It is ſafer therefore to make the pellets of flour, kneaded with the juice of the night-ſhade, the ſcent of which will drive them away though they will not eat it. There is an Eaſt Indian animal called *mungoes*, which bears a natural antipathy to rats; if this animal was introduced into the ſugar iſlands, it would probably extirpate the whole race of theſe noxious vermin. The *formica omnivora* of Linnæus, the carnivorous ant, which is called in Jamaica the *raffle's ant*, would ſoon clear a ſugar plantation of rats.

The ſugar-cane is alſo ſubject to a diſeaſe which no foreſight can obviate, and for which human wiſdom has hitherto in vain attempted to find a remedy. This diſeaſe is called the *blaſt*, and is occaſioned by the *aphis* of Linnæus. When this happens, the fine, broad, green blades become ſickly, dry, and withered; ſoon after they appear ſtained in ſpots; and if theſe ſpots are carefully examined, they will be found to contain innumerable eggs of an inſect like a bug, which are ſoon quickened, and cover the plants with the vermin: the juice of the canes thus affected becomes ſour, and no future ſhoot iſſues from the joints. Ants alſo concur with the bugs to ſpoil the plantation, and againſt theſe evils it is hard to find a remedy.

Sugar.

19 And inſects.

20 Time at which the crop ripens.

The crops of ſugar-canes do not ripen preciſely at the ſame period in all the colonies. In the Daniſh, Spaniſh, and Dutch ſettlements, they begin in January, and continue till October. This method doth not imply any fixed ſeaſon for the maturity of the ſugar-cane. The plant, however, like others, muſt have its progreſs; and it hath been juſtly obſerved to be in flower in the months of November and December. It muſt neceſſarily follow, from the cuſtom theſe nations have adopted of continuing to gather their crops for 10 months without intermiſſion, that they cut ſome canes which are not ripe enough, and others that are too ripe, and then the fruit hath not the requiſite qualities. The time of gathering them ſhould be at a fixed ſeaſon, and probably the months of March and April are the fitteſt for it; becauſe all the ſweet fruits are ripe at that time, while the four ones do not arrive to a ſtate of maturity till the months of July and Auguſt.

Raynal's Hiſtory of the Eaſt and Weſt Indies, vol. iv.

The Engliſh cut their canes in March and April; but they are not induced to do this on account of their ripeneſs. The drought that prevails in their iſlands renders the rains which fall in September neceſſary to their planting; and as the canes are 18 months in growing, this period always brings them to the preciſe point of maturity (D).

21 A ſeaſon of feſtivity.

"The time of crop in the ſugar iſlands (ſays Mr Edwards) is the ſeaſon of gladneſs and feſtivity to man and beaſt. So palatable, ſalutary, and nouriſhing, is the juice of the cane, that every individual of the animal creation, drinking freely of it, derives health and vigour from its uſe. The meagre and ſickly among the negroes exhibit a ſurpriſing alteration in a few weeks after the mill is ſet in action. The labouring horſes, oxen, and mules, though almoſt conſtantly at work during this ſeaſon, yet, being indulged with plenty of the green tops of this noble plant, and ſome of the ſcummings from the boiling-houſe, improve more than at any other period of the year. Even the pigs and poultry fatten on the refuſe. In ſhort, on a well-regulated plantation, under a humane and benevolent director, there is ſuch an appearance during crop-time of plenty and buſy cheerfulneſs, as to ſoften, in a great meaſure, the hardſhips of ſlavery, and induce a ſpectator to hope, when the miſeries of life are repreſented as inſupportable, that they are ſometimes exaggerated through the medium of fancy."

Edwards, vol. ii. p. 226.

The plants being cut, the branches at the top are given to the cattle for food; the top-ſhoot, which is full of eyes, — is

(D) The account given in the text concerning the time when the ſugar-canes are collected, we have taken from the Abbé Raynal's Hiſtory of the Trade and Settlements of the Eaſt and Weſt Indies; but Mr Cazaud obſerves, that in February, March, and April, all the canes, whatever be their age, are as ripe as the nature of the ſoil ever allows them to be. He ſays farther, that the dryneſs of the weather, and not the age of the canes, which increaſes from January to April, is the cauſe that in January 400 gallons of juice commonly yield 48 gallons of ſugar and molaſſes, one with another; in February from 56 to 64; in March from 64 to 72; in April ſometimes 80; after which period the ſugar ferments, and even burns, when the refiner is not very expert at his buſineſs.

Philoſoph. Tranſact. vol. lxix.

Sugar.

is preſerved for planting. The canes are cut into pieces about a yard long, tied up in bundles, and carried in carts to the mill, where they are bruiſed, and the juice is extracted from them. The mill conſiſts principally of three upright iron-plated rollers or cylinders, from 30 to 40 inches in length, and from 20 to 25 inches in diameter; and the middle one, to which the moving power is applied, turns the other two by means of cogs. Between theſe rollers, the canes (being previouſly cut ſhort, and tied into bundles) are twice compreſſed; for having paſſed through the firſt and ſecond rollers, they are turned round the middle one by a circular piece of frame work or ſcreen, called in Jamaica the *Dumb-returner*, and forced back through the ſecond and third; an operation which ſqueezes them completely dry, and ſometimes even reduces them to powder. The cane juice is received in a leaden bed, and thence conveyed into a veſſel called the *receiver*. The refuſe, or macerated rind of the cane (which is called *cane-traſh*, in contradiſtinction to *field-traſh*), ſerves for fuel to boil the liquor.

22 The canes when cut are ſent to the mill.

23 The juice extracted from them.

The juice as it flows from the mill, taken at a medium, contains eight parts of pure water, one part of ſugar, and one part conſiſting of coarſe oil and mucilaginous gum, with a portion of eſſential oil.

24 Veſſels uſed for purifying it are,

As the juice has a ſtrong diſpoſition to fermentation, it muſt be boiled as ſoon as poſſible. There are ſome water-mills that will grind with great eaſe canes ſufficient for 30 hogſheads of ſugar in a week. It is neceſſary to have boiling veſſels, or clarifiers, that will correſpond in dimenſions to the quantity of juice flowing from the receiver. Theſe clarifiers are commonly three in number, and are ſometimes capable of containing 1000 gallons each; but it is more uſual to ſee them of 300 or 400 gallons each. Beſides the clarifiers which are uſed for the firſt boiling, there are generally four coppers or boilers. The clarifiers are placed in the middle or at one end of the boiling-houſe. If at one end, the boiler called the *teache* is placed at the other, and ſeveral boilers (generally three) are ranged between them. The teache is ordinarily from 70 to 100 gallons, and the boilers between the clarifiers and teache diminiſh in ſize from the firſt to the laſt. Where the clarifiers are in the middle, there is uſually a ſet of three boilers of each ſide, which conſtitute in effect a double boiling-houſe. On very large eſtates this arrangement is found uſeful and neceſſary. The objection to ſo great a number is the expence of fuel; to obviate which, in ſome degree, the three boilers on each ſide of the clarifiers are commonly hung to one fire.

25 The clarifier.

The juice runs from the receiver along a wooden gutter lined with lead into the boiling-houſe, where it is received into one of the clarifiers. When the clarifier is filled, a fire is lighted, and a quantity of Briſtol quicklime in powder, which is called *temper*, is poured into the veſſel. The uſe of the lime is to unite with the ſuperabundant acid, which, for the ſucceſs of the proceſs, it is neceſſary to get rid of. The quantity ſufficient to ſeparate the acid muſt vary according to the ſtrength of the quicklime and the quality of the liquor. Some planters allow a pint of lime to every 100 gallons of liquor; but Mr Edwards thinks that little more than half the quantity is a better medium proportion, and even then, that it ought to be diſſolved in boiling water, that as little of it as poſſible may be precipitated. The heat is ſuffered gradually to increaſe till it approaches within a few degrees of the heat of boiling water, that the impurities may be thoroughly ſeparated. But if the liquor were ſuffered to boil with violence, the impurities would again incorporate with it. It is known to be ſufficiently heated when the ſcum begins to riſe in bliſters, which break into white froth, and appear generally in about 40 minutes. The fire is then ſuddenly extinguiſhed by means of a damper, which excludes the external air, and the liquor is allowed to remain about an hour undiſturbed, during which period the impurities are collected in ſcum on the ſurface. The juice is then drained off either by a ſyphon or a cock; the ſcum being of a tenacious gummy nature, does not flow out with the liquor, but remains behind in the clarifier. The liquid juice is conveyed from the clarifier by a gutter into the evaporating boiler, commonly termed the *grand copper*; and if it has been obtained from good canes it generally appears tranſparent.

Sugar.

26 And four coppers.

In the evaporating boiler, which ſhould be large enough to receive the contents of the clarifier, the liquor is allowed to boil; and as the ſcum riſes it is taken off. The ſcumming and evaporation are continued till the liquor becomes finer and thicker, and ſo far diminiſhed in bulk that it may be eaſily contained in the ſecond copper. When put into the ſecond copper, it is nearly of the colour of Madeira wine; the boiling and ſcumming are continued, and if the impurities be conſiderable, a quantity of lime-water is added. This proceſs is carried on till the liquor be ſufficiently diminiſhed in quantity to be contained in the third copper. After being purified a third time, it is put into the fourth copper, which is called the *teache*, where it is boiled and evaporated till it is judged ſufficiently pure to be removed from the fire. In judging of the purity of the liquor, many of the negroes (ſays Mr Edwards) gueſs ſolely by the eye (which by long habit they do with great accuracy), judging by the appearance of the grain on the back of the ladle: but the practice moſt in uſe is to judge by what is called the *touch*; i. e. taking up with the thumb a ſmall portion of the hot liquor from the ladle; and, as the heat diminiſhes, drawing with the fore-finger the liquid into a thread. This thread will ſuddenly break, and ſhrink from the thumb to the ſuſpended finger, in different lengths, according as the liquor is more or leſs boiled. The proper boiling height for ſtrong muſcovado ſugar is generally determined by a thread of a quarter of an inch long. It is evident, that certainty in this experiment can be attained only by long habit, and that no verbal precepts will furniſh any degree of ſkill in a matter depending wholly on conſtant practice.

27 After being clarified it is cooled, granulated, and freed from its molaſſes.

The juice being thus purified by paſſing through the clarifier and four coppers, it is poured into coolers, which are uſually ſix in number. The removal from the teache to the cooler is called *ſtriking*. The cooler is a ſhallow wooden veſſel 7 feet long, from 5 to 6 wide, about 11 inches deep, and capable of containing a hogſhead of ſugar. As the liquor cools, the ſugar grains, that is, collects into an irregular maſs of imperfect cryſtals, ſeparating itſelf from the molaſſes. It is then removed from the cooler, and conveyed to the curing-houſe, where the molaſſes drain from it. For receiving them there is a large ciſtern, the ſloping ſides of which are lined with boards. Directly above the ciſtern a frame of joiſt-work without boarding is placed, on which empty hogſheads without heads are ranged. The bottoms of theſe hogſheads are pierced with 8 or 10 holes, in each of which the ſtalk of a plantain leaf is fixed ſo as to project 6 or 8 inches below the joiſts, and riſe a little above the top of the hogſhead. The hogſheads being filled with the contents of the cooler, conſiſting of ſugar and molaſſes, the molaſſes being liquid, drain through the ſpungy ſtalk, and drop into the ciſtern. After the molaſſes are drained off, the ſugar becomes pretty dry and fair, and is then called *muſcovado*, or *raw ſugar*.

We have deſcribed the proceſs for extracting ſugar, which is generally adopted in the Britiſh Weſt India iſlands, according to the lateſt improvements; and have been anxious to preſent it to our readers in the ſimpleſt and moſt perſpicuous form, that it might be intelligible to every perſon; and

Sugar. have therefore avoided to mention the obſervations and propoſed amendments of thoſe who have written on this ſubject. Had we done ſo, we ſhould have ſwelled the preſent article to too great a ſize, without accompliſhing the purpoſe which we have in view; for our intention is not to inſtruct the planters, but to give a diſtinct account of the moſt approved methods which the planters have generally adopted. But though we judge it uſeleſs to trouble our readers with all the little varieties in the proceſs which different perſons employ, we flatter ourſelves it will not be diſagreeable to learn by what methods the French make their ſugar purer and whiter than others. A quantity of ſugar from the cooler is put into conical pans or earthen pots, called by the French *formes*, having a ſmall perforation at the apex, which is kept cloſed. Each cone, reverſed on its apex, is ſupported in another earthen veſſel. The ſyrup is ſtirred together, and then left to cryſtallize. At the end of 15 or 16 hours, the hole in the point of each cone is opened, that the impure ſyrup may run out. The baſe of theſe ſugar loaves is then taken out, and white pulverized ſugar ſubſtituted in its ſtead; which being well preſſed down, the whole is covered with clay moiſtened with water. This water filters through the maſs, carrying the ſyrup with it which was mixed with the ſugar, but which by this management flows into a pot ſubſtituted in the place of the firſt. This ſecond fluid is called *fine ſyrup*. Care is taken to moiſten and keep the clay to a proper degree of ſoftneſs as it becomes dry. The ſugar loaves are afterwards taken out, and dried in a ſtove for eight or ten days; after which they are pulverized, packed, and exported to Europe, where they are ſtill farther purified. The reaſon aſſigned why this proceſs is not univerſally adopted in the Britiſh ſugar iſlands is this, that the water which dilutes and carries away the molaſſes diſſolves and carries with it ſo much of the ſugar, that the difference in quality does not pay for the difference in quantity. The French planters probably think otherwiſe, upwards of 400 of the plantations of St Domingo having the neceſſary apparatus for claying and actually carrying on the ſyſtem.

28 Method of purifying uſed by the French.

Chaptal's Chemiſtry, vol. iii.

29 The art of refining ſugar introduced by a Venetian.

The art of refining ſugar was firſt made known to the Europeans by a Venetian, who is ſaid to have received 100,000 crowns for the invention. This diſcovery was made before the new world was explored; but whether it was an invention of the perſon who firſt communicated it, or whether it was conveyed from China, where it had been known for a conſiderable time before, cannot now perhaps be accurately aſcertained. We find no mention made of the refining of ſugar in Britain till the year 1659, though it probably was practiſed ſeveral years before. For in the Portugueſe iſland of St Thomas in 1624 there were 74 ſugar ingenios, each having upwards of 200 ſlaves. The quantity of raw ſugar imported into England in 1778 amounted to 1,403,995 cwts.; the quantity imported into Scotland in the ſame year was 117,285 cwts.; the whole quantity imported into Great Britain in 1787 was 1,926,741 cwts.

Anderſon's Origin of Commerce.

30 In refining it is mixed with lime-water and bullock's blood, and expoſed to heat.

The ſugar which undergoes the operation of refining in Europe is either raw ſugar, ſometimes called *muſcovado* or *caſſonado*, which is raw ſugar, in a purer ſtate. The raw ſugar generally contains a certain quantity of melaſſes as well as earthy and feculent ſubſtances. The caſſonado, by the operation of earthing, is freed from its melaſſes. As the intention of refining theſe ſugars is to give them a higher degree of whiteneſs and ſolidity, it is neceſſary for them to undergo other proceſſes. The firſt of theſe is called *clarification*. It conſiſts in diſſolving the ſugar in a certain proportion of lime-water, adding a proper quantity of bullock's blood, and expoſing it to heat in order to remove the impurities which ſtill remain. The heat is increaſed very gradually till it approach that of boiling water. By the aſſiſtance of the heat, the animal matter which was thrown in coagulates, at the ſame time that it attracts all the ſolid feculent and earthy matter, and raiſes it to the ſurface in the appearance of a thick foam of a browniſh colour. As the feculencies are never entirely removed by a firſt proceſs, a ſecond is neceſſary. The ſolution is therefore cooled to a certain degree by adding ſome water; then a freſh quantity of blood, but leſs conſiderable that at firſt, is poured in. The fire is renewed, and care is taken to increaſe the heat gently as before. The animal ſubſtance ſeizes on the impurities which remain, collects them on the ſurface, and they are then ſkimmed off. The ſame operation is repeated a third and even a fourth time, but no addition is made to the liquor except water. If the different proceſſes have been properly conducted, the ſolution will be freed from every impurity, and appear tranſparent. It is then conveyed by a gutter into an oblong baſket about 16 inches deep, lined with a woollen cloth; and after filtering through this cloth, it is received in a ciſtern or copper which is placed below.

Sugar.

31 Then freed from its remaining impurities by evaporation.

The ſolution being thus clarified it undergoes a ſecond general operation called *evaporation*. Fire is applied to the copper into which the ſolution was received, and the liquid is boiled till it has acquired the proper degree of conſiſtency. A judgment is formed of this by taking up a ſmall portion of the liquid and drawing it into a thread. When, after this trial, it is found ſufficiently viſcous, the fire is extinguiſhed, and the liquid is poured into coolers. It is then ſtirred violently by an inſtrument called an *oar*, from the reſemblance it bears to the oar of a boat. This is done in order to diminiſh the viſcoſity, and promote what is called the *granulation*, that is, the forming of it into grains or imperfect cryſtals. When the liquid is properly mixed and cooled, it is then poured into moulds of the form of a ſugar loaf. Theſe moulds are ranged in rows. The ſmall ends, which are loweſt, are placed in pots; and they have each of them apertures ſtopped up with linen for filtering the ſyrup, which runs from the moulds into the pots. The liquor is then taken out ſlowly in ladlefuls from the coolers, and poured into the moulds. When the moulds are filled, and the contents ſtill in a fluid ſtate, it is neceſſary to ſtir them, that no part may adhere to the moulds, and that the ſmall cryſtals which are juſt formed may be equally diffuſed thro' the whole maſs. When the ſugar is completely cryſtallized, the linen is taken away from the apertures in the moulds, and the ſyrup, or that part which did not cryſtallize, deſcends into the pots in which the moulds are placed. After this purgation the moulds are removed and fixed in other pots, and a ſtratum of fine white clay diluted with water is laid on the upper part of the loaf. The water deſcending through the ſugar, by its own weight, mixes with the ſyrup which ſtill remains in the body of the loaf, and waſhes it away. When the clay dries, it is taken off, and another covering of moiſt clay put in its place; and if it be not then ſufficiently waſhed, a third covering of clay is applied. After the loaves have ſtood ſome days in the moulds, and have acquired a conſiderable degree of firmneſs and ſolidity, they are taken out, and carried to a ſtove, where they are gradually heated to the 50° of Reaumur (64° of Fahernheit), in order to diſſipate any moiſture which may be ſtill confined in them. After remaining in the ſtove eight days, they are taken out; and after cutting off all diſcolouring ſpecks, and the head if ſtill wet, they are wrapped in blue paper, and are ready for ſale. The ſeveral ſyrups collected during the different parts of the proceſs, treated in the ſame manner which we have juſt deſcribed, afford ſugars of inferior quality; and the laſt portion, which no longer affords any ſugar, is ſold by the name of *melaſſes*.

32 Afterwards poured into moulds, where the ſyrup is drained from it.

33 Laſtly expoſed to a certain degree of heat.

The

Sugar.

The beauty of refined ſugar, when formed into loaves, conſiſts in whiteneſs, joined to a ſmallneſs of grain; in being dry, hard, and ſomewhat tranſparent. The proceſs which we have deſcribed above refers to ſugar once refined; but ſome more labour is neceſſary to produce double refined ſugar. The principal difference in the operation is this, the latter is clarified by white of eggs inſtead of blood, and freſh water in place of lime-water.

34 In what the beauty of ſugar conſiſts; how farther refined.

Sugar-candy is the true eſſence of the cane formed into large cryſtals by a ſlow proceſs. When the ſyrup is well clarified, it is boiled a little, but not ſo much as is done for the proof mentioned in the proceſs for making common ſugar. It is then placed in old moulds, having their lower ends ſtopped with linen, and croſſed at little diſtances with ſmall twigs to retain the ſugar as it cryſtallizes. The moulds are then laid in a cool place. In proportion as the ſyrup cools cryſtals are formed. In about nine or ten days the moulds are carried to the ſtove, and placed in a pot; but the linen is not removed entirely, ſo that the ſyrup falls down ſlowly in drops. When the ſyrup has dropped away, and the cryſtals of the ſugar-candy are become dry, the moulds are taken from the ſtove and broken in pieces, to diſengage the ſugar, which adheres ſtrongly to the ſides of the moulds. If the ſyrup has been coloured with cochineal, the cryſtals take a ſlight taint of red; if indigo has been mixed, they aſſume a bluiſh colour. If it be deſired to have the candy perfumed, the eſſence of flowers or amber may be dropped into the moulds along with the ſyrup.

35 How ſugar-candy is made.

Having now given ſome account of the method uſually employed for refining ſugar, it will not be improper to ſay a few things concerning its nature and its uſes.

36 Chemical qualities of ſugar.

Sugar is ſoluble in water, and in a ſmall degree in alcohol. When united with a ſmall portion of water, it becomes fuſible; from which quality the art of preſerving is indebted for many of its preparations. It is phoſphoric and combuſtible; when expoſed to fire emitting a blue flame if the combuſtion be ſlow, and a white flame if the combuſtion be rapid. By diſtillation it produces a quantity of phlegm, acid, oil, gas, and charcoal. Bergman, in treating ſugar with the nitrous acid, obtained a new acid now known by the name of the *oxalic acid*: but he has omitted to mention the principles of which ſugar is compoſed. Lavoiſier, however, has ſupplied this omiſſion; and after many experiments has aſſigned three principles in ſugar, hydrogene, oxygene, and carbone. If the juice expreſſed from the ſugar-cane be left to itſelf, it paſſes into the acetous fermentation; and during the decompoſition of the ſugar, which is continued for three or four months, a great quantity of glutinous matter is ſeparated. This matter when diſtilled gives a portion of ammoniac. If the juice be expoſed to the ſpirituous fermentation, a wine is obtained analogous to cyder. If this wine, after being kept in bottles a year, be diſtilled, we obtain a portion of *eau de vie*.

37 Its uſes in medicine, &c.

The uſes to which ſugar are applied are indeed numerous and important: It can be made ſo ſolid as in the art of preſerving to receive the moſt agreeable colours and the greateſt variety of forms. It can be made ſo fluid as to mix with any ſoluble ſubſtance.—It preſerves the juice and ſubſtance of fruits in all countries and in all ſeaſons. It affords a delicious ſeaſoning to many kinds of food. It is uſeful in pharmacy, for it unites with medicines, and removes their diſagreeable flavour: it is the baſis of all ſyrups. M. Macquer has ſhown in a very ſatisfactory manner how uſeful ſugar would be if employed in fermenting wines. Sugar has alſo been found a remedy for the ſcurvy, and a valuable article of food in caſes of neceſſity. M. Imbert de Lennes, firſt ſurgeon to the late Duke of Orleans, publiſhed the following ſtory in the *Gazette de Santé*, which confirms this aſſertion. A veſſel laden with ſugar bound from the Weſt Indies was becalmed in its paſſage for ſeveral days, during which the ſtock of proviſions was exhauſted. Some of the crew were dying of the ſcurvy, and the reſt were threatened with a ſtill more terrible death. In this emergency recourſe was had to the ſugar. The conſequence was, the ſymptoms of the ſcurvy went off, the crew found it a wholeſome and ſubſtantial aliment, and returned in good health to France.

Sugar.

38 Affords the greateſt quantity of nouriſhment of any kind of food.

"Sugar (ſays Dr Ruſh) affords the greateſt quantity of nouriſhment in a given quantity of matter of any ſubſtance in nature; of courſe it may be preſerved in leſs room in our houſes, and may be conſumed in leſs time, than more bulky and leſs nouriſhing aliment. It has this peculiar advantage over moſt kinds of aliment, that it is not liable to have its nutritious qualities affected by time or the weather; hence it is preferred by the Indians in their excurſions from home. They mix a certain quantity of maple ſugar, with an equal quantity of Indian corn, dried and powdered, in its milky ſtate. This mixture is packed in little baſkets, which are frequently wetted in travelling, without injuring the ſugar. A few ſpoonfuls of it mixed with half a pint of ſpring water afford them a pleaſant and ſtrengthening meal. From the degrees of ſtrength and nouriſhment which are conveyed into animal bodies by a ſmall bulk of ſugar, it might probably be given to horſes with great advantage, when they are uſed in places or other circumſtances which make it difficult or expenſive to ſupport them with more bulky or weighty aliment. A pound of ſugar with graſs or hay has ſupported the ſtrength and ſpirits of an horſe during a whole day's labour in one of the Weſt-India Iſlands. A larger quantity given alone has fattened horſes and cattle, during the war before laſt in Hiſpaniola, for a period of ſeveral months, in which the exportation of ſugar, and the importation of grain, were prevented by the want of ſhips."

Tranſactions of the American Philoſophical Society, vol. iii.

39 An excellent antidote againſt worms.

"The plentiful uſe of ſugar in diet is one of the beſt preventives that has ever been diſcovered of the diſeaſes which are produced by worms. Nature ſeems to have implanted a love for this aliment in all children, as if it were on purpoſe to defend them from theſe diſeaſes. Dr Ruſh knew a gentleman in Philadelphia, who early adopted this opinion, and who, by indulging a large family of children in the uſe of ſugar, has preſerved them all from the diſeaſes uſually occaſioned by worms.

40 And probably againſt the plague and other malignant fevers.

"Sir John Pringle has remarked, that the plague has never been known in any country where ſugar compoſes a material part of the diet of the inhabitants. Dr Ruſh thinks it probable that the frequency of malignant fevers of all kinds has been leſſened by this diet, and that its more general uſe would defend that claſs of people who are moſt ſubject to malignant fevers from being ſo often affected by them.

"In the numerous and frequent diſorders of the breaſt, which occur in all countries where the body is expoſed to a variable temperature of weather, ſugar affords the baſis of many agreeable remedies. It is uſeful in weakneſſes, and acrid defluxions upon other parts of the body. Many facts might be adduced in favour of this aſſertion. Dr Ruſh mentions only one, which, from the venerable name of the perſon whoſe caſe furniſhed it, cannot fail of commanding attention and credit. Upon my inquiring of Dr Franklin, at the requeſt of a friend (ſays our reſpectable author), about a year before he died, whether he had found any relief from the pain of the ſtone from the blackberry jam, of which he took large quantities, he told me that he had, but that he believed the medicinal part of the jam reſided wholly in the ſugar; and as a reaſon for thinking ſo, he added, that he often found the ſame relief by taking about half a pint of a

41 Has given relief from the pain of the ſtone.

ſyrup,

Sugar. syrup, prepared by boiling a little brown ſugar in water, juſt before he went to bed, that he did from a doſe of opium. It has been ſuppoſed by ſome of the early phyſicians of our country, that the ſugar obtained from the maple-tree is more medicinal than that obtained from the Weſt India ſugar-cane; but this opinion I believe is without foundation. It is preferable in its qualities to the Weſt-India ſugar only from its ſuperior cleanlineſs.

"Caſes may occur in which ſugar may be required in medicine, or in diet, by perſons who refuſe to be benefited, even indirectly by the labour of ſlaves. In ſuch caſes the innocent maple ſugar will always be preferred. It has been ſaid, that ſugar injures the teeth; but this opinion now has ſo few advocates, that it does not deſerve a ſerious refutation."

42 Not hurtful to the teeth.

In the account which we have given above of the method of cultivating and manufacturing ſugar, we have had in our eye the plantations in the Weſt Indies, where ſlaves alone are employed; but we feel a peculiar pleaſure in having it in our power to add a ſhort deſcription of the method uſed in the Eaſt Indies, becauſe there ſugar is manufactured by free men, on a plan which is much more economical than what is followed in the Weſt Indies. The account which we mean to give is an extract from the report of the committee of Privy-council for trade on the ſubject of the African ſlave-trade, drawn up by Mr Botham We ſhall give it in the author's own words.

43 Sugar manufactured in the Eaſt Indies by freemen,

"Having been for two years in the Engliſh and French Weſt-Indian iſlands, and ſince conducted ſugar eſtates in the Eaſt-Indies; before the abolition of the ſlave-trade was agitated in parliament, it may be deſirable to know that ſugar of a ſuperior quality and inferior price to that in our iſlands is produced in the Eaſt-Indies; that the culture of the cane, the manufacture of the ſugar and arrack, is, with theſe material advantages, carried on by free people. China, Bengal, the coaſt of Malabar, all produce quantities of ſugar and ſpirits; but as the moſt conſiderable growth of the cane is carried on near Batavia, I ſhall explain the improved manner in which ſugar eſtates are there conducted. The proprietor of the eſtate is generally a wealthy Dutchman, who has erected on it ſubſtantial mills, boiling and curing houſes. He rents this eſtate to a Chineſe, who reſides on it as a ſuperintendant; and this renter (ſuppoſing the eſtate to conſiſt of 300 or more acres) relets it to freemen in parcels of 50 or 60 on theſe conditions: "That they ſhall plant it in canes, and receive ſo much *per* pecul of 133½ pounds for every pecul of ſugar that the canes ſhall produce."

44 Of a ſuperior quality and at a lower price.

45 How ſugar eſtates are managed at Batavia.

When crop time comes on, the ſuperintendant collects a ſufficient number of perſons from the adjacent towns or villages, and takes off his crop as follows. To any ſet of tradeſmen who bring their carts and buffaloes he agrees to give ſuch a price *per* pecul to cut all his crop of canes, carry them to the mill and grind them. A ſecond to boil them *per* pecul. A third to clay them and baſket them for market *per* pecul. So that by this method of conducting a ſugar eſtate the renter knows to a certainty what the produce of it will coſt him *per* pecul. He has not any permanent or unneceſſary expence; for when the crop is taken off, the taſkmen return to their ſeveral purſuits in the towns and villages they came from; and there only remains the cane planters who are preparing the next year's crop. This like all other complex arts, by being divided into ſeveral branches, renders the labour cheaper and the work more perfectly done.

Only clayed ſugars are made at Batavia; theſe are in quality equal to the beſt ſort from the Weſt Indies, and are ſold ſo low from the ſugar eſtates as eighteen ſhillings ſterling *per* pecul of 133½lbs. This is not the ſelling price to the trader at Batavia, as the government there is arbitrary, and ſugar ſubject to duties impoſed at will. The Shabander exacts a dollar *per* pecul on all ſugar exported. The price of common labour is from 9d to 10d *per* day. By the method of carrying on the ſugar eſtates, the taſkmen gain conſiderably more than this not only from working extraordinary hours, but from being conſidered artiſts in their ſeveral branches. They do not make ſpirits on the ſugar eſtates. The melaſſes is ſent for ſale to Batavia, where one diſtillery may purchaſe the produce of an hundred eſtates. Here is a vaſt ſaving and reduction of the price of ſpirits; not as in the Weſt Indies, a diſtillery, for each eſtate; many centre in one, and arrack is ſold at Batavia from 21 to 25 rix-dollars *per* leaguer of 160 gallons; ſay 8 d *per* gallon. Sugar.

46 Deſcription of the ſugar maple.

The SUGAR MAPLE, (the *acer ſaccharinum* of Linnæus), as well as the ſugar-cane, produces a great quantity of ſugar. This tree grows in great numbers in the weſtern counties of all the middle ſtates of the American union. Thoſe which grow in new York and Pennſylvania yield the ſugar in a greater quantity than thoſe which grow on the waters of Ohio.—Theſe trees are generally found mixed with the beech, hemlock, white and water aſh, the cucumber-tree, linden, aſpen, butter nut, and wild cherry trees. They ſometimes appear in groves covering five or ſix acres in a body, but they are more commonly interſperſed with ſome or all of the foreſt trees which have been mentioned. From 30 to 50 trees are generally found upon an acre of ground. They grow only in the richeſt ſoils, and frequently in ſtony ground. Springs of the pureſt water abound in their neighbourhood. They are, when fully grown, as tall as the white and black oaks, and from two to three feet in diameter. They put forth a beautiful white bloſſom in the ſpring before they ſhow a ſingle leaf. The colour of the bloſſom diſtinguiſhes them from the acer rubrum, or the common maple, which affords a bloſſom of a red colour. The wood of the ſugar maple-tree is extremely inflammable, and is preferred upon that account by hunters and ſurveyors for firewood. Its ſmall branches are ſo much impregnated with ſugar as to afford ſupport to the cattle, horſes, and ſheep of the firſt ſettlers, during the winter, before they are able to cultivate forage for that purpoſe. Its aſhes afford a great quantity of potaſh, exceeded by few, or perhaps by none, of the trees that grow in the woods of the United States. The tree is ſuppoſed to arrive at its full growth in the woods in twenty years. Tranſactions of the American Philoſophical Society, vol. iii.

47 The oftener this tree is tapped the more ſyrup is obtained from it.

It is not injured by tapping; on the contrary, the oftener it is tapped, the more ſyrup is obtained from it. In this reſpect it follows a law of animal ſecretion. A ſingle tree had not only ſurvived, but flouriſhed after forty-two tappings in the ſame number of years. The effects of a yearly diſcharge of ſap from the tree, in improving and increaſing the ſap, are demonſtrated from the ſuperior excellence of thoſe trees which have been perforated in an hundred places, by a ſmall wood-pecker which feeds upon the ſap. The trees, after having been wounded in this way, diſtil the remains of their juice on the ground, and afterwards acquire a black colour. The ſap of theſe trees is much ſweeter to the taſte than that which is obtained from trees which have not been previouſly wounded, and it affords more ſugar.

From twenty-three gallons and one quart of ſap, procured in twenty-four hours from only two of theſe dark coloured trees, Arthur Noble, Eſq; of the ſtate of New York, obtained four pounds and thirteen ounces of good grained ſugar.

4 What quantity of ſap will produce a certain quantity of ſugar.

A tree of an ordinary ſize yields in a good ſeaſon from twenty to thirty gallons of ſap, from which are made from five to ſix pounds of ſugar. To this there are ſometimes remarkable exceptions. Samuel Lowe, Eſq; a juſtice of peace

Sugar.

peace in Montgomery country, in the ſtate of New York, informed Arthur Noble, Eſq; that he had made twenty pounds and one ounce of ſugar between the 14th and 23d of April, in the year 1789, from a ſingle tree that had been tapped for ſeveral ſucceſſive years before.

49 This quantity might be increaſed by culture.

From the influence which culture has upon foreſt and other trees, it has been ſuppoſed, that by tranſplanting the ſugar maple-tree into a garden, or by deſtroying ſuch other trees as ſhelter it from the rays of the ſun, the quantity of the ſap might be increaſed, and its quality much improved. A farmer in Northampton country, in the ſtate of Pennſylvania, planted a number of theſe trees above twenty years ago in his meadow, from three gallons of ſap of which he obtains every year a pound of ſugar. It was obſerved formerly, that it required five or ſix gallons of the ſap of the trees which grow in the woods to produce the ſame quantity of ſugar.

50 The ſap diſtils from the wood in the ſpring months.

The ſap diſtils from the wood of the tree. Trees which have been cut down in the winter for the ſupport of the domeſtic animals of the new ſettlers, yield a conſiderable quantity of ſap as ſoon as their trunks and limbs feel the rays of the ſun in the ſpring of the year. It is in conſequence of the ſap of theſe trees being equally diffuſed through every part of them, that they live three years after they are girdled, that is, after a circular inciſion is made through the bark into the ſubſtance of the tree for the purpoſe of deſtroying it. It is remarkable that graſs thrives better under this tree in a meadow, than in ſituations expoſed to the conſtant action of the ſun. The ſeaſon for tapping the trees is in February, March, and April, according to the weather which occurs in theſe months.

51 Is increaſed by warm days and froſty nights.

Warm days and froſty nights are moſt favourable to a plentiful diſcharge of ſap. The quantity obtained in a day from a tree is from five gallons to a pint, according to the greater or leſs heat of the air. Mr Lowe informed Arthur Noble, Eſq; that he obtained near three and twenty gallons of ſap in one day (April 14. 1789.) from the ſingle tree which was before mentioned. Such inſtances of a profuſion of ſap in ſingle trees are however not very common.

52 How the ſap is drained from the tree.

There is always a ſuſpenſion of the diſcharge of ſap in the night if a froſt ſucceed a warm day. The perforation in the tree is made with an axe or an auger. The latter is perferred from experience of its advantages. The auger is introduced about three quarters of an inch, and in an aſcending direction (that the ſap may not be frozen in a flow current in the mornings or evenings), and is afterwards deepened gradually to the extent of two inches. A ſpout is introduced about half an inch into the hole made by this auger, and projects from three to twelve inches from the tree. The ſpout is generally made of the ſumach or elder, which uſually grows in the neighbourhood of the ſugar trees. The tree is firſt tapped on the ſouth ſide; when the diſcharge of its ſap begins to leſſen, an opening is made on the north ſide, from which an increaſed diſcharge takes place. The ſap flows from four to ſix weeks, according to the temperature of the weather. Troughs large enough to contain three or four gallons made of white pine, or white aſh, or of dried water aſh, aſpen, linden, poplar, or common maple are placed under the ſpout to receive the ſap, which is carried every day to a large receiver, made of either of the trees before mentioned. From this receiver it is conveyed, after being ſtrained, to the boiler.

53 Is reduced to ſugar by three modes.

We underſtand that there are three modes of reducing the ſap to ſugar; by evaporation, by freezing, and by boiling; of which the latter is moſt general, as being the moſt expeditious. We are farther aſſured, that the profit of the maple-tree is not confined to its ſugar. It affords moſt agreeable melaſſes, and an excellent vinegar. The ſap which is ſuitable for theſe purpoſes is obtained after the ſap which affords the ſugar has ceaſed to flow, ſo that the manufactories of theſe different products of the maple-tree, by ſucceeding, do not interfere with each other. The melaſſes may be made to compoſe the baſis of a pleaſant ſummer beer. The ſap of the maple is moreover capable of affording a ſpirit; but we hope this precious juice will never be proſtituted to this ignoble purpoſe. Should the uſe of ſugar in diet become more general in this country (ſays Dr Ruſh), it may tend to leſſen the inclination or ſuppoſed neceſſity for ſpirits, for I have obſerved a reliſh for ſugar in diet to be ſeldom accompanied by a love for ſtrong drink.

Sugar || Suicide.

54 Sugar procured from many other vegetables.

There are ſeveral other vegetables raiſed in our own country which afford ſugar; as beet-roots, ſkirrets, parſneps, potatoes, celeri, red-cabbage ſtalks, the young ſhoots of Indian wheat. The ſugar is moſt readily obtained from theſe, by making a tincture of the ſubject in rectified ſpirit of wine; which, when ſaturated by heat, will depoſit the ſugar upon ſtanding in the cold.

Acid of Sugar. See CHEMISTRY-*Index.*

SUGILLATION, in medicine, an extravaſation of blood in the coats of the eye, which at firſt appears of a reddiſh colour, and afterwards livid or black. If the diſorder is great, bleeding and purging are proper, as are alſo diſcutients.

SUICIDE, the crime of ſelf-murder, or the perſon who commits it.

We have often wiſhed to ſee a hiſtory of crimes drawn up by a man of ability and reſearch. In this hiſtory we would purpoſe that the author ſhould deſcribe the crimes peculiar to different nations in the different ſtages of ſociety, and the changes which they undergo in the progreſs of civilization. After having arranged the hiſtorical facts, he might, by comparing them with the religion and the knowledge of the people, deduce ſome important general concluſions, which would lead to a diſcovery of the cauſe of crimes, and of the remedy moſt proper to be applied. Some crimes are peculiar to certain ſtages of ſociety, ſome to certain nations, &c.

1 Suicide among the Jews.

Suicide is one of thoſe crimes which we are led to believe not common among ſavage nations. The firſt inſtances of it recorded in the Jewiſh hiſtory are thoſe of Saul and Ahitophel; for we do not think the death of Samſon a proper example We have no reaſon to ſuppoſe that it became common among the Jews till their wars with the Romans, when multitudes ſlaughtered themſelves that they might not fall alive into the hands of their enemies. But at this period the Jews were a moſt deſperate and abandoned race of men, had corrupted the religion of their fathers, and rejected that pure ſyſtem which their promiſed Meſſiah came to Jeruſalem to announce.

2 Among the Greeks.

When it became remarkable among the Greeks, we have not been able to diſcover: but it was forbidden by Pythagoras, as we learn from Athenæus, by Socrates and Ariſtotle, and by the Theban and Athenian laws. In the earlieſt ages of the Roman republic it was ſeldom committed; but when luxury and the Epicurean and Stoical philoſophy had corrupted the ſimplicity and virtue of the Roman character, then they began to ſeek ſhelter in ſuicide from their misfortunes or the effects of their own vices.

3 The Bramins and Gentoos.

The religious principles of the bramins of India led them to admire ſuicide on particular occaſions as honourable. Accuſtomed to abſtinence, mortification, and the contempt of death, they conſidered it as a mark of weakneſs of mind to ſubmit to the infirmities of old age. We are informed that the Modern Gentoos, who ſtill in moſt things conform to the cuſtoms of their anceſtors, when old and infirm, are frequently brought to the banks of rivers, particularly to

those

Holwell's Intereſting Events, &c. vol. i.

thoſe of the Granges, that they may die in its ſacred ſtreams, which they believe can waſh away the guilt of their ſins. But the maxims of the bramins, which have encouraged this practice, we are aſſured by Mr Holwell, are a corruption of the doctrines of the Shaſtah, which poſitively forbid ſuicide under the ſevereſt puniſhment. The practice which religion or affection has eſtabliſhed among the Gentoos for women at the death of their huſbands to burn themſelves alive on the funeral pile, we do not think ought to be conſidered as ſuicide, as we are not anxious to extend the meaning of the word; for were we to extend it thus far, it would be as proper to apply it to thoſe who chooſe rather to die in battle than make their eſcape at the expence of their honour. Thus we ſhould condemn as ſuicides the brave Spartans who died at Thermopylæ in defence of their country: we ſhould alſo be obliged to apply the ſame diſgraceful epithet to all thoſe well-meaning but weak-minded Chriſtians in Britain who in the laſt century choſe rather to die as martyrs than comply with commands which were not morally wrong. According to the Gentoo laws, "it is proper for a woman after her huſband's death to burn herſelf in the fire with his corpſe. Every woman who thus burns ſhall remain in paradiſe with her huſband three crore and fifty lacks of years. If ſhe cannot, ſhe muſt in that caſe preſerve an inviolable chaſtity. If ſhe remain chaſte, ſhe goes to paradiſe; and if ſhe do not preſerve her chaſtity, ſhe goes to hell."

4 Among the Americans. Robertſon's America.

A cuſtom ſimilar to this prevailed among many nations on the continent of America. When a chief died, a certain number of his wives, of his favourites, and of his ſlaves, were put to death, and interred together with him, that he might appear with the ſame dignity in his future ſtation, and be waited upon by the ſame attendants. This perſuaſion is ſo deeply rooted, that many of their retainers offer themſelves as victims; and the ſame cuſtom prevails in many of the negro nations of Africa.

5 The Japaneſe, and

If we can believe the hiſtorians of Japan, voluntary death is common in that empire. The devotees of the idol Amida drown themſelves in his preſence, attended by their relations and friends, and ſeveral of the prieſts, who all conſider the devoted perſon as a ſaint who is gone to everlaſting happineſs. Such being the ſuppoſed honours appropriated to a voluntary death, it is not ſurpriſing that the Japaneſe anxiouſly cheriſh a contempt of life. Accordingly it is a part of the education of their children "to repeat poems in which the virtues of their anceſtors are celebrated, an utter contempt of life is inculcated, and ſuicide is ſet up as the moſt heroic of actions."

Raynal's Hiſtory of the Eaſt and Weſt Indies, vol. i.

6 Scythians,

A notion ſeems alſo to have prevailed among the ancient Scythian tribes, that it was puſillanimous and ignoble for a man whoſe ſtrength was waſted with diſeaſe or infirmity, ſo as to be uſeleſs to the community, to continue to live. It was reckoned an heroic action voluntarily to ſeek that death which he had not the good fortune to meet in the field of battle. Perverſion of moral feeling does not ſpring up, we hope, ſpontaneouſly in any nation, but is produced by ſome peculiarities of ſituation. A wandering people like the Scythians, who roamed about from place to place, might often find it impoſſible to attend the ſick, or to ſupply from their precarious ſtore the wants of the aged infirm. The aged and infirm themſelves, no longer able to ſupport the character of warriors, would find themſelves unhappy. In this way the practice of putting to death ſuch perſons as were uſeleſs to the community might originate, and afterwards be inculcated as honourable; but he who put an end to his infirmities by his own hand, obtained a character ſtill more illuſtrious.

The tribes of Scandinavia, which worſhipped Odin the "father of ſlaughter," were taught, that dying in the field of battle was the moſt glorious event that could befal them. This was a maxim ſuited to a warlike nation. In order to eſtabliſh it more firmly in the mind, all were excluded from Odin's feaſt of heroes who died a natural death. In Aſgardia ſtood the hall or Odin; where, ſeated on a throne, he received the ſouls of his departed heroes. This place was called *Valhalla*, ſignifying "the hall of thoſe who died by violence." Natural death being thus deemed inglorious, and puniſhed with excluſion from Valhalla the paradiſe of Odin he who could not enjoy death in the field of battle was led to ſeek it by his own hands when ſickneſs or old age began to aſſail him. In ſuch a nation ſuicide muſt have been very common.

Suicide.

7 And Scandinavians.

8 It prevailed much in the decline of the Roman empire.

As ſuicide prevailed much in the decline of the Roman empire, when luxury, licentiouſneſs, profligacy, and falſe philoſophy, pervaded the world, ſo it continued to prevail even after Chriſtianity was eſtabliſhed. The Romans, when they became converts to Chriſtianity, did not renounce their ancient prejudices and falſe opinions, but blended them with the new religion which they embraced. The Gothic nations alſo, who ſubverted the Roman empire, while they received the Chriſtian religion, adhered to many of their former opinions and manners. Among other criminal practices which were retained by the Romans and their conquerors, that of ſuicide was one; but the principles from which it proceeded were explained, ſo as to appear more agreeable to the new ſyſtem which they had eſpouſed. It was committed, either to ſecure from the danger of apoſtacy, to procure the honour of martyrdom, or to preſerve the crown of virginity.

9 Too common in modern times, but not more ſo in England than in other countries.

When we deſcend to modern times, we lament to find ſo many inſtances of ſuicide among the moſt poliſhed nations, who have the beſt opportunities of knowing the atrocity of that unnatural crime. The Engliſh have long been reproached by foreigners for the frequent commiſſion of it; and the "gloomy month of November" has been ſtigmatized as the ſeaſon when it is moſt common. But this diſgraceful imputation, we think, may be juſtly attributed, not to the greater frequency of the crime in England than in other places, but to the cuſtom of publiſhing in the newſpapers every inſtance of ſuicide which is known. Mr Moore, who lately publiſhed a full inquiry into this ſubject, was at great pains to obtain accurate information concerning the perpetration of this crime in different countries. Mercier, who wrote in 1782, ſays, that the annual number of ſuicides in Paris was then about 150. He does not tell us how he came by the information; but we have the authority of the Abbé Fontana for aſſerting, that more perſons put an end to their lives in Paris than in London. The Abbé had this information from the lieutenant of the police. Mr Moore was informed by one of the principal magiſtrates of Geneva, that in that city, which contains about 25,000 inhabitants, the average number of ſuicides is about *eight*. The average number of ſuicides, from what cauſe ſoever, for the laſt 28 years, has been 32 each year for London, Southwark, and Weſtminſter. In Edinburgh, which contains 80,000 inhabitants, we are convinced the average number of ſuicides does not exceed *four*. Mr Moore found, from the accounts with which he was favoured by the ſeveral coroners of the county of Kent, that for the laſt 18 years the number has been upwards of 32 each year. Kent is ſuppoſed to contain 200,000 inhabitants, and London 800,000. It is eaſy therefore to ſee, that in the metropolis many inſtances of ſuicide muſt occur which are never the ſubject of legal inquiry, and conſequently never made known to the world. Whereas in the country towns and villages of Kent it is ſcarcely poſſible to conceal ſuch an action as ſelf murder

Mercier's Tableau de Paris.

10 The number of ſuicides in Paris, London, Geneva, &c. according to the beſt accounts.

Suicide.

from the knowledge of the whole neighbourhood. The calculation therefore respecting Kent we may receive as true, while we must increase the avarage number in London very considerably. Mr Moore computes the average number of suicides in England every year at a thousand; but the principles on which he founds this opinion are so imperfect and vague, that we do not think it can be depended on as coming near the truth.

11 In what rank and situation suicide is most common.

It might lead to some interesting conclusions to compare together, not only the number of suicides in different countries, but also the rank and principles, the sex and age, of those unhappy persons by whom it has been committed. Mercier says, that at Paris it was the lower ranks who were most commonly guilty of it; that it was mostly committed in garrets or hired lodgings; and that it proceeded from poverty and oppression. A great many, he says, wrote letters to the magistrates before their death. Mr Moore's correspondent from Geneva informed him, that from the year 1777 to 1787 more than 100 suicides were committed in Geneva; that two-thirds of these unfortunate persons were men; that few of the clerical order have been known to commit it; and that it is not so much the end of an immoral, irreligious, dissipated life, as the effect of melancholy and poverty. By the information obtained from the coroners of Kent, it appears, that of the 32, three-fourths have destroyed themselves by hanging; that the proportion of males to females has been about two-thirds of the former; that no one season of the year is more distinguished for this crime than another; and that suicide is upon the increase. Our accounts respecting the city of London are very imperfect; but we think ourselves intitled to conclude, that suicide is more common among the great and wealthy than among the lower ranks, and that it is usually the effect of gaming and dissipation.

Moore's Full inquiry into the Causes of Suicide.

12 Physical causes to which it has been ascribed in Britain.

Those who have inquired into the causes of suicide in Britain have enumerated many physical as well as moral causes. They have ascribed it to the variableness of climate, to the great use of animal food, to strong spirituous liquors, to tea, and to the sulphureous exhalations of the pit-coal used as fuel, which are said to produce a depression of spirits and nervous affections. Of the climate, there is no cause to complain, nor is there any reason to impute any of the vices to its influence. There are many climates much more unfavourable where suicide is scarcely known. That an excessive quantity of gross animal food, or of strong liquors, or of tea, will powerfully affect the human constitution, we will not deny: but before we consider these as causes, it must first be determined, whether those who are guilty of self-murder be much addicted to them; and if they are, whether there be not other causes much more violent in their nature which have operated on their mind; for we ought not rashly to attribute vicious effects to any of those things which seem to have been created on purpose for the comfort or convenience of man. We are rather surprised to find that coal is mentioned even as a distant cause of suicide; for it is one of the blessings of that island: and a good coal fire has always been found rather conducive to good spirits than injurious to them.

Among the moral causes which are supposed to co-operate in producing suicide in Britain, the freedom of its constitution and laws is reckoned one. That rational liberty should have any tendency to encourage crimes of any kind, a Christian philosopher can never allow; for such an opinion is totally discountenanced by enlightened views of nature. Mercier has ascribed the frequency of suicide in Paris to the oppression of the late government. Now it appears somewhat extraordinary, that suicide in one country should be occasioned by liberty, and in another by the want of it. One of these opinions must be false, and it is surely not difficult to distinguish which.

Sui[illegible] 13 And more[illegible] caus[illegible]

14 Not owing always to insanity;

Humanity would in most cases dispose us to conclude, that suicide is the effect of insanity, were there not so many instances of cool deliberate self-murder. That suicide is an unnatural crime, which none but a madman would commit, compassion indeed may suppose: but the murder of a wife, a father, a child, are also unnatural; yet compassion does not teach us in all cases to ascribe such a crime to madness. Passion may often arise to such a height of outrage as to be scarcely distinguishable from madness in its symptoms and its effects; yet we always make a distinction between that madness with arises from disease and that which is owing to a violent perturbation of mind. If a person be capable of managing his worldly affairs, of making a will, and of disposing of his property, immediately before his death, or after he formed the resolution of dying by his own hands, such a man is not to be considered as insane.

15 But often also to vicious passion.

But though a regard for truth prevents us from ascribing suicide in all cases to insanity, we must ascribe it either to insanity or to vicious passion. These two divisions, we imagine, will comprehend every species of it, whether arising from melancholy, *tædium vitæ* or *ennui*, disappointment in schemes of ambition or love, pride, gaming, or a desire to avoid the shame of a public execution; passions which are often increased by false views of God, of man, and of a future state, arising from deism and infidelity. If these be the causes of suicide in modern times, what a disgraceful contrast do they form to those principles which actuated many of the ancient philosophers, the Gentoos, the Japanese, and the worshippers of Odin? When they committed suicide, they committed it from principle, from a belief of its lawfulness, and the hope of being rewarded for what they judged an honourable sacrifice. But in modern times, we are sorry to say, when it is not the effect of madness, it is the effect of vice: and when it is the effect of vice, it proves that the vicious passions are then indulged to the highest degree; for there is no crime which a man can commit that is so strong a symptom of the violence of particular passions. It is from not attending to this circumstance, that it has been found so difficult to refute the arguments in favour of suicide. If the criminality of suicide be confined merely to the violent action, many apologies may be made for it; but if it be considered solely as the effect of vice, as the strongest symptom of ungoverned passion, he who undertakes its defence must undertake the defence of what all men will loudly condemn (A).

It is unnecessary then to enter particularly into the argu-

(A) Several of the heathens entertained a very just sense of the atrocity of suicide. Quintus Curtius introduces Darius with the following speech, when he had lost his empire: "I wait (says the unfortunate monarch) the issue of my fate: you wonder, perhaps, that I do not terminate my own life; but I choose rather to die by the crime of another than by my own.

We cannot refuse ourselves the pleasure of presenting to our readers the following beautiful passage upon this subject from Fitzosborne's letters:* "I am persuaded (says this elegant writer) this disgust of life is frequently indulged out of a principle of mere vanity. It is esteemed as a mark of uncommon refinement, and as placing a man above the ordinary level

* Letter lv.

Suicide.

16 Unnecessary to enter into the arguments of casuists upon this subject.

ments of those casuists who have undertaken the despicable office of advocates for the crime of suicide. Their talents might surely have been employed more usefully to the world, and more honourably to themselves, than in pleading for a crime which, if it were committed by every man to whom their principles would make it lawful, would totally destroy some of the noblest virtues, fortitude, patience, and resignation; nay, would destroy society itself, and teach us to despise the opinion that this world is a state of preparation for another. "I came into life without my own consent, and may I not quit it at pleasure?" (say the advocates for suicide). If, because we came into life without our own consent, we might quit it at pleasure, why may we not spend our life also as we please? Why may we not rob and murder, and commit every kind of crime, if *mere inclination* is to be the rule of action? Thus upon the principles of suicide the highwayman and murderer may reason, and every man may find a sufficient apology for any crime which he is tempted to commit. Or this absurdity may be otherwise answered; As we came into life without our own consent, we must have come with the consent of some other being; and logic says, that with the consent of that Being only can we lawfully quit it.

17 Its great criminality and imprudence.

It is sufficient shortly to say, that suicide is contrary to the strongest principle of the human constitution, self-preservation; that it is rebellion against God; that it is cruelty to the feelings and reputation, and often takes away the subsistence of a wife, a child, or a father; that it proves a want of fortitude to brave misfortunes; that it delivers only from imagined to plunge into real evils. We may add, that almost every instance of suicide of which we have heard was rash, imprudent, and premature, interrupted a useful life, or prevented a more honourable death. Had Cato's pride permitted him to yield himself to the generosity of Cæsar, his character and his influence might have contributed to retard the slavery of his country which his death tended to hasten. Had Brutus and Cassius not executed the fatal resolution which they had formed, of dying by their own hands in case of misfortune, the battle of Philippi might have had a very different issue. Had Hannibal surrendered himself to the Romans, instead of swallowing poison, he would have gained more glory in braving their tortures than he won in the battle of Cannæ; for to die innocently and heroically is the greatest exertion of human fortitude.

Suicide

18 How punished by the Greeks, Ceans, &c.

As suicide was deemed a crime by the most illustrious and virtuous of the Greek and Roman philosophers, it was considered as a crime by the laws, and treated with ignominy. By the law of Thebes suicides were to have no honours paid to their memory †. The Athenian law ordained the hand which committed the deed to be cut off, and burned apart from the rest of the body. The body was not buried with the usual solemnities, but was ignominiously thrown into some pit. In Cea and Massilia (the ancient *Marseilles*), it was considered as a crime against the state; and it was therefore necessary for those who wished to destroy themselves to obtain permission from the magistrates. § Plutarch acquaints us, that an unaccountable passion for suicide seized the Milesian virgins; from indulging which they could not be prevented by the tears and entreaties of parents and friends: but what persuasion and entreaty could not effect was accomplished by very different means. A decree was issued, "that the body of every young woman who hanged herself should be dragged naked through the streets by the same rope with which she had committed the deed." This wise edict put a complete stop to the extraordinary frenzy, and suicide was no longer committed by the virgins of Miletus.

† Petite Comment. in Leges Atticas, p. 523.

§ Plutarch on the Virtues of Women.

19 By the Romans.

In the early part of the Roman history there seems to have been seldom occasion for framing any laws against suicide. The only instance recorded occurs in the reign of Tarquinius Priscus. The soldiers who were appointed to make drains and common sewers, thinking themselves disgraced by such servile offices, put themselves to death in great numbers. The king ordered the bodies of all the self-murderers to be exposed on crosses, and this put an effectual stop to the practice. It is doubtful whether there was any standing law against suicide during the existence of the republic; but during the reign of the emperors it was thought proper to lay it under certain regulations, though not absolutely to condemn it as a crime. In Justinian's Digests there is a law, by which it was enacted, "that if persons accused, or who had been found guilty, of any crime should make away with themselves, their effects should be confiscated."

Lib. xlviii. Tit. xxi. par. 3.

---

level of his species, to seem superior to the vulgar feelings of happiness. True good sense, however, most certainly consists not in despising, but in managing our stock of life to the best advantage, as a cheerful acquiescence in the measures of Providence is one of the strongest symptoms of a well constituted mind. Self-weariness is a circumstance that ever attends folly; and to condemn our being is the greatest, and indeed the peculiar infirmity, of human nature. It is a noble sentiment which Tully puts into the mouth of Cato, in his Treatise upon old Age; *Non lubet mihi* (says that venerable Roman) *deplorare vitam, quod multi, et ii docti, sæpe fecerunt; neque me vixisse pœnitet: quoniam ita vixi, ut non frustra me natum existimem.*

"It is in the power, indeed, of but a very small portion of mankind to act the same glorious part that afforded such high satisfaction to this distinguished patriot; but the number is yet far more inconsiderable of those who cannot, in any station, secure themselves a sufficient fund of complacency to render life justly valuable. Who is it that is placed out of the reach of the highest of all gratifications, those of the generous affections, and that cannot provide for his own happiness, by contributing something to the welfare of others? As this disease of the mind generally breaks out with most violence in those who are supposed to be endowed with a greater delicacy of taste and reason than is the usual allotment of their fellow-creatures, one may ask them, whether there is any satiety in the pursuits of useful knowledge? or, if one can ever be weary of benefiting mankind? Will not the fine arts supply a lasting feast to the mind? or, can there be wanting a pleasurable enjoyment, so long as there remains even one advantageous truth to be discovered or confirmed? To complain that life has no joys, while there is a single creature whom we can relieve by our bounty, assist by our counsels, or enliven by our presence is, to lament the loss of that which we possess, and is just as rational as to die for thirst with the cup in our hands. But the misfortune is, when a man is settled into a habit of receiving all his pleasures from the mere selfish indulgencies, he wears out of his mind the relish of every nobler enjoyment, at the same time that his powers of the sensual kind are growing more languid by each repetition. It is no wonder, therefore, he should fill up the measure of his gratifications long before he has completed the circle of his duration; and either wretchedly sit down the remainder of his days in discontent, or rashly throw them up in despair."

Suicide ‖ Suit.

confiſcated." But this puniſhment only took place when confiſcation of goods happened to be the penalty appointed by the law for the crime of which the ſelf-murderer was accuſed or found guilty, and was not inflicted for ſuicide committed in any other circumſtances.

20 And by Chriſtians.

When the Chriſtian church had extended its juriſdiction in the Roman empire, it was decreed in the ſixth century, that no commemoration ſhould be made in the euchariſt for ſuch as deſtroyed themſelves; neither ſhould their bodies be carried out to burial with pſalms, nor have the uſual ſervice ſaid over them. This eccleſiaſtical law continued till the reformation, when it was admitted into the ſtatute code of England by the authority of parliament. As an additional puniſhment, however, confiſcation of land and goods ſeems to have been adopted from the Danes, as we learn from Bracton ‡. At preſent the puniſhment conſiſts in confiſcating all the perſonal property of a *felo de ſe* for the uſe of the crown, and in excluding his body from interment in conſecrated ground. The warrant of the coroner requires that the body ſhould be buried in ſome public highway, and a ſtake driven through it to increaſe the ignominy.

‡ De Legibus et Conſuetudinibus Angliæ, Lib. iii. Tract. ii.

21 Difficult to deviſe a puniſhment that would be an effectual preventive.

To inquire into the prevalence and cauſes of crimes, in order to diſcover the moſt judicious methods of preventing them, is the duty of the patriot and the Chriſtian. Suicide, we find, is a common and an increaſing evil: but it is a difficult matter to find an effectual remedy; for what motives can be held out ſufficient to influence that man's mind who is deaf to the voice of nature ſpeaking within him, and to the voice of nature's God declaring that he is ſtationed at a poſt which it is his duty to maintain? His reputation and property are indeed within the reach of the laws, his body may be treated with ignominy, and his property confiſcated; but this puniſhment will not be a preventive, even if it could be always inflicted; and that it is ſeldom inflicted, though the laws have decreed it, is well known. The humanity of the preſent age diſpoſes us to ſympathiſe with the relations of the deceaſed, inſtead of demanding that the ſentence of the law ſhould be executed. It is a generally received opinion, and a juſt one, that puniſhments decreed by human laws ſhould be directed only againſt ſuch crimes as are injurious to ſociety; but when it is hence inferred, that ſuicide ought not to be ſubject to the cognizance of human laws, every rule of logic is violated. There is no man, however mean in ſtation and in talents, whoſe life may not, on ſome occaſions, be uſeful to the community at large; and to conclude, that a perſon who fancies himſelf uſeleſs may therefore lawfully put a period to his life, is as falſe reaſoning as it would be to conclude, that by killing a poor man, who lives on the public, we ſhould perform an action not only innocent but meritorious, as we ſhould thereby free ſociety from one of its burdens.

SUIDAS, a Greek writer, according to ſome, flouriſhed in the 11th century, under the reign of the Emperor Alexius Comnenus; according to others, before the 10th century. He wrote in Greek an Hiſtorical and Geographical Dictionary or Lexicon; a work which, though not always ſtrictly accurate, is nevertheleſs of great importance, as it contains many things taken from the ancients that are nowhere elſe to be found. The beſt edition of Suidas is that of Kuiſter, in Greek and Latin, with notes, printed in 3 vols fol. which has been much improved by Toup.

LAPIS SUILLUS. See *Swine-Stone*.

SUIT, is uſed in different ſenſes; as, "1. Suit of court, or ſuit-ſervice, which is an attendance the tenant owes to his lord's court. 2. Suit-covenant, where a perſon has covenanted to do ſervice in the court of the lord. 3. Suit-cuſtom, which is where one and his anceſtors have owed ſuit time out of mind. 4. It is uſed for a petition to the king or any perſon of dignity, where a lord diſtrains his tenant for ſuit, and none is due. In this caſe, the party may have an attachment againſt him to appear in the king's court."

Suit.

SUIT, in law, the ſame with action. The Romans introduced pretty early ſet forms for actions and ſuits into their law, after the example of the Greeks; and made it a rule, that each injury ſhould be redreſſed by its proper remedy only. "*Actiones*, (ſay the Pandects) *compoſitæ ſunt quibus inter ſe homines diſceptarent, quas actiones ne populus prout vellet inſtitueret, certas ſolemneſque eſſe voluerunt.*" The forms of theſe actions were originally preſerved in the books of the pontifical college as choice and ineſtimable ſecrets, till one Cneius Flavius, the ſecretary of Appius Claudius, ſtole a copy and publiſhed them to the people. The concealment was ridiculous: but the eſtabliſhment of ſome ſtandard was undoubtedly neceſſary to fix the true ſtate of queſtion of right; leſt, in a long and arbitrary proceſs, it might be ſhifted continually, and be at length no longer diſcernible. Or, as Cicero expreſſes it, "*ſunt jura, ſunt formulæ, de omnibus rebus conſtitutæ, ne quis aut in genere injuriæ, aut in ratione actionis, errare poſſit. Expreſſæ enim ſunt ex uniuſcujuſque damno, dolore, incommodo, calamitate, injuria, publicæ à prætore formulæ, ad quas privata lis accommodatur.*" And in the ſame manner Bracton, ſpeaking of the original writs upon which all our actions are founded, declares them to be fixed and immutable, unleſs by authority of parliament. And all the modern legiſlators of Europe have found it expedient, from the ſame reaſons, to fall into the ſame or a ſimilar method. In England, the ſeveral ſuits, or remedial inſtruments of juſtice, are, from the ſubject of them, diſtinguiſhed into three kinds; actions *perſonal*, *real*, and *mixed*. Blackſt. Comment.

Perſonal actions are ſuch whereby a man claims a debt, or perſonal duty, or damages in lieu thereof; and likewiſe whereby a man claims a ſatisfaction in damages for ſome injury done to his perſon or property. The former are ſaid to be founded upon contracts, the latter upon *torts* or wrongs: and they are the ſame which the civil law calls "*actiones in perſonam, quæ adverſus eum intenduntur qui ex contractu vel delicto obligatus eſt aliquid dare vel concedere.*" Of the former nature are all actions upon debt or promiſes; of the latter are all actions of treſpaſſes, nuiſances, aſſaults, defamatory words, and the like.

Real actions (or, as they are called in the Mirror, *feudal actions*), which concern real property only, are ſuch whereby the plaintiff, here called the *demandant*, claims title to have any lands or tenements, rents, commons, or other hereditaments, in fee-ſimple, fee-tail, or for term of life. By theſe actions formerly all diſputes concerning real eſtates were decided; but they are now pretty generally laid aſide in practice, upon account of the great nicety required in their management, and the inconvenient length of their proceſs; a much more expeditious method of trying titles being ſince introduced, by other actions perſonal and mixed.

Mixed actions are ſuits partaking of the mixture of the other two, wherein ſome real property is demanded, and alſo perſonal damages for a wrong ſuſtained. As for inſtance, an action of waſte: which is brought by him who hath the inheritance, in remainder or reverſion, againſt the tenant for life, who hath committed waſte therein, to recover not only the land waſted, which would make it merely a real action; but alſo treble damages, in purſuance of the ſtatute of Glouceſter, which is a perſonal recompenſe; and ſo both, being joined together, denominate it a *mixed action*.

Sully Sulphur.

The ordinary parts of a ſuit are theſe: 1. The original *writ*. 2. The *proceſs*. 3. The *pleadings*. 4. The *iſſue* or demurrer. 5. The *trial*. 6. The *judgment*, and its incidents. 7. The proceedings in nature of *appeals*. 8. The *execution*. See theſe articles.

SULLY. See BETHUNE.

SULPHAT, in the new chemical nomenclature, denotes a compound of the ſulphuric acid with ſome other ſubſtance.

SULPHUR, a well known ſubſtance, which is yellow, taſteleſs, hard, brittle, and when rubbed becomes electric. Its ſpecific gravity is from 1,9 to 2,35. According to Bergman it gently evaporates at 170, melts at 185, and flames at 302 of Fahrenheit. It burns with a blue flame, and a diſagreeable ſuffocating ſmell; in cloſe veſſels it ſublimes without decompoſition, or only a decompoſition proportionable to the quantity of air they contain; when melted it becomes red, but recovers its colour on cooling. It is inſoluble in water, though by long trituration it is ſaid water will take up ſome of it, but it is rather diffuſed than diſſolved in it; neither can ſpirit of wine unite to it, except when both are in a vaporous ſtate, and then 72 parts of ſpirit of wine take up 1 of ſulphur; it is ſoluble in hot oils, and alſo in fixed alkalis, both in the dry and liquid way; it is decompoſed by boiling in concentrated nitrous acid, partly decompoſed and partly diſſolved by the vitriolic and oxygenated muriatic acid. See CHEMISTRY-*Index*.

Kirwan's Mineralogy.

Sulphur was formerly ſuppoſed to conſiſt of ſulphuric acid and phlogiſton, in the proportion of 60 parts of the former to 40 of the latter; but by the new ſyſtem which is now generally adopted, ſulphur is reckoned a ſimple ſubſtance, and the ſulphuric acid a compound of ſulphur and oxygene or vital air. This concluſion is founded on the following facts: 1. Sulphur does not burn unleſs vital air have acceſs to it. 2. During combuſtion it abſorbs vital air from the atmoſphere. 3. The ſulphuric produced by the combuſtion of ſulphur is equal in weight to the ſulphur employed and the quantity of air that has been conſumed.

Sulphur is found ſometimes pure, and ſometimes in combination with other ſubſtances. Of pure ſulphur there are ſeven varieties. 1. Tranſparent ſulphur, in eight-ſided cryſtals, with two truncated pyramids. It is generally depoſited by water on the ſurface of calcareous ſpar. Cadiz ſulphur is of this kind. 2. Tranſparent ſulphur in irregular fragments. Such is the ſulphur of Switzerland. 3. Whitiſh pulverulent ſulphur, depoſited in ſiliceous geodes. In Franche Compté there are flints full of ſulphur. 4. Pulverulent ſulphur depoſited on the ſurface of mineral waters, ſuch as thoſe of Aix-la-Chapelle. 5. Cryſtalline ſulphur that has been ſublimed, found in the neighbourhod of volcanoes. 6. Pulverulent ſulphur ſublimed from volcanoes, found in abundance at Solfatara in the vicinity of Naples. 7. Sulphur in ſtalactites, formed by volcanic fires.

Fourcroy's Chemiſtry.

Sulphur is alſo found united with different ſubſtances, as with metals, when it is called *pyrites*; a ſhort account of which may be ſeen under the article PYRITES. Sometimes it is combined with calcareous earth, as in fetid calcareous ſtones and ſwine-ſtone. It has lately been diſcovered, that ſulphur is formed by a natural proceſs in animals and vegetables beginning to putrefy. It is found on ſtable-walls and in privies. It is alſo extracted from vegetables, from dock-root, cochlearia, &c. M. Deyeux obtained it from the white of eggs. It has been alſo procured from horſe-dung.

The ſulphur uſed in Great Britain is generally brought in a pure ſtate from volcanic countries, where it abounds in an inexhauſtible quantity. It is well known, however, that ſome of the metallic ores in that country abound with it; but from the common mode of purifying them, the ſulphur is diſſipated and loſt. Dr Watſon has ſhown, in a paper on lead-ore in the Philoſophical Tranſactions, that not leſs than 700 tons are annually diſſipated in the various lead-mines of England. Sulphur.

It is extracted from pyrites in the following manner in Saxony and Bohemia. The pyrites is put in ſmall pieces into earthen tubes: one of the tubes is placed on a furnace, and the other paſſes into a ſquare veſſel of caſt iron containing water. The ſulphur is diſunited by the heat from the pyrites, and paſſes into the veſſel; but it is then very impure. It is afterwards melted in an iron ladle, when the earthy and metallic particles are depoſited by their weight, and the ſulphur being light riſes to the top. It is then poured off into a copper boiler, where it is farther purified, and afterwards poured into cylindrical moulds of wood, from which it receives the ſhape in which it is uſually ſold.

When melted ſulphur is gently heated, it flies off in a yellow powder, which is called *flowers of ſulphur*. The operation is performed in this manner: Common ſulphur in powder is put into an earthen cucurbit, to the top of which a number of earthen pots inſerted in one another is fixed, known by the name of *aludels*. The cucurbit is then heated till the ſulphur becomes liquid; it then riſes and attaches itſelf to the ſides of the aludels.

Sulphur combined with an alkali is called *hepar ſulphuris, liver of ſulphur*, becauſe it reſembles in colour the liver of animals. In the French nomenclature it is called *ſulphure*, and by thoſe Britiſh chemiſts who have adopted the new ſyſtem *ſulphuret*.

Water decompoſes the ſulphuret. The ſulphur is precipitated by acids, when a particular gas is extricated commonly called *hepatic gas*, or, what is more expreſſive of its compoſition, *ſulphurated hydrogenous gas*. The fetor of this gas is inſufferable, and is fatal to animals. It communicates a green colour to ſyrup of violets, and burns with a light-blue flame. It acts on metals and metallic oxides, eſpecially thoſe of lead and biſmuth, which it ſoon blackens. It is decompoſed by vital air; and accordingly, when it comes into contact with atmoſpheric air, a portion of the ſulphur is ſeparated. For this reaſon ſulphureous waters do not contain genuine liver of ſulphur.

The mineral acids act differently on ſulphur. If the ſulphuric acid be boiled on ſulphur, the acid acquires an amber colour, and a ſulphureous ſmell; the ſulphur melts and ſwims like oil. When cooled, it concretes into globules of a greeniſh hue; but a ſmall portion of the ſulphur is diſſolved in the acid, which may be precipitated by an alkali. The flaming red nitrous acid acts powerfully on ſulphur. When poured upon melted ſulphur, it occaſions detonation and inflammation. The common muriatic acid produces no effect upon it; but the oxygenated muriatic acid acts upon it with force.

Sulphur unites readily with all metallic ſubſtances, excepting gold, platina, and zinc; at leaſt we have not found the means of uniting it with theſe directly, and without ſome intermediate ſubſtance. The degrees of affinity with which ſulphur combines with thoſe metals to which it may be readily united are different; for it not only unites more eaſily and abundantly with ſome than with others, but it alſo quits thoſe with which it has a leſs affinity, to unite with others to which it has a ſtronger affinity.

The affinities of ſulphur, according to Mr Geoffroy's table, are, fixed alkali, iron, copper, lead, ſilver, regulus of antimony, mercury, and gold; and, according to Mr Gellert's table, they are, iron, copper, tin, lead, ſilver, biſmuth, regulus

Sulphur. regulus of antimony, mercury, arſenic, and cobalt: gold and zinc are marked in this table as being incapable of uniting with ſulphur.

The compounds formed by ſulphur with different metals are different; but all of them poſſeſs a metallic luſtre, without any ductility: theſe combinations of ſulphur and of metals are very frequently found in a natural ſtate. Almoſt all the metals which we dig from the earth are naturally found combined with ſulphur, forming moſt of the ores and metallic minerals.

It is a curious phenomenon, that nitre mixed with ſulphur burns rapidly, even in cloſe veſſels; this is eaſily explained by the new ſyſtem. Nitre, when heat is applied to it, yields a great quantity of vital air; and ſulphur is a combuſtible body, or, which is the ſame thing, has a ſtrong attraction for vital air. As vital air is thus ſupplied, which is the only principle neceſſary to combuſtion, communication with the atmoſpheric air is unneceſſary. The ſulphur will burn till the whole vital air which the nitre furniſhes be conſumed. The products obtained by this proceſs are different according to the proportions of nitre and ſulphur which are employed. If eight parts of ſulphur and one of nitre be ſet on fire in a cloſe veſſel, ſulphuric acid is produced; and this is the method by which oil of vitriol or ſtrong ſulphuric acid was formerly made in Great Britain. The veſſels in which the operation was performed were large glaſs balloons, with very large necks, each containing 400 or 500 pints. But it was attended with great expence, on account of the high price and brittleneſs of the balloons. A few years ago a cheaper method has been attempted with ſucceſs in France. The ſulphur is burned on a kind of grid-irons, in large apartments lined with lead. As the acid condenſes it is conveyed by gutters into a reſervoir, and afterwards concentrated. It muſt be obſerved, that the ſulphuric acid thus obtained is always combined with a little ſulphur and ſulphat of pot-aſh, a ſmall quantity of aluminous ſulphat and ſulphat of lead; but theſe ſubſtances are in ſo ſmall a proportion, that for common uſe it is not neceſſary to ſeparate them. If neceſſary, however, it may eaſily be done by diſtilling the acid to dryneſs.

Gunpowder, the terrible effects of which are owing to its ſtrong tendency to combuſtion, is a mixture of ſulphur, nitre, and charcoal. (See GUNPOWDER). But there is another mixture of which ſulphur is an ingredient ſtill more violent in its effects: This is called *fulminating powder*, and is compoſed of three parts of nitre, two parts of the carbonate of pot-aſh, and one of powdered ſulphur. Theſe being cloſely united together by trituration in a hot marble mortar, when expoſed to a ſlight degree of heat, will melt, and produce a violent detonation like the report of a cannon. A dram of this mixture is ſufficient for the experiment.

Sulphur is of great uſe in chemiſtry, in medicine, and the arts. Sulphur is uſeful in making ſome fuſions, precipitations, and ſeparations of metals and minerals; but is particularly uſeful, as being the ſubſtance from which the ſulphuric acid is obtained. Hepar ſulphuris is employed in chemiſtry for making ſeveral ſolutions.

Sulphur is employed in medicine both internally and externally. It is given either in flowers or in lozenges, made up with ſugar, or joined to magneſia, cryſtals of tartar, manna, caſſia, lenitive electuary, &c. Two or three drams generally prove laxative; and it is given in ſuch doſes in caſes of piles, of uterine, and other hæmorrhagies; becauſe it does not ſtimulate nor heat during its operation, nor leave a diſpoſition to coſtiveneſs, as rhubarb, aloes, and other hot reſinous purges do. Sulphur was formerly much recommended in coughs and diſeaſes of the breaſt, but of late its virtues as a pectoral have been much doubted. When applied externally, it is mixed with ſome unctuous ſubſtance, as hogs-lard, butter, &c. and is rubbed on ſuch parts of the body as are affected with eruptions. Sulphur ‖ Sultan.

Some phyſicians and chemiſts, conſidering that ſulphur is inſoluble in water, and capable of reſiſting the action of moſt menſtruums, have affirmed, that it can produce no effect when taken internally, ſingle and unaltered; but this aſſertion ſeems to be without foundation; for it is certain, that the ſweat and perſpiration of thoſe who take ſulphur internally have a ſmell evidently ſulphureous. Beſides, ſulphur is much more ſoluble than is generally believed. It is attacked by all oily and ſaponaceous ſubſtances, and conſequently by almoſt all animal liquors.

We cannot eaſily form a very diſtinct and clear idea of the manner in which ſulphur acts internally upon our bodies; but, from obſervations made upon its effects, it appears to be dividing, ſtimulating, and ſomewhat heating: it principally acts upon the perſpirable parts of the body, the chief of which are the ſkin and lungs; and from this property it is particularly uſeful in ſome diſeaſes of theſe parts.

Sulphur is alſo a powerful repellent, as appears from its curing ſeveral kinds of itch, merely by external application, in form of ointments and pomatums. Several mineral waters, which are drunk or uſed as baths for ſome diſeaſes, owe their good qualities to ſulphur contained in them.

Sulphur is alſo uſed in ſeveral arts. By means of it fine impreſſions of engraved ſtones are taken. Matches are formed of it; and its utility as an ingredient in the preparation of gunpowder and fireworks is well known. Laſtly, it is uſed for whitening wool, ſilk, and many other matters expoſed to its vapour during its combuſtion; the colours and redneſs of which could not be deſtroyed by any other ſubſtance, but are quickly effaced by this acid vapour.

SULPHUR-Wort, in botany. See PEUCEDANUM.

SULPHURIC-ACID, the name adopted by the French chemiſts for the vitriolic acid. It is formed by a combination of ſulphur with vital air, as deſcribed under the article SULPHUR. When ſulphur is burned with a low degree of heat, it burns with a blue flame, and diffuſes a ſuffocating vapour, which, when collected, is called *ſulphureous acid*. When ſulphur is expoſed to ſtrong heat it burns rapidly, and emits a lively white flame, and has no ſmell; the reſidue is called *ſulphuric acid*. The ſulphureous is a weaker acid than the ſulphuric, owing to its containing a leſs quantity of oxygene.

SULPICIA, an ancient Roman poeteſs, who lived under the reign of Domitian, and has been ſo much admired as to be termed the *Roman Sappho*. We have nothing, however, left of her writings but a ſatire, or rather the fragment of one, againſt Domitian, who publiſhed a decree for the baniſhment of philoſophers from Rome: which ſatire is to be found in Scaliger's *Appendix Virgiliana*. She is mentioned by Martial and Sidonius Apollinaris; and is ſaid to have addreſſed a poem on conjugal love to her huſband Calenus, a Roman knight.

SULPICIUS (Severus), an eccleſiaſtical writer who flouriſhed about the beginning of the 5th century, and was contemporary with Rufinus and St Jerome. He was the diſciple of St Martin of Tours, whoſe life he has written; and the friend of Paulinus biſhop of Nola, with whom he held an intimate correſpondence. The principal of his works is his *Hiſtoria Sacra*, from the creation of the world to the conſulate of Stilicho and Aurelian, about the year 400; in which his ſtyle is elegant beyond the age he lived in.

SULTAN, or SOLDAN, a title or appellation given to the emperor of the Turks.

Vattier will have the word Turkiſh, and to ſignify *king*

Sulzer. *of kings;* adding, that it was firſt given to the Turkiſh princes Angrolipex and Maſgud, about the year 1055: others will have it originally Perſian, alleging, in proof hereof, an ancient medal of Coſroe: others derive it from *ſoldanus, quaſi ſolus dominus*: others from the Hebrew שלט, *ſchalat* or *ſheleth*, "to rule, reign."

It had its riſe under Mahmoud, ſon of Sebecteghin, the firſt emperor of the dynaſty of the Gaznevides, towards the cloſe of the fourth century of the era of the Hegira: when that prince going to Segeſtan to reduce Kalaf governor of that province, who affected the ſovereignty, Kalaf was no ſooner advertiſed of his coming than he went out to meet him, delivered the keys of his fortreſs, and owned him his *ſultan*, that is, his lord or commander. The title pleaſed Mahmoud ſo well, that he aſſumed it ever afterwards; and from him it paſſed to his deſcendants, and to other Mahometan princes. It is chiefly confined to the Turkiſh and Perſian monarchs.

SULZER (M.), a celebrated philoſopher, was born at Winterthun, in the canton of Zurich, October 16. 1720. He was the youngeſt of 25 children. His early education did not promiſe much, tho' it was by no means neglected. He had little inclination for what is called in the ſchools the ſtudy of *humanity*, and made but a ſmall progreſs in the learned languages, which were to prepare him for the ſtudy of theology, for which profeſſion his parents deſigned him. At the age of 16, when he went to the academical ſchool of Zurich, he had not the ſmalleſt notion of the ſciences, or of elegant literature, and conſequently no taſte for ſtudy. The firſt incident that developed a hidden germ of philoſophical genius, was his meeting with Wolfe's Metaphyſics: this was the birth of his taſte for ſcience; but he wanted a guide. The clergyman with whom he lodged was an ignorant man; and the academical prelections were, as yet, above the reach of his comprehenſion. On the other hand, a ſedentary life was not the thing he liked, nor to which he had been accuſtomed; and, moreover, a ſociable turn of mind led him often into company, where he loſt much time in frivolous amuſements, yet without corrupting his morals. Who, that obſerved him at this period, ſays Mr Formey in his *Eulogium*, would have thought that Sulzer would one day be numbered among the moſt knowing and wiſe men of his time? The learned Geſner was the inſtrument of Providence that rendered Sulzer's inclination to ſtudy triumphant over his paſſion for amuſement and company. Animated by the counſels and example of this worthy and learned man, he applied himſelf to philoſophy and mathematics with great ardour, and reſumed the purſuit of Grecian literature and the Oriental languages. The contemplation of nature became his noble and favourite paſſion. An eccleſiaſtical ſettlement in a rural ſcene, that exhibited happy objects and occaſions for this delightful ſtudy, began to render his days happy and uſeful; and he publiſhed, in 1741, *Moral Contemplations of the Works of Nature;* and the year following an *Account* of a journey he had made through the Alps; which ſhowed, at the ſame time, his knowledge of natural hiſtory, and the taſte and ſenſibility with which he ſurveyed the beauties of nature, and the grandeur and goodneſs of its Author. He afterwards became private tutor to a young gentleman at Magdeburg. This procured him the acquaintance of Meſſrs Maupertuis, Euler, and Sack, which opened to his merit the path of preferment, and advanced him ſucceſſively to the place of mathematical profeſſor in the King's College at Berlin, in 1747, and to that of member of the Royal Academy in 1750.

In this laſt quality he diſtinguiſhed himſelf in a very eminent manner, enriched the claſs of ſpeculative philoſophy with a great number of excellent memoirs, and was juſtly conſidered as one of the firſt-rate metaphyſicians in Germany. But his genius was not confined to this branch of ſcience. His *Univerſal Theory of the Fine Arts* is a valuable production. A profound knowledge of the arts and ſciences, and a perfect acquaintance with true taſte, are eminently diſplayed in this work, and will ſecure to its author a permanent and diſtinguiſhed rank in the republic of letters. The firſt volume of this excellent work was publiſhed in 1771, and the ſecond in 1774. We ſhall not here give a catalogue of the writings of M. Sulzer; but we cannot help mentioning his *Remarks on the Philoſophical Eſſays* of the late Mr Hume, as a work of real merit, which does juſtice to the acuteneſs, while it often detects the ſophiſtry, of the Britiſh Bayle. The moral character of M. Sulzer was amiable and virtuous: ſociability and beneficence were its characteriſtical lines; and his virtues were animated by that ſacred philoſophy that forms the Chriſtian, ennobles man, and is the only ſource of that heart-felt ſerenity and ſedate fortitude which ſupport humanity, when every other object of confidence fails. His dying moments were calm, humble, and ſublime; and when he expired, the placid and compoſed air of his countenance made his mourning friends doubt, for ſome time, whether it was death or ſleep that had ſuſpended his converſation. He had no enemy; and his friends were numerous, affectionate, and worthy of the tender returns he made them.

Sulzer || Sumatra.

The king of Pruſſia diſtinguiſhed him by repeated marks of munificence and favour. We learn, however, that his royal protector had never ſeen him before the end of the year 1777, though he had been member of the academy from the year 1750. The audience, indeed, though late vouchſafed, was honourable to M. Sulzer, with whom the monarch converſed for a long time with the greateſt affability and condeſcenſion.

SUM, ſignifies the quantity that ariſes from the addition of two or more magnitudes, numbers, or quantities together.

SUMACH, in botany. See RHUS.

SUMATRA, an iſland of Aſia, the moſt weſtern of the Sunda Iſlands, and conſtituting on that ſide the boundary of the Eaſtern Archipelago. Its general direction is nearly north-weſt and ſouth-eaſt. The equator divides it into almoſt equal parts, the one extremity being in 5. 33. N. and the other in 5. 56. S. Lat. Acheen head, at the north extremity of the iſland, is in longitude 95. 34. eaſt. It lies expoſed on the ſouth-weſt ſide to the Indian Ocean; the north point ſtretches into the bay of Bengal; to the north eaſt it is divided from the peninſula of Malacca by the ſtraits of that name; to the eaſt by the ſtraits of Banca, from the iſland of that name; to the ſouth-eaſt by the commencement of what are called the *Chineſe Seas;* and on the ſouth by the ſtraits of Sunda, which ſeparate it from the iſland of Java. It is about 900 miles in length, but from 100 to 150 only in breadth. No account had been given of this iſland by any Engliſhman till the year 1778, when Mr Charles Miller (ſon of the late botanical gardener) publiſhed an account of the manners of a particular diſtrict, in the 68th volume of the Philoſophical Tranſactions. Theſe were the Battas, a people who live in the interior parts, called the *Caſſia Country*. They differ from all the other inhabitants in language, manners, and cuſtoms. They eat the priſoners whom they take in war, and hang up their ſkulls as trophies in their houſes. He obſerves, however, that human fleſh is eaten by them *in terrorem*, and not as common food, though they prefer it to all others, and ſpeak with peculiar raptures of the ſoles of the feet and palms of the hands. They expreſſed much ſurpriſe that the white people did not kill, much leſs eat, their priſoners. From this

Brooke's Gazetteer.

Sumatra. this country the greateſt part of the caſſia that is ſent to Europe is procured. It abounds alſo with the camphire trees, which conſtitute the common timber in uſe; and in theſe trees the camphire is found native, in a concrete form. It is remarkable, that in this ſtate it is ſold to the Chineſe at the price of 250l. or 300l. *per* cwt. but theſe dexterous artiſts contrive to furniſh the Europeans with it at about a quarter of that price. In 1783, Mr Marſden, who had been ſecretary to the preſident and council of Fort Marlborough, publiſhed a Hiſtory of Sumatra, with very copious particulars of the iſland. He repreſents it as ſurpaſſed by few in the beautiful indulgences of nature. A chain of high mountains runs through its whole extent; the ranges in many parts being double and treble; their altitude, though great, is not ſufficient to occaſion their being covered with ſnow during any part of the year. Between theſe ridges are extenſive plains, conſiderably elevated above the ſurface of the maritime lands. In theſe the air is cool; and from this advantage they are eſteemed the moſt eligible portion of the country, are the beſt inhabited, and the moſt cleared from woods, which elſewhere, in general, throughout Sumatra, cover both hills and valleys with an eternal ſhade. Here too are found many large and beautiful lakes, that facilitate much the communication between the different parts. The heat of the air is far from being ſo intenſe as might be expected from a country occupying the middle of the Torrid Zone; and it is more temperate than many regions within the Tropics; the thermometer at the moſt ſultry hour, about two in the afternoon, generally fluctuating between 82 and 85 degrees. Mr Marſden divides the inhabitants into Malays, Acheneſe, Battas, Lampoons, and Rejangs; and he takes the latter as his ſtandard of deſcription, with reſpect to the perſons, manners, and cuſtoms, of the inhabitants. They are rather below the middle ſtature; their bulk in proportion; their limbs for the moſt part ſlight, but well ſhaped, and particularly ſmall at the wriſts and ancles; and, upon the whole, they are gracefully formed. Their hair is ſtrong, and of a ſhining black. The men are beardleſs, great pains being taken to render them ſo when boys, by rubbing their chins with a kind of quicklime. Their complexion is properly yellow, wanting the red tinge that conſtitutes a copper or tawny colour. They are in general lighter than the Meſtees, or half-breed, of the reſt of India; thoſe of the ſuperior claſs, who are not expoſed to the rays of the ſun, and particularly their women of rank, approaching to a degree of fairneſs. If beauty conſiſted in this one quality, ſome of them would ſurpaſs the brunettes in Europe. The major part of the females are ugly, many of them even to diſguſt; yet among them are ſome whoſe appearance is ſtrikingly beautiful, whatever compoſition of perſon, features, and complexion, that ſentiment may be the reſult of. Some of the inhabitants of the hilly parts are obſerved to have the ſwelled neck or goitre; but they attempt no remedy for it, as theſe wens are conſiſtent with the higheſt health. The rites of marriage among the Sumatrans conſiſt ſimply in joining the hands of the parties, and pronouncing them man and wife without much ceremony, excepting the entertainment which is given upon the occaſion by the father of the girl. The cuſtoms of the Sumatrans permit their having as many wives as they can purchaſe, or afford to maintain; but it is extremely rare that an inſtance occurs of their having more than one, and that only among a few of the chiefs. This continence they owe, in ſome meaſure, to their poverty. The dictates of frugality are more powerful with them than the irregular calls of appetite, and make them decline an indulgence from which their law does not reſtrain them. Mothers carry their children, not on the arm as our nurſes do, but ſtraddling on the hip, and uſually ſupported by a cloth which ties in a knot on the oppoſite ſhoulder. The children are nurſed but little; are not confined by any ſwathing or bandages; and being ſuffered to roll about the floor, ſoon learn to walk and ſhift for themſelves. When cradles are uſed, they ſwing ſuſpended from the ceilings of the rooms. Sumatra.

The Sumatrans are ſo fond of cock-fighting, that a father on his death-bed has been known to deſire his ſon to take the firſt opportunity of matching a cock for a ſum equal to his whole property, under a blind conviction of its being invulnerable. When a cock is killed, or runs, the other muſt have ſufficient ſpirit and vigour left to peck at him three times on his being held up to him for that purpoſe, or it becomes a drawn battle; and ſometimes an experienced cocker will place the head of his vanquiſhed bird in ſuch an uncouth ſituation as to terrify the other, and render him unable to give this proof of victory.

The wild beaſts of Sumatra are tigers, elephants, rhinoceroſes, bears, and monkeys. The tigers prove to the inhabitants both in their journeys and even their domeſtic occupations moſt deſtructive enemies. The number of people annually ſlain by theſe rapacious tyrants of the woods is almoſt incredible. Whole villages have been depopulated by them; yet from a ſuperſtitious prejudice, it is with difficulty they are prevailed upon, by a large reward which the India Company offers, to uſe methods of deſtroying them, till they have ſuſtained ſome particular injury in their own family or kindred. The ſize and ſtrength of the ſpecies which prevails on this iſland is prodigious. They are ſaid to break with a ſtroke of their fore paw the leg of a horſe or a buffalo; and the largeſt prey they kill is without difficulty dragged by them into the woods. This they uſually perform on the ſecond night, being ſuppoſed on the firſt to gratify themſelves with ſucking the blood only. Time is by this delay afforded to prepare for their deſtruction, either by ſhooting them, or placing a veſſel of water ſtrongly impregnated with arſenic near the carcaſe, which is faſtened to a tree to prevent its being carried off. The tiger having ſatiated himſelf with the fleſh, is prompted to aſſuage his thirſt with the tempting liquor at hand, and periſhes in the indulgence. Their chief ſubſiſtence is moſt probably the unfortunate monkeys with which the woods abound. They are deſcribed as alluring them to their fate by a faſcinating power, ſimilar to what has been ſuppoſed of the ſnake; and, ſays Mr Marſden, "I am not incredulous enough to treat the idea with contempt, having myſelf obſerved, that when an alligator or a crocodile, in a river, comes under an overhanging branch of a tree, the monkeys, in a ſtate of alarm and diſtraction, crowd to the extremity, and, chattering and trembling, approach nearer and nearer to the amphibious monſter that waits to devour them as they drop, which their fright and number render almoſt unavoidable." Theſe alligators likewiſe occaſion the loſs of many inhabitants, frequently deſtroying the people as they bathe in the river, according to their regular cuſtom, and which the perpetual evidence of the riſk attending it cannot deter them from. A ſuperſtitious idea of their ſanctity alſo preſerves them from moleſtation, although, with a hook of ſufficient ſtrength, they may be taken without much difficulty. The other animals of Sumatra are buffaloes, a ſmall kind of horſes, goats, hogs, deer, bullocks, and hog-deer. This laſt is an animal ſomewhat larger than a rabbit, the head reſembling that of a hog, and its ſhanks and feet like thoſe of the deer. The bezoar-ſtone found in this animal has been valued at 10 times its weight in gold; it is of a dark brown colour, ſmooth on the outſide; and the coat being taken off, it appears ſtill darker, with ſtrings running underneath the coat: it will ſwim on the top of the water. If it be infu-

Sumatra. fed in any liquid, it makes it extremely bitter: the virtues uſually attributed to this ſtone are cleanſing the ſtomach, creating an appetite, and ſweetening the blood.

Of birds they have a greater variety than of beaſts. The coo-ow, or Sumatran pheaſant, is a bird of uncommon beauty. They have ſtorks of prodigious ſize, parrots, dung-hill fowls, ducks, the largeſt cocks in the world, wood-pigeons, doves, and a great variety of ſmall birds, different from ours, and diſtinguiſhed by the beauty of their colours. Of their reptiles, they have lizards, flying-lizards, and cameleons. The iſland ſwarms with inſects, and their varieties are no leſs extraordinary than their numbers. Rice is the only grain that grows in the country; they have ſugar-canes, beans, peas, radiſhes, yams, potatoes, pumkins, and ſeveral kinds of pot-herbs unknown to Europe; and here are to be found moſt of the fruits to be met with in other parts of the Eaſt Indies, in the greateſt perfection. Indigo, Braſil-wood, two ſpecies of the bread-fruit tree, pepper, benjamin, coffee, and cotton, are likewiſe the produce of this iſland, as well as caſſia and camphire mentioned above. Here alſo is the cabbage-tree and ſilk cotton tree; and the foreſt contains a great variety of valuable ſpecies of wood, as ebony, pine, ſandal, eagle or aloes, teek, manchineel, and iron-wood, and alſo the banyan tree. Gold, tin, iron, copper, and lead, are found in the country; and the former is ſuppoſed to be as plentiful here as in Peru or Mexico. The fineſt gold and gold-duſt are found in the country of *Limong*, immediately contiguous to the preſidency of *Fort Marlborough*, to which the merchants repair annually for the purchaſe of opium, and ſuch other articles as they may be in want off, and give for them gold of ſo pure a nature as to contain little or no alloy. The native indolence of the *Malay* diſpoſition prevents them from collecting more than is ſufficient to ſupply the few and ſimple wants of a race of men as yet unenlightened by civilization and ſcience, and ignorant of the full extent of the advantages of the country inhabited by them. The roads leading to this golden country are almoſt impervious; affording only a ſcanty path to a ſingle traveller, where whole nights muſt be paſſed in the open air, expoſed to the malignant influence of a hoſtile climate, in a country infeſted by the moſt ferocious wild beaſts. Theſe are circumſtances that have hitherto checked curioſity; but perſeverance and ſtudied precaution will ſurmount the obſtacles they furniſh, and ſuch diſcoveries might be made as would amply compenſate for the difficulties leading to them. The gold merchants who come from the neighbouring and leſs rich conntries, give us ſuch accounts of the facility of procuring gold as border nearly on the marvellous, and would be altogether incredible, if great quantities of that metal produced by them did not in ſome degree evince the certainty of their accounts.

Aſiatic Reſearches, vol. i.

This great abundance of gold in Sumatra induces Mr Marſden to ſuppoſe that iſland to be the Ophir of Solomon; a conjecture which, in his opinion, derives no ſmall force from the word *Ophir's* being really a *Malay* ſubſtantive, of a compound ſenſe, ſignifying a mountain containing gold. The natives, he confeſſes, have no oral tradition on the ſubject; and we have elſewhere made it probable, that Ophir was ſituated in a different quarter of the world (ſee OPHIR). Beſides the metals and different ſpecies of wood which we have mentioned, Sumatra produces ſulphur, arſenic, ſalt-petre, and bees-wax, with edible birds neſts, which are there commodities of great importance (ſee *Birds-Neſts*).

The Engliſh and Dutch have factories on this iſland; the principal one of the former being Fort Marlborough, on the ſouth-weſt coaſt. The original natives of Sumatra are Pagans; but it is to be obſerved, that when the Sumatrans, or any of the natives of the eaſtern iſlands, learn to read the Arabic character, and ſubmit to circumciſion, they are ſaid to become Malays; the term *Malay* being underſtood to mean *Muſſulman*. See ACHEEN.

Summary ‖ Sumptuary.

SUMMARY, in matters of literature. See ABRIDGEMENT.

SUMMER, the name of one of the ſeaſons of the year, being one of the quarters when the year is divided into four quarters, or one half when the year is only divided into two, ſummer and winter. In the former caſe, ſummer is the quarter during which, in northern climates, the ſun is paſſing through the three ſigns Cancer, Leo, Virgo, or from the time of the greateſt declination, till the ſun come to the equinoctial again, or have no declination,; which is from about the 21ſt of June till about the 22d of September. In the latter caſe, ſummer contains the ſix warmer months, while the ſun is on one ſide of the equinoctial; and winter the other ſix months, when the ſun is on the other ſide of it. It is ſaid that a froſty winter produces a dry ſummer, and a mild winter a wet ſummer.

Summer-Iſlands. See BERMUDAS.

Summer Red-Bird. See MUSCICAPA.

SUMMIT, the top or vertex of any body or figure, as of a triangle, cone, pyramid, &c.

SUMMONS, in law, a citing or calling a perſon to any court, to anſwer a complaint or to give his evidence

SUMMONS, in war. To ſummon a place, is to ſend a drum or trumpet to command the governor to ſurrender, and to declare that if the place be taken by ſtorm, all muſt ſubmit to the mercy of the conqueror. See CAPITULATION and CHAMADE.

SUMMUM BONUM, in ethics, the chief good.

SUMP, in metallurgy, a round pit of ſtone, lined with clay within, for the receiving the metal on its firſt fuſion from the ore.

SUMP, in the Britiſh ſalt-works, where ſea-water is boiled into ſalt, is the name of a ſort of pond, which is made at ſome diſtance from the ſaltern on the ſea-ſhore, between full ſea and low water mark. From this pond a pipe is laid, through which, when the ſea is in, the water runs into a well adjoining to the ſaltern; and from this well it is pumped into troughs, through which it is carried to the ciſterns, in order to be ready to ſupply the pans. See SALT.

SUMPH, in mining, denotes a pit ſunk down in the bottom of the mine, to cut or prove the lode ſtill deeper than before; and in order to ſlope and dig it away if neceſſary, and alſo to drive on the lode in depth. The ſumph principally ſerves as a baſon or reſervoir, to collect the water of a mine together, that it may be cleaned out by an engine or machine.

SUMPTER-HORSE, is a horſe that carries proviſions and neceſſaries for a journey.

SUMPTUARY LAWS *(Leges Sumptuariæ)*, are laws made to reſtrain exceſs in apparel, coſtly furniture, eating, &c.

Moſt ages and nations have had their ſumptuary laws; and ſome retain them ſtill, as the Venetians, &c. But it is obſerved, that no laws are worſe executed than ſumptuary laws. Political writers have been much divided in opinion with reſpect to the utility of theſe laws to a ſtate. Monteſquieu obſerves, that luxury is neceſſary in monarchies, as in France, but ruinous to democracies, as in Holland. With regard to England, whoſe government is compounded of both ſpecies, it may ſtill be a dubious queſtion, ſays judge Blackſtone, how far private luxury is a public evil; and as ſuch cognizable by public laws.

The ſumptuary laws of that ancient Locrian legiſlator Zaleucus are famous: by theſe it was ordained, that no woman ſhould go attended with more than one maid in

Sun ‖ Sunday.

the ſtreet except ſhe were drunk: that he ſhould not go out of the city in the night, unleſs ſhe went to commit fornication: that ſhe ſhould not wear any gold or embroidered apparel, unleſs ſhe propoſed to be a common ſtrumpet; and that men ſhould not wear rings or tiſſues except when they went a whoring, &c.

Among the Romans, the ſumptuary laws were very numerous: By the *Lex Orchia*, the number of gueſts at feaſts was limited, though without any limitation of the charges: by the Fannian law, made 22 years afterwards, it was enacted, that more that 10 *aſſes* ſhould not be ſpent at any ordinary feaſt: for the ſolemn feaſts, as the Saturnalia, &c. an hundred aſſes were allowed; ten of which, Gellius informs us, was the price of a ſheep, and an hundred of an ox. By the Didian law, which was preferred 18 years after, it was decreed, that the former ſumptuary laws ſhould be in force, not only in Rome, but throughout all Italy; and that for every tranſgreſſion, not only the maſter of the feaſt, but all the gueſts too, ſhould be liable to the penalty.

The Engliſh have had their ſhare of ſumptuary laws, chiefly made in the reigns of Edw. III. Edw. IV. and Henry VIII. againſt ſhoes with long points, ſhort doublets, and long coats; though all repealed by ſtatute 1 Jac. I. c. 25. As to exceſs in diet, there remains ſtill one law unrepealed. Under King Henry IV. Camden tells us, pride was got ſo much into the foot, that it was proclaimed, that no man ſhould wear ſhoes above ſix inches broad at the toes. And their other garments were ſo ſhort, that it was enacted, 25 Edw. IV. that no perſon, under the condition of a lord, ſhould, from that time, wear any mantle or gown, unleſs of ſuch length, that, ſtanding upright, it might cover his privy members and buttocks.

SUN, Sol, ☉ in aſtronomy, the great luminary which enlightens the world, and by its preſence conſtitutes day. See Astronomy-*Index*.

Mock-Sun. See Parhelion.

Sun-Fiſh of the Iriſh. See Squalus.

Sun-Flower, in botany. See Helianthus.

Sun-Dew, in botany. See Drosera.

SUNDA-ISLANDS, a general name for a cluſter of iſlands in the India Ocean, between 93° and 120° of eaſt longitude, and between 8° north and 8° ſouth latitude. The particular names of the iſlands are *Borneo*, *Sumatra*, *Java*, *Bally*, *Banca*, &c.

SUNDAY, or the Lord's-day, a ſolemn feſtival obſerved by Chriſtians on the firſt day of every week, in memory of our Saviour's reſurrection. Sabbath.

In the breviary and other offices we meet with Sundays of the firſt and ſecond claſs. Thoſe of the firſt claſs are, Palm, Eaſter, Advent, and Whitſunday, thoſe of *Quaſimodo* and *Quadrageſima*. Thoſe of the ſecond claſs are the common Sundays. Anciently each Sunday in the year had its particular name, which was taken from the introit of the day; which cuſtom has only been continued to ſome few in lent; as *Reminiſcere*, *Oculi*, *Lætare*, *Judica*.

Some are of opinion that the Lord's-day, mentioned in the Apocalypſe, is our Sunday; which they believe was ſo early inſtituted by the apoſtles. Be this as it will, it is certain a regard was had to this day even in the earlieſt ages of the church; as appears from the firſt apology of Juſtin Martyr, where he deſcribes the exerciſe of the day not much unlike to ours.

But it was Conſtantine the Great who firſt made a law for the proper obſervation of Sunday; and who, according to Euſebius, appointed it ſhould be regularly celebrated throughout the Roman empire. Before him, and even in his time, they obſerved the Jewiſh Sabbath as well as Sunday; both to ſatisfy the law of Moſes and to imitate the apoſtles, who uſed to meet together on the firſt day.

Suovetaurilia ‖ Superficies.

By Conſtantine's law, made in 321, it was decreed, that for the future the Sunday ſhould be kept a day of reſt in all cities and towns; but he allowed the country people to follow their work. In 538, the council of Orleans prohibited country labour; but becauſe there were ſtill many Jews in Gaul, and the people fell into many ſuperſtitious uſages in the celebration of the new Sabbath, like thoſe of the Jews among that of the old, the council declares, that to hold it unlawful to travel with horſes, cattle, and carriages, to prepare food, or to do any thing neceſſary to the cleanlineſs and decency of houſes or perſons, favours more of Judaiſm than of Chriſtianity. See *Sabbath-Breaking*.

Sunday-Schools. See *Sunday-Schools*.

SUOVETAURILIA, an ancient Roman ſacrifice, ſo called becauſe it conſiſted of a pig *(ſus)*, a ſheep or rather ram *(ovis)*, and a bull *(taurus)*. They were all males, to denote the maſculine courage of the Roman people. It was likewiſe called *ſolitaurilia*, becauſe the animals offered up were always *ſolida*, whole or uncut.

SUPERCARGO, a perſon employed by merchants to go a voyage, and overſee their cargo or lading, and diſpoſe of it to the beſt advantage.

SUPERCILIUM, in anatomy, the eye-brow. See Anatomy, n° 142.

SUPEREROGATION, in theology, what a man does beyond his duty, or more than he is commanded to do. The Romaniſts ſtand up ſtrenuouſly for works of ſupererogation, and maintain that the obſervance of evangelical councils is ſuch. By means hereof, a ſtock of merit is laid up, which the church has the diſpoſal of, and which ſhe diſtributes in indulgences to ſuch as need.

This abſurd doctrine was firſt invented towards the cloſe of the 12th century, and modified and embelliſhed by St Thomas in the 13th: according to which, it was pretended that there actually exiſted an immenſe treaſure of merit, compoſed of the pious deeds and virtuous actions which the ſaints had performed beyond what was neceſſary for their own ſalvation, and which were therefore applicable to the benefit of others; that the guardian and diſpenſer of this precious treaſure was the Roman pontiff; and that of conſequence he was empowered to aſſign to ſuch as he thought proper a portion of this inexhauſtible ſource of merit, ſuitable to their reſpective guilt, and ſufficient to deliver them from the puniſhment due to their crimes.

The reformed churches do not allow of any work of ſupererogation; but hold with the apoſtles, that when we have done our beſt, we are but unprofitable ſervants.

SUPERFETATION, in medicine, a ſecond or after-conception, happening when the mother, already pregnant, conceives of a later coition; ſo that ſhe bears at once two fœtuſes of unequal age and bulk, and is delivered of them at different times. We meet with inſtances of ſuperfetations in Hippocrates, Ariſtotle, Du Laurens, &c.: but they are ſaid to be much more frequent in hares and ſwine.

SUPERFICIES, or Surface, in geometry, the outſide or exterior face of any body. This is conſidered as having the two dimenſions of length and breadth only, but no thickneſs; and therefore it makes no part of the ſubſtance or ſolid content or matter of the body.

The terms, or bounds, or extremities, of a ſuperficies, are lines; and ſuperficies may be conſidered as generated by the motions of lines. Superficies are either rectilinear, curvilinear, plane, concave, or convex. A rectilinear ſuperficies is that which is bounded by right lines. Curvilinear ſuperfi-

Superfine ‖ Superſtition.

cies is bounded by curve lines. Plane ſuperficies is that which has no inequality in it, nor riſings, nor ſinkings, but lies evenly and ſtraight throughout, ſo that a right line may wholly coincide with it in all parts and directions. Convex ſuperficies is that which is curved and riſes outwards. Concave ſuperfices is curved and ſinks inward. See GEOMETRY.

SUPERFINE, in the manufactories, a term uſed to expreſs the ſuperlative fineneſs of a ſtuff: thus a cloth, a camblet, &c. are ſaid to be ſuperfine when made of the fineſt wool, &c. or when they are the fineſt that can be made.

SUPERFLUOUS INTERVAL, in muſic, is one that exceeds a true diatonic interval by a ſemitone minor. See INTERVAL.

SUPERINTENDANT, denotes an eccleſiaſtical ſuperior in ſeveral reformed churches where epiſcopacy is not admitted: particularly among the Lutherans in Germany, and the Calviniſts in ſome other places.

The ſuperintendant is ſimilar to a biſhop; only his power is ſomewhat more reſtrained than that of Engliſh dioceſan biſhops. He is the chief paſtor, and has the direction of all the inferior paſtors within his diſtrict or dioceſe. In Germany they had formerly ſuperintendants general, who were ſuperior to the ordinary ſuperintendants. Theſe, in reality, were archbiſhops; but the dignity is ſunk into diſuſe; and at preſent none but the ſuperintendant of Wirtemberg aſſumes the quality of ſuperintendant general.

SUPERIOR, a perſon raiſed above another in rank, office, or talents.

SUPERIOR, in Scots law. See Law, N° clxiv. 3. clxv. 2. & clxvi.

SUPERLATIVE, in grammar, one of the three degrees of compariſon, being that inflection of adjective nouns that ſerves to augment and heighten their ſignification, and ſhows the quality of the thing denoted to be in the higheſt degree. See GRAMMAR.

SUPERNUMERARY, ſomething over and above a fixed number. In ſeveral of the offices are ſupernumerary clerks, to be ready on extraordinary occaſions.

SUPERPARTICULAR PROPORTION, or *Ratio*, is that in which the greater term exceeds the leſs by unit or 1. As the ratio of 1 to 2, or 2 to 3, or 3 to 4, &c.

SUPERPARTIENT PROPORTION, or *Ratio*, is when the greater term contains the leſs term once, and leaves ſome number greater than 1 remaining. As the ratio

of 3 to 5, which is equal to that of 1 to $1\frac{2}{3}$;
of 7 to 10, which is equal to that of 1 to $1\frac{3}{7}$, &c.

SUPERSEDEAS, in law, a writ iſſued in divers caſes, importing in general a command to ſtay or forbear ſome ordinary proceedings in law, which in appearance ought to be done or purſued, were it not for the cauſe whereon this writ is granted.

Thus a man regularly is to have a ſurety of peace againſt him of whom he will ſwear he is afraid; and the juſtice required hereunto cannot deny it him: yet, if the party be formerly bound to the peace, either in chancery or elſewhere, this writ lies to ſtay the juſtice from doing that which otherwiſe he ought not to deny.

SUPERSTITION, a word that has been uſed ſo indefinitely, that it is difficult to determine its preciſe meaning. From its reſemblance in ſound to the Latin word *ſuperſtes*, "a ſurvivor," it is evidently derived from it, and different attempts have been made to trace their connection in ſignification. Balbus, in the dialogue *De Natura Deorum* of Cicero, ſays, that they who prayed and ſacrificed whole days that their children might *ſurvive* them, were called ſuperſtitious. Lactantius cenſures this etymology, and ſays they were not called ſuperſtitious who wiſhed that their children might ſurvive them (for this we all wiſh), but becauſe they who ſurvived their parents worſhipped their images. Others again ſay, that ſuperſtition is derived from *ſuperſtes*, becauſe it conſiſted in conſidering the dead as if they were alive. But theſe etymologies are ſolely conjectural; and we conſider conjectures as abſurd in philology as we do in ſcience; they may miſlead, but are ſeldom of any benefit. The uſual meaning affixed to the word *ſuperſtition*, both in the Latin and Engliſh languages, is ſo different from *ſuperſtes*, that its change of meaning muſt be owing to ſome accident which it is in vain to inquire after. If we had not known that the word *paganus* "a pagan" was derived from *pagus* "a village," becauſe the heathens in a certain period of the Chriſtian hiſtory lived in villages, the whims and fancies of etymologiſts would not have thrown much light on the ſubject. Superſtition.

Without labouring, from the aid of etymology, to define ſuperſtition, which is a word of a very extenſive ſignification, we will conſider to what objects it is applied; and then, by obſerving what is common to them all, we ſhall be enabled to fix with ſome degree of preciſion the meaning of the term. We apply it to the idolatry of the heathens; we apply it alſo to the Jews, who made the will of God of no effect by their traditions, and ſubſtituted ceremonies in place of the religion of their fathers. We ſay alſo that Chriſtians are guilty of ſuperſtition; the Roman Catholics, who believe in tranſubſtantiation and in the efficacy of prayers to ſaints; and thoſe Proteſtants who eſteem baptiſm and the Lord's ſupper, and the punctual performance of other ceremonies, without regard to morality, as ſufficient to enſure ſalvation. Thoſe perſons alſo are reckoned ſuperſtitious who believe, without any evidence, that prophecies are ſtill uttered by the divine inſpiration, and that miracles are ſtill performed. The word is alſo extended to thoſe who believe in witchcraft, magic, and apparitions, or that the divine will is declared by omens or augury; that the fortune of individuals can be affected by things indifferent, by things deemed lucky or unlucky, or that diſeaſes can be cured by words, charms, and incantations.

Through all the particulars which we have enumerated, there runs one general idea, the belief of what is falſe and contrary to reaſon. From this, however, we muſt not ſuppoſe that whatever is falſe and contrary to reaſon may be denominated ſuperſtition. We think that it is falſe and irrational to ſuppoſe that there ever lived on earth a race of men who walked on one leg, and had their eyes in their breaſt; or that there were giants 90 feet high: yet we do not call the philoſopher who believes theſe chimeras ſuperſtitious, but credulous. Superſtition has always a reference to God, to religion, or to beings ſuperior to man. We do not however diſtinguiſh all falſe and irrational opinions in religion by the name of ſuperſtition. We do not, for inſtance, apply this name to the opinions which ſome of the ancients entretained, that God is the ſoul of the world, and that men are only portions of him ſeparated for a time, or that the ſoul after death lives ſucceſſively in different bodies. If we examine the ſubject with more attention, we ſhall diſcover that the foundation of ſuperſtition is ignorance of the moral attributes of God; for we never ſay a man is ſuperſtitious for entertaining erroneous opinions of the natural attributes of God. Some of the Socinians have denied the preſcience of God; and a French philoſopher has not only rejected the belief that He is a ſpirit, but has preſumed to ſay that he is compoſed of a ſpecies of cryſtals. The firſt of theſe opinions diſcovers very imperfect ideas of God, and the ſecond is the height of impiety and abſurdity; yet the

So-

Superſtition. Socinians have not been accuſed of ſuperſtition, nor can this French philoſopher be ſuſpected of it. We do not call every falſe opinion concerning the unity or moral attributes of God by the name of ſuperſtition, as, for inſtance, the opinion which ſome ſceptics have ſupported, that God is not good; for, as was mentioned before, ſuperſtition always involves the idea of credulity. It does not conſiſt in falſely denying that God poſſeſſes any particular moral attributes, but in believing more than what is true concerning them; in forming mean, unworthy ideas of them; in ſuppoſing that he is guided by blind paſſion like mankind, and enjoins upon his creatures commandments which are irrational and abſurd.

As ſuperſtition ariſes from ignorance and credulity in the underſtanding, ſo it has alſo a ſeat in the paſſions. Fear has been commonly conſidered as the paſſion of the human mind from which it chiefly derives its origin; and there is no doubt that more ſuperſtition has ariſen from fear united with ignorance and credulity than from any other paſſion. Yet it would certainly be improper to exclude all other paſſions. We cannot account for the ſuperſtition of the Egyptians, without ſuppoſing that much of it aroſe from gratitude. They worſhipped the Nile, becauſe it diſtributed fertility and abundance over the land of Egypt; and they worſhipped ſome animals, merely becauſe they prevented the increaſe of other animals which were noxious. Thus they adored the ibis, becauſe it deſtroyed the eggs of the crocodile.

Having thus endeavoured to analyze the ideas comprehended under the word ſuperſtition, we may ſum them up in a few words. It reſpects God and beings ſuperior to man, and extends to our religious opinions, worſhip, and practices; and may be defined *abſurd opinions and actions ariſing from mean and defective ideas of the moral attributes of God.* Let us apply this definition to the different ſpecies of ſuperſtition already mentioned.

But before entering upon this application, it may be proper to obſerve, that ſuperſtition involves the idea of a blameable inattention to reaſon, or a credulity ariſing from an indolence of underſtanding. We generally make a diſtinction between the imperfect opinions which a ſavage, from the neceſſary effects of his ſituation, forms of the attributes of God, and thoſe which civilized nations entertain. We ſay the ſavage is ignorant, and we aſcribe his ignorance to his ſituation; but we call the Roman Catholic ſuperſtitious, and we blame him for not having thoſe juſt ideas of God which he might have obtained by opening his Bible, or by the exerciſe of his underſtanding in the favourable ſituation in which he is placed. Superſtition then does not originate ſo much from the natural weakneſs of the human underſtanding, as from a miſapplication or a neglect of it (A).

We cannot therefore with any propriety apply the name *ſuperſtition* to polytheiſm in general; for what all the ancient philoſophers, after much ſtudy and reflection, concluded to be true, could never proceed from credulity and inattention, but from their ſituation. We ſpeak very properly, however, when we call idolatry by the name of ſuperſtition; becauſe there is no man ſo devoid of underſtanding as not to be capable of diſcovering, that a piece of metal, or wood, or ſtone, can neither hear nor anſwer petitions. *Superſtition* was a name which the ancient philoſophers gave to thoſe who entertained mean opinions of the gods, or did fooliſh things to obtain their favour. According to Theophraſtus, the ſuperſtitious man is one who, having waſhed his hands, and ſprinkled himſelf all round, leaves the temple with a laurel leaf in his mouth, with which he walks about the whole day. Or, if a weaſel ſhould croſs the road, he will not advance a ſtep till he has thrown three ſtones over the road. If he finds a ſerpent in his houſe, he rears a place of devotion on the ſpot. He purifies his houſe often, will not ſit upon a grave, nor touch a dead perſon. He is anxious about the interpretation of his dreams, will not offer a ſacrifice unleſs his wife go along with him, or, if ſhe is engaged, he takes the nurſe and the little children. He purifies himſelf with onions; and when he ſees a mad or an epileptic perſon, he ſpits in their boſom. Such was the character of ſuperſtition in the days of Theophraſtus. All theſe whimſical ceremonies were done to prevent miſchief, and to avert the wrath of the gods; and therefore perfectly correſpond with the definition given above.

Theophraſtus's Characters, xvi.

Superſtition.

It is only neceſſary to conſider a little the ſuperſtitious opinions and practices among Jews and Chriſtians, to be ſenſible that they have all ariſen from mean and abſurd ideas of the moral attributes of God; for they have generally entertained noble opinions of his natural attributes. The Jews conſidered God as a partial Being, who had a predilection for their nation in preference to all others, and preferred external homage and ceremony to moral purity. If the Roman Catholics think conſiſtently, they muſt eſteem God as a Being who can be prevailed upon by the importunity of one dead man to aſſiſt another, or as a Being whoſe patience would be fatigued with hearing prayers conſtantly. Hence their practice of praying to ſaints. They in effect believe, however they may deceive themſelves, that God is unjuſt, or they could not believe tranſubſtantiation; for it ſuppoſes that God can give commands directly contrary to thoſe principles of belief with which he has endued the human mind. They conſider a ſtrict adherence to a variety of ceremonies, to forms, to pomp, and ſhow, as eſſential to the worſhip of God: this is treating God as a vainglorious Being. They thought it their duty to extirpate heretics: this was ſuppoſing God a cruel and revengeful Being. Even among Proteſtants, we are ſorry to ſay, a great deal of ſuperſtition remains: we have not yet learned to conſider God as a ſpirit, who is to be worſhiped in ſpirit and in truth, as a pure moral benevolent Being; and hence ariſes all the ſuperſtitious practices which prevail among us.

Beſides thoſe ſuperſtitious opinions and practices which entirely reſpect our duty to God, there are others which may be termed *vulgar ſuperſtitions*. Theſe alſo ariſe from imperfect and mean ideas of the moral attributes of God. To believe vulgar prophecies, which are always the effuſions of madneſs or knavery, is to ſuppoſe that God, who has drawn a veil over futurity, and only delivers prophecies to accompliſh ſome great moral purpoſe, ſometimes gives them for no purpoſe at all, or to gratify idle curioſity, or to diſcloſe ſuch a knowledge of what is to happen as is inconſiſtent with the free agency of man and the moral adminiſtration of the world. Nor is it leſs ſuperſtitious to believe in vulgar miracles. To believe in them, is to believe that God ſuſpends the laws of nature for the moſt trivial purpoſes, or to countenance fraud and worldly ambition: it is to receive the moſt extraordinary facts upon the moſt unſatisfactory evidence. The belief of witchcraft, of apparitions, and the ſecond ſight, may be reſolved into the ſame principle. To ſuppoſe that God would communicate the power of doing miſchief, and of controling his laws, to any being merely for gratifying their own paſſions, is unworthy of God. The belief of apparitions is equally inconſiſtent with the goodneſs of God (ſee SPECTRE). The ſame objection riſes againſt the ſecond ſight as againſt the belief of vulgar prophecies, and may alſo be extended to omens, to aſtrology, to things lucky and unlucky, to fortune-telling, &c. As to the different devices and charms for preventing and curing diſorders, they reſemble in every reſpect falſe miracles.

(A) We do not pretend to ſay that this is the ſenſe in which ſuperſtition is always uſed, becauſe it is often uſed improperly.

Superſtition.

A judicious hiſtory of ſuperſtition would be a curious and entertaining work, and would exhibit the human character in a remarkable point of view. Superſtition is moſt prevalent among men of weak and uncultivated minds; it is more frequent in the female ſex than among men; and abounds more in the rude than in the refined ſtages of ſociety. The general features of it have been the ſame in all ages; but it aſſumes certain peculiarities according to the diverſity of character of different nations. It gained admiſſion into the ſcience of medicine at an early period. He who was endowed with ſuperior genius and knowledge was reckoned a magician. Dr Bartolo was ſeized by the inquiſition at Rome in the laſt century, becauſe he unexpectedly cured a nobleman of the gout. Diſeaſes were imputed to faſcination, and hundreds of poor wretches were dragged to the ſtake for being acceſſary to them. Mercatus, phyſician to Philip II. of Spain, a writer of uncommon accuracy and information, appears ſtrongly inclined to deny the exiſtence of faſcinatory diſeaſes: but he is conſtrained to acknowledge them for two reaſons *1ſt*, Becauſe the inquiſition had decided in favour of their reality; *2dly*, Becauſe he had ſeen a very beautiful woman break a ſteel-mirror to pieces, and blaſt ſome trees by a ſingle glance of her eyes.

Manchester Tranſactions, vol. iii.

As the opinions concerning the cauſes of diſeaſes were ſuperſtitious, thoſe concerning the method of curing them were not leſs ſo. In the Odyſſey we read of a cure performed by a ſong. Joſephus relates, that he ſaw a certain Jew, named *Eleazar*, draw the devil out of an old woman's noſtrils by the application of Solomon's ſeal to her noſe in preſence of the Emperor Veſpaſian. Many different kinds of applications were uſed for expelling the devil. Flagellation ſometimes ſucceeded admirably; purgatives and antiſpaſmodics were other modes of diſcharging him. Dr Mynſight cured ſeveral bewitched perſons with a plaſter of aſſafœtida. How the aſſafœtida was ſo efficacious, was much diſputed. Some thought the devil might conſider ſo vile an application as an inſult, and run off in a paſſion; but others very ſagely obſerve, that as devils are ſuppoſed to have eyes and ears, it is probable they may have noſes too.

Nor was it only in medicine theſe ſuperſtitious opinions were entertained; they prevailed alſo in natural philoſophy. The pernicious effects in mines, which we now know are occaſioned by noxious air, were confidently imputed to the demons of the mine. Even Van Helmont, Bodinus, Strozza, and Luther, attributed thunder and meteors to the devil. Chemiſts were employed for centuries in ſearch of the philoſopher's ſtone, with which they were to do miracles. It was a common queſtion among philoſophers in the laſt century, whether the imagination could move external objects? A queſtion generally decided in the affirmative.

Though ſuperſtition be generally the mark of a weak mind, ſuch is the infirmity of human nature, that we find many inſtances of it among men of the moſt ſublime genius and moſt enlightened minds. Socrates believed that he was guided by a demon. Lord Bacon believed in witchcraft; and relates that he was cured of warts by rubbing them with a piece of lard with the ſkin on, and then nailing it with the fat towards the ſun on the poſt of a chamber window facing the ſun. Henry IV. one of the moſt illuſtrious of monarchs, was very uneaſy before his aſſaſſination on account of ſome prophecies *. Sully declares, that one of the conſiderations that kept him faithful to his maſter in the moſt unpromiſing ſtate of his affairs, was a prediction of La Broſſe, that Henry would make his fortune †. The aſtrologer Morin directed Cardinal Richelieu's motions in ſome of his journeys ‡. The enlightened Cudworth defended prophecies in general, and called thoſe who oppoſed the belief of witchcraft by the name of *atheiſts*; and the predictions of Rice Evans have been ſupported in the preſent century by the celebrated names of *Warburton* and *Jortin*. Dr Hoffman, the father of the Modern Theory and Practice of Medicine, in a diſſertation publiſhed in the large edition of his works in 1747, ſays, that the devil can raiſe ſtorms, produce inſects, and act upon the animal ſpirits and imagination; and, in fine, that he is an *excellent optician and natural philoſopher* on account of his long experience. Dr Johnſon, the leviathan of literature is ſuppoſed to have believed the ſecond ſight.

* Memoirs of Sully.

† Ibid.

‡ Bayle, Art. Morin.

With reſpect to the effects of ſuperſtition on the human mind, they are indeed deplorable. It chains down the underſtanding, and ſinks it into the moſt abject and ſordid ſtate, and keeps it under the dominion of fear, and ſometimes of cruelty. Where once it takes poſſeſſion, it has a tendency to become extreme, and generally becomes ſo intolerable, that men of reflection and learning conſpire its deſtruction. The Chriſtian religion gave a violent ſhock to the heathen ſuperſtition; the reformation in a great meaſure demoliſhed the ſuperſtition of the church of Rome; and the ſuperſtition which remained among Proteſtants after their ſeparation from that church has been gradually yielding to the influence of enlightened reaſon, or to the bold and daring attacks of infidelity and deiſm. We behold the proſpect of its ruins with pleaſure, and thank the deiſts for their zeal; but it is from the firm hope that the religion of Jeſus will ariſe in all its beauty and ſimple majeſty, and be admired and reſpected as it deſerves: for mean and contemptible as ſuperſtition certainly is, we would rather ſee men do what they reckon their duty from ſuperſtitious principles, than ſee anarchy and vice prevail, even though attended with all the knowledge and liberality of ſentiment which deiſm and infidelity can inſpire.

Supervisor ‖ Supper.

SUPERVISOR, a ſurveyor or overſeer.

SUPINATION, in anatomy, the action of a ſupinator muſcle, or the motion whereby it turns the hand ſo as that the palm is lifted up towards heaven.

SUPINE, in Latin grammar, part of the conjugation of a verb, being a verbal ſubſtantive of the ſingular number and the fourth declenſion.

There are two kinds of ſupines: One, called the *firſt ſupine*, ending in *um* of the accuſative caſe, which is always of an active ſignification, and follows a verb of motion; as *abiit deambulatum*. The other, called the *laſt ſupine*, and ending in *u* of the ablative caſe, is of a paſſive ſignification, and is governed by ſubſtantives or adjectives; as, *facile dictu*, &c.

They have their name, ſays Probus, and after him Voſſius, *quod ad inſtar* ſupinorum *& otioſorum hominum omnia habent confuſa*: or, according to Priſcian, *quod naſcantur a participiis paſſivis, quæ* ſupina *appellata ſunt, quia in infimo loco ſita, totam conjugationis molem ſuſcipiunt*.

SUPPER, the evening repaſt.—Suppers that are heavy ſhould be avoided, becauſe the ſtomach is more oppreſſed with the ſame quantity of food in an horizontal poſture than in an erect one, and becauſe digeſtion goes on more ſlowly when we ſleep than when we are awake. They ſhould be eaten long enough before bed-time, that they may be nearly digeſted before going to ſleep; and then a draught of pure water will dilute that which remains in the ſtomach.

I Definition.

Supper of the Lord, otherwiſe called the *Euchariſt*, is a ſacrament ordained by Chriſt in his church, of which the outward part is bread and wine, and the inward part or thing ſignified the body and blood of Chriſt, which the majority of Chriſtians believe to be in ſome ſenſe or other taken and received by the faithful communicants. See Sacrament.

There is no ordinance of the Goſpel which has been the ſubject of more violent controverſies between different churches, and even between different divines of the ſame church,

Supper. church, than this ſacrament: and though all confeſs that one purpoſe of its inſtitution was to be a bond of love and union among Chriſtians, it has, by the perverſeneſs of mankind, been too often converted into an occaſion of hatred. The outward and viſible ſign, and the inward and ſpiritual grace, have equally afforded matter of diſputation to angry controvertiſts. Many members of the church of Rome condemn the Greek church and the Proteſtants for uſing leavened bread in the Lord's Supper, contrary to the example ſet them by our Saviour; whilſt the Greek church in general, and ſome Proteſtant ſocieties in particular, unite with the church of Rome in cenſuring all churches which mix not the wine with water, as deviating improperly from primitive practice. See EUCHARIST.

2 Controverſies about the outward and viſible ſign,

That it was unleavened bread which our Lord bleſſed and brake and gave to his diſciples as his body, cannot be queſtioned; for at the time of the paſſover, when this ordinance was inſtituted, there was no leavened bread to be found in Jeruſalem.* For the mixed cup, the evidence is not ſo deciſive. It is indeed true, as we have obſerved under the article EUCHARIST, that the primitive Chriſtians uſed wine diluted with water; and if we may believe Maimonides,† it was the general cuſtom of the Jews, as well at their paſſover as at their ordinary meals, to add a little water to their wine on account of its great ſtrength; but that this was *always* done, or that it was done by our *Saviour in particular*, there is no clear evidence. Origen indeed affirms,‡ that our Lord adminiſtered in wine unmixed; and he was not a man to hazard ſuch an affirmation, had there been in his days any certain tradition, or ſo much as a general opinion, to the contrary. On this account we have often heard with wonder the neceſſity of the mixed cup inſiſted on by thoſe who without heſitation make uſe of leavened bread; for if it be eſſential to the ſacrament that the very ſame elements be employed by us that were employed by our Saviour, the neceſſity of unleavened bread is certainly equal to that of wine diluted by water.

* Exod. xii. 15, 19.

† In Miſhnam.

‡ Hom. 12. in Hieremiam.

But the mixed cup is ſaid to be emblematical of the blood and water which flowed from the ſide of our Lord when pierced by the ſpear of the Roman ſoldier, while the abſence of leaven is emblematical of no particular circumſtance in His paſſion. This argument for the mixture is as old as the era of St Cyprian, and has ſince been frequently urged with triumph by thoſe who ſurely perceived not its weakneſs. The flowing of the blood and water from our Saviour's ſide was the conſequence either of the ſpear's having pierced the *pericardium*, or more probably of an *aſcites* or *hydrothorax*, occaſioned by his cruel and lingering death (ſee MEDICINE, n° 342, 343) But whatever was the cauſe of it, how can the mixing of wine with water in the ſacrament be emblematical of the flowing of blood and water ſeparately? Such a mixture ſurely bears a more ſtriking reſemblance to the reunion of the *ſerum* and *craſſamentum*, after they had been ſeparated by whatever cauſe. See BLOOD,

Supper.

We urge not theſe objections to the mixed cup from any diſlike that we have to the practice. It is unqueſtionably harmleſs and primitive; and we wiſh that greater regard were paid to primitive practices than the generality of Chriſtians ſeem to think they can claim: but let the advocates for antiquity be conſiſtent; let them either reſtore, together with the mixed cup, the uſe of unleavened bread, or acknowledge that neither the one nor the other is eſſential to the ſacrament. This laſt acknowledgment muſt indeed be made, if they would not involve themſelves in difficulties from which they cannot be extricated. If either the mixed cup or unleavened bread be abſolutely neceſſary to the validity of the ſacrament, why not wine made from the grapes of Judæa? why not that particular kind of wine which was uſed by our Saviour? and where is that wine to be found?

3 Frivolous.

4 About the thing ſignified.

But the controverſies reſpecting the outward part or ſign of the Lord's Supper are of little importance when compared with thoſe which have been agitated reſpecting the inward part or thing ſignified; and of theſe we haſten to give as comprehenſive a view as the limits preſcribed to ſuch articles will admit.

Our Bleſſed Lord, in the ſame night that he was betrayed, "took bread, and bleſſed it, and brake it, and gave it to the diſciples, and ſaid, Take, eat; this is my body. And he took the cup, and gave thanks, and gave it to them, ſaying, Drink ye all of it; for this is my blood of the New Teſtament, which is ſhed for many for the remiſſion of ſins." Such was the inſtitution of the Lord's Supper as it is recorded in the Goſpel by St Matthew; and we have the ſame account of it, in almoſt the very ſame words, by three other inſpired writers, St Paul, St Mark, and St Luke. That it was the bread which Chriſt bleſſed and brake that is here called his body, and the wine over which he gave thanks that he ſtyles his blood of the New Teſtament, will admit of no reaſonable doubt (A); but in what ſenſe they became ſo, has been the ſubject of many controverſies.

5 Doctrine of the church of Rome.

The church of Rome, which holds, that after conſecration, Jeſus Chriſt, God and man, is really, truly, and ſubſtantially, contained under the outward appearances of the bread and wine, informs us, that about the middle of the maſs, when the prieſt, taking into his hand, firſt the bread and then the wine, pronounces over each ſeparately the ſacred words of conſecration, the ſubſtance of theſe elements is immediately changed by the almighty power of God into the body and blood of Chriſt; but that all the outward appearances of the bread and wine, and all their ſen-

(A) Some over-zealous Proteſtants have indeed affirmed, that it was not the conſecrated bread and wine, but thoſe elements, *together with the whole action* of taking them into his hands, bleſſing them, breaking the bread, and diſtributing the bread and wine to the diſciples, that Chriſt calls his body and blood. This novel and ſingular opinion reſts upon no better foundation than a very childiſh criticiſm. Our Saviour, after bleſſing and breaking the bread, gave it to the diſciples, ſaying, in the original, Λαβετε, φαγετε· ΤΟΥΤΟ εστι το σωμα μου. Now, ſay our critics, τουτο, in the neuter gender, can never agree with the antecedent αρτος in the maſculine, but muſt refer to all the circumſtances of the action taken together, and conſidered as one complex neuter noun. But this noun, whether complex or ſimple, certainly denotes what could be *eaten*; and to ſuppoſe that our bleſſed Lord deſired his apoſtles to eat *actions*, is as repugnant to human reaſon as any doctrine of the church of Rome. The truth is, that the word τουτο, which is more properly a definite article than a demonſtrative pronoun (ſee GRAMMAR, Chap. II.), refers directly to the thing, whatever it was, which our Saviour held in his hand and gave to the diſciples; and the clauſe, when completed, is τουτο ον εστι το σωμα μου; this *thing*, this *ſubſtance*, *is my body*. There was no neceſſity for characteriſing that ſubſtance by any analogy to ſex, in order that it might be diſtinguiſhed from every other ſubſtance; for the apoſtles could not but ſee it in the hand of their Maſter.

Supper. sensible qualities remain. This more than miraculous change is called TRANSUBSTANTIATION; and is founded on the philosophy of Aristotle, which resolves all bodies into *matter* and *form* (see METAPHYSICS, n° 142—150.); for it is only the *matter* or imperceptible substance which supports the *forms* or sensible qualities of bread and wine, that is changed into the *substance* or matter of the body and blood of Christ, so that this divine matter, coming into the place of the former earthly matter, supports the same identical *forms* which it supported. Hence we are told, "that Jesus Christ, now present instead of the bread and wine, exhibits himself to us under those very same outward *forms* or appearances which the bread and wine had before the change."

Could this doctrine be true, it would be abundantly mysterious; but to add to the mystery, we are farther informed, that under each kind is contained Jesus Christ whole and entire, his body and blood, his soul and divinity; so that when a man eats what has the appearance of a wafer, he really and truly eats the body and blood, the soul and divinity, of Jesus Christ; and when he afterwards drinks what has the appearance of wine, he drinks the very same body and blood, soul and divinity, which not a minute perhaps before he had wholly and entirely eaten! The ingenious author from whose work we have taken this account of the Romish doctrine concerning the real presence, may perhaps reject our inference that the orthodox members of his church must believe the *soul* and *divinity* of Christ to be *eaten* and *drunk* in the Lord's Supper; but he cannot deny that, according to his statement of the Catholic faith, the soul and divinity are both received whole and entire into the stomach of each communicant. He says indeed, that "communion consists in receiving Jesus Christ whole and entire, his sacred body, his precious blood, his blessed soul, and his adorable divinity, into our *souls*;" but that which was formerly bread and wine unquestionably goes into the *stomachs* of the communicants; and since, according to him, it is now the body and blood of Christ, the soul and divinity must go thither with it, for these four cannot be separated. This our author himself grants. "The Scripture (says he) positively declares, that *Christ rising again from the dead, dieth no more; death shall no more have dominion over him* (Rom. vi. 9.) Consequently his body, his blood, and his soul, shall never more be separated from one another; and as the union of his divine and human natures can never more be broken, so neither can these, his two natures, united in his divine person, be ever separated. From this it necessarily follows, that wherever the body of Christ is, there also his blood, his soul, and his divinity, must of necessity be in like manner."

Now, whether we suppose, with our author, that the soul and divinity of Christ directly carry his body and blood with them into the human soul, or, trusting in some degree to the evidence of sense, believe that the body and blood carry the soul and divinity with them directly into the stomach of each communicant—is it credible, is it possible, that the high and lofty One, who inhabiteth eternity, and whom the oracles of truth assure us that even the heaven of heavens cannot contain, should be *substantially* received *whole* and *entire* into a finite spirit like the human soul, or into a body so limited as the human stomach? Our author says it is; declaring that, "by the blessed *presence* of Jesus Christ, *whole and entire within us*, are communicated to our souls all the heavenly graces which are the effects of the holy communion: such as the sanctification of the soul by an increase of justifying grace; the rendering of it more pure, more holy, more beautiful, more agreeable, in the eyes of God; the cleansing of the soul from all those venial sins and imperfections of which we repent, and preserving us from falling into mortal sins; the uniting of us in a most intimate manner with Jesus Christ, who comes to us in this holy sacrament on purpose to dwell in our souls and abide with us; and the giving us a pledge and earnest of a glorious immortality, to the enjoyment of which it brings us at last, if we persevere to the end in the grace of God." Supper.

The consequence of the doctrine of transubstantiation is the *sacrifice of the mass*, by which, it is said, God's acceptance of Christ's sacrifice on the cross is obtained for the actual benefit of those persons in particular for whom the mass is offered. In the work so often quoted, we are told, that "Jesus Christ our redeemer, who is both our high-priest and our victim, who, in order to perfect the work of our redemption, and reconcile man with his offended Creator, offered himself once in a bloody manner upon the cross, in order to communicate and apply to the souls of individuals those graces, which, by his death, he merited for mankind in general, continues to offer himself daily upon the altar in an unbloody manner, by the ministry of his priests, in the *mass*. The sacrifice of the cross and that of the mass are both one and the same sacrifice, because in both the victim is the same and the high priest the same, viz. Jesus Christ. The only difference is in the *manner* of offering. On the cross he offered himself in a bloody manner and actually died; whereas on the altar he is offered up to God in an unbloody manner, not *actually* dead, but under the *appearance* of death;" so that the communicants not only eat the man Jesus Christ, but even eat him alive (B)!

It is known to all our readers that this doctrine of transubstantiation was one cause of the breach between the church of Rome and those various societies which call themselves reformed churches. The real and substantial change of the bread and wine into the body and blood of our Lord is rejected by every reformer as a change contradictory and impossible, and fraught with the most impious consequences; and volumes have been written to expose the weakness of those arguments which have so often been vainly urged in its support. It has been shown to imply numberless absurdities, such as, that the same thing can be in a million of different places, *whole* and *entire*, at the 6 Implies numberless contradictions.

(B) This whole account of the Romish doctrine respecting the sacrament of the Lord's Supper is taken from a work in two small volumes, called *The Sincere Christian instructed in the Faith of Christ, from the Written Word.* Its author is a man of learning, and great personal worth; and as he fills a high station in the church of Rome, we cannot doubt but that he has given a fair view of the doctrine of that church respecting this and every other article of which he treats. We are sorry however that his zeal should have impelled him, in a *popular* work, to write in the manner that he has done of the salvation of those who are not members of his church, or who cannot embrace all his opinions; for if his doctrine on this subject be implicitly received by those "over whom he has the rule, and for whose souls he is appointed to watch," they must necessarily look upon the majority of their fellow-citizens as reprobates doomed to eternal perdition. Let this be our apology for treating some of those opinions, which he thinks so absolutely

Supper. the same instant of time; that it is near 1800 years old, and yet may be not more than one minute; that *forms* or sensible qualities are real things independent of their subject and the sentient beings who perceive them; that the infinite and eternal God, who created and sustains the universe, is himself wholly and substantially comprehended by the human soul; and that the half, or fourth, or tenth part of the body of Christ, is equal to the whole of that body. That these are necessary consequences of transubstantiation has been so completely proved in various works (c) to which every reader may have access, that it is needless for us to repeat arguments so hackneyed; but there are two objections to that doctrine, which, as we do not remember to have met with them elsewhere, and as they appear to us absolutely conclusive, it may be worth while to state in this place.

The advocates for the real presence in the Lord's Supper contend, that every word relating to that ordinance is to be taken in the strictest and most literal sense, and they affect to triumph over the Protestants, because their notions of the sacrament cannot be supported without having recourse to figure and metaphor. This however is a very vain triumph; for we hesitate not to affirm, that supposing transubstantiation possible, and even capable of proof, there is not in the whole New Testament a single word or a single phrase which, if interpreted *literally*, gives the slightest countenance to that wonderful doctrine. The reader will remember, that transubstantiation, as we have stated it from a dignitary of the Romish church, and as it is in fact stated by the council of Trent (D), consists in a change of the *matter*, *imperceptible substance*, or *substratum* of the bread and wine into the *matter*, *imperceptible substance*, or *substratum* of Christ's body and blood; for all parties agree that the sensible qualities of the bread and wine remain, and, according to the Romanist, are after consecration either supported by the *matter* of Christ's body and blood, or hung upon nothing. But the phrase τουτο εστι το σωμα μου, if taken in the literal sense, cannot possibly denote the consequence of such a change as this; for every person at all acquainted with the Greek language, especially the language of the Peripatetic school, knows that το σωμα μου signifies, not the *matter* or *substratum* of my body divested of its sensible qualities; but the body of me in its natural state, consisting of *matter* and *qualities*, or *matter* and *form united*. Unless therefore the *sensible qualities*, as well as the *matter* of the bread and wine, give place to the sensible *qualities* as well as the *matter* of our Saviour's body and blood, and unless he appear glorified on the altar as he appeared on the mount at his transfiguration, the words το σωμα μου must be interpreted figuratively. Had the apostles understood their Master's words in the sense in which they are understood by the church of Rome, they would have rendered them into Greek, not τουτο εστι το σωμα μου, "this is my *body*," but τουτο εστι η ὑλη του σωματος μου, "this is the *matter* of my body." In like manner, when St John relates ‖ that Jesus said, "Whoso eateth my flesh and drinketh my blood, hath eternal life, and I will raise him up at the last day," had he understood his adorable Master to speak of his flesh and blood in the Eucharist in the sense in which they are taught to be there by the church of Rome, he would have represented him as saying, not ὁ τρωγων μου την σαρκα, και πινων μου το αἱμα, but ὁ τρωγων την ὑλην μου της σαρκος, και πινων την ὑλην μου του αἱματος, "Whoso eateth the *matter* of my flesh, and drinketh the *matter* of my blood, hath eternal life, and I will raise him up at the last day."

‖ Chap. vi. verse 54.

7 Is contrary to Scripture,

Supper.

But further, supposing this singular conversion possible in itself, it cannot be rendered credible, however stated in any language that ever was or ever will be spoken by man. At first sight it may appear paradoxical to affirm, that a possible fact cannot be so related as to obtain credit; but that transubstantiation, if possible, is such a fact, will be apparent on the slightest consideration.

8 And incapable of proof.

The relation that subsists between things and words is arbitrary; so that what is termed *body* in English, is σωμα in Greek, and *corpus* in Latin; and the same thing might with equal propriety (had the authors of these languages so pleased) have been expressed in the first by *soul*, in the second by νους, and in the third by *anima*. (See LANGUAGE, n° 3, &c.) The consequences of this are, that there is no universal language spoken; that the natives of one country understand not the speech of those of another; and that different men speaking the same language are perpetually liable to mistake each other's meaning. Between the *substrata* of bodies and their *sensible qualities* there is a relation founded in nature, so that the sensible qualities which indicate the substance to which they belong, to be *gold*, for instance, in one country, indicate the same thing in every other country, and have done so from the beginning of time. The sensible appearances of bodies therefore are an universal language, the language of the Author of Nature, by which he declares to his creature man, that though the ὑλη πρωτη, or primary matter of all bodies, may be the same kind of substance; yet the ὑλη προσεχης of one body, or the internal combination of its primary parts, differs from that of another;

---

necessary to salvation, with less ceremony than perhaps we should have done, had he less positively pronounced our damnation for not having it in our power to embrace them. He is not indeed much less severe on the most virtuous heathens, though they never saw the New Testament, or heard the doctrines of his church preached. But perhaps this severity may be occasioned by the following question of Cicero: "Cum fruges, *Cererem*; vinum, *Liberum* dicimus, genere nos quidem sermonis utimur usitato: sed ECQUEM TAM AMENTEM esse putas, qui illud, quo vescatur, deum credat esse?" *De Natura Deorum*, Lib. 3. Cap. 16.

(c) Among other works on this subject, we may confidently recommend to the reader a small tract published by Dr Abernethy Drummond, about twenty years ago, in the form of *A Dialogue between Philalethes and Benevolus*. In that treatise, together with a defence of it, which were both printed for Balfour and Drummond, Edinburgh, the absurd consequences which we have mentioned are, by arguments unanswerable, proved to flow from the doctrine of transubstantiation; and the artful sophistry, by which a very acute genius endeavoured to keep these consequences out of sight, is detected and exposed on acknowledged principles of the soundest metaphysics.

(D) The canon of that council which establishes transubstantiation is thus translated by the author of *The Sincere Christian Instructed*: "If any man shall say, that in the blessed sacrament of the Eucharist the substance of the bread and wine remains along with the body and blood of our Lord Jesus Christ, and shall deny that wonderful and singular conversion of the whole substance of the bread into the body, and of the whole substance of the wine into the blood, the appearances of the bread and wine only remaining, which conversion the Catholic Church calls *transubstantiation*, let him be anathema."

Supper. ther; that gold, for inſtance, has a different *ſubſtratum* or *baſis* from iron, lead, or ſilver; that the internal organization or ſtructure of the body of an ox is different from that of a horſe; and that the *internal ſubſtance* or *ſubſtratum* which exhibits the appearances of bread and wine is different from that which ſupports the ſenſible qualities of fleſh and blood (See METAPHYSICS, Part I. Chap. I. and Part II. Chap. I. and II. Suppoſing therefore the doctrine of tranſubſtantiation to be poſſible and even true, it would ſtill be impoſſible, by any ſtatement of it in human language, or by any argument urged in its ſupport, to render that doctrine an object of rational belief; for if it be ſaid that the words τουτο εστι το σωμα μου were ſpoken by a divine perſon, who could neither be deceived himſelf nor intended to deceive us, it may be replied, that the ſenſible appearances of bread and wine, which are confeſſed to remain, are likewiſe the language of a divine perſon, even of the Creator and Governor of heaven and earth; that this language addreſſed to the ſight, the taſte, the touch, and the ſmell, is equally intelligible to all nations; that ſince the creation of the world its meaning has never been miſtaken by the ſcholar or the clown, the ſage or the ſavage, except in this ſingle inſtance of our Lord's fleſh and blood exhibiting the ſenſible appearances of bread and wine; and that it is therefore infinitely more probable that the members of the church of Rome ſhould miſtake the meaning of the words τουτο εστι το σωμα μου, which, though ſpoken by Chriſt, are part of the language of men, and liable to all its ambiguities, than that all mankind ſhould miſtake the language of God himſelf, which is liable to no ambiguities, and which was never in any other inſtance miſunderſtood by a ſingle individual. Should tranſubſtantiation therefore be really true, its truth can never be proved or rendered probable, but by an immediate operation of the ſpirit of God on the mind of man; and he who is conſcious of no ſuch operation on his own mind, may reſt aſſured that the Father of mercies, who knows whereof he is made, will never bring upon him, for his incredulity in this inſtance, any of the anathemas denounced by the church of Rome upon thoſe who place implicit confidence in the univerſal language of Him who created them, in oppoſition to her figurative and contradictory interpretations of the written word. Of the tranſubſtantiation of the elements a viſible miracle would afford no proof. Had the water been changed into wine at the marriage in Cana of Galilee, for the expreſs purpoſe of bearing teſtimony to this ſingular converſion, what muſt have been the conſequence on the minds of thoſe who witneſſed that miracle? Nothing, we think, but ſcepticiſm or a diſtruſt of their own faculties; for they would have had the very ſame evidence that *no* ſubſtantial change was wrought on the elements, as that the water was *actually* turned into wine.

Though the reformed churches unanimouſly reject the doctrine of tranſubſtantiation, and of courſe the ſacrifice of the maſs, its inſeparable conſequence, they are far from being agreed among themſelves reſpecting the nature of the Lord's Supper; and the notions of this ordinance entertained by ſome of them appear to us as untenable as any part of the doctrine of the church of Rome. The Lutherans believe, that the body and blood of Chriſt are really and ſubſtantially preſent with the bread and wine; that the body is really and truly eaten, and the blood really and truly drank, by the communicants; and that whatever motion or action the bread has the body has the ſame §. According to them, therefore, the ſame ſenſible appearances are exhibited by two ſubſtances united in ſome inexplicable manner, which is neither a perſonal union, nor incorporation, nor the incloſure of the body within the bread; nor does it laſt longer than while the ſacrament is celebrating. This union is generally called CONSUBSTANTIATION; but they reject the term, contenting themſelves with aſſerting the real preſence, without preſuming to define the mode by which the body and blood of Chriſt are united to the ſacramental elements.

9 Doctrine of the Lutherans incredible.

§ Luther. Cogit. MS. 400 Gerbard in Loc. Theol. de Sacra Cœna.

It would be ſuperfluous to waſte time in replying to this doctrine. Every reader ſees that it implies the poſſibility of the ſame thing's being whole and entire in a million of places at one and the ſame inſtant of time, which has been ſo often urged as an unanſwerable objection to the Romiſh doctrine; and it is fraught with this additional abſurdity peculiar to itſelf, that two bodily ſubſtances may at once occupy the ſame place, which is directly contrary to our notions of ſolidity. It may be obſerved too, that whatever be the real ſenſe of our Saviour's words, he ſays expreſsly, "This is my body"—this thing which I give you, and which you ſee and feel; whereas, had he meant what Luther and his followers teach, he would ſurely have ſaid, "*With* this bread receive my body, *with* this cup receive my blood."

10 Of the early Calviniſts

The notions of ſome of the early Calviniſts reſpecting the Lord's Supper are very myſterious, and expreſſed in language of which we are not ſure that we underſtand the meaning. In the year 1561 an attempt was made in France to bring the Catholics and Proteſtants to an uniformity of doctrine on this great topic of controverſy; and deputies were appointed by both parties to meet at *Poiſſy*, and debate the queſtion in a friendly manner. The principal managers on the ſide of the Catholics were the cardinals of *Lorraine* and *Tournon*; thoſe on the ſide of the Proteſtants were *Beza* and *Peter Martyr*. After ſeveral meetings, diſputes, and violent ſeparations, the Proteſtant deputies declared their faith in the following words: "We confeſs, that Jeſus Chriſt, in the Supper, does truly give and exhibit to us the ſubſtance of his body and blood by the efficacy of his Holy Spirit; and that we do receive and eat ſpiritually, and by faith, *that very body which was offered and immolated for us*, ſo as to be bone of his bone and fleſh of his fleſh, to the end that we may be enlivened thereby, and receive what is conducive to our ſalvation. And becauſe faith, ſupported by the word of God, makes thoſe things preſent, which it apprehends, and by that faith we do in *deed* and *reality* receive the *true natural* body and blood of Chriſt, by the power of the Holy Spirit; by this means, we confeſs and acknowledge the preſence of his body and blood in the Supper." One of the Catholic delegates expreſſing his diſlike of this laſt clauſe, the Proteſtant miniſters gave the following explanation of their ſentiments: "No diſtance of place can hinder us from communicating of the body and blood of Chriſt, for the Lord's Supper is a heavenly thing; and though on earth we receive with our mouths bread and wine, which are the true ſigns of his body and blood, yet by faith, and the efficacy of the Holy Ghoſt, our minds, which are fed with this food, *are rapt up into heaven*, and enjoy the preſence of the body and blood; and that by this means it may be ſaid that the body is truly joined to the bread, and the blood to the wine; but after the manner of a ſacrament, and not at all according to place or natural poſition *."

* Thuanus lib. 28. See alſo Johnſon's Unbloody Sacrifice, vol. I.

If the reader can diſcover the preciſe meaning of theſe paſſages, his ſagacity exceeds ours. That the Proteſtant deputies believed, or profeſſed to believe, that the *natural* body and blood of Chriſt are by the faithful received in the Lord's Supper, is indeed evident; but their notions reſpecting the manner of this reception are very unintelligible, if not contradictory. In the former quotation, they confeſs that Chriſt's body and blood are really preſent

11 Unintelligible.

Supper. in the ſacrament; that they are made preſent by faith (we ſuppoſe the faith of the communicants); and that the *very body* which was offered and immolated for us is eaten *ſpiritually* and by *faith*. In the latter quotation, they ſeem to ſay that Chriſt's body and blood are in heaven, at a great diſtance from the true ſigns of them; that on earth the communicants receive only theſe ſigns, which are bread and wine; but that, by faith and the efficacy of the Holy Spirit, their minds, during actual communion, are rapt up into heaven, where they enjoy the preſence of the body and blood; and that by this means the body and blood are truly joined to the bread and wine through the medium of the mind of the communicant, which is at once preſent both to the ſign and to the thing ſignified. To this myſterious doctrine it is needleſs to urge objections. Every man who is accuſtomed to think, and to uſe words with ſome determinate meaning, will at once perceive that the authors of this declaration muſt have had very confuſed notions of the ſubject, and have pleaſed themſelves with ſound inſtead of ſenſe, ſatisfied that they could not be wrong if they did not ſymbolize with the Lutherans or the Council of Trent.

12 Of the churches of Britain.

The churches of England and Scotland, in their eſtabliſhed doctrines reſpecting the Lord's Supper appear to be Calviniſtical; but the compilers of the thirty-nine Articles and of the Confeſſion of Faith muſt have been much more rational divines than Beza and Peter Martyr. They agree in condemning the doctrine of tranſubſtantiation as contrary to common ſenſe, and not founded in the word of God; they teach, that to ſuch as rightly, worthily, and with faith, receive the ſacrament, the bread which we break is a partaking of the body of Chriſt, and the cup of bleſſing a partaking of the blood of Chriſt; and they add, that the body and blood of Chriſt are eaten and drunk, nor corporally or carnally, but only after a heavenly and ſpiritual manner, by which the communicants are made partakers of all the benefits of his death *. In one important circumſtance theſe two churches ſeem to differ. The Confeſſion of Faith, as we underſtand it ‡, affirms, that in the Lord's Supper there is no ſacrifice made at all. The thirty-firſt article of the church of England likewiſe condemns the Popiſh ſacrifice of the maſs as a *blaſphemous fable* and *dangerous deceit*; but in *the order for the adminiſtration of the Lord's Supper or Holy Communion*, the celebrator "beſeeches God muſt mercifully to accept the alms and *oblations* of the congregation," and again "to accept *their ſacrifice of praiſe* and thankſgiving:" from which petitions many have inferred that, in the Lord's Supper, that church offers a commemorative and euchariſtical ſacrifice. This inference ſeems not to be wholly without foundation. In the order for the adminiſtration of the Lord's Supper, according to the form of the Book of Common Prayer ſet forth by act of parliament in the ſecond and third years of king Edward the Sixth, the elements were ſolemnly offered to God as a ſacrifice of praiſe and thankſgiving; and though the prayer containing that oblation was, at the review of the liturgy ſome years afterwards, removed from the prayer of conſecration, to which it was orginally joined, and placed where it now ſtands in the poſt communion ſervice; yet the very act of parliament which authorized that alteration, calls king Edward's "a very godly order, agreeable to the word of God and the primitive church, and very comfortable to all good people deſiring to live in Chriſtian converſation."

* Articles of the Church of England, Art. 28. and Confeſſion of Faith, chap. 29.

‡ Chap. 29. § 3.

The Engliſh church, however, has not poſitively determined any thing reſpecting this great queſtion; and whilſt ſhe condemns the doctrine of the real preſence, with all its dangerous conſequences, ſhe allows her members to entertain very different notions of this holy ordinance, and to publiſh theſe notions to the world. Accordingly, many of her moſt eminent divines (E) have maintained that, in the celebration of the Lord's Supper, the elements of bread and wine are offered to God as a ſacrifice commemorative of Chriſt's one ſacrifice for the ſins of the whole world; that theſe elements, though they undergo no ſubſtantial change, yet receive ſuch a divine virtue by the deſcent of the Holy Ghoſt, as to convey to the worthy communicant all the benefits of Chriſt's paſſion; that they are therefore called his body and blood, becauſe being, after their oblation, eaten and drunk in remembrance of Him, they ſupply the place of his body and blood in the feaſt upon his ſacrifice; and that it is cuſtomary with our Saviour to give to any thing the name of another of which it completely ſupplies the place, as when he calls himſelf the *door* * of the ſheep, becauſe there is no entrance into the church or kingdom of God but by faith in him. They obſerve, that the Euchariſt's being commemorative, no more hinders it from being a proper ſacrifice, than the typical and figurative ſacrifices of the Old Law hindered them from being proper ſacrifices: for as to be a type doth not deſtroy the nature and notion of a legal ſacrifice, ſo to be repreſentative and commemorative doth not deſtroy the nature of an evangelical ſacrifice. To prove that, in the celebration of the Lord's Supper, there is a real ſacrifice offered to God as well as a ſacrament received by the communicants, they appeal to St Paul, who ſays expreſsly †, that "Chriſtians have an *altar*, whereof they have no right to eat who ſerve the tabernacle," and who by contraſting the cup of the Lord with the cup of devils, and the table of the Lord with the table of devils ¶, teaches plainly, that thoſe cups and thoſe tables had the ſame ſpecific nature. That the *table of devils* ſpoken of by the apoſtle was the Pagan altars, and the *cup of devils* the wine poured out in libations to the Pagan divinities, will admit of no diſpute; and therefore, ſay the advocates for the euchariſtical ſacrifice, the table of the Lord muſt be the Chriſtian altar, and the cup of the Lord the wine offered to God as the repreſentative of the blood of Chriſt; otherwiſe there would not be that *abſurdity* which the apoſtle ſuppoſes, in the ſame perſon drinking the cup of the Lord and the cup of devils, and partaking of the Lord's table and the table of devils. They obſerve farther, that in all the ancient liturgies extant there is a ſolemn form of oblation of the ſacramental elements, and that all the Chriſtian writers from the ſecond century downwards treat of the Lord's Supper as a ſacrifice as well as ſacrificial feaſt, having indeed no value in itſelf, but acceptable to God as repreſenting Chriſt's one ſacrifice for the ſins of the world. Our limits will not permit us to give even an abſtract of their arguments; but the reader who ſhall attentively peruſe *Johnſon's unbloody Sacrifice and Altar unveiled and ſupported*, will diſcover that their notions are better founded than probably he ſuppoſes, and that they are totally irreconcileable with the doctrine of tranſubſtantiation and the Popiſh ſacrifice of the *maſs*.

Supper

13 Some Engliſh divines hold the Lord's Supper to be a euchariſtical ſacrifice.

* St John x. 7.

† Heb. xiii. 10.

¶ 1 Cor. x. 16, &c.

Other Engliſh divines of great learning, with the celebrated Hoadley biſhop of Wincheſter at the head of them, contend ſtrenuouſly that the Lord's Supper, ſo far from being

14 Others, a mere memorial;

(E) The archbiſhops Laud and Wake; the biſhops Poynet, Andrews, Bull, and Patrick; the Doctors Hickes, Grabe, and Brett; Meſſrs Bingham, Johnſon, Mede, Wheatly, Scandaret, Bowyer, &c.

Supper. being a ſacrifice of any kind, is nothing more than bread and wine reverently eaten and drunk, in remembrance that Chriſt's body was broken and his blood ſhed in proof of his Father's and his own love to mankind; that nothing is eſſential to the ſacrament but this remembrance, and a ſerious deſire to honour and obey our Saviour as our head; that the ſacrament might be celebrated without uttering one prayer or thankſgiving, merely by a ſociety of Chriſtians, whether ſmall or great, jointly eating bread and drinking wine with a ſerious remembrance of Chriſt's death; that St Paul enjoins a man to examine himſelf before he eat of that bread and drink of that cup, not to diſcover what have been the ſins of his paſt life in order to repent of them, but only that he may be ſure of his remembering Chriſt's body broken and his blood ſhed; that, however, it is his duty in that as in every other inſtance of religious worſhip to reſolve to obey from the heart every precept of the Goſpel, whether moral or poſitive; and that to partake worthily of the Lord's Supper is acceptable to God, becauſe it is paying obedience to one of theſe precepts; but that no particular benefits or privileges are annexed to it more than to any other inſtance of duty. Biſhop Hoadley acknowledges, that when St Paul ſays,* "The cup of bleſſing which we bleſs, is it not the communion of the blood of Chriſt? The bread which we break, is it not the communion of the body of Chriſt?" he has been ſuppoſed by many learned men to affirm, that all the benefits of Chriſt's paſſion are in the Lord's Supper conveyed to the worthy communicant; but this (ſays he) is an idea which the apoſtle could not have in his thoughts as at all proper for his argument. The Greek word κοινωνια and the Engliſh *communion* ſignify only a partaking of ſomething in common with others of the ſame ſociety; and the apoſtle's meaning (he ſays) can be nothing more, than that in the Lord's Supper we do not eat bread and drink wine as at an ordinary meal, but as memorials of the body and blood of Chriſt, in honour to *him* as the *head* of that body of which we are all *members*. That the word κοινωνια is not meant to denote any inward or ſpiritual part of the Lord's Supper, he thinks evident, becauſe the ſame word is uſed with regard to the cup and the table of idols, where no ſpiritual part could be thought of, and in an argument which ſuppoſes an idol to to be nothing.§

* 1 Cor. x. 16.

§ A plain Account of the Nature and End of the Lord's Supper.

To this view of the nature and end of the Lord's Supper, it muſt appear no ſmall objection, that "he who eateth and drinketh unworthily is ſaid to be *guilty of the body and blood of the Lord, and to eat and drink a judgement to himſelf, not diſcerning the Lord's body.*" No doubt it would be ſinful to eat and drink a mere memorial of Chriſt's death without ſerious diſpoſitions; but we cannot conceive how a little wandering of the thoughts, which is all the unworthineſs which the author thinks there can be on ſuch an occaſion, ſhould be a ſin of ſo deep a dye as to be properly compared with the guilt of thoſe who murdered the Lord of life. Other divines therefore, feeling the force of this and ſimilar objections, ſteer a middle courſe between the mere memorialiſt and the advocate for a real ſacrifice in the holy Euchariſt, and inſiſt that this rite, though no ſacrifice itſelf, is yet a feaſt upon the one ſacrifice offered by Chriſt and ſlain upon the croſs. The moſt eminent patrons of this opinion have been Dr Cudworth, biſhop Warburton, and the preſent biſhop of Cheſter; and they ſupport it by ſuch arguments as the following: "In thoſe ages of the world when victims made ſo great a part of the religion both of Jews and Gentiles, the ſacrifice was always followed by a religious feaſting on the thing offered; which was called the *feaſt upon, or after the ſacrifice*, and was ſuppoſed to convey to the partakers of it the benefits of the ſacrifice. Now Jeſus (ſay they), about to offer himſelf a ſacrifice on the croſs for our redemption, did, in conformity to general practice, inſtitute the *laſt ſupper*, under the idea of *a feaſt after the ſacrifice*; and the circumſtances attending its inſtitution were ſuch, they think, that the apoſtles could not poſſibly miſtake his meaning. It was juſt before his paſſion, and while he was eating the paſchal ſupper, which was a Jewiſh *feaſt upon the ſacrifice*, that our bleſſed Lord inſtituted this rite; and as it was his general cuſtom to allude, in his actions and expreſſions, to what paſſed before his eyes, or preſented itſelf to his obſervation, who can doubt, when, in the very form of celebration, we ſee all the marks of a *ſacrificial ſupper*, but that the divine inſtitutor intended it ſhould bear the ſame relation to his *ſacrifice on the croſs* which the *paſchal ſupper* then celebrating bore to the oblation of the *paſchal lamb?* If this was not his purpoſe, and if nothing more was intended than a general memorial of a dead benefactor, why was this inſtant of time preferred for the inſtitution to all others throughout the courſe of his miniſtry, any one of which would have been equally commodious? Indeed any other time would have been more commodious for the inſtitution of a mere memorial; for the paſchal lamb and unleavened bread were certainly a ſacrifice; and the words uſed by our Saviour, when he gave the bread and wine to the apoſtles, were ſuch as muſt neceſſarily have led them to conſider that bread and wine as bearing the ſame relation to his ſacrifice that the paſchal ſupper bore to the paſchal ſacrifice. At that Jewiſh feaſt, it was the cuſtom of every father of a family to break the unleavened bread, and to give to every gueſt a portion, ſaying, "This is the bread of affliction, which our fathers did eat in the land of Egypt:" a cuſtom which, we may be ſure, that Chriſt, as father of his family, would religiouſly obſerve. The apoſtles knew well that they were not eating the identical bread which their fathers did eat in Egypt, but the feaſt upon the ſacrifice then offered in commemoration of their redemption from Egyptian bondage; and therefore when they ſaw their Maſter after ſupper break the bread again and give it to each of them, with theſe remarkable words, "This is my body which is given for you, do this in remembrance of me," they muſt have concluded, that his meaning was to inſtitute a rite which ſhould to the end of the world bear the ſame relation to his ſacrifice that the paſchal ſupper bore to the ſacrifice of the paſſover.

15 And others, a feaſt upon our Saviour's ſacrifice.

This inference, from the circumſtances attending the inſtitution, biſhop Warburton thinks confirmed by St Paul's mode of arguing with the Corinthians, on their impiety and abſurdity in partaking both of the Lord's table and the table of devils; for "what (ſays he) had the eaters of the ſacrifices to do with the partakers of the bread and wine in the Lord's Supper, if the Lord's Supper was not a feaſt of the ſame kind with their feaſts? If the three feaſts, Jewiſh, Pagan, and Chriſtian, had not one common nature, how could the apoſtle have inferred that this intercommunity was inconſiſtent? *Ye* CANNOT (ſays he) *drink the cup of the Lord and the cup of devils; ye* CANNOT *be partakers of the Lord's table and the table of devils.* For though there might be *impiety* in the promiſcuous uſe of Pagan and Chriſtian rites of any kind, yet the *inconſiſtency* ariſes from their having a common nature, and conſequently, as they had oppoſite originals, from their deſtroying one another's effects in the very celebration. Sacrifices, and feaſts upon ſacrifices, were univerſally conſidered as *federal* rites; and therefore the Lord's table and the table of devils being both *federal* rites, the ſame man could no more

be

Supper, Supplement.

be partaker of both, than he could at once engage to ſerve both God and the devil. This is the apoſtle's argument to the wiſe men, to whom he appeals; and we ſee that it turns altogether upon this poſtulatum, that the Chriſtian and Pagan feaſts had the ſame ſpecific nature, or were both feaſts upon ſacrifices. If this be admitted, it is eaſy to ſee why St Paul deemed thoſe who ate and drank unworthily guilty of the body and blood of the Lord; for if the Lord's Supper be a feaſt upon his ſacrifice, it muſt have been conſidered as the means of conveying to the communicants all the benefits of his death and paſſion; and the profanation of ſuch a rite, by rendering his death ineffectual, might be fitly compared and juſtly equalled to the enormous guilt of thoſe by whom his blood was ſhed." In reply to biſhop Hoadley's remarks upon the word κοινωνια, his brother biſhop obſerves, that "had the apoſtle meant what the learned writer makes him to mean, he would doubtleſs have ſaid κοινωνια ὑμων εις το σωμα, 'your communion in the body—your eating it jointly.' St Paul (continues he) knew how to expreſs himſelf properly, as appears from a paſſage in his epiſtle to the Philippians, where, profeſſedly ſpeaking of the joint participation of a bleſſing, he uſes theſe words, κοινωνια ὑμων εις το ευαγγελιον, 'your communion in the Goſpel.' To the other remark, that no ſpiritual part could be thought of in the table of idols, becauſe an idol is ſaid by the apoſtle to be *nothing*, biſhop Warburton replies, "that by St Paul the Gentiles are ſaid to have ſacrificed to devils, and thoſe who ate of ſuch ſacrifices to have had communion with devils: now the *devil* (continues his Lordſhip) was in St Paul's opinion *ſomething*." But the inference which the apoſtle draws from the acknowledged truth, that the cup of bleſſing which we bleſs is the communion of the blood of Chriſt, and the bread which we break the communion of the body of Chriſt, puts his meaning, our author thinks, beyond all doubt. He ſays †, that the partaking of one bread makes the receivers of *many* to become *one body*. A juſt inference, if this rite be of the nature of a *feaſt upon the ſacrifice*; for then *the communion of the body and blood of Chriſt* unites the receivers into one body by an equal diſtribution of one common benefit. But if it be only a general commemoration of a deceaſed benefactor, it leaves the receivers as it found them, not *one body*, but *many ſeparate profeſſors* of one common faith.

† 1 Cor. x. 17.

16 The ordinance not generally underſtood.

Thus have we given ſuch a view as our limits would permit us to give, of the principal opinions that have been held reſpecting the nature and end of the Lord's Supper. It is an ordinance which ſeems not to be generally underſtood; though, being intended to ſhow forth the Lord's death till he come, it is ſurely of ſufficient importance to engage the attention of every ſerious Chriſtian. The moſt conſiderable Proteſtant divines who have expreſsly written upon it are, Johnſon in his *Unbloody Sacrifice*; Cudworth in his *Diſcourſe concerning the true Nature of the Lord's Supper*; Hoadley in his *Plain Account*; and Warburton in his *Rational Account*. The notions of Cudworth and Warburton are the ſame, and perhaps they differ not ſo much from thoſe of Johnſon as many readers ſeem to imagine. At any rate, the arguments by which Warburton ſupports his doctrine muſt have ſome force, ſince it is ſaid that Hoadley himſelf acknowledged they would be unanſwerable, if it could be proved that the death of Chriſt was a real ſacrifice.

SUPPLEMENT, in literature, an appendage to ſupply what is wanting in a book. Books of various kinds require ſuch an appendage; but none ſo much as a dictionary of arts and ſciences, which, from the progreſſive courſe of phyſical ſcience, cannot be completed without it.

SUPPORTED, in heraldry, a term applied to the uppermoſt quarters of a ſhield when divided into ſeveral quarters, theſe ſeeming as it were ſupported or ſuſtained by thoſe below. The chief is ſaid to be ſupported when it is of two colours, and the upper colour takes up two-thirds of it. In this caſe it is ſupported by the colour underneath.

Supported ‖ Supralapſarians.

SUPPORTERS, in heraldry, figures in an atchievement placed by the ſide of the ſhield, and ſeeming to ſupport or hold up the ſame. Supporters are chiefly figures of beaſts: figures of human creatures for the like purpoſe are called *tenants*.

SUPPOSITION, in muſic, is when one of the parts dwells on a note, while another part makes two or more leſſer notes equivalent to it, by conjoint degrees.

Suppoſition is defined by a late author the uſing of two ſucceſſive notes, of the ſame value as to time; the one whereof, being a diſcord, ſuppoſes the other a concord.

The harmony, Mr Malcolm obſerves, is always to be full on the accented parts of the bar or meaſure; but, on the unaccented, diſcords, may tranſiently paſs, without any offence to the ear. This tranſient uſe of diſcords, followed by concords, make what we, after the French, call *ſuppoſition*.

Concords by ſuppoſition are thoſe where the continued baſs adds or ſuppoſes a new ſound below the fundamental baſs; whence ſuch concords always exceed the extent of the octave. Of theſe concords there are three ſorts, all which are concords of the ſeventh: the firſt, when the added ſound is a third below the fundamental ſound; ſuch is the concord of the ninth: and if the concord of the ninth is formed by the mediant, added below the ſenſible concord in the minor mode, then the concord is called the *ſuperfluous fifth*. The ſecond kind is, when the ſuppoſed ſound is a fifth below the fundamental ſound, as in the concord of the fourth or eleventh; and if the concord is ſenſible, and the tonic be ſuppoſed, this concord is called the *ſuperfluous ſeventh*. The third kind is that where the ſuppoſed ſound is below a concord of the diminiſhed ſeventh: if it is a fifth below, *i. e.* if the ſuppoſed ſound be the mediant, the concord is called the concord of the *fourth* and *ſuperfluous fifth*: if it is a ſeventh below, *i. e.* if the ſuppoſed ſound be the tonic, the concord is called the *leſſer ſixth* and *ſuperfluous ſeventh*.

SUPPOSITORY, a kind of medicated cone or ball, which is introduced into the anus for opening the belly.

It is uſually compoſed of common honey, mixed up with either ſoap or oil, and formed into pieces of the length and thickneſs of the little finger, only pyramidal. To the compoſition is ſometimes alſo added powder of ſcammony, euphorbium, colocynthis, ſalt, aloes, &c. according to the caſe of the patient.

The ſuppoſitory was invented for the convenience of ſuch as have an averſion to the taking of clyſters; or to be uſed when the diſeaſe does not allow thereof.

SUPPRESSION, in medicine, is generally uſed to ſignify a retention of urine or of the menſes.

SUPPURATION, the ſecond way wherein an inflammation terminates; being a converſion of the inſpiſſated blood and the firſt adjacent parts, as the veſſels and fat into pus or matter; which diſorder, when it has not yet found an opening, is generally called an *abſceſs*.

SUPRACOSTALES, in anatomy. See *Table of the Muſcles* in ANATOMY.

SUPRALAPSARIANS, in theology, perſons who hold that God, without any regard to the good or evil works of men, has reſolved, by an eternal decree, *ſupra lapſum*, antecedently to any knowledge of the fall of Adam, and independently of it to ſave ſome and to damn others; or in, other words, that God intended to glorify his juſtice

Supraſpinatus ‖ Surat.

in the condemnation of ſome, as well as his mercy in the ſalvation of others; and for that purpoſe decreed that Adam ſhould neceſſarily fall, and by that fall bring himſelf and all his offspring into a ſtate of everlaſting condemnation.

Theſe are alſo called *antelapſaries*, and are oppoſed to ſublapſaries and infralapſaries.

According to the ſupralapſarians, the object of predeſtination is, *homo creabilis et labilis*; and, according to the ſublapſarians and infralapſarians, *homo creatus et lapſus*.

SUPRASPINATUS, in anatomy. See *Table of the Muſcles* in ANATOMY.

SUPREMACY, the ſuperiority or ſovereingty of the king. See SOVEREIGNTY.

SUR, or SHUR (anc. geog.), a deſert of Arabia Petræa, extending between Paleſtine and the Arabian Gulph; into which the Iſraelites, after marching through the Red Sea, firſt came (Exod. xv. 22.) Again (Numb. xxxiii. 8.), it is ſaid, that from the ſea they went three days journey into the Wilderneſs of Etham; whence ſome conclude that Etham and Shur are the ſame wilderneſs; or only differ as a part from the whole, Shur being the general name, and Etham that part of it lying neareſt to the place of encampment of the ſame name. We know ſo little of the geography of theſe places that there is more room for diſputation than for deciſion. As to the route which the Iſraelites followed in their paſſage through the Red Sea, Mr Bryant, we think, has given the moſt ſatisfactory account in his late work on the Plagues of Egypt.—Shur is now called *Corondel*.

SURAT, a city of Indoſtan, belonging to Britain, on the weſtern coaſt of the peninſula, a little to the northward of Bombay, and about 16 miles up the river Tappee. It is but of modern date, and is a moſt remarkable inſtance of the power of trade to bring wealth and population to any ſpot where it can be brought to ſettle. Towards the middle of the laſt century this place was only the reſort of a few merchants, who, under the ſhelter of an old inſignificant caſtle, laid the firſt foundations of a city now almoſt as large and fully as populous as London within the walls, and containing many fine buildings of Indian architecture, which is partly Gentoo and partly Moriſque. Thoſe of the greateſt note are ſo contrived, that the gateway is defenſible againſt any ſudden irruption of a few armed men. The private apartments lie backwards for the conveniency of the women, of whom the Moors are remarkably jealous. They are fond of having one room, in the midſt of which a fountain keeps playing, and which, by its noiſe, lulls them to ſleep, and refreſhes the room by its coolneſs; but thus a damp is produced, which would be very dangerous to Europeans. They have alſo generally a ſaloon with fountains playing in it, which with the variegated flower-beds, in which they are very curious, makes a beautiful proſpect. During the intenſe heats of ſummer they have country retirements a little way out of town, where they reſide, or go in parties to amuſe themſelves. The ſtreets are irregularly laid out; but have one property which renders it agreeable to walk in them, viz. that a competent width being left at bottom, the upper ſtories of the houſes project over one another in ſuch a manner, that people may with eaſe converſe from them; by which means the ſtreet is agreeably ſhaded, at the ſame time that a proper ventilation is not impeded, but rather promoted. The ſhops, notwithſtanding the vaſt trade carried on in this great and populous city, have a very mean appearance, owing to the dealers keeping their goods in warehouſes, and ſelling by ſamples.

No place is better ſupplied with proviſions than the city of Surat while its communication with the country remains open. Beſides the unbounded importation, by which every article is brought here in great abundance, the natural productions of the ſoil are excellent, though leſs cheap than in other parts of India, as at Bengal eſpecially; yet in that place, though the cattle and poultry are bought originally at a very low rate, they turn out very dear by the time they are fed for the table. Here, however, all kinds of eatables may be had at a reaſonable price, ready, for immediate uſe, and as good as can be found anywhere. The wheat of Surat is famous all over India for its ſingular ſubſtance, whiteneſs, and taſte; and its ſallads and roots are likewiſe of an excellent quality. There are alſo many kinds of wild-fowl and other game to be had at an eaſy rate; but for wines and ſpirituous liquors they depend moſtly on importation. Surat.

Surat was ſurrounded with a wall in ſhort time after it had aſſumed the form of a town. The fortification, however, was meant only to prevent the incurſions of the Mahrattas, who had twice pillaged it; ſo that the place was by no means capable of ſtanding any regular ſiege. Even the caſtle appears but a poor defence, being mounted with cannon here and there, without any order, or without any thing like an attempt towards military architecture.

In this city, before the Eaſt India company became inveſted with the poſſeſſion of Bombay, was the preſidency of their affairs on the weſtern coaſt. For this purpoſe they had a factory eſtabliſhed there with great privileges by the Mogul government; and even after the preſidency was eſtabliſhed at Bombay, they continued a factory here at one of the beſt houſes in the city; which yet not being ſpacious enough to contain their effects, they hired another at ſome diſtance from it, and nearer the water-ſide, which was called the new factory. In the mean time, the city flouriſhed, and became the centre of all the Indian trade, being much more frequented for the ſake of foreign merchandize than for either the natural productions or manufactures of the country, though they alſo made a conſiderable part of its commerce. In ſhort, there was ſcarce any article of merchandize but what was to be found at all times in Surat, almoſt as readily as in London itſelf. While the Mogul government was in its vigour, there was ſuch a ſhow of juſtice kept up, as induced merchants of all religions and denominations to take up their reſidence in the city. The Gentoos eſpecially reſorted thither, in order to avoid the oppreſſions of their own government. Great care indeed was taken that no very flagrant acts of oppreſſion ſhould be committed; ſo that, in what ſometimes happened, appearances were at leaſt kept up; and the oppreſſions of government were chiefly owing to the animoſities and rivalſhip of the merchants themſelves. As an inſtance of the great extent to which commerce was puſhed in Surat, we ſhall here quote from Mr Groſe, what is ſaid by Captain Hamilton of a merchant named *Abdulgafour*, viz. "That he drove a trade equal to the Eaſt India company: for he had known him fit out in a year above 20 ſail of ſhips between 300 and 800 tons, none of which had leſs of his own ſtock than L. 20,000, and ſome of them L. 25,000. After that foreign ſtock was ſent away, it behoved him to have as much more of an inland ſtock for the following year's market." On the deceaſe of this merchant, the government ſeized on a million of his money; and his grandſon was not only deprived of all that he poſſeſſed, but barbarouſly murdered through the envy and treachery of his brother-merchants, and the rapacity of the governor.

The city of Surat was taken and ruined by the Portugueſe in 1520; and it was not till after this misfortune that it became ſuch a celebrated emporium. All the Indian merchants who had been accuſtomed to trade thither contributed to re-eſtabliſh it; but it was not till near a century after that it became the general ſtaple of Indian and

European

Surat, Surcharge.

European merchandize; when the Dutch appearing in the Indian ocean, had deprived the Portugueſe of all their conqueſts on that coaſt, and almoſt entirely ruined their trade. The Engliſh eſtabliſhed a factory here in 1609, the Dutch in 1616, and the French in 1665. In proceſs of time, the Indian ſeas being greatly infeſted by pirates, a naval officer was appointed by the Mogul to keep them in awe. This officer was named *Siddee* (A) *Muſſoot*, who had been chief of an Ethiopian colony ſettled at Rajapore. Here he had collected ſome veſſels of conſiderable force, and carried on ſome trade, till he was diſpoſſeſſed by the Mahrattas; upon which he repaired to Bombay, and afterwards to Surat, where he was appointed admiral on that ſtation to the Mogul, with a yearly revenue of about L. 36,000 Sterling. Though he had no power, independent of the marine, he ſeized on the Caſtle, encroached on the town, and appropriated to himſelf a third part of its revenues, under pretence of arrears due in his appointed revenue. Another third was paid to the Mahrattas, to prevent their depredations upon trade in the open country; but they, not ſatisfied with this ſtipulation, watched an opportunity to plunder the town, which was kept in ſubjection by Siddee Muſſoot till his death, which happened in 1756.

Siddee Muſſoot was ſucceeded by his ſon, who ſoon rendered himſelf very diſagreeable to the inhabtants. In 1758 the Engliſh factory was greatly oppreſſed by him, and the black merchants treated ſtill worſe; on which the latter applied to Mr Ellis the Engliſh chief at that time, deſiring him to recommend it to the preſidency of Bombay to take the caſtle by force out of the hands of the uſurper. This propoſal proving agreeable, Admiral Pococke, who was then with his ſquadron at Bombay, readily concurred in ſupporting the expedition. The enterprize was conducted with ſucceſs; and Captain Maitland the conductor took poſſeſſion of the caſtle with its revenue in name of the Eaſt India company, who were confirmed in the government by grants from the Mogul.

SURCHARGE OF THE FOREST, is when a commoner puts more beaſts in the foreſt than he has a right to. See FOREST.

SURCHARGE of Common, is a diſturbance of common of paſture, by putting more cattle therein than the paſture and herbage will ſuſtain, or the party hath a right to do. This injury can only happen where the common is appendant or appurtenant and of courſe limitable by law; or where, when in groſs, it is expreſsly limited and certain; for where a man hath common in groſs, *ſans nombre*, or without ſtint he cannot be a ſurcharge. In this caſe indeed there muſt be left ſufficient for the lord's own beaſts.

The uſual remedies for ſurcharging the common are by the lord's diſtraining the ſurplus number, or by his bringing an action of treſpaſs, or by a ſpecial action on the caſe, in which any commoner may be plaintiff. The ancient and moſt effectual method of proceeding is by writ of admeaſurement of paſture.

Writ of Second SURCHARGE, de ſecunda ſuperoneratione, is given by the ſtatute of Weſtm. 2. 13 Edw. I. cap. 8. when, after the admeaſurement of paſture hath aſcertained the right, the ſame defendant ſurcharges the common again; and thereby the ſheriff is directed to inquire by a jury whether the defendant has in fact again ſurcharged the common; and if he has, he ſhall then forfeit to the king the ſupernumerary cattle put in, and alſo ſhall pay damages to the plaintiff.

Surcingle & Surf.

SURCINGLE, a girdle wherewith the clergy of the church of England uſually tie their caſſocks. See GIRDLE.

SURCOAT, a coat of arms, to be worn over body armour.

The ſurcoat is properly a looſe thin taffety coat, with arms embroidered or painted on it. Such as is worn by heralds, anciently alſo uſed by military men over their armour to diſtinguiſh themſelves by.

SURD, in arithmetic and algebra, denotes any number or quantity that is incommenſurable to unity: otherwiſe called an *irrational number* or *quantity*. See ALGEBRA, Part I. Chap. IV.

SURETY, in law, generally ſignifies the ſame with BAIL.

SURF, is a term uſed by ſeamen to expreſs a peculiar ſwell and breaking of the ſea upon the ſhore. It ſometimes forms but a ſingle range along the ſhore, and at others three or four behind one another extending perhaps half a mile out to ſea. The ſurf begins to aſſume its form at ſome diſtance from the place where it breaks, gradually accumulating as it moves forward till it gain, not uncommonly, in places within the limits of the trade-winds, a height of 15 or 20 feet, when it overhangs at top, and falls like a caſcade with great force and a prodigious noiſe. Countries where ſurfs prevail require boats of a particular conſtruction very different from the greater part of thoſe which are built in Europe. In ſome places ſurfs are great at high, and in others at low water; but we believe they are uniformly moſt violent during the ſpring-tides.

It is not eaſy to aſſign the cauſe of ſurfs. That they are affected by the winds can hardly be queſtioned; but that they do not proceed from the *immediate* operation of the wind in the places where they happen, is evident from this circumſtance, that the ſurf is often higheſt and moſt violent where there is leaſt wind, and *vice verſa*. On the coaſt of Sumatra the higheſt are experienced during the ſouth-eaſt monſoon, which is never attended with ſuch gales as the north-weſt. As they are moſt general in the tropical latitudes, Mr Marſden, who ſeems to have paid much attention to the ſubject, attributes them to the trade-winds which prevail at a diſtance from ſhore between the parallels of 30 degrees north, and ſouth whoſe uniform and invariable action cauſes a long and conſtant ſwell, that exiſts even in the calmeſt weather, about the line, towards which its direction tends from either ſide. This ſwell, when a ſquall happens or the wind freſhens up, will for the time have other ſubſidiary waves on the extent of its ſurface, breaking often in a direction contrary to it, and which will again ſubſide as a calm returns, without having produced on it any perceptible effect. Sumatra, though not continually expoſed to the ſouth eaſt trade-wind, is not ſo diſtant but that its influence may be preſumed to extend to it; and accordingly at Poolo Peſang, near the ſouthern extremity of the iſland, a conſtant ſoutherly ſea is obſerved, even after a ſtrong north-weſt wind. This inceſſant and powerful ſwell rolling in from an ocean, open even to the pole, ſeems an agent adequate to the prodigious effects produced on the coaſt; whilſt its very ſize contributes to its being overlooked. It reconciles almoſt all the difficulties which the phenomena ſeem to preſent, and in particular it accounts for the decreaſe of the ſurf during the north-weſt monſoon, the local wind then counteracting the operation of the general one; and it is corroborated by an obſervation, that the ſurfs on the Sumatran coaſt ever begin

to

(A) When the Abyſſinian ſlaves are promoted to any office under the Mogul government, they are called *Siddees*.

Surface, Surfeit.

to break at their ſouthern extreme, the motion of the ſwell not being perpendicular to the direction of the ſhore. This explanation of the phenomena is certainly plauſible; but, as the author candidly acknowledges, objections may be urged to it. The trade-winds and the ſwell occaſioned by them are remarkably ſteady and uniform; but the ſurfs are much the reverſe. How then comes an uniform cauſe to produce unſteady effects?

In the opinion of our author it produces no unſteady effects. The irregularity of the ſurfs, he ſays, is perceived only within the remote limits of the trade-winds. But the equatorial parts of the earth performing their diurnal revolution with greater velocity than the reſt, a large circle being deſcribed in the ſame time, the waters thereabout, from the ſtronger centrifugal force, may be ſuppoſed more buoyant; to feel leſs reſtraint from the ſluggiſh principle of matter; to have leſs gravity; and therefore to be more obedient to external impulſes of every kind, whether from the winds or any other cauſe.

SURFACE. See SUPERFICIES.

SURFEIT, in medicine, a ſickneſs with a ſenſation of a load at the ſtomach, uſually proceeding from ſome error in diet, either with regard to the quantity or quality of the food taken. Sometimes, however, a ſurfeit is only a plethora from indolence and full but improper feeding; in which caſe perſpiration is defective; and eruptions form themſelves on the ſkin.

A ſurfeit from animal food, as muſcles, putrid fleſh, &c. is beſt remedied by the uſe of vegetable acids, which may be taken diluted with water, a vomit being premiſed, and this even though a vomiting and purging both attend.

When an exceſs of feeding is the cauſe, the primæ viæ being evacuated, and the nature of the plethora attended to, that the load may be properly evacuated, the indication of cure will be, to recover the perſpiratory diſcharge, conſiſtent with which diuretics may be uſed in preference to medicines which produce any other evacuation.

SURFEIT, in farriery. See FARRIERY, § xix.

Surfeit ‖ Surgeon.

SURGE, in the ſea language, the ſame with a wave. See WAVE.

SURGEON, or CHIRURGEON, one that profeſſes the art of SURGERY.

In England there are two diſtinct companies of ſurgeons now occupying the ſcience or faculty of ſurgery; the one company called *barbers*, the other *ſurgeons*, which latter are not incorporated.—The two are united to ſue, and be ſued, by the names of maſters or governors and commonalty of the myſtery of barbers and ſurgeons of London. 32 H. VIII. c. 42.

No perſon uſing any barbery or ſhaving in London, ſhall occupy any ſurgery, letting of blood, or other matter; drawing of teeth only excepted. And no perſon uſing the myſtery or craft of ſurgery ſhall occupy or exerciſe the feat or craft of barbery, or ſhaving, neither by himſelf, nor any other for his uſe. 32 H. VIII. c. 42.

By the ſame ſtatute, ſurgeons are obliged to have ſigns at their doors.

The French chirurgeons being refuſed to be admitted into the univerſities (notwithſtanding that their art makes a branch of medicine), on pretence of its bordering a little on butchery or cruelty, aſſociated themſelves into a brotherhood, under the protection of S. Coſmus and S. Damian: on which account, according to the laws of their inſtitution, they are obliged to dreſs and look to wounds *gratis* the firſt Monday of each month.

They diſtinguiſh between a chirurgeon of the long robe and a barber-chirurgeon. The firſt has ſtudied phyſic, and is allowed to wear a gown. The ſkill of the other, beſides what relates to the management of the beard, is ſuppoſed to be confined to the more ſimple and eaſy operations in chirurgy; as bleeding, tooth-drawing, &c.

They were formerly diſtinguiſhed by badges: thoſe of the long gown bore a caſe of inſtruments; the barber, a baſon.

SURGERY,

THAT part of medicine which treats of diſeaſes to be cured or alleviated by the hand, by inſtruments, or by external applications.

CHAP. I. *Hiſtory of Surgery.*

History.

THAT ſurgery was coeval with the other branches of medicine, or perhaps antecedent to any of them, will not admit of doubt. The wars and contentions which have taken place among mankind almoſt ever ſince their creation, neceſſarily imply that there would be occaſion for ſurgeons

1 Surgery early practiſed.

at a very early period; and probably theſe external injuries would for ſome time be the only diſeaſes for which a cure would be attempted, or perhaps thought practicable.—In the ſacred writings we find much mention of balſams, particularly the balm of Gilead, as excellent in the cure of wounds; though at the ſame time we are informed that there were ſome wounds which this balſam could not heal.

2 Hiſtory of it among the Greeks,

Concerning the ſurgery practiſed among the Egyptians, Jews, and Aſiatic nations, we know little or nothing. The Greeks were thoſe from whom the art deſcended to us, though they confeſſedly received it from the eaſtern nations. The firſt Greek ſurgeons on record are Æſculapius and his ſons Podalirius and Machaon. Æſculapius flouriſhed about 50 years before the Trojan war; and his two ſons diſtinguiſhed themſelves in that war both by their valour and ſkill in curing wounds. This indeed is the whole of the medical ſkill attributed to them by Homer; for in the plague which broke out in the Grecian camp, he does not mention their being at all conſulted. Nay, what is ſtill more ſtrange, tho' he ſometimes mentions his heroes having their bones broke, he never takes notice of their being reduced or cured by any other than ſupernatural means; as in the caſe of Æneas, whoſe thigh-bone was broken by a ſtone caſt at him by Diomed. The methods which theſe two famous ſurgeons uſed in curing the wounds of their fellow-ſoldiers ſeems to have been the extracting or cutting out the darts which inflicted them, and applying emollient fomentations or ſtyptics to them when neceſſary: and to theſe they undoubtedly attributed much more virtue than they could poſſibly poſſeſs; as appears from the following lines, where Homer deſcribes Eurypylus as wounded and under the hands of Patroclus, who would certainly practiſe according to the directions of the ſurgeons.

Patroclus cut the forky ſteel away;
Then in his hand a bitter root he bruis'd
The wound he waſh'd, the ſtyptic juice infus'd.
The *cloſing fleſh* that inſtant ceas'd to glow;
The wound to torture, and the blood to flow.

History. Till the days of Hippocrates we know very little of what was the practice of the Greek ſurgeons. From him, however, we learn, that the practice of blood-letting, cupping, and ſacrification, was known to them; alſo the uſe of warm and emollient fomentations, iſſues made with hot irons, peſſaries, injections, fumigations, &c. Hippocrates alſo gives directions with regard to fractures, luxations, ulcers, fiſtulas. He directs the extenſion, reduction, bandages, and ſplints, proper to be uſed in fractures and luxations of different bones, with ſeveral machines to increaſe the extenſion when neceſſary. He directs the laxity and tightneſs of the bandages; the intervals for unlooſing and binding them on again; the poſition and repoſe of the fractured member, and the proper regimen; and he mentions the time when a callus is uſually formed. He treats alſo of fractures of the ſkull, and the method of applying the trepan. In his treatment of ulcers, he ſpeaks of reducing fungous fleſh by means of eſcharotics, ſome of which are alum, nitre, verdigriſe, quicklime, &c.

In the time of Ptolemy Philopater of Egypt, medicine, all the branches of which had hitherto been practiſed by the ſame perſon, was now divided into three, viz. the dietetic, pharmaceutic, and ſurgical; from which time to the preſent, ſurgery has continued to be reckoned a diſtinct profeſſion from medicine, though very improperly, in the opinion of the beſt authors.

3 Among the Romans, Surgery appears not to have exiſted in Rome, notwithſtanding the warlike genius of the people, for more than 500 years. Archagathus, a Greek, was the firſt profeſſor of that art in the city; and ſo frequently employed the knife, hot irons, and other cruel methods of cure, that he was branded with the opprobrious title of *carnifex*, and expelled the city, where no phyſician or ſurgeon of eminence again made his appearance for 180 years. At this time Aſclepiades undertook the profeſſion of medicine; but ſeems to have dealt little in ſurgery. Neither have we any thing of importance on that ſubject till the time of Celſus, who flouriſhed during the reigns of Auguſtus and Tiberius.—In his ſurgery, all the improvements from Hippocrates to his own days are collected; the moſt minute and trifling diſeaſes are not omitted. An eminent ſurgeon, of the moderns, emphatically exhorts every perſon in that profeſſion "to keep Celſus in his hands by day and by night." He deſcribes the ſigns of a fractured ſkull, the method of examining for the fracture, of laying the ſkull bare by an inciſion in the form of the letter X, and afterwards of cutting away the angles, and of applying the trepan, with the ſigns of danger and of recovery. He obſerved, that ſometimes, though very rarely, a fatal concuſſion of the brain might happen, the blood-veſſels within the ſkull being burſt, yet the bone remaining entire. After the operation of the trepan, ſponges and cloths wetted with vinegar, and ſeveral other applications, were made to the head; and, throughout, ſevere abſtinence was enjoined. In violent fractures of the ribs, he ordered veneſection; low diet; to guard againſt all agitation of the mind, loud ſpeaking, motion, and every thing that might excite coughing or ſneezing. Cloths wetted with wine, roſes and oil, and other applications, were laid over the fracture. The cure of fractures, in the upper and lower extremities, he ſaid were nearly alike; that fractures differ in degree of violence and danger, in being ſimple or compound, that is, with or without a wound of the fleſh, and in being near to the joint. He directs the extenſion of the member by aſſiſtants; the reduction, by the ſurgeon's hands, of the fractured bones into their natural ſituation; and to bind the fractured part with bandages of different lengths, previouſly dipped in wine and oil: on the third day freſh bandages are to be applied, and the fractured member fomented with warm vapour, eſpecially during the inflammation. Splints, if neceſſary, are to be applied, to retain the bones in a fixed poſition. The fractured arm is to be ſuſpended in a broad ſling hung round the neck: the fractured leg is to be incloſed in a kind of caſe, reaching above the ham, and accommodated likewiſe with a ſupport to the foot, and with ſtraps at the ſide, to keep the leg ſteady: in the fractured thigh-bone, the caſe is to extend from the top of the hip to the foot. He deſcribes the method of treating compound fractures, and of removing ſmall fragments of ſplinters of bones; and the manner of extracting darts. In luxations of the ſhoulder, he mentions ſeveral methods of giving force to the extenſion, and of replacing the diſlocated bone. One method ſimilar to that of Hippocrates was, to ſuſpend the patient by the arm; the fore-part of the ſhoulder, at the ſame time, reſting upon the top of a door, or any other ſuch firm fulcrum. Another method was to lay the patient ſupine, ſome aſſiſtants retaining the body in a fixed poſition, and others extending the arm in the contrary direction; the ſurgeon, in the mean time, attempting, by his hands, forcibly to reduce the bone into its former place.

If a large inflammation was expected to enſue after a wound, it was ſuffered to bleed for ſome time, and blood was drawn from the arm. To wounds accompanied with conſiderable hæmorrhagy, he applied a ſponge wet in vinegar, and conſtant preſſure: If neceſſary, on account of the violence of the hæmorrhagy, ligatures were made round the veſſels, and ſometimes the bleeding orifice was ſeared up with the point of a hot iron. On the third day freſh dreſſings were applied. In conſiderable contuſions, with a ſmall wound of the fleſh, if neither blood-veſſels nor nerves prevented, the wound was to be enlarged. Abſtinence and low diet, upon all ſuch accidents, were preſcribed; cloths wet with vinegar, and ſeveral other applications, were to be applied to the inflamed part. He obſerves, that freſh wounds may be healed without compound applications. In external gangrene, he cut into the ſound fleſh; and when the diſeaſe, in ſpite of every effort, ſpread, he adviſed amputation of the member. After cutting to the bone, the fleſh was then ſeparated from it, and drawn back, in order to ſave as much fleſh as poſſible to cover the extremity of the bone. Celſus, though extremely diffuſe in the deſcription of ſurgical diſeaſes, and of various remedies and external applications, treats ſlightly of the method of amputating; from which, comparing his treatiſe with the modern ſyſtems, we might infer that the operation was then ſeldomer practiſed than at preſent. He deſcribes the ſymptoms of that dangerous inflammation the carbuncle, and directs, immediately to burn, or to corrode the gangrened part. To promote the ſuppuration of abſceſſes, he orders poultices of barley-meal, or of marſhmallows, or the ſeeds of linſeed and fenugreek. He alſo mentions the compoſitions of ſeveral repellent cataplaſms. In the *eryſipelas*, he applies ceruſe, mixed with the juice of ſolanum or nightſhade. Sal ammoniac was ſometimes mixed with his plaſters.

He is very minute in deſcribing diſeaſes of the eyes, ears, and teeth, and in preſcribing a multitude of remedies and applications. In inflammation of the eyes, he enjoined abſtinence and low diet, reſt, and a dark room: if the inflammation was violent, with great pain, he ordered veneſection, and a purgative; a ſmall poultice of fine flower, ſaffron, and the white of an egg, to be laid to the forehead to ſuppreſs the flow of pituita; the ſoft inſide of warm wheat bread dipped in wine, to be laid to the eye; poppy and roſes were alſo added to his collyriums, and various ingredients too tedious to enumerate. In chronic watery de-

fluxions

History. fluxions of the eyes, he applied aſtringents, cupped the temples, and burnt the veins over the temple and forehead. He couched cataracts by depreſſing the cryſtalline lens to the bottom of the orbit. Teeth, looſened by any accident, he directs, after the example of Hippocrates, to be faſtened with a gold thread to thoſe adjoining on each ſide. Previous to drawing a tooth, he ordered the gum to be cut round its neck; and if the tooth was hollow, it was to be filled with lead before extraction, to prevent its breaking by the forceps. He deſcribes not only the inflammation, but likewiſe the elongation, of the uvula: he alſo deſcribes the polypus, and ſome other diſeaſes affecting the noſe.

He deſcribes ſeveral ſpecies of herniæ or rupture, and the manual aſſiſtance required in thoſe complaints. After the return of the inteſtines into the abdomen, a firm compreſs was applied to that part of the groin through which they protruded, and was ſecured by a bandage round the loins. In ſome caſes, after the return of inteſtinal ruptures, he diminiſhed the quantity of looſe ſkin, and formed a cicatrix, ſo as to contract over the part, to render it more rigid and capable of reſiſting. He deſcribes various diſeaſes of the genital parts, the hydrocele or dropſy of the ſcrotum, a difficulty of urine, and the manner of drawing off the water by a catheter; the ſigns of ſtone in the bladder, and the method of ſounding or feeling for that ſtone. Lithotomy was at that time performed by introducing two fingers into the anus; the ſtone was then preſſed forward to the perinæum, and a cut made into the bladder; and by the finger or by a ſcoop the ſtone was extracted. He deſcribes the manner of performing this operation on both the ſexes, of treating the patient, and the ſigns of recovery and of danger.

Celſus directed various corroſive applications and injections to fiſtulas; and, in the laſt extremity, opened them to the bottom with a knife, cutting upon a grooved inſtrument or conductor. In old callous ulcers, he made a new wound, by either cutting away the hard edges, or corroding them with verdigriſe, quicklime, alum, nitre, and with ſome vegetable eſcharotics. He mentions the ſymptoms of caries in the bone; directs the bone to be laid bare, and to be pierced with ſeveral holes, or to be burnt or raſped, in order to promote an exfoliation of the corrupted part; afterwards to apply nitre and ſeveral other ingredients. One of his applications to a cancer was auripigmentum or arſenic. He directs the manner of tapping the abdomen in aſcites, and of drawing blood by the lancet and cupping-glaſſes. His cupping-glaſſes ſeem not to have been ſo convenient as the modern: they were made either of braſs or horn, and were unprovided with a pump. He cured varicoſe veins by uſtion or by inciſion. He gives directions for extracting the dead fœtus from the womb, in whatever poſition it ſhould preſent; and, after delivery, to apply to the private parts ſoft cloths wet in an infuſion of vinegar and roſes. In Celſus's works there is a great redundance and ſuperfluity of plaſters, ointments, eſcharotics, collyriums, of ſuppurating and diſcutient cataplaſms, and external applications of every kind, both ſimple and compound: Perhaps, amongſt the multitude, there are a few uſeful remedies now laid aſide and neglected.

The laſt writer of conſequence who flouriſhed at Rome was Galen, phyſician to the emperor Marcus Aurelius. His works are for the moſt part purely medicinal; although he wrote alſo on ſurgery, and made Commentaries on the Surgery of Hippocrates. He opened the jugular veins, and performed arteriotomy at the temples; directed leeches, ſcarification, and cupping-glaſſes, to draw blood. He alſo deſcribed with accuracy the different ſpecies of herniæ or ruptures.

4

History. In the year 500 flouriſhed Aëtius, in whoſe works we meet with many obſervations omitted by Celſus and Galen, particularly on the ſurgical operations, the diſeaſes of women, the cauſe of difficult labours, and modes of delivery. He alſo takes notice of the dracunculus, or Guinea worm. Aëtius, however, is greatly excelled by Paulus Egineta, who flouriſhed in 640; whoſe treatiſe on ſurgery is ſuperior to that of all the other ancients. He directs how to extract darts; to perform the operation ſometimes required in dangerous caſes of rupture or hernia. He treats alſo of aneuriſm. Galen, Paulus, and all the ancients, ſpeak only of one ſpecies of aneuriſm, and define it to be "a tumor ariſing from arterial blood extravaſated from a ruptured artery." The aneuriſm from a dilatation of the artery is a diſcovery of the moderns. In violent inflammations of the throat, where immediate danger of ſuffocation was threatened, Paulus performed the operation of bronchotomy. In obſtinate defluxions upon the eyes, he opened the jugular veins. He deſcribes the manner of opening the arteries behind the ears in chronic pains of the head. He wrote alſo upon midwifery. Fabricius ab Aquapendente, a celebrated ſurgeon of the 16th century, has followed Celſus and Paulus as text-books.

4
Among the Arabians. From the time of Paulus Egineta to the year 900, no writer of any conſequence, either on medicine or ſurgery, appeared. At this time the Arabian phyſicians Rhazes and Avicenna revived in the eaſt the medical art, which, as well as others, was almoſt entirely extinguiſhed in the weſt. Avicenna's *Canon Medicinæ*, or General Syſtem of Medicine and Surgery, was for many ages celebrated through all the ſchools of phyſic. It was principally compiled from the writings of Galen and Rhazes. The latter had correctly deſcribed the ſpina ventoſa, accompanied with an enlargement of the bone, caries, and acute pain. In difficult labours, he recommends the fillet to aſſiſt in the extraction of the fœtus; and for the ſame purpoſe, Avicenna recommends the forceps. He deſcribes the compoſition of ſeveral coſmetics to poliſh the ſkin, and make the hair grow, or fall off.

Notwithſtanding this, however, it was not till the time of Albucaſis that ſurgery came into repute among the Arabians. Rhazes complains of their groſs ignorance, and that the manual operations were performed by the phyſicians' ſervants. Albucaſis enumerates a tremendous liſt of operations, ſufficient to fill us with horror. The hot iron and cauteries were favourite remedies of the Arabians; and, in inveterate pains, they repoſed, like the Egyptians and eaſtern Aſiatics, great confidence in burning the part. He deſcribes accurately the manner of tapping in aſcites; mentions ſeveral kinds of inſtruments for drawing blood; and has left a more ample and correct delineation of ſurgical inſtruments than any of the ancients. He gives various obſtetrical directions for extracting the fœtus in caſes of difficult labour. He mentions the bronchocele, or prominent tumor on the neck, which he tells us, was moſt frequent among the female ſex. We are alſo informed by this writer, that the delicacy of the Arabian women did not permit male ſurgeons to perform lithotomy on females; but when neceſſary, it was executed by one of their own ſex.

From the 11th century to the middle of the 14th, the hiſtory of ſurgery affords nothing remarkable except the importation of that naſeous diſeaſe the leproſy into Europe. Towards the end of the 15th century the venereal diſeaſe is ſaid to have been imported from America by the firſt diſcoverers of that continent.

At the beginning of the 16th century, ſurgery was held in contempt in Britain, and was practiſed indiſcriminately

by

History. by barbers, farriers, and ſow-gelders. Barbers and ſurgeons continued, for 200 years after, to be incorporated in one company both in London and Paris. In Holland and ſome parts of Germany, even at this day, barbers exerciſe the razor and lancet alternately.

It is within the laſt three centuries that we have any conſiderable improvement in ſurgery; nor do we know of any eminent Britiſh ſurgical writers until within the laſt 130 years. "In Germany (ſays Heiſter) all the different ſurgical operations, at the beginning even of the 18th century, were left to empirics; while regular practitioners were contented to cure a wound, open a vein or an abſceſs, return a fractured of luxated bone; but they ſeldom or never ventured to perform any of the difficult operations." He alſo ſpeaks of their groſs ignorance of the Latin language.

5 Writers on ſurgery in the 16th century. The firſt ſurgical work of the 16th century worthy of notice is that of J. Carpus. F. ab Aquapendente, an Italian, publiſhed a Syſtem of Surgery, containing a deſcription of the various diſeaſes, accidents, and operations. Boerhaave pays this author the following compliment: *Ille ſuperavit omnes et nemo illi hanc diſputat gloriam; omnibus potius quam hocce carere poſſumus.* About the ſame period, A. Parey, a Frenchman, made ſeveral important additions to ſurgery, particularly in his collection of caſes of wounds, fractures, and other accidents which occur during war. The ancients, who were ignorant of powder and fire-arms, are defective in this part of military ſurgery. Parey pretends to have firſt invented the method of tying with a needle and ſtrong ſilk-thread waxed the extremities of large arteries, after the amputation of a member. The ligature of the blood-veſſels is, however, merely a revival of the ancient practice, which had fallen into diſuſe: Throughout the dark ages, the hot iron, cauteries, and ſtrong aſtringents, were ſubſtituted in its place. B. Maggius and. L. Botallus wrote on the cure of gunſhot wounds. J. A. Cruce wrote a ſyſtem of ſurgery.

6 In the 17th century. In the 17th century, ſurgery was enriched with ſeveral ſyſtems, and with detached or miſcellaneous obſervations. The principal authors are, M. A. Severinus, V. Vidius, R. Wiſeman, Le Clerc, J. Scultetus, J. Mangetus, C. Magatus, Spigellius, F. Hildanus, T. Bartholin, P. de Marchett.

Since the commencement of the preſent century, ſurgery has been enriched with many valuable and important improvements, of the greateſt part of which we have availed ourſelves in the courſe of the following treatiſe. But as it would far exceed the limits of a work of this nature to enumerate the names and writings of ſuch authors as have lived within the above period, and beſides, as it appears very unimportant to do ſo, we ſhall at once proceed to the next part of our ſubject.

Chap. II. *Of Wounds.*

Sect. I. *Of Simple Wounds.*

The firſt thing to be conſidered in the inſpection of a wound is, whether it is likely to prove mortal or not. This knowledge can only be had from anatomy, by which the ſurgeon will be able to determine what parts are injured; and, from the offices which theſe parts are calculated to perform, whether the human frame can ſubſiſt under ſuch injuries. It is not, however, eaſy for the moſt expert anatomiſt always to prognoſticate the event with certainty; but this rule he ought always to lay down to himſelf, to draw the moſt favourable prognoſis the caſe will bear, or even more than the rules of his art will allow. This is particularly incumbent on him in ſea-engagements; where the ſentence of death is executed as ſoon as pronounced, and the miſerable patient is thrown alive into the ſea, upon the ſurgeon's declaring his wound to be mortal. There are beſides, many inſtances on record, where wounds have healed, which the moſt ſkilful ſurgeons have deemed mortal. The following wounds may be reckoned mortal.

Simple Wounds.

7 Wounds which are neceſſarily mortal. 1. Thoſe which penetrate the cavities of the heart, and all thoſe wounds of the viſcera where the large blood-veſſels are opened; becauſe their ſituation will not admit of proper applications to reſtrain the flux of blood.

2. Thoſe which obſtruct or entirely cut off the paſſage of the nervous influence through the body. Such are wounds of the brain, cerebellum, medulla oblongata, and ſpinal marrow; though the brain is ſometimes injured, and yet the patient recovers. Wounds likewiſe of the ſmall blood-veſſels within the brain are attended with great danger, from the effuſed fluids preſſing upon the brain. Nor is there leſs danger where the nerves which tend to the heart are wounded, or entirely divided; for, after this, it is impoſſible for the heart to continue its motion.

3. All wounds which entirely deprive the animal of the faculty of breathing.

4. Thoſe wounds which interrupt the courſe of the chyle to the heart; ſuch are wounds of the receptacle of the chyle, thoracic duct, and larger lacteals, &c.

5. There are other wounds which prove fatal if neglected and left to nature: ſuch are wounds of the larger external blood-veſſels, which might be remedied by ligature.

8 Symptoms of wounds in different parts of the body. In examining wounds, the next conſideration is, whether the parts injured are ſuch as may be ſuppoſed to induce dangerous ſymptoms, either immediately or in ſome time during the courſe of the cure. In order to proceed with any degree of certainty, it is neceſſary to be well acquainted with theſe ſymptoms which attend injuries of the different parts of the body. If the ſkin only and part of the cellular ſubſtance is divided, the firſt conſequence is an effuſion of blood; the lips of the wound retract, become tumefied, red, and inflamed, leaving a gap of conſiderable wideneſs according to the length and deepneſs of the wound. Beſides, if a very conſiderable portion of ſkin and cellular ſubſtance is divided, a ſlight fever ſeizes the patient; the effuſion of blood in the mean time ſtops, and the wound is partly filled up with a cake of coagulated blood. Below this cake, the ſmall veſſels pour forth a clear liquor, which in a ſhort time is converted into pus (ſee the articles Pus and Mucus). Below this pus granulations of new fleſh ariſe, the cake of coagulated blood looſens, a new ſkin covers the place where the wound was, and the whole is healed up; only there remains a mark, called a *cicatrix* or *ſcar*, ſhowing where the injury had been received.

9 Of wounds of the ſkin and cellular ſubſtance.

10 Of the muſcles. All wounds are accompanied with a conſiderable degree of pain, eſpecially when the inflammation comes on, though the diviſion reaches no farther than the ſkin and cellular ſubſtance. If the muſcular fibres are divided, the pain is much greater, becauſe the ſound part of the muſcle is ſtretched by the contraction of the divided part and the action of the antagoniſt muſcle, which it is now leſs fitted to bear. The wound alſo gaps much more than where the cellular ſubſtance only is divided, inſomuch that, if left to itſelf, the ſkin will cover the muſcular fibres, without any intervention of cellular ſubſtance; and not only a very unſightly cicatrix remains, but the uſe of the muſcle is in ſome meaſure loſt.—If the muſcle happens to be totally divided, its parts retract to a very conſiderable diſtance; and unleſs proper methods be taken, the uſe of it is certainly loſt ever afterwards.

11 Of the arteries. If by a wound any conſiderable artery happens to be divided, the blood flows out with great velocity, and by ſtarts;

Simple Wounds.

ſtarts; the patient ſoon becomes faint with loſs of blood; nor does the hæmorrhagy ſtop until he faints away altogether, when the ends of the divided veſſel cloſe by their natural contractility; and if as much *vis vitæ* ſtill remains as is ſufficient to renew the operations of life, he recovers after ſome time, and the wound heals up as uſual. The part of the artery which is below the wound in the mean time becomes uſeleſs, and its ſides collapſe, ſo that all the inferior part of the limb would be deprived of blood, were it not that the ſmall branches ſent off from the artery above the wounded place become enlarged, and capable of carrying on the circulation. Nature alſo, after a wonderful manner, often produces new veſſels from the ſuperior extremity of the divided artery, by which the circulation is carried on as formerly. However, the conſequences of ſuch a profuſe hæmorrhagy may be very dangerous to the patient, by inducing extreme debility, polypous concretions in the heart and large veſſels, or an univerſal dropſy. This happens eſpecially where the artery is partially divided; becauſe then the veſſel cannot contract in ſuch a manner as to cloſe the orifice: however, if the wound is but ſmall, the blood gets into the cellular ſubſtance, ſwelling up the member to an extreme degree, forming what is called a *diffuſed aneuriſm*. Thus the hæmorrhagy ſoon ſtops externally, but great miſchief is apt to flow from the confinement of the extravaſated blood, which is found to have the power of diſſolving not only the fleſhy parts, but alſo the bones themſelves; and thus not only the uſe of the limb is entirely loſt, but the patient is brought into great danger of his life, if proper aſſiſtance be not obtained in a ſhort time.

12 Of the ligaments, nerves, and tendons.

Wounds of the ligaments, nerves, and tendons, are likewiſe attended with bad conſequences. When a nerve is entirely divided, the pain is but trifling, though the conſequences are often dangerous. If the nerve is large, all the parts to which it is diſtributed below the wound immediately loſe the power of motion and ſenſation; nor is it uncommon, in ſuch caſes, for them to be ſeized with a gangrene. This, however, takes place only when all or the greateſt part of the nerves belonging to a particular part are divided. If the ſpinal marrow, for inſtance, be divided near the head, the parts below ſoon loſe their action irrecoverably; or if the bundle of nerves paſſing out of the axilla be divided or tied, ſenſation in the greateſt part of the arm below will probably be loſt. But though a nerve ſhould be divided, and a temporary palſy be produced, it may again reunite, and perform its former functions. If a nerve be wounded only, inſtead of being divided, the worſt ſymptoms frequently enſue.

13 Of the thorax, and the viſcera which it contains.

Wounds which penetrate the cavities of the thorax are always exceedingly dangerous, becauſe there is ſcarce a poſſibility of all the viſcera eſcaping unhurt. A wound is known to have penetrated the cavity of the thorax principally by the diſcharge of air from it at each inſpiration of the patient, by an extreme difficulty of breathing, coughing up blood, &c. Such wounds, however, are not always mortal; the lungs have frequently been wounded, and yet the patient has recovered.—Wounds of the diaphragm are almoſt always mortal, either by inducing fatal convulſions immediately, or by the aſcent of the ſtomach, which the preſſure of the abdominal muſcles forces up through the wound into the cavity of the thorax; of this Van Swieten gives ſeveral inſtances.—Even though the wound does not penetrate into the cavity of the thorax, the very worſt ſymptoms may follow. For if the wound deſcends deeply among the muſcles, and its orifice lies higher, the extravaſated humours will be therein collected, ſtagnate, and corrupt in ſuch a manner as to form various ſinuſes; and after having eroded the pleura, it may at length paſs into the cavity of the thorax. The matter having once found a vent into this cavity, will be continually augmenting from the diſcharge of the ſinuous ulcer, and the lungs will at laſt ſuffer by the ſurrounding matter. If, in caſes of wounds in the thorax, the ribs or ſternum happen to become carious, the cure will be extremely tedious and difficult. Galen relates the caſe of a lad who received a blow upon his ſternum in the field of exerciſe: it was firſt neglected, and afterwards badly healed; but, four months afterwards, matter appeared in the part which had received the blow. A phyſician made an inciſion into the part, and it was ſoon after cicatrized: but in a ſhort time a new collection of matter made its appearance, and upon a ſecond inciſion the wound refuſed to heal. Galen found the ſternum carious; and having cut off the diſeaſed part, the pericardium itſelf was obſerved to be corroded, ſo that the heart could be ſeen quite naked; notwithſtanding which, the wound was cured in no very long time.

Simple Wounds.

There is ſometimes difficulty in determining whether the wound has really penetrated into the thorax or the abdomen; for the former deſcends much farther towards the ſides than at the middle. But as the lungs are almoſt always wounded when the cavity of the thorax is penetrated, the ſymptoms ariſing from thence can ſcarcely be miſtaken.—Another ſymptom which frequently, though not always, attends wounds of the thorax, is an emphyſema. This is occaſioned by the air eſcaping from the wounded lungs, and inſinuating itſelf into the cellular ſubſtance; which being pervious to it over the whole body, the tumour paſſes from one part to another, till at laſt every part is inflated to a ſurpriſing degree. An inſtance is given in the Memoirs of the Royal Academy, of a tumour of this kind, which on the thorax was eleven inches thick, on the abdomen nine, on the neck ſix, and on the reſt of the body four; the eyes were in a great meaſure thruſt out of their orbits by the inflation of the cellular ſubſtance; and the patient died the fifth day. This was occaſioned by a ſtab with a ſword.

14 Of the abdomen and its viſcera.

Wounds of the abdomen are not leſs dangerous than thoſe of the thorax, on account of the importance of the viſcera which are lodged there. When the wound does not penetrate the cavity, there is ſome danger of an hernia being formed by the protruſion of the peritonæum through the weakened integuments, and the danger is greater the larger the wound is. Thoſe wounds which run obliquely betwixt the interſtices of the muſcles often produce ſinuous ulcers of a bad kind. For as there is always a large quantity of fat interpoſed everywhere betwixt the muſcles of the abdomen, if a wound happens to run between them, the extravaſated humours, or matter there collected, not meeting with free egreſs through the mouth of the wound, often makes its way in a ſurpriſing manner through the cellular ſubſtance, and forms deep ſinuoſities between the muſcles; in which caſe the cure is always difficult, and ſometimes impoſſible.

If a large wound penetrates the cavity of the abdomen, ſome of the viſcera will certainly be protruded through it; or if the wound is but ſmall, and cloſed up with fat ſo that none of the inteſtines can be protruded, we may know that the cavity of the abdomen is pierced, and probably ſome of the viſcera wounded, by the acute pain and fever, paleneſs, anxiety, faintings, hiccough, cold ſweats, and weakened pulſe, all of which accompany injuries of the internal parts. The miſchiefs which attend wounds of this kind proceed not only from the injury done to the viſcera themſelves, but from the extravaſation of blood and the diſcharge of the contents of the inteſtines into the cavity of the abdomen; which, being of a very putreſcent nature, ſoon bring on the moſt violent diſorders. Hence wounds of the abdominal viſcera are very often mortal. This, however, is not always the caſe, for the ſmall inteſtines have been totally divided,

and

Simple Wounds.

and yet the patient has recovered. Wounds both of the ſmall and large inteſtines have healed ſpontaneouſly, even when they were of ſuch magnitude that the contents of the inteſtine was freely diſcharged through the wound in it, and after part of the inteſtine itſelf has been protruded through the wound of the integuments.

When the meſentery is injured, the danger is extreme, on account of the numerous veſſels and nerves ſituated there. Wounds of the liver, ſpleen, and pancreas, are alſo exceedingly dangerous, although there are ſome inſtances of the ſpleen being cut out of living animals without any conſiderable injury.

From the preceding account of the ſymptoms attending wounds in the different parts of the body, the ſurgeon may be enabled to judge in ſome meaſure of the event; though it muſt always be remembered, that wounds, even thoſe which ſeemed to be of the ſlighteſt nature, have, contrary to all expectation, proved mortal, chiefly by inducing convulſions, or a locked jaw; ſo that no certain prognoſtic can be drawn on ſight of recent wounds. We ſhall now, however, proceed to conſider their treatment.

15 Treatment of wounds.

For the cure of wounds, it has been already obſerved, that the ancients imagined balſams, the juice of herbs, &c. to be a kind of ſpecifics. In after-ages, and in countries where balſams are not eaſily to be procured, ſalves have been ſubſtituted in their place; and even at this day there are many who reckon a ſalve or ointment eſſentially neceſſary for healing the ſlighteſt cut. It is certain, however, that the cure of wounds cannot be effected, nay, not even forwarded in the leaſt, by ointments, unleſs in particular caſes or by accident. That power which the human frame has of repairing the injuries done to itſelf, which by phyſicians is called *vis medicatrix naturæ*, is the ſole agent in curing external injuries; and without this the moſt celebrated balſams would prove ineffectual. When a wound has been made with a ſharp inſtrument, and is not extenſive, if it be immediately cleaned, and all the extravaſated blood ſucked (A) out, it will almoſt always heal by the firſt intention in a very ſhort time. Indeed the cures performed by this ſimple proceſs are ſo ſurpriſing, that they would be incredible were we not aſſured of their reality by eye-witneſſes. When this proceſs is either neglected or proves unſucceſsful, there are three ſtages to be obſerved in the cure of a wound: the firſt, called *digeſtion*, takes place when the ends of the wounded veſſels contract themſelves, and pour out the liquor which is converted into pus. As ſoon as this appears, the ſecond ſtage, in which the fleſh begins to *grow up*, takes place; and as this proceeds, the edges of the wound acquire a fine bluiſh or pearl colour, which is that of the new ſkin beginning to cover the wound as far as the fleſh has filled it up. This proceſs continues, and the ſkin advances from all ſides towards the centre, which is called the *cicatrizing* of the wound. For the promoting of each of theſe proceſſes, ſeveral ointments were formerly much in vogue. But it is now found, that no ointment whatever is capable of promoting them; and that it is only neceſſary to keep the wound clean, and to prevent the air from having acceſs to it. This, indeed, nature takes care to do, by covering the wound with a cake of coagulated blood; but if a wound of any conſiderable magnitude ſhould be left entirely to nature, the pus would form below the cruſt of coagulated blood in ſuch quantity, that it would moſt probably corrupt, and the wound degenerate into a corroding ulcer. It is neceſſary, therefore, to cleanſe the wound frequently; and for this purpoſe it will be proper to apply a little ointment ſpread on ſoft ſcraped lint. For the firſt dreſſing, dry lint is uſually applied, and ought to be allowed to remain for two or three days, till the pus is perfectly formed; after which the ointment may be applied as juſt now directed; and, in a healthy body, the wound will heal without further trouble. As to the ointment employed, it is almoſt indifferent what it be, provided it has no acrid or ſtimulating ingredient in its compoſition.

Simple Wounds.

But though, in general, wounds thus eaſily admit of a cure, there are ſeveral circumſtances which require a different treatment, even in ſimple diviſions of the fleſhy parts, when neither the membranous nor tendinous parts are injured. Theſe are, 1. Where the wound is large, and gapes very much, ſo that, if allowed to heal in the natural way, the patient might be greatly diſfigured by the ſcar. It is proper to bring the lips of the wound near to each other, and to join them either by adheſive plaſter or by ſuture, as the wound is more ſuperficial, or lies deeper. 2. When foreign bodies are lodged in the wound, as when a cut is given by glaſs, &c. it is neceſſary by all means to extract them, before the wound is dreſſed; for it will never heal until they are diſcharged. When theſe bodies are ſituated in ſuch a manner as not to be capable of being extracted without lacerating the adjacent parts, which would occaſion violent pain and other bad ſymptoms, it is neceſſary to enlarge the wound, ſo that theſe offending bodies may by eaſily removed. This treatment, however, is chiefly neceſſary in gunſhot wounds, of which we ſhall treat in the next ſection. 3. When the wound is made in ſuch a manner that it runs for ſome length below the ſkin, and the bottom is much lower than the orifice, the matter collected from all parts of the wound will be lodged in the bottom of it, where, corrupting by the heat, it will degenerate into a fiſtulous ulcer. To prevent this, we muſt uſe compreſſes, applied ſo that the bottom of the wound may ſuffer a more conſiderable preſſure than the upper part of it. Thus the matter formed at the bottom will be gradually forced upwards, and that formed at the upper part will be incapable of deſcending by its weight; the divided parts, in the mean time, eaſily uniting when brought cloſe together. Indeed, the power which nature has of uniting different parts of the human body is very ſurpriſing; for, according to authors of credit, even if a piece of fleſh be totally cut out, and applied in a ſhort time afterwards to the place from whence it was cut, the two will unite. That a part cut out of a living body does not entirely loſe its vital power for ſome time, is evident from the modern practice of tranſplanting teeth; and from an experiment of Mr Hunter's at London, he put the teſticle of a cock into the belly of a living hen, which adhered to the liver, and became connected to it by means of blood-veſſels*. We have therefore the greateſt reaſon to hope, that the divided parts of the human body, when cloſely applied to each other, will cohere without leaving any ſinus or cavity between them. However, if this method ſhould fail, and matter ſtill be collected in the depending part of the wound, it will be neceſſary to make an opening in that part in order to let it out; after which the wound may be cured in the common way. 4. During the courſe of the cure, it ſometimes happens that the wound, inſtead of filling up with fleſhy granulations of a florid colour, ſhoots up into a glaſſy-like ſubſtance which riſes above the level of the ſurrounding ſkin, while,

* See Blood, n° 19.

(A) See an account of the method of ſucking wounds in Mr John Bell's *Diſcourſes on Wounds*, Part I. Diſcourſe v. p. 215.

Simple Wounds.

at the ſame time, inſtead of laudable pus, a thin ill-coloured and fetid ichor is diſcharged. In this caſe the lips of the wound loſe their beautiful pearl colour, and become callous and white, nor does the cicatrizing of the wound at all advance. When this happens in a healthy patient, it generally proceeds from ſome improper management, eſpecially the making uſe of too many emollient and relaxing medicines, an immoderate uſe of balſams and ointments. Frequently nothing more is requiſite for taking down this fungus than dreſſing with dry lint; at other times deſiccative powders, ſuch as calamine, tutty, calcined alum, &c. will be neceſſary; and ſometimes red precipitate mercury muſt be uſed. This laſt, however, is apt to give great pain, if ſprinkled in its dry ſtate upon the wound; it is therefore moſt proper to grind it with ſome yellow baſilicon ointment, which makes a much more gentle, though at the ſame time an efficacious eſcharotic. Touching the evergrown parts with blue vitriol is alſo found very effectual.

16 Of the regimen of patients in wounds.

Hitherto we have conſidered the wounded patient as otherwiſe in the ſtate of perfect health; but it muſt be obſerved, that a large wound is capable of diſordering the ſyſtem to a great degree, and inducing dangerous diſeaſes which did not before exiſt.—If the patient is ſtrong and vigorous, and the pain and inflammation of the wound great, a conſiderable degree of fever may ariſe, which it will be neceſſary to check by bleeding, low diet, and other parts of the antiphlogiſtic regimen, at the ſame that the inflamed lips of the wound and parts adjacent are to be treated with emollient formentations or cataplaſms till the pain and ſwelling abate. On the other hand, it may happen, when the patient is of a weak and lax habit, that the vis vitæ may not be ſufficient to excite ſuch an inflammation in the wound as is abſolutely neceſſary for its cure. In this caſe, the edges of the wound look pale and ſoft; the wound itſelf ichorous and bloody, without any ſigns of fleſhy granulations; or if any new fleſh ſhoots up, it is of the fungous glaſſy kind abovementioned. To ſuch wounds all external applications are vain; it is neceſſary to ſtrengthen the patient by proper internal remedies, among which the bark has a principal place, until the wound begins to alter its appearance. In ſuch perſons, too, there is ſome danger of a hectic fever by the abſorption of matter into the body when the wound is large; and this will take place during the courſe of the cure, even when the appearances have been at firſt as favourable as could be wiſhed. This happens generally when the wound is large, and a great quantity of matter formed; for by this diſcharge the patient is weakened; ſo that the pus is no ſooner formed, than it is by the abſorbent veſſels re-conveyed into the body, and feveriſh heats immediately affect the patient. For this the beſt remedy is to exhibit the bark copiouſly, at the ſame time ſupporting the patient by proper cordials and nouriſhing diet. Indeed, in general, it will be found, that, in the caſe of wounds of any conſiderable magnitude, a more full and nouriſhing regimen is required than the patient, even in health, has been accuſtomed to; for the diſcharge of pus alone, where the quantity is conſiderable, proves very debilitating, if the patient is not ſtrengthened by proper diet. And it is conſtantly found, that the cure of ſuch ſores goes on much more eaſily when the patient is kept in his uſual habit of body, than when his ſyſtem is much emaciated by a very low allowance; and, for the ſame reaſon, purgatives, and whatever elſe tends to weaken the conſtitution, are improper in the cure of wounds.

17 Of hemorrhagies from wounds.

Hæmorrhagies very frequently happen in wounds, either from a diviſion of one large artery, or of a number of ſmall ones. In this caſe, the firſt ſtep to be taken by the ſurgeon is to effect a temporary ſtoppage of the blood by means of compreſſion. He is then to tie up all the veſſels in the manner to be afterwards deſcribed.

Simple Wounds.

When the principal arteries of a wound have been tied, and a little blood continues to be diſcharged, but appears to come from ſundry ſmall veſſels only, an experienced ſurgeon is induced to think, that the neceſſary compreſſion of the bandages will in all probability effect a total ſtoppage of the hæmorrhagy. In a general oozing of a ſmall quantity of blood from the whole ſurface of a ſore, and when no particular veſſel can be diſtinguiſhed, there is a neceſſity for truſting to this remedy; but whenever an artery can be diſcovered, of whatever ſize it may be, it ought unqueſtionably to be ſecured by a ligature. But it frequently happens, that conſiderable quantities of blood are diſcharged, not from any particular veſſel, but from all the ſmall arteries over the ſurface on the ſore. In wounds of great extent, particularly after the extirpation of cancerous breaſts, and in other operations where extenſive ſores are left, this ſpecies of hæmorrhagy often proves very troubleſome by being exceedingly difficult to ſuppreſs.

Bleedings of this kind ſeem evidently to proceed from two very different and oppoſite cauſes. *Firſt*, Either from too great a quantity of blood contained in the veſſels, or from an over degree of tone in the veſſels themſelves; or, perhaps, from a combination of both theſe cauſes. But, *ſecondly*, Such evacuations undoubtedly happen moſt frequently in ſuch conſtitutions as are very relaxed and debilitated; either from a particular ſtate of the blood, or from a want of tone in the containing veſſels, or, in ſome inſtances, from a concurrence of both.

In conſtitutions perfectly healthy, on the occurrence of wounds even of the moſt extenſive nature, as ſoon as the larger arteries are ſecured, all the ſmall veſſels which have been divided are diminiſhed, not only in their diameters, but alſo in their length; in conſequence of which, they recede conſiderably within the ſurface of the ſurrounding parts. This cauſe of itſelf would probably, in the greateſt number of inſtances, prove ſufficient for reſtraining all loſs of blood from the ſmaller arteries. Another very powerful agent however is provided by nature for producing the ſame effect. From the extremities of the divided veſſels which at firſt diſcharged red blood only, there now, in their contracted ſtate, oozes out a more thin, though viſcid fluid, containing a great proportion of the coagulable parts of the blood; and this being equally diſtributed over the ſurface of the wound, by its balſamic agglutinating powers has a very conſiderable influence in reſtraining all ſuch hæmorrhagies.

When a tedious oozing occurs in a patient young and vigorous, and where the tone of the muſcular fibres is evidently great, the moſt effectual means of putting a ſtop to the diſcharge is to relax the vaſcular ſyſtem, either by opening a vein in ſome other part, or, what gives ſtill more immediate relief, by untying the ligature on one of the principal arteries of the part, ſo as to allow it to bleed freely: thoſe violent ſpaſmodic twitchings too, ſo frequent after operations on any of the extremities, when they do not depend on a nerve being included in the ligature with the artery, are in this manner more effectually relieved than by any other means.

By the ſame means the patient, from being in a febrile heat and much confuſed, ſoon becomes very tranquil: the violent pulſation of the heart and larger arteries abates, and the blood not being propelled with ſuch impetuoſity into the ſmaller veſſels of the part, they are thereby left at more liberty to retract. In the mean time the patient ought to be kept exceedingly cool; wine and other cordials ſhould be rigidly avoided; cold water, acidulated either with the mineral

Simple Wounds.

ral or vegetable acids, ought to be the only drink; motion of every kind, particularly of the part affected, ſhould be guarded againſt; and the wound being gently covered with ſoft charpie, ought to be tied up with a bandage ſo applied as to produce a moderate degree of preſſure on the extremities of the divided parts.

As ſoon as a ſufficient quantity of blood has been diſcharged, the wound being dreſſed, and the patient laid to reſt, a doſe of opium proportioned to the violence of the ſymptoms ought to be immediately exhibited. It ought to be remarked, however, that in all ſuch circumſtances, much larger doſes of the remedy are neceſſary than in ordinary caſes requiring the uſe of opiates. Small doſes, inſtead of anſwering any good purpoſe, ſeem frequently rather to aggravate the various ſymptoms; ſo that whenever they are here had recourſe to, they ought always to be given in quantities ſufficient for the intended effect.

But hæmorrhagies of this nature happen much more frequently in relaxed enfeebled habits, where the ſolids have loſt part of their natural firmneſs, and the fluids have acquired a morbid tenuity. In this caſe a moderate uſe of generous wine ought to be immediately preſcribed; for nothing tends ſo much, in ſuch circumſtances, to reſtrain hæmorrhagies, as a well-directed uſe of proper cordials. By tending to invigorate and brace the ſolids, they enable the arterial ſyſtem to give a due reſiſtance to the contained fluids; and have alſo a conſiderable influence in reſtoring to the fluids that viſcidity of texture, of which in all ſuch inſtances we ſuppoſe them to be deprived.

A nouriſhing diet alſo becomes proper; the patient ought to be kept cool; and the mineral acids, from their known utility in every ſpecies of hæmorrhagy, ought alſo to be preſcribed. Reſt of body is here alſo proper; and opiates, when indicated either by pain or ſpaſmodic affections of the muſcles, ought never to be omitted.

Together with theſe remedies adapted to the general ſyſtem, particular dreſſings, appropriated to the ſtate of the parts to which they are to be applied, have been found very beneficial. In healthy conſtitutions, ſoon after the diſcharge of blood is over, the parts are covered with a viſcid coagulable effuſion from the mouths of the now-retracted arteries; but in conſtitutions of an oppoſite nature, where the ſolids are much relaxed, the blood in general is found in ſuch an attenuated ſtate as to afford no ſecretion of this nature.

To ſupply as much as poſſible the deficiency of this natural balſam, different artificial applications have been invented. Duſting the part with ſtarch or wheat-flour has ſometimes been found of uſe, and gum arabic in fine powder has been known to anſwer when theſe failed.

Applications of this kind, indeed, have been uſed with ſucceſs in all ſuch hæmorrhagies, with whatever habit of body they happen to be connected; but they have always proved more particularly ſerviceable in relaxed conſtitutions, attended with an attenuated ſtate of the blood and an enfeebled muſcular ſyſtem. Alcohol, or any other ardent ſpirits, impregnated with as great a quantity as they can diſſolve of myrrh, or any other of the heating viſcid gums, may be here uſed with freedom, though in conſtitutions of an oppoſite nature they ought never to be employed. The balſamum traumaticum of the ſhops, a remedy of this nature, has long been famous for its influence in ſuch caſes: but that indiſcriminate uſe of this and ſimilar applications which has long prevailed with ſome practitioners, has undoubtedly done much harm; for as they are all poſſeſſed of very ſtimulating powers, they of courſe tend to aggravate every ſymptom in wounds connected with a tenſe ſtate of fibres, when much pain, and eſpecially when ſpaſmodic muſcular affections prevail.

Simple Wounds.

By a due perſeverance in one or other of the plans here pointed out, it will ſeldom happen that hæmorrhagies of this nature are not at laſt put a ſtop to: but when the contrary does occur, when, notwithſtanding the uſe of the remedies recommended, a diſcharge of blood ſtill continues; together with the means already adviſed, an equal moderate preſſure ought to be applied over the whole ſurface of the ſore, to be continued as long as the neceſſity of the caſe ſeems to indicate.

In finiſhing the dreſſings of ſuch wounds, after the charpie and compreſſes have been applied, a bandage properly adapted to the part ought to conclude the whole, and in ſuch a manner as to produce as equal a degree of preſſure over the ſurface of the ſore as poſſible. But it now and then happens that no bandage whatever can be ſo applied as to produce the deſired effect; and in ſuch caſes the hand of an aſſiſtant is the only reſource; which being firmly applied over the dreſſings, ſo as to produce a very equal degree of preſſure, will commonly ſucceed when no other remedy is found to have much influence.

18 Symptoms which ſometimes ſucceed blood-letting.

Wounds of the nerves, tendons, and ligaments, are attended with much more violent ſymptoms than thoſe where even conſiderable arteries are divided, and frequently reſiſt every method of cure propoſed by the moſt ſkilful practitioners. In the ſimple proceſs of blood-letting, it frequently happens that the tendinous expanſion called the *aponeuroſis* of the biceps muſcle is wounded, or even the tendon of that muſcle itſelf is punctured, by the point of the lancet; or ſometimes a nerve which happens to lie in the neighbourhood is partially divided. Any one of theſe wounds, though they are the ſmalleſt we can well ſuppoſe to be given, are frequently very dangerous and difficult of cure. It ſometimes immediately happens on the introduction of the lancet, that the patient complains of a moſt exquiſite degree of pain; and when this occurs, we may reſt aſſured that either a nerve or tendon has been wounded. On ſome occaſions, by proper management, ſuch as evacuating a conſiderable quantity of blood at the orifice newly made, by keeping the part at perfect reſt, and preſerving the patient in as cool a ſtate as poſſible, the pain at firſt complained of will gradually abate, and at laſt go off entirely, without any bad conſequence whatever. At other times, however, this pain which occurs inſtantaneouſly on the introduction of the lancet, inſtead of abating, begins ſoon to increaſe; a fullneſs, or ſmall degree of ſwelling, takes place in the parts contiguous to the wound; the lips of the ſore become ſomewhat hard and inflamed; and, in the courſe of 24 hours or ſo from the operation, a thin watery ſerum begins to be diſcharged at the orifice.

If, by the means employed, relief is not ſoon obtained, theſe ſymptoms generally continue in nearly the ſame ſtate for two or perhaps three days longer. At this time the violent pain which at firſt took place becomes ſtill more diſtreſſing; but inſtead of being ſharp and acute as before, it is now attended with the ſenſation of a burning heat, which ſtill goes on to increaſe, and proves, during the whole courſe of the ailment, a ſource of conſtant diſtreſs to the patient. The fullneſs and hardneſs in the lips of the wound begin to increaſe, and the ſwelling in the neighbouring parts gradually extends over the whole members. The parts at laſt become exceedingly tenſe and hard; an eryſipelatous inflammatory colour frequently appears over the whole member; the pulſe by this time has generally become very hard and quick; the pain is now intenſe, the patient exceedingly reſtleſs; twitchings of the tendons occur

Simple Wounds.

cur to a greater or leſſer degree; on ſome occaſions, a locked jaw and other convulſive affections ſupervene; and all theſe ſymptoms continuing to increaſe, it moſt frequently happens that the torture under which the patient has been groaning is at laſt terminated by death.

19 Opinions about the cauſes of theſe ſymptoms.

Different opinions have prevailed reſpecting the cauſe of theſe ſymptoms. By ſome they have been imputed to wounds of the tendons. By others the tendons are ſuppoſed to be ſo entirely deſtitute of ſenſibility, as to be quite incapable of producing ſo much diſtreſs; ſo that wounds of the nerves they conſider, on all ſuch occaſions, as the true cauſe of the various ſymptoms we have mentioned.

One or other of theſe ideas continued to be the only ſource for explaining the various phenomena found to occur in this malady, till a different opinion was ſuggeſted by the late ingenious Mr John Hunter of London. Mr Hunter ſuppoſes, that all the dreadful ſymptoms found now and then to be induced by the operation of blood-letting, may be more readily accounted for from an inflamed ſtate of the internal ſurface of the vein, than from any other cauſe. Such a ſtate of the vein he has often traced in horſes that have died of ſuch ſymptoms from veneſection, and the ſame appearances have ſometimes occurred alſo in the human body. And on other occaſions, inflammation having in this manner been once excited, has been known to terminate in ſuppuration; and the matter thus produced being in the courſe of circulation carried to the heart, Mr Hunter ſuppoſes that in ſuch caſes death may have been induced by that cauſe alone.

20 Mr John Hunter's opinion.

There can be no reaſon to doubt the fact held forth by Mr Hunter, that in ſuch inſtances the vein in which the orifice has been made has frequently after death been found greatly inflamed: but however ingenious his arguments may be for concluding that the ſtate of the vein is the original cauſe of all the bad ſymptoms enumerated, and although we muſt allow that ſuch an inflammatory affection of a vein muſt have a conſiderable influence in aggravating the various ſymptoms previouſly induced by other cauſes; yet we may very fairly conclude, that it could not probably in any one inſtance be able to account with ſatisfaction for their firſt production.

In many inſtances the patient, at the very inſtant of the operation, feels a very unuſual degree of pain. In ſome caſes, the violence of the pain is almoſt unſupportable. Now this we can never ſuppoſe to have been produced by the mere puncture of a vein; for although the coats of veins are not perhaps entirely deſtitute of feeling, yet we know well that they are not endowed with ſuch a degree of ſenſibility as to render it probable ſuch intenſe pain could ever be induced by their being punctured in any way whatever.

21 Not juſt.

This inflamed ſtate of the veins therefore, as detected by Mr Hunter after death, muſt be conſidered rather as being produced by, than as being productive of, ſuch affections; and that ſuch ailments ſhould frequently produce an inflammation of the contiguous veins, is a very probable conjecture. In the courſe of 48 hours or ſo from the operation, when the febrile ſymptoms are juſt commencing, ſuch a degree of hardneſs and evident inflammation is induced over all the parts contiguous to the orifice, that it would be ſurpriſing indeed if the vein, which is thus perhaps entirely ſurrounded with parts highly inflamed, ſhould eſcape altogether. We ſhall therefore proceed upon the ſuppoſition of this inflamed ſtate of the veins being a conſequence rather than the cauſe of ſuch ailments; and of courſe we now revert to one or other of the opinions long ago adopted on this ſubject, that all the train of bad ſymptoms found on ſome occaſions to ſucceed veneſection, proceeds either from the wound of a nerve or of a tendon.

22 Really owing to the partial wounding of a nerve or tendon.

That a partial wound of a nerve will now and then produce very diſtreſſing ſymptoms, no practitioner will deny: but it has been attempted to be ſhown, that tendons are almoſt totally deſtitute of ſenſibility; and it has therefore been ſuppoſed, that their being wounded can never account for the various ſymptoms known to occur in ſuch caſes. There is great reaſon however to think, that in different inſtances the ſame train of ſymptoms have been induced by different cauſes; that in one inſtance a wounded nerve, and in others pricks of the tendons, have given riſe to them, as we have already ſuppoſed.

Simple Wounds.

23 Method of obviating theſe ſymptoms, and curing the wound.

In order to prevent as much as poſſible the conſequent inflammation and other ſymptoms which uſually enſue, a conſiderable quantity of blood ſhould be immediately diſcharged at the orifice juſt made: the limb, for ſeveral days at leaſt, ought to be kept in a ſtate of perfect reſt, care being at the ſame time taken to keep the muſcles of the part in as relaxed a ſtate as poſſible: the patient ſhould be kept cool; on a low diet; and, if neceſſary, gentle laxatives ought to be adminiſtered.

When, notwithſtanding theſe means, the ſymptoms, inſtead of diminiſhing, rather become more violent; if the lips of the orifice turn hard and more inflamed, if the pain becomes more conſiderable, and eſpecially if the ſwelling begins to ſpread, other remedies come then to be indicated. In this ſtate of the complaint, topical blood-letting, by means of leeches applied as near as poſſible to the lips of the wound, frequently affords much relief; and when the pulſe is full and quick, it even becomes neceſſary to evacuate large quantities of blood by opening a vein in ſome other part.

The external applications uſually employed in this ſtate of the complaint are warm emollient fomentations and poultices. In ſimilar affections of other parts no remedies with which we are acquainted would probably be found more ſucceſsful; but in the complaint now under conſideration, all ſuch applications, inſtead of being productive of any advantage, rather do harm. The heat of the part is here one of the moſt diſtreſſing ſymptoms; and warm emollient applications rather tend to augment this ſource of uneaſineſs. The lips of the wound alſo are rendered ſtill more hard, ſwelled, and of courſe more painful; and the ſwelling of the contiguous parts is increaſed. The beſt external remedies are cooling aſtringents, eſpecially the ſaturnine applications. The parts chiefly affected being alternately covered over with cloths wet with a ſolution of ſaccharum ſaturni, and pledgits ſpread with Goulard's cerate, are kept more cool and eaſy than by any other remedy hitherto uſed. The febrile ſymptoms which occur muſt at the ſame time be attended to, by keeping the patient cool, on a low diet, preſerving a lax ſtate of the bowels; and, if neceſſary, farther quantities of blood ought to be evacuated.

On account of the violence of the pain, which is ſometimes ſo exceſſive as to deſtroy entirely the patient's reſt, opiates ought to be freely exhibited; and when twitchings of the tendons and other convulſive ſymptoms ſupervene, medicines of this kind become ſtill more neceſſary. In order, however, to have a proper influence in this ſtate of the complaint, opiates ought to be given in very full doſes; otherwiſe, inſtead of anſwering any good purpoſe, they conſtantly tend to aggravate the different ſymptoms, not only by increaſing the heat and reſtleſsneſs, but by having an evident influence in rendering the ſyſtem more ſuſceptible than it was before of the pain and other diſtreſſing effects produced upon it by the wound.

It often happens, however, either from neglecting the wound or from improper treatment, that all theſe remedies are had recourſe to without any advantage whatever: the fever, pain,

Simple Wounds.

and ſwelling of the parts continuing, convulſive affections of the muſcles at laſt occur, all tending to indicate the moſt imminent danger. In this ſituation of matters, if we have not immediate recourſe to ſome effectual means, the patient will ſoon fall a victim to the diſorder; and the only remedy from which much real advantage is to be expected, is a free and extenſive diviſion of the parts in which the orifice producing all the miſchief was at firſt made. We know well, from the repeated experience of ages, that much more pain and diſtreſs of every kind is commonly produced by the partial diviſion either of a nerve or of a tendon, than from any of theſe parts being at once cut entirely acroſs. Now the intention of the operation here recommended, is to produce a complete diviſion of the nerve or tendon we ſuppoſe to have been wounded by the point of the lancet, and which we conſider as the ſole cauſe of all the ſubſequent diſtreſs.

This operation being attended with a good deal of pain, and being put in practice for the removal of ſymptoms from which it is perhaps difficult to perſuade the patient that much danger can occur, all the remedies we have mentioned ſhould be firſt made trial of before it is propoſed: but at the ſame time, care ought to be taken that the diſorder is not allowed to proceed too far before we have recourſe to it; for if the patient ſhould be previouſly much weakened by the feveriſh ſymptoms having continued violent for any length of time, neither this remedy nor any other with which we are acquainted would probably have much influence. So ſoon therefore as the courſe already preſcribed has been fairly tried, and is found to be inadequate to the effects expected from it, we ought immediately to have recourſe to a free diviſion of the parts chiefly affected.

24 Treatment of wounded or ruptured tendons.

Wherever a wounded or ruptured tendon may be ſituated, the limb ſhould be placed in ſuch a manner as will moſt readily admit of the retracted ends of the tendon being brought nearly together; and when in this ſituation, the muſcles of the whole limb in which the injury has happened muſt be tied down with a roller, ſo as to prevent them from all kinds of exertion during the cure, endeavouring at the ſame time to keep the parts eaſy and relaxed. Thus in a wound or rupture of the tendon of the rectus muſcle of the thigh, the patient's *leg* ſhould be kept as much as poſſible ſtretched out during the cure, while the thigh ſhould be in ſome degree bent, to relax the muſcle itſelf as far as poſſible.

In ſimilar affections of the tendo Achilles, the *knee* ſhould be kept conſtantly bent to relax the muſcles of the leg, and the foot ſhould be ſtretched out to admit of the ends of the ruptured tendon being brought nearly into contact. A roller ſhould be applied with a firmneſs quite ſufficient for ſecuring the muſcles and tendons in this ſituation; but care muſt be taken to prevent it from impeding the circulation. With this view, fine ſoft flannel ſhould be preferred either to linen or cotton; for being more elaſtic, it more readily yields to any ſwelling with which the limb may be attacked.

The late Dr. Monro was the firſt who gave any accurate directions for the treatment of rupture in the large tendons; and it is perhaps given with more preciſion, from his having himſelf experienced the effects of this misfortune in the tendo Achillis.

He uſed a foot-ſock or ſlipper, made of double quilted ticking, and left open at the toe; from the heel of which a ſtrap went up above the calf of the leg. A ſtrong piece of the ſame materials went round the calf, and was faſtened with a lace. On the back part of this was a buckle, through which the ſtrap of the foot-ſock was paſſed, by which the calf could be brought down, and the foot extended at pleaſure. Beſides, there was a piece of tin applied to the fore part of the leg, to prevent the foot from getting into any improper poſture during ſleep. After propoſing to walk, he put on a ſhoe with a heel two inches deep; and it was not till the expiration of five months that he ventured to lay aſide the tin plate; and he continued the uſe of the high-heeled ſhoe for two years. The whole apparatus is repreſented Plate CCCCXCII. fig. 124.

Simple Wounds.

From this treatment a knowledge may be formed of the treatment neceſſary to be followed in the laceration of tendons of other parts of the body.

25 Wounds of the thorax.

In wounds of the thorax, even though none of the viſcera ſhould be wounded, we may yet reaſonably expect that a conſiderable quantity of blood will be extravaſated; and this, if very large, muſt be evacuated if poſſible. However, it ought to be particularly obſerved, that this extravaſated blood ſhould not be diſcharged before we are aſſured that the wounded veſſels have done bleeding. When the pulſe appears ſufficiently ſtrong and equal, the extremities are warm, no hiccup or convulſion appears, and the patient's ſtrength continues, we may then know that the internal hæmorrhagy has ceaſed, and that the means for diſcharging the blood may now be ſafely uſed. Matter, water, blood, &c. have ſometimes vaniſhed from the cavities of the thorax, and been afterwards diſcharged by ſweat, urine, &c. Yet this but ſeldom happens; and if we were to truſt to nature only in theſe caſes, it is certain that many would periſh from a deſtruction of the vital viſcera by the extravaſated and putrid blood, who by an artificial extraction of the ſame blood might have been ſaved.

Wounds of the abdomen muſt be cloſed as ſoon as poſſible, and then treated as ſimple wounds; only they ought to be dreſſed as ſeldom and expeditiouſly as may be. A ſpare diet, with other parts of the antiphlogiſtic regimen, is here abſolutely neceſſary. It ſometimes happens, that, thro' a large wound of the abdominal integuments, the inteſtine comes out without being injured; yet, if it remains for any time expoſed to the air, the caſe is commonly very dangerous. The moſt certain method, in all ſuch caſes, is to return the protruded part as ſoon as poſſible; for although writers in general formerly recommended warm fomentations, &c. to be previouſly applied, the lateſt authors upon this ſubject conſider the moſt natural and proper fomentation to be that which is produced by the heat and moiſture of the patient's belly, and that therefore the inteſtines, if no mortification has taken place, are to be cleared from extraneous matter, and immediately returned.

26 Wounds of the abdomen.

When the wound of the abdomen is large, the inteſtines eaſily prolapſe, but are as eaſily returned. But when part of an inteſtine has been forced through a narrow wound, the diſorder is much more dangerous. For the prolapſed inteſtine being diſtended by flatus, or the ingeſted aliments driven thither by the periſtaltic motion, it will be inflamed, tumefied, and incapable of being returned through the ſtricture of the wound; whence a ſtoppage of the circulation and gangrene will ſoon follow. In this caſe the utmoſt care is to be taken to reduce the inteſtine to its natural ſize. When this cannot be accompliſhed by other means, ſome practitioners of great eminence have even adviſed the puncturing of the inteſtine in different places in order to diſcharge the flatus. This practice has alſo been recommended in an incarcerated hernia, but is exceedingly diſapproved of by Mr Pott and later writers; and it ſeems to be very dubious whether any good can poſſibly ariſe from it. To puncture any part that is already inflamed, muſt undoubtedly add to the inflammation; and it is very improbable that

the

Simple Wounds.

the discharge of flatus procured by the punctures would at all be a recompense for the bad consequences produced by the increased inflammation. The method of Celsus is much more eligible: It is to dilate the wound so as to reduce the intestine with ease. Sometimes part of the intestine is lost either by suppuration or gangrene. In this case, all that can be done is to strike a single stitch through the wounded bowel, and to fix it to the external wound by passing the future also through the sides of the wound. The ends of the intestine may perhaps adhere; or at any rate the wound will continue to perform the office of an anus, out of which the fæces will continue to be discharged during life. The directions given by some surgeons about inserting the upper end of the gut into the lower, and stitching them together, are perfectly impracticable, as Mr John Bell has shown in his important Discourses on Wounds*; and even if they were practicable, would certainly produce new mortification, which could not but be fatal.

* Part II. Discourses 4th and 5th.

When the omentum appears prolapsed, the same general treatment is to be observed; only that, when it is dry and mortified, the dead part may safely be extirpated.—We shall conclude the article of abdominal wounds with a case from the memoirs of the academy of sciences for the year 1705, which shows that we ought not to despair, even though the most desperate symptoms should take place, as long as any vis vitæ remains. A madman wounded himself in 18 different places of the abdomen. Eight of these penetrated the cavity, and injured the contained viscera; he had a diarrhœa, nausea, and vomiting, tension of the abdomen, with difficult respiration and violent fever, so that his life was despaired of. During the first four days he was blooded seven times; and during the greatest part of the cure his diet consisted almost entirely of flesh-broths, with the addition of some mild vegetables. By these means he was not only cured of his wounds, but restored to his right senses. Seventeen months after, he went mad again, and threw himself over a precipice, by which he was instantly killed: on opening the body, the wounds were found to have penetrated the middle lobe of the liver, the intestinum jejunum, and the colon.

Such extraordinary cures are to be imputed, according to the satisfactory explanation of Mr J. Bell, to the abdomen being perfectly full, and constantly subjected to strong pressure between the diaphragm and abdominal muscles; which keeps the parts contiguous to a wound closely applied to it, prevents the discharge of fæces or even of blood in some measure, and gives an opportunity for a very speedy adhesion between the parts.

27 Wounds of the head.

In wounds of the head, where the cellular membrane only is affected, and the aponeurosis and pericranium untouched, phlebotomy, lenient purges, and the use of the common febrifuge medicines, particularly those of the neutral kind, generally remove all the threatening symptoms. When the inflammation is gone off, it leaves on the skin a yellowish tint and a dry scurf, which continue until perspiration takes them away; and upon the removal of the disease, the wound immediately recovers a healthy aspect, and soon heals without further trouble. But in the worst kind of these wounds, that is, where a small wound passes through the tela cellulosa and aponeurosis to the pericranium, the patient will admit of more free evacuations by phlebotomy than in the former. In both, the use of warm fomentations is required; but an emollient cataplasm, which is generally forbid in the erysipelatous swellings, may in this latter case be used to great advantage. Where the symptoms are not very pressing, nor the habit very inflammable, this method will prove sufficient; but it sometimes happens that the scalp is so tense, the pain so great, and the symptomatic fever so high, that by waiting for the slow effect of such means the patient runs a risk from the continuance of the fever; or else the injured aponeurosis and pericranium, becoming sloughy, produce an abscess, and render the case both tedious and troublesome. A division of the wounded part, by a simple incision down to the bone, about half an inch or an inch in length, will most commonly remove all the bad symptoms; and if it be done in time, will render every thing else unnecessary.

Contused and Lacerated Wounds.

28 Wounds of the joints.

The wounds penetrating into the cavities of the joints do not seem at first alarming; yet, by exposure to the air, the lining membrane of such cavities acquire such a degree of sensibility as to endanger life when they are large. As soon therefore as any extraneous body, pushed into the joint, is removed, the admission of the external air is to be guarded against as much as possible. If the wound be not too large, this may be done by pulling the skin over the wound of the joint; and, to prevent its retraction, rather adhesive plaster, with proper bandaging, is to be used. But when inflammation is come on, repeated and copious blood-letting, together with fomentations, become necessary; and as the pain, in these cases, is apt to be violent, opiates must be administered; but should matter be formed in the cavity of the joint, free vent must be given to it.

Sect. II. *Of contused and lacerated Wounds.*

When the small vessels are broken by a blow with any hard instrument without penetrating the skin, at the same time that the solid fibres of the part are crushed, the injury is termed a *contusion:* and when at the same time the skin is broken, it is termed a *contused and lacerated wound;* because in this case the parts are not fairly divided as with a knife, but torn asunder or violently stretched.

29 Symptoms and effects of contusions.

Every contusion therefore, whether the skin is broken or not, may properly be reckoned a wound; for where the injury is so slight that none of the contents of the small vessels are extravasated, it scarce deserves to be mentioned. The immediate consequence of a contusion, therefore, is a swelling, by reason of the extravasation just mentioned; and the skin becomes discoloured by the blood stagnating under it: but as this fluid, even though covered by the skin, cannot long remain in its natural state, it thence happens, that the contused part soon loses its florid red colour, and becomes blue or black; the thinner parts being in the mean time gradually taken up by the absorbent vessels, which at last happens to the blood itself; the blue disappears, and is succeeded by a yellowish colour, showing that the blood is now dissolved; after which the part recovers its former appearance, and the ruptured vessels appear to have united as though nothing had happened.

These are the symptoms which attend the slightest kind of contusions; but it is evident, that where the blow is so violent as to rupture or crush some of the large nerves, or blood-vessels, all the bad consequences which attend simple wounds of those parts will ensue, and they will not at all be alleviated by the circumstance of the skin being whole. Hence it is easy to see how a contusion may produce ulcers of the worst kind, gangrene, sphacelus, carious bones, &c.; and if it happens to be on a glandular part, a scirrhus or cancer is very frequently found to ensue. Even the viscera themselves, especially of the abdomen, may be injured by contusions to such a degree as to produce an inflammation, gangrene, or scirrhus, nay instant death, without rupturing the skin.

Gun-shot Wounds.

Sect. III. *Of Gun shot Wounds.*

Gun-shot wounds can be considered in no other light than contused wounds. In those made by a musket or pistol ball, the most immediate considerations are, to extract the ball, or any other extraneous body which may have lodged in the wounded part; and to stop the hemorrhagy, if there is an effusion of blood from the rupture of some considerable artery.

30 Extraction of the ball or other foreign bodies.

It is frequently necessary to enlarge the wound in order to extract the ball; and if it has gone quite through, (provided the situation of the part wounded will admit of its being done with safety), the wound is to be laid freely open through its whole length; by which means any extraneous body will be more readily removed, and the cure facilitated.

In order to get at the ball, or any other foreign matter, probing is to be used as sparingly as possible: and this must evidently appear to any one who will only consider the nature of the symptoms attendant on penetrating wounds of the breast or belly, either from a bullet or sharp instrument; the thrusting in a probe to parts under such circumstances being unavoidably a fresh stab on every repetition of such practice. Wherever probing is necessary, the finger is to be preferred as the best and truest probe, where it can be used.

If a ball, or any other foreign body, happens to be lodged near the orifice, or can be perceived by the finger to lie under the skin, though at some distance from the mouth of the wound, we should cut upon it and take it out: but when it is sunk deep, and lies absolutely beyond the reach of the finger, it must appear evident, upon the least reflection, that thrusting, first a long probe in quest of the bullet, and then, as has been practised likewise, a longer pair of forceps, either with or without teeth, into a wound of that kind, though with a sort of certainty to extract it, must either contuse, or irritate and inflame, the parts to a great degree; and consequently do as much, or more mischief, than the ball did at first by forcing its passage such a length of way. And should they at the same time lay hold of any considerable artery or nerve along with the ball (which can scarce ever fail of being the case), what shocking consequences would attend such a proceeding! Nor would attempts of this sort be less injurious in case a bullet should happen to be lodged in the cavity of the belly or breast. Such attempts are the less necessary, because a great number of instances have occurred, where balls have been quietly lodged in several parts of the body, till after many years they have worked themselves a passage towards the surface, and were very easily extracted; and many where balls have been entirely left behind.

31 Dilatation of the wound.

In case the wound be occasioned by a musket or pistol shot, and of course but small, it will be necessary to dilate it without delay, provided the nature of the part will admit of this with safety: for in wounds near a joint, or in very membranous or tendinous parts, the knife, as well as forceps, should be put under some restraint; nor should any more opening be made than what is absolutely requisite for the free discharge of the matter lodged within.

Where the wounded person has not suffered any great loss of blood, and this is generally the case, it will be advisable to open a vein immediately, and take from the arm a large quantity; and to repeat bleeding as circumstances may require, the second, and even the third day. Repeated bleedings in the beginning draw after them many advantages. They prevent a good deal of pain and inflammation, lessen any feverish assaults, forward the digestion, and seldom fail to obviate impostumations, and a long train of complicated symptoms which are wont otherwise to interrupt the cure, miserably harass the poor patient, and too often endanger his life; and even where the feverish symptoms run high, and there is almost a certainty that matter is forming, bleeding, in that state, is very frequently of great advantage.

32 Advantages of bleeding.

33 Regimen.

For the first 12 days it will be proper to observe a cooling regimen, both in respect of the medicines that may be prescribed, and the diet requisite for the support of nature. It is absolutely necessary likewise that the body be constantly kept open. Unless, therefore, nature does this office of herself, a stool should be every day procured, either by emollient clysters, or some gentle laxative taken at the mouth; and whenever there is much pain in the wounded parts, immediate recourse must be had to opium.

34 External applications.

As to external applications, whatever is of a hot spirituous nature is remarkably injurious on these occasions, and what no wounded part can in any degree bear. The wound may be dressed with pledgits of any emollient ointment; the whole being covered with a common poultice, or, in some cases, the preparations of lead may be used. An opiate should now be administered; and the part affected being placed in the easiest and most convenient posture, the patient should be laid to rest. The formation of matter, in every contused wound, is an object of the first importance; for, till this takes place, there is often reason to suspect that gangrene may happen. With a view to hasten suppuration, the warm poultices should be frequently renewed, and they should be continued till the tension and swelling, with which wounds of this kind are usually attended, be removed, and till the sore has acquired a red, healthy, granulating appearance, when it is to be treated like a common ulcer.

Gun-shot wounds are commonly covered from the beginning with deep sloughs, and various remedies are recommended for removing them. Every appearance, however, of this kind with which they are attended proceeds entirely from contusion; and, excepting the injury be extensive, the slough is not often perceptible, or it is so thin as to come away along with the matter at the first or second dressing. Although emollient poultices be extremely useful, they ought to be no longer continued than till the effects already mentioned are produced; otherwise they will not only relax the parts, but also produce too copious a discharge of matter, which is sometimes attended with great danger. A too copious flow of matter may proceed from different causes; but in whatever way it may have been produced, the practice to be adopted must be nearly the same. Every collection which appears must have a free outlet, and the limb laid in that posture which will most readily admit of its running off. In such circumstances, nourishing diet and Peruvian bark in considerable quantities are highly useful. When the discharge continues copious, in spite of every effort to check it, detached pieces of bone or some extraneous matter are probably the cause. In such a situation nothing will lessen the quantity of matter till such substances be removed. The wound ought therefore again to be examined, and loose bodies removed. Pieces of cloth have been known to be removed by setons, when that method was practicable, after every other method had failed. Opium likewise is frequently useful in checking an excessive discharge, when it happens to be kept up by irritation.

Although no considerable hemorrhagy may happen at first in gun-shot wounds; yet after the sloughs commonly produced upon such occasions have come off, some considerable arteries may be exposed, and then a dangerous hemorrhagy may ensue. The hemorrhagy is often preceded by a great heat in the injured parts, and with a throbbing pulsatory pain. At this period it may frequently be prevented

Poiſoned Wounds.

vented by plentiful blood-letting, particularly local. But if the hemorrhagy has fairly taken place, and from arteries of conſiderable ſize, nothing will do but the proper application of ligatures. As the diſcharge in theſe caſes would often prove dangerous before the ſurgeon could be procured, the attendants ſhould be furniſhed with a tourniquet, with directions to apply it, upon the firſt appearance of blood.

35 Scarifying improper.

Till of late years the ſcarifying of gun-ſhot wounds was a practice which prevailed very univerſally among ſurgeons; and it was expected by this, that the ſloughs with which wounds are ſometimes covered would ſooner ſeparate, and that the cure would thereby be more readily performed. It is now, however, known, that this practice, inſtead of being uſeful, very generally does harm by increaſing the inflammation. It ſhould therefore be laid entirely aſide. When a gun-ſhot wound cannot eaſily or ſafely be laid open from one end to the other, perhaps it may be proper to introduce a cord through the ſinus. This, however, ſhould not be attempted till the firſt or inflammatory ſtate of the wound is over: but when a cord cannot be properly introduced, on account of the ſituation or direction of the wound, compreſſion may prove equally uſeful here as in caſes of punctured wounds.

36 Mortification.

Mortification happening after gun-ſhot wounds, is to be treated in the ſame manner as if it had ariſen from any other cauſe, only bark is not to be promiſcuouſly uſed; as, in plethoric habits, it may prove hurtful, though in debilitated relaxed habits it will be extremely uſeful; but even in ſuch it ſhould never be given while much pain and tenſion continue.

SECT. IV. *Of Poiſoned Wounds.*

37 Treatment of wounds poiſoned by by the bite of animals.

POISON may be introduced into the ſyſtem various ways. The effects of the poiſon introduced by the ſtings of inſects may frequently be prevented by applying immediately vinegar or ardent ſpirits. After inflammation has come on, the moſt effectual remedy is the waſhing the parts with cold water. The bite of a viper is not always dangerous; but as we can never judge with certainty whether the wound be poiſoned or not, and as the poiſon of this animal acts very ſpeedily upon the ſyſtem, its bad effects ought to be prevented by every poſſible means. The injured part ought either to be cut out immediately, or deſtroyed with the actual or potential cautery.

Formerly ſuction was much employed, and frequently with ſucceſs: it ſhould not, however, prevent the removal of the part. After the part has been removed, we ſhould endeavour to produce a plentiful ſuppuration. When the poiſon appears to have entered the ſyſtem, the application of warm oil over the whole body has been extolled; and it has been ſaid that advantage has been derived from the internal uſe of it. From ſome late obſervations, however, the efficacy of this remedy is much to be doubted. Perhaps a plentiful ſweat, kept up for a conſiderable time, is the moſt certain method yet diſcovered. Small doſes of volatile alkali frequently repeated is more to be depended on for producing this effect than any other remedy.

38 Wounds from the bite of mad animals.

The bite of a mad animal occaſions the moſt formidable poiſoned wound known in this country. In theſe wounds hydrophobia indeed does not always enſue; but when it does, death is almoſt certainly the conſequence. A variety of noſtrums for preventing and curing this diſeaſe have been held forth to the public; but there is ſcarcely any well atteſted fact of any one of them proving uſeful. Nothing yet known can be depended upon but the immediate removal of the injured part, either with the ſcalpel or the actual or potential cautery; which, together with a plentiful ſuppuration, has, in different inſtances, appeared to anſwer the purpoſe effectually; at leaſt, patients treated in this manner have eſcaped, while others bit at the ſame time by the ſame animal have ſuffered. The ſooner the operation is performed, the more effectual it is likely to prove; but it ought not to be omitted, even though ſome time has elapſed from the time that the wound was inflicted; for there is reaſon to ſuppoſe that this poiſon does not enter the ſyſtem ſo quickly as ſeveral others are obſerved to do. Sea-bathing has been much recommended in all ages as a preventive; but there are few well atteſted caſes of its being attended with advantage. Many practitioners depend much on mercury; and as it can be uſed along with any other plan of treatment, it ought not to be neglected.

Inflammation and Suppuration.

When wounds are poiſoned by the application of matter from certain ſores, as thoſe of the venereal or cancerous kinds, or from any of the vegetable poiſons, it is better to remove the part affected immediately, than to undergo a courſe of medicines generally ſlow and often doubtful in their operation.

The metallic poiſons do not fall to be conſidered in this place; for however deleterious they may be when taken into the ſtomach, they ſeldom appear to be otherwiſe hurtful, when applied to wounds, than by irritating or corroding the parts with which they come in contact.

CHAP. III. *Inflammation and its Conſequences.*

SECT. I. *Of Inflammation and Suppuration.*

INFLAMMATION of any part is accompanied with increaſed heat, redneſs, and painful tenſion. For the remote and proximate cauſes of inflammation, together with the treatment of inflammatory diſeaſes, ſee *Phlegmaſiæ*, article MEDICINE. Inflammation is commonly divided into two ſpecies, the *phlegmonic* and *erythematic*. The firſt is diſtinguiſhed by conſiderable ſwelling, throbbing pain, and circumſcribed bright red colour. The ſecond by ſuperficial ſwelling, burning pain, dull red colour, apt to ſpread, diſappearing when preſſed, and quickly returning; the part affected is frequently covered with ſmall veſicles. The conſequences of inflammation are ſuppuration and gangrene, unleſs the inflammation be checked and terminated by reſolution.— That an inflammation will terminate in ſuppuration may be known from the length of time it has continued, from the remiſſion of the pain and hardneſs, the greater elevation of the ſkin in the middle part, a change of colour from red to bluiſh or livid, a ſlight fever with ſhivering, and from a fluctuation of matter perceived on handling the part.

39 Symptoms of inflammation.

40 Its conſequences, ſuppuration and gangrene.

During the firſt ſtage of the inflammation, however, we ought, for the moſt part, to endeavour to reſolve it, or prevent the ſuppuration. Yet ſome caſes muſt be excepted. For inſtance, thoſe inflammatory ſwellings which ſometimes occur in fevers, or ſucceed to them, ought always to be brought to ſuppuration; and it might be very dangerous to attempt a reſolution of them. In ſwellings of a ſcrophulous nature, it is perhaps beſt to do nothing at all, either with a view to reſolve or ſuppurate. Thus it might be dangerous to make uſe of repellent application, at the ſame time that it is by no means adviſable to promote their ſuppuration; the cure of ſuch ſwellings, when opened, proving always very troubleſome; while at the ſame time it is known, that ſuch ſwellings may remain for a very long time without any riſk to the patient. In the lues venerea, too, as we are poſſeſſed of a certain antidote for the diſorder, it is beſt not to attempt the ſuppuration of any buboes which may appear;

41 When reſolution ſhould be attempted.

Inflammation and Suppuration.

pear; as the cure of them, when opened, very often proves extremely troubleſome; and as their being opened cannot contribute any thing towards their cure.

42 Method of reſolving inflammation.

Where the inflammation is but beginning, and the ſymptoms are not ſo violent as to affect the general ſyſtem, topical remedies, with a due attention to regimen, often anſwer in reſolving them. The firſt thing to be attended to in the caſe of every inflammation, is the removal of the exciting cauſes, which either have brought on the inflammation originally, or which may continue it after it is begun. Such are extraneous bodies in wounds, pieces of fractured bones, luxations, &c. Of all the various applications for an inflamed part, thoſe of a ſedative nature are chiefly to be depended upon; and, next to theſe, emollients. Of the former kind we may conſider all the different preparations of lead diſſolved in vinegar; together with vinegar itſelf, which generally acts alſo as a ſedative. Among the latter we may place the mild expreſſed oils, as alſo the ſoft ointments made with theſe oils and pure wax.

When we ſpeak of ſedative medicines, however, it muſt not be underſtood that all of that claſs are to be uſed indiſcriminately. Thus opium, though one of the moſt powerful of all ſedatives, yet as its application, externally to the human body, is always attended with ſome degree of irritation, however uſeful it may at times be found in ſome particular ſpecies of inflammatory diſorders, will never, probably, as an external application, become of general uſe in theſe caſes. Warm emollient fomentations alſo, though powerful ſedatives, as tending more effectually to remove tenſion and pain than perhaps any other remedy, are conſtantly found to be improper where a reſolution is to be wiſhed for. Their conſtant effect is, either to bring the ſwelling to a ſuppuration, or to relax the parts in ſuch a manner as to render the removal of the diſorder always exceedingly tedious.

Mr Bell recommends the preparations of lead as proper applications, in caſes of external inflammation, where we wiſh for a reſolution. The beſt method of applying it, he ſays, is in the form of a watery ſolution; and he gives the following formula: "℞. Sacchar. ſaturn. ʒſs.; ſolve in acet. pur. ʒiv.; et adde aq. fontan. diſtillat. ℔ij. The addition of vinegar renders the ſolution much more complete than it otherwiſe would be; and without it indeed a very conſiderable proportion of the lead generally ſeparates and falls to the bottom.

In making uſe of this ſolution in caſes of inflammation, as it is of conſequence to have the parts affected kept conſtantly moiſt with it, cataplaſms prepared with it and crumb of bread in general anſwer that intention exceedingly well. But when the inflamed parts are ſo tender and painful as not eaſily to bear the weight of a poultice, which is frequently the caſe, pieces of ſoft linen moiſtened with the ſolution anſwer the purpoſe tolerably well. Both ſhould be applied cold, or at leaſt with no greater warmth than is merely neceſſary for preventing pain or uneaſineſs to the patient: they ſhould be kept almoſt conſtantly at the part, and renewed always before turning ſtiff or hard.

When the tenſion and irritation on the ſkin are conſiderable, emollients are often attended with very great advantage: the parts affected being, in ſuch a ſtate of the diſorder, gently rubbed over with any of the mild expreſſed oils two or three times a-day, the tenſion, irritation, and pain, are often very much relieved, and the diſcuſſion of the tumor thereby greatly promoted.

In every caſe of inflammation, indeed, emollient applications would afford ſome relief. But as the preparations of lead, already recommended, prove in all ſuch diſorders ſtill more advantageous; and as unguents of every kind tend conſiderably to blunt the action of lead; theſe two ſets of remedies ſhould as ſeldom as poſſible be allowed to interfere with one another; and emollients ſhould accordingly never be preſcribed, but when the circumſtances already mentioned of irritation, tenſion, and pain, are ſo conſiderable as to render their application altogether neceſſary. Inflammation and Suppuration.

When the part affected with inflammation is not very tender, or lies deep, applications of vinegar are often had recourſe to with conſiderable advantage: the moſt effectual form of uſing it ſeems to be by way of cataplaſm, made with the ſtrongeſt vinegar and crumb of bread. In ſuch caſes, an alternate uſe of this remedy, with the ſaturnine ſolution, has produced more beneficial effects than are commonly obſerved from a continued courſe of any one of them.

At the ſame time that theſe applications are continued, blooding with leeches, or cupping and ſcarifying, as near as poſſible to the part affected, is generally of very great ſervice; and in no caſe of local inflammation ſhould ever be omitted. In all ſuch caſes, the whole body, but more eſpecially the diſeaſed part, ſhould be preſerved as free as poſſible from every kind of motion; and, for the ſame reaſon, the neceſſity of a low cooling diet, in every inflammatory diſorder, appears obvious, as does alſo a total abſtinence from ſpirituous and fermented liquors.

43 Blood-letting, when proper for this purpoſe.

In ſlight caſes of inflammation, a due perſeverance of the ſeveral articles taken notice of will, in general, be found ſufficient for every purpoſe. But when there is likewiſe a full, hard, or quick pulſe, with other ſymptoms of fever, general blood-letting becomes neceſſary; the quantity of blood taken away being always to be determined by the violence of the diſorder, and by the age and ſtrength of the patient. Evacuation, however, ſhould never be carried to a greater height than what is merely neceſſary for moderating the febrile ſymptoms; for if ſuppuration ſhould take place after the ſyſtem is too much reduced, its progreſs is thereby rendered much more ſlow and uncertain, nor will the patient be ſo able to bear the diſcharge that muſt enſue upon opening the abſceſs. The uſe of gentle laxatives, together with cooling diaphoretic medicines, are alſo attended with very good effects.

Theſe different evacuations being premiſed, the next object of conſequence is to procure eaſe and quietneſs to the patient; which is often, in inflammatory caſes, of more real ſervice than any other circumſtance whatever. The moſt effectual remedy for this purpoſe is opium; which, when pain and irritation are conſiderable, as in extenſive inflammations very frequently happens, ſhould never be omitted. In large wounds, eſpecially after amputations and other capital operations, alſo in punctures of all kinds, large doſes of opium are always attended with remarkable good effects. In all ſuch caſes, however, opium, in order to have a proper influence, ſhould, as was obſerved, be adminiſtered in very large doſes; otherwiſe, inſtead of proving ſerviceable, it ſeems rather to have the contrary effect; a circumſtance which is perhaps the chief reaſon for opiates in general having been very unjuſtly condemned in every caſe of inflammation.

By a proper attention to the different circumſtances taken notice of, in the courſe of three or four days, and ſometimes in a ſhorter ſpace of time, reſolution of the tumor will in general begin to take place; at leaſt before the end of that period it may, for the moſt part, be known how the diſorder is to terminate. If the heat, pain, and other attending ſymptoms abate, and eſpecially if the tumor begins to decreaſe, without the occurrence of any gangrenous appearances, we may then be almoſt certain that by a continuance of the ſame plan a total reſolution will in time be effected.

But, on the contrary, if all the different ſymptoms rather

Inflammation and Suppuration.

increaſe; and eſpecially if the tumor turns larger, and ſomewhat ſoft, with an increaſe of throbbing pain; we may then with tolerable certainty conclude, that ſuppuration will take place; and ſhould therefore immediately deſiſt from ſuch applications as were judged proper while a cure was thought practicable by reſolution, and endeavour to aſſiſt nature as much as poſſible in the formation of pus, or what is called *maturation* of the tumor. For this purpoſe there is nothing better than to preſerve a proper degree of heat in the parts. This is commonly done by the means of warm fomentations and cataplaſms; and when theſe are regularly and frequently renewed, nothing, it is probable, could more effectually anſwer the purpoſe. But in the ordinary manner in which they are applied, by the cataplaſms being renewed only once, or at moſt twice a day, they muſt always, it is imagined, do more harm than good. For ſo ſoon as the degree of heat they were at firſt poſſeſſed of is diſſipated, the moiſture kept up by them, with the conſequent evaporation which enſues, muſt always render the part a great deal colder than if it had been merely wrapped in flannel without the uſe of any ſuch application.

44 Method of promoting ſuppuration.

In order to receive all the advantages of ſuch remedies, the part affected ſhould be well fomented with flannels preſſed out of any warm emollient decoction, applied as warm as the patient can eaſily bear them, continued at leaſt half an hour at once, and repeated four times a day.

Immediately after the fomentation is over, a large emollient poultice ſhould likewiſe be applied warm, and renewed every ſecond or third hour at fartheſt. Of all the forms recommended for emollient cataplaſms, a common milk-and-bread poultice, with a proportion of butter or oil, is perhaps the moſt eligible; as it not only poſſeſſes all the advantages of the others, but can at all times be more eaſily obtained.

Roaſted onions, garlic, and other acrid ſubſtances, are frequently made uſe of as additions to maturating cataplaſms. When there is not a due degree of inflammation in the tumor, and when it appears probable that the ſuppuration would be quickened by having the inflammatory ſymptoms ſomewhat increaſed, the addition of ſuch ſubſtances may then be of ſervice; but when ſtimulants are neceſſary in ſuch caſes, a ſmall proportion of ſtrained galbanum, or of any of the warm gums, diſſolved in the yolk of an egg, and added to the poultices, is a more certain form of applying them. Whenever the inflammation, however, takes place to a proper degree, ſuch ſtimulating ſubſtances never can be neceſſary; and in many caſes, it is apprehended, they may even do miſchief.

In ſuch tumors as, from their being poſſeſſed of little or no inflammation, are commonly ſaid to be of a cold nature, as they are generally indolent, and proceed very ſlowly to ſuppuration, plaſters compoſed of the warm gums are often had recourſe to with conſiderable advantage. In ſuch caſes, they are not only of uſe by the ſtimulus and irritation they occaſion, but by the heat which they tend to preſerve in the part. They become particularly neceſſary when the patient, by being obliged to go abroad, cannot have cataplaſms frequently enough renewed, or ſo coveniently applied; but when ſome ſuch objection does not occur, the latter, for very obvious reaſons, ſhould always be preferred.

45 Dry-cupping.

Dry cupping, as it is termed, that is, cupping without the uſe of the ſcarificator, upon or as near as poſſible to the part affected, is frequently had recourſe to with advantage in promoting the ſuppuration of tumors. It is only, however, in ſuch as theſe laſt mentioned, where there ſeems to be a deficiency of inflammation, that it can ever either be neceſſary or uſeful; but in all tumors of a real indolent nature, and where there is ſtill ſome probability of a ſuppuration, no remedy is more effectual.

Inflammation and Suppuration.

Theſe different applications, under the reſtrictions taken notice of, being continued for a longer or ſhorter time, according to the ſize of the tumor, its ſituation, and other circumſtances, a thorough ſuppuration may in general at laſt be expected.

46 Signs that matter is formed.

Matter being fully formed in a tumor, is known by a remiſſion of all the ſymptoms taking place; the throbbing pain, which before was frequent, now goes off, and the patient complains of a more dull, conſtant, heavy pain: the tumor points at ſome particular part, generally near to its middle; where, if the matter is not encyſted, or deep ſeated, a whitiſh yellow appearance is obſerved, inſtead of a deep red that formerly took place; and fluctuation of a fluid underneath is, upon preſſure, very evidently diſcovered. Sometimes, indeed, when an abſceſs is thickly covered with muſcular and other parts, though, from concurring circumſtances, there can be little doubt of there being even a very conſiderable collection of matter, yet the fluctuation cannot be readily diſtinguiſhed: it does not, however, often happen, that matter is ſo very deeply lodged as not to be diſcovered upon proper examination.

This, however, is a circumſtance of the greateſt conſequence in practice, and deſerves more attention than is commonly given to it. In no part of the ſurgeon's employment is experience in former ſimilar caſes of greater uſe to him than in the preſent; and however ſimple it may appear, yet nothing, it is certain, more readily diſtinguiſhes a man of obſervation and extenſive practice, than his being able eaſily to detect collections of deep ſeated matter; whilſt nothing, on the contrary, ſo materially affects the character of a ſurgeon, as his having, in ſuch caſes, given an inaccurate or unjuſt prognoſis; as the event, in diſorders of that nature, comes generally at laſt to be clearly demonſtrated to all concerned.

Together with the ſeveral local ſymptoms of the preſence of pus already enumerated, may be mentioned the frequent ſhiverings to which patients are liable on its firſt formation: theſe, however, ſeldom occur ſo as to be diſtinctly obſerved, unleſs the collection is conſiderable, or ſeated internally in ſome of the viſcera.

47 Of opening abſceſſes.

After the matter is fully formed, and the abſceſs brought to maturity, the only remedy is to open it, and give vent to the pus it contains. In many caſes, indeed, nature will do the work, and abſceſſes, when ſuperficially ſeated, will certainly burſt of themſelves: but where the matter lies deep, we are by no means to wait for this ſpontaneous opening; as the pus will acquire an acrimony before it can break through the integuments, which may prove very prejudicial to health. However, it is a general rule not to open abſceſſes till a thorough ſuppuration has taken place; for, when laid open long before that period, and while any conſiderable hardneſs remains, they commonly prove more troubleſome, and ſeldom heal ſo kindly.

In ſome caſes, however, it is neceſſary to deviate from this general rule, and to open them a good deal ſooner; particularly in all ſuch critical abſceſſes as occur in malignant fevers. In like manner, in the plague, we are commonly adviſed to open ſuch tumors, ſo ſoon as they are at all tolerably advanced, and not to wait till they are fully maturated; as, from experience in theſe diſorders, it is found to be of more conſequence, for the removal of the original diſeaſe, to have a quick diſcharge of matter produced, than any harm the patient can ſuffer from having a ſwelling ſomewhat prematurely laid open.

In abſceſſes, alſo, ſituated on any of the joints, or upon either

Inflammation and Suppuration.

either of the large cavities of the breaſt and abdomen, and more eſpecially when they ſeem to run deep, they ſhould always be opened as ſoon as the leaſt fluctuation of matter is diſcovered. For, when the reſiſtance is on every ſide equal, they juſt as readily point inwardly as outwardly: and the conſequence of a large abſceſs burſting into either of the large cavities, is well known moſt frequently to prove fatal: An inſtance of which, in the following caſe, with very little attention, might have been prevented. A ſurgeon of eminence, and of very extenſive practice, was applied to by a young healthy-looking man, with a large abſceſs upon the left ſide of his cheſt. A fluctuation of a fluid was, upon preſſure, very evidently diſcovered; and it was agreed by other two practitioners who were preſent, that an opening ſhould be made to give vent to the matter. But the operator, being much engaged in buſineſs, could not fix on an earlier period for doing it than the third day from the patient's applying to him: unluckily, however, the patient died ſuddenly in his bed the night before the abſceſs was to have been opened. On examining the body, the tumor had diſappeared entirely, without any external opening being obſervable; and, on opening the thorax, it was found to have burſt inwardly upon the lungs, and produced immediate ſuffocation.

In every other circumſtance, however, except in the caſes alluded to, the rule in opening abſceſſes is, as was already remarked, To allow a thorough ſuppuration to take place, before any vent whatever be given to the matter; and it being then determined to lay the collection open, the next queſtion that occurs, is with reſpect to the manner of doing it.

There are three ways of opening an abſceſs ſo as to give an outlet to the matter; by cauſtic, by inciſion, or by the introduction of a ſeton. The firſt is more agreeable to timid patients, who are afraid of the pain of inciſion, but is attended with ſome inconveniences which render the method of inciſion much preferable. Cauſtic acts ſlowly, and produces a long continued pain; beſides, no kind of cauſtic has yet been invented, the effects of which can be confined to a certain determinate extent; hence the patient is liable to ſuffer much unneceſſary pain, as the cauſtics commonly employed are either the lapis infernalis or lunar cauſtic. The abſceſs is to have a ſlip of adheſive plaſter applied to it, with a ſlit cut in it of a ſize ſomewhat leſs than the opening is intended to be. This ſlit is to be filled with cauſtic reduced into a powder, and wetted to make it act more quickly. It is then to be covered over with a plaſter, and the whole is ſecured with a firm compreſs and bandage. The time neceſſary for the cauſtic to make a ſufficient opening will depend upon the thickneſs of the ſkin, and ſtrength of the cauſtic; but generally it requires ſeveral hours. When we find that an eſchar is made, it is to be ſoftened with any emollient ointment until it can be readily ſeparated; after which, the matter is to be diſcharged, and the abſceſs treated as one opened by inciſion.

48 By cauſtic,

The method of opening abſceſſes by the knife is, to make an inciſion of ſuch a ſize as to give free vent to the matter. The opening is to be made in the under part of the tumor, that the matter may paſs readily out. It has been a practice among ſurgeons either to open a large abſceſs from end to end, or at leaſt through two-thirds of its length; but from the bad conſequences which often attend this method, the lateſt practitioners have thought it better merely to give a free diſcharge to the matter, without expoſing the part to the action of the air.

49 By the knife,

The third method, viz. that by the ſeton, is now frequently employed. It has the advantage of being attended with little pain, emptying the abſceſs in a gradual manner, and completely preventing the acceſs of the air, which, in the other two methods, is often attended with bad conſequences; and it frequently performs a cure in a much ſhorter time.

50 By a ſeton.

There are various inſtruments for introducing the ſeton: it may even frequently be done by a lancet and common probe; but the inſtruments repreſented in Plate CCCCLXXXVII. fig. 1. and 2. are more frequently employed. One of theſe being threaded with glover's ſoft ſilk, is to be introduced through the upper part of the tumor; but if the blunt one (fig. 2.) be employed, it will be neceſſary to have the aſſiſtance of a lancet; the inſtrument is then to be brought out at the under part of the tumor, and in this way the matter will be allowed to run gradually off.

The uſual mode of dreſſing an abſceſs the firſt time is with dry lint. In the courſe of dreſſing, it will be proper to have regard to the ſituation of the abſceſs, and as much as poſſible to make the patient favour the diſcharge by his ordinary poſture: and to this end alſo, the diſcharge muſt be aſſiſted by compreſs and bandage: the compreſs may be made of ſoft old linen, applied according to the nature of the part and the ſeaſon of the year. The frequency of dreſſing will depend on the quantity of diſcharge: once in 24 hours is ordinarily ſufficient; but ſometimes twice, or perhaps three times, is neceſſary.

SECT. II. *Of Gangrene.*

Gangrene.

THE other conſequence of inflammation is gangrene, which may terminate in mortification. When the colour of an inflamed part changes to a dark red, when bliſters ariſe on it containing an ichorous fluid, we know that it has become gangrenous. When it becomes black, flaccid, and inſenſible, when it loſes heat, and acquires a putrid ſmell, it has proceeded to complete mortification. A gangrene ſeldom affects thoſe who enjoy a good habit of body, though even in them, it may be brought on accidentally by whatever deſtroys the texture of *a part*; as contuſion, long continued preſſure, or whatever deprives *a part* of its nouriſhment. In like manner, cold, by putting a ſtop to the circulation, may produce gangrene, and frequently does ſo in cold climates. This comes on ſuddenly, without any pain or previous inflammation; and the patient himſelf is frequently inſenſible of it, till he is informed of his ſituation by ſome other perſon.

A defect in the circulation, in extreme old age, frequently occaſions mortification in the extremities.

51 Dry gangrene.

There are ſome inſtances of what is called *dry gangrene*, in which the parts continue totally mortified for a great length of time, without either turning very flaccid, or running into diſſolution. But ſuch caſes never occur from inflammation; they happen commonly from the flow of blood to ſuch parts being put a ſtop to by compreſſion of one kind or another, as tumors, ligatures, or other ſimilar cauſes, obſtructing the principal arteries which uſed to ſupply them; which, when the ſtoppage of the circulation is complete, always occaſions a very ſlow, tedious, mortification; and as the parts in ſuch inſtances are no longer ſupplied with freſh quantities of fluids, while a conſiderable evaporation muſt ſtill be going on, ſuch a degree of humidity cannot therefore poſſibly occur as does in other caſes of gangrene. So that ſpecies of the diſorder has, perhaps, with propriety enough, been termed the *dry gangrene*.

52 White gangrene.

There is another variety of the diſeaſe termed *white gangrene*; in which the parts ſuppoſed mortified do not turn black, but retain nearly their former colour, &c. Whether ſuch a complaint, however, can with propriety be denominated *gangrene* or not, may properly be doubted: but as it is chiefly that ſpecies of the diſorder which ſucceeds inflammation,

Gangrene.

mation that is here particularly treated of, and in which no such varieties are ever obſerved, it is not neceſſary to carry the inquiry farther.

53 Prognoſis.

The prognoſis in every caſe of gangrene is doubtful at firſt, as, even in the ſlighteſt caſes, the patient may ſuffer from the ſpreading of the diſeaſe; but ſlight caſes, from external injuries, are more favourable than thoſe which ariſe from internal cauſes, though no perſon can be conſidered ſafe till the diſeaſed parts are ſeparated, and even entirely caſt off. When inflammation happens round a mortified part, more eſpecially if pus be formed, we may pretty certainly pronounce that the mortified part will be thrown off.

54 Means of preventing gangrene ariſing from inflammation.

When there is reaſon to ſuſpect from the violence of the fever and great heat of the inflamed part, that it will terminate in gangrene, blood-letting, and whatever may have a tendency to moderate the inflammation, may check its progreſs. But as the patient, in ſuch caſes, is ſometimes apt to ſink afterwards, nothing more ought to be done than is merely neceſſary to moderate the preſent ſymptoms. If an inflamed ſurface put on a gangrenous appearance when the patient is weak, and the pulſe low, we muſt have recourſe to whatever may invigorate the ſyſtem, viz. a nouriſhing diet, with the free uſe of wine. Peruvian bark likewiſe is to be given in as great quantities as the ſtomach of the patient will permit. When the ſtomach cannot bear enough in ſubſtance, which is the beſt form of exhibiting it, it may be given either in form of tincture or joined with aromatics. External applications, ſuch as are of a ſtimulating nature, may likewiſe be uſeful.

55 Ariſing from cold.

In the caſe of gangrene ariſing from cold, the part muſt be immerſed in very cold water, or rubbed with ſnow; for if any thing warm be applied, or the patient brought near a fire, it certainly mortifies. If the whole body has become torpid with cold, the ſame practice muſt be followed; the very cold water ſhould be afterwards changed for ſome that is a little warmer, and the patient gradually brought to a proper degree of heat. Rubbing with ſalt is ſometimes found uſeful. If the whole body be benumbed, cordials are not to be adminiſtered too ſuddenly. A glaſs of cold wine ſhould firſt be given, afterwards warm wine by itſelf, or with ſpices. If ſtronger cordials be required, ardent ſpirits may be employed. Notwithſtanding the greateſt attention, however, a mortification ſometimes takes place, and in ſome inſtances very ſuddenly; as in the caſe of carbuncle, where, after an inflammation has continued for ſcarcely 24 hours, the parts become black, and end in real mortification.

56 Scarifications and external applications to mortified parts improper.

In the treatment of mortified parts, a variety of external applications have been pointed out, and particularly thoſe of the antiſeptic kind; ſuch as all the warm gums and balſams, ardent ſpirits, and even alcohol: and to admit of their nearer application to the ſound parts, with a view to the preſervation of theſe from putrefaction, deep ſcarifications through the diſeaſed, and into the found parts, have been generally recommended. But although ſuch articles may be of uſe in preſerving dead animal-ſubſtances from corruption; yet that they will always prove ſerviceable in the ſame manner in living bodies, is probably very much to be doubted. And it is even apprehended, by the ſtrong irritation they always occaſion when applied to a living fibre, that, in ſuch caſes as the preſent, they may rather do miſchief; it being only a very ſlight degree of inflammation that is required to bring on a ſuppuration. The inciſions, when carried into the ſound parts, with a view to facilitate the operation of ſuch remedies, may likewiſe do harm; not only from the riſk of wounding the blood-veſſels, nerves, and tendons, that lie in the way, but alſo by allowing a free and farther entrance of the putreſcent fluids into the parts not yet affected: and unleſs they are carried ſo deep as freely to reach the ſound parts, applications of the antiſeptic kind can never have any effect in anſwering the purpoſe for which they were intended. Ulcers.

All the advantages commonly obſerved from the great variety of applications recommended for gangrene, are obtained with more eaſe, and generally with more certainty, from the uſe of any gentle ſtimulating embrocation; which, by exciting a ſlight irritation upon the ſurface, and eſpecially when aſſiſted by a free uſe of the bark, at laſt commonly produces ſuch a degree of inflammation as is wiſhed for. With this view, a weak ſolution of ſal ammoniac in vinegar and water has been known to anſwer exceedingly well: a dram of the ſalt to two ounces of vinegar and ſix of water, form a mixture of a very proper ſtrength for every purpoſe of this kind; but the degree of ſtimulus can be eaſily either increaſed or diminiſhed according to circumſtances, by uſing a larger or ſmaller proportion of the ſalt.

Although, for the reaſons formerly advanced, inciſions may not in general be proper; yet in ſuch caſes where the mortification runs very deep, it is ſometimes of ſervice to make ſcarifications into the diſeaſed parts, ſo as to remove part of them; which, by taking off a conſiderable load perhaps of putrid fleſh, not only leſſens the fetor, which in ſuch caſes is always conſiderable, but often render it more eaſy for the ſound parts to free themſelves from the remainder. When with this view, however, inciſions are had recourſe to, care ſhould always be taken that they be not carried the length of the ſound parts.

When by the uſe of external or internal remedies, a ſeparation of the mortified part has been effected, and a diſcharge of pus produced, the remaining ſore is then to be conſidered merely as a ſimple purulent ulcer, and may be treated in the ſame manner.

CHAP. IV. *Of Ulcers, White Swellings, Cancers, and Burns.*

SECT. I. *Of Ulcers.*

A SOLUTION of continuity in any of the ſofter parts of the body, diſcharging either pus, ſanies, or any other vitiated matter, is termed *ulcer*; and when the ſame circumſtances happen to the bones, the term *caries* or *carious ulcer* is adopted.

57 Different kinds of ulcers.

Ulcers are diſtinguiſhed by their particular diſorders, though it ſeldom happens that the affections are not complicated; and when we lay down rules for the management of one ſpecies of ulcer, it is generally requiſite to apply them to almoſt all others. However, the characters of moſt eminence are, the callous ulcer, the ſinuous ulcer, and the ulcer with caries of the adjacent bone: beſides this there is the putrid, the corroſive, the varicoſe ulcers, &c.; but as they have acquired their names from ſome particular affection, we ſhall ſpeak of the treatment of them under the general head of ulcers.

It will be often in vain to purſue the beſt means of cure by topical application, unleſs we are aſſiſted by internal remedies; for as many ulcers are the effects of a particular indiſpoſition of body, it will be difficult to bring them into order while the cauſe of them remains. Thoſe which are cancerous and ſcrophulous ſeem to gain the leaſt advantage from phyſic; for if in their beginnings they have ſometimes been very much relieved, or cured, by ſalivation, or any other evacuation, they are alſo often irritated and made worſe by them.

58 Of callous ulcers.

When an ulcer becomes foul, and diſcharges a naſty thin ichor, the edges of it, in proceſs of time, tuck in, and, growing ſkinned and hard, give it the name of a *callous ulcer;*

Ulcers. cer; which, as long as the edges continue in that ſtate, muſt neceſſarily be prevented from healing. But we are not immediately to deſtroy the lips of it, in expectation of a ſudden cure; for while the malignity of the ulcer remains which was the occaſion of the calloſity, the new lips will be ſubject to a relapſe of the ſame kind, however often the external ſurface of them be deſtroyed: we are to endeavour to bring the body of the ulcer into a diſpoſition to recover by other methods. It ſometimes happens to poor laborious people, who have not been able to afford themſelves reſt, that lying a-bed will in a ſhort time give a diverſion to the humours of the part, and the callous edges, ſoftening, will without any great aſſiſtance ſhoot out a cicatrix, when the ulcer is grown clean and filled with good fleſh. The effect of a ſalivation is generally the ſame; and even an iſſue ſometimes diſpoſes a neighbouring ulcer to heal. But though calloſities be frequently ſoftened by theſe means, yet when the ſurface of the ulcer begins to yield thick matter and little granulations of red fleſh ſhoot up, it will be proper to quicken nature by deſtroying the edges of it, if they remain hard. The manner of doing this, is by touching them a few days with the lunar cauſtic, or *lapis infernalis*. Some chooſe to cut them off with a knife: but this is very painful, and not more efficacious. When the lips do not tuck down cloſe to the ulcer, but hang looſe over it, as in ſome venereal buboes, the eaſieſt method is to cut them off with the ſciſſars.

To digeſt the ulcer or to procure good matter from it when in a putrid ſtate, there are an infinity of ointments invented; but the baſilico flavum, alone, or ſoftened down ſometimes with turpentines, and ſometimes mixed up with different proportions of red precipitate, ſeems to ſerve the purpoſe of bringing an ulcer to cicatrization as well as any of the others. When the ulcer is incarned, the cure may be finiſhed as in other wounds; or if it do not cicatriſe kindly, it may be waſhed with aq. calcis, or aq. phag. or dreſſed with a pledgit dipt in tinct. myrrhæ: and if excoriations are ſpread round the ulcer, they may be anointed with ſperm. cet. ointment, or any other ſoft ointment.

The red precipitate has of late years acquired the credit it deſerves for the cure of ulcers; but, by falling into general uſe, is very often unſkilfully applied; when mixed with the baſilicon, or, what is nearer, a cerate of wax and oil, it is moſt certainly a digeſtive, ſince it hardly ever fails to make the ulcer yield a thick matter in 24 hours, which diſcharged a thin one before the application of it.

59 Of deſtroying fungous fleſh. If the ulcer produces a ſpongy fleſh, ſprouting very high above the ſurface, it will be neceſſary to deſtroy it by ſome of the eſcharotics, or the knife. This fungus differs very much from that belonging to healing wounds, being more eminent and lax, and generally in one maſs; whereas the other is in little diſtinct protuberances. It approaches often towards a cancerous complexion, and when it riſes upon ſome glands ſometimes actually degenerates into a cancer. When theſe excreſcences have ariſen in venereal ulcers, eſcharotics ſhould be applied. Thoſe in uſe, are the vitriol, the lunar cauſtic, the lapis infernalis, and more generally the red precipitate powder.

It is but ſeldom that theſe inveterate funguſes appear on an ulcer; but it is very uſual for thoſe of a milder kind to riſe, which may often be made to ſubſide by preſſure and the uſe of mild eſcharotics: however, if the aſpect of the ſore be white and ſmooth, as happens in ulcers accompanied with a dropſy, and often in young women with obſtructions, it will anſwer no purpoſe to waſte the excreſcences until the conſtitution is repaired, when moſt probably they will ſink without any aſſiſtance. In ulcers alſo, where the ſubjacent bone is carious, great quantities of looſe flabby fleſh will grow up above the level of the ſkin: but as the caries is the cauſe of the diſorder, it will be in vain to expect a cure of the excreſcence until the rotten part of the bone be removed; and every attempt with eſcharotics will be only a repetition of pain to the patient, without any advantage. Ulcers.

When the pain and inflammation are exceſſive, bleeding and other evacuations will often be ſerviceable; and above all things, reſt and a horizontal poſition; which laſt circumſtance is of ſo great importance to the cure of ulcers of the legs, that unleſs the patient will conform to it ſtrictly, the ſkill of the ſurgeon will often avail nothing: for as the indiſpoſition of theſe ſores is in ſome meaſure owing to the gravitation of the humours downwards, it will be much more beneficial to lie along than ſit upright, though the leg be laid on a chair; ſince even in this poſture they will deſcend with more force than if the body was reclined.

60 Ulcers accompanied with varices. In ulcers of the legs, accompanied with varices or dilatations of the veins, the method of treatment will depend upon the other circumſtances of the ſore; for the varix can only be aſſiſted by the application of bandage, which muſt be continued a conſiderable time after the cure. The neateſt bandage is the laced ſtocking, which is particularly ſerviceable in this caſe; though alſo, if the legs be œdematous, or if, after the healing of the ulcers, they ſwell when the patient quits his bed, it may be worn with ſafety, and advantage. There are inſtances of one vein only being varicous; which, when it happens, may be deſtroyed by tying it above and below the dilatation, as in an aneuriſm; but this operation ſhould only be practiſed where the varix is large and painful.

61 Cure of old ulcers dangerous. Ulcers of many years ſtanding are very difficult of cure; and in old people the cure is often dangerous, frequently exciting an aſthma, a diarrhœa, or a fever, which deſtroys the patient, unleſs the ſore break out again: ſo that it is not altogether adviſable to attempt the abſolute cure in ſuch caſes; but only the reduction of them into better order, and leſs compaſs, which, if they be not malignant, is generally done with reſt and proper care. The cure of theſe in young people may be undertaken with more ſafety; and in all caſes of ſtubborn ulcers, the bark, very copiouſly given, will be found of the utmoſt ſervice.

62 Of ſinuous ulcers. When an ulcer or abſceſs has any ſinuſes or channels opening and diſcharging themſelves into the ſore, they are called *ſinuous ulcers*. Theſe ſinuſes, if they continue to drain a great while, grow hard in the ſurface of their cavity, and then are termed *fiſtulæ*, and the ulcer a *fiſtulous ulcer*; alſo, if matter be diſcharged from any cavity, as thoſe of the joints, abdomen, &c. the opening is called a *ſinuous ulcer* or a *fiſtula*.

The treatment of theſe ulcers depends upon a variety of circumſtances. If the matter of the ſinus be thick, ſtrict bandage and compreſs will ſometimes bring the oppoſite ſides of the ſinus to a reunion: if the ſinus grow turgid in any part, and the ſkin thinner, ſhowing a diſpoſition to break, the matter muſt be made to puſh more againſt that part, by plugging it up with a tent; and then a counter opening muſt be made, which proves often ſufficient for the whole abſceſs, if it be not afterwards too much tented, which locks up the matter and prevents the healing; or too little, which will have the ſame effect: for dreſſing quite ſuperficially does ſometimes prove as miſchievous as tents, and for nearly the ſame reaſon; ſince ſuffering the external wound to contract into a narrow orifice before the internal one be incarned, does almoſt as effectually lock up the matter as a tent. To preſerve, then, a medium in theſe caſes, a hollow tent of lead or ſilver may be kept in the orifice, which, at the ſame time that it keeps it open, gives vent to the matter. The abſceſſes where the counter opening is made. 63 Treatment.

Ulcers.

made moſt frequently are thoſe of compound fractures, and the breaſt: but the latter do oftener well without dilatation than the former; though it muſt be performed in both, if practicable, the whole length of the abſceſs, when after ſome trial the matter does not leſſen in quantity, and the ſides of it grow thinner; and if the ſinuſes be fiſtulous, no cure need be expected without dilatation.

When an ulcer with looſe rotten fleſh diſcharges more than the ſize of it ſhould yield, and the diſcharge is oily and ſtinking, in all probability the bone is carious; which may eaſily be diſtinguiſhed by running the probe through the fleſh: and if ſo, it is called a *carious ulcer*. The cure of theſe ulcers depends principally upon the removal of the rotten part of the bone, without which it cannot heal. Thoſe caries which happen from the matter of abſceſſes lying too long upon the bone, are moſt likely to recover: thoſe of lues venerea very often do well, becauſe that diſtemper fixes ordinarily upon the middle and outſide of the denſeſt bones, which admit of exfoliation; but thoſe produced by ſcrophula, where the whole extremities of the ſpongy parts of the bone are affected, are exceedingly dangerous.

64 Of carious ulcers.

All enlarged bones are not neceſſarily carious; and there are ulcers ſometimes on the ſkin which covers them, which do not communicate with the bone, and conſequently do well without exfoliation: nay, it ſometimes happens, though the caſe be rare, that, in young ſubjects particularly, the bones will be carious to ſuch a degree, as to admit a probe almoſt through the whole ſubſtance of them; and yet afterwards admit of a cure, without any notable exfoliation.

65 Treatment.

The method of treating an ulcer with caries, is by applying a cauſtic of the ſize of the ſcale of the bone which is to be exfoliated; and after having laid it bare, to wait till the carious part can without violence be ſeparated, and then heal the wound. In order to quicken the exfoliation, there have been ſeveral applications deviſed; but that which has been moſt uſed in all ages, is the actual cautery, with which ſurgeons burn the naked bone every day, or every other day, to dry up, as they ſay, the moiſture, and by that means procure the ſeparation: but as this practice is never of great ſervice, and always cruel and painful, it is now pretty much exploded. Indeed, from conſidering the appearance of a wound, when a ſcale of bone is taken out of it, there is little doubt that burning retards rather than haſtens the ſeparation; for as every ſcale of a carious bone is flung off by new fleſh generated between it and the ſound bone, whatever would prevent the growth of theſe granulations would alſo in a degree prevent the exfoliation; which muſt certainly be the effect of a red hot iron applied ſo cloſe to it.

Some caries of the bones are ſo very ſhallow, that they crumble inſenſibly away, and the wound fills up; but when the bone will neither exfoliate nor admit of granulations, it will be proper to ſcrape it with a rugine, or perforate it in many points with a convenient inſtrument down to the quick. In ſcrophulous caſes, the bones of the carpus and tarſus are often affected; and from their ſponginеſs they are ſeldom cured: ſo that when theſe, or indeed the extremities of any of the bones, are carious through their ſubſtance, it is adviſable to amputate; though there are inſtances in the ſcrophula, but more eſpecially in critical abſceſſes, where, after long dreſſing down, the ſplinters, and ſometimes the whole ſubſtance, of the ſmall bones, have worked away, and a healthy habit of body coming on, the ulcer has healed; but theſe are ſo rare, that no great dependence is to be laid on ſuch an event. The dreſſings of carious bones, if they are ſtinking, may be doſſils dipped in the tincture of myrrh; otherwiſe thoſe of dry lint are eaſieſt, and keep down the edges of the ulcer better than any other gentle application.

White Swellings.

SECT. II. *Of White Swellings.*

THERE are two ſpecies of white ſwellings, Mr Benjamin Bell obſerves; the one of a mild nature, and frequently admitting of a cure; which the other never does. The former, named by our author the *rheumatic* ſpecies of white ſwelling, begins with an acute pain, ſeemingly diffuſed over the whole joint, and frequently extending along the tendinous aponeuroſes of the muſcles which communicate with it. There is, from the beginning, an uniform ſwelling of the whole ſurrounding integuments. Great tenſion generally prevails; but at firſt there is ſeldom any external change of colour. From the commencement of the diſeaſe the motion of the joint is attended with exquiſite pain, and the patient keeps it conſtantly in a relaxed poſture, finding that the eaſieſt. Hence the tendons become extremely ſtiff and rigid, till at laſt the joints have the appearance of complete and real anchyloſes. The ſwelling now begins to augment, till the joint has acquired three or four times its natural ſize; the cuticular veins become turgid and varicoſe; at the ſame time that the muſcular ſubſtance of the limb below decays, though it frequently acquires an equality in ſize by becoming œdematous; the pain becomes intolerable, eſpecially when the perſon is warm in bed or otherwiſe heated; abſceſſes form in different parts, which, either breaking of themſelves, or by being laid open, diſcharge conſiderable quantities of matter, but without any remarkable effect in reducing the ſize of the ſwelling. The pus diſcharged from theſe is at firſt of a tolerable good conſiſtence, but ſoon degenerates into a thin ill-conditioned ſanies. However, the orifices from whence it flows ſoon heal up, unleſs they are kept open by art; and new collections breaking out, they burſt and heal up as before; ſo that in long-continued diſorders of this kind, the ſurrounding integuments are often entirely covered with cicatrices.

66 Rheumatic white ſwelling.

In the mean time, the health of the patient gradually declines, from the violence of the pain, and the abſorption of matter into the ſyſtem, which takes place in ſome degree from its firſt formation in the different abſceſſes; but which never appears ſo evidently till the different abſceſſes have been laid open; after which a quick pulſe, night-ſweats, and a weakening diarrhœa, are ſure to occur, which generally carry off the patient, if the member is not either amputated, or the diſeaſe cured ſome other way.

67 Appearance of the affected limbs on diſſection.

On diſſecting limbs which have been amputated for white ſwellings, the original diſeaſe appears to have been a morbid thickening of the ſurrounding ligaments, without any other affection of the joint whatever; the bones and cartilages always remaining perfectly ſound, as likewiſe the ſynovia both in quantity and conſiſtence. In the more advanced ſtages of the diſorder, the thickneſs of the ligaments is more conſiderable, and is generally attended with an effuſion, into the ſurrounding cellular ſubſtance, of a thick glairy matter, which gives to ſwellings of this kind an elaſtic ſpringy feel, independent of the collections of matter the fluctuation of which may alſo be perceived. Through this glairy matter the collections of pus run in various directions, without ſeeming, however, to mix with it. In ſome inſtances alſo a great many ſmall hydatides are obſerved; all which form a confuſed maſs, incapable of further diſſection.

All the abovementioned appearances have been obſerved without any affection of the bones or cartilages. But when, by a very long continuance of the diſorder the ligaments come to be corroded by the different collections of matter

White Swellings.

matter, the cartilages and in conſequence thereof the bones, ſoon begin to ſuffer. The tendons of the flexor muſcles, though very ſtiff and contracted, do not, upon diſſection, ſhow any ſigns of diſeaſe.

68 Scrophulous white ſwelling.

The above is an hiſtory of the mildeſt ſpecies of white ſwelling; the more inveterate kind our author names the *ſcrophulous white ſwelling*. In this the pain is commonly very violent; more acute than in the former; and, inſtead of being diffuſed, is confined to a particular ſpot commonly the very middle of the joint. The ſwelling is commonly inconſiderable at firſt; inſomuch that, on ſome occaſions, even when the pain has been very violent, little difference in point of ſize could be obſerved between the diſeaſed and the ſound joint. The motion of the joint is attended with very great pain, and the tendons become ſtiff. As the diſorder advances, the pain becomes more violent, and the ſwelling increaſes, with an evident enlargement of the ends of the bones. The ſame elaſtic feel, together with ſimilar abſceſſes, occur in this as in the laſt: but upon opening them they commonly diſcharge a thin fetid ſtuff; the bones are found to be carious, and pieces of them are frequently diſcharged at the openings.

By the continuance of the diſorder, the conſtitution ſuffers, as in the firſt ſpecies of the diſeaſe; and a diarrhœa with night-ſweats commencing, the patient is ſoon reduced to little more than ſkin and bone.

69 Appearances on diſſection.

Upon ſuch joints being diſſected in the firſt ſtages of the diſorder, the ſoft parts ſeem very little affected: but there is conſtantly obſerved an enlargement either of the whole ends of the bones, or of their epiphyſes; frequently of thoſe on one ſide of the joint only; in others, again, the bones on both ſides have been affected.

This enlargement ſometimes occurs without any other evident diſeaſe: but in general, and always in a more advanced ſtate of the complaint, the ſoft ſpongy parts of ſuch bones appear diſſolved into a thin, fluid, fetid matter; and that too, in ſome caſes, without the cartilages which ſurround them ſeeming much affected. In proceſs of time the cartilages are likewiſe diſſolved; and then the matter of the bones and ſofter parts mixing together, ſuch ſwellings exhibit in that ſtate a ſtill more confuſed collection than is generally obſerved even in the worſt ſtages of the other ſpecies of the diſorder.

In the farther progreſs of this diſeaſe the ſurrounding ſoft parts likewiſe ſuffer: The ligaments become thickened, and the contiguous cellular membrane is ſtuffed with the viſcid glairy matter obſerved in the other ſpecies of the diſorder.

We come now to the conſideration of the different cauſes which tend to produce this diſeaſe. That the ligaments of the joints only are firſt affected in this diſorder is rendered evident by diſſection. The thick glairy effuſions into the cellular membrane are probably occaſioned by an exudation from the veſſels of thoſe ligaments that have been originally inflamed, as ſuch parts never furniſh a proper fluid for the formation of purulent matter: In the courſe of the diſeaſe, indeed, abſceſſes containing real pus always appear; but never till inflammation has been communicated to the ſurrounding parts. We may conclude, therefore, that the firſt ſpecies of white ſwelling is always occaſioned by an *inflammatory* or *rheumatic affection* of the ligaments of ſuch joints as it attacks, from whatever cauſe ſuch inflammation may originally have proceeded.

The other ſpecies of the diſorder ſeems to be originally an affection of the bones; the ſurrounding ſoft parts coming only to ſuffer in the progreſs of the diſeaſe from their connection with and vicinity to theſe. This laſt ſpecies of white ſwelling generally begins without the patient being in the leaſt able to account for it: and from the effects which it produces on the bones attacked, appears to be a ſpecies of *ſpina ventoſa*; a diſeaſe of the bones probably of the ſame nature as ſcrophula is of the ſoft parts. Indeed, the appearances of the two diſorders, after making allowance for their different ſituations, are exceedingly ſimilar: they both begin with conſiderable enlargements or ſwellings of the parts, which generally end in ulcerations; they both likewiſe frequently occur in the ſame perſon at the ſame time. This ſpecies of white ſwelling is generally either attended with other evident ſymptoms of ſcrophula; or the patient, in an early period of life, has been ſubject to that diſeaſe; or, which is nearly the ſame, he is deſcended from ſcrophulous parents, and probably has the ſeeds of that diſeaſe lurking in his conſtitution. From all theſe circumſtances, it may with probability be concluded, that this ſpecies of white ſwelling is of a ſcrophulous nature: and ſince the other ſpecies of the diſorder is to be conſidered as an inflammatory affection, a thorough diſtinction between them is of very great importance; it will not be improper therefore to give a ſhort enumeration of the ſeveral diagnoſtic or moſt characteriſtic ſymptoms of each.

White Swellings.

The pain in the firſt ſpecies is always, from the beginning, diffuſed over the whole joint, and ſometimes extends a conſiderable way along the muſcles that are attached to it: in the other ſpecies it is always at firſt, and ſometimes even when the complaint has been of conſiderable ſtanding, confined to a very ſmall circumſcribed ſpace. In the former, the ſwelling is always confined to the ſoft parts, and is from the beginning exceedingly evident: but in the latter, it is generally for ſome time hardly perceptible; and when it appears the bones are the parts chiefly affected, the ſurrounding teguments coming only to ſuffer on a farther progreſs of the diſeaſe. Theſe are the chief local differences of the two ſpecies of this diſorder; but ſome aſſiſtance in the diſtinction may likewiſe be obtained from the general habit of the patient, and from the manner in which the complaint may ſeem to have been produced. Thus, when ſuch ſwellings occur in young, ſtrong, plethoric, people, eſpecially in ſuch as have formerly been ſubject to rheumatiſm, they moſt probably will always prove of the mildeſt or rheumatic ſpecies of the diſorder: But when they appear in patients of ſcrophulous diſpoſitions, we need be under very little doubt in concluding them to be of a ſcrophulous nature.

The great utility of properly diſtinguiſhing the two different ſpecies of white ſwellings appears in no circumſtance ſo evident as in the treatment. In the one, there being ſome chance, by proper remedies, of being ſerviceable to the patient; whereas in the other, viz. the ſcrophulous, it is not probable that art will ever be able to afford much aſſiſtance.

71 Treatment in the rheumatic white ſwelling.

In the rheumatic white ſwelling, as it is always at firſt evidently of an inflammatory nature, conſiderable advantages are commonly obtained by a due attention to a proper cooling courſe. The firſt remedy which, with this view, ſhould be put in practice, is blood-letting immediately from the part affected. Cupping and ſcarifying is here a principal remedy. The inſtrument ſhould be applied to each ſide of the diſeaſed joint; on each ſide of the rotula, for inſtance, when the knee is the part affected, and at leaſt eight or ten ounces of blood diſcharged; and this to be repeated at proper intervals, once, twice, or oftener, according to the violence of the ſymptoms and ſtate of the patient's ſtrength at the time.

Cupping is, in theſe caſes, much ſuperior to leeches, becauſe it is more expeditious, and becauſe of the ſwelling occaſioned by the application of any conſiderable number of

White Swellings.

theſe animals proves frequently very troubleſome, and ſometimes interrupts for a time the uſe of other remedies.

Upon the anterior part of the joint, where the cupping-glaſſes have not been placed, a ſmall bliſter ſhould be directly applied, and the part kept open with iſſue ointment, till the wounds from the ſcarificator are ſo far healed that a veſicatory may likewiſe be laid on one ſide of the joint; and ſo ſoon as that is nearly healed, the other ſide ſhould be alſo bliſtered. By thus alternately applying them, firſt to the one ſide and then to the other, almoſt a conſtant ſtimulus is kept up; which, in deep-ſeated inflammations, ſeems to have fully a greater influence than all the diſcharge occaſioned by bliſters. Gentle cooling laxatives at proper intervals are alſo of uſe; and the patient ſhould, in every reſpect, be kept upon a ſtrict antiphlogiſtic courſe, both as to diet and every other circumſtance.

It is in the firſt ſtages only of the diſeaſe that ſuch a courſe can be of much ſervice; and in ſuch it has frequently been a means of curing diſorders which otherwiſe might have proceeded to the laſt ſtages of white ſwellings.

The original inflammatory affection being once over, theſe ſort of drains ſeem to have little or no influence, and ought not then to be long perſiſted in, as they prevent the uſe of other remedies, which in an advanced ſtate of the diſeaſe, are commonly more efficacious.

The inflammation being moſtly gone, and while there are yet no appearances of the formation of matter, mercury has ſometimes been known of uſe; not given ſo as to ſalivate, but merely to affect the mouth gently, and to keep it ſomewhat ſore for a few weeks.

The beſt form of uſing it is by way of unction, as it allows, at the ſame time, the application of friction; which, in all ſuch ſwellings, may of itſelf be in ſome meaſure conſidered as a remedy. For this purpoſe, an ointment of quickſilver and hog's lard ſhould be prepared; but with ſo ſmall a proportion of the former, that the patient may admit of two drams of the ointment being rubbed in three times a-day. In order to rub that quantity of the medicine in with gentle friction, an hour each time is at leaſt neceſſary; for in the ordinary way of continuing friction for a few minutes only, it can ſeldom have much influence.

By Le Dran, and other French writers, falls of warm water on ſwellings of this nature are much recommended; and there is no doubt, that a long continued and reiterated application of that remedy may, in the firſt ſtages of ſuch complaints, be often attended with very good effects. By a proper uſe of theſe different applications, viz. of the ſeveral topical remedies in the firſt or inflammatory ſtate of the diſeaſe, and afterwards (ſtill, however, before the formation of matter) of mercurials, friction, &c. many affections of this nature have been entirely removed.

It frequently happens, by the bent poſition the limb has been for a long time kept in, that the uſe of the joint comes to be entirely loſt, having often acquired ſuch a degree of ſtiffneſs, that any attempts to move it are commonly attended with very great pain. This has been conſtantly attributed to one or other of two different cauſes, which are both in their nature incurable, viz. either to the ends of ſuch bones as compoſe the joints having run into one another, ſo as to become firmly conjoined in conſequence of the ſurrounding cartilages being abraded; or to the inſpiſſation, as it is termed, of the ſynovia of the joints, whereby their cavities are entirely filled up, and no ſpace left for the future motion of the bones.

Both theſe opinions, however, are in general very ill founded: as the ſtiffneſs almoſt always proceeds from a contraction of the muſcles and tendons. It may often be cured by a long continued uſe of emollients.

The beſt emollient that can be uſed is pure olive oil applied warm; as much of it as can be eaſily rubbed in by an hour's gentle friction ſhould be regularly done at leaſt three times a-day; and inſtead of confining the friction altogether to the rigid tendons, it ſhould be extended over the whole muſcles, even to the inſertions of their other extremities; but more eſpecially on their fleſhy muſcular parts, where the principal cauſe of the continuance of ſuch complaints is probably ſeated. White Swellings.

The web or omentum of a new-killed ſheep, or of any other animal, applied over all the diſeaſed parts directly on being cut out of the animal, is ſometimes attended with advantage. The application ſhould be renewed as frequently as poſſible, once a day at leaſt, or oftener when it can be done; for on being more than four or five hours applied it becomes diſagreeable; and after that time, indeed, as it commonly turns ſtiff, it cannot then probably be of much ſervice.

The diſorder has hitherto been ſuppoſed not to be ſo far advanced as to have occaſioned the formation of matter; for when come that length, no conſiderable advantages can be expected from any of the remedies as yet recommended: but even in that ſtate of the complaint, if the patient's health does not abſolutely require it, amputation of the member ſhould not be immediately had recourſe to. For by opening the different abſceſſes ſoon after their formation, the matter may be prevented from deſtroying the capſular ligaments of the joints, which, if once effected, would no doubt render that operation neceſſary. Even in point of ſucceſs from the operation, it ought never to be adviſed till the complaint is pretty far advanced. For in this diſorder, eſpecially, a greater proportion of patients have recovered after amputation, who have previouſly been conſiderably reduced by diarrhœas and other weakening ſymptoms, than of ſuch as have ſtill remained in a full plethoric habit of body. Bell's Surgery. 72 When amputation ſhould be performed.

All the different obſervations hitherto made upon the treatment relate particularly to the rheumatic ſpecies of the diſorder; and when had recourſe to in time, and duly perſiſted in, they will frequently be found of ſervice: but when the diſeaſe is ſo far advanced as to have deſtroyed the capſular ligaments of the joint, and perhaps even the cartilages and bones themſelves, amputation of the member is then no doubt the only reſource.

In the ſcrophulous white ſwellings, when the diſeaſed parts of the bone begin to caſt off, a cure may in that way, by aſſiſting the efforts of nature, be ſometimes obtained in the ſmall joints; but in all the large joints, as the knee, ankle, &c. it is not probable that any other reſource than amputation will ever afford much relief. And even the effects of that operation can ſeldom be depended on as laſting; for when the general ſcrophulous taint ſtill ſubſiſts in the conſtitution, the diſorder will moſt probably appear again in ſome other part; which, however, in the advanced ſtages of the diſeaſe, it is ſometimes neceſſary to run the riſk of, the pain being often ſo tormenting as to make it more eligible to ſubmit to any hazard rather than to bear it longer.

When, however, for ſome reaſon or other, amputation is determined againſt, as there being almoſt a certainty of the complaint ſoon returning, from the ſcrophulous diſpoſition appearing very ſtrong in the ſyſtem, it then becomes neceſſary to have recourſe to palliatives, ſo as to render the complaint as tolerable as poſſible: and with this view, opiates in large doſes, by moderating the pain and procuring reſt to the patient, will in general be found the principal remedy. In other reſpects, all ſuch medicines and articles of regimen as are found beneficial in ſcrophula, may be had recourſe to.

SECT.

Cancers.

Sect. III. *Of Cancers.*

Cancers moſt commonly ariſe in the glandular parts of the body, where they are occaſioned by any bruiſe or contuſion, ſometimes a very ſlight one: and hence they are more common in the lips, and in the breaſts of women, than in any other parts of the body. Cancers have been generally diſtinguiſhed into *occult* and *open*. By the former are meant ſuch hard ſcirrhous ſwellings as are attended with frequent ſhooting pains, and which at laſt generally terminate in the latter.

73 Appearances of an ulcerated cancer.

By the *open cancerous ulcer*, is underſtood that ſpecies of ſore which commonly ſucceeds to hard ſwellings of the glands; although in ſome inſtances it occurs without any previous hardneſs. The edges of the ulcer are hard, ragged, and unequal, very painful, and reverſe in different ways, being ſometimes turned upwards and backwards, and on other occaſions inwards. The whole ſurface of the ſore is commonly very unequal, there being in ſome parts conſiderable riſings, and in others deep excavations. The diſcharge, for the moſt part, is a thin dark-coloured fetid ichor; and is often poſſeſſed of ſuch a degree of acrimony as to excoriate, and even deſtroy, the neighbouring parts. In the more advanced ſtages of the diſeaſe, by the eroſion of blood-veſſels which occurs, conſiderable quantities of pure blood are ſometimes alſo diſcharged.

Patients labouring under real cancerous affections univerſally complain of a *burning* heat over the whole ulcerated ſurface; which, in general, is the moſt tormenting ſymptom that attends the diſorder; and thoſe ſhooting lancinating pains, which were troubleſome in the more occult ſtate of the complaint, become now a great deal more ſo.

Theſe are the moſt frequent ſymptoms which attend an ulcerated cancer; but the appearances of ſuch ſores are ſo various, that it is almoſt impoſſible in any deſcription to comprehend every one. When two, three, or more, however, of thoſe enumerated, concur together in the ſame ulcer, we may always be pretty certain of its being of the cancerous kind.

74 Cauſes of cancer.

Concerning the cauſes of cancers, there have been a great many conjectures, but without any ſolid foundation. It is of ſome moment, however, to determine whether they ariſe from ſome general diſorder in the ſyſtem, or whether they are only to be accounted local diſeaſes. Many of the moſt eminent practitioners have been of opinion that they ariſe from a general diſorder of the ſyſtem; and hence conſider them as totally incurable even by extirpation, as the latent ſeeds of the diſeaſe, in their opinion, will not fail to bring on a return of it ſomewhere or other. Of this opinion the late Dr Monro appears to have been; and in a paper on this ſubject in the Edinburgh Medical Eſſays, declares, that "of near 60 cancers which he had been preſent at the extirparition of, only four patients remained free of the diſeaſe at the end of two years." From this bad ſucceſs, and the violent progreſs of the diſeaſe, he finally concludes againſt the extirpation of cancers, and propoſes only the palliative method of cure. But later practitioners have been a great deal more ſucceſsful; and a late publication by Mr Hill, ſurgeon at Dumfries, has put the uſefulneſs of extirpation beyond a doubt, when the operation is performed in time: though, after the diſeaſe has continued long, and the virus been abſorbed, the whole ſyſtem acquires a cancerous diſpoſition, and the diſeaſe almoſt certainly recurs in ſome other part. From internal medicines, we can expect little or nothing in the cure of cancers; and external applications can do no more than palliate. Great expectations were formed from the powder and extract of cicuta; but it has ſo univerſally failed, that few put much confidence in it at preſent. However, it has ſometimes been of ſervice in caſes of a ſimple indurated gland; and even where the diſeaſe has been farther advanced, it has produced a better diſcharge, and diminiſhed the fetor of the ſore; but as it cannot be depended upon for a radical cure, a delay of the operation is never to be recommended.

Cancers.

76 Cancer of the mamma.

No part of the body is more ſubject to cancer than the breaſts of women. Cancer of the mamma may ariſe at any period of life, though it ſeldom appears till about the time the menſes uſually diſappear. Tumors ariſing in the breaſt previous to this period have been conſidered by ſome practitioners as being only of a ſcrophulous nature; and it is probably owing to that circumſtance that ſeveral cures have been of late years made on tumors of the breaſt by mercurial frictions and other remedies.

77 Its ſymptoms.

Scirrhus and cancer of the breaſts are diſtinguiſhed by the following marks: When the tumor is firſt obſerved, it is commonly in form of a ſmall hard knot in the glandular part of the mamma, while the ſkin at the ſame time is free from inflammation. It frequently continues in this ſtate for ſeveral months: by degrees, however, it increaſes conſiderably in ſize, and at laſt a ſharp pain is felt ſhooting towards the axilla. The lymphatic glands at the under edge of the pectoral muſcle and in the axilla are often enlarged, and an occult cancer is now formed. By degrees the integuments over this part of the tumor in the mamma become diſcoloured, and at laſt an ulceration or open cancer breaks out. Violent hemorrhagies now frequently enſue; the pain becomes ſtill more excruciating; and, unleſs proper aſſiſtance be given, the patient is generally cut off in not many months after the breaking out of the cancer.

In early ſtages, the diſeaſe in general may be conſidered as entirely a local affection, and a radical cure may be of courſe expected; but in proportion as the ſkin ſhall afterwards be found diſeaſed and adhering to the gland, and that to the pectoral muſcle, and the lymphatic glands near the mamma and in the arm-pit ſwelled, the chance of a cure becomes more doubtful, as the cancerous matter may have been abſorbed, and part of it carried into the ſyſtem. The moſt unfavourable ſtate for an operation is when there are ulcerations in the breaſt, large, deep, and of long ſtanding; and particularly if theſe are attended with great pain, when the arm of the affected ſide has become œdematous, and the health of the patient is much impaired. In this laſt ſtate very little is to be expected from a ſurgical operation.

78 Method of extirpating the mamma.

In extirpating the mamma, which we ſhall firſt ſuppoſe is to be done where the ſkin is ſound, and where the tumor has no uncommon adheſion to the pectoral muſcle, the patient ought to be placed horizontally in a bed, or upon a table covered with a mattreſs, &c. The operator is to be ſeated, and to have proper aſſiſtants. A longitudinal inciſion is then to be made with a common ſcalpel through the ſkin and cellular ſubſtance along the whole extent of the tumor, and at a little diſtance from the nipple, which is to be ſaved. When the longeſt diameter of the tumor is acroſs the body, inſtead of a longitudinal inciſion, a tranſverſe one is to be made. The integuments being diſſected from the mamma on both ſides of the inciſion, the patient's arm is to be extended to ſave the pectoral muſcle; and the whole glandular part is to be detached from the muſcle, though a ſmall portion only ſhould be diſeaſed, beginning at the upper ſide, and ſeparating downwards. If there be any indurated glands, they are to be carefully removed. If the patient be faint, a glaſs of wine, or ſome other cordial, is to be given. After the diſeaſed parts are removed, the wound is to be cleaned with a ſponge wrung out of warm water, which will generally render the ſmall bleeding veſſels more conſpicuous. The integuments are next to be cloſely ap-

Cancers.

plied to the parts underneath, and retained there by the twiſted ſuture, and likewiſe by a few adheſive ſtraps. A large pledgit of ſimple ointment is now to be laid over the whole; and this is to be covered with a thick compreſs of lint, tow, or ſoft linen; and the dreſſings to be kept in their place, and moderate preſſure made by the napkin and ſcapulary bandage.

By this method the integuments will generally ſoon adhere, and a cure will be formed by the firſt intention. But it does not often happen that the operation is performed while this favourable mode of practiſing it will anſwer.

In general, before extirpation of a breaſt is recommended by the ſurgeon, or ſubmitted to by the patient, a conſiderable portion of the external integuments are ſo much diſeaſed as to render it neceſſary to ſeparate them along with the glandular part of the mamma. It ſometimes happens likewiſe that the tumor adheres to the pectoral muſcle, and that again to the ribs. In either of theſe caſes it becomes neceſſary to remove all the diſeaſed parts. For this purpoſe, two inciſions of an oval form, with ſharp extremities, of a ſufficient ſize to include the whole of the affected parts, become neceſſary. If again it be found, that beſides the diſeaſe of the breaſt, the lymphatic glands in the neighbourhood are indurated, or otherwiſe diſeaſed, the firſt inciſion ought to extend at once over theſe; and after the other parts have been removed, and the veſſels ſecured, the whole of the diſeaſed glands are to be extirpated; and in performing this part of the operation, conſiderable aſſiſtance may be given by ſupporting them with a hook, or a ligature paſſed through them, till they are entirely removed. When they lie deep in the axilla, the points of the fingers, or the end of the handle, will ſometimes be ſafer than the edge of the knife. After having removed all the glands which are in the ſmalleſt degree affected, the cut edges of the ſkin are to be brought as near to each other as the nature of the caſe will allow, ſo as to heal as much as poſſible by the firſt intention. After the wound is nearly, or perhaps entirely healed, an iſſue, inſerted into the arm of the oppoſite ſide, will be the beſt means of preventing a relapſe.

Sect. IV. *Burns.*

79 Conſequences of burns.

The immediate conſequence of burns is a greater or leſs degree of inflammation; and the danger attending ſuch accidents is in proportion to the extent of the injury. Burns which irritate the ſkin only, without deſtroying the cuticle, act nearly in the way of a common bliſtering plaſter. When the cuticle is deſtroyed, no bliſter takes place; a mortified

80 Cure.

ſlough is obſerved; and when this ſeparates, an ulcer is left. Where the cuticle is not deſtroyed, relief may be procured by holding the part affected a conſiderable time in very cold water, or ſometimes by plunging it two or three times into water a little below the boiling point. Solutions of ſaccharum ſaturni, and other preparations of lead, have been recommended, as in the caſe of other inflammations. Vinegar is found a very effectual application, whether the ſkin be ſound or bliſtered. The part may be entirely immerſed in it, or linen rags dipt in the vinegar may be applied, and the parts kept conſtantly moiſt, till the pain be removed. The ſame application is uſeful where the ſkin is rubbed off, or otherwiſe deſtroyed. In this caſe, indeed, the vinegar is apt to give additional pain on its firſt application; but this ſoon ceaſes, and the part becomes much cooler and eaſier. If the patient will not ſuffer the vinegar to be applied immediately to the ſurface of the ſore, a linen rag ſoaked in olive-oil may be previouſly laid on the part, covering the whole with the cloths dipped in vinegar; and theſe applications are to be occaſionally repeated till the pain and inflammation be entirely removed; after which the parts are to be dreſſed in the ſame manner as in the caſe of a common bliſter. In extenſive burns, where the irritation is great, along with external applications, opium ſhould be preſcribed, in doſes adequate to the degree of pain. Even that ſtupor with which patients in this ſituation are ſometimes attacked, is found to be more readily removed by opium than by any other remedy. With reſpect to the bliſters which ariſe upon burns, it has been diſputed whether they ought to be opened, or allowed to remain till they dry up of themſelves. But, according to the opinions of the lateſt authors, they ought to be opened as ſoon as any conſiderable quantity of fluid is found in them. After the ſerum is diſcharged, a thin liniment of wax and oil, with a little ſaccharum ſaturni, ſhould be applied to the part.

Burns.

In caſes of very ſevere burns, where, notwithſtanding the above treatment, there is danger of a violent inflammation being induced, blood-letting, cooling purgatives, and other remedies adapted to the peculiar ſymptoms, muſt be uſed. When, again, burns are from the firſt attended with loſs of ſubſtance, as commonly happens after the application of hot metallic bodies, we ought to have recourſe to the vinegar, as already mentioned, or to a liniment which is now in very common uſe for ſuch purpoſes, made of equal parts of linſeed oil and lime-water, which, when ſhaken together, forms a thick white ſubſtance, which often gives ſpeedy relief; and it may be readily applied by daubing the parts frequently over with a ſoft pencil well ſoaked in it. Though this has been conſidered as one of the beſt applications in burns, yet, in ſome caſes, more immediate relief has been procured from the application of Goulard's cerate, or the unguentum nutritum; and a weak ſolution of ſaccharum ſaturni has ſometimes been of ſervice.

81 Burns occaſioned by gunpowder.

When burns are occaſioned by the exploſion of gunpowder, ſome of the grains of the powder are apt to be forced into the ſkin. At firſt they produce much irritation; and if they are not removed, they commonly leave marks which remain during life. They ſhould, therefore, be picked out as ſoon as poſſible after the accident; and to prevent inflammation, as well as to diſſolve any powder which may remain, the parts afflicted ſhould be covered, for a day or two, with emollient poultices. In other reſpects, injuries of this ſort are to be treated like any other kind of burns.—When burnt parts are contiguous to each other, they are apt to adhere. To prevent this, pledgits covered with any proper dreſſing ought to be inſerted between them during the courſe of the cure. Ulcers ariſing from burns are apt to become ſoft and fungous, and to riſe above their natural level. When this is obſerved, the emollient ointments, which may have been previouſly uſed, ſhould be laid aſide, and thoſe of a moderately aſtringent nature applied. Gentle compreſſion with a roller is alſo of particular ſervice. Advantage is likewiſe derived from ſaturnine waſhes, &c. One of the beſt ointments, in ſuch caſes, is the common calamine cerate. Theſe will commonly anſwer the purpoſe; but when they prove inſufficient, burnt alum, blue vitriol, or even lunar cauſtic, may be neceſſary.

Chap. V. *Of Inflammatory Tumors.*

Inflammatory Tumors are ſuch as are quick in their progreſs when compared with thoſe of the indolent kind, and are attended with conſiderable pain and other ſymptoms of inflammation. We have here mentioned ſuch only whoſe treatment more properly belongs to the province of the ſurgeon, and which are placed according to their ſituations in the different parts of the body.

Sect.

Inflammatory Tumors.

Sect. I. *Inflammation and Abſceſs of the Breaſts of Women.*

This diſorder occurs moſt frequently in nurſes by the ſtoppage of the milk, which is always occaſioned by ſudden or imprudent expoſure to cold.

In the early ſtages of the affection, reſolution is always to be attempted, unleſs the ſwelling appears to have an evident tendency towards ſuppuration. The remedies uſed in inflammation, in general, ſeem uſeful in every caſe of inflammation of the breaſts. When the patient happens to be nurſing, a ſudden evacuation of blood is apt to diminiſh the quantity of milk: In ſuch caſes, therefore, blood is to be extracted in ſmall quantities at a time. The application of cooling ſaturnine poultices is adviſable. When ſuppuration has taken place, the matter is to be diſcharged by making an inciſion in the moſt depending part of the tumor.

Sect. II. *Inflammation of the Teſticles.*

This diſeaſe is often owing to expoſure to cold, violent exerciſe, &c.; but moſt frequently to gonorrhœa virulenta, and never to matter falling down upon the teſtes, as was ſuppoſed by thoſe who gave it the name of *hernia humoralis*. Inflammation here rarely terminates in ſuppuration.

The beſt method for diſcuſſing the inflammation is by the application of leeches; after which the penis ought to be kept conſtantly moiſtened with a ſolution of ſaccharum ſaturni, and the ſcrotum and teſtes ſupported by a proper bandage. The bowels ſhould be kept moderately open; the patient ſhould uſe a low diet, and keep as much as poſſible in an horizontal poſture. If lues venerea be preſent, a cure cannot be expected without mercury. If the diſeaſe is owing to a ſudden ſtoppage of the diſcharge in gonorrhœa, the running ought to be reſtored, and promoted by bathing the penis in warm water, injecting warm oil, and the uſe of bougies. Theſe means will generally diſcuſs the inflammation. If matter form, it muſt be diſcharged.

Sect. III. *Of Venereal Buboes.*

A swelling of any of the lymphatic glands of the body is called a *bubo*; and when ſuch a ſwelling proceeds from venereal poiſon, it is termed *venereal bubo*. They ſeldom or never appear except in the lymphatic glands of the groin, arm-pit, or extremities, and much more frequently in the groin than any where elſe.

In the treatment of buboes, a ſtrict antiphlogiſtic regimen is to be uſed to promote a reſolution; the application of leeches to the hardened glands is particularly proper. In diſcuſſing venereal buboes, the application of mercurial ointment has a conſiderable effect. After ſuppuration is completely formed, the application of cauſtic to open the bubo is dangerous, leſt it ſhould corrode ſome of the conſiderable blood-veſſels, which generally lie contiguous to the bubo. Buboes, when opened by the knife, are ſaid to heal with more difficulty, and generally to leave a ſcar behind them. To allow them to burſt of themſelves, is therefore for the moſt part proper, except when the collection is ſo conſiderable as to preſs upon the neighbouring blood veſſels. In ſuch a caſe, a ſmall inciſion may be made by the lancet, taking as much care as poſſible to prevent the admiſſion of the external air into the wound. When the edges of the opening grow callous, the application of lunar cauſtic to them becomes neceſſary. During the remaining part of the cure, mercury joined with opium is to be uſed.

Sect. IV. *Lumbar Abſceſs.*

The term *lumbar* may be applied to every abſceſs ſeated in the loins; but that which is here meant is ſuch as begins about the top of the os ſacrum, and is ſeated in the vicinity of the great pſoas muſcle. Inflammatory Tumours.

The ſymptoms begin with pain and tenſion about the loins, ſhooting upwards to the ſpine and downwards to the thigh. The diſeaſe has ſometimes a ſtrong reſemblance to nephritic affections, and is ſometimes miſtaken for lumbago. After ſuppuration takes place, ſhivering fits come on; and the pain now becoming dull, the patient imagines himſelf better, till matter points at the ſide of the anus, or in the groin. The firſt caſe is rare; and when it does occur, the tumor burſts, or is opened as a common abſceſs. In the other caſe, the matter is ſeated behind the faſcia of the groin, and ſometimes deſcends as far as the knee. The teguments commonly retain their natural appearance. Fluctuation is evident, eſpecially when the patient is in an upright poſture. It is often miſtaken for crural hernia; but may be eaſily diſtinguiſhed from it, by its ſlow progreſs, by pain in the lumbar region at the commencement of the diſeaſe, by the patient allowing the tumor to be handled freely, by fluctuation being evident, by the tumor becoming flaccid when the patient is in an horizontal ſituation, and by the abſence of all the ſymptoms by which hernia is diſtinguiſhed. Both diſeaſes may occur at once; but this is very rare, and a diſtinction is ſtill to be made. 82 Symptoms of lumbar abſceſs.

It is diſcovered that this diſeaſe has, in general, been induced by conſiderable injury being done to the ſmall of the back or loins, either by twiſts, or ſevere bruiſes, or by ſudden expoſure to cold after the heat occaſioned by ſevere exerciſe, particularly in ſcrophulous habits. Were accidents of this nature immediately treated with that attention which their importance deſerves, the diſeaſe might frequently be prevented. 83 Cauſe of this diſeaſe.

In the treatment the ſtricteſt antiphlogiſtic regimen ought to be obſerved. Blood-letting ought immediately to be performed, by ſcarifying deeply and leeching the injured part: neither are bliſters, opiates, gentle purgatives, and other remedies uſeful in inflammations, to be neglected. 84 Treatment.

Authors have an idea that little advantage can be derived from laying open the abſceſs, on account of the great danger which may enſue from the admiſſion of air. Mr Benjamin Bell, however, is of an oppoſite opinion, and has always given vent to matter here as elſewhere, and no bad conſequences have been obſerved. The matter, when long lodged, has been found to deſtroy the ſoft parts and bones, and ſometimes to make its way into the cavity of the abdomen; all of which might be prevented by an early evacuation. For this purpoſe a trocar ſhould be uſed, which was tried by Mr Bell in one caſe with complete ſucceſs.

Some other caſes are lately narrated by authors, where, by the introduction of a ſeton, and drawing off the matter by ſlow degrees, and then by uſing compreſs, and ſometimes injections of gently irritating fluids, a cure has been performed in the courſe of a few months. If the caſe is doubtful, an opening ſhould be made with the knife in the ſame manner as in hernia. If the flow of matter continue conſiderable for the ſpace of two or three weeks, injections of a weak ſolution of ſaccharum ſaturni, lime water, or other gentle aſtringents, may be employed.

Sect. V. *Paronychia or Whitloe, and Chilblains.*

Whitloe is a painful and inflammatory ſwelling at the extremities of the fingers under the nails, terminating in an effuſion of clear ſerum below the ſkin, which is ſometimes ſo acrid as to corrode the periоſteum, and render the bones carious. At other times the inflammation runs ſo high that the whole of the arm ſwells, particularly the lymphatics, and ſometimes even the glands in the axilla. 85 Of whitloes.

When this affection ariſes from external violence, the remedies

Inflammatory Tumors.

medies employed for inflammation, in general, will be of service. When it arises from unknown causes, ardent spirits and astringents have been found useful, particularly when topical and general bleedings have been previously used. When an effusion of a serous matter takes place, it is immediately to be discharged, as it is almost impossible to convert it into proper pus. When this serum has continued so long as to render the bone carious, a removal of the whole bone, or of the carious portion, becomes necessary, in order to effect a complete cure.

86 Chilblains.

Chilblains are inflammatory swellings, of a purple colour, chiefly affecting the heels, and sometimes also the fingers, toes, arms, hands, or feet, or even the tips of the nose and ears, attended with a stinging pain, and a degree of itching. The swelling sometimes cracks, and discharges an acrid serum: sometimes a mortification takes place, and an ulcer follows very difficult to heal.

This disorder is owing to the weaker action of the small vessels most remote from the heart, occasioned by cold or dampness, and occurs most frequently in people of a delicate constitution.

When the patient has been for some time exposed to the cold, and the parts are frost-bitten, they ought to be plunged into the coldest water and rubbed with salt; when they are only benumbed, rubbing them with camphorated spirit of wine will answer equally well; but when cracks take place, and an oozing of acrid matter ensues, poultices may be applied, but not long, as they are apt to give rise to fungous excrescences.

Sect. VI. *Of Contusions and Sprains.*

87 Symptoms of contusions and sprains.

Contusions of the integuments and muscles produce pain, swelling, and inflammation; and these, in some cases, may extend to a considerable degree; but in general they are less violent than what take place in cases of sprains of ligaments or tendons; for in these there is frequently a total loss of motion for many weeks, and sometimes for years, if proper attention be not paid. An effusion of fluids always succeeds the injury, which seems to be, for the most part, of a serous nature, as the skin usually retains its natural colour; sometimes the tumefied parts are of a deep red, or leaden colour, owing to a rupture of some vessels conveying red blood.

88 Treatment.

In the treatment of contusions and sprains, two circumstances require attention. 1. To endeavour to prevent the swelling as far as is practicable; 2. To employ those remedies afterwards which are known to be most powerful in preventing or removing inflammation. In contusions of the cellular substance, and even of the muscles, the effused fluids are commonly soon absorbed; but in sprains of the tendons or ligaments, a very troublesome, painful thickness of the injured parts is apt to continue for a great length of time, and in some instances even for life.

It is necessary, therefore, to obviate these symptoms as soon as possible; and for this purpose, cold astringent applications, as water, vinegar, &c. are most commonly used. Others again, with a view to relax the parts fully, make use of water as hot as the patient can bear it. By immersing the injured part in these immediately after the injury is received, the effusion will at least be somewhat obviated. When the pain is excessive, opiates become necessary.

After blood has been freely discharged, a repetition of the remedies already mentioned will be found to give great relief; care should be taken, at the same time, that the injured parts be kept in a relaxed and easy posture.

Chap. VI. *Of Indolent Tumors.*

These are such as are slow in their progress, and may continue for a long time without being attended with either pain or inflammation; though occasionally almost all of them may be inflamed, and some of them, in that state, attended with considerable pain. They are of different kinds according to the nature of their contents, and appear in various parts of the body. They are seated in the adipose and cellular membrane; whence it often happens that they take place in the viscera themselves, where they are frequently mortal. Sometimes they are filled with a substance of the consistence of honey, and are thence called *meliceratous* tumors; sometimes they are filled with an harder substance, and are then called *atheromatous* tumors; at other times they are filled with a substance of the consistence of fat, and are then called *steatomatous*. Sometimes, however, they are found to be repleniſhed with a fluid lymph coagulable by heat, and are then called *hydatids*. One set are filled with matter like the synovia of the joints, and get the name of *ganglions*.

Indolent Tumors.

89 Different kinds of indolent tumors.

90 How they are distinguished from other tumors and from one another.

Tumors of this kind are easily distinguished from all others, as having neither heat, pain, nor pulsation, as is to be observed in those which incline to suppurate; and they are distinguished from each other, before they are laid open, by fluctuation being readily perceived in the meliceris: the atheroma is soft and compressible, but has no fluctuation; while the steatoma is commonly firm and rolls under the skin. But these rules are liable to considerable exceptions. The meliceris and atheroma are most commonly found upon the head, and the steatoma upon the other parts of the body; while ganglions are situated over the tendons of the muscles. These tumors must be either extirpated entirely, or laid open so as to dispose the cyst to slough off or granulate. If the matter be fluid, we may evacuate it by an opening made with a lancet, or by means of a seton; but as the matter is apt to collect again, it is better to remove the sac entirely. If large vessels or nerves prevent this from being done, then it is to be laid freely open and exposed to the air, so that the bag may granulate, or be thrown off. When the tumor is to be extirpated, a longitudinal incision is to be made through the integuments; after which the tumor may be frequently removed by the point of the finger, or by the end of a spatula, replacing the integuments with a view to heal by the first intention. In every pendulous tumor of this kind, with a narrow neck, we ought to divide the teguments near the bottom of the tumor, in an oval form, so that the wound may be afterwards properly covered with the remaining integuments. After the tumor is removed, the skin is to be replaced over the wound, and fixed with adhesive straps, covering it with a pledgit of cerate, a small compress of linen, with a bandage above all, to make a gentle pressure on the parts.

91 Treatment.

Sect. I. *Of Steatomatous and Sarcomatous Tumors.*

92 Steatomatous tumors.

Steatomatous tumors have been ranked by authors among those of the encysted kind; but they have no other cyst containing them than the common cellular substance, somewhat condensed; and the particles of fat composing them are found of the same size with those in a sound part of the body.

Authors formerly advised the discussion of steatoms, or the prevention of their growth, by the application of pressure; but by such means the growth is rather promoted than retarded, nor have internal remedies been of any advantage. They can be removed therefore only by an operation which is the same with that for the extirpation of encysted tumors.

93 Sarcomatous tumors.

Sarcomatous tumors have nearly the same external appearance with those of the steatomatous kind. The term has been applied, in a general way, to scirrhi of the glands; but

Ganglions, or Swellings of the Burſæ Mucoſæ.

but ſarcomatous tumors are likewiſe found in various other parts of the body, and are diſtinguiſhed from ſteatoma by being firmer to the touch; internally they are found of a redder colour, or approaching that of muſcles, in conſequence of the greater number of veſſels entering into their ſubſtance. Theſe are to be treated in the ſame manner as ſteatoma; but the operation ought to be performed early, as they are more apt to degenerate into cancer.

SECT. II. *Of Ganglions, or Swellings of the Burſæ Mucoſæ.*

GANGLIONS of the tendons are likewiſe tumors of the encyſted kind, ſeated in the burſæ mucoſæ, or ſheaths of the tendons which belong to the extremities. They are moſt frequently met with over the tendons upon the back of the wriſt, and often likewiſe about thoſe of the ankle and other parts of the extremities. When preſſed, they are found to poſſeſs a conſiderable degree of elaſticity, from which, and from their ſituation, they may generally be diſtinguiſhed from other encyſted tumors. They ſeldom arrive at any great bulk, are not often attended with pain, and commonly the ſkin retains its natural appearance. On being laid open, they are found to contain a tough, viſcid, tranſparent fluid, reſembling the glaire of an egg.

They are generally produced by ſprains, or contuſions of the joints, or by rheumatiſm. In many inſtances, they go off inſenſibly, without any aſſiſtance from art; but as this is often not the caſe, means ought to be uſed for removing them. For this purpoſe, moderate friction frequently repeated, or gentle compreſſion applied to them by means of thin plates of lead, &c. ſometimes remove them. In ſome inſtances they have been removed by the application of bliſters; but the moſt certain method is, to make a ſmall puncture into the ſac, and to draw a cord through it; or, after the puncture is made, to preſs out the contents, and then inject ſome gently ſtimulating fluid, as port wine and water heated blood-warm. Sometimes, in tumors of this kind, bodies of a cartilaginous nature, and of different ſhapes and ſizes, are found; ſome quite ſmooth, others with pedunclcs; by which they are ſuppoſed by Dr Monro, in his work upon the burſæ mucoſæ, to have been attached to the burſæ. As theſe cannot be removed by any remedy with which we are yet acquainted, it is found neceſſary to diſcharge them. But as the parts may ſometimes ſuffer from inflammation when the tumor is laid fully open, it may be punctured at each end; and, after preſſing out the contents a ſmall cord may be introduced; after which gentle preſſure may be applied with a compreſs and bandage over the courſe of the tumor. The cord however ſhould not be continued ſo long as to induce any great degree of inflammation, for it is found that a ſlight degree of this ſufficiently anſwers the purpoſe.

94 Treatment of ganglions.

SECT. III. *Of Collections within the Capſular Ligaments of Joints, and of Cartilaginous Bodies contained there.*

COLLECTIONS here may conſiſt of ſerum, blood, or pus and ſynovia combined. They are moſt frequently met with in the joint of the knee, and may be produced either by internal or external cauſes. Theſe kinds of collections may in general be diſtinguiſhed from each other.

95 Cauſes of dropſical ſwellings of the joints.

Watery effuſions, commonly called *dropſical* ſwellings of the joints, ariſe chiefly in conſequence of ſevere rheumatic complaints; and when the tumor is not very large, the fluctuation of the fluid may be felt by preſſure. When a large effuſion appears immediately after a violent bruiſe, it is probable that it conſiſts chiefly of blood: but when it ſucceeds a violent ſprain, attended with great pain, inflammation, and ſwelling, terminating in an effuſion, there is every reaſon to think that the contained fluid conſiſts of pus mixed with ſynovia.

Collections within the Capſular Ligaments of Joints, &c.

Swellings of the joints are moſt apt to be confounded with collections in the burſæ mucoſæ, or with matter effuſed in the adjacent cellular ſubſtance. From the firſt of theſe they are generally diſtinguiſhed by the contained fluid paſſing readily from one ſide of the joint to the other, and from its being diffuſed over the whole of it; whereas, when it is contained in the burſæ, the tumor is confined to a particular part, and is ſeldom attended with much pain.

96 How diſtinguiſhed from other affections.

When ſuch collections can ſafely be allowed to remain, the capſular ligament ought never to be opened, as they can often be removed by diſcutients. Even conſiderable collections ariſing from rheumatiſm may commonly be diſcuſſed by friction, fomenting the parts with warm vapour, keeping them conſtantly moiſt with ſaturnine ſolutions, covering them properly with flannel, and applying bliſters. When theſe fail, ſupporting the part with a laced ſtocking, or with a roller, has frequently been of ſervice. But whether a rheumatic tumor can be diſcuſſed or not, it ought not to be opened; for the inconvenience attending it is more intolerable than the pain and inflammation which may enſue. But when the matter would do miſchief by lodging, it ſhould be diſcharged. Effuſed blood and matter which ſucceed high degrees of inflammation are of this kind. Blood is frequently extravaſated among ſoft parts without much detriment; but when in contact with cartilage or bone, it ſoon hurts them materially. The matter ought to be diſcharged ſo as moſt effectually to prevent the admiſſion of air into the cavity of the joint. For this purpoſe the opening ſhould be made with a trocar; and the ſkin, previouſly drawn tight to the upper part of the tumor, ſhould be pulled down immediately on withdrawing the canula. A piece of adheſive plaſter ſhould be directly laid over the opening, and the whole joint ſhould be firmly ſupported by a flannel roller properly applied. If the patient be plethoric, he ſhould be blooded to ſuch an extent as his ſtrength will bear; he ſhould be put upon a ſtrict antiphlogiſtic regimen, and in every reſpect ſhould be managed with caution; for inflammation being very apt to enſue, we cannot too much guard againſt it.

97 Treatment.

98 Method of diſcharging the matter.

Joints are ſometimes rendered painful and ſtiff by the formation of different ſubſtances within the capſular ligaments. Theſe are ſometimes looſe, and as firm as cartilage; and ſometimes of a ſoft membranous nature, ſimilar to thoſe already obſerved in treating of ſwellings of the burſæ mucoſæ.

99 Concretions in the joints,

In ſome caſes theſe ſubſtances, eſpecially the laſt ſpecies, retain nearly the ſame ſituation, without being much affected either by preſſure or by the motion of the joint: in that caſe the pain is conſtant, but ſeldom ſevere. The firſt ſpecies, however, is commonly very moveable; and on being touched, they ſlip with ſuch facility that it is difficult to fix them even with the fingers. Theſe are only painful in particular ſituations.

100 When perfectly looſe, may be extracted.

Where theſe concretions appear, upon examination, to be perfectly looſe and detached, if the pain which they excite is very ſevere, we ſhould venture in a cautious manner to take them out, by making an inciſion into the joint. But if there is reaſon to ſuſpect that they are connected with any part of the joint, the patient ought to be adviſed to ſubmit to the pain they induce, which in general will be rendered moderate by ſhunning exerciſe; but if, notwithſtanding this, it becomes inſupportable, amputation is the only reſource.

101 Manner of extracting them.

The limb being firmly ſecured by aſſiſtants, in that poſture which admits of the body to be taken out being felt moſt

Collections within the Capsular Ligaments of Joints, &c.

most distinctly, the surgeon should endeavour to fix it with his fingers towards the upper part of the joint, after an assistant has drawn the skin as much as possible upwards from the part where the incision is to be made. The operator with a scalpel is now to make an incision through the teguments and capsular ligament, directly upon the substance itself, of such a size as will admit of its being easily taken out; which may be done either with the finger or with the end of a blunt probe. If it is found to be connected by any small filaments either to the capsular ligament or to the cartilages of the joint, they should be cautiously divided, either with a probe-pointed bistoury, or probe-pointed scissars, after drawing the substance itself as far out as it can be got. When more concretions than one are found, they should all be taken out at the same opening, when this can be done; but when it cannot, it will be better to allow the first incision to heal before attempting the second, so as to avoid as much as possible the exciting of inflammation.

After the concretion is removed, the skin should be immediately drawn over the wound in the capsular ligament; and the lips of the opening in the skin being laid together, they should be secured in this situation by pieces of adhesive plaster, so as to prevent the air from finding access to the cavity of the joint. Till the wound be completely healed, the patient should not only be confined to bed, but the limb should be kept as much as possible in one posture, and a strict antiphlogistic regimen should be preserved.

Sect. IV. *Of Spina Bifida.*

Spina bifida, is a tumor which sometimes appears upon the lower part of the spine in new-born children. A fluctuation is distinctly perceived in it, and the fluid it contains can in some measure be pressed in at an opening between the vertebræ. In some cases this opening is owing to a natural deficiency of bone; in others, to the separation of the spinous processes of the vertebæ.

The disease proceeds from serum collected within the coverings of the spinal marrow. It is always fatal. Children labouring under it have been known to live for two or three years; but, in general, they linger and die in a few weeks. All that art has been able to do is to support the tumor by gentle pressure with a proper bandage. When a tumor of this kind is laid open or bursts, the child dies in a few hours. A tumour nearly of the same nature with this is sometimes met with upon different parts of the head in new-born children: it is formed by a fluid lodged beneath the membranes of the brain, which have been forced out at some unossified part of the skull. What we have said with respect to the former is exactly appplicable to this.

Sect. V. *Of Scrophulous Tumors.*

We shall here only mention the surgical treatment of scrophulous tumors, having spoken of scrophula in general under the article Medicine. Some practitioners have recommended poultices, &c. to bring scrophulous tumors to suppuration; but the best practitioners have laid them aside, because they increase the soft and spongy state of the parts, by which they are prevented from healing.

102 Treatment of scrophulous tumors.

As external applications are ineffectual, it is better to allow scrophulous tumors to be as much exposed as possible, as this frequently renders the subsequent ulcer more easily cured. The other methods recommended for discussing these tumors are, the internal use of cicuta, burnt sponge, muriated barytes, a long continued use of the cold bath, particularly of sea-bathing, and drinking mineral or sea-water. These, to produce any effect, should be begun early, while the tumors are small, and long persisted in. When the tumors come to a state of suppuration, if they are seated upon the thorax or abdomen, or any of the large joints, free vent ought always to be given to the matter to prevent its bursting into these cavities; and when the abscess is large, this should be done with a trocar, or by passing a cord thro' it, in order to exclude the external air. When the tumors are not situated upon great cavities, it is better to allow them to break of themselves, as the sores commonly heal more readily, and the scar is pretty similar in both. The most proper applications to scrophulous sores seem to be those of the saturnine kind, as they diminish inflammation, and in some measure prevent the sore from spreading. When the bones become carious, they are to be treated like carious bones from other causes; but amputation cannot here be attended with advantage, as the disease proceeds from a fault in the constitution. After the sores are healed up, the introduction of an issue may assist in preventing their return.

Scrophulous Tumors.

103 How distinguished from scirrhous tumors.

Tumors of a scrophulous nature are sometimes apt to be mistaken for those of the scirrhous kind, and thus may be improperly extirpated. Scrophulous tumors deeply seated commonly have a degree of firmness, which, if they happen to be seated near a suspicious part, as close by the side of a woman's breast, may give occasion to such a mistake. But they may generally be distinguished by the softness even of the firmest kind of them, when compared with scirrhus. They have always a smooth equal surface; whereas scirrhus is somewhat unequal or knotty, and seated in the real substance of the gland; and a shooting pain is commonly felt in it from time to time, even from its first appearance. They are generally accompanied, too, with other symptoms of scrophula, which is not necessarily the case with scirrhus.

Sect. V. *Of Bronchocele.*

This is a tumor on the fore-part of the neck, seated between the trachea and skin, termed in French *goitre*. In this country it is very rare; but it is frequent among the inhabitants of the Alps, and other mountainous countries, and is supposed to be owing to the use of snow-water. It is seated most frequently in the thyroid gland; tho' in two cases examined by Mr Benjamin Bell this gland was diminished from the compression of the tumor, which was chiefly formed of condensed cellular substance, with effusions in different parts of it of a viscid brown matter. Dr Prosser considers bronchocele as a dropsical affection of the thyroid gland; and in confirmation of this, he gives an account of a dissection of a diseased gland of this kind by Dr Hunter, who found in it a great number of capsules filled with water.

104 Symptoms of bronchocele.

The swelling is at first soft, without pain or any evident fluctuation, and the skin retains its natural appearance; but as the tumor advances in size, it becomes unequally hard; the skin acquires a copper colour, and the veins of the neck become varicose; the face becomes flushed, and the patient complains of frequent headachs, as well as of stinging pains through the body of the tumor.

105 Treatment.

Calcined egg-shells have been recommended by authors as a specific for this disease; but little dependence is to be placed on such a remedy. Frequent frictions are found useful, especially when employed early; saponaceous and mercurial plasters, too, have in some cases proved serviceable; and repeated blisters have been known to retard its progress. In the enlarged state of the tumor no remedy yet known is powerful enough to discuss it. When the disease is far advanced, the removal of the tumor by an operation must be attended with great danger, on account of the enlarged state of the arteries, as well as its vicinity to the common carotids. It is therefore thought by some of the most experienced practitioners, that in such a situation it would not

Nævi Materni, Corns, and Warts.

be advisable to attempt extirpation, and that the patient should rather trust to the common palliative treatment. When the tumor, however, is not much increased, if other remedies have failed, and the disease is advancing, a surgeon might be warranted in attempting its extirpation.

Sect. VI. *Of Nævi Materni, Corns, and Warts.*

106 Nævi materni.

Nævi materni are those marks which frequently appear upon the bodies of children at birth, and which are supposed to originate from impressions made on the mind of the mother during pregnancy. They are of various forms; their colour is likewise various; though most frequently resembling that of claret or red port-wine. Many of these marks are perfectly flat, and never rise above the level of the skin: these do not require the assistance of surgery; but in some cases they appear in the form of small protuberances, which frequently increase to a great size in the course of a few months. They appear to be firm and fleshy. They sometimes hang by slender attachments to the contiguous parts, but more generally they are fixed by broad bases. They may be removed with as little danger as any other tumor of the sarcomatous kind. They are supplied indeed more plentifully with blood than most other tumors are; and even sometimes they appear to be entirely formed by a congeries of small blood-vessels; but the arteries which supply them may, for the most part, easily be secured by ligature. The operation should never be long delayed; for as the size of the vessels corresponds with that of the tumor, they sometimes are so large as to throw out a good deal of blood before they can be secured. In performing it, the tumor is to be cut out, the arteries taken up, and the remaining skin brought as well together as the nature of the part will allow, and kept so by adhesive plaster or future. When the tumor is pendulous, and connected only by a narrow neck, it should be extirpated by ligature.

107 Corns.

Corns are small hard tubercles, commonly situated on the toes or other parts of the feet, and sometimes on the hands. They are of a horny nature. They proceed from a diseased state of the cuticle, occasioned by pressure. The part becomes hard and thickened, with a small white substance in the centre, which has a disposition to become prominent. It likewise forms a depression in the subjacent cutis vera, and sometimes is said to penetrate it. When corns are situated on parts much exposed to pressure, they irritate the skin, and produce an increased sensibility of the part, and thus occasion much pain. The best preventive of corns is the wearing of wide shoes, and avoiding every kind of pressure; and unless this be attended to, it will be found difficult to keep free from them. Various remedies are recommended for the cure or removal of corns. One is to bathe the part about half an hour in warm water, then to pare as much off them as possible without giving pain, and to apply over them any emollient ointment. If this treatment be frequently repeated, while pressure from shoes is prevented, they generally fall off, and do not return if pressure be afterwards avoided. Another method is to allow them to grow to some length through pieces of perforated leather, properly secured by plaster or by any other means, and afterwards to cut round their root, by which they may for the most part be easily turned out. Or if such irritating substances be applied to them as will raise a blister by separating the cuticle from the cutis, the corn will be raised along with the cuticle, and may then be readily removed by a scalpel or scissars. The surface of the cutis being now exposed, is to be healed like any other part that has been blistered.

108 Warts.

Warts are small, hard, indolent tumors, with a rough surface, appearing on different parts of the body, chiefly the hands and face, and more commonly in young people. When they appear in advanced life they are apt to degenerate into cancers, especially when of a livid colour and with a smooth surface. If they do not prove troublesome, nothing should be done to them, as they generally either fall off or waste gradually away. When from their size or situation they require to be removed, this, if they are pendulous or have narrow necks, is easily done by ligature; but if their bases be broad, the scalpel or escharotic applications will be necessary. As few, however, will submit to the former, the latter are generally employed. Escharotics of a mild nature give least pain, and are least apt to excite inflammation, which in these cases it is difficult to remove, and are found to be quite sufficient for the purpose. One of the best of these is crude sal ammoniac: it should first be moistened in water, and then well rubbed upon the warts two or three times a-day. Liquid salt of tartar, and sometimes spirit of hartshorn, has answered the same purpose: some recommend also the juice of onions.

Polypi.

109 Warts on the penis.

Warts appearing on the penis as a symptom of venereal infection, are of the same nature, and to be cured by the same means. Mercury is of no advantage here, and commonly indeed does harm. When every other part of the disease is eradicated, the warts may generally be removed by washing them morning and evening in lime-water, or in a weak solution of saccharum saturni. They may be removed also by the knife, and the parts from whence they are cut afterwards touched with lunar caustic, to prevent them from returning: but when this method is practised, the operator ought to be certain that he has removed the wart entirely, for where part has been left the most formidable symptoms have sometimes ensued.

Sect. VII. *Of Polypi.*

Polypi are pendulous, fleshy, indolent tumors, so called from their supposed resemblance to the animal of that name. They may be found in different cavities of the body, and originate from the lining membrane; but those which come under surgical treatment are found in the nose, mouth, throat, and outer passage of the ear, and in the vagina and rectum. They are divided into two classes; the one soft and compressible, the other extremely firm. Both of them bleed on being fretted or roughly handled. The soft kind shrivels and contracts in a dry atmosphere, (this is particularly the case with those of the nose); but the firm are not affected by the influence of the weather. Their colour is commonly pale and transparent, and sometimes a deep red.

110 Polypi divided into two kinds.

The pain at the commencement of the disorder is always inconsiderable; but increases in those of a hard nature as they increase in size. Sometimes polypi of this kind become unequal, and form ulcers over the whole surface, discharging fetid matter in considerable quantity. They are apt at this time, unless extirpated, to degenerate into cancer.

111 Their cause.

Most frequently they arise from local injury, or whatever tends to produce and support an inflamed state of the part. Scrophula and lues venerea, though considered by some authors as frequently giving rise to them, seem only to be exciting causes; for in lues venerea in particular, polypi when present remain after the disease is cured.

112 Prognosis.

The prognosis must depend much upon their situation and their consistence. The soft kind being seldom painful, may be removed at any period with little danger; but the hard kind are generally not only painful, but more apt to degenerate into cancer, or to return after being removed. The soft kind therefore may be removed in general with success; but when polypi of a harder nature exist, the prognosis will be much more unfavourable.

Polypi.

113 Treatment. With respect to the treatment.—As long as they remain stationary, they are not to be touched; but when they continue to grow, we ought to use astringent remedies, especially a strong solution of alum, a decoction of oak bark, vinegar, ardent spirits, &c. The softer kinds of polypi may frequently be prevented for a long time from increasing in size, and sometimes they even become considerably smaller. Mercury has been found rather to make them worse; caustic and other corroding applications have been of use in the softer kind, though they have not produced a cure. Setons have likewise been used with little advantage. It is therefore found necessary to have recourse to a more effectual practice; and with this view the knife, scissars, forceps, or ligature, are more generally recommended. The knife and scissars may be used when the roots of the tumor can be readily come at; but polypi are seldom so situated as to render excision practicable; and even when they are, the hemorrhagy may be attended with considerable danger. The removal of a polypus by tearing or twisting it with the forceps, Plate CCCCLXXXVII. fig. 4. is occasionally practised; but as ligatures are less painful, and fully as effectual, they are now more generally employed. The ligatures consist of wire, catgut, silk cord, &c. Different methods have been employed for passing these over polypi, according to their different situations.

114 Method of applying a ligature to them. When the ligature is to be applied, it is to be passed double over the tumor, and conducted to the root of it by means of the fingers or by slit probes, as in plate CCCCLXXXVII. fig. 5. or rings, Plate CCCCLXXXVII. fig. 6. as may be best suited to the shape and size of the passage. The ends of the ligature are then to be introduced into a single or double canula, as in Plate CCCCLXXXVII. fig. 7. which is to be pushed along the opposite side of the polypus till the end of the canula reach the root of it, when the ligature is to be drawn somewhat tight, and fastened to the canula which is to be left in the passage. The ligature is to be daily tightened till the tumor drop off. In this manner the largest polypus may be removed equally well with those of a smaller size. Should any part of it remain, it may be destroyed by caustic, and different instruments are contrived for conducting this to the root of the tumor.

What has been said of the treatment of polypi in general, readily applies to those seated in the nose, outer passage of the ear, the rectum, and the vagina. It likewise applies to those in the throat; only that instead of passing the ligature through the mouth it is to be passed through one of the nostrils. The operator is then to introduce one or two of his fingers into the mouth, and open the doubling of the ligature, which he is to pass over the polypus, and having pressed it down to the root of it, to proceed as before directed.

Chap. VII. *Of Diseases of the Bones.*

The bones, as well as the softer parts, are liable to be swelled, either throughout their whole length, or to have tumors formed on particular parts of them.

115 Exostosis. Exostosis is one species of tumor of the bone. According to Mr Bromefield, no swelling should be called so, but an excrescence continued from a bone, like a branch from the trunk of a tree. Under this head therefore is ranked the *benign node*, which may be produced by external injury, such as contusions and fractures: it can hardly be called a disease, as pain seldom succeeds, but rather a deformity.

116 Tophus. There are risings or tumors observable on the bones which are often the consequents of venereal virus, and are termed *tophi*, *gummi*, or *nodes*.—Tophus is a soft tumor in the bone; and seems to be formed of a chalky substance, that is intermediate between the osseous fibres. These cretaceous extravasations are sometimes found on the ligaments and tendons, as well as on the bone; and may sometimes be taken out by the knife. We have many instances where chalk stones in gouty people make their way out through the skin of the fingers and toes. Diseases of the Bones.

117 Gummi. Gummi is a soft tumor on the surface of the bone, between it and the periosteum; and its contents resemble gum softened, from whence it has taken its name. Possibly, by obstruction in the nutrient vessels of the bone, a rupture of some of them occasions the serous liquor to escape, which, by making its way between the the fibres of the bone, arrives at its surface; and being detained by the resistance of the periosteum, its most liquid parts being evaporated, and the remainder condensed by the inflammation, and consequently this inelastic covering being stretched, it becomes inspissated, and forms this species of *exostosis*, as it is generally called. When this is the cause, and the indisposition of the habit in general got the better of, pressure by a steel instrument, adapted to the part affected, is the proper cure.

118 Nodes. The confirmed venereal node has the appearance of a divarication of the osseous fibres, probably from some inspissated humour obstructing the nutrient vessels, but not extravasated; this occasioning an extension of the periosteum, produces a violent pain, which, when nocturnal, is the characteristic of a venereal cause. When the periosteum is thickened, but the bone not affected, a course of mercury, by attenuating the obstructed humour, and fitting it to be carried out of the body by the proper outlets, will often produce a perfect cure: but when the bone itself is diseased, this method will fail. But here the division of the extended periosteum has been known to give perfect ease.

The usual method, formerly, was to apply a caustic equal to the extent of the node, which being laid bare, required exfoliation before it could be cicatrized. If the incision is made early, that is, before matter be found under the investing membrane, it seldom requires exfoliation; and, as we often find that the bone itself is not affected, but only the periosteum thickened, we may be deceived even after a careful examination: it is therefore proper that the patient should be pretty far advanced in a course of mercurial unction before even the incision is made; for, should the tumor decrease, and the pain abate during the course, chirurgical assistance, with the knife, most likely may become unnecessary.

119 Abscessus in medulla, or true spina ventosa. A bone may become carious first in its internal parts; and that from external injury, as well as from a vitiated state of the animal-fluids. Authors seem not to agree as to the technical term for this kind of disease of the bones; some calling it *cancer* or *gangræna ossis*; others, *spina ventosa*, from the pointed extuberances usually attendant on this disorder of the bone; and some again *teredo*, from the appearance of the carious bone, like wood that is worm-eaten.

It is universally allowed, that this disease takes its rise from matter being formed either in the diploe, or in the marrow: whenever obstruction is begun in the vessels expanded on, or terminating in, the medullary cysts, the consequence will be inflammation, and, if not early removed, matter will form; for this reason this case may be called *abscessus in medulla*.

120 Symptoms of this disease. Whenever, then, a patient complains of dull heavy pain, deeply situated in the bone, possibly consequent to a violent blow received on the part some time before, though the integuments appear perfectly sound, and the bone itself not in the least injured, we have great reason to suspect an abscessus in the medulla. Children of a bad habit of body, though they have not suffered any external injury, will often become lame, and complain of the limb being remarkably heavy; and though not attended with acute pain,

Diſeaſes of the Bones.

pain, yet the dull throbbing uneaſineſs is conſtant. If rigors happen during the time the patient labours under this indiſpoſition, it generally implies that matter will be formed within the ſubſtance of the bone. If the extremities of the bone complained of begin, or if it becomes enlarged throughout its whole extent, it may be known to be an abſceſſus in medulla, or true ſpina ventoſa, as it is called: if neither of theſe ſymptoms take place, the great inſenſibility of the bone in ſome ſubjects will prevent that acuteneſs of pain uſual in other parts where matter is formed, though the acrid matter is eroding the bone during the whole time it is contained within it. This matter at length having made its way through, arrives at the perioſteum, where it creates moſt violent pain, as well from its ſharpneſs as from its increaſed quantity, occaſioning an extenſion of the perioſteum. The integuments then become ſwelled and inflamed, and have a ſort of emphyſematous feel. On being examined by preſſure, the tumor will ſometimes be leſſened, from part of the matter retiring into the bone: from this appearance to the touch, moſt likely the name of *ventoſa* was added to the term *ſpina*. When we are aſſured of matter being under the perioſteum, we cannot be too early in letting it out, as it will ſave a conſiderable deal of pain to the patient, though probably it may not be of any conſiderable advantage in reſpect to the carious bone; for, where the fluids in general are vitiated, no chance of cure can be expected from topical remedies; but where the conſtitution is mended, nature will ſometimes aſtoniſh us in her part, as the carious bone will be thrown off from the epiphyſes, or the teredines will be filled up by the oſſific matter that flows from the parts of the bone where ſome of the ſpinæ have come away.

121 Treatment.

If proper medicines are given, the children well ſupported, and the parts kept clean and dry, patience and perſeverance will frequently give great credit to the ſurgeon. In caſe it ſhould have been thought adviſable to apply a trephine, to give free diſcharge to the matter, the waſhing it away, as well as the ſmall crumblings of the carious bone, by means of deterſive and drying injections, has been known to contribute greatly to the curing this kind of caries, after the habit of body in general had been mended.

122 Of brittleneſs of the bones.

Beſides thoſe abovementioned, the bones are liable to two oppoſite diſeaſes; the one termed *friabilitas*, the other *mollities*; the former peculiar to adults, the latter more frequent in infants, though ſometimes ſeen in adults, from a vitiated ſtate of their juices.

The bones, when deprived of their cementing liquor, by paſſing through fire, become friable. From repeated ſalivations, and in old people, they have been rendered extremely brittle; inſomuch that in many ſubjects they have been fractured merely from their weight and the action of the muſcles: but in ſuch caſes, this is not owing to the friability of the bones, but to the loſs of ſubſtance, from the eroſion of the bone by an acrimonious humour thrown on it; to which cauſe perhaps may be attributed the diſeaſe called *rickets* in children. The effects of ſcorbutic humour in rendering the bones ſoft in many inſtances, have often been remarked.

123 Rickets.

By proper diet, gentle friction with coarſe cloths, exerciſe, and cold bathing, rickety children will frequently get their conſtitution ſo much changed, as that, by the time they arrive at the age of 20 years, there ſhall not remain the leaſt veſtige of their former diſeaſe. The epiphyſes are generally moſt affected in this ſpecies of the diſorder. For want of early attention to invalids of this ſort, we find that their bones not only become ſoft, and yield to the powers of the muſcles, but remain diſtorted the reſt of their lives, though they have acquired a perfect degree of ſolidity. In ſuch caſes, correcting the vitiated juices only will not reſtore the bones to their natural ſtate; therefore the aſſiſtance of a ſkilful mechanic is neceſſary both to ſupport the parts improperly acted on, and to alter the line of direction of the diſtorted oſſeous fibres.

Diſeaſes of the Bones.

124 Symptoms of rickets.

Though the curvature of the extremities, or thickneſs of the ends of the bones near their articulations, may give the firſt alarm to thoſe who are conſtantly with children, yet there are other ſymptoms that give earlier notice than theſe; and had they been timely diſcovered by proper judges, it is highly probable that the curvature of the limbs in many children might not have happened. The belly generally becomes larger in this diſeaſe, from the increaſed ſize of the contained bowels, as it is not unlikely but that the meſenteric glands are the firſt parts obſtructed; obſtructions of the liver, ſpleen, and pancreas, ſoon follow; the head then becomes enlarged; then a difficulty of breathing, which is generally ſuppoſed to be the effects of taking cold, ſucceeds; the ſternum is elevated and ſharp, and the thorax becomes contracted; the ſpine is protruded in ſeveral parts; the pelvis altered, according to the preſſure of the parts within, and habitual inclination of the patient, at times, to obtain that line of direction in which the perpendicular from the centre of gravity may fall within the common baſe of the body, the extremities of the cylindrical bones, and the ends of the ribs next the ſternum, become enlarged; ſoon after this the bones in general become ſoft and flexible, yielding in ſuch directions as the ſtrongeſt muſcles determine by their actions.

125 Appearance of the bones of rickety children.

The bones of children who die of this diſorder, we obſerve, are not only rendered ſoft, but the veſſels within their ſubſtance are replete with blood of a texture totally broken, and having more the appearance of thin chocolate than blood; the perioſteum in many places is ſeparated, and the intermediate ſpace between it and the bone filled with extravaſated fluid; and caries is almoſt as frequent as the ſeparation of the perioſteum. The muſcles in ſuch bodies generally appear pale and flabby.

126 Method of cure recommended by Mr Bromefield.

Where the affection of the meſenteric glands is evident, Mr Bromefield aſſerts, that after a doſe or two of the pulvis baſilicus to empty the inteſtines thoroughly, the purified crude quickſilver is by much the moſt efficacious medicine to remove obſtructions in thoſe glands. When the belly begins to ſoften and ſubſide, the chyle paſſes without interruption, and the child begins to get fleſh; then the cold bath becomes truly ſerviceable, and the decoction or cold infuſion of the Peruvian bark is a proper reſtorative; but the cold bath uſed too early, or the bark given before there is a free circulation of chyle through the lacteals, would be very injurious.

127 Of mollities oſſium.

The mollities oſſium, in ſome caſes, may be produced from a redundancy of the oleaginous parts of the blood, or from a laxity of the ſolids, by which the fluids are not ſufficiently attenuated, nor properly blended and mixed: the conſequence of which will be obſtructed perſpiration, the habit in general loaded with groſs, phlegmatic, and ſerous humours, and the oſſific matter not united or condenſed as in an healthy ſtate. The method of cure confirms us in the cauſe of theſe ſymptoms; for, by ſtrengthening the fibrous ſyſtem, by uſing gentle exerciſe, a dry diet, good air, aromatics, and cold bathing, this kind of invalids are generally reſtored to health.

128 Palſy of the lower extremities from curvature of the ſpine.

Among the diſeaſes of the bones we may likewiſe take notice of that *palſy of the lower extremities* which takes place, as is generally ſuppoſed, in conſequence of a curvature in ſome part of the ſpine. To this diſtemper both ſexes and all ages are equally liable. When it attacks an infant of only a year or two old or under, the true cauſe of it is ſel-

Diſeaſes of the Bones.

dom diſcovered until ſome time after the effect has taken place. The child is ſaid to be uncommonly backward in the uſe of his legs, or it is thought to have received ſome hurt in the birth. When the child is of an age ſufficient to have already walked, and who has been able to walk, the loſs of the uſe of his legs is gradual, though in general not very ſlow. He at firſt complains of being very ſoon tired, is languid, liſtleſs, and unwilling to move much or at all briſkly. Soon after this he may be obſerved frequently to trip and ſtumble, though there be no impediment in his way; and whenever he attempts to move briſkly, he finds that his legs involuntarily croſs each other, by which he is frequently thrown down without ſtumbling; and when he endeavours to ſtand ſtill in an erect poſture without ſupport, even for a few minutes, his knees give way and bend forward. As the diſtemper advances, it will be found that he cannot, without much difficulty and deliberation, direct either of his feet exactly to any one point; and very ſoon after this, both legs and thighs loſe a good deal of their natural ſenſibility, and become quite uſeleſs. In adults, the progreſs of the diſeaſe is much quicker, but the ſymptoms nearly the ſame.

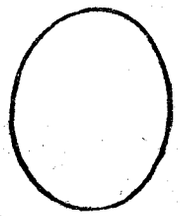
Until the curvature of the ſpine is diſcovered, the complaint generally paſſes for a nervous one; but when the ſtate of the back-bone is adverted to, recourſe is almoſt always had to ſome previous violence to account for it. That this might have been the caſe in ſome few inſtances might be admitted; but in by far the greateſt number ſome predisposing cauſe muſt be looked for.

Mr Pott, who has written a treatiſe upon this diſeaſe, recommends it to our obſervation, that though the lower limbs are rendered almoſt uſeleſs, or even entirely ſo, yet there are ſome circumſtances in which it differs from a common nervous palſy. The legs and thighs, though ſo much affected, have neither the flabby feel of a truly paralytic limb; nor have they that ſeeming looſeneſs at the joints, nor the total incapacity of reſiſtance which allows the latter to be twiſted almoſt in all directions: on the contrary, the joints have frequently a conſiderable degree of ſtiffneſs, particularly the ankles; by which ſtiffneſs the feet of children are generally pointed downward, and they are prevented from ſetting them flat upon the ground.

At firſt the general health of the patient ſeems not to be at all, or at leaſt not materially affected; but when the diſeaſe has continued for ſome time, and the curvature is thereby increaſed, many inconveniences and complaints come on; ſuch as difficulty in reſpiration, indigeſtion, pain, and what they call *tightneſs at the ſtomach*, obſtinate conſtipations, purgings, involuntary flux of urine and fæces, &c. with the addition of ſome nervous complaints, which are partly cauſed by the alterations made in the form of the cavity of the thorax, and partly by impreſſions made on the abdominal viſcera.

Mr Pott was led to a knowledge of the true cauſe and cure of this diſtemper, from obſerving the caſe of a youth of 14, who was reſtored to the uſe of his limbs immediately after a ſeemingly accidental abſceſs near the part. From this he was inclined to think, that the curvature of the ſpine was not the original cauſe of the diſorder, but that the ſurrounding parts were prediſpoſed towards it by ſome affection of the ſolids and fluids there; and he was confirmed in theſe ſuſpicions by a variety of appearances, which he obſerved both in the living body and upon diſſection of the ſubject after death; all of which are narrated at full length in his treatiſe upon this ſubject.

"The remedy (ſays he) for this moſt dreadful diſeaſe conſiſts merely in procuring a large diſcharge of matter, by ſuppuration, from underneath the membrana adipoſa on each ſide of the curvature, and in maintaining ſuch diſcharge until the patient ſhall have perfectly recovered the uſe of his legs. To accompliſh this purpoſe, I have made uſe of different means, ſuch as ſetons, iſſues made by inciſion, and iſſues made by cauſtic; and although there be no very material difference, I do upon the whole prefer the laſt. A ſeton is a painful and a naſty thing: beſides which it frequently wears through the ſkin before the end for which it was made can be accompliſhed. Iſſues made by inciſion, if they be large enough for the intended purpoſe, are apt to become inflamed, and to be very troubleſome before they come to ſuppuration; but openings made by cauſtic are not in general liable to any of theſe inconveniences, at leaſt not ſo frequently nor in the ſame degree: they are neither ſo troubleſome to make or maintain. I make the eſchars about this ſize and ſhape on each ſide the curve, taking care to leave a ſufficient portion of ſkin between them. In a few days, when the eſchar begins to looſen and ſeparate, I cut out all the middle, and put into each a large kidney-bean: when the bottoms of the ſores are become clean by ſuppuration, I ſprinkle, every third or fourth day, a ſmall quantity of finely powdered cantharides on them, by which the ſores are prevented from contracting, the diſcharge increaſed, and poſſibly other benefit obtained. The iſſues I keep open until the cure is complete; that is, until the patient recovers perfectly the uſe of his legs, or even for ſome time longer: and I ſhould think that it would be more prudent to heal only one of them firſt, keeping the other open for ſome time; that is, not only until the patient can walk, but until he can walk firmly, briſkly, and without the aſſiſtance of a ſtick: until he can ſtand quite upright, and has recovered all the height which the habit or rather the neceſſity of ſtooping, occaſioned by the diſtemper, had made him loſe."



Blood-letting.

Chap. VIII. *Of Blood-letting.*

Sect. I. *Of Blood-letting in general.*

Blood-letting is performed either to leſſen the quantity of circulating fluid, or to relieve a particular part: hence we have the terms of *general* and *local* blood-letting.

General blood-letting is either performed upon a vein or an artery; and from this circumſtance ariſe the appellations of *phlebotomy* and *arteriotomy*.

Local or topical blood-letting is performed by ſcarificators and cupping-glaſſes, by leeches, or by punctures made with a lancet, as may be moſt ſuitable to the nature of the diſeaſe it is intended to remedy.

129 General rules reſpecting blood-letting.

There are ſome general rules and obſervations which relate equally to this operation in whatever part of the body it is practiſed: theſe we ſhall in the firſt place enumerate, and ſhall afterwards proceed to treat particularly of blood-letting in the arm and other parts.

130 Poſture of the patient.

I. In this, as in every other operation, the ſituation of the patient, and of the operator likewiſe, ought to be preciſely fixed. The ſituation of a patient, during the operation of blood-letting, has a conſiderable influence on the effect produced, and therefore merits particular attention. In ſome diſorders, it is the object of this remedy to evacuate a conſiderable quantity of blood without inducing fainting: When this is the caſe, and when from former experience it is known that the patient is liable during the evacuation to fall into a faintiſh ſtate, a horizontal poſture ought to be preferred to every other; for fainting is not near ſo ready to occur in a horizontal as in an erect poſture. It now and then happens, however,

Blood-letting.

however, that one material advantage expected from the operation of blood-letting, is the production of a ſtate of deliquium; as, for inſtance, in caſes of ſtrangulated hernia, where a general relaxation of the ſyſtem is ſometimes deſirable. In all ſuch circumſtances, inſtead of a horizontal poſture, the more erect the patient is kept, the more readily will a ſtate of fainting be induced. The patient ought to be ſo placed, that the principal light of the apartment ſhall fall directly upon the part to be operated upon, that the vein to be opened may be made as apparent as poſſible.

131 Method of compreſſing the vein.

II. The patient being properly ſeated, the next ſtep is, by means of a proper bandage of ſilk, linen, or woollen cloth, which has more elaſticity, ſo to compreſs the vein intended to be opened, as to prevent the blood from returning to the heart. An equal degree of preſſure ought to be applied to all the other veins of the part: for if this be not attended to, the communication preſerved by the collateral correſponding branches would render the preſſure upon any one particular vein of very little importance. This preſſure upon the veins, by inducing an accumulation of their contents, tends to bring them more evidently into view, and conſequently renders it eaſier for the operator to effect a proper opening than he would otherwiſe find it. The preſſure, however, ought never to be carried ſo far as to obſtruct the circulation in the correſponding arteries, otherwiſe no diſcharge of blood can take place. When we ſee that it has the effect of raiſing the veins, while at the ſame time the pulſation of the artery is diſtinctly felt in that part of the member which lies on the ſide of the ligature moſt diſtant from the heart, we may be certain that it is to a very proper degree, and that it ought not to be carried farther; for by the ſwelling of the veins we are ſure that they are ſufficiently compreſſed; and by the arteries continuing to beat, it is evident that a continued flow of blood may be expected.

132 Inſtrument to be uſed.

III. The reflux of blood to the heart being in this manner prevented, the next queſtion to be determined is, the beſt method of making an opening into the vein. Different inſtruments have been invented for this purpoſe; but there are two only which have been retained in uſe, and which are all therefore that here require to be mentioned. Theſe are the lancet and the phlegm. This laſt, on being placed immediately on the part to be cut, is, by means of a ſpring, puſhed ſuddenly into the vein, and produces an opening of the exact ſize of the inſtrument employed.

When it is determined to employ the lancet, which is by far the ſafeſt, the form of that inſtrument is next the object of attention. The broad ſhouldered lancet ought to be laid entirely aſide; becauſe the broadneſs of its ſhoulders produces always a wound in the external teguments of perhaps three times the ſize of the opening made in the vein; a circumſtance which adds no advantage whatever to the operation; on the contrary, it produces much unneceſſary pain; renders it frequently a very difficult matter to command a ſtoppage of the blood; and the wounds produced by it are commonly ſo extenſive as to be liable to terminate in partial ſuppurations.

The ſpear pointed lancet, on the contrary, repreſented in Plate CCCCLXXXVII. fig. 8. is in every reſpect well calculated for the purpoſe of veneſection. From the acuteneſs of its point, it enters the teguments and vein with very little pain; which is with many patients a circumſtance of no ſmall importance. We are ſure of making the opening in the vein equal, or nearly ſo, to the orifice in the external teguments; and the diſcharge of blood produced by an opening made with one of theſe lancets, is commonly put a ſtop to with great eaſe immediately on removing the ligature upon the vein.

IV. The form of lancet being thus fixed upon, we come now to ſpeak of the method of uſing it. The ſurgeon and patient being both properly ſeated, and the ligature having been applied for a ſhort ſpace of time in order to produce ſome degree of ſwelling in the veins, that vein is to be made choice of which, at the ſame time that it appears conſpicuouſly enough, is found to roll leſs than the others on being preſſed upon by the fingers. It is ſcarcely thought neceſſary to obſerve here, that when a vein appears to be ſo immediately connected with a contiguous artery or tendon, as evidently to produce ſome riſk of wounding theſe parts in the operation, another vein not liable to ſuch hazard, if it can be procured, ought undoubtedly to be preferred. Veins may lie directly above both arteries and tendons, and yet no manner of riſk be incurred by opening them, provided the operator is ſufficiently ſteady and attentive; but it does now and then happen, that veins are ſo nearly and intimately connected with theſe parts, as to render it hazardous even for the moſt dexterous ſurgeon to attempt this operation.

Blood-letting.

133 Method of performing the operation.

The vein being at laſt made choice of, the ſurgeon, if he is to uſe his right-hand in the operation, takes a firm hold of the member from whence the blood is to be drawn with his left, and with the thumb of the ſame hand he is now to make ſuch a degree of preſſure upon the vein, about an inch and a half below the part where the orifice is to be made, as not only to render the ſkin and teguments ſomewhat tenſe; but at the ſame time to interrupt for a little all communication between the under part of the vein and that portion of it lying between the ligature and the thumb placed as thus directed.

The lancet being drawn out ſo as to form nearly a right angle with the ſcales, the operator now takes it between the finger and thumb of his right-hand; and leaving at leaſt one half of the blade uncovered, he reſts his hand on the middle-finger, ring-finger, and little-finger, all placed as conveniently as poſſible in the neighbourhood of the vein from whence the blood is to be taken; and having puſhed the point of the inſtrument freely through the ſkin and teguments into the vein, he now carries it forward in an oblique direction, till the orifice is of the ſize he inclines to have it; taking care, during the time of puſhing on the lancet, that its point be kept in as ſtraight a direction as poſſible, for fear of dipping into the parts below.

The inſtrument is now to be withdrawn; and the ſurgeon, removing the thumb of his left hand, is to allow the vein to empty itſelf freely into the different cups previouſly provided for the purpoſe.

It is of importance to obſerve, that during the time the blood is diſcharging, the member ought to be kept in exactly the ſame poſture it was in when the lancet was firſt introduced: otherwiſe the orifice in the ſkin is apt to ſlip over the opening in the vein; a circumſtance which always proves inconvenient, and on ſome occaſions produces a good deal of trouble by the blood from the vein inſinuating itſelf into the ſurrounding cellular ſubſtance.

134 Method of producing a ſufficient flow of blood.

V. When the vein is properly cut, and the orifice is made ſufficiently large, it rarely occurs that any difficulty is experienced in procuring all the blood that is wanted. But when this laſt circumſtance occurs, from the patient becoming faintiſh, a ſtream of freſh air ought to be admitted to the apartment, wine or ſome other cordial ſhould be adminiſtered, and the patient ought to be laid in a horizontal poſture. By theſe means the faintiſhneſs will in general be ſoon removed; but if ſtill the blood ſhould not flow freely, the member ought to be put into all the variety of poſitions that can probably aſſiſt in bringing the openings of the ſkin and other teguments to correſpond with that of the vein; which will ſoon be known to have happened by the blood

Veneſection in different Parts of the Body.

blood beginning inſtantly to flow. Throwing the muſcles of the part into conſtant action, by giving the patient a cane or any other firm ſubſtance to turn frequently round in his hand when the operation is done in the arm, will often anſwer in producing a conſtant flow of blood from a vein when every other means has failed: And, laſtly, when the pulſe in the inferior part of the member is felt very feeble, or eſpecially if it cannot be diſtinguiſhed at all, we may be thereby rendered certain that the ligature is too tight, and may in general have it in our power to produce an immediate flow of blood, by removing the compreſſion thus improperly made upon the arteries of the part.

135 Method of ſtopping too great a flux.

VI. A quantity of blood proportioned to the nature of the diſorder being thus diſcharged, the preſſure upon the ſuperior part of the vein ſhould be immediately removed; and this being done, if the ſpear-pointed lancet has been uſed, all farther loſs of blood will in general ſtop immediately. The contrary of this, however, ſometimes occurs, and blood continues to flow freely even after the ligature is removed. When this is the caſe, the operator ought to compreſs the vein both above and below the orifice, by means of the finger and thumb of one hand, ſo as to prevent any farther loſs of blood. This being done, and the orifice being cleared of every particle of blood, the ſides of it ſhould be laid as exactly together as poſſible; and a piece of court or any other adheſive plaſter being ſo applied as to retain them, it will ſeldom happen that any kind of bandage is neceſſary: but when the blood has iſſued with uncommon violence during the operation, and has been difficult to command after the removal of the ligature, in ſuch inſtances it will be prudent to apply a ſmall compreſs of linen over the plaſter, and to ſecure the whole with a linen roller properly applied round the member.

Sect. II. *Of Veneſection in different Parts of the Body.*

136 Veneſection in the arm.

When veneſection is to be performed in the arm, the ligature for ſtopping the circulation ought to be placed about an inch or an inch and a half above the joint of the elbow, and brought twice round: in order to prevent the ends of it from interfering with the lancet, the knot ſhould be made on the outſide of the arm. In general, one knot might anſwer; but a ſlip-knot being made above the reſt, renders it more ſecure, and it is very eaſily done.

In forming the choice of a vein from whence blood is to be taken, the general rules we have already laid down upon this point muſt be here particularly attended to. In general the artery lies ſo low in this place, that the median baſilic vein, under which it commonly runs, may be opened with perfect ſafety; and as this vein in general appears more conſpicuous than any of the others, probably from the continued pulſation of the artery below obſtructing in ſome meaſure the paſſage of its contents, it is in this reſpect therefore more properly calculated for this operation than any of the others. Other circumſtances occur too which render the median baſilic preferable to the cephalic or median cephalic veins for the operation of blood-letting. The former, viz. the median baſilic, is leſs deeply covered with cellular ſubſtance; and by lying towards the inner part of the arm, it is more thinly covered with the tendinous expanſion of the biceps muſcle than either of the others. From theſe circumſtances, the operation is always attended with leſs pain when done in this vein than in any of the others.

In very corpulent people, it ſometimes happens that all the larger veins lie ſo deep as not to be diſcovered by the eye; but when they are ſenſibly felt by the fingers, even although they cannot be ſeen, they may be always opened with freedom. In a few inſtances, however, they can neither be diſtinguiſhed by the eye nor by the finger: in ſuch a ſituation, as they may in general be met with about the wriſt or on the back part of the hand, the ligature ſhould be removed from the upper part of the arm; and being applied about half way between the elbow and wriſt, the veins below will thereby be brought into view; and wherever a vein can be evidently obſerved, there can be no danger in having recourſe to the operation.

Veneſection in different Parts of the Body.

137 Veneſection in the neck.

There is only one vein of the neck, viz. the poſterior external jugular, which can eaſily be brought ſo much into view as to be with propriety opened; and even this lies deeply covered with parts, not only with the ſkin and cellular ſubſtance, but with the fibres of the platiſma myoides muſcle; ſo that a conſiderable degree of preſſure becomes neceſſary in order to raiſe it to any height. With a view to produce this, the operator's thumb is commonly adviſed to be placed upon the vein, ſo as to compreſs it effectually about an inch or an inch and a half below where the opening is to be made. This, however, ſeldom proves ſufficient for the purpoſe, as the blood, on being ſtopped in its progreſs through this branch, eaſily finds a paſſage to the other veins; ſo that unleſs the principal vein on the other ſide of the neck is alſo compreſſed, the vein to be opened can never be fully diſtended. In order to effect this, a firm compreſs of linen ſhould be applied on the largeſt vein on the oppoſite ſide of the neck; and an ordinary garter, or any other proper ligature, being laid directly over it, ſhould be tied with a firm knot below the oppoſite arm pit; taking care to make ſuch a degree of preſſure, as to put an entire ſtop to the circulation in the vein, which in this way may be eaſily effected without producing any obſtruction to the patient's breathing. But to prevent every inconvenience of this kind, ſee an inſtrument contrived for the purpoſe, Plate CCCCLXXXVII. fig. 9.

This being done, and the patient's head properly ſupported, the operator, with the thumb of his left hand, is now to make a ſufficient preſſure upon the vein to be opened; and with the lancet in his right hand is to penetrate at once into the vein; and before withdrawing the inſtrument, an orifice ſhould be made large enough for the intended evacuation. It may be proper to obſerve, that a more extenſive opening ought always to be made here than is neceſſary in the arm, otherwiſe the quantity of blood is generally procured with difficulty: and beſides, there is not the ſame neceſſity for caution on this point here that there is in the arm; for it ſeldom or never happens that any difficulty occurs in this ſituation, in putting a ſtop to the blood after the preſſure is removed from the veins; all that is commonly neceſſary for this purpoſe being a ſlip of adheſive plaſter without any bandage whatever.

In order to bring the vein more clearly into view, ſo as afterwards to be able to open it with more exactneſs, it has been recommended, that the ſkin, cellular ſubſtance, and muſcular fibres covering the vein, ſhould be previouſly divided with a ſcalpel before attempting to puſh the lancet into it. There is not, however, any neceſſity for this precaution, as it rarely happens that any difficulty is experienced in procuring a free diſcharge of blood by opening the vein and teguments at once in the manner directed. And it is here, as in every inſtance where it is neceſſary to take blood by a lancet, if it is not done at once, the patient is much diſappointed, and is ſure to attribute the failure entirely to a fault in the operator.

138 Veneſection in the ankles and feet.

When blood is to be diſcharged from the veins of the ankle or feet, the ligature being applied a little above the ankle-joint, all the branches of the vena ſaphena, both in the inſide and outſide of the foot, come at once into view; and as this vein lies everywhere very ſuperficial, being in general covered with ſkin only, wherever a proper

Venesection in different Parts of the Body.

per vein appears conspicuously it may with safety be opened.

With a view to encourage the discharge of blood, it has been a constant practice in blood-letting, in these veins, to dip the feet into warm water immediately on the orifice being made. But this is a very inaccurate method of proceeding, as the quantity of blood taken in this manner can never be ascertained with precision; for the blood being all mixed with the water, the operator can never be in any degree certain as to this point: and besides, there does not appear to be any necessity for this assistance; for when the compression of the superior part of the veins is made effectual, and the orifice is of a proper size, there is seldom more difficulty in obtaining a full discharge of blood from the veins of these parts than from any other veins of the body.

On removing the ligature, the discharge is generally stopped at once; so that a piece of adhesive plaster applied over the orifice answers all the purpose of a bandage. The arm, neck, and ankles are the parts from whence blood is usually taken by venesection; but on some occasions, where the contiguous parts have been particularly affected, it has been thought adviseable to perform venesection in other places.

139 Venesection under the tongue.

When venesection is to be performed in the veins called *ranulæ* under the tongue, the apex of the tongue is to be elevated, and the vein on each side opened, because the opening of one only will hardly ever discharge blood enough. After a sufficient quantity has been discharged, some cold astringent fluid taken into the mouth will generally stop the hemorrhagy.

140 Venesection in the penis.

The vena dorsalis penis, which runs along the back or upper side of this member, being generally pretty much distended, and conspicuous in an inflammation of this part, may be opened about the middle or back part of the penis; and a sufficient quantity of blood be discharged proportionable to the urgency of the symptoms. This being done, apply a compress and bandage proper for the penis. The arteries and nerves which lie on each side of the vein are to be avoided: nor ought the bandage to be too tight, otherwise the inflammation and other symptoms may turn out worse than before.

When it is found necessary to discharge blood in this manner from the penis, the veins can be easily brought into view, by producing an accumulation of their contents in the same manner as in other parts of the body, through the intervention of a ligature: but in the tongue, in the hæmorrhoidal veins about the anus, and other parts where compression cannot be applied, all that the surgeon can do, is to make an orifice of a proper size in that part of the vein which shows itself most evidently; and if a sufficient discharge of blood is not thus produced, as there is no other method of effecting it, immersing the parts in warm water may in such circumstances be a very necessary measure.

141 Venesection in the eyes.

There are several ways of performing the operation of blood-letting in the eyes. We shall here only relate the chief: First, the patient is to be seated conveniently on the bed side or on a chair, with his head held in a proper posture by an assistant; which done, the surgeon makes a transverse incision with a lancet upon the turgid small vessels in the corners of the eye, so as to open them or cut them quite across. Some use a small pair of scissars, instead of a lancet, to divide the vessels; but in using either of them, the eye-lids must be separated from each other by the fingers of one hand, while the vessels are cut by instruments held in the other. Some, again, elevate the small turgid vessels with a crooked needle before they divide them, the eye-lids being in the mean time held asunder by an assistant. The small vessels being thus opened or divided, their discharge of blood should be promoted by fomentations of warm water frequently applied to the eye by means of a sponge or soft linen rags.

Arteriotomy.

Among other methods that have been proposed for scarifying the blood-vessels of the eye, the beards of rough barley were at one period much extolled, and are still employed by some individuals. By drawing them over the surface of the eye, in a direction contrary to the sharp spiculæ with which they are furnished, a considerable discharge of blood is thereby produced: But the pain attending this operation is exquisite; and as it does not possess any superior advantage to the method with the lancet, it is now falling into general disuse.

Sect. III. *Of Arteriotomy.*

Whatever particular advantages may in theory have been expected from arteriotomy, and however some of its supporters may have recommended it, not only as being in many instances preferable to venesection, but as an operation perfectly safe even in vessels of considerable size; yet the most strenuous friends to the practice have shrunk from any real attempt of this kind on the larger arteries. Instances have no doubt occurred of large arteries having been opened without any danger ensuing; but these are so exceedingly rare, that no practitioner of experience will, from that consideration, be induced coolly to proceed to open any artery of importance. The smaller branches of arteries may indeed be opened with great safety, when they are not deeply covered, and especially when they lie contiguous to bones; but in any of the larger arteries, the attempt must be always attended with so much hazard, and the advantages to be expected from it, in preference to venesection, are apparently so trifling, as must in all probability prevent it from ever being carried into execution.

142 Arteriotomy seldom practised.

143 Arteries usually opened.

There are very few arteries, therefore, which, with any propriety, can be opened: the different branches of the temporal are the only arteries indeed from whence blood, in ordinary practice, is ever taken; for although the opening of some other branches of arteries has by some been proposed, yet they are situated in such a manner that they either cannot be readily come at, or being in the neighbourhood of so large nerves, the opening of them might be attended with bad consequences. In performing this operation on any of the temporal branches, if the artery lies superficial, it may be done with one push of the lancet, in the same manner as was directed for venesection; but when the artery lies deeply covered with cellular substance, it is always necessary to lay it fairly open to view, before making the orifice with the lancet: for in all the smaller arteries, when they are cut entirely across, there is little chance of being able to procure any considerable quantity of blood from them; as, when divided in this manner, they are sure to retract considerably within the surrounding parts, which commonly puts a stop to all farther evacuation.

144 Method of performing the operation.

Some degree of nicety is also necessary in making the opening into the artery of a proper oblique direction, neither quite across nor directly longitudinal; for a longitudinal opening never bleeds so freely, either in an artery or in a vein, as when its direction is somewhat oblique.

If the opening has been properly made, and if the artery is of any tolerable size, it will at once discharge very freely without any compression; but when the evacuation does not go on so well as could be wished, the discharge may be always assisted by compressing the artery immediately above the orifice, between it and the corresponding veins. The quantity of blood being thus discharged, it will commonly happen, that a very slight compression on these smaller arteries will suffice for putting a stop to the evacuation: and,

whatever

Toppical Blooding.

whatever preſſure is found neceſſary, may be here applied in the ſame manner as was directed in veneſection.

It happens, however, in ſome inſtances, that this does not ſucceed, the orifice continuing to burſt out from time to time, ſo as to be productive of much diſtreſs and inconvenience.

145 Method of ſtopping the blood.

In this ſituation there are three different methods by which we may with tolerable certainty put a ſtop to the farther diſcharge of blood. 1ſt, If the artery is ſmall, as all the branches of the temporal arteries commonly are, the cutting it entirely acroſs, exactly at the orifice made with the lancet, by allowing it to retract within the ſurrounding parts, generally puts an immediate ſtop to the diſcharge. 2d, When that is not conſented to, we have it always in our power to ſecure the bleeding veſſel with a ligature, as we would do an artery accidentally divided in any part of the body. And, laſtly, if neither of theſe methods is agreed to by the patient, we can, by means of a conſtant regular preſſure, obliterate the cavity of the artery at the place where the operation has been performed, by producing the accretion of its ſides. Different bandages have been contrived for compreſſing the temporal artery; but none of them anſwer the purpoſe ſo eaſily and ſo effectually as the one figured in Plate CCCCLXXXVII. fig. 10. This method is more tedious; but to timid patients it generally proves more acceptable than either of the other two.

Sect. IV. *Of Topical Blooding.*

When, either from the ſeverity of a local fixed pain, or from any other cauſe, it is wiſhed to evacuate blood directly from the ſmall veſſels of the part affected, inſtead of opening any of the larger arteries or veins, the following are the different modes propoſed for effecting it, viz. by means of leeches; by ſlight ſcarifications with the ſhoulder or edge of a lancet; and, laſtly by means of an inſtrument termed a *ſcarificator*, (Plate CCCCLXXXVII. fig. 11.); in which ſixteen or twenty lancets are commonly placed, in ſuch a manner, that, when the inſtrument is applied to the part affected, the whole number of lancets contained in it are, by means of a ſtrong ſpring, puſhed ſuddenly into it, to the depth at which the inſtrument has been previouſly regulated. This being done, as the ſmaller blood-veſſels only by this operation are ever intended to be cut, and as theſe do not commonly diſcharge freely, ſome means or other become neceſſary for promoting the evacuation.

146 Method of blooding with the ſcarificator.

147 And cupping-glaſſes.

Various methods have been propoſed for this purpoſe. Glaſſes fitted to the form of the affected parts, with a ſmall hole in the bottom of each, were long ago contrived; and theſe being placed upon the ſcarified parts, a degree of ſuction was produced by a perſon's mouth ſufficient for nearly exhauſting the air contained in the glaſs: and this accordingly was a ſure enough method of increaſing the evacuation of blood to a certain extent. But as this was attended with a good deal of trouble, and beſides did not on every occaſion prove altogether effectual, an exhauſting ſyringe was at laſt adapted to the glaſs: which did indeed anſwer as a very certain method of extracting the air contained in it; but the application of this inſtrument for any length of time is very troubleſome, and it is difficult to preſerve the ſyringe always air-tight.

The application of heat to the *cupping-glaſſes*, repreſented in Plate CCCCLXXXVII. fig. 12. has been found to rarefy the air contained in them to a degree ſufficient for producing a very conſiderable ſuction. And as the inſtrument in this ſimple form anſwers the purpoſe in view with very little trouble to the operator, and as it is at all times eaſily obtained, the uſe of the ſyringe has therefore been laid aſide.

Topical Blooding.

There are different methods adopted for thus applying heat to the cavity of the glaſs. By ſupporting the mouth of it for a few ſeconds above the flame of a taper, the air may be ſufficiently rarefied; but if the flame is not kept exactly in the middle, but is allowed to touch either the ſides or bottom of the glaſs, it is very apt to make it crack. A more certain, as well as an eaſier, method of applying the heat, is to dip a piece of ſoft bibulous paper in ſpirit of wine; and having ſet it on fire, to put it into the bottom of the glaſs, and, on its being nearly extinguiſhed, to apply the mouth of the inſtrument directly upon the ſcarified part. This degree of heat, which may be always regulated by the ſize of the piece of paper, and which it is evident ought always to be in proportion to the ſize of the glaſs, if long enough applied, proves always ſufficient for rarefying the air very effectually, and at the ſame time, if done with any manner of caution, never injures the glaſs in the leaſt.

The glaſs having been thus applied, if the ſcarifications have been properly made, they inſtantly begin to diſcharge freely: and ſo ſoon as the inſtrument is nearly full of blood, it ſhould be taken away; which may be always eaſily done by raiſing one ſide of it, ſo as to give acceſs to the external air. Where more blood is wiſhed to be taken, the parts ſhould be bathed with warm water; and being made perfectly dry, another glaſs, exactly the ſize of the former, ſhould be inſtantly applied in the very ſame manner: and thus, if the ſcarificator has been made to puſh to a ſufficient depth, ſo as to have cut all the cutaneous veſſels of the part, almoſt any neceſſary quantity of blood may be obtained. It ſometimes happens, however, that the full quantity intended to be diſcharged cannot be got at one place. In ſuch a caſe, the ſcarificator muſt be again applied on a part as contiguous to the other as poſſible; and this being done, the application of the glaſſes muſt alſo be renewed as before.

When it is wiſhed to diſcharge the quantity of blood as quickly as poſſible, two or more glaſſes may be applied at once on contiguous parts previouſly ſcarified; and, on ſome occaſions, the quantity of blood is more quickly obtained by the cupping-glaſſes being applied for a few ſeconds upon the parts to be afterwards ſcarified. The ſuction produced by the glaſſes may poſſibly have ſome influence in bringing the more deep-ſeated veſſels into nearer contact with the ſkin, ſo that more of them will be cut by the ſcarificator.

A ſufficient quantity of blood being procured, the wounds made by the different lancets ſhould be all perfectly cleared of blood; and a bit of ſoft linen or charpie, dipped in a little milk or cream, applied over the whole, is the only dreſſing that is neceſſary. When dry linen is applied, it not only creates more uneaſineſs to the patient, but renders the wounds more apt to feſter than when it has been previouſly wetted in the manner directed.

148 Dry cupping.

Dry cupping conſiſts in the application of the cupping-glaſſes directly to the parts affected, without the uſe of the ſcarificator. By this means a tumor is produced upon the part; and where any advantage is to be expected from a determination of blood to a particular ſpot, it may probably be more eaſily accompliſhed by this means than by any other.

When the part from which it is intended to produce a local evacuation of this kind is ſo ſituated, that a ſcarificator and cupping-glaſſes can be applied, this method is greatly preferable to every other; but in inflammatory affections of the eye, of the noſe, and of other parts of the face, &c. the ſcarificator cannot be properly applied directly to the parts affected. In ſuch inſtances, leeches are commonly had

149 Application of leeches.

Iſſues. had recourſe to, as they can be placed upon almoſt any ſpot from whence we would wiſh to diſcharge blood.

In the application of theſe animals, the moſt effectual method of making them fix upon a particular ſpot, is to confine them to the part by means of a ſmall wine-glaſs. Allowing them to creep upon a dry cloth, or upon a dry board, for a few minutes before application, makes them fix more readily; and moiſtening and cooling the parts on which they are intended to fix, either with milk, cream, or blood, tends alſo to cauſe them adhere much more ſpeedily than they otherwiſe would do. So ſoon as the leeches have ſeparated, the ordinary method of promoting the diſcharge of blood, is to cover the parts with linen cloths wet in warm water. In ſome ſituations, this may probably be as effectual a method as any other; but wherever the cupping-glaſſes can be applied over the wounds, they anſwer the purpoſe much more effectually.

Chap. IX. *Of Iſſues.*

Issues are a kind of artificial ulcers formed in different parts of the body with a view to procure a diſcharge of purulent matter, which is frequently of advantage in different diſorders.

150 Uſe of iſſues. Practitioners were formerly of opinion that iſſues ſerved as drains to carry off the noxious humours from the blood, and therefore they placed them as near the affected part as poſſible. But as it is now known that they prove uſeful merely by the quantity of matter which they afford, they are generally placed where they will occaſion the leaſt inconvenience. The moſt proper parts for them are, the nape of the neck; the middle, outer, and fore part of the humerus; the hollow above the inner ſide of the knee; or either ſide of the ſpine of the back; or between two of the ribs; or wherever there is a ſufficiency of cellular ſubſtance for the protection of the parts beneath: they ought never to be placed over the belly of a muſcle; nor over a tendon, or thinly covered bone; nor near any large blood-veſſel.

The iſſues commonly uſed are, the bliſter-iſſue, the pea-iſſue, and the ſeton or cord.

151 The bliſter-iſſue. When a bliſter-iſſue is to be uſed, after the bliſter is removed, a diſcharge of matter may be kept up by dreſſing the part daily with an ointment mixed with the powder of cantharides. If the diſcharge be too little, more of the powder may be uſed; if too great, or if the part be much inflamed, the iſſue ointment may be laid aſide, and the part dreſſed with baſilicon, or with Turner's cerate, till the diſcharge be diminiſhed and the inflammation abated. It is moſt proper ſometimes to uſe the iſſue ointment and a mild one alternately.

152 The pea-iſſue. A pea iſſue is formed either by making an inciſion with a lancet, or by cauſtic, large enough to admit one or more peas; though ſometimes inſtead of peas, kidney-beans, Gentian root, or orange-peas, are uſed. When the opening is made by an inciſion, the ſkin ſhould be pinched up and cut through, of a ſize ſufficient to receive the ſubſtance to be put into it. But when it is to be done by cauſtic, the common cauſtic or lapis infernalis of the ſhops anſwers beſt: it ought to be reduced to a paſte with a little water or ſoft ſoap, to prevent it from ſpreading; and adheſive plaſter, with a ſmall hole cut in the centre of it, ſhould be previouſly placed, and the cauſtic paſte ſpread upon the hole in the centre. Over the whole an adheſive plaſter ſhould be placed to prevent any cauſtic from eſcaping. In ten or twelve hours, the whole may be removed, and in three or four days the eſchar will ſeparate, when the opening may be filled with peas, or any of the other ſubſtances already mentioned.

The ſeton is uſed where a large quantity of matter is wanted, and eſpecially where it is wiſhed for from deep ſeated parts. It is frequently uſed in the back of the neck for diſeaſes of the head or eyes, or between two of the ribs in affections of the breaſt. Sutures. 153 The ſeton.

When the cord, which is to be made of threads of cotton or ſilk, is to be introduced, the parts at which it is to enter and paſs out ſhould be previouſly marked with ink, and a ſmall part of the cord being beſmeared with ſome mild ointment, and paſſed through the eye of the ſeton-needle, Plate CCCCLXXXVII. fig. 13. the part is to be ſupported by an aſſiſtant, and the needle paſſed fairly through, leaving a few inches of the cord hanging out. The needle is now to be removed and the part dreſſed. By this method matter is produced in quantity proportioned to the degree of irritation applied; and this can be increaſed or diminiſhed by covering the cord daily before it is drawn with an irritating or mild ointment.

Chap. X. *Of Sutures and Ligatures of Arteries.*

Sect. I. *Of Sutures.*

The intention of ſutures is to unite parts which have been divided, and where the retraction of the lips of the wound has been conſiderable. The ſutures in ordinary uſe at preſent, among ſurgeons, are the interrupted, the quilled, and the twiſted. Beſides theſe ſutures, adheſive plaſters are uſed for uniting the lips of wounds, which have been termed the *falſe* or *dry* ſuture, in oppoſition to the others which have obtained the name of *true* or *bloody*. The true ſuture is uſed in caſes of deep wounds, while the falſe is employed in thoſe of a ſuperficial nature.

154 Of the interrupted ſuture. The interrupted ſuture is made as follows. The wound being emptied of the grumous blood, and the aſſiſtant taking care that the lips of it lie quite even, the ſurgeon is carefully to carry the needles from the bottom outwards; uſing the caution of making them come out far enough from the edge of the wound, which will not only facilitate the paſſing the ligature, but will alſo prevent it from cutting through the ſkin and fleſh; as many more ſtitches as may be required will be only repetitions of the ſame proceſs. The threads being all paſſed, let thoſe be firſt tied which are in the middle of the wound: though, if the lips are held carefully together all the while, as they ſhould be, it will be of no great conſequence which is done firſt. The moſt uſeful kind of knot is a ſingle one firſt, and then a ſlip-knot, which may be looſened upon any conſiderable inflammation taking place. If a violent inflammation ſhould ſucceed, looſening the ligature only will not ſuffice; it muſt be cut through and drawn away, and the wound be treated afterwards without any ſuture. When the wound is ſmall, the leſs it is diſturbed by dreſſing the better; but in large ones, there will ſometimes be a conſiderable diſcharge; and if the threads be not cautiouſly carried through the bottom of it, abſceſſes will frequently enſue from the matter being pent up underneath, and not finding iſſue. If no accident happen, after the lips are firmly agglutinated, the ligatures are to be removed, and the orifices which they leave dreſſed.

It will readily be underſtood, that the ſtrength of the ligature and ſize of the needle ought always to be proportionable to the depth of the ſore and retraction of the parts. The proper form of needles is repreſented in Pl. CCCCLXXXVII. fig. 14.

It muſt likewiſe be remembered, that during the cure the ſuture muſt be always aſſiſted by the application of bandage, if poſſible, which is frequently of the greateſt importance; and that ſort of bandage with two heads, and a ſlit in the middle,

Sutures.

middle, which is by much the beſt, will in moſt caſes be found practicable.

155 Of the quilled ſuture.

In deep wounds, attended with much retraction, it is always a neceſſary precaution, to aſſiſt the operation of the ligatures by means of bandages, ſo applied as to afford as much ſupport as poſſible to the divided parts: But even with every aſſiſtance of this nature, it now and then happens, that the divided parts cannot be kept together, retraction occurs to a greater or leſſer degree, and the ligatures of courſe cut aſunder the ſoft parts they were at firſt made to ſurround.

With a view to prevent this receding of the teguments and other parts, it was long ago propoſed to add to the interrupted ſuture what was ſuppoſed would afford an additional ſupport, viz. quills or pieces of plaſter rolled up into the form of quills; one of which being placed on each ſide of the wound, the double of the ligature is made to include the one, and the knot to preſs directly upon the other, inſtead of being made immediately on the edges of the ſore, as was directed for interrupted ſutures.

It is at once evident, however, that the ligatures muſt here make the ſame degree of preſſure on the parts through which they paſs as they do in the interrupted ſuture; and this being the caſe, it is equally obvious, that the interpoſition of theſe ſubſtances cannot be of any uſe. This ſuture is accordingly now very rarely practiſed, and it is probable that it will be ſoon laid entirely aſide.

156 Of the twiſted ſuture.

By the term *twiſted ſuture*, is meant that ſpecies of ligature by which parts, either naturally or artificially ſeparated are united together, by means of ſtrong threads properly twiſted round pins or needles puſhed through the edges of the divided parts.

157 Uſes to which it may be put.

This ſuture is commonly employed for the purpoſe of uniting the parts in caſes of hare-lip; and this indeed is almoſt the only uſe to which it has been hitherto applied: But it may with great advantage be put in practice in a variety of other caſes, particularly in all artificial or accidental diviſions either of the lips or cheeks; and in every wound in other parts that does not run deep, and in which ſutures are neceſſary, this ſuture is preferable to the interrupted or any other. The pins made uſe of for twiſting the threads upon ought to be made of a flat form, ſo as not to cut the parts through which they paſs ſo readily as the ligatures employed in the interrupted ſuture. And thus one great objection to the latter is very effectually obviated: for every practitioner muſt be ſenſible of this being the moſt faulty part of the interrupted ſuture, that when muſcular parts are divided ſo as to produce much retraction, the ligatures employed for retaining them almoſt conſtantly cut them through before a reunion is accompliſhed; whereas the flatneſs of the pins uſed in the twiſted ſuture, and upon which the whole preſſure produced by the ligatures is made to reſt, proves in general a very effectual preventive againſt all ſuch occurrences.

The pins uſed in this operation are repreſented in Plate CCCCLXXXVII. fig. 15. They are commonly made of gold or ſilver; and in order to make them paſs with greater eaſe, ſteel points are added to them. They are ſometimes uſed, however, of gold or ſilver alone.

158 Method of employing the twiſted ſuture.

The manner of performing this operation is as follows. The divided parts intended to be reunited, muſt by the hands of an aſſiſtant, be brought nearly into contact; leaving juſt as much ſpace between the edges of the ſore as to allow the ſurgeon to ſee that the pins are carried to a proper depth. This being done, one of the pins muſt be introduced through both ſides of the wound, by entering it on one ſide externally, puſhing it forwards and inwards to within a little of the bottom of the wound, and afterwards carrying it outwardly through the oppoſite ſide, to the ſame diſtance from the edge of the ſore that it was made to enter at on the other. Sutures.

The diſtance at which the needle ought to enter from the edge of the ſore muſt be determined by the depth of the wound, and by the degree of retraction produced in the divided parts. In general, however, it is a proper regulation, in deep wounds, to carry the pins nearly to the ſame diſtance from the ſide of the ſore as they are made to penetrate in depth: And whatever the deepneſs of the wound may be, the pins ought to paſs within a very little of its bottom: otherwiſe the parts which lie deep will run a riſk of not being united; a circumſtance which muſt always give riſe to troubleſome collections of matter.

The firſt pin being paſſed in this manner very near to one end of the ſore, and the parts being ſtill ſupported by an aſſiſtant, the ſurgeon, by means of a firm waxed ligature, paſſed three or four times round and acroſs the pin, ſo as nearly to deſcribe the figure of 8, is to draw the parts through which it has paſſed into immediate and cloſe contact: and the thread being now ſecured with a looſe knot, another pin muſt be introduced in the ſame manner at a proper diſtance from the former; and the thread with which the other was fixed being looſed, and in the ſame manner carried round this pin, others muſt be introduced at proper diſtances along the whole courſe of the wound; and the ſame ligature ought to be of a ſufficient length for ſecuring the whole.

159 Number of pins to be uſed.

The number of pins to be uſed muſt be determined entirely by the extent of the wound. Whenever this ſuture is practiſed, a pin ought to be introduced very near each end of the wound, otherwiſe the extremities of the ſore are apt to ſeparate ſo as not to be afterwards eaſily reunited. In large wounds, if the pins are introduced at the diſtance of three quarters of an inch from one another, it will in general be found ſufficient; but in cuts of ſmaller extent a greater number of pins become neceſſary in proportion to the dimenſions of the ſores.

Thus in a wound of an inch and half in length, three pins are abſolutely requiſite; one near to each end, and another in the middle of the ſore: whereas five pins will always be found fully ſufficient for a wound of three inches and a half in extent, allowing one to be within a quarter of an inch of each extremity of the wound, and the others to be placed along the courſe of the ſore at the diſtance of three quarters of an inch from one another.

The pins being all introduced and ſecured in the manner directed, nothing remains to be done, but to apply a piece of lint wet with mucilage all along the courſe of the wound, with a view to exclude, as effectually as poſſible, every acceſs to the external air.

When the pins remain long they generally do harm, by the unneceſſary irritation and conſequent retraction of parts with which they are always attended; and if they are not continued for a ſufficient length of time, that degree of adheſion is not produced between the divided parts which is neceſſary for their future retention; ſo that the effect of the operation comes to be in a great meaſure, if not entirely, loſt.

In wounds of no great depth, for inſtance of three quarters of an inch or ſo, a ſufficient degree of adheſion always takes place in the ſpace of five days; and ſix, or at moſt ſeven days, will generally be found ſufficient for wounds of the greateſt depth. But with reſpect to this circumſtance, it muſt always be underſtood, that the patient's ſtate of health muſt have a conſiderable influence on the time neceſſary for producing adheſion between divided parts.

When the pins are withdrawn, the uniting bandage may be

Ligature of Arteries.

be applied with great advantage; but as ſlips of leather ſpread with ordinary glue, when applied to each ſide of the cicatrix, may, by means of ligatures properly connected with them, be made to anſwer the purpoſe more effectually, this mode of ſupporting the parts ought of courſe to be preferred.

Sect. II. *Of the Ligature of Arteries.*

When a ſurgeon is called immediately to a wound of any great artery of a limb, he ſhould clap the point of his finger upon the wounded artery, or make his aſſiſtant hold it; cut the wound ſo far open as to ſee the artery fairly; draw it out if it be cut acroſs, and have ſhrunk among the fleſh; or tie it like the artery of the arm in aneuriſm by paſſing ligatures under it. When, however, the wound happens in ſuch ſituations that we cannot command the blood, it is better to cloſe the lips of the wound, and try to make them adhere by means of a very ſteady compreſs and bandage. Thus an aneuriſm will form; the operation for the cure of which ſhall be afterwards deſcribed.

When accidents of this nature occur in any of the extremities, and where preſſure can be made with eaſe on the ſuperior part of the artery, we are poſſeſſed of an inſtrument which never fails to put a ſtop to all further loſs of blood: we mean the tourniquet. See Plate CCCCLXXXVII. fig. 16.

160 The tourniquet.

The tourniquet has undergone many improvements; but the one here repreſented is conſidered as the beſt. By means of it the blood in any limb is very eaſily and effectually commanded; and as it graſps the whole member equally, all the collateral branches, as well as the principal arteries, are equally compreſſed by it. It has this material advantage too over every other inſtrument of this kind, that, when properly applied, a ſingle turn, or even half a turn, of the ſcrew, is ſufficient for producing either a flow of blood, or for putting a total ſtop to it. The manner of uſing it is as follows.

161 Manner of uſing it.

Let a cuſhion of three inches in length by one inch and half in diameter be prepared of a linen roller, tolerably firm, but not ſo hard as to render preſſure produced by it very painful. This being placed upon the courſe of the principal artery of the limb, is to be firmly ſecured in that ſituation by one or two turns of a circular roller, of the ſame breadth with the cuſhion itſelf.

The inſtrument, with the ſtrap connected with it, being now placed upon the limb, with the handle of the ſcrew on the oppoſite ſide of the member to the cuſhion upon the artery, the ſtrap is to be carried round the limb directly over the cuſhion, and to be firmly connected on the other ſide of the buckle. In thus connecting the ſtrap and buckle together, particular attention is neceſſary in doing it with great firmneſs, ſo as that the ſcrew may afterwards operate with as much advantage as poſſible in producing a ſufficient degree of preſſure. When proper attention is paid to this circumſtance, a ſingle turn of the ſcrew proves ſufficient for putting an entire ſtop to the circulation of blood in the limb: but when the ſtrap has not originally been made very tight, ſeveral turns of the ſcrew become neceſſary; an occurrence which may be always very eaſily prevented, and which, when not attended to, frequently proves very embarraſſing in the courſe of an operation.

162 Method of tying arteries by means of the tenaculum.

Various methods have been invented for ſecuring arteries by means of ligatures. The practice till lately in ordinary uſe was, by means of a curved needle, to paſs a ligature of ſufficient ſtrength round the mouth of the bleeding veſſel, including a quarter of an inch all round of the ſurrounding parts, and afterwards to form a knot of a proper tightneſs upon the veſſel and other parts comprehended in the nooſe. But this method was found to give ſo much pain, and in ſome caſes to be attended with ſuch violent convulſions, not only in the part chiefly affected, but of the whole body, that the beſt practitioners have thought proper to reject it, and to tie up the blood-veſſels by themſelves; for it is now well known that even very ſmall arteries are poſſeſſed of much firmneſs; and that even in the largeſt arteries a ſlight degree of compreſſion is ſufficient not only for reſtraining hemorrhagy, but for ſecuring the ligature on the very ſpot to which it is firſt applied.

Ligature of Arteries.

In order to detect the arteries to be tied, the tourniquet, with which they are ſecured, muſt be ſlackened a little by a turn or two of the ſcrew; and the moment the largeſt artery of the ſore is diſcovered, the ſurgeon fixes his eye upon it, and immediately reſtrains the blood again by means of the tourniquet. An aſſiſtant now forms a nooſe on the ligature to be made uſe of; and this nooſe being put over the point of the tenaculum, Plate CCCCLXXXVII. fig. 17. the operator puſhes the ſharp point of the inſtrument through the ſides of the veſſel, and at the ſame time pulls ſo much of it out, over the ſurface of the ſurrounding parts, as he thinks is ſufficient to be included in the knot which the aſſiſtant is now to make upon the artery. In forming this ligature a ſingle knot moderately drawn, and over it another ſingle knot, is perfectly ſufficient.

163 With the crooked needle.

When from the deepneſs of a wound, or from any other cauſe, ſome particular artery cannot be properly ſecured by the tenaculum; in this caſe there is a neceſſity of employing the crooked needle, and the following is the method of uſing it.

A needle of the ſhape repreſented Pl. CCCCLXXXVII. fig. 14. armed with a ligature of a ſize proportioned to itſelf and to the veſſel to be taken up, is to be introduced at the diſtance of a ſixth or eighth part of an inch from the artery, and puſhed to a depth ſufficient for retaining it, at the ſame time that it is carried fully one half round the blood-veſſel. It muſt now be drawn out; and being again puſhed forward till it has completely encircled the mouth of the artery, is is then to be pulled out; and a knot to be tied of a ſufficient firmneſs, as was already directed when the tenaculum is uſed.

Chap. XI. *Of Aneuriſms.*

164 Definition.

The term *Aneuriſm* was originally meant to ſignify a tumor formed by the dilatation of the coats of an artery; but by modern practitioners it is made to apply not only to tumors of this kind, but to ſuch as are formed by blood effuſed from arteries into the contiguous parts. There are three ſpecies; the true or encyſted, the falſe or diffuſed, and the varicoſe aneuriſm.

165 The true or encyſted aneuriſm.

The *true* or *encyſted* aneuriſm, when ſituated near the ſurface of the body, produces a tumor at firſt ſmall and circumſcribed; the ſkin retains its natural appearance; when preſſed by the fingers, a pulſation is evidently diſtinguiſhed; and with very little force the contents of the ſwelling may be made to diſappear; but they immediately return upon removing the preſſure. By degrees the ſwelling increaſes, and becomes more prominent; but ſtill the patient does not complain of pain: on preſſure the tumor continues of an equal ſoftneſs, and is compreſſible. After this the ſwelling becomes large, the ſkin turns paler than uſual, and in more advanced ſtages œdematous: the pulſe ſtill continues; but parts of the tumor become firm from the coagulation of the contained blood, and yield little to preſſure: at laſt the ſwelling increaſes in a gradual manner, and is attended with a great degree of pain. The ſkin turns livid, and has a gangrenous appearance. An oozing of

Aneurisms. bloody serum occurs from the integuments; and, if a real mortification do not take place, the skin cracks in different parts; and the artery being now deprived of the usual resistance, the blood bursts out with such force as to occasion the almost immediate death of the patient. Thus the disease terminates in the large cavities of the body; but in the extremities we can, by means of the tourniquet, prevent the sudden termination of the disease.

When affections of this kind happen in the larger arteries, the effects produced upon the neighbouring parts are often surprising: the soft parts not only yield to a great extent, but even the bones frequently undergo a great degree of derangement.

166 The false or diffused aneurism.

The *false* or *diffused* aneurism consists in a wound or rupture in an artery, producing, by the blood thrown out of it, a swelling in the contiguous parts. It is most frequently produced by a wound made directly into the artery.

The following is the usual progress of the disorder. A tumor, about the size of a horse-bean, generally rises at the orifice in the artery soon after the discharge of the blood has been stopped by compression. At first it is soft, has a strong degree of pulsation, and yields a little to pressure, but cannot be made entirely to disappear; for here the blood forming the tumor being at rest, begins to coagulate. If not improperly treated by much pressure, it generally remains nearly of the same size for several weeks. The enlargement however proceeds more rapidly in some cases than in others. Instances have occurred of the blood being diffused over the whole arm in the space of a few hours; while, on the contrary, swellings of this kind have been many months, nay even years, in arriving at any considerable size.

As the tumor becomes larger, it does not, like the true aneurism, grow much more prominent, but rather spreads and diffuses itself into the surrounding parts. By degrees it acquires a firm consistence; and the pulsation, which was at first considerable, gradually diminishes, till it is sometimes scarcely perceptible. If the blood at first thrown out proceed from an artery deeply seated, the skin preserves its natural appearance till the disorder is far advanced: but when the blood gets at first into contact with the skin, the parts become instantly livid, indicating the approach of mortification; and a real sphacelus has sometimes been induced. The tumor at first produces little uneasiness; but as it increases in size, the patient complains of severe pain, stiffness, numbness, and immobility of the whole joint; and these symptoms continuing to augment, if the artery be large, and assistance not given, the teguments at last burst, and death must ensue.

167 Varicose aneurism.

When an artery is punctured through a vein, as in bloodletting at the arm, the blood generally rushes into the yielding cellular substance, and there spreads so as to shut the sides of the vein together. But in some instances where the artery happens to be in contact with the vein, the communication opened has been preserved; and the vein not being sufficiently strong for resisting the impulse of the artery, must consequently be dilated. This is a varicose aneurism. It was first accurately described by Dr Hunter, and since that time has been frequently observed by different practitioners. Here the swelling is entirely confined to the veins. Soon after the injury the vein immediately communicating with the artery begins to swell, and enlarge gradually. If there be any considerable communications in the neighbourhood, the veins which form them are also enlarged. The tumor disappears upon pressure, the blood contained in it being chiefly pushed forwards in its course towards the heart; and when the tumor is large, there is a singular tremulous motion, attended with a perpetual hissing noise, as if air was passing into it through a small aperture. Aneurisms.

If a ligature be applied upon the limb immediately below the swelling, tight enough to stop the pulse in the under part of the member, the swelling disappears by pressure, but returns immediately upon the pressure being removed. If, after the swelling is removed by pressure, the finger be placed upon the orifice in the artery, the veins remain perfectly flaccid till the pressure is taken off. If the trunk of the artery be compressed above the orifice so as effectually to stop the circulation, the tremulous motion and hissing immediately cease; and if the veins be now emptied by pressure, they remain so till the compression upon the artery be removed. If the vein be compressed a little above, as well as below the tumor, all the blood may generally, though not always, be pushed through the orifice into the artery; from whence it immediately returns on the pressure being discontinued.

When the disease has continued long, and the dilatation of the veins has become considerable, the trunk of the artery above the orifice generally becomes greatly enlarged, while that below becomes proportionably small; of consequence the pulse in the under part of the member is always more feeble than in the sound limb of the opposite side.

168 Causes of aneurism.

The causes producing aneurisms, in general, are a natural disease of the arteries. Thus a partial debility of their coats may readily produce the disease; or they may arise, especially in the internal parts of the body, from great bodily exertions. They are likewise produced by wounds of the coats of the arteries, as now and then happens in bloodletting at the arm; or from acrid matter contained in a neighbouring sore; or from the destruction of surrounding parts, by which the natural support is removed.

169 Diagnosis

Aneurisms have frequently been mistaken for abscesses and other collections of matter, and have been laid open by incision; on which account great attention is sometimes required to make the proper distinction. In the commencement of the disease the pulsation in the tumor is commonly so strong, and other concomitant circumstances so evidently point out the nature of the disorder, that little or no doubt respecting it can ever take place; but in the more advanced stages of the disease, when the swelling has become large and has lost its pulsation, nothing but a minute attention to the previous history of the case can enable the practitioner to form a judgment of its nature.

Aneurisms may be confounded with soft encysted tumors, scrophulous swellings, and abscesses situated so near to an artery as to be affected by its pulsation. But one symptom, when connected with strong pulsation, may always lead to a certain determination that the swelling is of the aneurismal kind, viz. the contents of the tumor being made easily to disappear upon pressure, and their returning on the compression being removed. The want of this circumstance, however, ought not to convince us that it is not of that nature; for it frequently happens, especially in the advanced stages of aneurisms, that their contents become so firm that no effect is produced upon them by pressure. Hence the propriety, in doubtful cases, of proceeding as if the disease was clearly of the aneurismal kind.

170 Prognosis.

In the prognosis, three circumstances are chiefly to be attended to; the manner in which the disease appears to have been produced, the part of the body in which the swelling is situated, and the age and habit of the body of the patient.

If an aneurism has come forward in a gradual manner, without any apparent injury done to the part, and not succeeding any violent bodily exertion, there will be reason to suppose

suppose that the disease depends upon a general affection either of the trunk in which it occurs, or of the whole arterious system. In such cases art can give little assistance: whereas if the tumor has succeeded an external accident, an operation may be attended with success.

171 An operation seldom necessary in varicose aneurism.

In the varicose aneurism a more favourable prognosis may generally be given than in either of the other two species. It does not proceed so rapidly; when it has arrived at a certain length, it does not afterwards acquire much additional size; and it may be sustained without much inconvenience for a great number of years. As long as there is reason to expect this, the hazard which almost always attends the operation ought to be avoided.

In the second volume of the London Medical Observations, two cases are related by Dr Hunter of the varicose aneurism. One of them at that time was of 14 years standing, and the other had subsisted for five years, without there being any necessity for an operation. And in vol. iii. of the same work a similar case of five years duration is related by Dr Cleghorn.

In a letter afterwards from Dr Hunter to Mr Benjamin Bell, the Doctor says, "The lady in whom I first observed the varicose aneurism is now living at Bath in good health, and the arm is in no sense worse, although it is now 35 years since she received the injury:" and the Doctor farther observes, that he never heard of the operation being performed for the varicose aneurism which was known to be such.

Mr Bell says, he was informed by Dr William Cleghorn of Dublin, that the case of varicose aneurism, related in the 3d volume of the London Medical Observations, remained nearly in the same state as at the time that account of it was made out, which included a period of at least 20 years; only that the veins were rather more enlarged. The patient recovered, and the limb became nearly as strong and serviceable as the other. Mr Pott also met with three different instances of this species of aneurism; and observes, that the operation never became necessary in any of them.

Among other instances of varicose aneurism which have appeared here, a young man from Paisley was examined several years ago by different surgeons of this place. The disease was very clearly marked, and no operation was advised. He was afterwards found serving in the navy, where he underwent great fatigue without any inconvenience from the aneurism, though then of 13 years standing.

But though this aneurism, when it has arrived at a certain size, commonly remains stationary, and may be borne without much inconvenience for a long time, this is not always the case; for some instances have occurred, where the disease was attended with great uneasiness, and where the operation was performed with much difficulty.

In judging further of the probable event of aneurisms in general, the situation of the tumor next requires attention. When it is so situated that no ligature or effectual compression can be applied for stopping the circulation in the part, if the artery be large, there would be the greatest danger in opening it. In this case therefore the most fatal consequences are to be apprehended.

When aneurisms are situated near the upper parts of the extremities, surgeons have been hitherto doubtful whether, after tying up the humeral or femoral arteries, the lower parts of the limb would be supplied with blood; and tho' several successful instances of performing that operation have been published, the success has been pretty generally ascribed to unusual branching of the great arteries of those patients, on whom the operation was performed, above the aneurism. Mr. John Bell, however, in his late very ingenious and important *Discourses on Wounds*, has proved, to our satisfaction at least, that the inosculations which take place between the internal iliac and the arteries of the leg, by means of the glutæal arteries and the profunda femoris, are in every case sufficient to supply nourishment to the limb; that the same is the case in the arm; and that therefore in every aneurism, even of the humeral or femoral artery, we ought to perform the operation. Several instances of success are there related; among others, an operation performed by Mr J. Bell himself, which, as it is perhaps the greatest that has hitherto been performed, we shall here abridge for the gratification of our readers. A leech-catcher fell as he was stepping out of a boat; and a pair of long-pointed scissars pierced his hip exactly over the sciatic notch, where the great iliac artery comes out from the pelvis. The artery bled furiously: the patient fainted. The surgeon easily stopt up the wound, as it was very narrow and deep, and healed it. A great tumor soon formed. The man travelled from the north country in six weeks to the Edinburgh infirmary, with a prodigious tumor of the hip, the thigh rigidly contracted, the ham bent, the whole leg shrunk and cold and useless. There was no pulsation nor retrocession of blood on pressure; but the distention was attended with great pain, and the man was extremely anxious to have an operation performed. Though there was little doubt of its being aneurism, it might be a great abscess. It was resolved therefore to make a small incision, and just touch the bag with the point of a lancet, and if it contained blood, a full consultation was to be called. Mr Bell accordingly made an incision two inches and a half in length; the great fascia formed the coat of the tumor, and under it were seen the fibres of the great glutæus muscle. As soon as it was opened at one point, great clots of blood came out; and Mr Bell, after being certain that it was an aneurism of the great artery of the thigh, closed up the wound with a tent-like compress, put the patient to bed, and a pupil held his hand on the hip. This was done at one o'clock; at four the consultation met, and the operation was performed. On making an incision eight inches long, the blood was thrown out with a whishing noise, and with such impetuosity, that the assistants were covered with it. In a moment twenty hands were about the tumor, and the bag was filled with sponges and cloths of all kinds; the blood, however, still made its way; and the man who had supported himself on his elbow, fell down; his arms and head hung down, he uttered two or three heavy groans, and they thought him dead. At that critical moment Mr Bell ran the bistoury upwards and downwards, and at once made the wound two feet long; thrust his hand to the bottom of the tumor, felt the warm jet of blood, put his finger on the mouth of the artery, the pulse of which he felt distinctly; which first assured him that the man was alive. The artery was then tied; and when Mr Bell lifted up his finger, it was discovered to be the posterior iliac; that it had been cut fairly across, and had bled with open mouth. The patient was so low, that after dressing the wound, they were obliged to bring in a bed, and leave him to sleep in the operation room. He was cured of this great wound in less than seven months, and afterwards recovered the use of his leg completely.

172 Remarkable aneurism.

173 Effects of pressure in aneurisms.

In every case of aneurism, the use of pressure has been indiscriminately recommended, not only in the incipient period of the disease, but even in its more advanced stages.

In the diffused or false aneurism, as pressure cannot be applied to the artery alone, without at the same time affecting the refluent veins; and as this, by producing an increased resistance to the arterial pulsations, must force an additional quantity of blood to the orifice in the artery—no advantage

Aneurisms. is to be expected from it, though it may be productive of mischief.

In the early stages of encysted aneurism, while the blood can be yet pressed entirely out of the sac into the artery, it often happens, by the use of a bandage of soft and somewhat elastic materials, properly fitted to the part, that much may be done in preventing the swelling from receiving any degree of increase; and on some occasions, by the continued support thus given to the weakened artery, complete cures have been at last obtained. In all such cases, therefore, particularly in every instance of the varicose aneurism, much advantage may be expected from moderate pressure.

But pressure, even in encysted aneurism, ought never to be carried to any great length; for tight bandages, by producing an immoderate degree of reaction in the containing parts to which they are applied, instead of answering the purpose for which they were intended, have evidently the contrary effect. Indeed the greatest length to which pressure in such cases ought to go, should be to serve as an easy support to the parts affected, and no farther.

174 Method of performing the operation for aneurism.

In performing the operation for aneurism, the first step ought to be to obtain a full command of the circulation in the inferior part of the member by means of the tourniquet. This being done, the patient should be so placed, that the diseased limb, on being stretched on a table, is found to be of a proper height for the surgeon; who, as the operation is generally tedious, ought to be seated. The limb being properly secured by an assistant, the operator is now with the scalpel, Plate CCCCLXXXVII. fig. 18. to make an incision through the skin and cellular substance along the whole course of the tumor; and as freedom in the remaining parts of the operation is here a matter of much importance, it is even of . o carry this external incision half an inch or so both above and below the fartheſt extremities of the swelling.

All the effused blood ought then to be wiped off by means of a sponge; and the softest part of the tumor being discovered, an opening ought there to be made into it with the lancet, Plate CCCCLXXXVII. fig. 19. large enough for admitting a finger of the operator's left-hand. This being done, and the finger introduced into the cavity of the tumor, it is now to be laid open from one extremity to the other, by running a blunt-pointed bistoury, Plate CCCCLXXXVII. fig. 20. along the finger from below upwards, and afterwards from above downwards, so as to lay the whole cavity fairly open.

The cavity of the tumor being thus laid freely open, all the coagulated blood is to be taken out by the fingers of the operator, together with a number of tough membranous filaments commonly found here. The cavity of the tumour is now to be rendered quite dry, and free from the blood which, on the first opening of the swelling, is discharged into it from the veins in the inferior part of the member: the tourniquet is then to be slackened to discover, not only the artery itself, but the opening into it, from whence the blood collected in the tumor has been all along discharged. This being done, the next point to be determined is the manner of securing this opening into the artery, so as to prevent in future any farther effusion of blood. Various means have been proposed for accomplishing this; but the effects of all of them may be comprehended under the three following heads.

175 Method of securing the wound of the artery,

176 By astringents,

1. The effects of ligature upon a large artery having on some occasions proved fatal to the inferior part of the member, it was long ago proposed, that so soon as the opening into the artery has been discovered, instead of applying a ligature round it, which for certain is to obliterate its cavity entirely, a piece of agaric, vitriol, alum, or any other astringent substance, should be applied to the orifice, in order if possible to produce a reunion of its sides. Aneurisms.

177 Or by sutures,

2. Upon the same principle with the preceding, viz. that of still preserving the circulation in the artery, it was several years ago proposed by an eminent surgeon of Newcastle, Mr Lambert, that the orifice in the artery should be secured by means of the twisted future. A small needle being pushed through the edges of the wound, they are then directed to be drawn together by a thread properly twisted round the needle, as was formerly directed when treating of futures.

178 Improper.

Strong objections, however, occur to both of these methods. In the first place, no astringent application with which we are acquainted is possessed of such powers as to deserve much confidence. In almost every instance in which they have been used, the hemorrhagy has recurred again and again, so as to prove very distressing, not only to the patient, but to the practitioner in attendance; little or no attention is therefore to be paid to remedies of this kind in ordinary practice.

Mr Lambert's method of stitching the orifice in the artery is certainly a very ingenious proposal; and would in all probability, at least in most instances, prove an effectual stop to all farther discharge of blood: but as we have yet only one instance of its success, little can be said about it. Two material objections, however, seem to occur to this practice. One is, that in the operation for the aneurism, in almost every instance, a very few only excepted, the artery lies at the back-part of the tumor; so that when all the collected blood is removed, there is such a depth of wound, that it must be always a very difficult matter, and on many occasions quite impracticable, to perform this nice operation upon the artery with that attention and exactness which, in order to ensure success, it certainly requires. But there is another very material objection. By introducing a needle through the sides of the orifice, and drawing these together by a ligature, the cavity of the artery must undoubtedly be at that point much diminished. Indeed Mr Lambert, in his account of the case in which this operation was performed, acknowledges that the diameter of the artery was thereby diminished. Now the passage of the blood being thus contracted at one point, the impulse upon that particular part must be very considerable: So that the very remedy employed for the cure of one species of aneurism, will in all probability prove a very powerful agent in inducing another; for the blood being thus obstructed in its usual course, there will be no small danger incurred of a dilatation being produced immediately above this preternatural stricture.

3. Neither of the methods we have yet been considering being found eligible for securing the orifice in the artery, we shall now proceed to describe the ordinary manner of performing this operation; which consists in obliterating the arterial cavity entirely by means of ligatures.

179 Method of doing it by ligature.

The artery being laid bare in the manner directed, and all the coagulated blood being carefully removed from the cavity of the tumor, on the tourniquet being now slackened so as to bring the orifice in the artery into view, a small probe curved at the extremity is to be introduced at the opening, in order to raise the artery from the neighbouring parts, so as that the surgeon may be enabled with certainty to pass a ligature round it, without comprehending the contiguous nerves, which in general run very near to the large blood-vessels of a limb. By this precaution the nerves may be always avoided; and by doing so, a great deal of mischief may be prevented, which otherwise might supervene. When the disorder is situated either in the ham, or in the usual part of blood-letting in the arm, bending the joints of

the

Aneurisms. the knee or of the elbow, as it relaxes the artery a little, renders this part of the operation more easily effected than when the limbs are kept fully stretched out.

The artery being thus gently separated from the contiguous parts, a firm waxed ligature must be passed round it, about the eighth part of an inch or so above the orifice, and another must in the same manner be introduced at the same distance below it.

The ligatures being both finished in the manner directed, the tourniquet is now to be made quite loose; and if no blood is discharged at the orifice in the artery, we may then rest satisfied that the operation is so far properly completed.

180 Subsequent treatment of the patient.

The wound is now to be lightly covered with soft lint, with a pledgit of any emollient ointment over the whole; and a compress of linen being applied over the dressings, all the bandage in any degree requisite is two or three turns of a roller above and as many below the centre of the wound, making it press with no more tightness than is absolutely necessary for retaining the application we have just now mentioned.

The patient being now put into bed, the member should be laid in a relaxed posture upon a pillow, and ought to be so placed as to create the least possible uneasiness from the posture in which it is laid.

As the operation for the aneurism is always tedious, and produces much pain and irritation, a full dose of laudanum should be given immediately on the patient being got into bed. In order to diminish sensibility during some of the more capital operations, different trials have been made of opiates given an hour or so before the operation. On some occasions this proved evidently very useful; but in others it seemed to have the contrary effect; particularly in weak nervous constitutions, in which with any doses, however small, they appeared to be rendered more irritable and more susceptible of pain, than if no opiate had been given. Immediately after this operation, however, an opiate ought to be exhibited, to be repeated occasionally according to the degrees of pain and restlessness.

181 State of the limb after the operation.

In some few cases of aneurism, it has happened that the pulse in the under part of the member has been discovered immediately after the operation. This, however, is a very rare occurrence: For as this disorder is seldom met with in any other part than at the joint of the elbow as a consequence of blood-letting, and as it rarely happens that the brachial artery divides till it passes an inch or two below that place, the trunk of this artery is therefore most frequently wounded; and when, accordingly, the ligature, in this operation, is made to obliterate the passage of almost the whole blood which went to the under part of the arm, there cannot be the least reason to expect any pulsation at the wrist, till in a gradual manner the anastomosing branches of the artery have become so much enlarged as to transmit such a quantity of blood to the inferior part of the member as is sufficient for acting as a stimulus to the larger branches of the artery.

Immediately after the operation, the patient complains of an unusual numbness or want of feeling in the whole member; and as it generally, for a few hours, becomes cold, it is therefore right to keep it properly covered with warm soft flannel; and in order to serve as a gentle stimulus to the parts below, moderate frictions appear to be of use. In the space of ten or twelve hours from the operation, although the numbness still continues, the heat of the parts generally begins to return; and it frequently happens, in the course of a few hours more, that all the inferior part of the member becomes even preternaturally warm.

Immediately after this operation, the want of feeling in the parts is often very great; and in proportion as the circulation in the under part of the member becomes more considerable, the degree of feeling also augments. If we could suppose the nerves of the parts below to be always included in the ligature with the artery, that numbness which succeeds immediately to the operation might be easily accounted for; but it has been also known to happen when nothing but the artery was secured by the ligature. Aneurisms.

In the mean time, the patient being properly attended to as to regimen, by giving him cordials and nourishing diet when low and reduced, and confining him to a low diet if his constitution is plethoric, the limb being still kept in an easy relaxed posture, towards the end of the fourth or fifth day, sometimes much sooner, a very weak feeble pulse is discovered in the under part of the member, which becoming stronger in a gradual manner, the patient in the same proportion recovers the use and feeling of the parts.

So soon as there is an appearance of matter having formed freely about the sore, which will seldom happen before the fifth or sixth day, an emollient poultice should be applied over it for a few hours, in order to soften the dressings, which may be then removed. At this time the ligatures might be taken away; but as their continuance for a day or two longer can do no harm, it is better to allow them to remain till the second or third dressing, when they either drop off themselves, or may be taken away with perfect safety. The dressings, which should always be of the softest materials, being renewed every second or third day according to the quantity of matter produced, the sore is in general found to heal very easily; and although the patient may for a considerable time complain of great numbness and want of strength in the whole course of the diseased limb, yet in most instances a very free use of it is at last obtained.

182 Hemorrhagies often succeed the operation.

Very often after the artery seems to be secured it gives way, and fatal hemorrhagies ensue; nor is the patient free from this danger for a great length of time. In one of Mr Hunter's operations the artery gave way on the 26th day. It is to this difficulty of procuring adhesion between the sides of the artery that a great part of the danger of this operation is to be ascribed.

CHAP. XII. *Of Affections of the Brain from External Violence.*

183 Symptoms of compression of the brain.

WHEN the brain is compressed, a set of symptoms ensue extremely dangerous, though sometimes they do not make their appearance till after a considerable interval. But at whatever time they appear, they are uniformly of the same kind, and are in general as follow: drowsiness, giddiness, and stupefaction, dimness of sight, dilatation of the pupil; and, where the injury done to the head is great, there is commonly a discharge of blood from the eyes, nose, and ears. Sometimes the fractured bone can be discovered through the integuments, at others it cannot. There is an irregular and oppressed pulse, and snoring or apoplectic stertor in breathing. There is likewise nausea and vomiting, with an involuntary discharge of fæces and urine. Among the muscles of the extremities and other parts, there is loss of voluntary motion, convulsive tremors in some parts of the body, and palsy in others, especially in that side of the body which is opposite to the injured part of the head.

Some of the milder of these symptoms, as vertigo, stupefaction, and a temporary loss of sensibility, are frequently induced by slight blows upon the head, but commonly soon disappear, either by rest alone, or by the means to be afterwards pointed out. But when any other symptoms ensue, such as dilatation of the pupils, and especially when much blood is dis-

Fracture and Depreſſion of the Cranium, &c.

diſcharged from the eyes, noſe, and ears, and that there is an involuntary diſcharge of fæces and urine, it may be reaſonably concluded that compreſſion of the brain is induced.

The cavity of the cranium, in the healthy and natural ſtate, is everywhere completely filled by the brain; whatever therefore diminiſhes that cavity, will produce a compreſſion of the brain.

184 Cauſes of theſe.

The cauſes producing ſuch a diminution may be of various kinds, as fracture and depreſſion of the bones of the cranium; the forcible introduction of any extraneous body into the cavity of the cranium; effuſion of blood, ſerum, pus, or any other matter; the thickneſs of the bones of the cranium in certain diſeaſes, as in lues venerea, rickets, or ſpina ventoſa; or water collected in hydrocephalous caſes. The firſt ſet of cauſes ſhall be conſidered in their order. The four laſt mentioned belong to the province of the phyſician, and have been conſidered in a former part of this Work.

SECT. I. *Of Fracture and Depreſſion of the Cranium producing Compreſſion of the Brain.*

FRACTURES of the cranium have been differently diſtinguiſhed by different authors; but it ſeems ſufficient to divide them into thoſe attended with depreſſion, and thoſe which are not ſo.

In fracture and depreſſion of the cranium, the treatment ought to be,—to diſcover the ſituation and extent of the fracture;—to obviate the effects of the injury done to the brain, by raiſing or removing all the depreſſed parts of the bone;—to endeavour to complete the cure by proper dreſſings, and attention to the after treatment.

185 Method of diſcovering the ſituation of fractures of the cranium.

When the teguments correſponding to the injury done to the bone are cut or lacerated, and, as is ſometimes the caſe, entirely removed, the ſtate of the fracture is immediately diſcovered; but when the integuments of the ſkull remain entire, even though the general ſymptoms of fracture be preſent, there is ſometimes much difficulty in aſcertaining it. When, however, any external injury appears, particularly a tumor from a recent contuſion, attended by the ſymptoms already deſcribed, there can be no doubt of the exiſtence of a fracture. But it ſometimes happens that compreſſion exiſts without the ſmalleſt appearance of tumor. In ſuch caſes, the whole head ought to be ſhaved when an inflammatory ſpot may frequently be obſerved. Sometimes the place of the fracture has been diſcovered by the patient applying the hand frequently on or near ſome particular part of the head.

When the ſymptoms of a compreſſed brain are evidently marked, no time ought to be loſt in ſetting about an examination of the ſtate of the cranium, wherever appearances point out, or even lead us to conjecture, in what part a fracture may be ſituated. For this purpoſe an inciſion is to be made upon the ſpot through the integuments to the ſurface of the bone, which muſt be ſufficiently expoſed to admit of a free examination.

Some authors have recommended a crucial inciſion; others one in form of the letter T; while many adviſe a conſiderable part of the integuments to be entirely removed. But as it is more agreeable to the preſent mode of practice to ſave as much of the ſkin as poſſible, a ſimple inciſion is generally preferred, unleſs the fracture run in different directions, and then the inciſion muſt vary accordingly. It will frequently happen, that a conſiderable part of the integuments muſt be ſeparated from the ſkull, in order to obtain a diſtinct view of the full extent of the fracture; but no part of the integuments is to be entirely removed.

When blood-veſſels of any conſiderable ſize are divided, either before or in time of the examination, they ought to be allowed to bleed freely, as in no caſe whatever is the loſs of blood attended with more advantage than the preſent. When, however, it appears that the patient has loſt a ſufficient quantity, the veſſels ought to be ſecured.

Fracture and Depreſſion of the Cranium, &c.

After the integuments have been divided, if the ſkull be found to be fractured and depreſſed, the nature of the caſe is rendered evident; but even where there is no external appearance of fracture, tumor, diſcoloration, or other injury, if the patient continue to labour under ſymptoms of a compreſſed brain, if the pericranium has been ſeparated from the bone, and eſpecially if the bone has loſt its natural appearance, and has acquired a pale white or duſky yellow hue, the trepan ought to be applied without heſitation at the place where theſe appearances mark the principal ſeat of the injury.

Again, although no mark either of fracture or of any diſeaſes underneath ſhould appear on the outer table of the bone, yet there is a poſſibility that the inner table may be fractured and depreſſed. This indeed is not a common occurrence, but it happens probably more frequently than ſurgeons have been aware of; and where it does happen, the injury done to the brain is as great, and attended with as much danger, as where the whole thickneſs of the bone is beat in. The application of the trepan is therefore neceſſary.

But if, after the application of the trepan, it happens that no mark of injury appears either in the outer or inner table in that part, or in the dura mater below it, and that the ſymptoms of a compreſſed brain ſtill continue, a fracture in ſome other part is to be ſuſpected; or that kind of fracture termed by practitioners *counter fiſſure*, where the ſkull is fractured and ſometimes depreſſed on the oppoſite ſide to, or at a diſtance from, the part where the injury was received. This is fortunately not a very frequent occurrence, and has even been doubted by ſome; but different inſtances of it have, beyond all queſtion, been found. If therefore the operation of the trepan has been performed, and no fracture is diſcovered, no extravaſation appears on the ſurface of the brain; and if blood-letting and other means uſually employed do not remove the ſymptoms of compreſſion, the operator is to ſearch for a fracture on ſome other part. The whole head ſhould again be examined with much accuracy; and, by preſſing deliberately but firmly over every part of it, if the ſmalleſt degree of ſenſibility remains, the patient will ſhow ſigns of pain, either by moans or by raiſing his hands, when preſſure is made over the fractured part. In this way fractures have been frequently detected, which might otherwiſe have been concealed.

186 Method of removing and elevating depreſſed portions of the cranium.

Having now conſidered every thing preparatory to the operation of the trepan, we ſhall next point out the means beſt adapted for the removal or elevation of a depreſſed portion of the bone.

The firſt thing to be done is, after ſhaving the head, to make an inciſion as deep as the bone, and directly upon the courſe of the fracture.

The patient ought to be laid on a table, with a mattreſs under him, while his head is placed upon a pillow, and ſecured by an aſſiſtant. When the extent of the fracture has been determined, and the bleeding from the inciſion ſtopped, the depreſſed bone is now to be elevated; but previous to this it is neceſſary to ſearch for detached pieces. Should any be found, they ought to be removed by a pair of forceps adapted to this purpoſe. By the ſame inſtrument any ſplinters of bone which may have been beaten in may be removed; but when a part of the bone is beaten in beyond the level of the reſt of the cranium, as much of the pericranium is then to be removed by a raſpatory, Plate CCCCLXXXVIII. fig. 21. as will allow the trephine, Plate CCCCLXXXVIII. fig. 22. to be applied; or, if the operator incline, for the ſake of diſpatch, he may uſe the trepan,

Fracture and Depreſſion of the Cranium, &c.

Plate CCCCLXXXVIII. fig. 23. and 24.; or the operation may be begun and finiſhed with the trephine, while the trepan may perform the middle and principal part of the work. This part of the work is begun by making a hole with the perforator (fig. 24.), which is ſcrewed on to the lower end of fig. 23. deep enough to fix the central pin of the trephine, in order to prevent the ſaw from ſlipping out of its central courſe, till it has formed a groove ſufficiently deep to be worked ſteadily in; and then the pin is to be removed. If the bone be thick, the teeth of the ſaw muſt be cleaned now and then by the bruſh (fig. 25.) during the perforation, and dipped in oil as often as it is cleaned, which will conſiderably facilitate the motion, and render it more expeditious; making it at the ſame time much leſs diſagreeable to the patient, if he poſſeſs his ſenſes. That no time may be loſt, the operator ought to be provided with two inſtruments of the ſame ſize, or at leaſt to have two heads which can be readily fitted to the ſame handle.

After having made ſome progreſs in the operation, the groove ought to be frequently examined with a pick-tooth, or ſome ſuch inſtrument, in order to diſcover its depth; and if one ſide happen to be deeper than the other, the operator ought to preſs more on that ſide which is ſhalloweſt. Precautions are more particularly neceſſary when the operation is performed upon a part of the ſkull which is of an unequal thickneſs, eſpecially after the inſtrument has paſſed the diploe. And though it be ſaid by writers in general that the inſtrument may be worked boldly till it comes at the diploe (which is generally known by the appearance of blood), yet the operator ſhould be upon his guard in this point, examining from time to time if the piece be looſe, leſt thro' inadvertence the dura matter be wounded; for in ſome parts of the ſkull there is naturally very little diploe, and in old ſubjects ſcarcely any. It ought likewiſe to be remembered, that the ſkulls of children are very thin. When the piece begins to vacillate, it ought to be ſnapped off with the forceps (fig. 26), or levator (fig. 26. *a*); for the ſawing ought by no means to be continued till the bone be cut quite through, otherwiſe the inſtrument may plunge in upon the brain, or at leaſt injure the dura mater. If the inner edge of the perforation be left ragged, it is to be ſmoothed with the lenticular (fig. 28. *b*), to prevent it from irritating the dura mater. Particular care is to be taken in uſing the inſtrument, leſt it ſhould preſs too much upon the brain.

The next ſtep is to raiſe the depreſſed part of the bone with the levator, or to extract the fragments of the bone, grumous blood, or any extraneous body. After this, if there appear reaſon to apprehend that blood, lymph, or matter, is contained under the dura mater, it ought to be cautiouſly opened with a lancet, endeavouring to avoid the blood-veſſels running upon it, or lying immediately under it.

When the trepan is to be uſed on account of a fiſſure in which the bone will not yield, the inſtrument ſhould be applied ſo as to include part of it, if not directly over it, as it is moſt probable that the extravaſated fluid will be found directly under it. And when the fiſſure is of great extent, it may be proper to make a perforation at each end, if the whole can be conveniently brought into view; and in ſome caſes ſeveral perforations may become neceſſary.

When it is propoſed to make ſeveral perforations to remove depreſſed fragments of the bone which are firmly fixed, and having the internal ſurface larger than the external, or to raiſe them ſufficiently, it is neceſſary to apply the trepan as near the fractured parts as poſſible; making the perforations join each other, to prevent the trouble of cutting the intermediate ſpaces.

When the ſkull is injured over a ſuture, and it is not thought adviſable to uſe the trepan, a perforation ought to be made on each ſide of the ſuture, eſpecially in young ſubjects, in whom the dura mater adheres more ſtrongly than in adults; becauſe there cannot be a free communication between the one ſide and the other, on account of the attachment of that membrane to the ſuture.

Fracture and Depreſſion of the Cranium, &c.

187 Treatment of the patient after the operation.

After the elevation of the depreſſed pieces, or the removal of thoſe which are quite looſe, the extraction of extraneous bodies, and the evacuation of extravaſated fluids, &c. the ſore is to be dreſſed in the lighteſt and eaſieſt manner; all that is neceſſary being to apply a pledget of fine ſcraped lint, covered with ſimple ointment, to that part of the dura mater which is laid bare by the trepan, or otherwiſe; after which the edges of the ſcalp are to be brought together or nearly ſo, and another pledget laid along the whole courſe of the wound; a piece of fine ſoft linen is to be laid over all, and the dreſſings may be retained in their place by a common night-cap applied cloſe to the head, and properly fixed.

The patient is to be placed in as eaſy a poſition in bed as poſſible, with his head and ſhoulders elevated a little more than ordinary. If the operation be attended with ſucceſs, the patient will ſoon begin to ſhow favourable ſymptoms; he will ſoon ſhow ſigns of increaſing ſenſibility, and the original bad ſymptoms will gradually diſappear. After this he ought to be kept as quiet as poſſible; proper laxatives are to be adminiſtered, and ſuch as may be leaſt of a nauſeating nature. His food ought to be ſimple and eaſy of digeſtion, and his drink of the moſt diluent kind. If he complain of the wound being uneaſy, an emollient poultice ſhould be immediately applied, and renewed three or four times in the twenty-four hours. By theſe means there will commonly be a free ſuppuration from the whole ſurface of the ſore.

Every time the wound is dreſſed, the purulent matter ought to be wiped off from it with a fine warm ſponge; and if any degree of ſloughineſs take place on the dura mater or parts adjacent, it will then be completely ſeparated. Granulations will begin to form, which will continue to increaſe till the whole ariſe to a level with the ſurface of the cranium. The edges of the ſore are now to be dreſſed with cerate ſtraps, and the reſt of it covered with fine ſoft lint, kept gently preſſed on by the night-cap properly tied. In this way the cure will go on favourably; luxuriance of granulations will commonly be prevented; the parts will cicatrize kindly; and as all the ſkin has been preſerved in making the firſt inciſion, the cicatrix will be but little obſerved.

But things do not always proceed in this favourable manner. Sometimes in a few hours after the operation the patient is ſeized with a kind of reſtleſſneſs, toſſing his arms, and endeavouring to move himſelf in bed, while the ſymptoms of a compreſſed brain remain nearly the ſame as formerly. In this caſe, eſpecially if the pulſe be quick and ſtrong, the patient ought to be bled freely, as there will be reaſon to ſuſpect ſome tendency to inflammation in the brain. Sometimes, though the trepan has been properly applied, the ſymptoms are not relieved, on account of extravaſated fluids collected internally under the dura mater, or between the pia mater and brain, or in the cavity of the ventricles. The danger in theſe caſes will be in proportion to the depth of the collection. Particular attention therefore ought always to be paid to the ſtate of the dura mater after the perforation has been made. If blood be collected below the dura mater, this membrane will be found tenſe, dark coloured, elaſtic, and even livid; in which caſe, an opening becomes abſolutely neceſſary to diſcharge the extra-

Fracture and Depreſſion of the Cranium, &c.

vaſated fluid. Gentle ſcratches are to be made with a ſcalpel, till a probe (fig. 27), or directory (fig. 28.), can be introduced; upon which the membrane is to be ſufficiently divided in a longitudinal, and ſometimes even in a crucial direction, till an outlet to the fluid be given.

After the dura mater has been cut in this manner, there is ſome danger of the brain protruding at the opening; but the danger from this is not equal to the bad effects ariſing from effuſed fluids compreſſing the brain.

188 Of fungi.

A troubleſome and an alarming appearance now and then follows the operation of the trepan; namely, the excreſcences called *fungi*, formerly ſuppoſed to grow immediately from the ſurface of the brain, but which in general, originate from the ſurface of the dura mater or cut edge of the bone granulating too luxuriantly.

It often happens that they poſſeſs little ſenſibility; and then the beſt method to prevent their riſing to any great height is to touch them frequently with lunar cauſtic: but ſome caſes occur where their ſenſibility is ſo great that they cannot be touched, unleſs they hang by a ſmall neck; and then a ligature may be put round them, and tightened from time to time till they drop off, which will commonly be in the courſe of a few days. It ſeldom happens, however, that there is any occaſion for applying ſuch means, for the removal of theſe tumors, for they generally fall off as the perforations of the bone fill up.

If they do not, as the connection between them and the brain will be then in a great meaſure intercepted, they may be with more ſafety removed, either by exciſion, by cauſtic, or by ligature.

The cure being thus far completed, only a ſmall cicatrix will remain, and in general the parts will be nearly as firm as at firſt: but when much of the integuments have been ſeparated or deſtroyed, as they are never regenerated, the bone will be left covered only by a thin cuticle, with ſome ſmall quantity of cellular ſubſtance. When this is the caſe, the perſon ought to wear a piece of lead or tin, properly fitted and lined with flannel, to protect it from the cold and other external injuries.

This is the method now commonly practiſed in caſes of compreſſion; but it frequently happens, that inſtead of compreſſion, ſuch a degree of concuſſion takes place that no aſſiſtance from the trepan can be attended with any advantage; for the effects of concuſſion are totally different from thoſe of compreſſion, and therefore to be removed in a different manner.

Sect. II. *Of Concuſſion of the Brain.*

By concuſſion of the brain is meant ſuch an injury, from external violence, as either obſtructs or deſtroys its functions, without leaving behind it ſuch marks as to allow its nature to be aſcertained by diſſection.

189 Symptoms of concuſſion of the brain.

Moſt of the ſymptoms attending compreſſion of the brain occur alſo in concuſſion; but in a compreſſed ſtate of the brain they are more permanent. There is no diſcharge of blood from the eyes, noſe, or ears, which frequently happens in compreſſion; and inſtead of that apoplectic ſtertor in breathing which accompanies compreſſion, the patient ſeems to be in a ſound and natural ſleep. The pulſe is irregular and ſlow in compreſſion, and grows ſtronger and fuller by blood-letting; but in concuſſion it is weaker, being ſoft and equal, and ſinks by blood-letting. There are beſides convulſions in compreſſions, which are not obſerved in a ſtate of concuſſion. The ſymptoms ariſing from concuſſion come on immediately after the injury is received. In the violent degrees of theſe the patient remains quite inſenſible; the pupils are much dilated, and do not contract though the eyes be expoſed to the ſtrongeſt light.

In more violent ſymptoms, eſpecially when the patient is rendered inſenſible, it is extremely difficult to diſtinguiſh between concuſſion and depreſſion; for ſymptoms which have been ſuppoſed to ariſe entirely from concuſſion have, after death, been found to be owing to extravaſation or undiſcovered fracture; and extravaſation has been blamed, when, on diſſection not the leaſt morbid appearance could be diſcovered.

Concuſſion of the Brain.

190 Treatment.

In concuſſion the pulſe will frequently ſink and become feeble, even after the diſcharge of eight or ten ounces of blood: In doubtful caſes, therefore, blood-letting ſhould be practiſed with great caution. If the pulſe become fuller and ſtronger after diſcharging a moderate quantity, if the blood appear ſizy, and eſpecially if the patient become more ſenſible, it may be concluded that the ſymptoms depend upon extravaſation, depreſſion of the ſkull, or ſome degree of inflammation; and as long as advantage ſeems to be derived from blood-letting, we may repeat it: but if, upon drawing a few ounces of blood, the pulſe becomes feeble, and eſpecially if along with this the patient become more weakly, we ſhould immediately deſiſt from any farther evacuation of blood; and in place of it we ought to give ſuch remedies as may ſupport and ſtrengthen the patient: cordials ought to be given internally, and ſtimulants applied externally. Warm wine ſhould be given in proportion to the degree of debility induced; the patient, who is apt, in this caſe, to become cold, ſhould be kept warm by proper coverings; a bliſter ought to be put to all that part of the head in which the ſkin has not been injured; ſinapiſms ſhould be applied to the feet; gentle laxatives are uſeful, and ſhould be regularly given, ſo as to keep the body open. If the patient cannot ſwallow wine in ſufficient quantity, volatile alkali, ardent ſpirits, and other cordials of a ſtimulating kind, ſhould be given. In concuſſions of the brain, Mr Bromefield has recommended the uſe of opiates, and ſeveral other practitioners agree with him; though ſome conſider it as hurtful in the early ſtages of the diſorder, and are of opinion that even wine and other cordials ought to be given with ſome degree of caution. Iſſues, or the frequent repetition of bliſters to the different parts of the head and neck, by which an almoſt conſtant ſtimulus is preſerved, are much recommended. When patients are recovering from accidents of this kind, a liberal uſe of bark, ſteel, and mineral waters, &c. have ſometimes been of ſervice. When the ſtomach is loaded, gentle vomits become neceſſary; and white vitriol is reckoned the beſt in ſuch caſes. When much languor, inactivity, and loſs of memory continue, electricity long applied has been attended with advantage. This remedy, however, would be hurtful where any ſymptoms of compreſſion or inflammation of the brain are preſent.

Sect. III. *Of Inflammation of the Membranes of the Brain, or of the Brain itſelf, from external Violence.*

191 Symptoms of inflammation of the brain and its membranes.

Inflammation of the brain and of its membranes is attended with ſymptoms which occur in inflammations affecting other parts of the body, and from ſimilar cauſes, and likewiſe with ſymptoms peculiar to the brain itſelf. This diſorder differs eſſentially from concuſſion in its not appearing immediately; ſeldom till ſeveral days after the accident, and ſometimes not till two, three, or more weeks, or even as many months, have elapſed; when the patient begins to feel an univerſal uneaſineſs over his head, attended with liſtleſſneſs, ſome degree of pain in the part upon which the injury was inflicted, though of this there was perhaps no previous ſenſation. Theſe ſymptoms gradually increaſe; the patient appears dull and ſtupid; there is now a ſenſation of fulneſs, as if the brain were girt or compreſſed; he complains of giddineſs and of naufea, which ſometimes terminate in vomiting; he is hot, and extremely uneaſy; his

ſleep

Inflammation of the Brain, &c.

sleep is much disturbed, neither natural sleep nor that procured by opiates affording him relief; the pulse is hard and quick; the face is flushed; the eyes inflamed and unable to bear an exposure to much light. Sometimes, where a wound of the head accompanies these symptoms, its edges become hard and swelled, and an erysipelatous inflammation spreads quickly over the whole head, and especially towards the forehead and eyelids, which frequently swell to such a degree as to shut up the eyes entirely. This swelling is soft and painful to the touch; it receives the impression of the finger, and frequently originates merely from the external wound; on which account the attending symptoms are commonly easily removed by the means best suited to erysipelas of the parts. In a few instances, however, this symptom is likewise connected with, and seems to originate from, some affection of the dura mater. Its tendency is then of the most dangerous kind, and therefore requires the greatest attention. Soon after these symptoms become formidable, the part which received the blow begins to put on a diseased appearance. If the bone has been exposed by the accident, it now loses its natural complexion, becomes pale, white, and dry, either over its whole surface or in particular spots: but when the bone has not been denuded, nor the softer parts divided, but merely contused, they now swell, become puffy, and painful to the touch; and when the head is shaved, the skin over the part affected is redder than the rest of the scalp; and if the swelled part be laid open, the pericranium will probably be found to be detached from the skull, and a little bloody fetid ichor will be observed between this membrane and the bone, which will be found discoloured in nearly the same manner as if it had been laid bare from the beginning.

By the application of proper remedies these symptoms are frequently entirely removed; but when neglected, or when they do not yield to the means employed, they constantly become worse. Delirium ensues; the patient becomes extremely hot; and is at times seized with slight shiverings, which continue to increase and are attended with some degree of coma or stupor. The former symptoms now in a great measure disappear; palsy of one side is soon followed by deep coma; the pupils are dilated; the urine and fæces are passed involuntarily; subsultus tendinum and other convulsions ensue; and death certainly follows, if the patient be not speedily relieved.

Of the above symptoms, the first set point out the inflammatory, the other the suppurative, stage of the disease. The remedies which are useful in the one are highly improper in the other. During the inflammatory stage, blood-letting is the principal remedy; but this is improper after the suppurative symptoms appear, for then the trepan is the only thing that can give relief.

192 Method of cure.

The indications of cure are; 1. To employ the most effectual means for preventing inflammation. 2. To endeavour to procure the resolution of inflammation by general and topical remedies. 3. When the inflammation cannot be removed by resolution, and when suppuration has taken place, to give a free vent to the matter. 4. If the affected parts be attacked with gangrene, to endeavour to remove it and obviate its effects.

193 Blood-letting proper at first,

To answer the first indication, when the contusion is considerable, blood-letting, both general and topical, ought to be employed, and to a considerable extent; the bowels ought to be kept open by the use of laxatives; a watery solution of saccharum saturni should be applied to the part affected, and a low diet, with a total abstinence from exercise, ought to be enjoined: but if these means fail, or as frequently happens, the practitioner has not been called in soon enough for their proper application, and if inflammation have actually commenced, the second indication ought then to be attended to. For this purpose, blood-letting, not from the feet according to the advice of old practitioners, but as near as possible to the part affected, is to be performed, by leeching, cupping, or scarifying with a lancet or scalpel. Inflammation of the Brain, &c.

When instead of this, general blood-letting is thought more advisable, it is commonly reckoned best to open the external jugular vein, or the temporal artery; and the rule, with regard to the quantity to be evacuated, ought to be, to draw blood as long as the pulse continues firm; so that in violent cases taking away from 20 to 25 ounces at once will be found to answer the purpose better than to extract even a larger quantity, but at different intervals. A few hours afterwards, if the symptoms continue violent, it may be proper to discharge an additional quantity; but this must depend upon the strength of the patient and the fulness of the pulse.

194 And purgatives.

Along with the liberal use of blood-letting, brisk purgatives should be given. The bowels should not merely be kept open; but in order to receive full advantage from the practice, a smart purging should be kept up by repeated doses of calomel, jalap, or some other neutral salt. Where the patient cannot swallow in sufficient quantity, stimulating injections should be frequently exhibited.

A moist state of the skin is useful in every case of inflammation, and ought therefore to be here particularly attended to. In general a mild perspiration may be induced by applying warm fomentations to the feet and legs, and by laying the patient in blankets instead of linen. But when these means are insufficient, diaphoretics or even sudorifics may be given.

When much pain or restlessness takes place, opiates should be administered freely, which are now found to be attended with real advantage.

195 External treatment.

With respect to the external treatment of this disorder, attention should be paid to those means which may most readily induce a free discharge of purulent matter from the seat of the injury. With this view, if the original accident be attended with a wound or division of the integuments, as the lips of the sore are commonly observed to be hard, painful, and dry, it should be covered with pledgets spread with an emollient ointment, and warm emollient poultices laid over the whole; by which means, and especially by a frequent renewal of the poultices, a free discharge of matter will commonly be induced, and the bad symptoms will generally be much mitigated, or entirely removed.

In cases unattended with a division of the integuments, as soon as it is suspected that bad symptoms may supervene, the tumor should be divided down to the pericranium; and if that membrane be found separated from the bone, it ought likewise to be divided; and by inducing a suppuration in the way already mentioned, the inflammatory symptoms will probably be removed. As matter formed here is commonly of an acrid nature, and therefore apt to affect the bone, and by communication of vessels the membranes under it, instead of wasting time till fluctuation be distinctly perceived, a free incision should be made as soon as a tumor is observable. But this would be extremely improper in the treatment of tumors which immediately succeed to external injuries; for it often happens that such tumors disappear spontaneously, or by the use of astringent applications. It is only when a tumour attended with pain appears at a distant period upon the spot where the injury was received, that it ought to be opened as soon as perceived.

The next part of the practice regards the remedies to be

Inflammation of the Brain, &c.

uſed when the diſorder has either proceeded to ſuppuration, or when, on a removal of a portion of the cranium, the dura mater is obſerved to be ſloughy with a tendency to gangrene; and this includes the third and fourth indications of cure.

196 Treatment when ſuppuration has taken place.

The ſuppurative ſtate of the diſeaſe is known by the inflammatory ſymptoms, inſtead of yielding to the remedies already adviſed, increaſing in violence; and being ſucceeded by coma, dilatation of the pupils, a ſlow and full pulſe, involuntary diſcharge of fæces and urine, palſy, and irregular convulſive motions, and eſpecially when theſe ſymptoms are ſucceeded by fits of rigor and ſhivering.

The exiſtence of matter within the cranium being aſcertained, as no other remedy can be depended upon for removing it, the operation of the trepan ſhould be immediately employed, and as many perforations ought to be made as may be ſufficient for evacuating the matter. But if, after the ſkull is perforated, little or no matter appear between the bone and membranes; if the dura matter ſeem more tenſe than uſual; this membrane is likewiſe to be opened, ſo as to give a free diſcharge to any matter which may be between the brain and its membranes.

When it is perceived that the dura matter has already become ſloughy, with ſome tendency to grangrene, the greateſt danger is to be dreaded. If mortification has commenced, there will be much reaſon to think that death will ſoon follow; but different inſtances have occured of ſloughs forming upon the dura mater, and of cures being made after theſe have ſeparated. All that can be attempted is to keep the ſores clean, to give a free diſcharge to the matter, to apply nothing but light eaſy dreſſings, and to give bark in as great quantities as the ſtomach can bear. If there be ſtill ſome tendency to inflammation, the diet ſhould be low and cooling, the patient ſhould drink freely of whey or other diluent liquors, and the bowels ſhould be kept moderately open: But if, on the contrary, the ſyſtem be low and the pulſe feeble, wine is the moſt effectual cordial.

Sect. IV. *Of Fiſſures, or ſimple Fractures of the Skull.*

The term is here meant to imply a mere diviſion of one or both the tables of the ſkull, with or without a wound of the integuments, not attended with depreſſion. Fractures of this kind are not dangerous as far as affects the ſkull only, for it frequently happens that extenſive fiſſures heal without producing bad ſymptoms. But as they are frequently attended with effuſions of blood or ſerum upon the brain or its membranes, or as they may tend to excite inflammation in theſe, they require particular attention.

When effuſions occur, ſymptoms of compreſſion immediately follow. The remedies beſt ſuited to this diſeaſe muſt then be applied; and the trepan is alone to be depended upon. The fiſſures ſhould be traced through their whole extent, and a perforation made on the moſt depending part of each of them. If this be unſucceſsful, the operation ſhould be repeated along the courſe of the fiſſures as long as ſymptoms of a compreſſed brain continue; and as the effuſed matter will commonly be found contiguous to the fiſſures, they ought to be included in each perforation.

197 Methods of diſtinguiſhing fiſſures.

If the fiſſure be ſo large as to produce an obvious ſeparation of the two ſides of the bone, the nature of the caſe will be at once rendered evident; but where it is extremely ſmall, there is difficulty in diſtinguiſhing it from the natural ſutures, or from ſutures ſurrounding ſmall bones, which ſometimes occur, and get the name of *oſſa triquetra*. But this may be known by the firmer adheſion which always exiſts between the pericranium and ſutures; whereas this membrane is always ſomewhat ſeparated from that part of the bone where a fiſſure is formed. When the pericranium is ſeparated by the accident for a conſiderable way from the ſurface of the bone, various means have been contrived for diſcovering the nature of the caſe; as pouring ink upon the part ſuſpected to be fractured, which in caſe of a fracture cannot be wiped entirely off; or making the patient hold a hair or piece of catgut between his teeth, while the other extremity of it is drawn tenſe, which, when ſtruck, is ſaid to produce a diſagreeeble ſenſation in the fractured part. But ſuch teſts are little to be depended on; ink will penetrate the ſutures; and the others are ineffectual, unleſs the fracture be extenſive, and the pieces conſiderably ſeparated from each other. The oozing of the blood from a fiſſure is a better mark. The aſcertaining of this point, however, appears not very material; for unleſs alarming ſymptoms are preſent, although there ſhould be a fiſſure, no operation is neceſſary; and if ſuch ſymptoms occur, the bone ought to be perforated whether there be a fiſſure or not.

Wounds of the Eyelids and Eyeball.

When a fiſſure is not attended with ſymptoms of a compreſſed brain, the trepan ought not to be applied, eſpecially as the operation itſelf tends in ſome degree to increaſe inflammation of the part. The fiſſure ſhould be treated merely as a cauſe which may induce inflammation. The patient ſhould be blooded according to his ſtrength; the bowels ſhould be kept lax, and the ſore treated with mild, eaſy dreſſing; and violent exertion ſhould be avoided as long as there is any danger of inflammation occuring.

Chap. XIII. *Diſeaſes of the Eyes.*

Sect I. *Of Wounds of the Eyelids and Eyeball.*

198 Treatment of wounds of the eyelids.

In caſes of ſuperficial wounds of the eyelids, it will be ſufficient to bring the edges of the wounds together and retain them in their place by ſlips of adheſive plaſter: but when a wound is deep, particularly when the tarſus is divided, it will be neceſſary to employ either the interrupted or the twiſted ſuture, care being taken that the ſutures be not carried through the inner membrane of the eyelid otherwiſe the eye would be irritated and inflamed. After ſuch an operation, the motion of both eyelids ſhould be prevented as much as poſſible, elſe no union of the divided parts can be obtained. After the ſutures are finiſhed, the eyelids ſhould be cloſed and covered with a pledget of emollient ointment, and over this ſhould be laid a compreſs of ſoft lint, and one of a ſimilar nature ought likewiſe to cover the ſound eye; then a napkin ſhould be made to preſs equally on both eyes, and be properly fixed. Inflammation ſhould be guarded againſt, or, if already preſent, it muſt be removed in the manner directed under the article *Ophthalmia*, (ſee Medicine.) The ſutures may be removed in about three days from their introduction, when the parts will commonly be found reunited.

When a portion of the eyelids is ſo much deſtroyed, or perhaps ſo completely removed, as to prevent the remaining parts from being brought together, without obſtructing the motion of the eye, the beſt method will be to treat them with light eaſy dreſſings, truſting to nature for ſupplying the deficiency.

199 Of wounds of the eyeball.

If the cornea be wounded, it will commonly be attended with partial or total blindneſs. If any of the other parts of the ball be wounded, the danger will generally by in proportion to the extent of the wound. The principal attention ought to be directed to the prevention or removal of inflammation. When pain occurs, it ought to be removed by opiates; and with theſe a ſtrict antiphlogiſtic courſe is to be enjoined.

When the wound is large, and the humours completely evacuated,

Diſeaſes of the Eyelids.

evacuated, blindneſs, with ſinking of the eyeball, will almoſt always be the conſequence; but in wounds of a ſmall extent, by proper treatment, a cure may be made and the ſight preſerved.

Sect. II. *Of Diſeaſes of the Eyelids.*

200 Tumors of the eyelids.

The eyelids are ſubject to be infeſted with tumors of different kinds, which frequently require the aſſiſtance of ſurgery. The firſt of theſe is the hordeolum or ſtye, which frequently grows on the edge of the eyelid, and is attended with heat, ſtiffneſs, and pain; and unleſs proper means be taken to prevent it, a ſuppuration is frequently the conſequence. It may be conſidered as a common abſceſs ſeated in an obſtructed ſebaceous duct or gland. It may generally be removed by diſcutient applications. Should theſe prove ineffectual, it ought to be brought to ſuppurate by a ſmall emollient poultice, when it will commonly heal of itſelf; but if it do not, it may be opened with the point of a lancet, that the matter may be diſcharged; and the part may be anointed afterwards with ſaturnine ſolution.

The eyelids are ſubject to encyſted tumors, ſteatoms, warts, &c. which are to be treated like the ſame tumors when ſeated in other parts of the body; only in extirpating theſe tumors, ſhould part of the eyelid be removed entirely, no dreſſings can be applied, as, however mild they may be, they would irritate and inflame the ball of the eye. All that can be done therefore, in ſuch caſes, is to lay the lips of the ſore as nearly together as poſſible, and frequently to remove any matter that may form on it.

201 Inverſion of the cilia or eye-laſhes.

The eye-laſhes are ſometimes ſo much inverted as to rub upon the eye and create much pain and inflammation. Various cauſes are aſſigned for this, ſuch as the hairs themſelves taking a wrong direction; inverſion of the tarſus or cartilage of the eyelid; ſome cicatrix formed upon the ſkin of this part after wounds or abſceſſes; tumors preſſing the hairs in upon the eye; and, finally, a relaxation of the external integuments.

The treatment of this diſorder muſt depend much upon a knowledge of the cauſe. When it is owing to a derangement of the cilia themſelves, if they have remained long in this ſtate, it will be extremely difficult to make them recover their proper direction. They ought therefore to be pulled out by a pair of forceps, and the part waſhed with ſome aſtringent lotion; and if the new hairs appear to take a ſimilar direction, which is very apt to happen, as ſoon as they are long enough they ought to be turned back upon the eyelid, and kept there for ſeveral days, or even weeks, by adheſive plaſter. When the diſeaſe proceeds from a contraction of the orbicular muſcles, the contracted part may be cut from the inner ſurface of the eyelid; in which place a cut commonly ſoon heals. If the cauſe proceed from a tumor or cicatrix, this muſt be removed before a cure can be expected; or if it be owing to relaxation of the ſkin, the parts ought to be bathed with ſome ſtrong aſtringent. If this fail, the relaxed ſkin ſhould be removed, and the part healed by the firſt intention. Sometimes the cilia of the upper eyelid are turned in on account of dropſical ſwelling in that place. When this happens, the water is to be evacuated by a few punctures with a lancet; but when ſuch means fail, and when the diſeaſe is quite local, if viſion be diſturbed, a ſufficient part of the ſkin ought to be removed with a ſcalpel, and a cure made by adheſive plaſter or the twiſted ſuture.

202 The gaping eye, or turning out of the eyelids.

When the gaping eye takes place to any great degree, it is attended not only with much deformity and uneaſineſs, from a large portion of the lining of the eyelid being turned outwards, but likewiſe from too much of the eye being expoſed. This diſorder may ariſe from an enlargement of the eyeball, from dropſical ſwelling, or from the cicatrix of an old wound or abſceſs: hence it is frequently produced by the ſmall-pox, burns, or ſcrophula; but more frequently by a laxity of the part in old age.

Diſeaſes of the Eyelids.

When the diſorder is induced by an enlargement of the ball of the eye, nothing but a removal of this ſwelling can be effectual. If from dropſical ſwelling, when this is connected with general anaſarca, the affection of the ſyſtem muſt firſt be cured; but if it appear to be local, nothing anſwers ſo well as punctures. When it ariſes from a cicatrix, the ſkin ſhould be divided, and the effects of inflammation guarded againſt. If it be owing to inflammation, the antiphlogiſtic courſe muſt be uſed; when it ariſes from old age, the eyes ought to be daily bathed with cold water, or ſome aſtringent and ſtimulant ſolution.

203 Concretion of the eyelids.

Concretion of the eyelids ſometimes ariſes from a high degree of opthalmia; in which caſe the eyelids are not only connected by their edges to each other, but now and then grow to the ſurface of the eyeball. A coheſion is ſometimes obſerved alſo in children at birth. When the adheſion is ſlight, it may in general be removed by the end of a blunt probe; but when it is conſiderable, a cure can only be effected by a cautious diſſection. If the eyelids on one ſide be ſound, they will ſerve as a guide to direct the inciſion. The tarſi are carefully to be divided from each other; after which, if there be no other adheſions, the eyelids may be readily opened: But if they adhere to the eye, the operator is gently to pull and ſeparate the eyelids, while the patient is deſired to move the eye in the oppoſite direction. When this is effected, nothing is further neceſſary than to drop a little oil upon the eye, and cover the eyelids with ſoft lint ſpread with ſome cooling emollient ointment. The oil and ointment are frequently to be repeated, and every precaution taken to prevent inflammation and irritation.

Sect. III. *Of Specks, Filmes, or Excreſcences on the Eye.*

204 Of ſpecks on the cornea.

Specks are ſometimes formed upon the white part of the eye, but more frequently upon the cornea. In the former caſe they are ſeldom attended with much inconvenience, but in the latter they are often the cauſe of partial or total blindneſs. They are almoſt univerſally the conſequence of inflammation, and ſeldom go much deeper than the tunica adnata. Two very different ſtates of the diſorder occur; the one from an effuſion immediately under the outer layer of the cornea, and in this caſe the cornea does not appear to be raiſed; the other takes place from one or more little ulcers, which breaking, leave as many opaque ſpots in the centre, which are more elevated than the reſt of the cornea: and the inconvenience attending either ſituation muſt always be in proportion to their extent and degree of opacity, or their vicinity to the pupil. When viſion is little affected by them, they need ſcarcely be conſidered as an object of ſurgery; but whenever viſion is materially impaired, remedies become neceſſary, and theſe ſhould be ſuch as are beſt ſuited for removing inflammation, promoting abſorption, and reſtoring tone to the veſſels. For the means adapted for removing inflammation, ſee Medicine, n° 175.

205 Treatment.

Veſſels running upon the ſurface of the eye into the ſpeck are to be divided, and the eye frequently bathed with ſome refrigerant collyrium. By theſe means the ſimpleſt kind of ſpecks, when recently formed, may generally be removed; but where they have been of long ſtanding, their removal is attended with great difficulty. Where the ſpeck is owing to an effuſion of fluids between the layers of the cornea, and where it is not attended with any prominence, local applications are of little advantage, as it

is

Specks, &c. on the Eye.

is impoſſible to remove the effuſed matter without injuring the cornea; but conſiderable ſervice is derived from the uſe of ſuch remedies as are moſt effectual for promoting abſorption; and with this view a gentle, long continued courſe of mercury, briſk purgatives occaſionally, and iſſues in the neck, are found to be the moſt effectual remedies.

In the management of ſpecks which are prominent upon the cornea, and where inflammation is removed and the opacity is conſiderable, if the cornea beneath be ſound, the removal of the diſeaſed part will leave it tranſparent and fit for viſion. The remedies proper for this purpoſe are eſcharotics or the knife. The former are applied in the form of a powder, an ointment, or a waſh; and theſe ought to be very finely prepared, otherwiſe they will be in danger of irritating and inflaming the eye; and they ought merely to be of ſuch ſtrength as the eye can eaſily bear.

The applications ſhould be long perſiſted in and frequently repeated; and to make them ſtill more uſeful, ſome of the powders or ointments may be applied evening and morning, and the ſolution two or three times through the courſe of the day. To the remedies already mentioned cauſtic is ſometimes preferred. With this the centre of the ſpeck is to be frequently touched, till the patient complain of conſiderable pain, when pure water is to be applied by a pencil, or by dipping the eye in water, with the eyelids open, till the pain occaſioned by the application of the cauſtic be removed. The eye is then to be covered with compreſſes moiſtened in ſome ſolution, and this frequently repeated. The cauſtic to be repeated every ſecond or third day, unleſs prevented by inflammation. When the ſurgeon chooſes to employ the knife, which frequently may be more effectual, the eye is to be fixed by a ſpeculum (fig. 29.), or levator (fig. 30); the tumor is then to be cautiouſly ſeparated by means of a ſmall knife, and every attention paid to prevent inflammation. Theſe are the methods moſt likely to be of ſervice; and when properly managed, they will frequently remove ſpecks, which otherwiſe would entirely deprive the patient of the uſe of the eye; though it is to be regretted that caſes frequently occur which baffle art.

206 Of the excreſcence called pterygium.

A membranous excreſcence, called *pterygium*, is frequently found upon the white part of the eye, which often ſpreads over the cornea ſo as entirely to deſtroy viſion. It is ſometimes owing to external injuries; at other times it ariſes from a general diſeaſe of the ſyſtem, as lues venerea or ſcrophula; but inflammation is always the more immediate cauſe.

207 Method of removing excreſcences.

By a proper application of the remedies abovementioned affections of this kind may generally be prevented from becoming formidable; but when the reverſe takes place, and excreſcences begin to ſpread over the cornea, other means muſt be uſed. When the diſeaſed part is only ſlightly attached, it may be freely removed by a cut of the knife; but when this cannot be done without difficulty, it is better to deſtroy the veſſels by the extenſion of which this ſubſtance is chiefly formed. The manner of performing the operation in general is this: The patient being properly ſeated, the eyelids opened, and the eye ſecured, the operator, with a ſmall knife, makes a ſcarification through the whole thickneſs of the excreſcence, entirely round, and at a little diſtance from the circumference, by which the ſource of nouriſhment will be cut off; and, after the blooding is abated, one or two inciſions more may be made, in a ſimilar manner, within the former. Some practitioners raiſe the excreſcence with a needle and ligature before the inciſion is made; and, in ſome caſes, this may be done with advantage, though not in others.

After the bleeding is over, the part is to be bathed two or three times a-day with a weak ſaturnine ſolution; and the operation may be repeated occaſionally till the excreſcence is removed. In this way the operation commonly proves effectual; but inſtances ſometimes occur where, inſtead of being uſeful, it increaſes the diſeaſe. Whenever this happens, a palliative courſe is the only thing to be tried; and although it will not remove the diſorder, it may commonly prevent the excreſcence from acquiring any additional ſize. With this intention it ought to be frequently bathed with the ſolution laſt mentioned, and afterwards covered with a cooling ointment. When the diſorder cannot even be palliated, when viſion is deſtroyed, and particularly when the pain attending it is ſevere, there is reaſon to ſuſpect cancer. In this caſe the eye ought to be extirpated, otherwiſe deeper parts may ſuffer, and the life of the patient be endangered. The method of performing this operation will be afterwards pointed out.

Abſceſſes in the Globe of the Eye.

Sect. IV. *Of Abſceſſes in the Globe of the Eye.*

Though inflammation of the eye generally terminates by reſolution, inſtances ſometimes occur in which an abſceſs enſues. This is owing either to improper treatment, or a bad habit of body which counteracts all remedies. The greateſt danger attending theſe complaints is when they are ſituated on the cornea, as the cicatrix left by them may deſtroy viſion. When deep ſeated, a purulent matter is ſometimes apt to be found in ſome of the chambers of the eye, the ball becomes enlarged, the humours are diſturbed, and neither the iris, pupil, nor lens can be diſtinguiſhed. In ſome rare caſes again, after theſe appearances have continued ſome time, the cornea burſts, part or whole of the humours are evacuated, and the iris protrudes in a thickened diſtended ſtate. This has now the appearance of an excreſcence, which is called *ſtaphyloma* from a kind of reſemblance to a grape. But under this term ſome authors include all collections like thoſe above deſcribed. In moſt inſtances the cornea protrudes, but in others the tunica ſclerotica or opaque part is affected with partial ſwellings or protruſions.

While the diſeaſe is forming, beſides the loſs of ſight, the patient commonly feels great diſtreſs in the eye and head, accompanied by ſymptoms of fever. When no other diſtreſs is experienced than the loſs of ſight, the ſwelling is but ſmall, and contains chiefly a watery fluid. In the treatment, as viſion is ſeldom preſerved, the principal thing is to abate the pain and remove deformity. There is another kind of abſceſs in the eye, termed *hypopyon*, where the matter is lodged in the ſubſtance of the coats. It is ſometimes produced by external injuries, but more frequently from puſtules of ſmall-pox. If this termination cannot be prevented by the remedies mentioned in the article Medicine, n° 175, the mater muſt be evacuated by an inciſion into the eye, not regarding the humours, as viſion previous to this time is entirely deſtroyed. The proper part is the cornea or the moſt prominent part of the tumor.

A variety of this diſorder ſometimes, though rarely, happens, where the humours are abſorbed; but ſtill the ſame external appearances are obſerved. In this caſe the tumor is formed by a thickening of the coats, eſpecially the iris. The only means of relief is extirpation of the prominent part by the uſe of the knife. After the contents of the eye have been diſcharged, the parts are to be covered with a compreſs moiſtened with a ſaturnine ſolution, and the antiphlogiſtic courſe followed, till a cure is perfected, or at leaſt inflammation removed. If the ulcers diſcharge a thin acrid matter, they may be waſhed two or three times a day with a ſolution of corroſive ſublimate, or of white vitriol, &c. Fungous excreſcences, ſometimes conſidered as a cancer of the eye, are apt to form in both theſe diſeaſes after the matter is evacuated; but they may be prevented from increaſing

Dropsical Swellings of the Eye.

creasing to a considerable size by burnt alum finely powdered, or by touching them occasionally with lunar caustic.

208 Ulcers of the eye.

Ulcers on the eye may arise from the same causes which produce ulcers on other parts of the body, as wounds, burns, &c; or they may arise from a general affection of the constitution, as lues or scrophula; but they are more immediately produced by inflammation In the treatment therefore of such diseases, blood-letting, blistering, laxative and cooling applications, as already described in the case of ophthalmia, are to be employed. When the inflammatory state is removed, their management must be almost the same with that for similar affections in other parts of the body. When the disorder arises from an affection of the system, the primary disease must be attended to before a cure can be performed. With respect to the sores themselves, if acrid matter be discharged, we must have recourse to detergent ointments and washes before a cicatrix can be formed. When these have not the desired effect, and when the sore becomes soft and higher than the rest of the eye, astringent applications are most efficacious. If excrescences be present, these are to be removed by escharotics, or by the knife. In some rare instances excrescences of a fungous nature are found to be connected with the interior parts of the eye, and become so prominent as even to rest upon the cheek. When such occur, nothing but the removal of the eye itself can effect a cure.

Sect. V. *Of Dropsical Swellings of the Eye.*

209 Symptoms of dropsy of the eye.

The eye is sometimes enlarged by an accumulation of the aqueous humour. The symptoms are, a sense of fullness in the eyeball; by degrees the motions of the eyelids become impeded; vision gradually becomes more and more imperfect, till at last the patient can only distinguish light from darkness. As the disease increases, the ball of the eye becomes greatly enlarged, and at this time the cornea begins to protrude; when, if a puncture be not made, the eye bursts and empties itself. This disease is apt to be confounded with staphyloma. But in the dropsical swelling the patient is always sensible to the effects of light, and the pupil is observed to contract, which does not happen in staphyloma. In the early stages of this disease vision may

210 Treatment.

be preserved by puncturing the under edge of the cornea, and allowing the aqueous humour to pass out by the anterior chamber; or by puncturing the tunica sclerotica a little behind the iris, by which the fluid will pass out by the posterior chamber. The puncture may be made either with a lancet, pointed knife, or with a very small flat trocar. The eye ought afterwards to be dressed with a compress made moist with a saturnine solution, guarding against excessive inflammation. When the use of the eye is somewhat recovered, tone may be restored to the parts, and a return of the disease as much as possible prevented, by frequently bathing the eye in astringent lotions; but where the cornea is destroyed, the sight cannot be restored: We can then only diminish the size of the eye, and render it somewhat more comfortable to the patient.

211 Blood effused into the eye.

Blood may be effused into the chambers of the eye from various causes, as in putrid diseases, or in consequence of inflammation, but most frequently from a rupture of the blood-vessels induced by external injury. In whatever way it gets into the eye, it mixes with the aqueous humour, and renders it opaque. It is sometimes taken up by the absorbents; when it is otherwise, it ought to be discharged by a puncture.

A few instances have occurred where the blood has fallen to the under side of the eye, and remained there without mixing with the aqueous humour. In such a situation it ought to be allowed to remain.

Protrusion of the Eyeball beyond its Socket.

When a puncture is necessary, it is to be made in the same manner as in cases of dropsy of the eye; only the opening may require to be somewhat larger, otherwise the blood may not pass readily out. After the operation, nothing is necessary but to apply a compress of soft lint, moistened with a weak saturnine solution.

Sect. VI. *Of the Protrusion of the Eyeball beyond its Socket.*

The eye may protrude in consequence of external violence, or from tumors forming behind it, or on account of some of the ulcers, excrescences, or dropsical swellings, already mentioned. When the eye is forced out of its socket by external violence, if the eyeball be not entirely separated from the neighbouring parts, it ought to be freed from any extraneous matter which may adhere to it, and immediately replaced; and if the optic nerve be not quite divided, the use of the eye may be recovered. With a view to prevent or moderate inflammation, every part of the antiphlogistic regimen ought to be strictly adhered to. If the protrusion is occasioned by a tumor, the cure must depend upon the removal of this; and if the disease has advanced so far that the bones are become carious, they must likewise be separated. But more frequently, instead of the bones becoming carious, they assume a gelatinous or rather cartilaginous nature. In such a situation an operation could be of little advantage. The best method to prevent the bones from being so affected is an early performance of the operation.

A few instances have happened of the eye being pushed from its socket by an enlargement of the lachrymal gland. When this occurs, if the enlargement be considerable, the structure of the eye will most probably be so much injured that vision will be destroyed; but instances have occured of this gland, in the enlarged state, having been removed without any injury being done to the eye.

Sect. VII. *Of Cancer of the Eye, and Extirpation of the Eyeball.*

212 Symptoms of cancer of the eye.

Scirrhus and cancer may arise from repeated inflammations of the eye, or from staphyloma, or some of the other diseases which frequently attack this organ. The symptoms are, an enlargement, hardness, and protrusion of the ball, with a red, fungous appearance, sometimes discharging thick, yellow matter, but more frequently a thin acrid ichor. At first there is only a sensation of heat in the tumor; but this gradually increasing, changes at last into darting pains, which likewise shoot through to the opposite side of the head. In this situation blood-letting, opiates, and emollient applications, may alleviate the pain. A hemlock poultice applied to the eye, and a wash of lime-water, with a little opium dissolved in it, and applied every time the poultice is renewed, gives some relief; but although the pain be moderated by these means, it does not prevent the disease from spreading, nor can any thing else but extripation produce a radical cure.

213 Method of extirpating the eye.

After the disease is discovered to be cancerous, the operation should be performed without delay, to prevent the parts in the neighbourhood, as well as the constitution at large, from suffering. In performing the operation, the patient should be placed in a proper light, and the head supported by an assistant. If the eyelids are diseased, they must be separated along with the tumor; but where they are found, they ought to be carefully preserved; and for this purpose they may be kept out of the way by two levators held by assistants. When the eyeball protrudes considerably, the operator may lay hold of it with his fingers; but if this be impracticable, a broad ligature should be introduced through the centre of it, that it may be the more

Cataract. readily removed from the orbit. Sometimes it will be neceſſary to enlarge the opening of the eyelids, by cutting the external angle to allow the eyeball to be more readily removed. The whole of the diſeaſed parts are now to be ſeparated by a knife bent ſo as to correſpond with the ſides of the orbit, guarding at the ſame time againſt wounding the perioſteum or the bones of the orbit, which are commonly extremely thin. The eye being in this manner extirpated, the hemorrhagy from the ocular arteries is to be ſuppreſſed by means of agaric, or by a bit of ſponge; then over this is to be laid ſoft lint, with a napkin to cover the whole. After ſuppuration takes place, the dreſſings are to be removed, when a little lint, applied with an emollient pledget over it, will be ſufficient as long as any matter is diſcharged. After the wound is healed, the deformity may be in ſome meaſure obviated by wearing an artificial eye; though it is chiefly in caſes where part of the humours of the eye have been evacuated that this can be uſed with much propriety; for when the orbit is empty the artificial eye ſinks too far into it.

Sect. VIII. *Of the Cataract.*

214 Symptoms of cataract. The ancients, and ſome of the modern writers, had a confuſed idea of the ſeat of the cataract; different authors placing it in different parts of the eye. It conſiſts of an affection of the cryſtalline lens or of its capſule, by which the rays of light are prevented from falling upon the retina; and is therefore the ſame diſeaſe with the glaucoma of the ancients. It commonly begins with a dimneſs of ſight; and this generally continues a conſiderable time before any opacity can be obſerved in the lens. As the diſeaſe advances the opacity becomes ſenſible, and the patient imagines there are particles of duſt or motes upon the eye, or in the air. This opacity gradually increaſes till the perſon either becomes entirely blind, or can merely diſtinguiſh light from darkneſs. The diſeaſe commonly comes on rapidly, though ſometimes its progreſs is ſlow and gradual. The opacity of the lens is found to be nearly in proportion to the degree of blindneſs the patient is affected with; it gradually changes from a ſtate of tranſparency to a perfectly white, or light grey colour. In ſome very rare inſtances a black cataract is found. Sometimes the diſeaſe is confined to a particular ſpot of the lens, but generally the whole is affected. The conſiſtence alſo varies, being at one time hard, at another entirely diſſolved. When the eye is otherwiſe ſound, the pupil moves according to the degree of light in which it is placed. This diſeaſe is ſeldom attended with pain; ſometimes, however, every expoſure to light creates uneaſineſs, owing probably to inflammation in the bottom of the eye. The real cauſe of cataract is not yet well underſtood. Numbers of authors conſider it as proceeding from a preternatural contraction of the veſſels of the lens, ariſing ſometimes from external violence, though more commonly from ſome internal and occult cauſe. The diſeaſe is diſtinguiſhed from the gutta ſerena, by the pupils in the latter being never affected with light, and from no opacity being obſerved in the lens. It is diſtinguiſhed from hypopyon, ſtaphyloma, or any other diſeaſe in the fore part of the eye, by the evident marks which theſe affections produce, as well as by the pain attending their beginning. But it is difficult to determine when the opacity is in the lens or in its capſule. The lens is generally affected; when the capſule is the ſeat of the diſeaſe, it is termed the membranous cataract.

215 Methods of treatment. With reſpect to the treatment: If the diſeaſe be in the incipient ſtate, mercury, particularly calomel in ſmall doſes, has been attended with ſome advantage. When any degree of inflammation is preſent, blood-letting and cooling regimen will ſometimes be neceſſary. Electricity, extract. hyoſcyami, Cataract. flammula Jovis, &c. have likewiſe been extolled; but after theſe or other remedies have failed, the cure muſt depend upon a chirurgical operation. For this purpoſe two methods are in general uſe. The firſt of theſe, and which was practiſed for a long time before the other, is called *couching*. It is done with a view to allow the rays of light to fall upon the retina; and it conſiſts in removing the lens from its capſule, and lodging it in ſome part of the vitreous humour, where it may be entirely off the axis of the eye, and where it is ſuppoſed, in courſe of time, to diſſolve.

The other method is termed *extraction*, where, after an inciſion has been made in the cornea, the lens is puſhed through the pupil, and then entirely removed from the eye. Each of theſe methods has been much practiſed, and it is ſtill a matter of doubt to which we ought to give the preference. The next circumſtance deſerving attention is the time at which the operation for couching or extracting can with moſt propriety be performed. Formerly it was thought neceſſary to wait till the lens had a certain degree of conſiſtence, or was become ripe; but no certain marks of fluidity or firmneſs have been yet diſcovered; neither indeed is there any neceſſity for attending particularly to it, as the operation may be practiſed in every period of the diſeaſe, providing the retina be ſound, the iris have the power of contracting, and the cornea be tranſparent. The proper time for the operation is when the opacity of the lens is ſo conſiderable as to prevent the patient from following his ordinary occupation. When this is not the caſe, or when the patient has the uſe of one eye, it ought not to be performed, as it is always attended with ſome degree of danger.

216 Method of couching the cataract. When the operation is to be performed, the following is the method of doing it: And firſt, *of couching the cataract*. To guard as much as poſſible againſt the effects of inflammation, the patient ſhould be confined, for ſeveral days previous to the operation, to a low regimen; and two or three doſes of ſome cooling laxative ſhould be given at proper intervals. After this he is to be ſeated with his face towards the light; but ſunſhine ought to be avoided. Some, however, prefer a ſide-light both on account of the operator and patient. One aſſiſtant is to ſupport the head, while others ſecure the arms. The operator is either to be ſeated with his elbow reſting upon a table; or, which is preferred by ſome, he ought to ſtand, reſting his arm upon the ſide of the patient. The eye being fixed by the ſpeculum (fig. 29.), or in ſuch a manner as to allow the whole of the cornea and a ſmall portion of the ſclerotic coat to protrude, a couching needle (fig. 31.) is to be held in the right hand, in the manner of a writing pen, if the left eye be the ſubject of operation; the ring and little fingers are to be ſupported upon the cheek or temple of the patient: The needle is to be entered in an horizontal direction through the ſclerotic coat, a little below the axis of the eye, and about one fourth of a line behind the edge of the cornea, ſo as to get entirely behind the iris. If the needle be of the flat form, the flat ſide ought to be oppoſed to the iris, to prevent that ſubſtance from being wounded. The point of the needle is to be carried forwards till it be diſcovered behind the pupil. The operator is now commonly directed to puſh the point into the lens, and depreſs it at once to the bottom of the eye; but in this way the lens either burſts through the capſule at an improper place, or it carries the capſule with it, tearing it from the parts to which it is connected. Inſtead of this, the needle ought firſt to be puſhed into the lens near its under edge, as Dr Taylor adviſes, and then carried ſome way down into the vitreous humour, ſo as to clear the way for the lens. It is then to be drawn a little back, and carried to the upper

Cataract.

part of the capſule, when, by preſſing upon it, the lens, if, ſolid, is to be puſhed down by one, or, if fluid, by ſeveral movements, to the bottom of the vitreous humour. It ſhould then be puſhed downwards and outwards, as Mr Bell directs, ſo as to leave it in the under and outer ſide of the eye; where, in caſe it ſhould riſe, the paſſage of the light would be little obſtructed. The needle is then to be withdrawn, the ſpeculum removed, and the eyelids cloſed; and a compreſs ſoaked in a ſaturnine ſolution is to be applied over them. Mr Pellier's method is to cover each eye with a linen bag half filled with fine wool, applied dry and fixed to a circular bandage of linen paſſed round the forehead: the whole is retained by a triangular napkin. The patient is then to be laid in bed, upon his back, with his head very little raiſed; and to be kept in this ſituation for about a week in a dark room. Unleſs he be of a weakly habit, he ought to be bled at the neck, or leeched at the temple, a few hours after the operation. He ſhould be kept upon low diet, and get ſmall doſes of opiates frequently repeated. His belly ſhould be kept moderately open by gentle purgatives. The dreſſings ſhould not be removed till inflammation is at leaſt ſo far gone that no danger will ariſe from uncovering the eye, which may generally be about the eighth or tenth day. Sometimes the patient perceives light immediately on the dreſſings being removed, but more frequently not till ſome time after.

217 Treatment afterwards.

Upon removing the dreſſings, if the cataract has again got back to the axis of the eye, a repetition of the operation may become neceſſary. Some time, however, after the inflammatory ſymptoms are gone, ſhould be allowed to elapſe before any other operation is again attempted; for the cataract frequently diſſolves, providing the aqueous humour get free acceſs to it. Mr Pott ſometimes, when he found the cataract to be of the mixed kind, did not attempt depreſſion, but contented himſelf with a free laceration of the capſule; in which caſes the lens hardly ever failed of diſſolving ſo entirely as not to leave the ſmalleſt veſtige of a cataract. When the operation is to be performed upon the right eye, the ſtraight needle muſt either be uſed by the left hand, or the operator muſt place himſelf behind the patient. A needle (fig. 32.) has been contrived, however, with a large curve, by which the operation may be readily performed with the right hand, while the ſurgeon is placed before the patient; only the needle is entered towards the inner, inſtead of the outer, angle of the eye.

218 Method of extracting the cataract.

The firſt hint of extracting the lens ſeems to have been ſuggeſted by Mr Petit, who propoſed to open the cornea and extract the lens when it was forced into the anterior chamber of the eye either by external violence or accidentally in couching. At firſt it was conſidered as a dangerous operation, and was ſeldom practiſed till about the year 1737, when Mr Daviel propoſed and practiſed extraction in preference to couching. The operation is now performed in the following manner: The patient and operator being placed, and the eye fixed in the ſame manner as for couching, the ſpeculum, when the operation is to be done upon the left eye, is to be held in the left hand of the operator. It is neceſſary to make as much preſſure as will ſecure without hurting the eye. Neither ought the cornea to be preſſed too near the iris, leſt the latter be wounded. The operator now takes the knife (fig. 33.), and holds it in the ſame way as he does the needle for couching; he then enters the point of it with the edge undermoſt into the cornea about the diſtance of half a line from its connection with the ſclerotic coat, and as high as the centre of the pupil; he is then to paſs it acroſs the pupil to the inner angle in an horizontal direction, keeping the edge a little outwards to prevent the iris from being cut; the point is then to be puſhed through oppoſite to where it entered; the under half of the cornea is next to be cut, and at the ſame diſtance from the ſclerotics with the parts at which the point of the knife went into and came out from the eye. Cataract.

In cutting the under half of the cornea the preſſure of the ſpeculum upon the eye ſhould be gradually leſſened; for if the eye be too much compreſſed, the aqueous humour, with the cataract and part of the vitreous humour, are apt to be forced ſuddenly out immediately after the inciſion is made. The operator then takes a flat probe, and raiſes the flap made in the cornea, while he paſſes the ſame inſtrument, or another probe (fig. 34.), rough at the extremity, cautiouſly through the pupil, to ſcratch an opening in the capſule of the lens. This being done, the eye ſhould be ſhaded till the lens be extracted, or the eyelids are to be ſhut to allow the pupil to be dilated as much as poſſible; and while in this ſituation, if a gentle preſſure be made upon the eyeball at either the upper or under edge of the orbit, the cataract will paſs through the pupil more readily than it would do when the eyelids are open.

If the lens cannot be eaſily puſhed through the opening of the cornea, no violent force ſhould be uſed, for this would tend much to increaſe the inflammation. The opening ſhould be enlarged, ſo as to allow the lens to paſs out more freely. When the cataract does not come out entire, or when it is found to adhere to the contiguous parts, the end of a ſmall flat probe, or a ſcoop (fig. 35.), is to be introduced, to remove any detached pieces or adheſions that may be preſent. The iris ſometimes either projects too much into the anterior chamber, or is puſhed out through the opening of the cornea. When this happens, it is to be returned to its natural ſituation by means of the probe already mentioned. Sometimes the opacity is not in the body of the lens, but entirely in the capſule which contains it. The extraction of the lens alone would here anſwer no uſeful purpoſe. Some practitioners attempt to extract, firſt the lens, and then the capſule by forceps; others, the lens and capſule entire. Thoſe who have had much practice in this branch of ſurgery, as Pellier, ſay they find ſuch a method practicable; but others think it better to truſt entirely to time and a cooling regimen for the cure, which, in ſome inſtances, has taken place. When the operation is to be performed on the right eye, the operator is either to uſe the left hand, to take his ſtation behind the patient, or to employ a crooked knife (fig. 36.)

219 Treatment after the operation.

After the operation is finiſhed, the eyelids are to be ſhut, and the ſame treatment obſerved as in couching. When the operation ſucceeds, the wound in the cornea is generally healed in little more than eight or ten days; but previous to this time, the eye ought not to be examined; and even then it ſhould only be done in a dull light, otherwiſe it may ſuffer conſiderably from the irritation which a ſtrong light might occaſion. When the eye is to be examined, if the eyelids be found adhering together, they ought to be waſhed with ſome gentle aſtringent. With this the eye ought alſo to be frequently waſhed afterwards, by which it will gradually recover ſtrength and ſight. About the end of the third week the dreſſing may be entirely removed, and a piece of green ſilk put over the eyes as a ſhade; and if every thing has ſucceeded, the patient may generally go out after a month from the time at which the operation was performed.

It ſometimes happens, that in extracting the lens a portion of the vitreous humour is evacuated. This does not in general prevent the ſucceſs of the operation. The eye ſoon begins to fill again, and in the courſe of two or three

Fiſtula Lachrymalis.

weeks it is for the moſt part as large as it was previous to the operation. Whether this be owing to a renewal of the vitreous humour, or merely an aqueous ſecretion, is not yet determined; though the latter circumſtance is generally ſuppoſed.

Chap. XIV. *Of Fiſtula Lachrymalis.*

By this diſeaſe is properly underſtood a ſinuous ulcer of the lachrymal ſac or duct with callous edges, though every obſtruction of this paſſage is commonly called *fiſtula lachrymalis*.

220 Symptoms of the diſeaſe in its moſt ſimple form.

The firſt and moſt ſimple ſtate of the diſeaſe is that termed a *dropſy of the lachrymal ſac*. The ſymptoms are, a tumor between the inner cornea of the eye and ſide of the noſe. This diſappears by preſſure, the tears mixed with mucus paſſing partly into the noſe, but chiefly back upon the eye and over the cheek.

This ſtate of the diſeaſe is what the French have called the *hernia*, or *hydrops jacculi lachrymalis*. It is frequently met with in children who have been rickety, or are ſubject to glandular obſtructions: and in this ſtate it ſometimes remains for ſeveral years, ſubject to little alterations, as the health or habit ſhall happen to vary, the ſacculus being ſometimes more, ſometimes leſs full and troubleſome; the contents which are preſſed out are ſometimes more, ſometimes leſs cloudy; and now and then the diſeaſe is attended with a ſlight ophthalmy, or an inflammation of the eyelids, but which, by common care, is eaſily removed. If the ſacculus be not much dilated, the diſcharge ſmall, and produced only by preſſure, the chief inconveniences are the weeping eye, and the gumming together of the lids after ſleeping: but theſe, by being attended to, may be kept from being very troubleſome; and if the diſeaſe makes no further progreſs, may be ſo regulated as to render any more painful proceſs totally unneceſſary. If the dilatation be conſiderable, the ſwelling is more viſible, and the quantity of fluid is larger; it is alſo in this ſtate more frequently mixed and cloudy, and more troubleſome, from the more frequent neceſſity of emptying the bag; but if the patient be an adult, it may, even in this more dilated ſtate of it, be kept from being very inconvenient.

If an inflammation comes on, the tumor is thereby conſiderably increaſed, the diſcharge is larger, as well during ſleep as upon preſſure; the ſkin covering it loſes its natural whiteneſs and ſoftneſs, becomes hard, and acquires an inflamed redneſs, and with the tears a mixture of ſomething, which in colour reſembles matter, is diſcharged, eſpecially if the preſſure be made with any force, or continued for any time.

When the parts are in this ſtate, the contents of the bag have ſo much the appearance of purulent matter that they are now generally conſidered as ſuch, though Mr Pott and ſeveral others have been of a different opinion, conſidering the fluid as merely mucus under a different form; allowing, however, that pus is ſometimes diſcharged. If the puncta lachrymalia be naturally large and open, and the inflammation confined to the ſurface of the ſac, its contents will paſs off pretty freely, and the ſkin will remain entire.

221 In its advanced ſtate.

But when the ſkin covering the lachrymal bag has been for the time inflamed, or ſubject to frequently returning inflammations, it moſt commonly happens that the puncta lachrymalia are affected by it, and the fluid, not having an opportunity of paſſing off through them, diſtends the inflamed ſkin; ſo that at laſt it becomes ſloughy, burſts externally, and forms an opening in the moſt prominent part of the tumor, at which the tears and matter contained in it are diſcharged. When the opening thus formed is ſmall, it commonly heals again in a few days, but it burſts as ſoon as a conſiderable quantity of this fluid is collected; and it continues thus to collect and burſt alternately, till the opening becomes ſufficiently large to prevent any farther collection. This ſtate of the diſorder exhibits exactly the appearances of a ſinuous ulcer, with callous, and ſometimes with retorted edges; and this ſtage forms properly the real fiſtula lachrymalis. Tears, mucus, and purulent matter, are now abundantly diſcharged from the ſore. When the bone beneath is ſound, this diſcharge is ſeldom either acrid or offenſive to the ſmell, for the opening being in general in the under part of the tumor, the matter is readily evacuated; but when any of the contiguous bones are carious, they are not only found to be ſo by the introduction of a probe, but by the appearance, ſmell, and effects of the matter upon the neighbouring parts. In this caſe it is thin, fetid, and commonly ſo acrid as to fret and corrode the integuments moſt contiguous to the ulcer; and when the diſorder is connected with ſcrophula or with lues venerea, which is by no means an unfrequent occurrence, the diſcharge and appearance of the ſore will vary according as it happens to be combined with one or other of theſe diſeaſes.

Fiſtula Lachrymalis.

222 The diſeaſe divided into four ſtages.

From what has been ſaid, we may divide this diſeaſe into four general heads or ſtates, under which all its more minute diſtinctions may be comprehended. The firſt conſiſts in a ſimple dilatation of the ſacculus and obſtruction of the naſal duct, diſcharging, upon preſſure, a fluid either quite clear or a little cloudy; the ſkin covering the bag being entire and perfectly free from inflammation. In the ſecond, the tumor is ſomewhat larger; the ſkin which covers it is in an inflamed ſtate, but entire; and the diſcharge made through the puncta lachrymalia is of a pale yellow or purulent colour. In the third, the ſkin covering the ſacculus is become ſloughy, and burſts; by which means the ſwelling is in ſome meaſure leſſened: but the matter which, while the ſkin was entire, uſed to be preſſed out through the puncta lachrymalia now diſcharges itſelf through the new aperture. The ductus ad nares, both in this and the preceding ſtate, are not otherwiſe diſeaſed than by the thickening of its lining. In the fourth, the paſſage from the ſacculus lachrymalis into the noſe is totally obliterated, the inſide of the former being either ulcerated or filled up with a fungus, and attended ſometimes with a caries of the bone underneath.

223 Treatment during the firſt ſtage.

In the firſt and moſt ſimple ſtate of the diſeaſe, viz. that of mere obſtruction without inflammation, much pains have been taken to reſtore the parts to their natural ſtate and uſe, without making any wound or diviſion at all. The introduction of a probe, the injection of aſtringent fluids, and a conſtant compreſſion made on the outſide of the ſacculus in the corner of the eye, are the principal means by which this has been attempted.

224 M. Anel's probe and ſyringe.

Several years ago, M. Anel made a probe (fig. 37.) of ſo ſmall a ſize as to be capable of paſſing from the eyelid into the noſe, being introduced at one of the puncta lachrymalia, and paſſing through the ſacculus and duct; with which probe he propoſed to break through any ſmall obſtruction which might be found in its paſſage. He alſo invented a ſyringe (fig. 38.), the pipe of which is ſmall enough to enter one of the puncta, and thus furniſhes an opportunity of injecting a liquor into the ſacculus and duct; and with theſe two inſtruments he pretended to be able to cure the diſeaſe whenever it conſiſted in obſtruction merely, and the diſcharge was not much diſcoloured. The firſt of theſe, viz. the paſſage of a ſmall probe through the puncta, has a plauſible appearance; but will, upon trial, be found very unequal to the taſk aſſigned: the very ſmall ſize of it, its neceſſary flexibility, and the very little reſiſtance it is capable of making, are manifeſt deficiencies in the inſtrument;

225 Of little uſe.

Fiſtula-Lachrymalis.

ment; the quick ſenſation in the lining of the ſac and duct, and its diſeaſed ſtate are great objections on the ſide of the parts, ſuppoſing it were capable of anſwering any valuable end, which it moſt certainly is not.

That the paſſing a fine probe from one of the puncta lachrymalia into the noſe is very practicable, is known from experience; but the pain it gives, and the inflammation it often excites, are much greater than any benefit which does or can ariſe from it. It is ſaid that the principal uſe of this probe is to clear the little ducts leading from the puncta into the ſacculus, and the obſtruction of thoſe ducts is often mentioned as a part of this diſeaſe. Hence one would be led to ſuppoſe that it was a circumſtance which frequently occurred; whereas it is ſeldom, if ever, met with. Nor, even if it did happen, could it ever produce the diſeaſe in queſtion; the principal characteriſtic of which is a diſcharge into the inner corner of the eye upon preſſure made in the angle.

The ſyringe, if uſed judiciouſly while the diſeaſe is recent, the ſac very little dilated, and the mucus perfectly clear, will ſometimes be found ſerviceable; it gives no pain; and a few trials render the uſe of it by no means troubleſome. There is very little occaſion, however, to take much trouble, or to put the patient to ſo much uneaſineſs; for if the ſac be emptied by compreſſion, if the liquor which was to have been injected be applied to the puncta, they will abſorb it as readily as the fluid which naturally paſſes through them.

226 Screw invented by Fabricius ab Aquapendente.

Fabricius ab Aquapendente invented an inſtrument, which was ſo contrived as by means of a ſcrew to make a preſſure externally on the lachrymal bag; from the uſe of which, he ſays, his patients received much benefit. This inſtrument has been conſiderably improved by late practitioners, and is ſtill recommended as very uſeful. See fig. 39.

All the good that can be obtained by compreſs and bandage, this ſcrew is capable of procuring; but it is alſo ſubject to all the ſame inconveniences, ariſing from the impoſſibility of determining exactly the due degree of preſſure: for if it be ſo great as to bring the ſides of the upper part of the ſac into contact, all communication between it and the puncta will be thereby ſtopped; if it be but ſlight, the accumulation will not be prevented; nor does it in either caſe contribute to the removal of the obſtruction in the naſal duct, the primary and original cauſe of the diſeaſe. If the curative intention was to procure an union of the ſides of the ſacculus, as in the caſe of parts ſeparated from each other by the formation of matter or ſloughs, and the preſſure could be made uniformly and conſtantly, poſſibly it might be ſo managed as to anſwer a valuable purpoſe; but as that is not the intention, the preſſure, whether made by an inſtrument or by a common roller and compreſs, contributes little or nothing toward a cure.

When the diſeaſe is only beginning to form, if the lachrymal ſac be frequently preſſed with the finger, the contents of it will be diſcharged before they become acrid, and the complaint, though ſeldom to be cured in this manner, may be ſometimes endured without any other aſſiſtance.

227 Treatment during the ſecond and third ſtages.

But when the diſeaſe has advanced ſo far as to be in a ſtate of inflammation, conſiderable relief may be obtained from ſuch remedies as are found to be uſeful in inflammatory affections of other parts of the body, as blood-letting, laxatives, and low diet, together with ſaturnine applications to the parts affected. But when theſe fail, and it is found that the paſſage of the tears to the noſe is completely obſtructed, as the matter, if it does not burſt outwardly, may be in danger of corroding the bone underneath, a different practice is to be followed.

In this ſtate, an opening in the upper part of the ſacculus lachrymalis becomes in general abſolutely neceſſary; and as a wound made by a knife leaves a much leſs diſagreeable ſcar than that which neceſſarily follows the burſting of the ſac, one being a mere ſimple diviſion, the other a loſs of ſubſtance; it will always be found beſt to anticipate the accident of burſting, by making the opening as ſoon as the integuments are in ſuch a ſtate as to threaten it.

Fiſtula-Lachrymalis.

For making this inciſion, authors have been very particular in their directions with regard to its place, manner, and form. But all that the ſurgeon need obſerve is, to take care to keep the knife at a proper diſtance from the juncture of the palpebræ, to begin the inciſion a very little above a line drawn from that juncture toward the noſe, and to continue it downward ſo as to lay the ſac completely open; and the beſt inſtrument to make it with is a ſcalpel of the common form, but of a ſmall ſize. If the ſacculus be already burſt, the place of opening is determined; and the orifice may be enlarged with a knife, or dilated.

The inciſion being made, the contents of the tumor ſhould be moderately preſſed out; after which, ſome practitioners adviſe that the naſal duct ſhould be ſearched for by means of a probe; and if found, that a piece of catgut, bougie, or lead, ſhould be introduced, and kept there, its edge being bent a little downwards till the ſides of the duct are ſkinned over and healed. In the mean time, the ſore is to be dreſſed with ſimple pledgets of wax and oil, which are to be retained by means of adheſive plaſter. As ſoon as the paſſage of the tears into the noſe is ſufficiently ſecured, the ſubſtance which has been left in it is to be withdrawn, and the wound healed.

228 During the laſt ſtage.

The laſt ſtate of this diſorder is that in which the natural paſſage from the ſacculus to the noſe is ſo diſeaſed as to be quite obliterated, or in which the bones are ſometimes found to be carious. The methods hitherto deſcribed have all been calculated to preſerve the natural paſſage, and to drive the lachrymal fluid again through it. In this attempt they are ſometimes ſucceſsful; but when every trial for diſcovering the naſal duct has been unſucceſsful, recourſe muſt be had to an artificial opening for the tears. In performing this part of the operation, the patient ſhould be ſeated oppoſite to a window, with his head ſupported by an aſſiſtant. The ſurgeon is to place himſelf immediately before him, either in a ſitting or ſtanding poſture. The canula of the trocar (fig. 40.) is now to be introduced to the under and back part of the lachrymal ſac, and held with one hand, while the ſtilette is to be paſſed into it by the other, in a direction obliquely downwards and inwards, between the two ſpongy bones, till it reach the cavity of the noſe, which will be known by ſome bloody mucus paſſing out at the noſtril. As ſoon as the inſtrument has penetrated the noſe, the opening ſhould be made ſufficiently large; then the ſtilette ſhould be withdrawn, and a bit of catgut or bougie, or what is more clearly and conveniently, a leaden probe, is to be introduced, and the canula removed. One end of the probe ought to remain in the noſe, and the other bent in ſuch a way as to hang over the edge of the wound, and at the ſame time be in no danger of coming out. The ſore is now to be covered with a pledget of lint ſpread with emollient ointment, and the whole retained with adheſive plaſter. The probe muſt be removed every day or two, ſo as to allow it and the paſſage to be cleaned; and at each dreſſing ſome aſtringent injection ſhould be thrown in, when the parts are to be dreſſed as at firſt. Several weeks will commonly be neceſſary for rendering the paſſage perfectly callous; but this muſt depend much upon the ſtate of the parts, as well as the conſtitution of the patient.

229 Method of making an artificial naſal duct.

After the paſſage is become ſufficiently callous, the dreſſings and probe are to be withdrawn, and the parts cleared from any mucus with which they may be ſtuffed. The

Fiſtula Lachrymalis.

ſides of the wound, now already ſufficiently contracted, are to be laid together, and covered with ſome adheſive plaſter. If this be ineffectual, the wound is to be touched with cauſtic, when the cure will generally be quickly completed. To give tone to the parts, moderate preſſure ſhould frequently be made upon the ſac, either by the patient's finger or by the machine already mentioned, and this ſhould be continued for a conſiderable time. Sometimes the diſeaſe returns after a cure has been made, owing to diſeaſes of the conſtitution, carious bone contiguous to the ſore, or ſometimes too ſmall an opening having been formed. In this caſe a canula of gold, ſilver, or lead, is ſometimes introduced into the artificial paſſage, and the ſkin healed over it; by which means the paſſage will afterwards remain completely open, and no diſeaſe of the conſtitution can ever affect it. We ſhall deſcribe Mr Pellier's method of performing this operation, who has made ſeveral improvements on it.

230 Mr Pellier's method of performing this operation.

The patient is to be ſeated, and his head properly ſupported by an aſſiſtant; then the ſac is to be laid freely open at its inferior part; the naſal duct is to be ſearched for with a firm probe, or with a conductor (fig. 41.) made for the purpoſe; and Pellier aſſerts that he never fails in finding it. As ſoon as this is diſcovered, a conical tube (fig. 42.) with a projection at the top, and another in the middle for ſecuring it in its place, muſt be put upon the conductor, previouſly furniſhed with a compreſſor (fig. 43.), and it ſhould be of ſuch a ſize that the conductor may fit it exactly. The point of the conductor is now to be paſſed into the lachrymal duct; and being puſhed in till it reaches the noſtril, which may be known either by inſerting a probe into it, or by a few drops of blood falling from the noſe, the conductor is to be withdrawn; leaving the compreſſor upon the brim of the canula, which muſt be firmly preſſed down with the left hand, while the conductor is removed with the other. This being done, the compreſſor muſt next be taken out; and to diſcover whether the canula be at a proper depth, a little milk or water ſhould be injected thro' it. If the injection paſs, it will ſhow that the canula is properly placed. If, on the contrary, any obſtruction occur, there will be reaſon to ſuſpect that it is already puſhed too far, and that it preſſes againſt the os ſpongioſum inferius; in which caſe the canula muſt be withdrawn, ſhortened, and reintroduced as before.

The ſore ought to be kept open for eight or ten days after the operation with ſoft lint ſpread with emollient ointment, and the whole covered with a compreſs of ſoft linen ſecured with a bandage. An injection of milk and water ſhould be daily paſſed through the canula; and as ſoon as the ſore looks clean and healthy, the dreſſings ſhould be entirely removed, and a piece of court plaſter laid over it. In this ſtate it is to be left to heal; but the plaſter muſt be renewed, if matter appear to form beneath it. By this method Mr Pellier finds, that fiſtula lachrymalis, not depending upon diſeaſes of the contiguous bones or of the conſtitution, may commonly be completely cured in two or three weeks, which, by the uſual practice, might require ſeveral months.

Chap. XV. *Of Affections of the Noſe.*

Sect. I. *Of Hemorrhagies from the Noſe.*

When the means mentioned for this complaint in the article Medicine have failed, recourſe muſt be had to compreſſion. Doſſils of lint introduced into the noſtrils are ſometimes effectual; or the gut of ſome ſmall animal, tied at one end, then introduced by a probe into the noſe as far as the pharinx, and filled with cold water, or that and vinegar, and ſecured by a ligature, by adapting itſelf to all the parts, and preſſing equally on them, has been attended with advantage. When theſe remedies likewiſe fail in their effect, a piece of catgut or wire may be introduced through the noſe into the throat, and brought out at the mouth; a piece of ſponge, or a bolſter of lint of a ſize ſufficient to fill the back-part of the noſtril, is then to be fixed to it; the ſponge is next to be drawn back and properly applied. Another is to be applied to the anterior part of the noſtril and ſecured. The ſame may be done to the other noſtril, if it be neceſſary; or the ſponge may be of ſuch a ſize as to fill the ends of both noſtrils at the ſame time. By this contrivance the blood not finding an outlet, will ſoon coagulate, and prevent any farther evacuation.

Affections of the Noſe.

Sect. II. *Of Ozæna.*

By this is underſtood an ulceration within the noſe, which may be occaſioned by external violence, by expoſure to cold, by irritating ſubſtances, or by whatever produces inflammation in the membrane lining the noſtrils. Sometimes it ariſes from venereal infection; and in this caſe the diſcharge becomes ſo acrid as to corrode, and produce caries in the bones of the noſe. When the diſeaſe is local, and not depending upon any conſtitutional affection, aſtringent ſolutions are found to be the moſt uſeful, ſuch as a decoction of bark or that mixed with alum. Doſſils of lint dipped in theſe are to be introduced into the noſtrils three or four times a-day, or ſome prefer the injection of ſuch fluids by means of a ſyringe as being more effectual. If ſtronger aſtringents be neceſſary, a ſolution of ſtyptic powder ought to be uſed. At bed-time an ointment prepared with zinc or with lapis calaminaris ought likewiſe to be applied. Upon ſome occaſions the application of a bliſter to the temple has cured the diſeaſe.

Inſtances, however, occur, where the diſcharge is occaſioned by a collection of matter within the antrum maxillare; and then it is apt to reſiſt every effort till a proper outlet be given to it.

When the complaint is owing to venereal infection, the primary diſeaſe is to be attended to, and mercurial preparations are to be applied to the part; but when the bones are carious, till theſe are removed we need neither expect that the diſcharge will ceaſe, nor the diſeaſe be otherwiſe completely cured.

Sect. III. *Of Imperforated Noſtrils.*

Sometimes the noſtrils are in part or entirely obliterated. This may be owing to burns; ſmall-pox; different kinds of ſores, eſpecially thoſe of a venereal nature; and ſometimes it is the effect of original conformation, for it has been obſerved in new-born children.

When any opening appears in the obſtructed noſtril, it may be readily dilated by the introduction of a furrowed probe, and then cutting upon it in the courſe of the adheſion: but when no paſſage appears, the operator muſt endeavour, by means of a ſcalpel, to diſcover one of the noſtrils; and when diſcovered, it muſt be enlarged by a director and biſtoury, as in the former caſe. The other noſtril is to be treated in the ſame manner. After the openings are formed, they might be preſerved of a proper ſize by the introduction of doſſils of lint, which ſhould be frequently cleaned or renewed; but metallic tubes anſwer the purpoſe better, and allow the patient to breathe freely through them till a cure be performed. Previous to their introduction, they ought to be covered with ſoft leather ſpread with emollient ointment, and retained till the ſores are completely healed.

Affections of the Mouth and Throat.

Chap. XVI. *Of Affections of the Mouth and Throat.*

Sect. I. *Of the Diviſion of the Parotid Duct.*

When the parotid duct is divided, the ſaliva which it tranſmits paſſes over the cheek inſtead of going into the cavity of the mouth.

When the ſurgeon is called to a recent diviſion of the duct, he ought to lay the divided ends of it as exactly together as poſſible, and retain them in their ſituation till they are united, by adheſive plaſters, or by the twiſted ſuture if there be conſiderable retraction of the parts. But when the portion of the duct next the mouth is entirely obliterated, an artificial paſſage muſt be made into the mouth, and an union formed between the opening and that part of the duct which proceeds from the parotid gland. The artificial paſſage ought to be as much as poſſible in the direction of the natural duct. For this purpoſe a perforation of a proper ſize is to be made obliquely into the mouth with the torcar (fig 44.), from the ſide of the wound exactly oppoſite and contiguous to the under extremity of the upper portion of the duct; and then a piece of leaden probe of the ſize of the perforator ſhould be introduced by means of the canula, and be kept in the cheek till the ſides of the opening become callous; when the lead being withdrawn, the extremities of the artificial and natural ducts are to be brought into contact, and retained there by adheſive plaſter till the cure is completed. Another method has, in a few inſtances, been followed by Mr Latta (ſee his *Syſtem of Surgery*), of introducing one end of a bit of catgut into the artificial opening, and bringing it out at the mouth, while the other is introduced a little way into the extremity of the natural duct, and retained by adheſive plaſter till the wound is healed. Whichever way the operation is done, the patient ſhould live upon ſpoon-meat, and make as little motion as poſſible with his lips or jaws.

Sect. II. *Of the Hare lip.*

The hare-lip is a fiſſure in the upper lip, very ſeldom in the under one. It is attended with want of ſubſtance, and has its name from a reſemblance to the lip of a hare. In general it is only a ſimple fiſſure, though ſometimes it is double; in which caſe it renders a cure more difficult to be executed. There are many lips where the want of ſubſtance is ſo great, that the edges of the fiſſure cannot be brought together, or at leaſt where they can but juſt touch, and then the attempt ſhould be forborne. It is likewiſe improper in infants, and ought not to be performed till ſeveral months after they have been weaned, when they will have acquired more ſtrength to undergo the operation, and will be leſs liable to be attacked with bowel complaints, which frequently make them cry at an earlier period of infancy.

231 Operation for the hare-lip.

In proceeding to the operation, the patient, if a child, ſhould be ſecured upon a perſon's knee, or rather perhaps upon a table; but if an adult, he is to be ſeated upon a chair, in a proper light. The frænum connecting the gums to the upper lip is to be divided; if a fore-tooth project ſo much as to prevent the parts from being brought properly together, it is to be extracted; or when the fiſſure runs through the bones of the palate, if a ſmall portion of the bone project, this muſt be removed. Matters being ſo far adjuſted, the operator is to lay hold of one ſide of the fiſſure between the thumb and fore-finger, or between the forceps (fig. 45.), then a pair of ſharp and very ſtrong ſciſſars (fig 46.), or with a ſcalpel, to cut off a thin portion of the lip, and to repeat the ſame thing upon the other ſide of the fiſſure, ſo as to render the whole edges of the fiſſure completely raw; by which, if the operation be properly performed, a piece will be ſeparated in form like an inverted V. After the inciſions have been made, the veſſels ſhould be allowed to bleed freely to prevent inflammation; and when the bleeding has ceaſed, the ſides of the wound are to be brought accurately together, and kept in that ſtate by the twiſted ſuture. The firſt pin ought to be as near as poſſible to the under edge of the lip; another is to be inſerted near the upper angle; and if the patient be an adult, a third pin will generally be neceſſary, half way between the other two. In paſſing them, they ought to go rather deeper than half through the lip, that the edges of the wound may be kept properly in contact. An aſſiſtant now keeps the parts together, while the operator applies a firm waxed ligature firſt to the under pin; and having made three or four turns with it in the form of an eight figure (fig. 47.), it ſhould then be carried about the ſecond, and in a ſimilar way about the third, care being taken that the thread be drawn of a proper tightneſs. After the ligature is ſecured, a piece of lint, covered with ſome mucilage, ſhould be laid over the wound to protect it from the air; and this is commonly all the bandage neceſſary. When, however, from a great want of ſubſtance, the retraction has been conſiderable, ſome advantage is derived from the uſe of adheſive plaſters applied to the cheeks and tied between the pins. During the time of the cure the patient ſhould be fed upon ſpoon-meat, and prevented from making any exertion with the lips, otherwiſe the cure might be conſiderably retarded. At the end of five or ſix days the pins may be taken out, when the parts will commonly be found completely united.

In the caſe of a double hare-lip, the operation ſhould be firſt done upon one fiſſure; and when a cure is completed there, it may be done ſafely upon the other.

Sect. III. *Of Extirpation of Cancerous Lips.*

The under lip is much more frequently attacked with cancer than the upper, or indeed than any other part of the body: And as little dependence is to be placed upon external applications or internal remedies, recourſe muſt be had to the knife as the only certain method of cure.

When the diſeaſe has not attacked any conſiderable part of the lip, the diſeaſed part is to be cut out, and the wound cured by the twiſted ſuture. The operation ought therefore to be performed early, to allow the parts to be brought properly together. The general ſteps of the operation are nearly the ſame as in the operation for hare-lip, and therefore need not be repeated. It is only to be obſerved, that all the diſeaſed parts are to be removed, taking care to make the cut in ſuch a way as will moſt readily admit of the twiſted or hare-lip ſuture. When the parts can be brought together, the lip will have nearly the ſame appearance as in the operation for hare-lip; but when the diſeaſe ſpreads over a conſiderable part of the lip, ſo as to prevent the ſound parts from being united after the diſeaſed parts have been removed, all that can be done is to remove the part affected, ſecure the bleeding veſſels, and dreſs the ſore like any other recent wound.

Sect. IV. *Of Affections of the Teeth.*

232 Dentition.

In dentition the gums inflame and ſwell about the parts where the teeth are afterwards to appear; the child is continually rubbing the gums with its finger; the ſaliva is commonly increaſed in quantity, though ſometimes the contrary happens; ſometimes the bowels are remarkably coſtive though more frequently the reverſe: there is generally quick pulſe, with heat, and other ſymptoms of fever; and on ſome occaſions theſe ſymptoms are attended with convulſions. The means found to be moſt uſeful here are ſuch as

Affections of the Teeth.

are moſt effectual in allaying irritation; as opiates, bliſters, and eſpecially warm-bathing. When theſe fail, cutting the gum by means of a fleme (fig. 48.), over the approaching tooth, is frequently found to remove every ſymptom; but this ought to be done earlier than it commonly is to have the full effect. Whenever the ſymptoms give reaſon to think that a tooth is approaching, the gums ſhould be cut freely over that part where the teeth may be firſt expected. When the ſymptoms recur, the operation ſhould be repeated. A crucial inciſion is attended with ſtill more effect; and the bleeding which afterwards takes place is of conſiderable ſervice. The inciſion ſhould always be carried as far as the tooth, which ought to be ſomewhat expoſed; and when properly done, is frequently followed with immediate relief. Sometimes the ſame kind of ſymptoms attend the cutting of the ſecond ſet particularly of the dentes ſapientiæ. When this is owing to the thickneſs of the gums, ſcarifying gives the greateſt relief; but ſometimes it is for want of room in the jaw, and then the tooth ſhould be drawn.

233 Derangement of the teeth.

Derangement of the teeth happens more frequently in the ſecond than in the firſt ſet, and more commonly in the fore than in the back teeth. This may be owing to the firſt ſet remaining in the jaw after the ſecond have appeared. Another cauſe is a waſte of ſpace in the jaw; and a third is a mal-conformation of the teeth, where they are too large in proportion to the jaw, and therefore overlope each other. The remedy is the ſame in each of theſe caſes, viz. to extract the teeth which ſtand in the way of the reſt, to allow thoſe which are out of their place to come into the row, and put on a more uniform appearance.

The uſual method of moving teeth which are out of the row is, by fixing them with a ligature to the neareſt teeth; or the ſame thing is done by metallic plates or pieces of wire. But theſe methods have not been found fully to anſwer the purpoſe intended, though in ſome caſes they may be uſeful. When one or more front teeth are accidentally drawn out of the jaw, they ought to be immediately replaced. When the teeth are broken over or otherwiſe injured, they may be ſupplied with others tranſplanted from the jaws of another perſon; but this can only be done when the ſockets have been newly emptied, for after inflammation comes on it is impracticable. In theſe caſes the inflammation muſt be allowed to ſubſide, and then artificial teeth can be readily adapted.

234 Of looſe teeth.

When the teeth are looſened by external violence, by falls and blows, or by improper uſe of inſtruments in pulling diſeaſed teeth in the neighbourhood of ſound ones, they may again be made tolerably faſt by preſſing them as firmly as poſſible into their ſockets, and preſerving them ſo with ligatures of catgut, Indian weed, or waxed ſilk, and keeping the patient upon ſpoon-meat till they are firm. When looſe teeth are owing to tartar, nothing will faſten them till the cauſe be removed; and this ought to be done early, otherwiſe it will have no effect. Frequently the teeth become looſe from a ſpongineſs in the gums, often, but improperly, attributed to ſcurvy. The beſt remedy is ſcarifying the gums deeply, and allowing them to bleed freely; this ſhould be repeated till they are fully faſtened. Mild aſtringents as tincture of bark, are here attended with good effects, tho' thoſe of a ſtrong nature will certainly do harm. The mouth ſhould be frequently waſhed with cold water ſtrongly impregnated with theſe, and the patient ſhould not uſe the teeth which have been looſe till they become firm again. The looſening of the teeth in old age cannot be remedied, as it is owing to a waſting of their ſockets, from which the teeth loſe their ſupport.

The teeth ſometimes become yellow or black without any adventitious matter being obſerved in them; at other times they become foul, and give a taint to the breath, in conſequence of the natural mucus of the mouth, or part of the food remaining too long about them. The moſt frequent cauſe of foul teeth is the ſubſtance called *tartar*, which ſeems to be a depoſition from the ſaliva, and with which the teeth are often almoſt entirely incruſted. When this ſubſtance is allowed to remain, it inſinuates itſelf between the gums and the teeth, and then gets down upon the jaw in ſuch a manner as frequently to looſen the teeth. This indeed is by far the moſt common cauſe of looſe teeth, and when they have been long covered with this or with any other matter, it is ſeldom they can be cleaned without the aſſiſtance of inſtruments. But when once they are cleaned, they may generally be kept ſo by rubbing them with a thin piece of ſoft wood made into a kind of bruſh, and dipped into white-wine vinegar; after which the mouth is to be waſhed with common water.

Affections of the Teeth.

235 Of cleaning the teeth.

When the teeth are to be cleaned by inſtruments, the operator ought, with a linen cloth or with a glove, to preſs againſt the points of the teeth, ſo as to keep them firm in their ſockets, with the fingers of the one hand, while he cleans them with the neceſſary inſtruments, fig. 51. n° 1, 2, 3, 4, 5, held in the other; taking care not to ſcrape them ſo hard as to looſen them, or to rub off the enamel. This being done, the teeth ſhould be rubbed over with a ſmall bruſh, or a piece of ſponge dipped in a mixture of cream of tartar and Peruvian bark. The ſame application may be made to the teeth for a few days, after which they may be kept clean as already directed.

Plate CCCCLXXXIX.

The teeth are ſometimes covered over with a thin dark coloured ſcurf, which has by ſome been miſtaken for a waſting of the enamel, but which is only an extraneous matter covering it. By perſeverance this may be cleaned off as completely as where the teeth are covered with tartar; but it is apt, after ſome time, to appear again. When this is obſerved, the ſame operation muſt be repeated.

For the purpoſe of applying powders or waſhes to the teeth, a bruſh or a ſponge is commonly employed; the latter is certainly preferable, as being leſs in danger of wearing down the enamel, or of ſeparating the teeth.

236 Of toothach.

The cauſes producing toothach may be, expoſure of the nerve of a tooth, by breaking or waſting of the enamel, inflammation in or about the tooth, or from ſympathy when diſtant parts are affected, as the eye, the ear, the ſtomach, or the uterus, as in time of geſtation. After toothach has once been produced and removed, it is apt to return by expoſure to cold, by taking hot liquids, by hard bodies preſſed againſt the nerve in the time of chewing, by the uſe of a pick-tooth, &c.

237 Method of cure.

With reſpect to the cure of the diſeaſe, no rule can be laid down which will anſwer with certainty upon all occaſions. No remedy has yet been diſcovered which will at all times even moderate the pain; relief, however, is frequently obtained from acrid ſubſtances applied to the tooth, ſo as to deſtroy the irritability of the nerves, ſuch as opium, ſpirit of wine, camphire, and eſſential aromatic oils. When theſe fail, bliſters behind the ear, or deſtroying the nerve by the cautious uſe of ſtrong acids, or by a red hot wire frequently applied to the part, have been attended with advantage.

When a black or mortified ſpot appears on a tooth, if it be quite ſuperficial, it may be removed; but if it go through the thickneſs of the enamel, it will be more adviſable to let it remain.

When a ſmall hole breaks out in a tooth, particular attention ſhould be paid to prevent the admiſſion of air. Tin, lead, or gold-leaf, commonly employed for this purpoſe, ſometimes give relief for many months, or even years; but

at

Affections of the Teeth.

at other times are of little advantage, and in ſome inſtances create great pain. Gum-maſtich or bees-wax are frequently employed, and can be made to fill the cavity of the tooth ſtill better than metalline ſubſtances. When ſtuffing is to be employed, it ought to be done in the intervals of the fits of toothach, otherwiſe it will give great uneaſineſs. When it is to be uſed, the whole cavity of the tooth ſhould be filled; and this is to be done with the inſtruments, fig. 52. n° 1, 2, 3.

238 Method of extracting the tooth.

When the remedies made uſe of for the removal of toothach have failed in their effect, and it is found that the complaint ſtill continues, it will be neceſſary to extract the tooth. In doing this, it may be obſerved, that all the teeth may be pulled to either ſide, excepting the dentes ſapientiæ of the lower jaw, which ought to be pulled outwards, otherwiſe the jaw may be ſplintered. As ſoon as the ſocket is cleared of blood, if the tooth be not much ſpoiled, it may be immediately replaced, when it will become as uſeful as before. It is difficult, however, to replace the large grinders, on account of their diverging roots. The more perpendicularly the teeth are pulled, the leſs contuſion and injury will be done to the jaws and alveoli. But as no inſtrument has been yet invented capable of effecting this properly, ſurgeons are obliged to be contented with an inſtrument which acts in a lateral direction. One of the beſt is that (fig. 53.) in form of a key, with a claw and fulcrum. Previous to the operation, this ſhould be covered with a linen rag, to prevent the gum from ſuffering. After dividing the gum, or ſeparating it from the tooth, the claw is to be fixed as deep between the teeth and gum as poſſible. Then the fulcrum is to be applied on the oppoſite ſide. The ſurgeon may now, with one turn of the handle of the inſtrument, pull the tooth out at once. But the turn ſhould not be effected by a ſudden jerk, but in the moſt cautious and ſlow manner. When it happens to be one of the great molares, whoſe roots diverge very much, and when they are firmly fixed, after only looſing it with the firſt pull, the claw of the inſtrument is to be applied to the other ſide of the tooth, and the turn given in a contrary direction to the firſt. After it has been ſufficiently looſened in this manner, it is to be laid hold of by a common teeth forceps (fig. 54.), and extracted in the eaſieſt manner. Upon extraction of the tooth, any detached ſplinters occurring are to be immediately removed. Should any conſiderable hemorrhagy take place, the patient may take ſome cold water, vinegar, or ſpirit of wine into his mouth, and doſſils of lint may be introduced into the ſocket. After all theſe fail, recourſe muſt be had to the actual cautery.

When ſtumps occur from caries, or when the teeth have broken in time of the extracting, the common key will ſometimes remove them; if that fail, the punch (fig. 55.) is to be uſed. The operator having this inſtrument in one hand, is to place the fore finger of the other, with a piece of cloth wrapped round it, upon the inſide of the jaw oppoſite to the ſtump, to protect the neighbouring parts.

239 Of tranſplanting teeth.

Teeth can never be tranſplanted with propriety in childhood or in old age. The conſtitution muſt be free from thoſe diſeaſes which affect the gums. The tooth to be tranſplanted muſt be taken from a perſon of a ſound conſtitution, otherwiſe it will convey infection. To guard as much as poſſible againſt infection, it ſhould be immerſed for a few minutes in lukewarm water, and then well dried and cleaned. It ought to fit the ſocket exactly; if it be too large, it may be filed down, avoiding the enamel as much as poſſible. The ſurface of it ſhould be at firſt on a level with the reſt, or rather a little more depreſſed, that it may be as ſecure as poſſible in its place. If the tooth fit the ſocket properly, there will be no occaſion for uſing a ligature to fix it; but if a ligature be found neceſſary, it may be made of threads of fine ſilk properly waxed. After the operation is finiſhed, the patient ought to avoid whatever may be in danger of ſhaking the tooth, and this is to be attended to till the tooth, is perfectly firm. He ſhould alſo guard againſt cold and moiſt air, and live upon ſpoon-meat.

Boils and Excreſcences of the Gums.

SECT. V. *Of Boils and Excreſcences of the Gums.*

240 Of gum boils.

GUM boils may ariſe from cold or from external violence, &c. but moſt frequently they are the conſequence of toothach. The complaint begins with pain attending a tumor on the parts affected; by degrees the ſide of the face ſwells conſiderably; the tumor of the gum now begins to point; and if it be not opened, it burſts and gives the patient immediate relief. When the boil is owing merely to inflammation after the matter is evacuated, the complaint goes off; but when it proceeds from a caries of a tooth, it will continue as long as the cauſe remains; the tooth therefore ought to be extracted. After the abſceſs has burſt, if the matter continue to be diſcharged, it may ſometimes be dried up by injecting ſome aſtringent liquor; but the moſt effectual method is to lay the abſceſs fully open, and to heal it from the bottom by doſſils of lint. Sometimes abſceſſes occur of a more obſtinate nature, owing to a carious ſtate of the jaw. In that caſe ſuppuration ought to be promoted, and the part laid open as ſoon as matter is formed; keeping the paſſage open for the diſcharge, being the only means for effecting a cure.

214 Excreſcences in the gums.

Excreſcences of various degrees of firmneſs ſometimes grow upon the gums. Some are ſoft and fungous, while others are of a warty nature. In general they are not attended with pain. They frequently originate from caries of the teeth, or of their ſockets; in which caſe the removal of the ſpoiled teeth, and the ſubſequent exfoliation, of the carious part of the jaw, will often accompliſh a cure. But when this does not happen, the tumor ſhould be removed as ſoon as it becomes troubleſome, otherwiſe there may be danger of its ending in cancer. The removal may be effected by a ligature or knife, according as the tumor may have a narrow or broad baſis. It is ſometimes neceſſary to uſe a ſpeculum oris to keep the mouth open. After the tumor is extirpated, the wound ſhould be allowed to bleed freely, to prevent ſubſequent inflammation. When the hemorrhagy proceeds too far, it ſhould be reſtrained by the application of ſpirit of wine, or tincture of myrrh, or ſolution of alum, &c. and ſhould theſe prove unſucceſsful, the lunar cauſtic will ſeldom fail of having the deſired effect. No dreſſings can be applied; but for ſome days after the operation, the mouth ſhould be frequently waſhed with a warm emollient decoction; and the cure will be afterwards promoted by the application of ſome gently aſtringent liquor, as port wine, tincture of roſes, &c.

SECT. VI. *Of Abſceſſes, &c. in the Antrum Maxillare.*

THIS diſeaſe is known by a pain and uneaſineſs beginning in the cheek, and extending upwards to the eyes, noſe, and ears, together with a ſwelling, which in the latter ſtages of the diſeaſe tends to a point, moſt frequently in the cheek. Sometimes a diſcharge enſues between the roots of the back-teeth, when they happen to penetrate the antrum. Sometimes a diſcharge of matter from the noſtrils takes place, particularly when the patient lies on the ſide oppoſite to the tumor. The diſeaſe may ariſe from cold, or whatever produces inflammation in general; but the moſt common cauſes are violent fits of the toothach, occaſioning exceſſive pain and inflammation of the membranes of the noſe and antrum.

The cure is performed by giving a free diſcharge to the con-

Ranula. contents of the tumor: and this is done in two ways; either by extracting one of the two anterior great molares, which are ſituated under the antrum, and making a perforation with a round trocar (fig. 49.) through the bottom of the ſocket; if this has not been already perforated by the fangs of the tooth or eroded, in which caſe the matter will paſs out immediately after the extraction: or the perforation may be made by the inſtrument repreſented in fig. 50. through that part of the antrum which projects outwardly over the molares. As moſt people wiſh to avoid the pulling of a tooth, when it does not appear to be abſolutely neceſſary, the perforation is commonly made in the way laſt mentioned. Some authors, however, object to this, as not giving a ſufficiently depending opening to the matter. As ſoon as the matter is diſcharged, a plug may be introduced into the perforation, which may be removed frequently to allow the matter to paſs out, and to admit aſtringent ſolutions of bark, &c. to be occaſionally thrown into the cavity of the antrum. In this way a cure is obtained, if the bones be ſound; but if they are carious, it is impoſſible to expect a cure till the diſeaſed portions of the bone exfoliate and be removed. When clotted blood is formed in the antrum, it is to be removed in the ſame manner. Sometimes the tumor of the cheek is owing to a ſwelling of the bones, and no matter is found in the antrum: In that caſe the operation does harm. No external application has yet been diſcovered for removing ſuch a ſwelling, though a long continued courſe of mercury has been found to be of ſome ſervice.

Plate 48.

Sect. VII. *Of Ranula.*

This is a tumor under the tongue, moſt frequently owing to an obſtruction in one of the ſalivary ducts. Sometimes it contains matter like the ſynovia of the joints, ſometimes a fatty matter, now and then ſtony concretions, but moſt commonly a fluid like ſaliva. It often acquires ſuch a ſize as to prevent ſucking in infants, or maſtication and ſpeech in adults. When the perſon attempts to ſpeak, he only makes a croaking noiſe: hence the name of the diſeaſe.

The beſt mode of treatment is to lay the tumour fully open by means of a ſcalpel or large lancet, to evacuate its contents completely, and then to waſh the cavity with any mild fluid, as milk and water. If the ſore be difficult to heal, tincture of bark or other aſtringents may be uſed. When the tumour is obſerved to be filled with a fatty or any other firm ſubſtance, it ought to be removed entirely. The only application neceſſary in the time of the cure, is the frequent injection of milk and water, or any other mild fluid, by means of a ſyringe.

Sect. VIII. *Ulcers within the Mouth.*

When ulcers of the mouth ariſe from a general affection of the ſyſtem, this muſt be removed before a cure can be expected. When they originate from ſharp points in the teeth, theſe are to be filed off, and ſome aſtringent ſolution taken occaſionally into the mouth. Notwithſtanding theſe and other remedies, the ſore ſometimes becomes worſe, diſcharging a thin fetid ſanies, attended with much pain, and putting on every appearance of cancer. In this ſituation, extirpation is the only thing that can effect a cure. If the ſore be only ſuperficial, it may pretty readily be extirpated; but when deep-ſeated, it may ſometimes be neceſſary to cut through the whole ſubſtance of the cheek, and heal the ſore by the hare-lip ſuture. When the tongue is the ſubject of operation, the operator ought to be ready to take up the bleeding veſſels by the tenaculum or the needle. Along with ligature, it may be neceſſary to uſe aſtringent gargles, or a mixture of vitriolic acid in water. If theſe fail, the potential or even actual cautery muſt be uſed.

Sect. IX. *Diviſion of Frænum Linguæ.*

Diviſion of Frænum Linguæ.

Sometimes the frænum linguæ extends to the point of the tongue, and tying it down; whereas, in the natural ſtate, it ends about one fourth of an inch farther back. When this is the caſe, it is to be divided, guarding againſt wounding the neighbouring veſſels, or the ends of the ſalivary ducts. The diviſion may be made with a common ſcalpel, but ſtill better with a pair of very ſharp ſciſſars with blunt points.

The child being laid acroſs the nurſe's knee, the ſurgeon ſhould open the mouth, and raiſe the tongue with the two firſt fingers of the one hand, while with the other he introduces the ſciſſars, and divides the frænum in the middle, and as far back as is neceſſary.

Sect. X. *Of Enlargement of the Tonſils and Uvula.*

241 Enlargement of the tonſils.

The tonſils ſometimes grow ſo large and hard as to become incurable, and even to threaten ſuffocation. The tumors here have been commonly conſidered as to be of ſcirrhous nature; but they are neither attended with ſhooting pain, nor are they apt to degenerate into cancer; neither do ſwellings return after the tonſils have been extirpated: hence they ought not to be removed till by their ſize they impede deglutition or reſpiration; but whenever they do this, they may be removed with ſafety. The only proper method of removing them is that by ligatures, which are not only void of danger, but ſeldom fail to perform a cure. If the baſe of the tonſil be ſmaller than the top, the ligature is to be uſed as for polypi in the throat; but however broad the baſe of it may be, much difficulty will ſeldom occur in fixing it, for the ſwelling is always very prominent. In diſeaſes of this kind both tonſils are generally affected; but if the removal of one of them forms a ſufficient paſſage for the food, the other may be allowed to remain. When, however, it is neceſſary to extirpate them both, the inflammatory ſymptoms produced by the extirpation of the firſt ſhould be allowed to ſubſide before any attempt be made to remove the other.

When the form of the tonſils happens to be conical, ſo that the ligature would be apt to ſlip over their extremities, Mr Cheſelden has recommended a needle (fig. 56.), with an eye near the point: a double ligature being put into the eye, the inſtrument is to be puſhed through the centre of the baſe of the tumor, and the ligature being laid hold of by a hook and pulled forwards, the inſtrument is to be withdrawn; then it is to be divided, and ſo tied that each part may ſurround one half of the tumor. This method however is ſcarcely ever found to be neceſſary.

243 And of the uvula.

Enlargements of the uvula, from inflammation or from other cauſes, may generally be removed by the frequent uſe of aſtringent gargles, as of ſtrong infuſions of red roſe-leaves or of Peruvian bark. But when theſe fail, and the enlargement is ſo conſiderable as to give great uneaſineſs by impeding deglutition, irritating the throat, and ſo cauſing cough, retching, and vomiting, extirpation is the only thing upon which any dependence can be placed. Exciſion is the readiſt method when the uvula is only elongated; but when the ſize is conſiderable, dangerous hemorrhages ſometimes attend this method; on which account a ligature is preferable. The operation may be readily performed by thoſe of the common kind; ſome prefer the curved probe-pointed biſtoury.

244 Extirpation of the uvula.

In performing the operation, the ſpeculum oris (fig. 57.) is neceſſary to keep the mouth ſufficiently open, and the uvula ſhould be laid hold of by a pair of forceps or a ſmall hook, ſo as to keep it firm, and prevent it from falling into the throat. After the operation, if the bleeding be conſiderable, it may be checked by aſtringent gargles, or by touch-

Scarifying and fomenting the Throat.

touching the part with lunar caustic; but this will seldom be necessary.

When a ligature is to be employed, it may be readily done according to the method recommended in the extirpation of polypi. A double canula with a ligature may be passed through the nose, or the ligature may be applied according to Cheselden's method in extirpation of the tonsils.

Sect. XI. *Of scarifying and fomenting the Throat.*

In inflammatory affections of the throat, the means commonly employed are gargles, fomentations, scarification, or top-bleeding. Gargles are useful for cleaning the fauces from thick mucus or other sordes; they may likewise be useful in cases of ulceration. In relaxation of the parts, they are employed to advantage when made of astringent materials. Fomentations may be of some use when externally applied; but the steam of water, &c. drawn into the throat by means of Mudge's inhaler (fig. 58.), is preferable. Sometimes it is necessary to draw blood from the part affected. Here recourse may be had to scarifying with a common lancet, the tongue being depressed with a spatula. It may be still more readily done by the scarificator (fig. 59). After a sufficient number of punctures have been made, the flow of blood may be promoted by the patient's frequently applying warm water to the punctures. When abscess forms, notwithstanding the use of these remedies, the matter may be discharged with the scarificator already mentioned.

Chap. XVII. *Of Diseases of the Ear, and Operations performed upon it.*

245 Imperforated meatus auditorius externus.

Sometimes a thin membrane is spread over the mouth of the external passage, while at other times a considerable part of the passage is filled up with a fleshy looking substance, occasioning deafness. When the first circumstance occurs, the skin is easily divided by a simple incision, and the accretion of its sides may be prevented by a dossil of lint or a bit of bougie inserted between the edges of the wound, and daily cleaned and returned till the part be rendered callous.

When the other cause is present, the incision must be continued considerably deeper, till the resistance be removed, or till the instrument reach near to the membrane of the tympanum, when the operator should desist, lest the membrane should be wounded; then the same kind of treatment may be followed as in the former case. The proper time for performing the operation is when children usually begin to speak; for previous to this the patient may be too weakly to bear it, and after this speech would be impeded.

Sometimes the meatus externus is entirely wanting in the temporal bone. For this an opening through the mastoid process has been proposed; but the operation has not been performed, at least in this country.

246 Extraneous bodies impacted in the ear.

Children sometimes push hard bodies into their ear, or different kinds of insects occasionally creep into it, so as to cause considerable uneasiness. Substances lying near the outer end of the passage may generally be extracted by the small forceps represented in (fig. 60.); but round, hard bodies situated deeper in the passage are more readily removed by a crooked probe. When insects are deep-seated in the ear, they ought first to be killed, by filling the passage with oil, or any other fluid which proves noxious to them, without hurting the tympanum. They may then be washed out by injecting warm water frequently by means of a syringe.

Wax is one of the most frequent causes of deafness, and it may be readily detected by looking into the ear in a clear sunshine.

Diseases of the Ear.

247 Of superabundance of wax in the ear.

Various methods have been proposed for removing wax from the ear; but one, not inferior to any, is to throw in frequently, by means of a syringe (fig. 61.), warm milk and water, or water in which a little soap has been dissolved. Assistance may likewise be given here, by using along with the injection a blunt probe or fine hair pencil, by which the bottom of the passage may be cleared out. After the wax is removed, the patient ought to guard against the effects of cold by introducing a little wool for some time into the meatus. When deafness is owing to a deficiency of wax in the ear, a little oil of almonds, or even oils of a hotter nature, or soap, or galbanum &c. have been of service.

248 Deficiency of wax.

249 A discharge of matter from the ear.

Purulent matter is now and then formed in the ears of adults, but oftener in those of children. Sometimes it is produced by ulcers situated in the lining of the meatus, or upon the membrane of the tympanum. It seems to be merely a local affection, and does not, as many have supposed, originate from morbid humours of the system. The remedies best calculated for removing it are such as are of a moderately astringent nature, as a weak solution of saccharum saturni. A little of this may be dropped in two or three times a-day, but it is still better to use a syringe. If the discharge has continued long, it may be proper, in addition to the other applications, to keep open a small blister for some time in the neck, arm, or wherever it may be thought most convenient.

It sometimes happens, particularly in old people, that, from exposure to a stream of cold air, the tympanum becomes affected, and a noise is heard by the patient like the rushing of water. In other cases the patient is incapable of accurately distinguishing the words of some persons speaking in a loud tone of voice; or, in mixed companies, he hears only a confusion of sounds. Complaints of this kind frequently originate from a relaxation of the soft parts of the tympanum; and though a complete cure is not very frequently performed, yet considerable advantage is sometimes derived from the use of hot stimulating oils, and from keeping the part warm at the same time with a little wool. When deafness arises from affections of this nature, some assistance may be derived from collecting the sound, so as to make a stronger impression upon the internal ear. A variety of instruments have been invented for this purpose. Some use a convoluted tube as is represented in fig 62, (see Trumpet); others a sort of cup, fig. 63. which is concealed under the hair, and fixed to the head with straps.

In scrophulous habits, suppurations sometimes occur in the neighbourhood of the ear, and penetrate into the external passage, or into the tympanum itself; after which it is not unusual for the small bones of the ear to lose their connecting membrane, and to be discharged along with the matter, and for caries to ensue in the tympanum; in consequence of which a high degree of deafness is produced, which can never be removed. In such a situation little else can be attempted than to preserve the parts clean and free from smell, which is readily done by injecting a little warm milk and water morning and evening by means of a syringe. If this be neglected, the matter from the carious bones is apt to become offensive; and it commonly continues till the diseased parts are either dissolved and discharged, or probably during the life of the patient.

250 Affections of the Eustachian tube.

Besides the affections which may arise in the meatus externus, and may be the cause of deafness, others may occur in or about the meatus internus or eustachian tube, which may have in part the same effect, though by no means in the same degree. Inflammation and its consequences may

The Wry Neck.

originate in the cavity of the tube, or ſwellings or ulcers in the throat may affect it ſo as to cauſe ſome degree of deafneſs. When this is the caſe, it is practicable to introduce a pipe, fig. 64. crooked at the extremity, through the mouth or noſe, and then to inject into the mouth of the euſtachian tube any mild fluid which may be thought fitteſt for the purpoſe, though no great dependence is to be placed upon the attempt.

251 Of perforating the lobes of the ears.

Formerly piercing the lobes of the ears was ſometimes recommended in complaints of the head, and was conſidered as a chirurgical operation; but it is now never practiſed, unleſs for the ſake of ornament. As the ſubſtances ſuſpended at the ears are ſometimes ſo heavy as to tear down the parts, the perforation ſhould be made as high on the lobes as can be done with propriety, and care ſhould be taken that the perforations be made exactly in the correſponding parts of the ears. Previous to the perforation the lobes may be marked with ink; then the patient being ſeated, the lobe of the ear ſhould be ſtretched upon a piece of cork placed beneath it, and perforated with an inſtrument, fig. 65. The cork is then to be withdrawn with the point of the inſtrument ſticking in it: A ſmall piece of lead, or ſilver, or gold-wire, is now to be inſerted into that part of the inſtrument which remains in the ear, and on being drawn into the perforation, the wire is to be left in it. By rubbing it with oil, and moving it daily, the paſſage will ſoon become callous, and fit for receiving the ornament intended for it.

Chap. XVIII. *Of the Wry Neck.*

252 Cauſes of wry neck.

Wry neck may be owing to different cauſes; as contraction of the ſkin in conſequence of burns, or other kinds of ſores; relaxation of the muſcles of one ſide of the neck, particularly the maſtoid, while thoſe of the other ſide continue to act with vigour; preternatural contraction of the muſcles of one ſide of the neck, the others having their uſual power; or, a bend in the vertebræ of the neck.

When the diſeaſe is owing to a contraction of the ſkin, this is to be divided through the whole of the contracted part, guarding againſt cutting the external jugular vein.

253 Treatment.

When the contraction of the maſtoid muſcle is the cauſe of the diſeaſe, the muſcle ſhould be divided by gentle ſtrokes, ſo as to run no riſk of wounding the great veſſels ſituated under it. When an inciſion is made either with a view to divide the muſcle or the ſkin, the head is afterwards, by means of a machine (fig. 66.), to be kept in a proper poſture during the cure until new granulations form and fill up the empty ſpace. When the diſeaſe is merely owing to a curve of the bones of the neck, the ſame kind of machinery may be uſeful with that recommended for cure in the other parts of the ſpine. But ſometimes the diſeaſe ariſes from an affection of the bones of a more ſerious nature. Here the diſeaſe in the vertebræ commonly begins with a ſlight pain, which gradually becomes worſe, and the head is turned over to the ſound ſide. As the diſeaſe becomes worſe, a fulneſs can be obſerved very painful to the touch; and moving the head becomes ſo diſtreſſing as to be almoſt impracticable. The only method which has been found to be effectual in this caſe, is the inſertion of a pea-iſſue on each ſide of the tumor, and retaining it till the pain and ſtiffneſs are entirely removed.

Chap. XIX. *Of Bronchotomy and Oeſophagotomy.*

254 Bronchotomy.

The operation of bronchotomy is an inciſion made in the trachea, to make way for air into the lungs, when reſpiration is obſtructed to ſuch a degree that life is in danger. If the patient's breathing be already ſtopped, the operation ought to be done with the greateſt expedition; uſing any inſtrument which will moſt readily make an opening in the trachea, as the delay of a few moments will often put a period to the perſon's exiſtence. Experience has ſhewn, indeed, that in by much the greater number of caſes, by a total ſtoppage of reſpiration for only five or ſix minutes, life is irrecoverably deſtroyed. Bronchotomy and Oeſophagotomy.

In performing the operation, where, from the nature of the caſe, ſufficient time is allowed, the patient is to be laid on his back upon a table, and properly ſecured by aſſiſtants. A longitudinal inciſion is to be made, about an inch and an half long, through the ſkin and cellular ſubſtance; beginning at the under edge of the thyroid cartilage; the ſterno-hyoid and thyroid muſcles are then to be ſeparated; the thyroid gland is to be avoided as much as poſſible, on account of its vaſcularity. As ſoon as the trachea is laid bare, the bleeding-veſſels, to prevent coughing, are to be ſecured; then, with a common lancet, a puncture is to be made as high as may ſeem practicable between two rings of the trachea, of ſuch a ſize as to admit the introduction of a double canula (fig. 65.), large enough to allow the patient to breathe freely, and of ſuch a length as neither to be in danger of ſlipping out, nor of irritating the back part of the treachea. Such a canula has long been recommended by Doctor Monro in his courſe of ſurgery. Previous to the introduction the canula may be put through ſeveral plies of linen compreſs; or theſe may be firſt ſlit half way down, and applied ſo that any of them may be removed and replaced at pleaſure. This double canula is to be fixed by a ſtrap round the neck; and when mucus obſtructs the paſſage of the inſtrument, the inner tube can be withdrawn, cleared, and readily replaced; while the patient is, during this time, breathing through the outer one; and by means of a ſcrew the tubes can be regulated according to the motions of the trachea. After the canula is fixed, it ought to be covered with a piece of muſlin or crape, to prevent the admiſſion of duſt, inſects, &c. As ſoon as the cauſes inducing ſuffocation are removed, the canula is to be withdrawn, and the ſkin immediately brought over the orifice, and retained there by a ſlip of adheſive plaſter.

255 Oeſophagotomy.

By œſophagotomy is underſtood the cutting open the œſophagus, to allow ſubſtances ſticking in it, and which cannot be extracted otherwiſe, to be removed. It is only to be done, however, in caſes of the moſt extreme danger, as it is attended with much hazard; and there are only two inſtances yet on record of its having been performed with ſucceſs, though there are ſeveral inſtances of wounds in the œſophagus being healed. The operation may be rendered neceſſary, where obſtructions of the œſophagus become ſo complete as to prevent the paſſage of nouriſhment into the ſtomach, or of air into the lungs. But it is evident, that when the obſtructing cauſe is in the under end of the œſophagus, any inciſion becomes uſeleſs.

In performing the operation, the patient is to be ſecured in the ſame manner as for bronchotomy, and an inciſion made through the ſkin and cellular ſubſtance as directly oppoſite as poſſible to the part obſtructed. If it be done with a view to remove an obſtruction, the muſcles over the trachea are to be pulled to one ſide, and the trachea to the other, by means of a blunt hook; by which the œſophagus will be brought into view. If the obſtructed part now come in ſight, the inciſion is to be made directly upon the obſtructing body, which is to be extracted by a pair of ſmall forceps; but if the obſtruction happen to be farther down than we can with ſafety have acceſs to the œſophagus, the inciſion is to be enlarged as much as poſſible, that the forceps may be able to reach and extract it. When the operation is performed, the wound will be difficult to heal,

Sore Nipples.

heal, as the ſides of it will be frequently ſeparated by the action of deglutition. On this account as great a degree of abſtinence as poſſible is to be adviſed; and nothing but nouriſhing liquids, in ſmall quantities, are to be allowed. The patient ſhould be prevented from moving his neck; and the wound is to be healed as ſoon as poſſible by the ſame methods which are uſed with wounds in other parts of the body. On the other hand, if the operation has been done for the purpoſe of conveying nouriſhment into the ſtomach, when the patient was diſtreſſed by a tumor either in the œſophagus itſelf or in ſome of the neighbouring parts, it will be neceſſary to keep the wound open during the continuance of the tumor, or the life of the patient.

Chap. XX. *Of Sore Nipples.*

Women are more generally affected with ſore nipples in ſuckling their firſt child than at any period afterwards. This may, in ſome meaſure, be owing to the ſmallneſs of the nipples; but very often it ariſes from their being unaccuſtomed to the irritation of ſucking. In ſome caſes, the nipples are ſo flat, and ſo much ſunk in the breaſt, as to render it difficult for the child to lay hold of them. Here aſſiſtance can ſometimes be given, by the mother preſſing back the prominent part of the breaſt, ſo as to make the nipple project between two of her fingers. Should this be inſufficient, the nipple may be made to project by applying to it a ſtout child ſeveral months old: but when this cannot be done, breaſt-glaſſes, ſuch as fig. 68. may anſwer the ſame purpoſe. By applying theſe to the nipple, and ſucking out the air, the child will commonly be enabled to lay hold of it.

The nipples at this time are liable to excoriations, cracks, or chops; which, though not attended with a formibable appearance, are frequently more diſtreſſing than large ulcers. Mild, aſtringent, and drying applications are moſt to be depended upon in ſuch complaints; as port wine, brandy properly diluted, or lime-water; all of which ought to be applied warm. After bathing the parts with any of theſe, the nipple ſhould be covered with unguentum nutritum, or Goulard's cerate; the firſt of which is conſidered as beſt. Even a little ſoft pomatum frequently rubbed upon the part, and covered with a ſoft linen rag, is ſometimes found to give conſiderable relief. But the nipple ſhould be perfectly cleared of theſe applications before the child is laid to the breaſt; and this may be done with a little port wine, or equal parts of brandy and vinegar. If proper attention be paid to theſe remedies, they will commonly be found to have the deſired effect; but if the contrary ſhould happen, another remains to be mentioned, which, in different inſtances, has given great relief: it conſiſts in the application of a thin ſkin to the nipple, as the neck and part of the body of a ſwine's bladder with an aperture in it; which, being properly moiſtened and fixed to the breaſt, will completely protect it in the time of ſucking. As long as the nipples remain any way affected, ſmall cups of glaſs or tin are uſeful for retaining the dreſſings, defending the nipples from the friction of the clothes, and receiving any milk which may fall from the breaſt.

Chap. XXI. *Of Paracenteſis of the Thorax.*

256 Fluids collected in the thorax.

When either the action of the heart or of the lungs is impeded by fluids collected in the cavity of the pleura, a diſcharge of theſe fluids by a perforation is the only chance the patient has for relief. The fluids which collect in the pleura are, ſerum, blood, air, or pus. A collection of water or ſerum is frequently found in the thorax, combined with dropſy in other parts of the body; but the affection is often local, and it is then chiefly that advantage is to be derived from an operation. Beſides, in the two great cavities of the thorax, collections of water are frequently met with in the pericardium, and are ſaid to be ſometimes diſcovered between the layers of the anterior mediaſtinum. The diſeaſe is marked by the following ſymptoms: There is a ſenſe of weight or oppreſſion in the thorax, and difficulty of breathing; the patient has frequently a more uneaſy ſenſation in one ſide than in the other; has ſudden ſtartings during ſleep, with a ſenſe of ſuffocation; is troubled with a frequent dry cough; the pulſe is ſmall and irregular; the ſkin dry, and the urine ſcanty.

Paracenteſis of the Thorax.

257 Symptoms of fluids being collected.

With theſe ſymptoms there are commonly other marks of dropſy; and the patient ſometimes, upon any ſudden motion, is ſenſible of an undulation within the cheſt; and when the quantity of water is conſiderable, the undulation will even be heard by the byſtanders, if the body be ſmartly agitated. For this purpoſe, the patient's body ſhould be uncovered while under examination; and the ſurgeon ſhould place his hand upon the breaſt near the ſternum; then an aſſiſtant ought to raiſe the patient ſuddenly from an horizontal to an erect poſture, or to ſtand behind the patient and make ſudden jerks; when, if water be preſent, the undulation will be felt; but it is neceſſary to guard againſt being deceived by the noiſe ſometimes made by the contents of the ſtomach.

When the water is collected in one ſide only, if the diſeaſe be of long ſtanding, for the moſt part that ſide is more prominent than the other. If the water be in the pericardium, the ſymptoms are nearly the ſame as thoſe above enumerated, with this difference, that the pain is generally felt behind, and to the left ſide of the ſternum; and the ſtroke of the heart is as if buried in water, while an undulatory motion has been ſaid to be felt oppoſite to the anterior extremities of the third, fourth, and fifth ribs.

258 Internal remedies of little advantage.

In the treatment of this diſeaſe, little advantage can be derived from internal remedies. Squills, cream of tartar mercury, and digitalis, are upon ſome occaſions attended with advantage; but the only method from which we can expect any degree of ſucceſs is the removing of the water by an operation, which ſhould be performed as ſoon as there is reaſon to expect that danger may ariſe from delaying it longer. The operation is done in the ſame way as ſhall be afterwards deſcribed in the caſe of empyema.

259 Blood collected in the thorax.

Blood collected in the thorax is always extravaſated thro' ſome wound or rupture of the veſſels of the lungs or thorax. The breathing becomes oppreſſed, the motion of the heart and arteries feeble and irregular, and all theſe ſymptoms are more diſtreſſing than collections of other fluids. As it frequently happens, in caſes of this kind, that ſome of the veſſels of the lungs are injured, part of the blood is thrown up by coughing; which, when conſiderable, gives a temporary relief to the lungs and heart; and while this is the caſe, no operation is neceſſary; but whenever the action of theſe parts becomes much impeded by a great accumulation of blood, a perforation ought to be made to diſcharge it. When the extravaſated blood is too firmly coagulated to paſs off by a perforation, the wound ought to be made conſiderably larger; and if this be inſufficient, injections of warm water ought to be thrown in, and allowed to remain for ſome time, to promote the diſſolution of the maſs, which is afterwards to be evacuated. If the extravaſation has been occaſioned by a wound in the lower part of the thorax, a new perforation will be unneceſſary; an enlargement of the wound will be quite ſufficient. But if it be ſituated in the upper part of the cavity, a perforation in the

Paracentesis of the Thorax.

middle and lateral part of the thorax ought to be made, that the blood may be freely discharged. In case of a rib being fractured, or a vessel ruptured, the incision ought to be made as near as possible to the part affected, to allow the blood to escape, and loose pieces of bones to be removed.

260 Air collected in the thorax.

The discharge of air into the cavity of the thorax produces symptoms little less alarming than those proceeding from the effusion of blood. In general they are, oppression in breathing; a tightness of the breast, attended with pain; inability to breathe in the recumbent posture; a flushing and swelling of the face; a feeble, and at last an irregular pulse: The extremities become cold, and cold sweats break out on the forehead. With these symptoms there is frequently a swelling over the external parts of the body, by air getting from the ruptured lungs into the common cellular substance; and all these complaints increasing, the patient, if not quickly relieved, soon dies; sometimes in a few hours, with marks of suffocation.

Air may be produced in the cavity of the thorax by wounds in the lungs, by mortification generating air in any of thoracic viscera, by erosion of ulcers, by laceration in consequence of fracture in any of the bones of the thorax.

We distinguish this from other collections by the sudden oppression in breathing, by the flushing of the face, by no blood being thrown up, and by the emphysematous swelling of the chest and other parts, which has a crackling noise upon being pressed.

The treatment of this complaint consists in making small punctures in the affected part of the skin, so as to allow the air to escape from the cellular substance; and if the air shall have spread to distant parts of the body, it will escape most readily by such openings. But if this give no relief to the oppressed breathing, paracentesis ought to be performed. In former times, patients labouring under such symptoms were almost constantly left to their fate. Within these few years, however, some cases have occurred where the patients have been completely relieved by an operation being performed. This is done in the same way as in the evacuation of other fluids.

261 Empyema or pus collected in the thorax.

Purulent matter is more frequently collected in the thorax than any other fluid: it is much more frequently formed, however, than confined there. As the matter is usually spit up as fast as it is generated, in the dissections of those who have died of this species of consumption, much extravasated pus is rarely found in the cavity of the thorax, though a great portion of the lungs be destroyed. Cases not unfrequently occur, however, which require the operation; and these may be distinguished by the following symptoms: The patient at first generally complains of a fixed pain in some part of the thorax, attended with heat, quick pulse, and other symptoms of inflammation; respiration becomes oppressed; he is unable to lie on the sound side; or, if both sides be affected, can only lie on his back; has a constant tickling cough, clammy sweats, frequent rigors or shiverings. If these symptoms be attended with an enlargement of the affected side, or with a soft œdematous fulness there, and, along with these, if there be a sensible undulation of a fluid, it may be concluded that a collection of matter is formed. The matter is commonly first formed in the substance of the lungs, and is afterwards discharged into the cavity of the pleura, though in many instances large quantities of purulent matter have been found to originate from an inflamed state of the pleura.

The operation ought to be performed as soon as there is evidence of the collection being the cause of the oppressed breathing, and that there are no signs of this being relieved by expectoration. The operation ought to be done upon the part where the collection is supposed to be situated; and this may be known by the seat of the previous pain, and perhaps by the matter being distinguished between two of the ribs. If no matter flow, it is probably seated in the substance of the lungs; but even in this case, such an opening may be useful, by taking off the support and giving the abscess an opportunity of bursting. If the undulation of the fluid be general, the operation is to be performed in the following manner: The patient is to be laid in an horizontal posture, with the affected side inclining a little over a table. An incision is then to be made with a scalpel, through the skin and cellular substance, between the sixth and seventh ribs, and half way between the spine and sternum, from one to two inches in length, and in the direction of the ribs. The muscles are then to be cut through, keeping as near as possible to the upper edge of the inferior rib to avoid wounding the intercostal vessels and nerves. As there is no occasion for the bottom of the wound being of the same length with the external incision, it may be gradually contracted, so as at last to be only about the half. The pleura being now exposed, is to be divided by slight scratches, taking the assistance of a furrowed probe to prevent the lungs from being injured, in case they shall be found adhering to the ribs. If the contrary takes place, the fluid will rush out immediately upon a small opening being made into the cavity of the thorax; but if an adhesion appear, and if it be slight, which may be known by the introduction of a blunt probe, as much of it may probably be separated as to allow the fluid to escape. In case it be considerable, the incision is either to be continued a little nearer to the sternum, or an attempt made in some other part. After the fluid is observed to flow, it will be proper to introduce a silver canula, fig. 69. at the opening; by which means it will run more readily off, or can be more easily stopped in case the patient become faint. If the quantity of fluid be not considerable, it may generally be drawn off at once; but if it be great, partial evacuations ought to be made at different intervals, as circumstances may direct.

Paracentesis of the Thorax.

262 Method of performing the operation of discharging fluids from the thorax.

The canula therefore should be so formed, that by means of a strap put round the body of the patient, it can be readily secured. Its mouth is to be shut by means of a cork. A pledget of emollient ointment is to be laid over the wound; and the whole being fixed by a napkin and scapulary bandage, the patient should be laid to rest. The remainder may be drawn off, probably in a day or two, or as soon as it is supposed the patient can bear it. After the fluid is carried off, the canula is to be withdrawn and the wound healed; or in case the operator be afraid of bad effects being produced upon the lungs by irritation from the canula, though of this there will be little danger, as the lungs will generally be out of its reach, the skin may be so drawn back before the first incision is made as afterwards to serve the purpose of a valve. And for some days after the operation, the incision in the integuments may be brought opposite to that in the pleura, to allow the matter to run off, or to produce a radical cure by exciting a certain degree of inflammation over the lungs and inside of the thorax.

After the matter is evacuated, the wound ought to be kept open a considerable time for the purpose of discharging the matter as fast as it is collected. If the wound be apt to heal up too soon, which will be known by the symptoms of oppression being renewed, it will be proper to keep the passage open by tents, or to introduce a bougie or silver canula a few hours occasionally, till the source of the matter be dried up; which, however, seldom happens for a considerable time, and frequently never. By attending to this circumstance, the patient may enjoy good health; whereas,

Paracentesis of the Abdomen, &c.

as, by the neglect of it, a repetition of the first operation would soon be necessary.

CHAP. XXII. *Of Paracentesis of the Abdomen, or Tapping.*

THIS operation is an opening made into the abdomen, in order to empty any quantity of extravasated water collected in that species of dropsy called the *ascites*.

263 Symptoms of a fluid in the abdomen.

A fluid in the cavity of the abdomen is discovered by the swelling which it produces; by a sense of tightness in the part affected; by laborious and difficult breathing, especially when in the horizontal posture; but particularly by a sense of fluctuation being communicated to the fingers placed on one side of the abdomen, while the swelling is forcibly struck on the opposite side. There is besides much thirst, a dry skin, scantiness of urine, &c. Whatever may be the influence of diuretics and other evacuations in the cure of general dropsical affections, they are rarely serviceable in local diseases of this kind, and even the operation of tapping seldom cures the distemper; but it commonly gives the patient ease for the present time, and is attended with very little pain.

264 Manner of performing the operation of paracentesis.

Upon the supposition that nothing forbids the extraction of the water, the manner of operating is this: Having placed the patient in an horizontal situation, as best suited to prevent fainting, and to allow the water to run freely off, the part to be perforated ought to be marked with ink; and the most approved part for the operation seems to be at a point lying at nearly an equal distance between the umbilicus and the centre of the spine of the os ilium, this being most out of the way of any of the viscera, and sufficiently depending to allow the water to escape; and as the spleen is less frequently enlarged than the liver, the left side is generally preferred. Various means have been used for applying an equal pressure in this operation. Some apply pressure by the hands of assistants; others use a broad piece of flannel, or other kinds of cloth, slit a certain way from each end; then the ends are drawn by assistants till sufficient pressure is made. Broad belts are used by some practitioners; but one of the best contrivances for this purpose is the bandage invented by the late Dr Monro, (fig. 70.) Till very lately, a puncture was first made with a lancet, then a trocar of a round form (fig. 71.), and with a triangular point, was constantly used: but the entrance of this instrument being always attended with difficulty and pain, a flat trocar is now very frequently employed; and that invented by Mr Andree (fig. 72.) seems the best which has yet appeared. The bandage being now applied and drawn a little tight, the part to be punctured is to project a little over the edge of the bed. The operator fixes the head of the trocar in the palm, while the fore finger directs the point of the instrument. He is then to push it forwards till he is satisfied, by the want of resistance, that the end of the canula has reached the cavity of the abdomen. The perforator is now to be withdrawn, and the water allowed to flow as long as any of it can be taken off, the bandage being from time to time pulled to favour the discharge. But if the patient become faint, a stop for a few minutes should be put to the discharge every now and then, by placing the point of the finger upon the mouth of the canula. If any of the viscera happen to stop the flow of the water before the swelling is much diminished, a blunt probe is to be introduced, but bent at the end, lest it slip into the cavity of the abdomen. When the serum is thick and gelatinous, it may sometimes be necessary to introduce a larger trocar than the one first employed. When the water does not flow, because it is collected into cists, the canula is to be withdrawn, and the wound covered with a pledget of simple ointment. The operation may then be renewed immediately, or on the following day, upon the opposite side of the abdomen, or in the most depending part of the tumor, in whatever part of the abdomen it may be placed.

Plate CCCCXC.

Paracentesis of the Abdomen, &c.

During the operation it is necessary to keep up a pressure on the abdomen, otherwise the patient will be apt to fall into faintings from the weight on the great vessels of the abdomen being taken off, and the sinking of the diaphragm succeeding, in consequence of which more blood flows into the inferior vessels than usual, the superior ones are left too empty, and thus the regular progress of the circulation is interrupted. To obviate this, the pressure must not only be made during the operation, but be afterwards continued. As to the dressing, it has been already mentioned, that the wound may be covered with a pledget of simple ointment; but between the skin and the roller some recommend a piece of flannel dipped in brandy or spirit of wine to be applied. The bandaging in this manner may even have some effect in preventing a return of the disorder. When the water again collects, the operation should be repeated whenever the swelling has acquired a considerable size: and though this operation does not always effect an absolute cure, yet it sometimes preserves life a great many years, and even a comfortable one, especially if the waters have been long collected.

After the operation, practitioners advise the abdomen to be frequently rubbed with astringent spirituous applications. This cannot be done for the first two days after the operation, as it would then be improper to remove the bandages; but after that time, they may be removed daily, for about a quarter of an hour; and camphorated spirit of wine, or other applications which may have a similar effect, may be applied with strong friction over the abdomen, the body being kept, during this period, in the horizontal situation, and the bandage applied immediately after the friction is finished.

265 Of Tympanites.

Sometimes, instead of water, we find air contained in the abdomen; and the inflation is of two kinds: First, that in which the air is contained in the intestines; in which case the patient has frequent explosions of wind, with a swelling of the belly frequently unequal. Secondly, where the air is collected in the cavity of the abdomen; and here the swelling is more equal, without any considerable emission of air. In both varieties of the disease the swelling is more tense than where water is contained, and the belly sounds when struck, and affords to the touch and pressure nearly the same sensation as is received from a bladder filled with air. Of these two disorders the former is by much the most common. Many extensive practitioners have never met with an instance of true abdominal tympanites. A few well authenticated cases, however, have occurred, where the air was collected between the containing and contained parts of the abdomen. In some of them the air was found to have escaped by a small hole in the intestines, from which it has been supposed that the other cases were of the same nature. When the symptoms become urgent, there is as much necessity for discharging the air as for drawing off the water in cases of dropsy. The pressure and perforation are to be made in the same manner as directed for ascites, with this difference only, that a trocar of the very smallest size ought to be used, for by it the air can be as easily discharged, and the wound will heal more readily than when a large opening is made. After the air has been extracted, the treatment ought to be nearly the same as that recommended in cases of ascites.

CHAP.

Herniæ in general

Chap. XXIII. *Of Herniæ.*

Sect. I. *Of Herniæ in general.*

266 Definition of a hernia.

The name of *hernia* might with propriety be applied to every ſwelling occaſioned by the diſlodgment of parts from thoſe boundaries within which, in a ſtate of health, they are contained; but the general acceptation of the term implies a tumor produced by the protruſion of ſome part or parts from the cavity of the abdomen.

267 Situation and contents of herniæ.

The parts in which herniæ uſually appear are the groin, ſcrotum, labia pudendi, the upper and fore part of the thigh, the umbilicus, and different points between the interſtices of the abdominal muſcles. If the ſituation of ſuch tumors be various, the viſcera which produce them are ſtill more ſo; inſtances having occurred of the ſtomach, uterus, liver, ſpleen, and bladder, being found to form their contents. But a part of the inteſtinal canal, or a portion of the omentum, are from experience known to be the moſt frequent cauſe of their formation.

268 Their different names.

From theſe circumſtances of ſituation and contents, all the different appellations are derived by which herniæ are diſtinguiſhed. Thus they are termed *inguinal*, *ſcrotal*, *femoral*, *umbilical*, and *ventral*; from their appearing in the groin, ſcrotum, thigh, navel, or belly. When the tumor is confined to the groin, the hernia is ſaid to be incomplete, and is termed *bubonocele*; but when the ſwelling reaches down to the bottom of the ſcrotum, the rupture is then ſuppoſed to be complete, and the diſeaſe obtains the name of *ſcrotal rupture*, or *oſchiocele*.

Of theſe diſorders the inguinal hernia is by much the moſt frequent; next to that is the femoral. The umbilical is ſeldom obſerved in men, or even in women who have not born children.

The cauſes which tend to the production of hernia in its more uſual form are theſe:

269 Cauſes which produce them.

I. The containing parts of the abdomen we know to be elaſtic and compreſſible; whatever, therefore, tends to produce a diminution of capacity in the cavity of the abdomen, muſt occaſion a proportional degree of riſk of ſome of the contained parts being puſhed from their natural ſituations. Violent coughing, crying, laughter, or great bodily exertion, are attended with more or leſs contraction of the abdominal muſcles, and particularly of the diaphragm; and as the contraction of theſe muſcles muſt always diminiſh the abdominal cavity, theſe cauſes therefore are frequently found to be productive of hernia.

II. Falls, in conſequence of the derangement they produce in the abdominal viſcera, from the ſudden and violent ſhock with which they are often attended, are not unfrequently the immediate cauſes of hernia.

III. Perſons of a preternatural laxity of frame are very liable to herniæ. The containing parts of the abdomen, from the want of a ſufficient tone and firmneſs, are unable in ſuch people to reſiſt on all occaſions the weight of the different viſcera; and they are therefore more particularly expoſed to diſorders of this kind on the ſlighteſt application of any of the cauſes already mentioned.

IV. Sprains are apt to induce a laxity of the part injured; and have therefore a ſimilar influence in inducing herniæ with general laxity.

V. It has been obſerved that the people of thoſe countries where oil is much uſed as an article of diet, are particularly liable to herniæ.

In whatever parts the parietes of the abdomen happen to be weakeſt, theſe various cauſes will moſt readily operate in producing herniæ; and accordingly we find, that deſcents of the bowels uſually occur only in ſuch parts.

Herniæ in general.

In whatever ſituation a protruſion of any portion of the inteſtines occurs, except in the caſe of the hernia congenita, as all the viſcera are contained within the peritonæum, a portion of that membrane, it is evident, muſt be carried down together with the parts protruded; and in every ſuch inſtance, it is this portion of the peritonæum which goes down along with the gut, that is termed the *hernial ſac*. The ſize of this ſac is various in different ſubjects, and in different ſtages of the ſame diſorder. On the firſt appearance of the diſeaſe, it is commonly of no very conſiderable ſize, as ſuch ſwellings ſeldom acquire any great bulk at once: but by repeated deſcents of the bowels, it comes to be puſhed lower and lower, till in ſome inſtances its bulk becomes very conſiderable indeed; and when in this advanced period of the diſorder the ſac happens to be laid open, it is found to contain either large quantities of omentum or inteſtine, and frequently large portions of each. As the peritonæum has this property in common with many other parts of the body, of thickening according to the degree of any gradual extenſion applied to it, ſo in many inſtances, the thickening and firmneſs of the hernial ſac are often really aſtoniſhing.

270 Of the hernial ſac.

271 Cauſe of the bad ſymptoms which appear in hernia.

All the bad ſymptoms which are found to occur in herniæ, proceed, as may be readily ſuppoſed, either from obſtruction to the paſſage of the fæces when the inteſtinal canal forms the tumor, or from a ſtoppage of circulation occaſioned by ſtricture on the prolapſed parts: ſo that the attending ſymptoms, it is evident, will be always more or leſs hazardous according to the nature of the parts ſo protruded.

Thus, when omentum alone forms the ſubſtance of hernial ſwellings, as that organ does not appear to be ſo immediately neceſſary for life as many of the other viſcera, ſuch tumors accordingly are not ſo frequently productive of bad conſequences, at leaſt they are ſeldom in any degree ſo hazardous as when a part of the alimentary canal is either protruded by itſelf or along with omentum.

Although this, however, is in general the caſe, yet it does ſometimes happen, that even an omental rupture is productive of no ſmall degree of danger. When a ſtricture ſo complete upon it occurs as to occaſion a ſtoppage of circulation in the protruded part, mortification with all its bad conſequences muſt be the certain event: And beſides, the connection between the omentum, ſtomach, and other viſcera, is ſuch, that a ſudden deſcent of any conſiderable portion of the former ſometimes brings on vomiting, hickup, and other troubleſome ſymptoms: And laſtly, although a rupture containing omentum only might not of itſelf produce any thing bad; yet as the paſſage through which the omentum has ſlipped muſt of neceſſity continue open ſo long as that viſcus remains protruded, and as that circumſtance alone muſt, ſo long as it continues, render it more eaſy for a portion of gut likewiſe to get down, this of itſelf is a ſufficient reaſon for intitling even this ſpecies of hernia to the ſerious attention of practitioners.

But whatever the contents of ſuch ſwellings may be, as their remaining in ſome inſtances for a conſiderable length of time without being productive of any bad ſymptoms, muſt proceed entirely from the circulation continuing to go freely on, notwithſtanding the derangement of parts; ſo, whenever a ſtricture occurs up the protruded viſcera, ſufficient to produce either a ſtoppage of the circulation, or of the fæcal contents of the alimentary canal, when a portion of gut forms the diſeaſe, the following in general are the ſymptoms which accrue.

272 Enumeration of theſe ſymptoms.

An elaſtic colourleſs ſwelling is obſerved at the part affected; a ſlight pain is felt not only in the ſwelling itſelf, but, if part of the alimentary canal is down, an univerſal uneaſineſs

Herniæ in general.

easineſs is perceived over the whole abdomen; and this pain is always rendered worſe by coughing, ſneezing, ar any violent exertion. The patient complains of nauſea; frequent retching; can get no diſcharge by ſtool; becomes hot and reſtleſs; and the pulſe is commonly found quick and hard. When the ſwelling is formed entirely by a portion of gut, if no fæces be contained in it, it has a ſmooth, equal ſurface; and is eaſily compreſſible, but inſtantly returns to its former ſize on the preſſure being removed: but in gut-ruptures of long ſtanding, where hard fæces have collected in the protruded bowels, conſiderable inequalities are detected. When again the tumor is compoſed both of gut and omentum, its appearance is always unequal, it feels ſoft and ſomewhat like dough, and of courſe is not ſo elaſtic as when part of the inteſtinal tube only is down; for although, like the other, it is compreſſible, it does not ſo readily regain its former dimenſions on the preſſure being taken off.

473 Never happen in omental hernia.

It will be readily ſuppoſed, that the ſymptoms we have deſcribed never can happen from the preſence of omentum *only:* For although ſtricture produced on a portion of omentum, even when no part of the inteſtinal tube is down, does now and then occaſion a good deal of diſtreſs, ſuch as pain in the part, ſickneſs, vomiting, and twitching pains through the whole belly; yet no obſtruction of the gut ever occurs from this, and of courſe none of the ſymptoms ever prove ſo alarming as when any part of gut is affected. If theſe ſymptoms we have deſcribed as being produced by a ſtrangulated gut, are not now obviated by a removal of the ſtricture which produced them, the nauſea and retching terminate in frequent vomitings, firſt of a bilious, and afterwards of a more fetid matter; the belly becomes tenſe; the pain turns more violent; a diſtreſſing convulſive hickup comes on; the fever, which before was not apparently of much conſequence, now becomes very formidable; and a total want of reſt, with a very diſagreeable ſtate of anxiety, continues through the whole courſe of the complaint.—Theſe ſymptoms having gone on with violence for ſome time, the patient is at laſt commonly relieved in a ſudden from all manner of pain; and then he flatters himſelf that all danger is over. But inſtead of that, the pulſe, from having been hard and frequent, becomes languid and interrupted; cold ſweat breaks out over the whole body, but eſpecially on the extremities; the eyes acquire a kind of languor; the tenſeneſs of the abdomen ſubſides, and the ſwelling of the part affected diſappears; the teguments covering the parts, which before were either of a natural appearance, or had ſomewhat of a reddiſh inflamed caſt, now acquire a livid hue, and a windy crepitous feel is diſtinguiſhable all over the courſe of the ſwelling. If the protruded parts have not of themſelves gone entirely up, their return is now in general eaſily effected by a ſmall degree of preſſure, and the patient then diſcharges freely by ſtool; but the cold ſweats increaſing, the hickup turns more violent, and death itſelf is at laſt uſhered in by its uſual forerunners, ſubſultus tendinum, and other convulſive twitchings.

274 Symptoms of mortification of the inteſtine.

Theſe are the ordinary ſymptoms of what is termed a *ſtrangulated* or *incarcerated gut-hernia:* that is, when the parts protruded become ſo affected by ſtricture as to produce pain; and do not either return to their natural ſituations on the patient's getting into a horizontal poſture, or cannot even be immediately replaced by the hands of a practitioner.

275 Cure.

In whatever ſituation a ſtrangulated hernia occurs, the only rational method of cure, it is evident, muſt conſiſt in the removal of that ſtricture which prevents the return of the protruded parts. It is that ſtricture which ought to be conſidered as the cauſe of all the miſchief; and unleſs it be removed, nothing effectual can be done for the relief of the patient. Herniæ in general.

Various methods have been attempted by practitioners for the removal of ſtricture in theſe diſorders; all of which may be comprehended under two general heads.

I. Such as effect a reduction of the protruded parts, without the interpoſition of inciſion or any chirurgical operation properly ſo called; and,

II. A diviſion of the parts producing the ſtricture, ſo as to admit of a replacement of the deranged viſcera, conſtituting what is termed the *operation for the hernia.*

The remedies to be employed for accompliſhing the firſt of theſe are, a proper poſture of the patient, with the manual aſſiſtance of a practitioner; blood-letting, ſtimulating clyſters, opiates, the warm bath, and proper applications to the tumor itſelf.—If theſe fail, there is then no other means of cure left but the operation of dividing the integuments, and replacing the viſcera.

276 Method of reducing the inteſtine.

As ſoon as the aſſiſtance of a practitioner is deſired for the removal of ſymptoms in caſes of hernia, the firſt circumſtance requiring his attention is the placing of his patient in ſuch a poſture as will moſt probably favour the return of the protruded parts. Placing the patient's feet over the ſhoulders of another perſon, while his body is allowed to hang downwards, and cauſing him to be a good deal jolted about, has on ſome occaſions anſwered when other means have failed.

The ſurgeon ſhould at the ſame time endeavour to aſſiſt the return of the bowels, by means of gentle preſſure with his hands and fingers. In the inguinal or ſcrotal hernia, this preſſure ſhould be made obliquely upwards and outwards to correſpond with the opening in the external oblique muſcle; in the femoral hernia it ought to be made directly upwards; in the umbilical and ventral hernia directly backwards.—The ſwelling ſhould be graſped with one hand at the bottom, while with the fingers of the other hand an attempt is made to puſh gently the contents of the tumor into their place, always obſerving that the parts laſt protruded be firſt reduced. This operation is by authors termed the *taxis.*

When the means now mentioned have failed, no remedy affords more relief than blood-letting. The quantity to be drawn ought chiefly to be determined by the ſtrength of the patient. There is ſcarcely any diſeaſe, however, where ſuch large quantities of blood can with propriety be taken from weak people. Blooding till the patient is in a ſtate of deliquium animi, is frequently known to produce a more effectual relaxation of the muſcles than can be done by any other means. On that account it is ſometimes adviſed in caſes of hernia, and the practice is now and then attended with advantage.

As an obſtinate coſtiveneſs is commonly one of the moſt alarming ſymptoms of hernia, it has been a common practice to exhibit a variety of ſtimulating purgatives both by the mouth and anus; but they are very ſeldom of much ſervice, and in that caſe almoſt univerſally do injury, by increaſing not only the ſickneſs at ſtomach, but the tenſion and pain of the tumor. When they are to be employed, they ought to be thrown up by the anus. For this purpoſe aloes and other ſtimulating ſubſtances, but particularly tobacco-ſmoke, are employed; and although this laſt remedy, which is to be thrown in by double bellows, &c. does not always act as a purgative, it may be uſefully employed as an anodyne. Where an evacuation by ſtool is wanted, it may in general be readily procured by the injection of warm water, in which a little Caſtile ſoap is diſſolved, in the proportion of a drachm or a drachm and a half of the latter to a pound of the former. Warm bathing is another remedy greatly extolled, either by general immerſion or local application,

by

Hernia in general.

by means of warm water put into ox-bladders covered with flannel, and laid acrofs the abdomen.

To diminifh the fize of the tumor, remedies of an oppofite quality from thefe have been ufed; and though by fome this practice has been confidered as hazardous, yet by others, particularly by the late Dr Monro and Mr Benjamin Bell, more advantage has been found from cooling applications than from thofe of a different nature. Snow, ice, or cloths dipped in a recent folution of fal ammoniac in water and vinegar, or cold faturnine applications, or cold water and vinegar, have been employed with advantage. If, notwithftanding thefe remedies, the difeafe becomes worfe, and no probability remains of fuccefs, the divifion of the parts producing the ftricture can alone fave the life of the patient.

277 When the operation for reducing the inteftine fhould be performed.

To determine the exact time at which to proceed to an operation, has been confidered as one of the niceft points in furgery. In general, when every attempt has failed, and no repetition of the former remedies is likely to fucceed, the furgeon ought certainly to proceed to the operation. A few hours, even when affiftance has been early applied, is perhaps all the time which ought ever to be conſumed in trials of this nature. But however neceffary this operation may be when a patient's life is in danger, as it is always attended with fome degree of hazard, it ought never to be practifed where fymptoms of ftrangulation do not exift.

In this kind of hernia called *chronic*, the circulation of the part forming the hernia, as well as the periftaltic motion of fuch parts of the alimentary canal as have been protruded, go freely and regularly on. There are many inftances of large herniæ falling down even to the bottom of the fcrotum, and continuing there for many years, without producing any interruption to the ufual difcharge by ftool. All that can be done here is, to prevent any accumulation of fæces in the inteftine, by prefcribing a proper diet, and the occafional ufe of gentle laxatives; and obviating any inconvenience which might arife from the weight of the tumor, by the application of a proper truſs or fuſpenſary bandage; to warn them of the rifk to which they are conftantly liable, and to caution them againft violent exercife, particularly leaping, and every fudden exertion. The truſs ought to be fitted exactly to the part for which it is intended, for without the utmoft nicety in this refpect, it muft always do more harm than good; for the fole purpofe of a bandage, in cafes of hernia, is to prevent effectually the falling down of fuch parts as have been newly replaced. If therefore the pad or bolfter of the bandage does not bear properly againft the opening upon which it is placed, a portion of gut may flip out, and be materially injured by the preffure of the pad. Fig. 74. repreſents a truſs for an inguinal or femoral hernia of one fide, fig. 75. a truſs for the fame difeafe in both fides, and fig. 76. a truſs for an umbilical hernia.

278 Method of performing it.

We fhall now proceed to defcribe the circumftances to be attended to in performing the operation for hernia in general. A table of convenient fize and height being placed in a proper light, the patient muft be fo laid on it as to relax the difeafed parts as much as poffible, and then fecured by proper affiftance. To leffen the contents of the abdomen as much as poffible, the bladder ought to be emptied previous to the operation. An incifion is to be made with a common round edged fcalpel through the fkin and part of the cellular fubftance, long enough to allow the ftricture to be fully expofed. The reft of the cellular fubftance is then to be divided with the greateft attention. That part of the mufcle forming the ftricture or ring muft next be laid diftinctly in view. A fmall portion of the protruding fac muft alfo be expofed; after which the directory (fig. 77.) is to be paffed between the ring and the fac. A ftraight probe-pointed fcalpel is now to be introduced into the groove of the directory, and by it the ring is to be dilated till the point of the finger can be introduced. The finger is here confidered as the fafeft director; for it being infinuated into the aperture in the tendon immediately above the protruded parts, the point of the knife is eafily introduced upon it; and by keeping the end of the finger always a little before the knife, the opening may be enlarged to any neceffary extent without rifk of wounding any of the contiguous parts.

Hernia in general.

By the eafe with which the finger is introduced, the operator will be enabled to judge when the ring is fufficiently dilated; and if the ftrangulation was entirely in the ring, it will now be evident that every obftacle to the reduction muft be removed, and of conſequence that the prolapſed parts may be returned with little difficulty. If the patient be young, or if the difeafe has continued a conſiderable time, fuch a degree of inflammation frequently enſues in the neck of the fac as to produce thickening and ftraitneſs; ſo that, after the fac and its contents have been entirely freed from the ſtricture of the ring, the inteſtines cannot be reduced. We judge this to be the caſe when, after the ſtricture of the ring has been removed, the parts prolapſed do not expand into their natural ſize, and farther, when they make reſiſtance when we attempt to return them. In this caſe, the neck of the ſac muſt be opened with the utmoſt caution, to avoid wounding the parts within it.

If the herniary ſac, under the ſtraitened place of its neck, be thin and tranſparent, and there is little or no reaſon to ſuſpect an adheſion of the bowels to the ſac, the beſt method, as Dr Monro, in his publication on the Burſæ Mucoſæ, obſerves, will be to make a ſmall hole in the ſac below the ſtricture, and then to introduce a ſmall furrowed probe, and to cut cautiouſly upon it. But if the ſac be thick and dark coloured, and there is likewiſe a ſuſpicion that the bowels may adhere to it, the eaſieſt and ſafeſt manner will be to make the hole in the peritoneum above the ſtricture; then to introduce a common probe, bent near its point into a ſemicircle, with its point directed downwards through the ſtricture into the ſac; and upon the point of it to make, with great caution, another ſmall hole; after which we may either cut upon the probe, or introduce a furrowed probe, and divide the neck of the ſac.

After this, the bowels are to be returned by preſſure upon the ſac, without opening it farther; and the ſides of the wound in the ſkin are to be brought together, and kept ſo by means of ſlips of adheſive plaſter, though ſtitches made at the diſtance of a finger-breadth from each other will exclude the air, and prevent the return of the bowels more effectually. Over theſe are to be laid ſeveral folds of charpee, and the whole is to be ſecured by a bandage adapted to the nature of the part.

279 Treatment afterwards.

The patient, upon being carried to bed, ſhould be ſo placed as to have the part upon which the operation was performed higher than the reſt of his body, or at leaſt as high as the ſituation of the part operated upon will allow, in order to prevent a return of the diſeaſe. After the operation, opiates are particularly uſeful, and ought to be repeated as circumſtances may require. It is likewiſe neceſſary that the patient be kept cool. In plethoric habits, blood-letting is proper, together with a rigid attention to low diet. A frequent uſe of clyſters and gentle laxatives, to keep the belly moderately open, ought not to be neglected. When the conſtitution has been previouſly much reduced, inſtead of blood-letting and a low diet, a nouriſhing regimen is neceſſary. The dreſſings ought not to be removed till the third or fourth day after the operation, when the

Herniæ in general.

sides of the wound will be found almoſt adhering together; and if attention be paid to the ſubſequent treatment, the ſore will be generally healed in two or three weeks. As ſoon as the wound is firmly cicatrized, a truſs ought to be properly fitted to the part, and ſhould never, in any future period of life, be laid aſide.

280 Method of performing the operation when adheſions or mortifications have taken place.

When the hernia is of long ſtanding, and when there is reaſon to think adheſions have taken place between the ſac and bowels, or that mortification has already begun, or that ſome filaments run acroſs the ſac and prevent the reduction, or that there is water in the ſac, or that the gut is in danger of being entangled from a part of the omentum being down, a different method of operating becomes neceſſary.

The patient is to be placed as already directed. The operator is to graſp the tumor with the one hand, ſo as to make the ſkin tenſe on the fore part of it, while with the ſcalpel in the other he divides the ſkin from one end of the tumor to the other. The cellular ſubſtance is by gentle ſtrokes to be divided, till not only the ring, but the whole length of the ſac, is laid bare. An opening is now, in the moſt cautious manner, to be made into the ſac by ſlight ſcratches, to avoid hurting any of its contents.

In making this perforation, which is conſidered as the niceſt part of the operation, conſiderable aſſiſtance is obtained from the uſe of the ſmall directory, upon the point of which the fibres of the ſac are to be ſucceſſively raiſed and divided till an opening is made. The opening is to be enlarged till it admit the fore-finger of the left hand which ſerves as a directory for conducting the ſtraight probe-pointed ſcalpel with which the ſac is to be divided through its whole length.

The ſac being laid fully open, the parts contained in it ought to be examined with the niceſt attention, to diſcover whether they are all ſound or not; and if, upon an attentive inſpection, it is found that they are not evidently in a gangrenous ſtate, even although they ſeem conſiderably inflamed, they ſhould be immediately returned into the abdomen. When adheſions take place between different parts of the protruded gut, the greateſt caution is neceſſary in ſeparating them. When one part of a gut adhears ſo firmly to another as not to be ſeparated but with difficulty, it is much better to return the whole, even in that ſtate, into the abdomen, than to run the riſk of hurting the inteſtine materially by uſing much force. When adheſions occur between the hernial ſac and the gut, or between the gut and omentum, if the filaments producing the connection cannot be otherwiſe removed, as there is no great hazard in wounding the omentum, and ſtill leſs in hurting the ſac, a very ſmall portion of theſe may be diſſected, and returned with the gut into the abdomen. When the bowels cannot be reduced with eaſe, the ring is to be dilated by the blunt-pointed ſcalpel in the manner already directed. After returning the contents of the ſac into the cavity of the abdomen, it has been propoſed by ſome authors to paſs a ligature round the neck of the ſac, with a view of procuring a reunion of its ſides, ſo as to prevent a future deſcent of the bowels; and various other methods, even actual and potential cauteries, have been propoſed; but as none of them yet attempted have been found ſufficiently to anſwer the purpoſe, the only thing that can be recommended is a well made truſs.

281 Treatment when the bowels are in a ſtate of gangrene.

When the bowels are actually in a ſtate of gangrene, as the returning of ſuch mortified parts might be attended with the very worſt conſequences, a great degree of caution is neceſſary. When the omentum is found in a mortified ſtate, as the exciſion of a portion of this ſubſtance is not attended with much riſk, it is the common practice to cut away the diſeaſed parts, and to obviate any inconvenience which might enſue from the hemorrhagy. We are adviſed to make a ligature on the ſound parts previous to the removal of thoſe which are mortified; whilſt the ends of the ligature being left hanging out of the wound, the ſurgeon has it in his power to remove them when circumſtances appear to render it proper. Theſe ligatures on the omentum, however, are frequently productive of bad conſequences. No hemorrhagy of any importance ever occurs from a diviſion of this membrane, even in a ſound umortified ſtate; ſuch parts as have become gangrenous may therefore be freely cut off, and the remaining ſound parts be afterwards, without the intervention of ligatures, ſafely introduced into the abdomen. If a veſſel of any ſize in the omentum has been divided, a ligature may be paſſed above the veſſel itſelf, and the ends left hanging out of the wound; the threads may be afterwards pulled away at pleaſure. When a rupture has been of long duration, it ſometimes happens, that from the preſſure made by the truſs, and other circumſtances, portions of the omentum are collected together into hard lumps. If theſe be ſmall, they may be returned into the abdomen without producing any inconvenience; but if from their bulk and hardneſs they are likely to do miſchief, they ought to be cut off. When part of the omentum is to be removed, it ought to be previouſly expanded and divided with ſciſſars, which will be more convenient than any other inſtrument. When again a ſmall portion of gut is found mortified, we are to endeavour, by means of a needle-ligature, to connect the ſound part of the gut immediately above the mortified ſpot to the wound in the abdomen already made. By this means, when the mortified part ſeparates, or perhaps what is better, when it has been immediately cut out, the fæces are diſcharged by the wound; and there are different inſtances where, after ſuch a diſcharge has continued for ſome time, the wound has entirely healed.

Herniæ in general.

But when the mortified portion of gut is of conſiderable extent, and includes the whole circumference of the inteſtine, all that can be done is to remove it, and to draw, by means of a ligature, the upper end of the gut towards the under, and afterwards connect them to the inner edges of the wound. This at leaſt affords a chance of the ends of the gut being brought to reunite; and if unfortunately that event ſhould not take place, a paſſage of the fæces will ſtill be ſecured. All ſuch mortified parts as are to be removed ought to be cut off, and the remaining ſound inteſtine retained, before the opening in the ring can be dilated with ſafety, leſt the gangrenous portion ſlip in together with the ſound. The parts forming a hernia being all completely replaced, when the ſac in which they were contained is found thick, hard, and much enlarged, as in ſuch a ſtate no good ſuppuration can take place, and as its preſervation cannot be in any degree uſeful, ſuch parts of it as can be cut away with propriety ought to be removed. All the lateral and fore parts of the ſac may be cut off with ſafety; but as it is commonly firmly connected with the ſpermatic veſſels behind, this part of it ought not to be touched.

SECT. II. *Of Bubonocele, or Inguinal and Scrotal Hernia.*

282 Symptoms of bubonocele.

THIS ſpecies of hernia is formed by a protruſion of ſome of the abdominal bowels through the rings of the external oblique muſcles. It is known by the general ſymptoms of hernia already enumerated, and by a ſoft and ſomewhat elaſtic ſwelling, beginning in the groin, and deſcending by degrees into the ſcrotum in men, and into the labia pudendi in women. When the hernia contains omentum only, the ſwelling is both more ſoft, compreſſible, and more unequal than when the gut alone is down; the ſcrotum becomes more oblong than in the inteſtinal hernia; and when the quantity of omentum is large it is alſo much more weighty than a gut rupture of the ſame ſize; but frequently the tu-

Bubonocele or inguinal and Scrotal Hernia.

mor is compoſed of both gut and omentum, and then the diſtinguiſhing ſymptoms of each can never be ſo clearly marked.

283 How diſtinguiſhed from other diſeaſes.

Bubonocele may be confounded with certain other diſeaſes; but may be diſtinguiſhed by the following marks which are preſent in theſe diſorders, while the ſymptoms of hernia are abſent: From venereal bubo, by the preſence of that incompreſſible hardneſs with which all ſuch ſwellings are at firſt attended, and by the fluidity of matter which in the ſuppurative ſtate is always obſervable: From hernia humeralis, or ſwelling of the teſtes, by the abſence of the hardened and enlarged ſtate of the teſtis and epidydimus, and likewiſe of the pain, the tumor of the teſticle being remarkably heavy in porportion to the bulk, the ſpermatic proceſs being commonly free from the ſwelling. In the hernia humeralis alſo the inteſtines are unobſtructed, and the general ſymptoms of hernia are wanting. From the hydrocele of the tunica vaginalis teſtis, by the tumor generally feeling more ſmooth to the touch than in hernia, by the ſwelling here beginning in the under part of the ſcrotum and aſcending, by the ſpermatic cord being always free and diſtinct, and by a fluctuation being evident. From hydrocele of the ſpermatic cord, ſometimes with much difficulty, and therefore it requires here particular attention. In every caſe of tumor in the teſtes, where the moſt perfect certainty is not obtained, and when it is neceſſary to have recourſe to an operation, the ſurgeon ought to proceed as in a caſe of real hernia.

284 Treatment.

The treatment of bubonocele is the ſame with that already adviſed in the treatment of hernia in general, only making allowance for the ſituation of the diſeaſe. In attempting the reduction by means of the hand, the preſſure ſhould be obliquely upwards and outwards, correſponding with the ring of the abdominal muſcle. In performing the operation, the patient ſhould be laid on a table, with his head and body almoſt horizontal, whilſt at the ſame time his buttocks are ſomewhat elevated by pillows placed beneath them. The legs hanging over the edge of the table ought to be ſeparated, ſo as to admit the operator between them; and ſhould in that ſituation be firmly ſecured by an aſſiſtant on each ſide, who ſhould take care to keep the thighs ſo far raiſed as to relax all the abdominal muſcles. The parts being previouſly ſhaved, an inciſion muſt be made with a common round-edged ſcalpel through the ſkin and part of the cellular ſubſtance, beginning at leaſt an inch above the ſuperior end of the tumor, and continuing it down to between two and three inches below the ring.

Although in by much the greateſt proportion of hernial ſwellings the ſpermatic veſſels lie behind the protruded parts, yet on ſome occaſions they have been found on the anterior part of the tumor; ſo that in order to avoid the riſk of wounding them, as ſoon as the ſkin is divided, the remainder of the operation ought to be done in the moſt cautious manner, care being taken to avoid every large blood-veſſel which makes its appearance. The ring muſt now be laid diſtinctly in view; a ſmall portion of the protruding ſac muſt alſo be expoſed; after which the directory is to be introduced between the ring and the ſac, placing the point of the inſtrument obliquely upwards and outwards. A blunt pointed biſtoury is now to be introduced into the groove of the directory, and by it the ring is to be dilated till the point of the finger can be introduced. The directory is now to be laid aſide, and the finger uſed in place of it through the reſt of the operation. After the operation is finiſhed, the dreſſings are to be applied, and the whole ſecured by a T bandage, or ſuſpenſory bag, properly ſtuffed with ſoft lint.

The patient, on being carried to bed, ſhould have a pillow under the buttocks, to elevate them a little above the reſt of the body, and ſhould be treated in the manner which has been already directed. As ſoon as the wound is firmly cicatrized, a truſs ought to be properly fitted and uſed through the reſt of the perſon's life. Females are liable to this ſpecies of rupture as well as men; and as the opening in the external oblique muſcles is exceedingly ſimilar in both ſexes, the treatment of this ſpecies of hernia in females is very ſimilar to what is found to anſwer in men. When clyſters, blood-letting, and the other remedies formerly enumerated, fail, the ſame operation of enlarging the opening in the tendon of the oblique muſcle is here equally proper as in the other ſex.

Hernia Congenita

As modeſt women are apt to conceal diſorders of this kind, they may frequently happen when the ſurgeon receives no information about them. Whenever, therefore, ſuch ſymptoms of colic occur as give reaſon to ſuſpect the exiſtence of hernia, a particular examination ought always to be made, in order, if poſſible, to detect the cauſe of the miſchief, from the removal of which alone a cure can be expected.

Sect. III. *Of Hernia Congenita*

The teſtes in the fœtus are, till near the time of delivery, lodged in the cavity of the abdomen When they deſcend into the ſcrotum, they puſh before them a portion of the peritonæum, which afterwards forms the vaginal coat. The paſſages by which they deſcend are ſoon ſhut up; but ſometimes the contrary happens, and then a portion of ſome of the abdominal viſcera paſſing down, forms that ſpecies of hernia to which new-born infants are liable, termed by Haller the *hernia congenita*. The teſticle and protruded inteſtine being here in contact with one another, the tunica vaginalis teſtis forms the hernial ſac.

285 How hernia congenita is diſtinguiſhed from bubonocele.

It has been affirmed by ſome of the lateſt writers, that hernia congenita cannot be diſtinguiſhed from that contained in the common herniary ſac; and that though there was a diſtinction, it could be of no material uſe in practice. But Dr Monro obſerves, that a hernia congenita may be diſtinguiſhed in an adult by an evident external mark; which is, that the bowels puſh down between the ſac and the forepart and ſides of the teſticle, ſo as often in a great meaſure to conceal it; whereas, in the common hernia, every part of the teſticle can be felt diſtinctly: And that it is of material uſe to make the diſtinction; becauſe in whatever manner we operate in hernia congenita, unleſs we take the utmoſt care to exclude the air, there will be a more violent inflammation and greater diſtreſs than in common caſes, becauſe the teſticle will partake of the inflammation.

286 Treatment.

In the treatment of ruptures of the congenital kind, little difference occurs from the management of the common ſcrotal hernia; only a truſs ought never to be applied to infants, unleſs the teſticle can be felt in the ſcrotum, after the contents of the hernia have been reduced; as it would entirely prevent the deſcent of the teſticle, which yet remains in the abdomen. If any operation has been performed, the teſticle ſhould, immediately after the bowels are reduced, be covered with the vaginal coat, and at each dreſſing care ſhould be taken that the air be excluded. In every other reſpect the treatment of congenital hernia is the ſame with that of hernia in general.

Sect. IV. *Of Femoral or Crural Hernia.*

287 Situation of the protruded bowels in femoral hernia.

The ſeat of this ſpecies of hernia is upon the upper and fore part of the thigh; the protruded bowels paſſing out at the ſame opening through which the large blood-veſſels of the thigh are tranſmitted from the abdomen, and of conſequence under that part of the tendon at the under end of the abdomen known by the name of *Poupart's* or *Fallopius's ligament*. Sometimes the bowels which protrude are ſituated

imme-

Femoral or Crural Hernia.

immediately over the femoral veſſels, ſometimes on the outſide of theſe, but more frequently they lie upon their inner ſide. The diſeaſe is more frequent in women than in men, on account of the width of the female pelvis, and of conſequence the length and laxity of the ligament. The femoral hernia is more in danger of being confounded with inguinal hernia than with any other; the tumor, however, is deeper, and the ring of the abdominal muſcles, which lies entirely above the tumor in femoral hernia, completely ſurrounds the parts in that of the inguinal kind.

288 Treatment.

In the treatment of femoral hernia, when ſymptoms of ſtrangulation occur, we muſt uſe all the remedies commonly practiſed for hernia in general; only that here, in attempting to reduce the parts by the hand, the preſſure ſhould be made directly upwards. An inciſion of ſufficient length is to be made through the integuments, ſo as to allow that part of the tendon which forms the ſtricture to be laid fairly in view; and after dividing the integuments, we are cautiouſly to cut the faſcia lata of the thigh, and ſeparate any glands which may come in the way till the ſtricture and part of the ſac diſtinctly appear. The ſtricture is then to be divided, by cutting fibre after fibre ſucceſſively. The ſpermatic veſſels in the male, or round ligament in the uterus in the female, may be avoided by cutting in a direction towards the umbilicus, carefully dividing the tendon tranſverſely. Some authors, from a ſenſe of the danger attending this part of the operation, have recommended merely to dilate the paſſage, inſtead of dividing the tendon; but in ſuch a ſituation, to attempt a farther dilatation without the aſſiſtance of the knife, would probably be ſeldom attended with any advantage. After the parts are reduced, the wound is to be dreſſed as directed in the treatment of hernia in general: a piece of thin leather ſpread with ſome adheſive plaſter retains the dreſſings better, and with much more eaſe, than any other bandage.

Sect. V. *Of other Species of Hernia.*

289 Exomphalos, or umbilical hernia.

In umbilical hernia the parts protruded paſs out at the umbilicus, and are commonly the inteſtines, or omentum, or both; ſometimes part of the ſtomach, the liver, and even the ſpleen, have been found in the ſac. Here, as in other ruptures, the peritonæum forms the ſac, and in recent caſes it is generally very evident; but by the ſize of its contents, or a long continuance of the diſorder, it ſometimes becomes ſo connected with the ſurrounding parts, that by many its exiſtence has been doubted, and ſometimes the ſwelling has increaſed to ſuch a degree as to burſt even the ſkin itſelf. The diſeaſe occurs moſt frequently in infancy, ſoon after birth. In the adult ſtate corpulent people are more ſubject to it than thoſe of a contrary habit; and pregnant women are particularly ſubject to it, on account of the ſize of the uterus. The diagnoſis in this diſeaſe is readily made, as the diſorder can ſcarcely be confounded with any other. If the diſeaſe be attended to in due time, a bandage properly fitted will generally effect a cure; and in ſuch ſwellings as occur in pregnancy, delivery will commonly remove the diſorder; but even in caſes of pregnant women, a bandage early applied and properly uſed will give conſiderable relief, till a cure can be obtained by delivery. In this diſeaſe the omentum is more frequently puſhed out than any other viſcus; hence umbilical herniæ in general are not productive of ſuch bad ſymptoms as uſually occur in the other kinds of rupture. When, however, the inteſtines protrude, the uſual ſymptoms of a ſtrangulated hernia are apt to be induced; and when the means uſually employed for returning the gut into the abdomen do not ſucceed, a cure it is evident muſt depend entirely on a thorough removal of the ſtricture. In performing this operation, an inciſion through the integuments is the firſt ſtep to be taken, ſo as to expoſe the ſtricture of the tendon and the neck of the ſac. The ſtricture is to be removed in the manner already deſcribed; and as the tendon completely ſurrounds the neck of the ſac, the ſtricture may be cut wherever it can be moſt readily dilated. A radical cure ſimilar to that for the other ſpecies has been propoſed, but with as little probability of ſucceſs.

Other Species of Hernia.

290 Ventral hernia.

Ventral rupture is a protruſion of ſome of the bowels through the interſtices of the abdominal muſcles, and is moſt frequently obſerved in ſome of the parts moſt contiguous to the linea alba. The treatment of this ſpecies of diſeaſe is exactly the ſame with that of exomphalos.

291 Cyſtic hernia, or rupture of the urinary bladder.

Hernia of the bladder of urine, though leſs frequent than that of the omentum or inteſtines, is not very uncommon. The ſituation in which it occurs is in the groin, through the abdominal ring, in the fore part of the thigh, under Poupart's ligament, ſo as to form inguinal or crural hernia. Inſtances have likewiſe occurred of the bladder being puſhed into the perinæum. Sometimes it occurs by itſelf, without any complication; at other times it is accompanied with inteſtines and omentum, both in inguinal and femoral herniæ: when complicated with bubonocele, the protruded part of the bladder is ſituated between the inteſtine and ſpermatic cord.

292 Symptoms.

The uſual ſymptoms are a tumor, attended with fluctuation either in the groin, in the fore part of the thigh, or perinæum, which generally ſubſides when the patient voids urine. When the ſwelling is large, before water can be made with freedom, it is commonly neceſſary to have recourſe to preſſure, at the ſame time that the tumor, when in the groin or thigh, is as much elevated as poſſible; but when the ſwelling is ſmall, and eſpecially when no ſtricture is as yet produced, the patient generally makes water with great eaſe, and without any aſſiſtance from external preſſure. When the diſeaſe occurs without any complication, it is commonly owing to a ſuppreſſion of urine. In the diagnoſis care ought to be taken not to miſtake it for a hydrocele. In recent caſes, the part protruding may in general be eaſily reduced, eſpecially if we attend to the ſuppreſſion of urine, which probably gave riſe to the diſeaſe. A proper truſs ought afterwards to be worn for a conſiderable time. When the diſeaſe has been of long ſtanding, adheſion takes place between the bladder and cellular ſubſtance of the ſcrotum. In this caſe, therefore, as long as no ſymptoms occur to render the operation neceſſary, a ſuſpenſory bandage, ſo fitted as effectually to ſupport the prolapſed parts, is the only probable means of relief.

293 Hernia vaginalis.

Sometimes the bladder, owing to a ſuppreſſion of urine, at other times part of the inteſtines, have been found to protrude through the vagina. In the former caſe a fluctuation of water is perceptible to the touch.

The reduction is made by laying the patient on her back with her loins ſomewhat raiſed, and preſſing with the fore-finger from the vagina. Deſcents may in future be generally prevented, by evacuating the urine often, and by the uſe of a peſſary introduced into the vagina. Nearly the ſame means are employed in reducing the inteſtine when it is found to protrude.

Chap. XXIV. *Of Hydrocele.*

Every tumor formed by a collection of water might with propriety be named *hydrocele*, but the chirurgical acceptation of the term implies a watery ſwelling ſituated in the ſcrotum or ſpermatic cord. Hydrocele is either anaſarcous or encyſted. In the former, the ſerum is chiefly diffuſed in the cellular ſubſtance: In the latter, the water is collected in a diſtinct bag. The ſcrotum with its contents are liable

to both varieties of the diſeaſe; ſo is the ſpermatic cord with its coverings.

Anaſarcous Hydrocele of the Scrotum.

Sect. I. *Anaſarcous Hydrocele of the Scrotum.*

294 Symptoms of this diſeaſe.

As ſoon as water has collected in any conſiderable quantity in the ſcrotum, a ſoft, inelaſtic, colourleſs tumor is obſerved over the whole of it; impreſſions are eaſily received and retained for ſome time; the ſkin at firſt preſerves its natural appearance, and the rugæ of the ſcrotum are not much altered; but as the ſwelling advances, they gradually diſappear, and are at laſt totally obliterated. The ſwelling, from being at firſt ſoft, and of a conſiſtence ſimilar to dough, by degrees turns more firm, and the ſkin at laſt acquires an unnatural white ſhining appearance. The tumor at length becomes large; and though originally confined to the ſcrotum, it at laſt ſpreads up the groin. The penis likewiſe becomes affected, and often ſo ſwelled and diſtorted as to excite much inconvenience and diſtreſs; and although the ſcrotum is compoſed of parts which readily admit of dilatation, the tumor ſometimes becomes ſo enormous that it burſts from one end to the other.

295 Treatment.

In the ſurgical treatment of this diſeaſe, punctures made with the point of a lancet are moſt adviſeable, as large ſcarifications, in anaſarcous habits, are ſometimes apt to produce inflammation and mortification; while ſimple punctures readily heal, and can be renewed with very little pain as frequently as may be neceſſary: and beſides, punctures are equally uſeful with the inciſions; for as the cells of the ſcrotum communicate freely, if the punctures be made fairly through the ſkin, the water drains off very readily, though not ſo ſoon as by ſcarification. Previous to the operation, beſmearing the part with ſome tough ointment of an innocent nature, and afterwards keeping it as dry as poſſible by a frequent renewal of dry ſoft linen cloths, in order to imbibe the moiſture, is here a neceſſary piece of attention. The want of this ſeems to be the cauſe of much of the miſchief which frequently enſues from operations of this kind. When ſcarifications or punctures go wrong by beginning to inflame and turn painful, &c. a cold ſolution of ſaccharum ſaturni, applied upon ſoft linen, proves moſt effectual in putting a ſtop to the farther progreſs of the inflammation, and affords moſt immediate relief to the patient in the preſent diſtreſs. Lime water, employed in the ſame manner, proves alſo a very uſeful application. When, however, the diſorder proceeds to gain ground by a real mortification coming on, we ſhould immediately have recourſe to bark and other medicines uſually employed in ſuch affections.

296 Sometimes owing to a local cauſe.

Although the anaſarcous hydrocele, for the moſt part, depends upon a general dropſical tendency, ſome inſtances occur of a local cauſe producing a mere local dropſy of the ſcrotum. Thus, it has been known to happen from ſwellings in the groin and in the abdomen obſtructing the paſſage of the lymphatics. When this is the caſe, if tumors producing ſuch obſtructions can be extirpated, no other means will afford ſuch effectual relief; but when they are ſo deeply ſeated as to render any attempt for removing them improper, the practice we have already pointed out of making punctures in the moſt depending part of the tumor muſt be employed with a view to palliate ſuch ſymptoms as occur. It ſometimes happens in ſuppreſſion of urine, whether ariſing from ſtrictures in the urethra or from ſtones impacted in it, that the urethra burſts, and the urine in this manner getting acceſs to the cellular texture of the ſcrotum, an anaſarcous ſwelling riſes immediately over the whole of it; nor does it commonly diminiſh till the cauſe by which it is produced is removed.

In order to prevent the formation of ſinuſes, which in ſuch circumſtances will otherwiſe be apt to occur, an inciſion ſhould be made into the tumor, and carried to ſuch a depth as is ſufficient for reaching the wound in the urethra. In this manner a free vent will not only be given to the urine already diffuſed, but the farther collection of it may probably be prevented. If a ſtone impacted in the urethra be found to be the cauſe of effuſion, it ſhould be cut out; and if the obſtruction be produced by ſtrictures in the urethra, they muſt be removed by a proper uſe of bougies. The cauſe being thus removed, if the habit of body of the patient is good, and untainted with any venereal or other general affection, by dreſſing the ſore properly with ſoft eaſy applications, the opening into the urethra will probably heal, and a complete cure will in this manner be obtained. But when theſe ailments are complicated with any general affection, particularly with old venereal complaints, it frequently happens that neither mercury nor any other medicine has much influence in removing them.

Hydrocele of the Tunica Vaginalis Teſtis.

Sect. II. *Hydrocele of the Tunica Vaginalis Teſtis.*

In the healthy ſtate of the body, a ſmall quantity of aqueous fluid is exhaled for lubricating the ſurface of the teſticle, the ſuperfluous part of which is abſorbed by veſſels appointed for that purpoſe. When the ſecretion of this fluid is either morbidly increaſed, or its abſorption diminiſhed, a preternatural collection of water is formed in the cavity of the vaginal coat, and hydrocele of the vaginal coat produced.

297 Symptoms of this diſeaſe.

The ſymptoms are, a fulneſs at firſt obſerved about the inferior parts of the teſticle, and moſt remarkable when the patient is erect, becoming gradually more tenſe as the diſeaſe advances; the tumor by degrees changing from the globular to the pyramidical form; no degree of preſſure making the ſwelling diſappear at any period of the diſeaſe. In the early part of the diſeaſe therefore, if it be not combined with hernia, or with a hydrocele of the cord, the ſpermatic proceſs may be diſtinctly felt, becauſe the ſwelling does not extend beyond the ſcrotum. In its more advanced ſtate, it cannot be diſtinguiſhed: the weight of the tumor now drags the ſkin of the neighbouring parts ſo much as to cauſe the penis almoſt to diſappear; and in this ſtate of the diſeaſe the teſticle cannot be felt without much difficulty. On a minute examination, a hardneſs is always to be felt along that part of the ſcrotum where the teſticle is ſituated; and at this point preſſure excites ſome uneaſineſs. Fluctuation of a fluid may in general be diſtinguiſhed through the whole courſe of the diſeaſe. In late ſtages, however, the appearance of a fluid is not very evident.

The tranſparency of the tumor has been generally ſuppoſed to be the principal criterion of this ſpecies of the diſorder; but this muſt depend upon the nature of the contents, or thickneſs of the ſac; ſo that, though the tranſparency of the tumor is a certain ſign of the exiſtence of water, its opacity cannot upon any account be conſidered as an indication of its abſence. Through the whole courſe of the diſeaſe the tumor is not attended with pain, but ſome uneaſineſs is commonly felt in the back by the weight of the ſwelling of the ſpermatic cord. This is more particularly the caſe when a ſuſpenſory bandage is not uſed.

298 Cure.

In the radical cure of hydrocele, in whatever way it is attempted, ſome degree of fever and inflammation will take place. Under the circumſtances mentioned in the prognoſis, the operation, if properly performed, is generally attended with the moſt complete ſucceſs. But if the patient be very old, infirm, and diſeaſed, an operation may be attended with ſuch a degree of inflammation, and conſequent ſuppuration,

Hydrocele of the Tunica Vaginalis Teſtis.

puration, as to be in danger of deſtroying a conſtitution already greatly impaired, and therefore ought not to be performed.

Various methods have been propoſed for the cure of hydrocele, all of which may be reduced to two general heads: Such as have in view only a temporary relief, and which is therefore termed the palliative cure; and ſuch as are meant to effect a radical cure. When the tumor has become ſo large as to be inconvenient from its ſize, an evacuation of the water by ſurgical means becomes neceſſary. In this caſe, if the patient either refuſes to ſubmit to the operation for a radical cure, or if his ſtate of health render that operation improper, the palliative treatment, or a mere evacuation of the water by puncture, is the only means which can be employed.

299 Method of operating for the palliative cure.

A lancet-pointed trocar was many years ago recommended for drawing off the water in this manner by the preſent Dr Monro; and ſince that time it has in an improved ſtate (fig. 77.), been recommended by Mr Andree; another (fig. 78.) has been propoſed by Mr Bell. With any of theſe an opening may be made into the tunica vaginalis with ſafety.

The operator with one hand ſhould graſp the tumor behind, to preſs the contained fluid to the anterior and under part of it. If a round trocar is to be uſed, a puncture with a lancet ſhould be made where the trocar is to enter; but where a flat trocar is to be employed, the aſſiſtance of the lancet is unneceſſary.

As ſoon as the inſtrument has pierced the vaginal coat, the ſtilette ſhould be withdrawn, and the canula left in the ciſt. The water will now run off; and if the tumor be not uncommonly large, it may be all drawn off at once; but as the ſudden diſcharge of it, by taking off the ſupport, might be in danger of rupturing ſome of the veſſels, it ſhould be diſcharged by ſlow degrees. When the whole is evacuated, a piece of adheſive plaſter ſhould be immediately applied to the orifice; and a compreſs of ſoft linen being laid over the ſcrotum, the whole ſhould be firmly ſupported with a ſuſpenſory bag (fig. 79.) or a T bandage. The patient in this ſtate being laid in bed, all kind of uneaſineſs is in a few minutes commonly gone, and he is able to follow his ordinary buſineſs without interruption.

300 For the radical cure.

The intention of every means now in uſe for the radical cure of this ſpecies of the diſeaſe, is to induce ſuch a degree of inflammation on the parts in which it is ſeated as may obliterate entirely the cavity of the tunica vaginalis, by making it adhere to the ſurface of the teſticle. The means at preſent generally employed for effecting a cure are, exciſion of the tunica vaginalis; the application of cauſtic; the uſe of a ſeton; a ſimple inciſion of the ſac; and the injecting of acrid liquors into the tunica vaginalis, after drawing off the fluid which it contained. The method of cure, by the removal of the vaginal coat, is, firſt to lay open the vaginal coat, and then to cut it away by different ſnips of a pair of ſciſſars. The ſac being removed, the parts are to be dreſſed and treated in the ſame manner as in the operation where ſimple inciſion is uſed.

301 By exciſion of the tunica vaginalis.

302 By cauſtic.

The cure by cauſtic is attempted in the following manner: The ſcrotum being ſhaved, a piece of common paſte cauſtic, properly ſecured with adheſive plaſter, is applied, of about a finger's breadth, the whole length of the tumor; and if, on removing the cauſtic, it has not penetrated into the vaginal coat, an opening is made in it with a ſcalpel, ſo as to evacuate the contents, lay bare the teſticle, and admit of proper dreſſings. But Mr Elſe, one of the lateſt writers in favour of the method of cure by cauſtic, ſays, that there is no neceſſity for ſuch an extenſive application of cauſtic as many have recommended; that an eſchar of the ſize of a ſhilling is ſufficient; that this may be always fully obtained by the application of cauſtic paſte of the ſize of a ſixpence, which is to be laid on the anterior and under part of the ſcrotum, and to be properly ſecured by plaſter, in order to prevent it from ſpreading. The cauſtic commonly produces all its effects in five or ſix hours, and may then be removed. At this time digeſtives, or an emollient poultice, muſt be applied over the ſcrotum, and the whole ſuſpended with a bandage. Inflammation, Mr Elſe obſerves, is ſoon induced over the whole tunica vaginalis; and the febrile ſymptoms which ſucceed, he adviſes to be kept moderate by bloodletting, injections, emollient poultices, and a low regimen. In a few days the eſchar of the ſcrotum ſeparates, and comes away; and in a gradual manner, in the courſe of four, five, or ſix weeks, the whole tunica vaginalis comes off, when the wound for the moſt part ſoon heals, and a complete cure is obtained.

Hydrocele of the Tunica Vaginalis Teſtis.

303 By a ſeton.

Where it is intended to treat hydrocele by means of a ſeton, it may be done in the following manner: An opening is made with a ſcalpel, or the ſharp-pointed biſtoury, in the ſuperior part of the tumor, large enough to admit with eaſe a thick cord of common white ſewing ſilk. A director, with an eye at one end, in which the cord is inſerted, is introduced at this opening; and its farther extremity being carried down to the moſt depending part of the tumor, an opening is there made, of about half an inch in length, by cutting upon the director with the biſtoury; the director being now drawn till a ſufficient quantity of ſilk is left hanging out below, the operation is in this manner finiſhed.

Another very ſimple method of introducing a ſeton is by means of a ſilver canula and perforator.

304 By inciſion.

In the operation for a radical cure by inciſion, the patient being laid upon a table of convenient height, and properly ſecured by aſſiſtants, with the ſcrotum lying nearly on the edge of the table, the operator with one hand ſhould graſp the tumor behind, ſo as to keep it firm and make it ſomewhat tenſe anteriorly: With a common round edged ſcalpel in the other hand, he ſhould now divide the external integuments by one continued inciſion from the upper to the under end of the tumor. An opening is next to be made in the vaginal coat with a large lancet, or a ſharp pointed biſtoury (fig. 80.), at the upper end of the firſt inciſion. This opening ſhould be of ſuch a ſize as freely to receive the finger of the operator, which is to conduct a blunt pointed biſtoury, ſo as to divide the ſac down to its bottom, which is conſidered as being of advantage, by preventing partial adheſions and the riſk of a return of the diſeaſe.

The inciſion being completed, the teſticle is now brought fully into view; and if the tunica vaginalis be found, the dreſſing may be finiſhed immediately. But if the ſac be diſeaſed, it is to be removed, which may be readily accompliſhed by a ſcalpel or biſtoury.

When the hydrocele, as ſometimes happens, affects both ſides at the ſame time, if, when the operation is done on one ſide, an opening be made into the vaginal coat of the oppoſite ſide, at the upper part, through the ſeptum ſcroti, and the inciſion carried down to the bottom of the tumor, the ciſt can be equally well laid open, the water as completely evacuated, and a return of the diſeaſe as much prevented, as when the operation is done in the uſual manner, and at different times.

In whichever way the inciſion is made, if the teſticle be found, the wound ought to be quickly dreſſed; for it is found, that on this much of the ſucceſs of the operation depends. For if the vaginal coat be merely applied to the teſticle, or united by ſutures, as ſome have adviſed, partial adheſions are apt to take place, before a degree of inflammation is produced over the whole ſufficient for making a complete

Hydrocele of the Tunica Vaginalis Teſtis.

complete cure. In this manner cavities are left, which either fill with pus during the cure, and require to be laid open, or they afterwards give riſe to collections of water, and thereby occaſion a return of the diſeaſe. The practice of ſtuffing the cavity of the ſore with dreſſings is alſo a frequent cauſe of miſchief, by exciting too great a degree of inflammation in the part. But when the dreſſings are properly managed, ſymptoms of violence almoſt never occur. The lateſt authors adviſe, that in dreſſing the parts after the operation, two pieces of lint or ſoft old linen are to be dipped in oil, or in a liniment of wax and oil, and then, by the help of a probe, are to be inſerted into the bottom of the ſac on each ſide of the teſticle, leaving a ſufficient quantity of the pledgets hanging out of the wound, ſo as to admit of being eaſily withdrawn at the firſt or ſecond dreſſing. The edges of the wound are next to be dreſſed with pledgets of cerate, and the ends of the oiled pledgets turned over on each ſide. Several pieces of ſoft lint are then to be laid over the wound, and theſe ſhould be more of leſs numerous in proportion to the heat of the ſeaſon. A compreſs of linen is now to be laid over the whole, and the dreſſings ſupported by a T bandage or ſuſpenſory bag properly fitted. The patient is then to be carried to bed; an anodyne ſhould be given, eſpecially if there be much pain; and he ought to be adviſed to lie as much as poſſible upon his back for a few days after the operation.

In the third or fourth day after the operation, all the dreſſings, except thoſe between the teſticle and tunica vaginalis, are to be removed; and if this cannot be done readily, as the parts are otherwiſe apt to become uneaſy, a ſponge dipped in warm water ſhould be applied. On ſome occaſions, at the firſt dreſſing, and always at the ſecond or third, the pledgets inſerted between the tunica vaginalis come away; and whenever this happens, they ſhould be renewed. It is alſo proper to renew them daily for the firſt fourteen or fifteen days after the operation; not however of the ſame depth as the firſt, for during the latter part of the cure they need only to be inſerted as far as to prevent the divided edges of the tunica vaginalis from adhering to the teſticle, before the adheſive proceſs has taken place in the parts more deeply ſeated. Particular attention however is neceſſary to this part of the treatment; for when the diſeaſe returns, it has been found to be chiefly owing to the edges of the vaginal coat being allowed to adhere to the teſticle, before adheſion had taken place between the deeper parts.

A complete adheſion of the two coats of the teſticle, the tunica vaginalis, and tunica albuginea, takes place moſt frequently about the third week after the operation. Previous to this time, inflammation continuing gradually to increaſe, the tumor becomes larger till it acquire ſomewhat of the ſize of a ſwelled teſticle from gonorrhœa; but after this period it gradually ſubſides, and the ſore produced by the inciſion, and now reduced to a line, heals in ſome time between the fourth and eighth week, according to the habit of body, age of the patient, and other circumſtances.

305 Comparative advantages of each of theſe methods.

Having thus given an account of the methods uſually employed in the cure of hydrocele, we ſhall now make a few obſervations on the comparative advantages of the three laſt. From the teſtimony of many authors of credit, it is evident, that any of theſe methods, in moſt inſtances, prove effectual; but every practitioner being apt to be prejudiced in favour of a particular method, he generally continues to follow that mode and no other; and finding it commonly ſucceed, he by degrees perſuades himſelf, that other methods of cure with which he has not had ſuch opportunities of becoming acquainted, are liable to objections, which thoſe who have practiſed them do not find to be the caſe. The reſult of Mr B. Bell's obſervation upon this ſubject is, that although all the three modes of operating, by cauſtic, the ſeton, and ſimple inciſion, are perhaps equally capable of producing a radical cure; yet, that of the three, the latter, viz. the mode by the ſimple inciſion, is liable to feweſt objections, and effects a cure, both with leaſt trouble to the operator, and leaſt riſk to the patient: and of the other two, the treatment by cauſtic appears to be the beſt. He has ſeen all the three produce troubleſome ſymptoms, ſuch as, pain and tenſion of the abdomen, inflammation, and fever; but heſitates not to ſay, that the ſeton is more frequently productive of theſe effects than any of the other methods.

Hydrocele of the Tunica Vaginalis Teſtis.

306 Radical cure by injection.

Beſides the methods already mentioned, another has been lately revived, viz. the injecting of irritating liquors into the vaginal coat of the teſticle. This method is particularly deſcribed by a Monſieur Lambert of the laſt century, and may be of much older date for any thing which is known to the contrary. From ſome cauſe or other it ſeems to have been entirely laid aſide till about the middle of the preſent century, when it was practiſed by Mr Monro (afterwards a phyſician-general in the Weſt Indies), under the ſanction of the late Dr Monro, and favourably received and followed by ſome of the firſt ſurgeons of Edinburgh. But in general, though the cure appeared complete, the diſeaſe returned.

The perference is uſually given to wine, and commonly that is ſomewhat diluted; but where no pain is excited by the injection, the liquor ſhould be diſcharged, and a ſtronger one uſed. For where no pain takes place, a cure is not to be expected.

The following is the moſt approved method of performing the operation: The operator ſhould be provided with a flat trocar and canula, and with a bag of reſina elaſtica, fitted with a ſtop-cock and pipe, which ought exactly to ſuit the canula. See fig. 81.

The patient being laid in an horizontal poſture, either upon a bed or a table, the water ſhould be drawn entirely off from the tumor by a flat trocar paſſed into the under and fore part of it. The operator ſecuring the canula with the one hand, is with the other to paſs the tube of the injection-bag fairly through it, and with gentle preſſure to force in as much of the liquid as may reach the whole ſurface of the vaginal coat, as well as the whole ſurface of the teſticle. The bag ſhould now be removed, leaving the tube within the canula of the trocar, ſo that by turning the ſtop-cock the injection may be retained in the cavity of the tumor. The canula of the trocar ought ſtill to be kept fixed, otherwiſe it might recede, by which the liquid would inſinuate into the cellular ſubſtance of the ſcrotum. The liquor ſhould likewiſe be brought into contact with every part of the cavity; and after remaining about four, or at the moſt five, minutes in the ſac, it ſhould be entirely diſcharged through the canula of the trocar, after withdrawing the tube of the elaſtic bag.

Sometimes intenſe pain is felt immediately after the liquor is thrown in. When this is the caſe, it ſhould be diſcharged as ſoon as it has paſſed over the different parts of the tunica vaginalis. Some recommend a repetition of the ſame kind of injection immediately after the firſt has been diſcharged and to be retained for the ſame period, though this is not commonly practiſed.

The whole of the injection ſhould be completely diſcharged, after which the ſcrotum ſhould be covered with a pledget of cerate, a compreſs being applied over it, and retained with a ſuſpenſory bag. The patient ought to be in bed for ſeveral days, and ſupport the ſcrotum in the bandage by means of a ſmall pillow.

Though it is difficult to aſcertain the proportion of thoſe who

Hydrocele of the Spermatic Cord.

who are cured by the method of injections, and though it is to be regretted that hitherto the diſeaſe is found to return in a great proportion of thoſe upon whom this operation has been performed; yet, on account of the facility with which it can be done, the comparatively ſmall pain with which it is attended, the quickneſs of the cure, and chiefly becauſe it does not, in caſe of a return of the diſeaſe, preclude the future operation of inciſion, it appears a method which, in all probability, will be more and more adopted into practice.

Sect. III. *Of Hydrocele of the Spermatic Cord.*

307 Anaſarcous hydrocele of the ſpermatic cord.

Anasarcous hydrocele of the ſpermatic cord ſometimes accompanies aſcites, and at other times it is found to be confined to the cellular ſubſtance in or about the ſpermatic cord. The cauſes of this diſeaſe may be, obſtructions in the lymphatics leading from the part in conſequence of ſchirhous affections of the abdominal viſcera, or the preſſure of a truſs applied for the cure of hernia.

308 Symptoms.

When the affection is connected with anaſarca in other parts, it is then ſo evident as to require no deſcription. When it is local, it is attended with a colourleſs tumour in the courſe of the ſpermatic cord, ſoft and inelaſtic to the touch, and unaccompanied with fluctuation. In an erect poſition of the body it is of an oblong figure; but when the body is recumbent, it is flatter and ſomewhat round. Generally it is no longer than that part of the cord which lies in the groin, though ſometimes it extends as far as the teſticle, and even ſtretches the ſcrotum to an uncommon ſize; an inſtance of which is related by Mr Pott, who from a ſwelling of this kind diſcharged 11 Engliſh pints at once. By preſſure a great part of the ſwelling can always be made to recede into the abdomen. It inſtantly, however, returns to its former ſituation on the preſſure being withdrawn.

When the tumor is connected with general anaſarca of the ſyſtem, it can only be cured along with the reſt of the diſeaſe; but when the ſwelling is local, the remedy is alſo to be locally applied. An inciſion is to be made of ſuch a ſize it may be ſufficient for diſcharging the whole of the water; in the performance of which, attention is neceſſary to guard againſt hurting the ſpermatic veſſels. The contents of the tumour being diſcharged, the ſore is to be treated like any other ſimple wound.

309 Of encyſted hydrocele of the ſpermatic cord.

Encyſted hydrocele of the ſpermatic cord ſometimes begins in the upper, but generally at the lower part of the ſpermatic cord. On its firſt appearance it is ſo ſmall as to give little or no trouble; hence it is ſeldom particularly attended to till it has acquired a conſiderable ſize. By degrees it extends as far as the abdominal muſcles, and ſometimes reaches to the bottom of the ſcrotum; and to a perſon unacquainted with the appearance of the diſorder may be miſtaken for a hydrocele of the tunica vaginalis. But here the tumor is always above the teſticle, which is diſtinctly felt below; and even in the advanced ſtate of the diſeaſe the teſticle is found in the back part of it perfectly unconnected with the ſwelling; whereas, in the advanced ſtages of hydrocele in the vaginal coat, although ſome hardneſs is diſcovered where the tunica vaginalis adheres to the teſticle, yet when the ſwelling is great the teſticle cannot be diſtinctly felt. In the encyſted hydrocele of the cord, the figure and ſize of the penis is little altered; whereas, in caſes of common hydrocele, the penis frequently diſappears almoſt entirely. In other reſpects the two diſeaſes are nearly ſimilar. It ſometimes happens that the water is contained in two diſtinct cells. In that caſe the tumour is ſomewhat puckered up, or diminiſhed in its diameter. A ſimilar appearance alſo occurs, when this variety of the diſeaſe is connected with hydrocele of the tunica vaginalis, which ſometimes takes place.

310 Symptoms.

Hæmatocele Scroti.

The only other tumors with which this one may be confounded are, the anaſarcous hydrocele of the ſpermatic cord, and a real hernia. But in neither of theſe is the fluctuation of a fluid perceptible, and to the touch they are both ſoft and inelaſtic; whereas, in this variety of hydrocele, the tumor has a ſpringy feel, and a fluctuation is ſenſible to the touch; and in both the one and the other the ſwelling recedes ſomewhat upon preſſure, which it never does here.

From hernia it is chiefly diſtinguiſhed by the tumor beginning ſome way down the cord. In hernia the tumor turns leſs when the patient is in an horizontal poſture, and is conſiderably affected by coughing and ſneezing; but this kind of hydrocele is not altered in ſize by any ſuch circumſtances, nor has it the common ſymptoms which attend a hernia.

Infants are frequently ſubject to this diſeaſe, as well as to an anaſarcous ſwelling of the cord, and an œdematous tumor of the ſcrotum. But here the complaint is ſeldom permanent; for in moſt inſtances it readily yields to gentle friction, with any ſtimulating or aſtringent application, as a ſtrong ſolution of ſal ammoniac in vinegar, &c. But in adults, the ciſt, in every variety of encyſted hydrocele, becomes ſo firm as not to be affected by external applications; ſo that when the tumor becomes large, it is neceſſary to uſe means for producing either a palliative or radical cure, in the ſame manner as is done for a hydrocele in the vaginal coat.

Sect. IV. *Of Hæmatocele Scroti.*

We ſhall mention in this place the diſeaſe called *hæmatocele ſcroti*, which is occaſioned by blood extravaſated in the inner ſubſtance of the ſcrotum, in the tunica vaginalis, or in the ſpermatic cord; but the uſual ſituation is in the tunica vaginalis teſtis.

Tumours of this kind may be produced by any thing which ruptures the blood-veſſels of the part, but they are commonly the conſequence of external violence. In the tunica vaginalis this diſorder may be produced by the point of a trocar or of a lancet in tapping for hydrocele. In ſuch a caſe, we are commonly informed of the accident by blood being diſcharged along with the water; though ſometimes it does not appear till the whole of the water is evacuated, and then a tumor of a conſiderable ſize ſuddenly takes place. Sometimes it happens where the quantity of water has been ſo uncommonly great that the ſudden diſcharge of it, by taking away the ſupport which the veſſels have been accuſtomed to receive, has been the cauſe of their rupture; and it ſeems certain, that whenever a tumor is produced either in the ſcrotum or cord ſuddenly after the water of a hydrocele has been evacuated by tapping, that it is entirely owing to an extravaſation of blood.

In the ſpermatic cord injuries of the ſame kind will be attended with a ſimilar effect upon the veſſels of the ſac containing the water. The diſtinction between blood and water in the ſubſtance of the ſcrotum is readily made by the colour; for where the diſeaſe is produced by blood, it forms a real eſchymoſis. The tumor feels heavier in the tunica vaginalis when filled with blood than where it is filled merely with water; the treatment is nearly the ſame with that in hydrocele. In the commencement of the anaſarcous or diffuſed hæmatocele, when produced from ſlight external violence, the application of ſtimulating or aſtringent fluids will ſometimes diſcuſs it; but if this prove ineffectual, the tumor is to be laid open, and treated exactly as was directed for hydrocele; only if a ruptured veſſel be diſcovered, it muſt be ſecured by ligature. In like manner, all collections

&c

Varicocele, Circocele, Spermatocele, and Pneumatocele.

of blood either in the vaginal coat or ſpermatic cord are to be laid open, and treated as in hydrocele. If bleeding veſſels appear, they are to be ſecured. Sometimes however theſe cannot be detected; an oozing takes place which it is difficult to reſtrain, even by the uſe of bark, vitriolic acid, and other means generally employed in ſuch caſes. It has been uniformly found, that local remedies prove chiefly uſeful here, particularly the application of ardent ſpirits, æther, or tincture of myrrh, to the ſurface of the ſore. Pledgets of ſoft lint, ſoaked in one or other of theſe, not only ſerve to check the diſcharge of blood, but in general tend to promote the formation of good matter.

Chap. XXV. *Of Varicocele, Circocele, Spermatocele, and Pneumatocele.*

311 Varicocele.

Varicocele is a preternatural diſtenſion of the veins of the ſcrotum, which in this ſtate form a tumor of hard, knotty inequalities, ſeldom painful, and generally attended with no inconvenience excepting what ariſes from its bulk.

312 Circocele.

Circocele is ſimilar in its nature to the former, but ſituated in the ſpermatic cord, extending from the abdominal ring to the ſuperior part of the ſcrotum, and produced by a varicoſe ſtate of the ſpermatic vein. Both of theſe diſorders are occaſionally produced by obſtruction in the veins; but are moſt frequently owing to a relaxed ſtate of theſe veſſels; to which we may add, that on account of the ſmallneſs of the correſponding artery, they are not ſufficiently affected by its influence. The tumor produced by theſe diſorders is ſometimes ſo large as to appear like a hernia or hydrocele; but we diſtinguiſh it from theſe by the touch, for varicoſe veins are like worms filled with elaſtic matter. We have another mark upon which we can ſtill more depend: The tumor in the erect poſture of the body is much increaſed, while in the horizontal ſituation it almoſt entirely diſappears.

313 Of collections of blood within the tunica albuginea.

Another diſorder is obſerved by late authors, where a collection of blood is ſometimes found within the tunica albuginea teſtis, and is ſuppoſed to be a kind of hæmatocele, or more probably varicocele. Sometimes the collection is ſo conſiderable, that a fluctuation reſembling that of an hydrocele of the vaginal coat of the teſticle is obſervable. When this is miſtaken for hydrocele, and an opening is made into it with a trocar, a diſcharge is produced of a duſky-coloured blood, ſomewhat reſembling thin chocolate: But though the tumor may be diminiſhed by the evacuation thus obtained, yet the alteration is inconſiderable; nor is the patient ever relieved, but on the contrary made worſe by ſuch an operation. Caſtration, after this, becomes neceſſary; but even this has been found ineffectual: ſo that the patient had better be adviſed to truſt to nature, aſſiſted by a proper ſuſpenſory bandage, than to ſuffer the attempt of a radical cure; for it has been obſerved, that in ſome inſtances they have remained ſtationary for many years, whereas they never fail to become much worſe by any attempt to evacuate the fluid.

When tumors, or the preſſure of a truſs, has been the cauſe of ſuch complaints, a proper attention to theſe ought to be the firſt attempt towards a cure. But when a relaxed ſtate of the veins is ſuſpected, we ought to recommend a ſuſpenſory bandage, an horizontal poſture, the cold bath, and the application of a ſolution of alum and other aſtringents. By a proper exhibition of theſe, the diſeaſe may at leaſt be prevented from increaſing, ſo as to render any operation unneceſſary.

314 Spermatocele.

By ſpermatocele is underſtood a morbid diſtenſion of the vas deferens and epidydimis. The diſeaſe may ariſe from tumors, ſtricture, or inflammation about the vas deferens, or its termination in the penis; but more probably from inflammation there. When an inflammatory diſpoſition is diſcovered, general and topical blood-letting, gentle laxatives, a low cooling diet, and reſt of body, will commonly be found the beſt remedies. When tumors are found to preſs upon the vas deferens, they ought either to be brought to a ſtate of ſuppuration, or entirely extirpated, if that can be properly effected. If the diſeaſe proceed from a venereal cauſe, nothing can be ſo uſeful as a courſe of mercury properly directed.

Sarcocele, or Scirrhous Teſticle.

315 Pneumatocele.

By pneumatocele is underſtood a diſtenſion of the ſcrotum from a collection of air.

The principal cauſe of this diſeaſe, which rarely happens, is wounds in the lungs, by which air paſſes through the common cellular ſubſtance into the ſcrotum; but from whatever cauſe the tumor is produced, the diſeaſe is to be treated by making ſmall punctures with the point of a lancet, as in the caſe of anaſarcous ſwellings formed by water.

Chap. XXVI. *Of Sarcocele, or Scirrhous Teſticle.*

Sarcocele implies a fleſhy, enlarged ſtate of the teſticle, much firmer and harder to the touch than is obſerved in hernia humeralis or inflamed teſticle.

The ſymptoms vary exceedingly in different patients; but the following are the moſt general: The firſt ſymptom is commonly a ſmall enlargement, without much pain, and no diſcolouration of the part. The tumor becomes gradually larger, and the hardneſs increaſes; but for a conſiderable time the ſurface remains ſmooth; and when the conſtitution is otherwiſe good, the diſorder will ſometimes remain in this ſituation for a conſiderable number of years; and in a few rare inſtances, by a moderate diet, keeping the belly open, ſuſpending the tumor properly, and avoiding violent exerciſe, or any thing which may conſiderably increaſe the impetus of the blood, the diſorder has not only been prevented from increaſing, but has in a gradual manner diſappeared entirely. More commonly, however, the tumor increaſes in ſize, and becomes ragged and unequal on its ſurface. Smart and ſevere ſhooting pains are frequently felt through its ſubſtance. Sometimes ſerum is extravaſated in the vaginal coat, or matter is collected in different parts of the tumor. The ſcrotum, now much diſtended burſts, and thin, fetid, bloody matter diſcharging, the diſeaſe terminates in an ulcerated cancer of the worſt kind.

The ſpermatic cord is commonly unaffected till the tumor has acquired a conſiderable ſize, and generally not till collections of matter have been formed. After this, from being at firſt only ſlightly ſwelled, it gradually increaſes in hardneſs and bulk; after which it becomes very painful, knotty, or unequal through its whole extent. The diſcharge from the ſcrotum ſtill continues; but although the matter increaſes in quantity, the ſize of the tumor is not thereby diminiſhed, but, on the contrary, continually increaſes; the edges of the ſore become hard, livid, and retorted, and fungous excreſcences puſh out from every part of it; the health of the patient becomes entirely deſtroyed, and he is at laſt carried off in great miſery.

Hernia humeralis produced by venereal infection has been conſidered, by ſome authors, as a frequent cauſe of the worſt kind of ſcirrhous teſticle; but the fact is very much otherwiſe; and ſuch an idea has this bad tendency, that it prevents the perſeverance in the uſe of ſuch remedies as might have removed the diſeaſe without the neceſſity of extirpation.

Another cauſe mentioned by authors as producing

Sarcocele, or Scirrhous Teſticle.

ſcirrhus of the teſticle, is the hydrocele of the vaginal coat; but though ſarcocele is frequently combined with this diſeaſe, there is every reaſon to think that the primary diſorder was in the teſticle itſelf, and that the water is only a conſequence of the other complaint. When the hydrocele happens to be the original diſeaſe, the teſticle is alſo found frequently altered in its appearance. It is here paler than in its natural ſtate. It is ſometimes diminiſhed, but more frequently enlarged. The enlargement however is ſoft, harmleſs, and free from pain; and in ſuch a ſituation ſhould never be extirpated. To this point particular attention ought to be paid, otherwiſe we run the riſk of committing a miſtake, into which practitioners have been too frequently led—the extirpation of a teſticle which ought to have been ſaved. To keep free of this error, we ought to attend to the following circumſtances.

316 In what caſes the teſticle may be extirpated.

When the diſeaſe begins in the teſticle itſelf, eſpecially in the body or glandular part, or when it becomes hard and enlarged previous to any collection of water in the vaginal coat, it is to be conſidered as of a different nature from that in which an enlargement of the part ſucceeds to a collection of water; or if, upon evacuating the water, the teſticle be found hardened, enlarged, and attended with pain and other marks of ſcirrhus, eſpecially if the ſurface be unequal or ulcerated, extirpation ought certainly to be performed. The ſymptoms abovementioned ſometimes, though rarely, begin in the epidydimis. In ſuch caſes, however, extirpation will ſeldom be adviſable, as there is here always a ſuſpicion of a venereal affection; and then we ought by all means to try the remedies commonly uſed in ſuch diſeaſes. In the prognoſis, we attend to the age and habit of the body, as well as to the ſtate of the diſeaſe and length of time it has continued.

When the patient is young and the conſtitution unbroken, we may always hope for a cure, although the ſymptoms ſhould be very conſiderable; whereas, in old infirm people, and in habits attended with an emaciated look, with indigeſtion, and other ſymptoms of obſtructed viſcera, whatever ſtate the diſeaſe may be in, there will be but a ſmall chance of ſucceſs.

If the diſeaſe has ſubſiſted for a long time without conſiderably increaſing in ſize, we may reaſonably think it is of a milder nature than where it has made a rapid progreſs. As long as the teſticle is only hard and free from the formation of matter, we may expect a favourable event; but where collections of matter have already formed, either in the ſubſtance or upon the ſurface of the teſticle, there is no other chance of ſaving the patient than by means of extirpation. Previous to this, however, we are to attend to the ſtate of the ſpermatic cord; for were any of it left in a diſeaſed ſtate, little advantage could be derived from extirpation; nor ought the operation ever to be performed but where we can reach the whole of the diſeaſed parts. We are not to be prevented from performing it though the cord ſhould be conſiderably enlarged, providing it do not evidently partake of the diſeaſe of the teſticle; for the cord is generally ſomewhat enlarged in the diſeaſed ſtate of the teſticle; but this enlargement is for the moſt part merely either a varicoſe ſtate of the veins, or a watery diſpoſition of the cellular ſubſtance.

317 Method of performing the operation.

But ſuppoſing no obſtacle to the operation, the method of doing it may be this. The parts being previouſly ſhaved, the patient is to be laid upon a ſquare table of about three feet four inches high, letting his legs hang down; which, as well as the reſt of his body, muſt be held firm by aſſiſtants; or, he may be laid acroſs a bed in the ſame manner. Then with a knife the inciſion is to be begun above the rings of the abdominal muſcles, that there may be room afterwards to ſecure the veſſels; then carrying it through the membrana adipoſa, it muſt be continued downward to the bottom of the ſcrotum. A firm, waxed, flat ligature, compoſed of ſmall threads, is next, by means of a curved needle, to be paſſed round the ſpermatic cord, at leaſt an inch above the diſeaſed part, or as near the abdominal ring as poſſible; after which the veſſels are to be ſecured by a running knot, and divided about a quarter or half an inch below the ligature. The cord and teſticle are then to be removed from the ſurrounding parts by diſſecting from above downwards, and no inſtrument is better for this purpoſe than the common ſcalpel. After the diſeaſed parts are removed, the knot upon the cord muſt be ſlackened to diſcover the ſpermatic arteries and veins; both of which, by means of the tenaculum or a common forceps, are to be taken up. The ligature upon the ſpermatic cord is now to be left looſe, ſo as to act as a tourniquet if a hemorrhagy ſhould enſue; nor is there more occaſion for leaving the ligature tied than for leaving a tourniquet firmly applied to one of the extremities after amputation; beſides, where patients have ſuffered ſuch pain as is ſometimes mentioned by authors, it has been found to be owing to the tightneſs of the ligature rather than to any other cauſe. In dividing the ligatures of the blood-veſſels at the extremities of the cord, they muſt be left of ſuch a length without the wound as to be readily removed, however much the cord may retract in the time of the cure.

In ſeparating the teſticle, a conſiderable hemorrhagy ſometimes enſues from the diviſion of the ſcrotal arteries. In ſuch a caſe, they ought always to be fixed with ligatures before proceeding in the operation. The parts being removed, and the blood-veſſels ſecured, the wound is to be cured, if poſſible, by the firſt intention; and for this purpoſe the ſides of the ſcrotum are to be brought together in the moſt accurate manner, beginning at the under end, and ſecuring the parts by adheſive plaſter as we proceed upwards, and in ſuch a way that the ſides of the ſore may be kept properly together. About two inches of the ligatures of the cord are to be left out, and this part of the wound treated in the ſame manner as the reſt; the whole to be ſecured by a compreſs of linen and a T bandage.

318 Treatment after the operation.

The patient ſhould now be laid to reſt, and an opiate adminiſtered; and if, upon the ſecond or third day, any inflammatory ſymptoms enſue, they are to be removed by methods commonly employed upon theſe occaſions; as topical blood-letting, gentle laxatives, and keeping the part conſtantly moiſt with a ſolution of ſugar of lead. The dreſſings ought not to be allowed to ſhift, elſe the cure will be greatly retarded. They are to be examined about four or five days after the operation; and if nothing material has happened, they may be allowed to remain two or three days longer, by which time generally the ligature can be readily removed; and the wound will be healed by the firſt intention, excepting ſome ſmall opening in the ſkin, more eſpecially where the ligatures were placed. Theſe are to be drawn together by adheſive ſtraps, and dreſſed in the ſame manner as formerly. In this way, if the patient be otherwiſe healthy, a cure may be expected in little more than a fortnight.

The method of dreſſing moſt frequently practiſed is to apply a quantity of ſoft lint to the ſore, and then a compreſs of linen over it, and to ſecure the whole with a T bandage or a ſuſpenſory bag. The patient is then laid to reſt, and an opiate given. The ſore is not to be touched till a free ſuppuration takes place, which will commonly be

Stone in the Bladder.

about the fifth or ſixth day, and then the dreſſings are to be removed, and renewed from time to time; once every two days, or oftener, as the quantity of matter may render it neceſſary. Sometimes after the operation the patient complains of pain in the ſore, and of tenſion and uneaſineſs in the belly. In ſuch a caſe, warm fomentations ſhould be applied to the abdomen, and the ſore covered with an emollient poultice, and this repeated as often as may be neceſſary.

Chap. XXVII. *Of the Stone.*

Sect. I. *Of Stone in the Bladder.*

319 Cauſes of the formation of calculi.

A variety of cauſes have been aſſigned as tending to the formation of calculi in the bladder of urine; as, a decompoſition of a ſuperabundant quantity of earthy matter from the blood, on account of a ſedentary life; certain articles of diet or drink, containing a greater quantity of earthy matter than others; a continued uſe of ſolid food without a ſufficient quantity of drink; the peculiar action of abſorbent veſſels; the particular ſtructure of the kidney; the nature of the different excretory veſſels; the time the urine may remain in the kidney; the habit of retaining the water in the bladder; particles of blood getting into the kidney or bladder, and attracting the ſtony matter ſo as to form a nucleus. A certain change of the veſſels of the kidney forming the urine has by ſome been conſidered as a more probable cauſe than any of the former. The formation of calculus ſometimes begins in the kidneys, at other times in the bladder.

After a calculus has begun to be formed, it ſometimes acquires a great ſize in a few months from the firſt obvious ſymptoms; but ſometimes it remains in the bladder for many years without arriving at any conſiderable ſize.

320 Symptoms of calculus.

The ſymptoms commonly come on gradually, and bear ſome kind of proportion to the ſize and inequalities of the ſtone. One of the firſt commonly taken notice of is an uneaſy ſenſation at the point of the urethra, which for ſome time is perceptible only upon making water, or upon uſing violent or jolting exerciſe. This ſenſation gradually increaſes; and there is along with it a frequent deſire to make water, which is commonly voided in ſmall quantities, and ſometimes only in drops. When running in a full ſtream, it often ſuddenly ſtops, though the patient is conſcious that a conſiderable quantity ſtill remains, and feels a ſtrong inclination to void it. If the ſtone be large the patient has a conſtant dull pain about the neck of the bladder, and frequent deſire of going to ſtool. The urine is generally of a limpid colour; but it is frequently thick, depoſiting a mucous ſediment, and when the diſeaſe is violent it is often tinged with blood. All theſe complaints are greatly increaſed by exerciſe, eſpecially by riding on horſeback; and from a long continuance of pain, the patient's health by degrees becomes much impaired, and unleſs effectual means are employed for removing the cauſe of the diſorder, death alone puts an end to his miſery.

We are rendered certain of the exiſtence of calculus when ſmall pieces of ſtone are frequently paſſed along with the urine. When this does not occur, we cannot be certain that the ſymptoms do not ariſe from an ulcer or tumor in the body or neck of the bladder, or from the preſſure of tumors in the neighbouring parts. In doubtful caſes, however, we have one mark by which we can judge with certainty, and that is by means of ſounding.

321 Method of ſounding.

This is performed by introducing an inſtrument called a *ſound* (fig. 82.), formed of ſteel finely poliſhed, and having the natural curvature of the urethra. The patient is to be laid upon a table or acroſs a bed, with his ſhoulders raiſed upon a pillow, to bring the ſtone to the neck of the bladder, and his thighs a little elevated and ſeparated from each other. A ſound adapted to the ſize of the urethra is to be choſen; and previous to the introduction it is to be laid in warm water till it be of the heat of the body, and then wiped and rubbed over with bland oil, butter, or axunge. The ſurgeon lays hold of the penis with his left hand, while with his right he introduces the ſound with its concave ſide towards the abdomen. He is now with his left hand to draw the penis gently forward upon the inſtrument, which is to be gradually puſhed into the bladder. If any difficulty occur about the neck of the bladder, this may be obviated by introducing the finger into the anus, and raiſing the point of the inſtrument; or the ſame purpoſe is more readily anſwered by depreſſing the handle of the ſound. If ſtill it does not paſs with eaſe, much force ought by no means to be uſed, leſt the inſtrument perforate the membranous part of the urethra.

Stone in the Bladder.

As ſoon as the inſtrument enters the bladder, if it happen at once to touch the ſtone, a tremulous motion will be communicated to the fingers of the operator, and the buſineſs of ſounding is then accompliſhed, the nature of the diſeaſe being now aſcertained. Great care, however, is here always neceſſary, as a few particles of ſand, or a hardened ſtate of the bladder, have ſometimes communicated the ſame ſenſation. If the ſtone be not ſoon diſcovered, the inſtrument is to be moved in all directions; and ſhould the operator be ſtill unſucceſsful, one of the fingers of the left hand is to be introduced into the rectum, ſo as to raiſe that part of the bladder in which a ſtone may probably be concealed. If even this attempt prove ineffectual, the body of the patient is to be put into different poſitions, and perhaps one of the beſt is depreſſing the ſhoulders and raiſing the pelvis. By this mean a ſtone may generally be felt, providing it is not contained in a cyſt, which very rarely happens. If after all theſe different attempts the ſurgeon ſhould fail in diſcovering the ſtone, the inſtrument is to be withdrawn; and if ſymptoms of ſtone be ſtrongly marked, and it appear that neither ſcirrhus nor inflammation, which might give riſe to theſe ſymptoms, do exiſt, a ſecond or even a third trial is to be made on the following days.

322 Of lithontriptics.

Various lithontriptics have been recommended for diſſolving the ſtone in the bladder; ſuch as lime-water, cauſtic alkali, ſoap, &c. but none of them can be conveyed in ſuch a ſtate into the bladder as to be much depended upon, as they undergo the greateſt change in the courſe of the circulation. To obviate theſe changes, it has been recommended to inject certain fluids of this claſs through the urethra into the bladder; but this has not been attended with any material advantages, and has generally been found to do injury to the bladder. The only effectual method of removing ſtones from the bladder is by means of a chirurgical operation; the ſucceſs of which depends much upon the dexterity of the ſurgeon, as well as on the conſtitution of the patient.

323 Symptoms forbidding lithotomy.

When the conſtitution has been ſo much impaired that the patient complains greatly of ſickneſs and oppreſſion at ſtomach, with nauſea and an inclination to vomit, eſpecially upon taking food; when he has likewiſe a conſtant thirſt, and the pulſe is as high as a hundred ſtrokes in the minute—an operation is improper till theſe ſymptoms are removed. The operation is improper alſo when the patient labours under a ſevere fit of the ſtone; for then inflammation of the bladder is apt to enſue to ſuch a degree as to produce ſuppuration. By frequent attacks and continuance of theſe fits, the coats of the bladder are apt to be thickened and greatly contracted. This laſt circumſtance may be known by the introduction of the ſound; for then it will ſtop after

Stone in the Bladder.

ter getting paſt the ſphincter of the bladder, and cannot be puſhed farther without conſiderable force, and at the ſame time giving the patient the moſt exquiſite pain. Nor ought the operation to be performed when the bladder is ulcerated, eſpecially where the patient is old and much debilitated, and where the diſcharge of matter is great.

Children more readily recover from the operation of lithotomy than adults; and old people from the age of 55 to that of 70, whoſe conſtitutions have not been broken, are in leſs danger than thoſe in the full vigour of life, probably owing to inflammatory ſymptoms being more apt to proceed to a dangerous length in the extremes of ages than at the middle period of life. When the conſtitution, however, is not much impaired by the continuance of the diſeaſe, the operation may be undertaken with a probable degree of ſucceſs almoſt at any period of the patient's life.

Several methods have been recommended for performing this operation; but there are only two which can be practiſed with any propriety. One is, where the operation is to be performed immediately above the pubes, in that part of the bladder which is not covered with peritonæum: the other, where it is done in the perinæum, by laying open the neck and lateral part of the bladder, ſo as to allow of the extraction of the ſtone.

324 High operation.

Franco, a French ſurgeon, finding a ſtone in a child of two years of age too large to be extracted through an opening in perinæo (the place where the operation was then performed), was induced to make an inciſion into the bladder above the pubes; but though the ſtone was extracted and the child recovered, Franco, who publiſhed the caſe in 1561, never attempted the operation again, and even diſſuades others from doing it. It does not appear indeed to have been much practiſed anywhere till ſome time after the commencement of the preſent century, about the year 1720, when it was adopted and frequently performed in Britain and other parts of Europe for the ſpace of about 12 or 15 years. The lateral operation came then to be more generally known, and ſince this period the high operation has been ſeldom practiſed.

325 Method of performing it.

In performing the high operation, the bladder muſt be in a diſtended ſtate, ſo as to make it riſe above the oſſa pubis, to allow an inciſion to be made into that part of it which is uncovered by the peritonæum, and thereby to prevent the abdomen from being opened or its contents expoſed. Some days, or even weeks, previous to the operation, the patient ought to be deſired to retain his urine as long as he can, ſo as to diſtend the bladder till it can hold at leaſt a pound and a half, when the perſon is an adult and of an ordinary ſize; or the penis may be tied up to allow the urine to collect. As theſe methods may be attended with great diſtreſs, ſome prefer diſtending the bladder by injecting warm water by ſlow degrees till the bladder is ſufficiently full, which may be eaſily known by relaxing the abdominal muſcles and feeling above the pubes.

When the operation is to be performed, the patient is to be laid upon a table of convenient height, with the pelvis higher than the ſhoulders, that the parts may be fully on the ſtretch, and to prevent the bowels from preſſing upon the bladder. The legs and arms are to be properly held by aſſiſtants. An incition is to be made through the ſkin, in the very middle of the under and fore part of the abdomen, from ſome way under the umbilicus to the ſymphyſis pubes. The cellular ſubſtance, the tendon of the oblique muſcles, the muſculi recti and pyramidales, are now to be ſeparated; and it is better to make this ſeparation from the pubes upwards, ſo as to be in no danger of cutting into the abdomen. The ſurface of the bladder will now appear uncovered by the peritonæum. Then the operator, with a common ſcalpel, or an abſceſs lancet, or, what is better, with a concave ſharp pointed knife, makes a perforation into the moſt prominent part of the bladder, till the fore-finger of the left hand can be introduced. The ligature is now to be removed from the penis; then with a probe-pointed biſtoury, making the finger ſerve as a conductor, the wound is to be made ſufficiently large for the extraction of the calculus, taking particular care, however, not to carry the inciſion ſo high as to cut the peritonæum. This part of the operation being finiſhed, the ſtone is to be extracted with the finger; or if that be impracticable, the forceps are to be employed. Should it unfortunately happen that the ſtone is broken in the extraction, the pieces are to be removed entirely by the fingers rather than by ſcoops, which were ſometimes uſed. The edges of the wound in the integuments are now to be drawn together by means of the twiſted ſuture, leaving about an inch and a half immediately above the pubes for the diſcharge of any urine which may be there evacuated. The patient is to be laid in bed, with the pelvis ſtill kept higher than the ſhoulders. Gentle laxatives are to be occaſionally given, and the antiphlogiſtic plan ſtrictly adhered to.

Stone in the Bladder.

326 Advantages and diſadvantages of this operation.

The advantages of this method are, that larger ſtones can be extracted by this than by the lateral operation, and that fiſtulous ſores are leſs apt to enſue. The diſadvantages are, the danger of opening or wounding the peritonæum, and thereby expoſing the abdominal bowels; the frequent occurrence of inflammation about the beginning of the urethra, ſo as to occaſion the urine to be diffuſed in the cellular ſubſtance on the outſide of the bladder, and thereby producing ſinuſes difficult to cure; the extreme difficulty of healing the wound, eſpecially in bad conſtitutions; and, laſtly, the ſmall number of patients, after the age of thirty, who have been found to recover from this operation.

327 Lateral operation.

Frere Jacques, a French prieſt, was the inventor of the lateral operation. He firſt appeared at Paris in 1697, and afterwards operated in a great number of caſes.

328 Frere Jacques's method of performing lithotomy.

He introduced a ſound through the urethra into the bladder with a ſtraight biſtoury, cut upon the ſtaff, and carried his inciſion along the ſtaff into the bladder. He then introduced the fore-finger of the left hand into the bladder, ſearched for the ſtone, which, having withdrawn the ſound, he extracted by means of forceps. The patient was now carried to bed, and the after treatment left to the attendants.

329 Improved by Profeſſor Rau.

Profeſſor Rau of Holland improved upon this method, by making a groove in the ſtaff, which enabled him, with greater certainty, to continue his inciſion into the bladder: but inſtead of dividing the urethra and proſtate gland, the latter of which he was afraid of wounding, he diſſected by the ſide of the gland, till the convex part of the ſtaff was felt in the bladder, where he made his inciſion, and extracted the ſtone; but this method was too difficult to perform, and attended with too many inconveniencies and dangers ever to be generally received. It ſuggeſted, however, to the celebrated Cheſelden the lateral method of cutting, as it is now with a few alterations very generally practiſed. We ſhall attempt to deſcribe the different ſteps of this operation in its preſent improved ſtate.

330 Suggeſted the lateral operation.

331 Manner of preparing the patient.

The manner of preparing the patient depends upon a variety of circumſtances. If he be plethoric, a few ounces of blood ſhould be taken away, and at proper intervals the bowels ought to be emptied by any gentle laxative which will not gripe. The diet ſhould conſiſt of light food for ſome time previous to the operation. If the pain be violent, opium is neceſſary. Sometimes it is relieved by keeping the patient in bed with the pelvis raiſed, ſo as to remove the ſtone from the neck of the bladder. He ought not to

Stone in the Bladder.

fit up, or take any exercise, in the time of preparation. The warm bath ought to be used two or three times, and the patient should remain in it half an hour at each time. A laxative ought to be given on the day preceding the operation, and an injection a few hours before it is performed. The patient ought to drink plentifully of some diluent liquor, and to retain the urine several hours previous to the operation. If this cannot be readily effected, a slight compression, by means of a ligature, may be made upon the penis, so as to have the bladder sufficiently distended, that there may be no danger of the posterior surface being hurt by the end of the gorget. The perinæum and parts about the anus should be well shaved.

332 Manner of performing the operation.

A table somewhat more than three feet in height, and of sufficient strength, is now to be firmly placed, and properly covered with blankets, pillows, &c. Upon this the patient is to be laid and properly secured; and for this purpose there ought to be two pieces of broad firm tape, each about five feet in length, which are to be doubled, and a noose formed upon them. A noose is then to be put upon each wrist, and the patient desired to lay hold of the middle of his foot upon the outside. One end of the ligature is to go round the hand and foot, and the other round the ankle and hand, and cross again, so as to repeat the turns in the reverse way. A running knot is then to be tied, by which the hand and foot will be properly secured. The buttocks are then to be made to project an inch or two over the table, and to be raised considerably higher than the shoulders by a couple or more pillows, and one ought to be put under his head.

The operator is now to introduce a grooved staff (fig. 83.) of proportionable size, and open to the very end, through the urethra into the bladder; and having again fully satisfied himself of the existence of a stone, he inclines the staff, if the surgeon be right-handed, obliquely over the right groin, so that the convex part of the staff may be felt in the perinæum on the left side of the raphe. He then fixes it, and delivers it to his assistant, who is to hold it with his right hand, desiring him to press it gently, in order to make the sulcus of the staff project in the direction in which he received it. With his left hand the same assistant is to raise and support the scrotum.

The thighs of the patient being sufficiently separated by the assistants, and the surgeon being seated upon a chair of a proper height, and in a convenient light, he makes an incision with a common convex edged scalpel through the skin and cellular substance, immediately below the symphysis of the ossa pubis, which is a little below the scrotum, and where the crus penis and bulb of the urethra meet, and on the left side of the raphe, and continues it in a slanting direction downwards and outwards to the space between the anus and tuberosity of the ischium, ending somewhat lower than the basis of that process, by which a cut will be made of three or four inches in length. This incision ought not to be shorter than is here directed, otherwise there will not be room for the rest of the operation. As soon as the integuments are thus divided, he ought to introduce two of the fingers of the left hand. With one he keeps back the lip of the wound next the raphe, and with the other he presses down the rectum. He ought likewise particularly to guard against cutting the crures of the penis, which he can readily feel, and separate at their under part with one of the fingers. He next makes a second incision almost in the same direction with the first, but rather nearer to the raphe and anus, by which he preserves the trunk of the arteria pudica. By this incision he divides the transversalis penis, and as much of the levator ani and cellular substance within these as will make the prostate gland perceptible to the finger. If any considerable vessel be cut, it is immediately to be secured, though this is seldom necessary. After this he will have a view of the membranous part of the urethra, which is distinguished from that covered by the bulb by being very thin. He is now to search for the groove of the staff with the fore finger of his left hand, the point of which he presses along from the bulb of the urethra to the prostate gland, which surrounds the neck of the bladder. He keeps it there; and turning the edge of the knife upwards, he cuts upon the groove of the staff, and freely divides the membranous part of the urethra, from the prostate gland to the bulb of the urethra, till the staff can be felt perfectly bare, and that there is room to admit the point of the finger; and as the finger assists in keeping the parts stretched, and effectually prevents the rectum from being hurt, the incision into the urethra may be made with perfect ease and safety.

Stone in the Bladder.

The next part of the operation, viz. dividing the prostate gland and neck of the bladder, might, by a dexterous operator, be safely performed with a common scalpel, with the edge turned the opposite way. But to guard against accidents, a more convenient instrument, called the *cutting gorget* (fig. 84.), is now in general use. It was originally invented by Mr Hawkins of London, and since his time has undergone various alterations. Fig. 85. is a double gorget invented by Dr Monro. The inner plate, which is blunt, is made to slip forwards to protect the back part of the bladder. The membranous part of the urethra being now divided, and the fore-finger still retained in its place, the point of the gorget, previously fitted to the groove, is to be directed along the nail of the finger, which will serve to conduct it into the groove of the staff; and as this is one of the nicest parts of the operation, the most particular attention is here required that the point of the gorget be distinctly heard to rub in the bare groove, and that nothing is interposed.

In the introduction of the gorget into the bladder, if the assistant could be depended upon, the staff might be allowed to remain in his hand: the operator, however, generally chooses to manage it himself. He now rises from his seat, takes the staff from the assistant, raises it to near a right angle, and presses the concave part against the symphysis of the ossa pubes; satisfies himself again that the point or beak is in the groove, and then pushes on the gorget, following the direction of the groove till the beak slip from the point of the staff into the bladder. The gorget is not to be pushed farther than this, otherwise it may wound the opposite side of the bladder, &c.

The gorget having now entered the bladder, which is readily known by the discharge of urine from the wound, the staff is to be withdrawn, and the finger introduced along the gorget to search for the stone, which, when felt, will point out the direction to be given to the forceps; at any rate, the introduction of the finger serves to dilate the wound in the bladder; and this being done, a pair of forceps (fig. 86.) of a proper size, and with their blades as nearly together as their form will allow, are to be introduced, and the gorget withdrawn slowly, and in the same direction in which it entered, so as to prevent it from injuring the parts in its return. After the forceps are introduced, and passed till they meet with a gentle resistance, but no farther, the handles ought to be depressed till they are somewhat in an horizontal direction, as this will most correspond with the fundus of the bladder. One blade of the forceps is to be turned towards the symphysis of the pubes to defend the soft parts there, the other of consequence will guard the return. After they have distinctly touched the stone, by moving them a little in various directions, they are then to be opened, and the stone laid hold of, which may generally

Stone in the Bladder.

rally be done with conſiderable eaſe. It frequently happens, however, that when the ſtone is ſmall, it is not readily felt with the forceps; and inſtances may happen where the under and back part of the bladder may be ſo depreſſed as to conceal the ſtone. In ſuch a ſituation, nothing will more readily bring it in the way of the forceps than to introduce the finger into the rectum, and elevate this part of the bladder. Straight forceps are generally uſed; crooked ones, in ſome very rare caſes, however, may be neceſſary, and therefore the ſurgeon ought to be provided with them.

After the forceps has laid hold of the ſtone, if it be ſmall and properly placed, it may readily be extracted; but if, on the contrary, the handles of the forceps are now obſerved to be greatly expanded, it is certain the ſtone is improperly fixed, or that it is remarkably large: in either caſe it ſhould not be held faſt, but allowed to move into the moſt favourable ſituation; or the finger is then to be introduced ſo as to place it properly for extraction. If this cannot be done with the finger, it ought to be allowed to ſlip out of the forceps, in order to get it more properly fixed; and as the moſt common form of the ſtone is flat and oval, or ſomewhat like a flattened egg, the forceps ſhould have hold of the ſmalleſt diameter, while an end preſents to the neck of the inſtrument. The ſtone ſhould be graſped with no greater firmneſs than is merely ſufficient to bring it fairly out. It ſhould be extracted in a ſlow and gradual manner.

When a ſtone is broken in the bladder, all the larger pieces are to be extracted by the forceps, which are to be introduced by means of the finger ſerving as a director. The ſmaller parts are to be removed by means of a ſcoop (fig. 87.), or probably the finger may be more convenient; and as the leaſt particle allowed to remain, or which is not waſhed off by the urine, may ſerve as the nucleus of another ſtone, a large quantity of water, properly warmed, is to be injected by a bag and pipe, or by a ſyringe; and for this purpoſe the body of the patient ſhould approach at leaſt to an upright poſture; and to give the particles of ſtone an opportunity of collecting near the inciſion of the bladder, the wound may be ſtopped for a little after the injection is thrown in.

When a ſtone is extracted of a regular, firm, and rough ſurface, it ſeldom happens that any others remain in the bladder. On the contrary, when it is of an irregular ſhape, and ſmooth and poliſhed, particularly in certain places, with impreſſions formed upon it, there is the greateſt probability of others remaining. There are exceptions, however, to theſe rules; and therefore the operator, inſtead of truſting to them, ſhould introduce his finger, which will anſwer the purpoſe without any other ſearcher.

333 Treatment after the operation.

If, after the operation, any conſiderable artery bleeds much, it is to be taken up with a ligature; but if this be impracticable, the hemorrhagy ought to be ſtopped by means of preſſure, and for this purpoſe a firm roller introduced at the wound anſwers ſufficiently: and to prevent any ſtoppage to the diſcharge of urine, a ſilver canula, covered with caddis, and duſted over with ſtyptic powder, may be introduced into the wound with advantage.

Sometimes it happens that a conſiderable quantity of blood, inſtead of paſſing off by the wound, is collected in the cavity of the bladder, and may produce very dangerous ſymptoms. To prevent this as much as poſſible, immediately upon the operation being finiſhed, the patient's pelvis ſhould be made conſiderably lower than the reſt of his body; by which means the wound will be kept in a depending poſture, and the blood will eſcape more readily by the wound. But if it be found that blood is ſtill lodged in the cavity of the bladder, it muſt be immediately extracted.

As ſoon as the blooding is ſtopped, the patient is to be untied, a piece of dry ſoft charpee put between the lips of the wound, and often renewed, and the thighs brought together. He is then to be laid in a bed, in ſuch a way that the pelvis may be conſiderably lower than the reſt of the body, to give a favourable direction to any blood which may afterwards flow from the wound. A conſiderable doſe of laudanum is now to be given. From 30 to 50 drops for an adult will commonly be neceſſary. From this period, unleſs the ſtone has been large and difficult to extract, the patient commonly falls aſleep, or at leaſt lies quiet for a few hours; but afterwards generally begins to complain of pain in the under part of the abdomen. Anodynes are now to be given both by the mouth and anus, and warm fomentations, by means of flannels or bladders filled with warm water, are to be applied to the region of the bladder, as the affection ſeems to be of the ſpaſmodic kind.

If by a continuance of theſe remedies the pain abates, no anxiety needs be entertained concerning it; but if it increaſe, and eſpecially if the abdomen become hard and ſwelled, and the pulſe full and quick, and theſe ſymptoms become gradually worſe, great danger is to be apprehended, as they moſt commonly take place in conſequence of inflammation. In this ſituation, as much blood ought to be taken as the patient can bear. A large injection of warm water and oil, or linſeed tea, ſhould be given every ſix or ſeven hours, and the fomentations continued at the abdomen. If the ſymptoms continue to grow worſe, the patient ſhould be immediately put into the ſemicupium or half bath.

By a proper continuance of theſe means, with a low diet and plenty of diluent drink, the above ſymptoms may frequently be removed. The reverſe, however, is ſometimes the caſe. The wound becomes ſloughy and ill-conditioned; all the ſymptoms, in ſpite of every effort continued to increaſe, and ſoon terminate in death.

But where matters end favourably, the wound by degrees puts on a better appearance; the urine paſſes almoſt from the beginning by the urethra (moſt frequently, however, it is diſcharged by the wound for the firſt two or three weeks); the pain in the abdomen gradually abates, the feveriſh ſymptoms are ſoon removed, a complete cicatrix is formed, and the wound is ſometimes cured in a month; though upon other occaſions three will be neceſſary. But it muſt depend greatly on the nature of the conſtitution.

Excoriation of the buttocks may be prevented by placing a ſheet under them ſeveral times doubled, the breadth to be 18 or 20 inches, and to be all rolled up, except the part which is to be laid under the patient, the reſt of the roll to be by his ſide, which is to be unrolled as the nurſe draws the wet part from under him. If, after the uſe of this, excoriations ſhould ſtill happen, the part may be waſhed with cold water; or the parts round the wound, after being well dried, may be rubbed with any tough ſimple ointment.

In patients of a debilitated conſtitution incontinence of urine frequently occurs after this operation. In general, this is removed as the patient acquires ſtrength. Nouriſhing diet, cold bath, the bark, and other tonics, are of much ſervice here; but where theſe are afterwards found ineffectual, inſtruments for compreſſing the penis, or others for receiving the urine, have been found uſeful, and are now made in ſuch a convenient way as to allow them to be conſtantly uſed ſo long as they may be found neceſſary.

334 Lithotomy in females.

An operation for ſtone in the bladder is much ſeldomer required in women than in men, on account of the ſhortneſs of the urethra in the former allowing a readier paſſage for the ſmall calculi which get into, or are formed in, the bladder. It is likewiſe in women more ſimple, and of courſe more readily performed. It might be done in the ſame manner

Stones in the Kidneys.

manner as in the male, but there would be the greateſt probability of wounding the vagina. In a few caſes the operation has been performed from the vagina itſelf; but it is by no means adviſable, as ſtones would not only be extracted with greater difficulty, but, on account of the thinneſs of the parts, the urine would moſt probably form a fiſtulous opening, and a communication be maintained between the bladder and vagina; or cicatrices here might be attended with great inconvenience in child-labour.

In the method commonly practiſed, the patient being placed and ſecured in the ſame manner as in the operation upon the male, the operator introduces a ſhort grooved ſtaff, ſlightly curved (fig. 88.), into the bladder; then by means of the common gorget already mentioned, with its point paſſed along the groove of the ſtaff, he lays open the whole of the urethra and the neck of the bladder. The ſtaff is now to be removed, the finger introduced upon the gorget, and to feel for the ſtone, which is to be removed as already directed for the operation on the male ſubject. Where incontinence of urine occurs after the wound is healed, a peſſary is to be uſed within the vagina, or a ſponge applied, or a tin machine to receive the urine.

Sect. II. *Of Stones in the Kidneys.*

The ſymptoms of ſtone in the kidneys are, pain in the region of the kidneys, ſickneſs, and vomiting, the urine ſometimes mixed with blood, at other times with mucus or even purulent matter; but the ſame ſymptoms are often induced by other cauſes, eſpecially from inflammation and ſuppuration of the kidney. Nephritic complaints have frequently ſubſiſted for a long time, where ſtones have been blamed as being the cauſe of them; and yet upon diſſection purulent matter alone has been detected. From this circumſtance, as well as from the great depth of the parts and the large ſize of the blood-veſſels of the kidney, the operation of nephrotomy could not be performed, but with the greateſt uncertainty and moſt imminent danger, and is therefore never attempted. A few caſes indeed have appeared where inflammation induced by a ſtone in the kidney terminated in abſceſs, and the ſtones were taken out; but it was not till they had worked their way out of the kidneys into the cellular ſubſtance, ſo that it only remained to open the abſceſs and extract them; but otherwiſe the operation is never to be thought of.

Sect. III. *Of Stones in the Urethra.*

Those who are troubled with calculous complaints frequently paſs ſmall ſtones along with their urine; and when theſe are angular or of conſiderable ſize, they ſometimes

335 Symptoms of ſtones in the urethra.

ſtick, and give much uneaſineſs. The ſymptoms are at firſt pain, then inflammation and ſwelling, attended with a partial, or total ſuppreſſion of urine, which, if long neglected, is apt to terminate in a rupture of the urethra, when the urine will be diſcharged into the neighbouring parts. The greateſt attention is therefore neceſſary to get the ſtone extracted as ſoon as poſſible.

336 Method of extracting them.

When a ſtone is in the urethra, unleſs it be of a large ſize, or has been long impacted, and the inflammation great, attempts ought to be made with the fingers to puſh it out; but previous to this, the penis ſhould be relaxed as much as poſſible, ſo as to remove a certain degree of ſpaſm which the preſence of ſtone here probably creates. Blood ought to be drawn by general or local means, according as the patient may be of a plethoric or emaciated habit. He ſhould be immerſed in a warm bath, and get a full doſe of laudanum, and warm oil ought alſo to be thrown into the urethra. After theſe remedies have relaxed the parts as much as may be, the extraction is to be attempted.

Stones in the Urethra.

For this purpoſe certain inſtruments have been contrived, particularly a tube containing a pair of elaſtic forceps (fig. 89.), to be introduced into the urethra ſo as to lay hold of the ſtone. In ſome caſes they certainly might anſwer the purpoſe, but they have not been found very uſeful; and as they may increaſe the irritation already preſent in the urethra, they are ſeldom, if ever, employed. Inſtead of them, the ſurgeon uſes gentle preſſure on the penis to puſh the ſtone outwards; and as calculi larger than a field bean have ſometimes been paſſed by the urethra, an operation ought not to be performed till gentler means have been perſiſted in for ſome time. When theſe means have failed, an inciſion ought to be made immediately upon the ſtone, which is then to be removed by a probe, or with a pair of ſmall forceps. When a ſtone is lodged near the neck of the bladder, after the patient has been placed and ſecured in the ſame manner as for the lateral operation, while an aſſiſtant ſupports the ſcrotum and penis, the operator introduces a finger oiled into the anus, to ſupport the ſtone in its place, and prevent it from ſlipping into the bladder. An inciſion is then to be made, and the ſtone turned out. The after treatment will be nearly the ſame as that after the operation of lithotomy.

When, again, a ſtone has advanced further in the urethra, the beſt method is to draw the ſkin ſtrongly forwards or backwards, and then to cut upon it and turn it out, when the ſkin will ſlide back ſo as to cover the wound, and prevent the urine from paſſing through it; and by this means it will generally heal by the firſt intention. If part of the urine paſs through the wound, and inſinuate into the cellular ſubſtance, an attempt is to be made with the hand to preſs it back. If that prove inſufficient, a cut is to be made through the ſkin oppoſite to the inciſion of the urethra; but this will ſeldom be found neceſſary. If a ſtone is fixed near the point of the urethra, it may be removed with a pair of forceps; or, if this fail, the urethra is to be dilated with a ſcalpel; and if this alſo be inſufficient, an inciſion is to be made as above directed. When the cure is nearly completed, a tube formed of ſilver or elaſtic gum, or a hollow bougie, may be uſed to keep the urethra of a proper ſize.

The worſt part of the urethra for a ſtone to ſtick in is that immediately behind the ſcrotum; for then the urine is apt to paſs by the inciſion into the cellular ſubſtances of the ſcrotum, ſo as to occaſion large ſwellings there. To prevent this, a ſtone ſo ſituated ought, if poſſible, to be puſhed forwards with the fingers; or if this be impracticable, it ſhould be puſhed back into the perinæum by means of a ſtaff. If both methods fail, a cut is to be made at the under part of the ſcrotum, which is to be well ſupported, and at one ſide of the ſeptum, and continued upwards till the ſtone is felt, when an inciſion is to be made into the urethra, and the ſtone extracted as before directed.

Chap. XXVIII. *Of Incontinence and Suppreſſion of Urine.*

Incontinence of urine may ariſe from various cauſes,

337 Cauſes of incontinence of urine.

as, from a loſs of power in the ſphincter of the bladder, while the natural tone of that organ remains unimpaired; or from irritation about the neck of the bladder, produced by the friction of ſtones contained in it; or from a laceration of parts by the operation of lithotomy; or from the preſſure of the uterus in a ſtate of pregnancy.

338 Treatment.

When the diſeaſe is owing to a want of tone in the ſphincter, the cure is very difficult, becauſe the conſtitution in general is frequently affected. The moſt uſeful remedies are tonics, eſpecially Peruvian bark, chalybeate waters, and the

Incontinence and Suppreſſion of Urine.

the cold bath, both generally and locally applied. Cold ſubſtances applied to the perinæum are perhaps of greater ſervice than any thing elſe, as cloths wet with vinegar and cold water, or with a ſtrong ſolution of ſaccharum ſaturni in vinegar; but the beſt method of applying cold is to daſh water immediately from the fountain upon the anus and perinæum. When it ariſes from the irritation of ſtones in the bladder, opiates and mucilaginous liquors plentifully uſed frequently give great relief. When incontinence of urine is owing to a laceration of parts in performing the operation of lithotomy, the diſeaſe is nearly of the ſame nature as that from the cauſe firſt mentioned, and therefore the ſame remedies are of ſervice. When theſe remedies fail in either of the caſes, compreſſion of the urethra prevents any inconvenience ariſing from the conſtant dripping of the urine; and for this purpoſe an inſtrument termed *jugum penis* (fig. 90.) is applied to the penis; or, to preſs againſt the urethra of the female, peſſaries (fig. 91. *a* and *b*) are contrived, which are made in ſuch a way as to be introduced into the vagina, and there to preſs upon the urethra. They are ſometimes made of ſponge, but thoſe of ivory or wood well poliſhed are more generally preferred. A ſmall bottle made of elaſtic gum, and open at both ends for the paſſage of the menſtrual diſcharge, anſwers the purpoſe equally well. Certain caſes however occur where preſſure upon the urethra is improper, eſpecially where there is a conſtant deſire to paſs water; and here much relief is obtained from the uſe of receivers, which are now ſuited to both ſexes. Fig. 92. repreſents one for the male, and fig. 93. one for the female.

Plate ccccxci.

339 Of ſuppreſſion of urine.

We ſhall here treat only of that ſpecies of ſuppreſſion of urine where the urine is collected in the bladder, but from ſome obſtructing cauſe is prevented from being diſcharged. It ariſes from a variety of cauſes.

340 Treatment when it ariſes from want of tone in the body of the bladder.

When it ariſes from a want of tone in the body of the bladder, it is often connected with palſy of the lower extremities; it is frequently owing alſo to retaining urine too long. The catheter, in this caſe, is commonly an effectual remedy, and ought to be employed as ſoon as the ſuppreſſion is evidently formed, and repeated from time to time, till the tone of the ſyſtem is recovered by the uſe of proper remedies. The method of introducing the catheter is the ſame with that already directed for ſounding for the ſtone. Fig. 94. a catheter for the male, fig. 95. one for the female.

When the affection ariſes from ſpaſm about the neck of the bladder, opiates, warm water thrown into the rectum, and afterwards the warm bath, are the beſt means of producing relief. When it proceeds from ſcirrhus of the proſtate gland, or from other tumors, or from obſtructions of the urethra in conſequence of gonorrhœa, the treatment to be afterwards deſcribed will be found beſt ſuited for ſuch complaints. When the ſuppreſſion ariſes from the preſſure of the uterus in the latter months of pregnancy, change of poſture is ſometimes found to have ſome effect; but if this fail, immediate relief can commonly be given by the introduction of the catheter, which in women is for the moſt part readily done.

341 From inflammation of the neck of the bladder.

Suppreſſion of urine from inflammation affecting the neck of the bladder is one of the moſt alarming varieties of the diſeaſe, as it produces pain, and ſuch a degree of ſwelling in the parts as to render the introduction of the catheter inadmiſſible. It may ariſe from the matter in gonorrhœa paſſing backwards along the courſe of the urethra. An improper uſe of injections has likewiſe frequently produced this ſpecies of the diſeaſe. The treatment is nearly the ſame as for inflammatory complaints in other parts of the body. Blood-letting ſhould be employed, and particularly leeches ſhould be applied to the perinæum. Opiates ought to be given in large doſes. Injections of warm water ſhould be frequently thrown up the rectum, and the whole body ſhould be immerſed in the warm bath. If theſe means be properly uſed, they will very ſeldom fail of ſucceſs; but when they do not prove effectual, when the bladder becomes painfully diſtended, and when every attempt to introduce the catheter has failed, nothing is to be depended upon but a puncture made into the body of the bladder, in order to diſcharge the water contained in it.

Incontinence and Suppreſſion of Urine.

342 Method of puncturing the bladder above the pubes.

Various methods have been propoſed for effecting this operation. Puncturing the bladder above the pubes has been recommended by many reſpectable authors. The following is the method of doing it: A lancet-pointed trocar, about two inches long, is to be at once introduced through the integuments, about an inch and half above the pubes, into the body of the bladder. The ſtilette is to be removed as ſoon as the water begins to flow through a groove formed in it, and the urine allowed to flow through the canula, which is ſecured to the body by means of a bandage. A cork is to be fitted to the canula, that the urine may paſs off at intervals only. The canula is to be retained till the cauſe which produced the obſtruction is ſo far removed that the patient can diſcharge the urine in the natural way. It ought to be removed every three or four days, and cleared from the ſordes which adheres to it, otherwiſe it ſoon becomes covered with a calculous cruſt, which renders the extraction exceedingly difficult. On theſe occaſions a firm probe, of ſufficient length, ought to be paſſed through it into the bladder, upon which it may again be eaſily returned as ſoon as it is properly cleaned.

This method of puncturing the bladder is not altogether free from objections; the bladder being ſuſpended for a long time on the canula, its tone is ſometimes deſtroyed; and if it happen to ſlip off the canula, the operation muſt be repeated; beſides, the urine may be diffuſed in the ſurrounding cellular ſubſtance.

343 Method of puncturing from the perinæum.

When the bladder is to be punctured from the perinæum, the trocar, which ought to be longer than the one for puncturing above the pubes, is to be introduced at a little diſtance from the rapha perinæi, and then paſſed into the body of the bladder, a little to the upper and outſide of the proſtate gland, carrying the point of the inſtrument a little upwards, to avoid wounding the ends of the ureter or ſeminal veſſels. Puncturing from the anus, or the vagina in females, is attended with ſo many inconveniences that it ought never to be attempted.

Chap. XXIX. *Diſeaſes of the Penis.*

Sect. I. *Of Obſtructions of the Urethra.*

344 Cauſes of obſtructions of the urethra.

Obstructions of the urethra frequently occur after repeated or ſevere attacks of the venereal diſeaſe. They may be owing to caruncles or fleſhy excreſcences in the urethra; to tumors in the lining membrane, or parts contiguous to the urethra, in conſequence of inflammation; to ſpaſmodic affections of the urethra; or to ſtrictures properly ſo called.

Till of late years almoſt every inſtance of obſtruction in the urethra has been attributed to caruncles, but their occurrence is much leſs frequent than was formerly imagined. They are rarely found except near the point of the urethra. They are conſidered to be nearly of the ſame nature with the warts which grow upon the prepuce or root of the glans in venereal caſes. Tumors obſtructing the paſſage in the urine may be occaſioned either immediately by inflammation, or in conſequence of old ſores within the ure-

thra.

Obſtructions of the Urethra.

thra; or tumors, from whatever cauſe, may be ſeated in the corpora cavernoſa contiguous to the urethra, and may preſs upon it in ſuch a manner as to cauſe an adheſion of its ſides, and thereby produce ſtoppage of the urine. Spaſmodic ſtrictures of the urethra ſometimes ariſe from ſtone in the bladder. Sometimes in gonorrhœa there is ſuch a degree of contraction that neither ſtaff nor bougie can enter. This variety of obſtruction is known by its coming on ſuddenly, and going off ſometimes almoſt completely in the ſpace of a few hours. Of the permanent ſtricture, or ſtricture properly ſo called, Mr Hunter obſerves, that in moſt of the caſes of this kind which he has ſeen, the diſeaſe extends no farther in breadth than if the part had been ſurrounded with a piece of packthread. He has however ſeen the urethra irregularly contracted for above an inch in length, owing to its coats or internal membrane being irregularly thickened and forming a winding canal. He farther obſerves, that a ſtricture does not ariſe, in all caſes, from an equal contraction of the urethra all round; but in ſome, from a contraction of one ſide, which throws the paſſage to the oppoſite ſide, and often makes it difficult to paſs the bougie. In ſome few caſes, he ſays, there are more ſtrictures than one; he has ſeen half a dozen in one urethra, and finds that the bulbous part is much more ſubject to ſtrictures than the whole of the urethra beſides; that they are ſometimes on this ſide of the bulb, but very ſeldom beyond it; and that they are often ſlow in forming, it being frequently years from the time they are perceived before they become very troubleſome. Contrary to the opinion of others, Mr Hunter doubts very much if the ſtricture commonly, or even ever, ariſes from the effects of the venereal diſeaſe, or the method of cure; for ſtrictures are common to other paſſages, and ſometimes happen in the urethra where no venereal complaint had ever been.

345 Methods of cure.

When obſtructions are occaſioned by caruncles in the urethra, bougies (fig. 96.) ſhould be introduced rubbed over with bland oil until a reſiſtance is met with. When a bougie cannot be introduced far enough, one with a ſmaller point is to be uſed, but not till the day following, leſt the part be too much irritated. They ought not to be allowed to remain long at firſt, particularly when they occaſion a conſiderable degree of pain.

When ſuppreſſion of urine ariſes from ſwellings in or about the urethra, in conſequence of inflammation, an attempt ſhould be made to diſcuſs theſe immediately, or bring them into a ſtate of ſuppuration, and diſcharge the pus as ſoon as it is formed. But when the nature of the tumor is ſuch as not to terminate in either of theſe ways, extirpation of the diſeaſed parts, when this is found practicable, is the only probable means of relief. Bougies ſhould at the ſame time be uſed to aſſiſt in the cure.

When ſpaſmodic affections are preſent in the urethra, the remedies to be employed are, warm emollients, as rubbing the part with warm oil; anodynes, as opium given by the mouth, but more eſpecially by the anus; blood-letting in plethoric habits and this to be generally and locally applied; bliſters put to the penis or perinæum; electricity, after plethora has been removed. Some caſes may be treated with bougies; but where the diſeaſe is purely ſpaſmodical, they are generally found to be hurtful; though in other caſes, when the violence of the diſeaſe is ſo far removed, if they can be introduced, they are of ſervice, by relieving any obſtructions which may remain after the remedies abovementioned have been exhibited. Coſtiveneſs ought likewiſe to be guarded againſt. The permanent ſtricture is to be cured by bougies.

Bougies act ſolely by preſſure, and by ſupporting the part; hence they ſhould be ſo large as to fill the paſſage, and ſufficiently flexible to be eaſily introduced. They are formed of various materials, as a compoſition of diachylon plaſter, oil, and wax melted and put upon linen, which is afterwards properly rolled up; or they are formed of leather, catgut, &c. properly prepared: but the beſt of any are thoſe which are formed of elaſtic gum. Bougies, when properly made, can ſometimes be kept in for ſix or eight hours together; but the length of time proper for their retention muſt depend much upon the feelings of the patient. At all times when they give much pain they ought to be removed, and not introduced again till the part is in a ſtate fit for receiving them. They ſhould be gradually increaſed in their ſize, till the paſſage returns to its natural dimenſions. They ought to be continued for ſome time after, till it appear that there is no danger of a return of the complaint.

Phymoſis and Paraphymoſis.

Sect. II. *Of Phymoſis and Paraphymoſis.*

346 Cauſes of phymoſis.

In phymoſis the prepuce is thickened, and contracted before the glans, ſo that it cannot be readily drawn behind it. In ſome people there is a conſtitutional phymoſis from the natural ſtraitneſs of the prepuce. Sometimes it ariſes from the matter ſecreted by the odoriferous glands at the root of the glans being confined and becoming acrid; ſometimes from an anaſarcous ſwelling of the ſcrotum and penis; but moſt frequently from venereal virus.

347 Cure.

The cure muſt depend upon the nature of the cauſe producing the diſeaſe. If the ſymptoms be inflammatory and of no long continuance, fomenting the parts frequently with warm emollient decoctions, or bathing them in warm milk, and then applying emollient poultices, or keeping the diſeaſed parts conſtantly moiſt with a cold aſtringent ſolution, and turning the penis upwards and ſupporting it againſt the belly, commonly give relief. If the inflammation has ariſen from a venereal cauſe, part of the fluid ought frequently to be injected, by means of a ſyringe, between the prepuce and glans, ſo as to waſh off any matter which may there be concealed; but if the inflammation ſtill continues to increaſe, blood-letting is neceſſary, both general and local. The veins of the penis are ſometimes adviſed to be opened with a lancet; but this is unſafe on account of the nerves. Leeches may be applied; but care muſt be taken, in venereal caſes, leſt the bites of theſe animals, by abſorbing venereal matter, turn into chancres. Along with the remedies already adviſed, gentle laxatives, low diet, and abſtinence, ought to be preſcribed. But if, after a due perſeverance in theſe means, it is found that they have had little effect in removing the diſorder, or perhaps that the ſymptoms are conſtantly increaſing, and that chancres are confined under the prepuce; in that caſe it is neceſſary to ſlit open the prepuce, which is beſt done by a ſharp-pointed biſtoury, concealed in a grooved directory, fig. 98. This is to be introduced between the prepuce and glans, till the director is found by the finger to have reached the upper or back part of the prepuce. The operator is now to keep the director firm with one hand, while with the other he puſhes forward the knife, till its point paſſes through the prepuce; then drawing the inſtrument towards him, he cuts the prepuce through its whole length.

The operation being performed, the parts are to be waſhed and cleaned with warm water, and the ſore dreſſed with a little ſoft lint, and a compreſs of linen laid over it. The whole may be retained by a ſmall bag properly adapted, and ſecured by two ſtraps to a bandage put round the body. This bag may be left open at the under end, to allow the patient to make water, without removing the dreſſings; but if this be found impracticable, the dreſſings may be removed with little inconvenience. If the glans be much

Phymosis and Paraphymosis.

much inflamed and excoriated, care should be taken to insert lint spread with emollient ointment between the glans and prepuce, otherwise troublesome adhesions are apt to ensue. It is evident, that when this disease is of the venereal kind, the sore will not readily heal till the poison be eradicated from the constitution.

In some cases of phymosis the preputium is so remarkably long, and the contraction so much confined to the point, that a circular incision is preferable to a longitudinal one; and it is easily effected, by separating such a portion as may be found necessary of the whole circumference of the prepuce. The dressings in this case are the same as when the prepuce is slit open.

348 Of paraphymosis.

Paraphymosis is the reverse of phymosis, being formed by a retraction of the prepuce, producing stricture behind the glans of the penis. Like the former disease, it arises most frequently from a venereal infection, but may be produced from whatever preternaturally enlarges the glans or constricts the prepuce.

349 Treatment.

In the incipient state, the patient may generally be relieved by the surgeon pushing the glans gently back with his thumbs, while with his fingers he brings the prepuce gradually forward. But a more effectual method than this is to inclose the glans with one of the hands, and press gently on all sides, by which the fluids forming the enlargement will be pushed into the body of the penis behind the stricture. If this method be persevered in for a considerable time, it will generally be found to answer the purpose: but should it prove ineffectual, we may try the effects of cold applications; and the best seem to be those of the saturnine kind. When the penis is evidently much swelled and inflamed, the patient should be kept cool, gentle laxatives and low diet should be prescribed, and a number of leeches applied to the penis. Should the disease still continue to increase, and an œdematous swelling appear about the under part of the prepuce, an operation is necessary to prevent a mortification from taking place in the glans. An incision is to be made on each side of the penis immediately behind the glans, so large as completely to divide the stricture. The wound ought to be allowed to blood freely; after which a pledget spread with simple ointment is to be applied, and an emollient poultice laid over the whole.

Sect. III. *Of an Incomplete Urethra.*

In children, especially males, the urethra is sometimes incomplete, ending before it reaches the usual place of termination. Sometimes it does so without any external opening, at other times it opens at a distance from the common termination. In the first case, a small trocar is to be introduced in the direction the urethra ought to take, till the urine be discharged; after which, the passage is to be kept open by the use of bougies, till the sides be rendered callous and an opening preserved. In the other case, as the opening which is already found affords a temporary passage for the urine, it will be better to delay doing any operation till the patient be farther advanced in life, when it is to be performed as in the former case.

After the operation, a piece of flexible catheter may be introduced, as well for the purpose of rendering the passage free and callous, as for carrying off the water till a cure is made.

Sect. IV. *Of Amputating the Penis.*

This operation is found necessary in certain diseases which will not yield to other remedies; as in cases of mortification and cancer. The following is the method of performing it:

Amputating the Penis.

A circular incision is first to be made through the sound skin a little beyond the diseased parts; the skin is then to be drawn back by an assistant, and the body of the penis divided by one stroke of the knife (fig. 99.) immediately at the edge of the retracted skin. The principal arteries, which are two or three on each side, are next to be secured by ligatures; and if an oozing of blood still continue, the surface of the sore ought to be dusted with some styptic powder. To allow the patient to make water, a silver canula (fig. 99. *a*) is to be introduced into the urethra, and retained there by two small ligatures fixed to the side of the canula, their other extremities being fastened to a bandage put round the body. The wound is to be dressed with soft lint, kept in its place by a piece of linen previously perforated for the introduction of the canula. The dressings are to be kept on by a narrow roller passed a few times round the penis, which, by gently compressing the penis upon the instrument, will effectually prevent any farther discharge of blood. The after treatment of the sore should be similar to wounds in other parts of the body. But it will not be necessary to make any farther compression of the penis upon the canula, as the discharge of blood will, previous to this time, be entirely stopped. The tube is to be allowed to remain in the urethra during the whole time of the cure.

Before any operation of this kind is attempted, the surgeon ought to examine attentively, whether the disease be in the penis itself, or only in the skin, as the prepuce alone is frequently so much enlarged and otherwise diseased as to give cause for suspicion that the glans and body of the penis are likewise affected. This precaution is the more necessary, as several instances have occurred where the glans and body of the penis have been removed, and, after the operation, have been found perfectly sound. Previous to amputation, therefore, where there is any cause for suspicion, the prepuce should be slit open, and the glans examined, so as to avoid amputating more than what is absolutely diseased.

350 Of shortness of the frænum.

It sometimes happens that the frænum of the penis is so short as to give considerable uneasiness in time of an erection. When this is the case, it may be safely divided by a pair of scissars, or by a sharp-pointed bistoury, and the wound dressed with a little charpie.

Sect. V. *Of Fistula in Perinæo.*

The term implies a sinuous ulcer in the perinæum, commonly communicating with the urethra, but sometimes opening into the bladder. The same term is also applied to similar sores opening into the scrotum, or into any part of the penis.

351 Causes of fistula in perinæo.

The disease may arise from wounds in the bladder, and of the urethra, from external violence; from a laceration of parts when performing the operation of lithotomy; from incision into the urethra for the extraction of calculi impacted there; from sinuses producing matter capable of corroding the membranous part of the urethra; from suppuration in the perinæum in consequence of inflammation; from the urine passing through an opening in the urethra into the perinæum or other neighbouring parts, and rendering the edges of the sore callous; and most frequently the disease is occasioned by venereal complaints.

352 Treatment.

In the treatment of this disease, when it is the consequence of a general affection of the system, a removal of the primary disorder is necessary before a cure can be attempted. When the complaint is of a local nature, a simple incision into the sinus is all that is necessary; and for this purpose a staff is to introduced into the urethra, so as to pass the opening at which the urine is discharged. A probe, or a small director, is now to be passed at the external opening of

Hemorrhoids or Piles.

the ſore till it reach the ſtaff; and cutting upon it, the ſinus is to be laid open through its whole length till it terminates either in the urethra, or, if neceſſary, in the bladder itſelf. When more openings than one are preſent, they are to be treated in the ſame manner; and if the ſinuſes are found to be remarkably hard, the removal of a ſmall portion of the diſeaſed part will expedite the cure, though the conſequent inflammation and ſuppuration will render this ſeldom neceſſary. After the operation, the wound is to be dreſſed with pledgets of emollient ointment, ſo as to allow it to fill up completely from its bottom. The whole is to be covered with a pledget of emollient ointment; and proper compreſſes being applied over it, the dreſſings are to be ſupported by a T bandage.

If ſymptoms of inflammation be violent, an emollient poultice is to be applied in the courſe of twenty-four hours after the operation; and as ſoon as free ſuppuration is formed, light eaſy dreſſings are to be uſed till the ſore is completely healed.

Chap. XXX. *Diſeaſes about the Anus.*

Sect. I. *Of Hemorrhoids or Piles.*

The treatment of piles has been already conſidered under the article Medicine; but it ſometimes happens, that although the means mentioned there have been employed, the diſeaſe becomes ſo violent as to require the aſſiſtance of the ſurgeon. Where the diſcharge of blood is ſo great as to endanger the life of the patient, we ought to attempt to ſtop it either by compreſſion, or by ſecuring the bleeding veſſels by a ligature; and here the tenaculum is preferable to the needle, becauſe, when the latter is uſed, a portion of the rectum is apt to be included in the ligature. When piles arrive at ſuch a ſize as to obſtruct the paſſage of the fæces, or to produce great irritation, the removal of them by the knife or by ligature becomes neceſſary. The firſt of theſe may be uſed when their ſize is of ſuch a nature as not to threaten a dangerous hemorrhagy; but when this is the caſe, they ought to be removed by ligature, the manner of applying which has been conſidered under the treatment of *Polypi*. The dreſſings are to be of a ſimple nature.

Sect. II. *Of Condylomatous Excreſcences, &c. of the Anus.*

Excrescences are ſometimes produced about the anus, which from their figure get the name of *fici*, *ariſtæ*, &c; but they are all of the ſame nature, and to be cured by the ſame means. They ſometimes grow within the gut itſelf, but more frequently are ſituated at the verge of the anus. They vary conſiderably in their colour, figure, and conſiſtence. Sometimes they are only one or two in number, but commonly all the ſkin about the anus becomes covered with them. They vary in ſize from that of ordinary warts to that of ſplit garden beans. They ſeem originally to be productions of the ſkin, though at laſt they ſometimes proceed as deep as the muſcles. They frequently remain long without producing much uneaſineſs. When this is the caſe, they ought not to be touched; but ſometimes they become ſo troubleſome as to render their removal neceſſary.

The ſofter kinds can frequently be removed by rubbing them often with gentle eſcharotics, as crude ſal ammoniac, or pulvis ſabinæ; but the harder kinds are to be removed chiefly by lunar cauſtic, or by the knife; the latter of which is greatly preferable, and may be done with the utmoſt ſafety.

The ſores are afterwards to be treated like wounds produced by any other cauſe. If cauſtic is to be uſed, care ought to be taken that it do not injure the rectum.

Fiſtula in Ano.

Sect. III. *Of Fiſtula in Ano.*

The fiſtula in ano is a ſinuous ulcer in the neighbourhood of the rectum. When it opens externally, and has likewiſe a communication with the gut, it is termed a *complete fiſtula*; but if it has no communication with the rectum, it is called *incomplete*. When the ulcer communicates with the gut, but has no external opening, it is named an *internal* or *occult fiſtula*. It is likewiſe diſtinguiſhed into ſimple and compound. The firſt is where one or more ſinuſes communicate with the internal ulcer, but where the parts in the neighbourhood are ſound. The compound fiſtula is where the parts through which the ſinus runs are hard and ſwelled, or where the ulcer communicates with the bladder, vagina, os ſacrum, and other contiguous parts.

353 Cauſes of fiſtula in ano.

The cauſes producing the diſeaſe may be, whatever tends to form matter about the anus, piles, condylomatous tumors, hardened fæces, or any cauſe which produces irritation and inflammation, ſo as to end in ſuppuration. As ſoon as a ſwelling about the anus appears to terminate in ſuppuration, every thing ought to be done which can accelerate the formation of matter. A proper degree of heat, warm poultices, fomentations, and the ſteams of warm water, are the means beſt ſuited for this purpoſe; and as ſoon as matter is formed, it ought to be diſcharged by a free inciſion in the loweſt part of the tumor. Much depends upon the proper treatment here; for if the opening be made too ſmall, or if long delayed, the matter gets into the looſe cellular ſubſtance, and inſtead of producing one, produces many ſinuſes, and theſe ſometimes running to a great depth. The parts ought then to be covered with ſoft lint ſpread with mild ointment, and an emollient poultice kept conſtantly over the whole. By this any remaining hardneſs will be removed, the cavity will fill up like impoſthumous tumors in other parts, and a complete cure will in general ſoon be made.

354 Treatment during the firſt ſtage of the ſimple fiſtula.

It more frequently happens, however, that the practitioner is not called in till the abſceſs has burſt of itſelf, and till matter has inſinuated into the ſurrounding cellular ſubſtance, and formed one or more real fiſtulæ.

The firſt thing to be done now is to diſcover the real courſe of the different ſinuſes, and the probe is the beſt inſtrument for this purpoſe. If there be openings in the external ſurface, there is commonly little difficulty in this. If they run along the perinæum or the muſcles, the probe will generally detect them. If they follow the direction of the gut, the beſt method is to introduce the fore-finger oiled into the rectum, while the probe is entered at the external orifice. If there be a communication between the gut and the ſinus, the probe may be made to paſs till its point is felt by the finger in the rectum. We diſcover with certainty if a ſinus communicate with the gut, when air or fæces are diſcharged, or when any mild fluid injected returns by the anus.

355 Treatment after ſinuſes are formed.

After the courſe of the ſinus has been diſcovered, the method of cure is next to be conſidered. Aſtringent or eſcharotic injections, preſſure, and ſetons, are inſupportable, on account of the violent pain which they produce. The only method therefore of bringing on a proper degree of inflammation is a free inciſion along the whole courſe of the ſinus. The courſe of the different ſinuſes having been previouſly diſcovered, a laxative ought to be given on the day preceding this operation, and a clyſter an hour or two before performing it. The patient is to be placed with his back

Fiſtula in Ano.

back towards a window, while his body leans upon a bed, table, or chair. The finger of the ſurgeon is to be rubbed over with oil, and introduced into the rectum. The end of a crooked probe-pointed biſtoury (fig. 100.) is then to be paſſed into the fiſtula, and puſhed againſt the finger in the rectum, if the fiſtula be complete. But in caſes of incomplete fiſtulæ, the point of the inſtrument muſt be made to perforate the gut before it can reach the finger. Some make the perforation with a ſharp-pointed biſtoury, which can be made to ſlip along the ſide of a probe-pointed one, as at fig. 101. After the biſtoury has reached the cavity of the rectum, the point of it is then to be brought out at the anus, and a cut made downwards to lay the ſinus completely open. In this operation the ſphincter ani muſcle is commonly cut, if the ſinus be high; but no inconvenience is found to ariſe from this circumſtance. It ſometimes, though rarely, happens, that the ſinus goes beyond the reach of the finger, and even as high as the upper end of the ſacrum. The only thing which can be done in this caſe is to cut as high as the finger can go, ſo as to give a free and eaſy vent to the matter.

Some practitioners, with a view to prevent troubleſome hemorrhagies, and others to free the patient from the dread of the knife, have propoſed to open the ſinuſes by means of ligature (fig. 102.). By introducing one end of a piece of ſilver or leaden wire into the ſinus, then bringing it out at the anus, and twiſting the ends together, the contained parts may be ſo compreſſed as to produce a complete diviſion of them. But this is both more painful and tedious than the ſcalpel, and appears to be by no means neceſſary.

356 Method of diſcovering the preſence of an occult fiſtula.

When the preſence of an occult fiſtula is ſuſpected, its exiſtence ought firſt to be fully aſcertained, by examining whether the matter which is paſſed by ſtool proceeds from an ulcer in the bowels or from an abſceſs at the ſide of the anus. It is diſcovered by matter from the bowels being mixed with the fæces, and no pain about the anus. In occult fiſtula, a hardneſs, ſwelling, and diſcoloration, are obſerved upon ſome ſpot near the anus, and there is a ſenſation of conſiderable pain upon preſſure being made upon it. The operation in this is the ſame with that in the other two varieties of the diſorder; only that an opening is previouſly to be made, by a lancet or ſcalpel, in that ſpot where the matter appears to be lodged. By this the ſore will be reduced to a complete fiſtula, and the reſt of the operation will be eaſily performed.

357 Treatment in compound fiſtula.

In this manner the different ſinuſes are to be operated upon, when in a ſimple ſtate; but in thoſe of a compound nature, where the parts in the vicinity of the ſores have been ſeparated from each other by an effuſion of matter into the cellular ſubſtance, and where all the under end of the rectum has, in ſome rare caſes, been attached from the ſurrounding parts, two modes of operating have been recommended; either to remove a conſiderable portion of the external integuments, ſo as to give free vent to the matter; or to extirpate all the lower end of the rectum which is found to be detached from the ſurrounding parts. But from the pain and ſubſequent diſtreſs which they occaſion, theſe methods are judiciouſly laid aſide. All that is neceſſary to be done here is to lay the detached portion of gut completely open, as in caſes of ſimple fiſtulæ; but if this be inſufficient for allowing the gut to apply properly to the contiguous parts, another inciſion ſhould be made on the oppoſite ſide. If the neighbouring bones be found ſound, and the conſtitution in other reſpects be unimpaired, a complete cure will probably be obtained.

The matter ſometimes inſinuates itſelf between the ſkin and muſcles of the perinæum, or of the hip. When this is obſerved, the ſac produced by it ſhould be laid open from one end to the other by one or more inciſions as circumſtances may require. Sometimes, from neglect or improper treatment, the matter collected does not find a proper outlet, and then the parts moſt contiguous to it inflame, become painful, and gradually acquire ſuch a morbid calloſity as to put on a ſcirrhous appearance. In ſuch caſes a cure may be effected by giving free vent to the matter, preventing every future collection, and inducing and preſerving a ſuppuration in the ſubſtance of the parts chiefly affected. To accompliſh this laſt circumſtance, however, it may ſometimes be neceſſary not only to lay the ſinuſes freely open, but to cut in upon the obdurated parts.

Fiſtula in Ano.

358 Treatment after laying open the ſinuſes.

The different ſinuſes having been laid open, care muſt be taken to apply the neceſſary dreſſings. Upon this much of the ſucceſs attending the operation depends. Dry lint, till lately, was much uſed by practitioners; but it has been found to produce ſo much irritation, eſpecially when too much crammed in, as to be one of the cauſes of that diarrhœa which is frequently ſo troubleſome after operations of this kind. Inſtead, therefore, of this ſort of dreſſing, pledgets, lint, or ſoft old linen ſpread with any ſimple ointment, are to be preferred. After the ſores have been cleared from clotted blood, the pledgets are to be gently inſinuated between their edges, but not to ſuch a depth, or with ſuch force, as to give any uneaſineſs. This being done, and a compreſs of ſoft linen with a T bandage being applied over the whole, the patient is to be carried to bed; and the dreſſings being renewed, either after every ſtool, or, when theſe are not frequent, once in the twenty four hours, the ſores will generally fill up from the bottom, and will at laſt cicatrize in the ſame manner as wounds in any other part of the body. Sometimes, however, they acquire a ſoft, flabby, unhealthy aſpect, and the matter diſcharged from them is thin, fetid, and occaſionally mixed with blood. Theſe appearances may ſometimes ariſe from ſome part of a ſinus having been overlooked. In this caſe advantage may follow from the part being laid completely open. But it more uſually proceeds from ſome affection of the general ſyſtem; and till this is eradicated the ſores cannot be expected to heal.

In the cure of ſores in other parts of the body, practitioners have ſometimes found great advantage to ariſe from the uſe of iſſues. The ſame thing is now found to be applicable here. Wherever therefore fiſtulæ are of long ſtanding, while any diſorder exiſting in the conſtitution is properly attended to, practitioners recommend, that an iſſue, in proportion to the quantity of the matter diſcharged by the ſores, ſhould be immediately employed. In this way, if the bones in the neighbourhood are not diſeaſed, there will be reaſon to expect that a complete cure will be obtained.

Sect. IV. *Of Prolapſus Ani.*

This is a protruſion of part of the rectum beyond the anus. It is often occaſioned by debility of the parts, but is moſt frequently owing to violent exertions made in the rectum in conſequence of irritation. The reduction ſhould be effected as ſoon as poſſible; for although this part of the inteſtine can bear expoſure to air much longer than any of the reſt, yet allowing it to remain a long time out would be attended with great uneaſineſs, and probably with danger. In the reduction, the tumor ought to be ſupported with the palm of one hand, while with the fingers of the other the part of the gut laſt protruded is to be returned. If the gut has been long expoſed previous to the reduction, veneſection may become neceſſary, and gentle aſtringents may be applied to the part. The patient during the reduction is to be kept in a reclined poſture. As ſoon as the bowels

Imperforated Anus.

are returned, a proper bandage (fig. 103.), is to be applied. Such remedies are afterwards to be exhibited as moſt tend to recover the tone of the parts.

Sect. V. *Of Imperforated Anus.*

This diſorder, though not frequent, now and then occurs; and when preſent; unleſs ſpeedy relief be given, muſt prove fatal. In ſome caſes, the end of the rectum protrudes at the uſual ſituation of the anus, and is only covered with the common integuments; but in others, no termination of that gut is diſcoverable. Sometimes the rectum ends within an inch of the uſual ſeat of the anus; at others, it reaches no farther than the top of the ſacrum. In ſome caſes it terminates in the bladder; in others, in the vagina. In the moſt favourable caſes, where the rectum protrudes, an opening may be readily made by a ſcalpel or lancet; but when no direction of this kind is met with, an inciſion is then to be made in the place where the anus is uſually ſituated, and is to be continued in the direction of the os coccygis and ſacrum, which is the courſe the inteſtine commonly takes. The finger is to be uſed as a director along it; the parts are to be cut either till fæces are obſerved, or till the inciſion has been made the length of the finger. If ſtill the fæces do not appear, a lancet-pointed trocar is to be puſhed forward upon the finger in ſuch a direction as the operator thinks will moſt probably reach the gut. An artificial anus is likewiſe to be attempted, where the gut terminates in the bladder or vagina. After the operation, the greateſt attention is neceſſary to preſerve the opening which has been made. Subſtances which irritate leaſt are the moſt uſeful; ſuch as doſſils of lint moiſtened in oil, and rolls of ſoft bougie plaſter.—We ſhall conclude this chapter with two ſhort ſections of imperforated hymen and prolapſus uteri, though they do not properly come under it.

Sect. VI. *Of an Imperforated Hymen.*

When the hymen is imperforated, the moſt troubleſome ſymptoms, at a certain period of life, may be produced by the accumulation of that fluid, which ought to be diſcharged; for then a tumor is formed, by which the moſt violent bearing-down pains are occaſioned. Theſe increaſe in ſeverity to ſuch a degree, as ſometimes to be miſtaken for labour-pains. They diſappear, however, during the intervals of the accuſtomed periods. In the treatment of this diſeaſe, all that is neceſſary is to make either a ſingle or a crucial inciſion into the obſtructing membrane, and then to prevent the accretion of its edges by doſſils of lint ſpread with ſome emollient ointment till the parts are healed.

Sect. VII. *Of Prolapſus Uteri.*

This is a falling down of the uterus, occaſioned by debility or by exceſſive ſtraining in the time of parturition. The diſorder ſeldom occurs before child-bearing, and is commonly met with in thoſe who are ſomewhat advanced in life. The parts protruding are to be reduced by gentle preſſure, while the patient is put in an horizontal poſture. Peſſaries (fig. 91. *a* and *b*) are to be employed, which ought to be made of the lighteſt materials, finely poliſhed, and ſomewhat compreſſible; and none poſſeſs theſe qualities in a more perfect degree than a peſſary made of the elaſtic gum bottle. This, or whatever elſe may be uſed to anſwer the purpoſe, is to be retained by a proper bandage till by tonic medicines the parts recover ſtrength to retain their natural ſituation.

Chap. XXXI. *Of Luxations.*

Sect. I. *Of Luxations in general.*

A bone is ſaid to be luxated when that part of it forming a joint is moved out of its place. When the bone is forced entirely out of its cavity, the luxation is termed *complete*; when this is not the caſe, it is *partial* or *incomplete*. When there is alſo a wound of the ſoft parts communicating with the joint, it is called a *compound*, and when there is no wound, a *ſimple luxation*.

Luxations in general.

359 Symptoms of luxation.

The common ſymptoms of a diſlocated bone are, inability to move the injured limb; pain, tenſion, deformity in the part affected; and ſometimes inflammation, ſubſultus tendinum, and fever: and theſe three laſt are greateſt in partial diſlocations. The ſwelling which firſt appears is always inflammatory; but afterwards a ſecondary ſwelling comes on, ſeemingly œdematous, and probably owing to the preſſure of the lymphatics by the diſlocated bone.

360 Prognoſis.

In judging of the practicability of reducing a luxation, we ought to attend to its nature and extent, the other circumſtances with which it may be complicated, and the length of time which it has continued. When a bone is only partially diſlocated, it is evident that it may be reduced with much more eaſe and certainty than where it is completely diſplaced. It is evident alſo that fracture attending diſlocation muſt render reduction much more difficult and uncertain. Indeed, when both the bones forming the joint are broken, there is the greateſt hazard of its remaining ſtiff during life, even when the greateſt attention has been paid. Luxated bones are moſt eaſily reduced immediately after they are diſplaced: the difficulty indeed of reducing them is generally proportional to the time that has intervened ſince the accident happened. When a bone has been ſome time lodged among the contiguous muſcles, it forms a ſocket for itſelf, and is firmly graſped by the ſurrounding ſoft parts. The cavity, too, from which it was diſlodged may be partially filled with ſome of the ſurrounding ſoft parts, or at leaſt diminiſhed by the conſtant action of the contiguous muſcles on its cartilaginous brim. Diſſections, however, ſhow, that inſpiſſated ſynovia does not, as was formerly ſuppoſed, fill up this cavity. In delicate conſtitutions and advanced periods of life, when the muſcles give little reſiſtance, diſlocations are more eaſily reduced than in the vigour of youth or in robuſt conſtitutions.

361 Treatment of ſimple luxations.

In the treatment, we ought, 1. To reduce diſlocation with as much eaſe and expedition as poſſible; 2. Retain the bone in its ſituation till the parts have recovered their tone; and, 3. Obviate all uneaſy ſymptoms.

1. When the ſurrounding ſkin and muſcles are much contuſed and inflamed, we ſhould endeavour to remove the inflammation by local blooding, ſaturnine applications, and laying the limb in an eaſy poſture, before we attempt to reduce the bone, as conſiderable injury may be done by ſtretching a limb while the parts ſurrounding the joint are inflamed. The upper part of the limb ſhould be kept ſteady while the ſurgeon endeavours to replace the under bone, which alone is commonly diſplaced. This is not eaſily done; for the contractile power of the muſcles acts ſtrongly againſt every attempt, and not only draws it beyond the contiguous bone againſt which it ſhould be placed, but frequently forces it out of its natural ſituation, and fixes it firmly in ſome neighbouring cavity, from which it is with difficulty removed. To prevent this reſiſtance as much as poſſible, the muſcles ought to be put into a ſtate of relaxation. If this is properly done, the force neceſſary for reducing a luxated bone may generally be obtained from aſſiſtants alone; ſometimes, however, machinery is required, and various inſtruments have been invented for this purpoſe. Freke's machine is the moſt generally uſed. The force ought always to be applied in a gradual manner, and to the diſlocated bone alone, and not to any more diſtant parts of the limb. After the end of the diſlocated bone is brought into a line with that to which it

is

Luxations of the Bones of the Head and Neck.

is oppoſed, the reduction is eaſily completed either by the action of the muſcles alone, or, if that is not ſufficient, by gentle preſſure.

2. After the reduction there is ſeldom any difficulty in retaining the bone in its place, unleſs it has often been diſlocated before. All that is neceſſary is to place the limb in a relaxed poſture, and to ſupport the bone with a bandage till the parts have recovered their tone.

3. The moſt urgent ſymptoms which accompany diſlocations are, pain, inflammation, and ſwelling. Theſe uſually abate ſoon after the reduction. If any degree of inflammation remain, the uſe of leeches is the beſt remedy.

When diſlocated bones are accompanied with fracture near the joint, the fracture muſt be allowed to heal before reduction be attempted. This, however, is not always neceſſary in very ſmall bones, as thoſe of the fingers. When the fracture is at a diſtance from the joint, the diſlocation may

362 Treatment of compound luxations.

generally be reduced immediately. Compound luxations are to be treated nearly as compound fractures. After the bone is replaced, leeches ſhould be applied to abate the inflammation; after which the ſore ſhould be dreſſed with Goulard's cerate, or any other mild ointment, and the pain moderated by opiates and a low regimen: care ought alſo to be taken that no matter lodge about the joint. When luxations are produced by tumors or collections of matter in the neighbourhood of the joints, they may be conſidered as incurable: when they proceed from too great a relaxation of the ligaments and tendons of the joint, the bone can hardly be prevented from being now and then diſplaced; but the inconvenience may be ſomewhat obviated by ſupporting the limb with a proper bandage, by the uſe of the cold bath, and by electricity.

SECT. II. *Luxations of the Bones of the Head and Neck.*

363 Luxations of the bones of the cranium.

If the bones of the cranium be ſeparated by external injury, all that can well be done is, to ſupport the parts by a bandage, to prevent inflammation, to keep the patient quiet, and in a proper poſture during the cure. The bones of the noſe are ſeldom luxated without fracture: when they are,

364 Of the bones of the noſe.

the injury is eaſily diſcovered by the touch. When one of the bones is driven inwards, it may be raiſed and reduced by puſhing a tube of a proper ſize, and covered with ſoft lint, into the noſtril; which may be afterwards retained till there is no danger of the bone being again diſplaced. If the bone be luxated outwards, it may be reduced by the fingers,

365 Of the lower jaw.

and retained by a double-headed roller. The lower jaw is luxated moſt frequently when the mouth is opened widely; it can only take place forwards and downwards, which are leaſt ſurrounded by the neighbouring parts: both ſides are generally luxated at once; and in that caſe the mouth is opened wide, the chin thrown forwards and towards the breaſt. When only one ſide is diſlocated, the mouth is diſtorted, and wideſt on the ſound ſide of the jaw, which is drawn a little towards the contrary ſide. The patient ſhould be ſeated, and his head ſupported. The ſurgeon ſhould puſh his thumbs, protected by a covering of ſtrong leather, as far as poſſible between the jaws, and then with his fingers, applied on the outſide of the angle of the jaw, endeavour to bring it forward till it move a little from its ſituation. He ſhould then preſs it forcibly down, and the condyles will immediately ſlip into their place. The thumbs ought to be inſtantly withdrawn, as the patient is apt to bite them involuntarily. The patient ſhould for ſome time avoid much ſpeaking or opening his mouth wide.

366 Of the head or neck.

When the head is luxated, it commonly falls forward on the breaſt, the patient is inſtantly deprived of ſenſe and motion, and ſoon dies if the luxation be not quickly reduced. In reducing the luxation, the patient ſhould be placed on the ground, and ſupported by an aſſiſtant: the ſurgeon ſtanding behind ſhould gradually pull up the head, while the ſhoulders are preſſed down by the aſſiſtant till the bones are brought into their place, which is known by a ſudden crack or noiſe: if the patient be not dead, he immediately recovers his faculties, at leaſt in ſome meaſure. He ſhould then be put to bed with his head elevated and retained in one poſture. He ſhould loſe a quantity of blood, and live for ſome time on a low diet.

Luxations of the Spine, Os Coccygis, Clavicle, and Ribs.

SECT. III. *Luxations of the Spine, Os Coccygis, Clavicle, and Ribs.*

367 Luxations of the vertebræ.

THE vertebræ are ſometimes partially, but hardly ever completely, diſlocated without fracture. When they occur high up, they are attended with the ſame ſymptoms as diſlocation of the head: when farther down, beſides diſtortion of the ſpine, paralyſis enſues of every part of the body ſituated under the luxated bone; there is commonly alſo either a total ſuppreſſion of urine, or it is diſcharged involuntarily together with the fæces. As luxations of this kind are generally owing to falls or violent blows, the diſplaced vertebra is driven either forwards or to one ſide; it is therefore very difficult to reduce it. The beſt, as well as the ſimpleſt method, is to lay the patient on his face over a cylindrical body, as a large caſk, and at the ſame time to attempt to replace the bone with the fingers. If the bone be very much diſplaced, there is very little reaſon to hope for ſucceſs.

368 Of the os coccygis.

The os coccygis is more liable to diſlocation than any other part of the ſpine. It is ſometimes forced outwards in laborious births. This is diſcovered by the great pain which is felt at the connection of the os coccygis with the ſacrum, and by the bone appearing to be diſplaced when examined. It may generally be eaſily reduced by preſſure with the fingers. The beſt ſupport afterwards is a compreſs, with the T bandage. When the coccyx is luxated inwardly, the patient complains of ſevere pain, teneſmus, and a ſenſe of fulneſs in the rectum; the fæces are paſſed with difficulty, and in ſome caſes a ſuppreſſion of urine takes place. The injury is eaſily diſcovered by introducing the finger into the anus. In this caſe the bone ſhould be preſſed outwards, by introducing the fore and middle fingers of one hand dipped in oil into the rectum, and ſupporting the parts which correſpond with it externally till the reduction is accompliſhed. Diſlocations of theſe bones are apt to excite inflammation, which often terminates in dangerous abſceſſes; it ought therefore to be guarded againſt by every means in our power.

369 Of the clavicle.

The clavicle is moſt frequently luxated at its junction with the ſternum; becauſe the violence which produces the injury is generally applied to the ſhoulder. The luxation is diſcovered by pain in the part, by the projection of the bone, and by the immobility of the ſhoulder. It is eaſily reduced by puſhing the bone into its place with the fingers, while an aſſiſtant draws back the arms and ſhoulders. It is not ſo eaſy to retain the bone in its place. When it is the inner extremity of the clavicle which has been diſlocated, the ſhoulder ſhould be kept in its natural ſituation, neither raiſed nor depreſſed: the fore arm ſhould be ſupported, as ſhould alſo the head and ſhoulders, and a moderate preſſure ſhould be made upon the diſplaced end of the bone. For this purpoſe the machine repreſented fig. 104. the invention of Mr Park of Liverpool, anſwers beſt. But when the outer extremity of the clavicle has been diſlocated, the ſhoulder muſt be conſiderably raiſed, the arm ſupported in a ſling, and the bone kept in its proper ſituation by a ſmall compreſs placed over its end, and ſecured by a roller forming the figure 8; or it may be retained by the

machine

Luxations of the Bones of the Superior Extremities.

machine abovementioned. The bandage ought to be retained for a conſiderable time.

Luxations of the ribs are exceedingly rare. The ſymptoms are nearly the ſame with thoſe ariſing from fracture, only that the pain is more ſevere at the articulation, and that no other ſpot but that will yield to preſſure. All that can be done is to bend the body forward over a caſk or ſome ſuch body, in order to aſſiſt the viſcera in preſſing out the rib. Bandages are of little uſe. The patient ſhould be kept quiet, and fed on a low diet: inflammation ſhould be prevented, and opiates given if he has a troublefome cough.

370 Of the ribs.

Sect. IV. *Luxation of the Bones of the Superior Extremities.*

371 Luxation of the head of the os humeri.

The head of the os humeri is moſt frequently diſlocated forwards and downwards, ſometimes downwards and backwards, but never upwards without a fracture of that part of the ſcapula which is placed above the joint. The luxation is diſcovered by the patient's inability to raiſe his arm, by violent pain attending the attempt, by the luxated arm being of a different length from the other, by the head of the humerus being felt out of its natural ſituation, while a vacuity is perceived under the acromion, and by the flatneſs of the injured joint, while the ſound one has its natural fulneſs. When the luxation is of long ſtanding, the whole arm is apt to become œdematous.

372 Method of reduction.

The patient ſhould be ſeated on a chair, and his body ſecured by a broad belt paſſed round it, and held by aſſiſtants. The elbow ſhould be bent, in order to relax the muſcles on the fore part of the luxated joint. A firm leather belt four or five inches broad, with ſtrong ſtraps, and lined with flannel, is to be tied round the arm immediately above the elbow: aſſiſtants are to extend the arm gradually, by pulling theſe ſtraps, while another aſſiſtant draws back the ſcapula. The ſurgeon ſtands on the outſide of the arm, directs the aſſiſtants, and varies the direction of the extenſion, according to the ſituation of the head of the bone. As ſoon as the head of the bone has cleared the brim of the ſocket, the muſcles draw it into its place, a crack is heard, the patient is relieved, and the anterior part of the ſhoulder acquires its uſual fulneſs.

373 Various methods of extending the arm.

Various other methods of extending the arm have been propoſed in difficult caſes; as, ſuſpending the patient by the luxated arm over the ſtep of a ladder or the top of a door, raiſing him up by the arm with ropes running over pulleys fixed in the ceiling of a room, &c. The jerk produced by the body being ſuddenly raiſed and let down again on a feather bed, has ſometimes ſucceeded when other means have failed. A gentler method is to lay the patient on the floor while two or three ſtout men ſtanding on a table lay hold of him by the arm and pull him up. But all theſe methods are in danger of lacerating the ſoft parts by the ſuddenneſs with which the force is applied, and even ſometimes of breaking the end of the humerus if it be preſſed againſt the neck of the ſcapula. Mr Freke's improvement on the ambé of Hippocrates has been conſidered as the beſt machine for extending the arm. But machinery is very ſeldom neceſſary; even caſes of long ſtanding may by proper management be reduced by means of aſſiſtants, provided reduction be at all practicable. Inflammation after the operation ſhould be obviated by the uſual remedies. If the bone be apt to ſtep out again, which ſometimes happens after repeated diſlocations, the arm ſhould be ſupported in a ſling till the parts have recovered their tone. Bliſters, friction, ſtimulating medicines applied to the ſhoulder, and cold water poured on it, have ſometimes been uſeful in reſtoring the ſtrength of the joint.

Luxations of the Bones of the Inferior Extremities.

Luxations at the elbow moſt commonly happen upwards and backwards; and then the fore-arm is ſhortened, the end of the ulna projects behind, and is higher than uſual, while the extremity of the humerus can be felt in the bend of the elbow. The ſurgeon ſhould take hold of the wriſt with one hand, and the upper part of the fore-arm (which is to be moderately bent) with the other, and gradually pull the top of the fore-arm downwards, while at the ſame time he increaſes the curvature of the elbow to diſengage the ends of the bones from each other. He ſhould then pull the bones forward into their ſituation. When the luxation happens upwards and forwards, it ſhould be reduced while the arm is extended. After the reduction, the muſcles of the fore-arm ſhould be kept relaxed by bending the elbow a little till the parts have recovered their tone. When the bones of the fore-arm are diſlocated from each other, which happens moſt frequently at the wriſt, the rotatory motion of the hand is deſtroyed. After the reduction, the bones ſhould be bound together by a tight flannel roller, or a couple of ſplints ſhould be applied along the fore-arm, and the arm ſupported in a ſling.

374 Luxations of the elbow.

375 Luxations at the wriſt.

The bones of the wriſt are not ſo often luxated as might be expected from the ſmallneſs of their ſize. When they are, great ſwelling and pain enſues, and the motion of the joint is entirely deſtroyed. Great attention is neceſſary, leſt luxation ſhould be miſtaken for a ſprain. The arm and hand ſhould be ſupported by aſſiſtants, but not ſtretched; and then the bones ſhould be puſhed into their place, and afterwards retained by proper bandages and ſplints. The bones of the metacarpus, when they happen to be diſlocated, which is very ſeldom, are to be reduced in the ſame manner. Diſlocations of the thumb or fingers are eaſily diſcovered. To reduce them, an aſſiſtant ſhould hold the phalanx from which the diſlocation happened, while the ſurgeon endeavours to elevate the bone from the one contiguous to it, and to paſs it into its place.

Sect. V. *Luxations of the Bones of the inferior Extremities.*

376 Luxation of the hip joint.

From the great ſtrength of the hip joint, it was formerly believed that the head of the thigh-bone was never luxated by external violence; but it is now known that it happens by no means unfrequently. The ball in ſtarting from its ſocket generally paſſes forwards and downwards into the foramen thyroideum. When this happens, the limb is conſiderably lengthened, the head of the bone is lodged near the under and fore part of the pelvis, the large trochanter is obſerved on the fore part of the thigh, a vacancy is perceived where the head of the bone and the trochanter ſhould be, and the toes are turned outwards. When the bone is diſlocated upwards and backwards, the limb is ſhortened, the great trochanter higher than uſual, the knee and foot turned inwards. When it is diſlocated upwards and forwards, the leg is ſhortened, the ball of the bone is felt on the os pubis in the groin, and the great trochanter on the upper and lower part of thigh; a vacancy is diſcovered in the correſponding part of the hip; the knee and toes are turned outwards. When the ball ſlips downwards and backwards, the leg is lengthened, the toes turned inwards, and the great trochanter is lower than that of the other limb. If the ball ſlip directly downwards, the leg is lengthened, but the knee and toes keep nearly their natural ſituation. It is ſometimes difficult to diſtinguiſh between luxation and fracture of the neck of the bone. In fractures the bone is moſt frequently puſhed upwards, and the leg ſhortened, the knee and point of the toes are turned inwards, and may be moved much more readily outwards and inwards than when the bone is diſlocated.

377 Symptoms.

For

Luxations of the Bones of the Inferior Extremities.

For reduction, the patient ſhould be laid on a mattreſs on the ſound ſide, and a wooden roller covered with ſeveral folds of flannel placed between his thighs, and fixed firmly by ſtraps to the wall. A ſtrong bandage of buff leather, or ſomething ſimilar, ſhould be applied to the under end of the thigh, with ſtraps fixed to it to make the extenſion. The trunk of the body ſhould be properly ſecured, and the joint of the knee bent. The extenſion ſhould be made at firſt gently, and increaſed gradually, while, at the ſame time, the thigh is made to roll in different directions. When the extenſion is ſufficient, two aſſiſtants ſhould lay hold of the roller, and attempt to raiſe the bone; the extending force ſhould then be ſlackened, and the ſurgeon ſhould puſh the head of the bone upwards and outwards, while an aſſiſtant preſſes the knee forcibly inwards. The muſcles themſelves will then commonly bring the bone into its place; and this is done with ſuch a jerk and noiſe, that it is heard by the by-ſtanders. If the reduction be not obtained, the extenſion muſt be repeated with greater force. Inſtead of the roller a broad ſtrap or table cloth is frequently uſed. The limb ſhould not be uſed for ſome time after reduction, and inflammation ſhould be prevented by the proper remedies.

378 Method of reduction.

379 Luxation of the patella.

The patella can neither be luxated upwards or downwards, without rupture of the tendons of the extenſors muſcles, or of the ſtrong ligament which fixes it to the tibia; but it may be luxated to either ſide. The luxation produceſs lameneſs, and much pain on attempting to move the joint. In recent caſes the injury is eaſily diſcovered; but when the ſurgeon is not called immediately, the ſwelling may be ſo great as to render it more difficult. For reduction, the limb ſhould be kept extended; the ſurgeon, by depreſſing the edge of the patella moſt diſtant from the joint, is enabled to raiſe the other, and puſh the bone into its place.

It may be neceſſary to remain a day or two in bed till the knee recover its tone. Sometimes after the bone has been diſplaced, returns of the ſame complaint become frequent. In ſuch caſes, proper machinery applied to the ſide of the tumor, where the bone is apt to ſtart out, is uſed with advantage.

380 Luxation of the tibia at the knee.

From the ſize of the joint, and the great ſtrength of the ligaments, luxations of the tibia from the os femoris rarely occur. When it does, it is eaſily diſcovered by the pain, lameneſs, and deformity of the limb. The patient ſhould be laid on a table, the muſcles relaxed, and the thigh ſecured by aſſiſtants; the limb ſhould then be extended, and the bones cleared of each other, when they will be eaſily replaced. After the reduction, the limb ſhould remain for ſome time perfectly at reſt; and inflammation, which is very apt to enſue, and is attended with very bad conſequences, ſhould be aſſiduouſly guarded againſt.

381 Luxation of the ankle-joint.

If the ankle joint be diſlocated forwards, the fore part of the foot is lengthened; if backwards, the foot is ſhortened and the heel lengthened (this is the moſt common variety); if to either ſide, there is an uncommon vacancy on the one ſide, and a prominency on the other. Diſlocation, however, can hardly take place outwardly without fracture of the end of the fibula.

For reduction, the limb ſhould be firmly held by aſſiſtants, the muſcles relaxed, and extenſion made till the bones are cleared of each other, when the aſtragulus will eaſily ſlip into its place.—The ſame rules ſhould be obſerved in reducing diſlocations of the bones of the foot. Luxations of the metatarſal bones and toes are reduced exactly in the ſame manner as the bones of the metacarpus and fingers.

Chap. XXXII. *Of Fractures.*

Fractures in general.

Sect. I. *Of Fractures in general.*

The term *fracture* is generally confined to ſuch diviſions in bones as are produced by external injury. When the integuments remain ſound, the fracture is called *ſimple;* when it communicates with a wound, it is called *compound.*

382 Symptoms of fracture.

The general ſymptoms of fracture are pain, ſwelling, and tenſion in the contiguous parts. A grating noiſe when the part is handled, diſtortion, and a certain degree of loſs of power in the injured part, accompany almoſt every fracture, except when it runs longitudinally, and the divided parts are not completely ſeparated from each other. When there is only a ſingle bone in a limb, a fracture is eaſily detected; but where only one of two bones of a limb has ſuffered, it is often difficult to judge with certainty, eſpecially if the contiguous ſoft parts be tenſe and painful before the practitioner is called. In that caſe, the opinion muſt be regulated, not only by the attendant ſymptoms, but, 1ſt, By the age and habit of the patient; for bones are more eaſily fractured in old than in young perſons. Different diſeaſes, too, induce brittleneſs of the bones, as the lues venerea and ſea-ſcurvy. 2d, By the ſituation of the part; for bones are more apt to be fractured in the ſolid parts of their bodies than towards their extremities, where they are more ſoft and pliant. 3d, By the poſture of the limb; for a weight may fracture a bone lying on an unequal ſurface, which it would have ſuſtained without injury if equally ſupported. Fractures are ſometimes attended with a great degree of echymoſis, occaſioned by the ends of the fractured bones wounding ſome of the contiguous blood-veſſels.

383 Prognoſis.

In giving a prognoſis of fracture, various circumſtances are to be attended to. It is evident that ſmall fractured bones are more eaſily healed than large ones, and that the fracture of the middle of a bone is not near ſo dangerous as near the extremity. A cure is effected much more readily in youth than in old age, and in good conſtitutions than in bad. We ought alſo to attend to the concomitant ſymptoms, and the injury which the neighbouring parts may have ſuſtained. The more moderate the ſymptoms, the more favourable our prognoſis may be.

384 Treatment.

The treatment of fractures conſiſts of three particulars; replacement, retention, and obviating bad ſymptoms.

1. When bones are fractured directly acroſs the parts, they are often very little moved from their natural ſituation; but when the fracture is oblique, they are apt to paſs over each other, and to produce much uneaſineſs and deformity; the contiguous muſcles are ſeverely injured, and the pain is aggravated by the ſlighteſt motion. The ſurgeon ſhould put the limb into the beſt poſture for relaxing all the muſcles connected with it, according to the practice firſt introduced by Mr Pott. If it be properly attended to, the ends of the bones will in general be eaſily replaced. When any difficulty occurs, a ſmall degree of extenſion may be made, taking care to keep the muſcles as relaxed as poſſible. Much attention ſhould be paid to replacing the bones properly, otherwiſe the limb will remain for ever after diſtorted.

2. After the bones are replaced, the limb ſhould be laid in the eaſieſt poſture, and the bones afterwards retained in their ſituation by proper compreſſes and bandages, not applied too tightly, till the cure be completed. The time neceſſary for this purpoſe depends on the ſize of the bone, the age and habit of the patient, the ſteadineſs with which the limb has been retained in its place, and the violence of the

Fractures in general.

the attending ſymptoms. In middle-aged perſons, and under favourable circumſtances, a fracture of the thigh bone, or of the bones of the leg, may be cured in two months; of the arm bone, or bones of the fore arm, in ſix weeks; of the ribs, clavicles, and bones of the hand, in three weeks. In infancy the cure will take a ſhorter, and in old age a longer, time than this.

3. In ſimple fractures the inflammatory ſymptoms generally ſubſide in a few days. When they become worſe, which is ſometimes the caſe, aſtringent applications ſhould be employed. If theſe fail, blood ought to be drawn from the parts affected. This is of ſo much advantage, that it ought never to be omitted where the ſurrounding ſoft parts are much injured. Friction with emollient oils, warm bathing, the uſe of Bath and other ſimilar waters, are alſo of much ſervice. The limb ſometimes puts on a clumſy appearance from an overgrowth of callus. When this tendency appears, ardent ſpirits and other aſtringents are conſidered as uſeful; ſometimes preſſure on the part by a thin plate of lead fixed by a bandage may be advantageous. Many inſtances occur, however, where no remedies prove ſucceſsful: The patient ought therefore to be acquainted beforehand with the probable event, to prevent unpleaſant reflections afterwards.

Sometimes the ends of the bone remain looſe long after they might have been reunited. This may be owing to ſome conſtitutional diſeaſe, to the bones not being kept ſteadily in contact, to ſome of the ſoft parts getting in between them, or to the bone being broken in different places, and the intermediate fractures being too ſmall to adhere. Pregnancy has alſo been mentioned as a cauſe. By removing theſe obſtructions, a perfect union may in recent caſes be accompliſhed. But where the caſe is of long ſtanding, callus of the bones become ſo hard and ſmooth as to move with the eaſe of a joint, ſo that no advantage can be derived from laying them together. In that caſe, an inciſion ſhould be made through the ſoft parts, and a ſmall portion of the ends of the bone removed with a ſaw. If this be properly performed, nature will ſupply the deficiency. When ſmall pieces of bone remain long looſe, they ſhould be extracted by making an opening. The intervention of muſcles or other ſoft parts is known by the very ſevere pain and tenſion, and by particular motions of the limb cauſing great pain and twitching of the muſcles which move it. The limb ſhould be put into all the variety of ſituation; and if this does not ſucceed, an opening muſt be made, and the ſoft parts removed. Sometimes in fractures blood-veſſels are ruptured by the ſharp ſpiculæ of the bone: this happens moſt commonly in compound fractures. When the effuſion of blood is great, the part ſwells ſo much that it is neceſſary to lay it open, and to ſecure the divided veſſels by a ligature. When the ſwelling is not great, the abſorption of the blood is truſted to nature. When the blood remains long in contact with the fractured bone, it ſometimes prevents the formation of callus; the periоſteum ſeparates from a conſiderable portion of the bone, and a thin fetid ſanies is diſcharged at the wound. When this happens, no cure can be expected till the parts of the bone deprived of periоſteum have exfoliated, or have been ſeparated by a ſaw.

Sect. II. *Fractures of the Bones of the Face.*

385 Fracture of the noſe.

Fractures of the noſe may impede reſpiration, affect the ſpeech, and ſenſe of ſmelling, give riſe to polypi and tedious ulcers, and may beſides be dangerous from their vicinity to the brain. When any part of the bones of the noſe has been raiſed above the reſt, it is to be preſſed into its place with the fingers; if it has been puſhed into the noſtril, it is to be raiſed with the end of a ſpatula or other ſimilar inſtrument. If any portion be almoſt entirely ſeparated from the reſt, it ſhould be removed; but if it adheres with conſiderable firmneſs, it is to be replaced. If the bones, after being replaced, do not remain in their proper ſituation, they are to be retained either by tubes introduced into the noſtrils, or by a double-headed roller, with proper compreſſes as the caſe may require. Inflammation ſhould be prevented by the proper remedies.

Fractures of the Clavicles, Ribs, Sternum, and Spine.

Much care is neceſſary in replacing the fractured bones of the face, and in dreſſing them, in order to prevent deformity. The dreſſings may be retained by adheſive plaſters. Inflammation, by which the eyes, noſe, or antrum maxillare is apt to be injured, ſhould be prevented. When matter collects in the antrum, it is to be removed by the methods formerly deſcribed.

386 Fractures of the lower jaw.

For replacing fractures of the lower jaw, the patient ſhould be ſeated in a proper light, with his head firmly ſecured. The ſurgeon ſhould preſs with one hand on the inſide of the bone, while with the other he guards againſt inequalities on the outſide. If a tooth come in the way, it ſhould be extracted; when any of the others are forced out of their ſockets, they ſhould be replaced, and tied to the neighbouring teeth till they become firm. The fractured parts being kept firm by an aſſiſtant, a thick compreſs of linen or cotton ſhould be laid over the chin, and made to extend from ear to ear over it; a four-headed roller ſhould be applied firm enough to keep the fractured parts in contact. The patient ſhould be kept quiet during the cure, and fed upon ſpoon-meat. The dreſſings ſhould be removed as ſeldom as poſſible. When the fracture is accompanied with an external wound, the parts ſhould be ſupported by an aſſiſtant during the dreſſing of it.

Sect. III. *Fractures of the Clavicles, Ribs, Sternum, and Spine.*

387 Fracture of the clavicle.

A fracture of the clavicle is eaſily diſcovered by the grating noiſe in the fractured bone upon moving the arm freely, by the ends of the bone yielding to preſſure, and by the motion of the humerus being impeded. All that can be done is to raiſe the arm, and ſupport it at a proper height, either by a ſling, or, which is better, by the leather caſe recommended in caſe of luxation of this bone. By this the fractured parts will be brought together, ſo far at leaſt as to prevent deformity, and render the bone ſufficiently ſtrong.

388 Of the ribs.

Fractures of the ribs are diſcovered by preſſures with the fingers. The ſymptoms are commonly moderate, and the patient ſoon gets well. In ſome caſes, however, the pain is ſevere, the breathing becomes difficult, attended with cough, and perhaps with ſpitting of blood, and the pulſe is quick, full, and ſometimes oppreſſed. Theſe ſymptoms ariſe from the ribs being beat in on the lungs.

In the treatment, it is proper in every caſe to diſcharge ſome blood. If one end of the rib riſe, it ought to be repreſſed by moderate preſſure; and to prevent its riſing again, a broad leather belt ſhould be applied pretty tight, and continued for ſome weeks. When a portion of the rib is forced inwards, an opening ſhould be made over it with a ſcalpel, and then it ſhould be elevated with the fingers or a forceps. When diſtreſſing ſymptoms proceed from air or blood collected in the cavity of the cheſt, theſe fluids ought to be diſcharged by an operation.

389 Of the ſternum.

The ſymptoms of a fractured ſternum are nearly the ſame with thoſe of the ribs. It requires great attention from the vicinity of the heart and large blood-veſſels. The patient ought to loſe a quantity of blood, and be kept on an antiphlogiſtic regimen. If the pain, cough, and oppreſſed breathing, do not yield to theſe remedies, and inciſion ſhould be made

Fracture of the Bones, &c.

made on the injured part, and the depreſſed piece raiſed with a levator. Should this be inſufficient, it may be effected by means of the trepan: this indeed requires the greateſt caution, but it may certainly be attended with advantage when the patient's life is in danger.

390 Of the vertebræ.

Fractures of the vertebræ generally end fatally. We judge of the exiſtence of fracture there by examining the parts, by the ſeverity of the pain, and by palſy occurring in the parts ſituated below the injured part.

When any parts of the vertebræ near the integuments are looſe, they may be replaced with the fingers, and retained by proper bandages. When this is impoſſible, ſome of the lateſt authors think it adviſable to make an inciſion, and raiſe any portions of the bone which may be depreſſed.

Sect. IV. *Fracture of the Bones of the Superior Extremities.*

391 Fracture of the ſcapula.

The ſcapula is ſeldom fractured; when it is, the fracture is eaſily diſcovered by the pain, the immobility of the arm, and by the touch. The parts may be replaced with greater eaſe if the muſcles connected with them be relaxed. They are retained with difficulty. A long roller ſhould be employed for this purpoſe, with which the head and ſhoulders are alſo to be ſupported. The arm ſhould alſo be ſuſpended to relax the muſcles as much as poſſible, and inflammation particularly guarded againſt by local bloodings.

392 Of the os humeri;

Fractures of the humerus are eaſily diſcovered by the pain, the immobility of the arm, and a grating noiſe on handling the parts. In reducing the fracture, the muſcles ſhould be completely relaxed by bending the arm and raiſing it to a horizontal poſture. Extenſion, if neceſſary, may be made by one aſſiſtant graſping the arm between the fracture and the ſhoulder, and another between the fracture and the elbow. After the reduction, one ſplint covered with flannel ſhould be laid along the whole outſide, and another along the whole inſide of the arm; and then a flannel roller applied ſufficiently tight to ſupport the parts without interrupting the circulation. The arm may either be ſupported in a ſling or Mr Park's leather caſe, (fig. 104). The bandages ſhould not be removed for ſeveral days, unleſs ſome urgent ſymptoms render it neceſſary. In about a week, however, the arm ſhould be examined to ſee whether the bones have been properly ſet.

393 Of the bones of the fore-arm;

When both of the bones of the fore-arm are broken, the fracture is eaſily diſcovered; but when only one bone is fractured, eſpecially if it be the radius, the firmneſs of the other renders the diſcovery more difficult; the grating noiſe, however, on moving the bone in different directions, will generally be a ſufficient ſymptom that a fracture has taken place. When the fracture happens near the wriſt, particular attention is neceſſary in order to prevent a ſtiff joint. In order to replace the parts, the muſcles are to be relaxed by bending the joints of the elbow and wriſt, and the limb extended a little above and below the fracture. After reduction, a ſplint reaching from the elbow to the ends of the fingers is to be applied along the radius, and another along the ulna; and both are to be ſecured with a roller or twelve tailed bandage. When the ſplints are applied, the palms ſhould be turned towards the breaſt as the moſt convenient poſture. The arm ſhould be hung in a ſling. A partial diſlocation of the bones of the wriſt ſometimes attends a fracture of the radius, by which a ſtiff joint, under the beſt practice, is apt to enſue, or permanent painful ſwellings of the fore-arm. In ſuch caſes, the patient ought to be warned of the danger, that no blame may be afterwards incurred.

394 Of the olecranum;

When the olecranum is fractured, the arm muſt be kept in an extended ſtate during the cure, by applying a ſplint oppoſite to the joint of the elbow, reaching from the middle of the humerus to the points of the fingers. The arm ſhould be hung by the patient's ſide, to which it ſhould be fixed by means of ſtraps. To prevent the conſequences of a ſtiff joint, the dreſſings ſhould be removed about the eighth or tenth day, the fore-arm for ſome time ſlowly moved backwards and forwards, and the joint rubbed with an emollient oil. By a repetition of this at proper intervals, a ſtiff joint may be prevented.

Fracture of the Bones, &c.

395 Of the bones of the wriſt;

Anchyloſis, or ſtiffneſs of the joint commonly ſucceeds fractures of the bones of the wriſt, owing to the great inflammation which enſues, and to their not readily reuniting from their ſmallneſs. To prevent this as much as poſſible, after replacing the bones, the injured parts ſhould be leeched freely, and in proportion to the violence of the ſymptoms. Splints ſhould be applied exactly as in fractures of the fore-arm, and the arm ſupported by a ſling.

396 Of the bones of the fingers.

In fractures of the metacarpal bones, a firm ſplint ſhould be applied over the whole palm and inſide of the arm, from the points of the fingers to the elbow, in order to prevent the action of the flexors of the fingers. The beſt ſplint for a fractured finger is a piece of firm paſteboard properly fitted and ſoftened in water till it can be readily moulded into the form of the part. This ſhould be applied along the whole length of the finger, and ſecured with a narrow roller. At the ſame time, a large roller ſhould be applied over the inſide of the hand to prevent the parts from being moved. To prevent ſtiffneſs, the dreſſings ſhould be removed about the end of the ſecond week, and the joint cautiouſly bent; and this ſhould be repeated daily till the cure be completed.

Sect. V. *Fractures of the Bones of the inferior Extremities.*

397 Fracture of the thigh-bone.

Fractures of the body of the thigh-bone are readily diſcovered by the grating noiſe when the ends of the bones are forcibly rubbed together, by the ſhortneſs of the limb if the fracture be oblique, and by the limb being unable to ſuſtain the body. But fractures of the neck of the bone are often not eaſily diſtinguiſhed from diſlocation of the joint. In general they may be diſtinguiſhed by the circumſtances mentioned in treating of luxations of this bone. In forming a prognoſis, we ought to conſider that no fractures are more apt to diſappoint our expectations than thoſe of the thigh, eſpecially when the neck of the bone is broken, owing to the difficulty of diſcovering the place of the fracture, and of retaining the bones even after they have been replaced. In order to reduce fractures of the thigh, the muſcles are to be relaxed by moderately bending the joints of the thigh and knee: when this is done, unleſs there be much pain and tenſion, the bones are eaſily replaced by one aſſiſtant holding the upper part of the thigh, while another ſupports and gently pulls down its lower extremity, while the ſurgeon is employed in adjuſting the fractured pieces. It is more difficult to reduce fractures of the neck of the bone, on account of the great ſtrength and various directions of the ſurrounding muſcles. In general, however, we ſhall ſucceed by moderate extenſion, if we take care previouſly to relax all the muſcles as much as poſſible: if we do not ſucceed, we muſt have recourſe to machinery.

The greateſt difficulty is to retain the bones in their ſituation after they are replaced. The limb muſt be firmly ſecured by ſplints made of thin ſlips of wood glued to leather (fig. 105. *a* and *b*), or of thick paſteboard. One ſplint, broad enough to cover half of the thigh, ſhould reach from the top of the hip joint to a little below the knee, and another, covering about a third part of the thigh, from the groin to a little below the knee. The ſplints ſhould be lined with flannel. They are to be ſecured by a twelve-tailed bandage, and over all a thin pillow ſhould be put nearly as long as the

Fracture of the Bones, &c.

the thigh. The ſplints and bandages may be put on in the following manner: The patient being placed on a firm hair mattreſs, with his knee moderately bent, the long ſplint bandage and pillow are to be applied to the outſide of the thigh, and the patient ſhould be turned ſomewhat towards the affected ſide, with the knee and leg raiſed a little higher than the body; the ſhort ſplint ſhould then be applied along the inſide of the thigh, and the bandage already placed without the other ſplint, applied ſo tight as to make an equal moderate preſſure over the whole: (See fig. 106.) To make the part ſtill more ſecure, it is proper to inſert a long firm ſplint of timber under the middle of the pillow, and to fix it by two broad ſtraps to the upper part of the limb. To prevent the limb from being affected by involuntary ſtartings, the pillow ſhould be fixed to the bed by ſtraps: to keep off the weight of the bed-clothes, a frame with hoops ſhould be placed over the thigh. The parts ſhould be examined after ſome time to ſee that the bones be not diſplaced. When there is pain, ſwelling, and inflammation, leeches and other remedies ſhould be applied. To render the ſituation of the patient as eaſy as poſſible during the cure, he may be allowed after the ſecond week to turn a little more towards his back, and at the ſame time to extend the joint of the knee in a ſmall degree: after this time a little flexion and extenſion of the limb may be daily repeated to preſerve the uſe of the joint.

The method here deſcribed generally ſucceeds. Sometimes, however, notwithſtanding all our care, the ends of the bone ſlip over each other. To prevent the deformity which this occaſions, it has been attempted to make extenſion and counter-extenſion by machines: but the pain and irritation have always been ſo great that little advantage has yet been derived from ſuch means. The invention (fig. 107.) of the late Mr Gooch of Norwich, improved by the late Dr Aitken of Edinburgh, has been recommended as one of the beſt machines for oblique fractures of the thigh. After endeavouring to remove the pain, ſwelling, and inflammation, which are ſometimes ſo great as to preclude the application of the ſimpleſt bandage, this machine may be tried. But if it be found impracticable to uſe it, the cure muſt be conducted in the uſual way with the chance of the fractured pieces overlopping one another, and of courſe the limb being ſomewhat ſhortened.

398 Fracture of the patella.

The *patella* is moſt frequently fractured tranſverſely, ſometimes lengthwiſe, and ſometimes into ſeveral pieces. Fractures of this bone have been ſaid commonly to end in a ſtiff joint; but this is perhaps moſt frequently owing to the limb being kept too long in an extended poſture. In the treatment of fractures of this bone, the leg ſhould be extended to relax as much as poſſible the ſoft parts connected with the bone. The patient ſhould be placed on a firm mattreſs, and a ſplint be placed under the limb long enough to reach from the top of the thigh to the under end of the leg, to which the limb ſhould be fixed by a number of ſtraps to keep it in a ſtate of extenſion. The fractured bones are then to be brought together, and ſuch a number of leeches applied to the joint as will remove as much blood as the patient can bear; and as long as much pain and tenſion continue, ſaturnine and other aſtringents are to be uſed for removing them. When this is accompliſhed, and the parts properly adjuſted, a large pledget of Goulard's cerate ſhould be laid over the joint, and a hooped frame employed to keep off the bed-clothes. In a longitudinal fracture the parts are eaſily kept together by a common uniting bandage or adheſive plaſter; but in tranſverſe fractures more force is neceſſary. Various bandages have been employed for drawing the pieces together in ſuch fractures: one of the beſt of theſe is that repreſented fig. 108. We need not be anxious, however, about bringing the pieces very cloſe together, as a cure may be made though they remain at a conſiderable diſtance. The bandages, unleſs particular ſymptoms occur, ſhould not be removed till the end of the ſecond week; after which the joint ſhould be cautiouſly bent every ſecond day to prevent ſtiffneſs.

Fracture of the Bones, &c.

399 Of the leg

The leg is commonly fractured near the lower end, this being the weakeſt part of the bones. In the treatment of a fractured leg the ſame rules apply which were given for a fractured thigh-bone. The muſcles ſhould be relaxed by bending the knee; but little advantage can be derived from bending the foot, for in proportion as the muſcles behind are relaxed thoſe before are put on the ſtretch: the patient may be therefore allowed to keep the foot in the eaſieſt poſture. The bones are commonly replaced by the gentle extenſion of the upper part of the limb by an aſſiſtant, while another ſupports it at the ankle. The bones being replaced, and the limb laid on its outſide with the knee bent, two ſplints (fig. 109.) are to be applied, long enough to reach from the upper part of the knee to the edge of the ſole, ſo as to prevent the motion both of the knee and ankle. The ſplints are to be retained by a twelve-tailed bandage, as in the caſe of fractured thigh-bone. See fig. 106.

If the patient be either very reſtleſs or troubled with ſpaſmodic affections of the muſcles of the leg, an additional ſplint, ſhaped to the form of the leg, ſhould be applied along the outſide of it, and fixed by a ſtrap at the upper, and another at the under part of the leg. When the patient cannot reſt when lying on either ſide, he may be placed on his back, and the curved ſtate of the knee ſtill preſerved by raiſing the leg a little above the level of the body on a frame made for the purpoſe. This variety of poſture may likewiſe be uſed in fractures of the thigh. The patient may from the firſt be laid in this poſture, or he may alternately change from the one to the other. No change of poſture, however, ſhould be allowed for the firſt ten or twelve days. When the fibula only is fractured, it is apt to be conſidered as a ſprain of ſome of the muſcles; but this ought to be particularly attended to, as the miſtake may be followed by bad conſequences. When both the bones of the leg are broken, the portion next the foot is commonly drawn towards the back part of the leg, ſo that a prominency is produced by the fractured part of the upper portion of the bone; and this is improperly termed the riſing end of the fractured bone. The appearance is entirely produced by the inferior portion falling back. Hence no advantage is derived from preſſure being made on the upper end of the bone: the inferior portion ſhould be raiſed ſo as to bring the parts into contact, and then by proper bandages they ought to be ſupported till they are perfectly united.

400 Of the bones of the foot and toes.

Fractures of the bones of the foot and toes are treated nearly in the ſame manner as fractures of the hand and fingers. Beſides the ſplint which may be neceſſary for the particular part, a large one ſhould be applied over the ſole; nor ſhould any motion be allowed for a conſiderable time either in the foot or ankle, otherwiſe the bones may be diſplaced, and a proper cure prevented.

SECT. VI. *Of Compound Fractures.*

401 Whether amputation ſhould be performed in caſes of compound fractures.

By compound fracture is now generally meant a fracture of a bone communicating with an external wound in the integuments. They are much more dangerous than ſimple fractures. The generality of authors have conſidered amputation as indiſpenſable in caſes of compound fractures; while a few, particularly Mr Bilguer, ſurgeon-general to the armies of the late king of Pruſſia, affirm that it is ſcarcely ever neceſſary. Both ſeem to have carried matters too far. Some of the lateſt and beſt ſurgeons have recommended

Compound Fractures.

mended never to amputate immediality in private practice, unleſs when the bones are ſo much ſhattered that they cannot reunite, or the texture of the ſoft parts completely deſtroyed; becauſe, even if amputation be at laſt neceſſary, the patient will have a greater chance of recovering than if it had been performed immediately after the accident: for the ſtate of weakneſs to which he is generally reduced render the attendant ſymptoms leſs violent. On the other hand, it has been conſidered as no bad rule in the army or navy, where patients cannot be kept in a proper ſituation, and where ſufficient attention cannot be given, to amputate immediately in caſes of compound fractures of the large bones of the extremities. When amputation is not performed immediately, it is not, for ſeveral days at leaſt, admiſſible. It may afterwards be rendered neceſſary by hemorrhagies, which cannot be ſtopped but by means more dangerous than amputation itſelf; by extenſive mortification; or by the ends of the fractured bones remaining long diſunited, while a great diſcharge of matter endangers the patient's life.

402 Treatment of compound fractures.

In treating compound fractures, all extraneous bodies ſhould be removed, as alſo all thoſe ſmall pieces of bone which will probably not unite with the reſt. For this purpoſe the opening, if neceſſary, ſhould be enlarged with a ſcalpel. The next ſtep is to replace the bones by relaxing the muſcles as in ſimple fractures. Sometimes part of a bone projects ſo far through the integuments that it cannot be replaced without either ſawing off the end of it, or enlarging the wound. If the fractured bone be long, ſharp, and projecting much, it is beſt to ſaw it off; for though it were reduced, it would not readily reunite, and it would be apt to excite much pain and inflammation: But if it be broad at the baſe, and of no great length, it ought certainly to be ſaved, even though it cannot be reduced without enlarging the wound. For the moſt part, it is only the ſkin which it is neceſſary to cut; but even the muſcles ought to be divided, though as much as poſſible in the direction of their fibres, when the bone cannot otherwiſe be replaced. After the reduction, a pledget of ſome emollient ointment is to be laid over the wound, and the limb placed on a firm ſplint, and ſtill kept in a relaxed poſture. In dreſſing the wound, the limb ought not to be moved: the many-tailed bandage, therefore, ſhould be uſed rather than a roller. Various contrivances have been fallen upon to allow the limb to be at reſt while the ſurgeon is dreſſing it. The fracture box, invented by the late Mr Rae ſurgeon in Edinburgh, is one of the beſt. When the leg is laid on this, it may be dreſſed with tolerable facility without moving it. We are happy to have it in our power to announce to the gentlemen of the medical faculty, that another machine has lately been invented by Mr Samuel James ſurgeon in Hoddeſden, Herts, which, we are told, will effectually relax the muſcles, and retain the bones in their natural ſituation, without pain to the patient or the leaſt inconvenience to the operator. See fig. 110.

Plate ccccxcii.

It is of the greateſt importance to prevent inflammation, which is apt either to produce mortification, or to give riſe to extenſive abſceſſes. The dreſſings ſhould be removed once or twice daily according to the quantity of matter. The common application of warm poultices, on account of their inconvenience, may be deferred till they become neceſſary by the approach of inflammation, which they are to be conſidered as the ſureſt means of preventing by exciting a diſcharge of matter. Whenever the inflammation ſubſides, and a free diſcharge of pus is produced, the poultices ought to be laid aſide, leſt they do harm by relaxing the parts too much, and exciting too copious a diſcharge. The ſore ought then to be dreſſed with mild aſtringents, and the patient kept on a nouriſhing diet with tonic medicines. A free paſſage ſhould be given to the matter by putting the limb in a favourable poſture, and by making a counter opening, if neceſſary, to the moſt depending part. But this may be frequently avoided, by covering the ſore with ſoft lint or ſponge to abſorb the matter. If the diſcharge become exceſſive, and cannot be leſſened by the means abovementioned, it will be found to proceed from a portion of looſe bone which has not been earlier noticed, by the removal of which it may be ſtopt. If, inſtead of producing matter, the inflammation terminate in gangrene, the danger is ſtill greater than under the moſt extenſive abſceſſes. For the treatment of this, the reader is referred to Chap. III. Sect. 2d.

Diſtortions.

Chap. XXXIII. *Of Diſtortions.*

403 Cauſes of diſtortions.

Distortions of the bones may ariſe from external injuries, from diſeaſed conſtitutions, from a morbid ſtate of the bones, or a contracted ſtate of the muſcles, or both; but the affection is moſt frequently owing to a weakly, delicate conſtitution, as in rickety or ſcrophulous caſes.

404 Treatment of diſtortion of the ſpine.

In the treatment of diſtortions of the ſpine, particular attention ought to be paid to the cauſe of the diſorder. If it appear to ariſe from the patient continuing too long in any particular poſture, every habit of this kind ſhould be guarded againſt on the firſt appearance of the diſeaſe. If the patient has turned too much to one ſide, the reverſe of this ſhould be adviſed. He ought to ſleep upon a firm hair mattreſs that his body may lie upon an equal ſurface. He ſhould uſe an invigorating diet, the cold bath, bark, and other tonics. By a ſtrict attention to the uſe of theſe remedies the diſeaſe has ſometimes been retarded in its progreſs. Various machines have been invented for removing diſtortions of the ſpine by preſſure; but conſiderable caution is here required, otherwiſe much injury may ariſe from it. Some advantage, however, in certain caſes, has been derived from the uſe of the common collar (fig. 111.); or the ſtays and machinery adapted to them (fig. 112.), for which a patent was granted to Mr M'Kechnie of Philadelphia, are found to be ſtill better ſuited to this purpoſe.

405 Of the limbs.

The ſame cauſes which produce diſtortions of the ſpine may likewiſe produce diſtortions of the limbs. Sometimes the diſtortion takes place with the original formation of the bones, at other times it occurs in infancy, and now and then at a more advanced period of life. In early infancy the bones are ſo pliable as to be readily affected by the poſtures of the body. When a child is too ſoon allowed to attempt to walk, its legs are apt to become crooked from their inability to ſupport the weight of the body. Certain diſeaſes likewiſe, eſpecially rickets ſoften the bones ſo much, that they yield to the poſture of the body, and to the common action of their muſcles.

When the diſtortion of a limb, is owing to a curvature in a bone, if the caſe be recent, and eſpecially if it occur in childhood, it may frequently be removed, without much difficulty, by making a gradual but conſtant preſſure, by the uſe of machinery, on the convex ſide of the limb, till it recover its natural appearance. When the deformity occurs in the leg, a method has been uſed, in ſeveral inſtances, which is to fix a firm ſplint of iron, lined with leather, in the ſhoe, on the concave ſide of the leg, the other end of the ſplint to reſt againſt the under end of the thigh; when, if a broad ſtrap or two be applied round the leg and ſplint, an eaſy gradual preſſure may be made, and conſiderable advantage derived from it. See fig. 113.

Along with the curvature abovementioned, it commonly happens that the feet and ankles are affected. When the bones of the leg are bent outward, the fore part of the foot is turned inward, and the inner edge upwards; and the reverſe, if the leg be bent inward. In theſe caſes the affec-

Amputation.

tions of the feet are generally owing to the curvature of the bones of the leg. By removing the curvature of these, the foot will commonly regain its natural situation, and the splint abovementioned will for the most part be sufficient for the purpose. But in cases where the sole of the foot is turned much out of its natural direction, it may be necessary to fix the splint and shoe to a frame (fig. 114.), which will render the cure still more effectual.

Besides the instrument already mentioned, some have used a kind of boot, cut lengthwise, made of hardened leather or of metal, &c. which may in some cases sufficiently answer the purpose.

In cases of club-foot, where the distortion is in the middle of the foot, a pair of shoes, such as are represented in fig. 115. have been found useful. After the feet are fixed in the shoes, the fore part of the feet may be separated by means of a screw in two plates, which are fixed to the sole.

Chap. XXXIV. *Of Amputation.*

Sect. I. *Of Amputation in general.*

In amputation, which in surgery signifies cutting off a limb, the great end to the aimed at is, the procuring of a handsome stump, in which the bone may not protrude, but be well covered with flesh; so that no excoriation or rawness may be apt to take place. As long ago as the year 1679, it was proposed by Jacob Young, an English surgeon, in a treatise intitled *Currus Triumphalis ex Terebinthino*, to preserve a flap of flesh and skin, which was to be folded over the bone, and which, uniting to the parts of the wound after amputation, would effectually cover the bone, and prevent the inconveniences abovementioned. No traces of the success of this method, however, can be found till the year 1696; when a Latin dissertation was published upon it by P. Adriens Verduin, an eminent surgeon in Amsterdam. The most sanguine expectations were formed of its success; and it was even thought that the flap would prevent the necessity of tying up the blood-vessels. However, it does not appear that the method as at that time practised either did or could succeed; and accordingly it was entirely laid aside; but it has been lately revived with considerable improvements.

406 Causes rendering amputation necessary.

Amputation may be rendered necessary when a member is so much diseased as to be useless, or when it puts life in danger.

The causes in general rendering this operation necessary are, bad compound fractures; extensive lacerated and contused wounds; part of the limb being carried off by a cannon ball or otherwise, the bones being unequally broken and not properly covered; extensive mortification; white swellings of the joints; large exostoses; ulcers attended with extensive caries; cancer or other incurable ulcers; varicose kinds of tumors; particular distortions of the bones.

Amputation may also be sometimes necessary from violent hemorrhagies of some principal artery during the cure of a fractured limb, or from such a purfuse discharge of matter taking place that the strength of the patient is exhausted. Lacerated and contused wounds may require amputation, on account of hemorrhagy ensuing which cannot be stopped. Extensive mortification may take place, and such large quantities of matter be formed, that the patient will be unable to bear up under the discharge.

Where part of the limb is carried off, it is necessary to amputate higher up, so as to cut the bone, as well as the soft parts, in such a manner as may admit of a much speedier and safer cure. When mortification occurs, every thing ought to be done for the support of the patient till the disease be stopped; the first sign of which is, the appearance of an inflamed circle between the diseased and sound parts. As soon as the diseased begin to separate from the sound parts, amputation of the limb ought to be performed, and no time ought now to the lost, lest the patient suffer from the absorption of putrescent matter.

Amputation.

No part of surgery is brought to greater perfection than the manner of performing amputation. Before the invention of the tourniquet, and the method of securing the vessels by ligature, the operation was seldom undertaken; and a great proportion of those upon whom it was performed died soon after. In the present improved method, one death does not happen in twenty, or even thirty cases. In performing the operation, particular attention is to be paid to the spot where the incision is to be made; the quantity of skin and cellular substance necessary to be saved, so as to cover the muscles and bone completely, without being stretched; cutting the muscles in such a manner that they may unite with each other and entirely cover the end of the bone; the prevention of hemorrhages during the operation; the tying of the arteries alone, without including the nerves or any of the contiguous parts; securing the integuments so as to prevent them from retracting after the operation; and a proper subsequent treatment of the case.

407 Method of performing amputation.

The following are the general steps of the operation: The patient being properly placed, with assistants to attend, and the apparatus in proper order, the flow of the blood to the limb is to be stopped by the tourniquet (fig. 16.). The first incision is to be made through the skin and cellular substance by one, or rather by two, strokes of the amputating knife represented in fig. 116. These are next to be separated from the muscles, as far as may appear sufficient for covering the stump. The separated skin or flap should be strongly drawn up, or what perhaps answers better, turned up all round the limb, leaving this part of the muscles quite bare. The flap is to be kept in this situation by an assistant, while the operator makes the next incision at the edge of the reflected skin, and cuts till he comes to the bone. This incision should be begun on the lower side of the limb, that the blood may not prevent the eye from readily following the edge of the knife during the whole cut. The muscles are now to be separated from the bone as high as may enable them afterwards completely to cover it. The soft parts in general are then to be drawn up by retractors, which may be either of leather, as in fig. 117. or metal, as in fig. 118. *a* and *b*. The periosteum is to be divided at the place where the saw is to be applied; but no part of the bone is to be denuded of this membrane, which is afterwards to cover the stump, otherwise troublesome exfoliations may ensue. At this place the saw (fig. 119.) is to be applied and the bone divided with long steady strokes. In this part of the operation a good deal depends upon the steadiness of the assistant who holds the limb; for if it be held too high, the motion of the saw will be impeded; while the bone may be splintered if it be not sufficiently raised. Any points or splinters which may be left should be immediately removed with the pincers (fig. 120.). The retractors are now to be laid aside, and the principal arteries separated from the nerves, and secured by the tenaculum (fig. 17.), or forceps (fig. 120. *a*), and ligatures.

The tourniquet should next be a little slackened, to allow the different branches to be discovered: The clotted blood is to be cleared away with a warm sponge. The patient should get some warm cordial drink, and all the arterial branches which can be discovered ought to be taken up. The ends of the ligatures are then to be cut of such a length as to allow them to hang without the lips of the wound. The muscles and skin are now to be drawn down and brought into

Amputating the Arm and Fore-arm.

into close contact, that the ſtump may by completely covered. The parts are next to be ſecured by proper bandaging; and if the operation has been properly performed, the cure will commonly be made by the firſt intention, and may be completed in the courſe of three or four weeks, and ſometimes in a ſhorter period. This however muſt depend much upon the conſtitution of the patient, as well as the manner of performing the operation.

Sect. II. *Of Amputating the Arm and Fore-arm.*

Amputation of the arm is performed according to the rules already laid down. No more of it ſhould be removed than is diſeaſed; for the longer the ſtump is, the more uſeful it proves. The tourniquet is to be applied a little above the part where the operation is to be performed: As much of the integuments ſhould be ſaved as may be perfectly ſufficient for covering the ſore. In taking up the artery after the bone has been divided, the operator ought to be attentive not to include the radial nerve, which may be readily diſcovered and ſeparated, as it lies cloſe upon the fore part of the artery. The fore-arm is to be amputated nearly in the ſame manner as the leg; only that the ſtump may be covered by amputating with the double inciſion, without the aſſiſtance of a flap, which it is neceſſary to form in the leg.

Sect. III. *Of Amputating the Thigh.*

408 Method of performing the amputation.

In performing this operation, the patient ought to be placed upon a table of ordinary height, with the diſeaſed limb ſupported and ſecured by an aſſiſtant ſeated before him, while other aſſiſtants take care of the other leg and the arms. The courſe of the blood is to be ſtopped by applying the tourniquet over the trunk of the femoral artery, near the upper part of the thigh. No more of the thigh ought to removed than is rendered neceſſary by the diſeaſe, as the more of it is left, the more uſeful it will be to the patient. An aſſiſtant ſhould graſp the limb with both hands a little above the place where the ſkin is to be divided, and draw it up as far as poſſible; while the operator, ſtanding on the outſide of the limb, makes a circular inciſion down to the muſcles by one or two ſtrokes of the knife. As much of the integuments is then to be diſſected with a ſcalpel from the muſcles as may cover the ſtump completely; and this part of the ſkin may either be turned back, or drawn tightly up by an aſſiſtant. The muſcles may then be divided quite acroſs to the bone by the edge of the ſkin, in the common way, or cut obliquely upwards, according to the method of Allanſon, ſo as to lay the bone bare two or three fingers-breadth higher than is done in the common way. The muſcles are next to be ſeparated from the bone with a ſcalpel a little way, that a ſufficient quantity may be left for covering the end of it. The reſt of the operation is to be performed exactly according to the general rules laid down in the firſt ſection of this chapter. The muſcles and integuments are to be drawn over the end of the bone, and applied cloſely together, that the ſkin may completely cover the ſtump, and retained in this ſituation by an aſſiſtant till a flannel or cotton roller, according to the ſeaſon of the year, which has been previouſly fixed round the body, be applied in ſuch a manner as to ſupport and fix them. For which purpoſe it ſhould be paſſed two or three times, in a circular direction, round the top of the thigh, and ſhould afterwards, with ſpiral turns, be brought down near to the end of the ſtump and faſtened with pins; and it ſhould not be tighter than may be ſufficient to aſſiſt the plaſters in preventing retraction.

409 Of dreſſing the ſtump.

The ends of the divided muſcles are now to be laid exactly over the bone; and the edges of the ſkin are to be brought into contact, either ſo as to form a ſtraight longitudinal line, according to the method of Mr B. Bell, &c.; or they are to be placed horizontally, "that the wound may appear only in a line with the angles at each ſide," as adviſed by Allanſon. The ligatures may either hang over the edges of the wound, or be brought to the angles. After the edges of the ſkin are in this manner exactly applied to each other, either a few ſlips of adheſive plaſter are to be laid acroſs the face of the ſtump, or two large pieces of adheſive plaſter, with ſeveral pieces of tape fixed to them, are to be applied to the ſurface of the ſkin. The tapes are then to be tied with a running knot immediately over the wound; by which the parts will be kept ſo cloſely together as to prevent any collection of matter from being formed. The whole ſurface of the ſtump ſhould next be covered with a large pledget ſpread with an emollient ointment, over which a compreſs of fine tow is to be put, and retained in its place by a broad croſs ſtrap of old linen paſſing ſome way up the thigh, ſo as to be ſecured by the roller, which is now to be paſſed two or three times round the ſtump; and the preſſure formed by the croſs ſtrap may afterwards be increaſed or diminiſhed at pleaſure, by drawing it with more or leſs tightneſs, and fixing it with pins to the roller. While the ſtump is dreſſing, the tourniquet is removed, but replaced again looſely to enable the attendants to check any hemorrhagy which may afterwards enſue.

Amputating the Thigh.

410 Treatment of the patient after the operation.

The patient is now to be laid to reſt, and the limb is to be placed upon a little tow covered with linen, or upon a thin ſoft pillow; and to prevent the patient from involuntarily moving the limb, and to guard againſt ſpaſmodic ſtartings, which frequently happen after this operation, it may be fixed to the bed by two ſtraps. A baſket or hooped frame ought to be placed over the ſtump to protect it from the bed-clothes. The patient ſhould immediately get an anodyne draught, which will generally procure eaſe through the reſt of the day. For this purpoſe, no more light ſhould be let into the room than is merely neceſſary for allowing the attendants to pay attention to the ſtump. As hemorrhagies ſometimes appear ſeveral hours after the operation, the perſon who takes the charge of the patient ſhould watch this circumſtance with the greateſt attention. If there be only a ſlight oozing of blood, there is no occaſion for being alarmed; but whenever it appears to proceed from a large artery, it muſt be ſecured. The ſpaſmodic affections which frequently occur after amputation are ſeldom troubleſome, unleſs ſome nerve has been included in ſecuring the arteries; but when they do appear, laying the limb in the eaſieſt poſture, and giving opiates, are the principal means of procuring relief.

To prevent inflammation as much as poſſible, the patient is to be kept upon a ſtrict antiphlogiſtic regimen, and his bowels kept open by laxative clyſters, till the inflammatory ſtage is over, which will generally be in a few days. If, notwithſtanding this treatment, the ſtump ſwells, and the patient complains of pain and thickneſs, we ought to endeavour to diſcover from what cauſe the uneaſineſs originates. If it be owing to the ſtraps being too tightly fixed, they muſt be ſlackened. If the ſtump be found much ſwelled, a ſaturnine ſolution ſhould be applied by means of ſeveral folds of linen; and if the patient be young and plethoric, he ought to loſe a few ounces of blood from the arm; but if he is weak and emaciated, a different mode of treatment muſt be followed.

At the end of the third, or fourth day at fartheſt, the ſtump ſhould be examined; and if it appear ſomewhat open and flaccid, the parts muſt be brought cloſer together and ſecured more firmly. After this time the dreſſings ſhould be renewed every day, or every ſecond day. In about a

week

Amputating the Leg.

week after the operation the ligatures may generally be removed with eaſe; but if they do not ſeparate readily, they may be gently pulled at every dreſſing, when they will, in a ſhort time, be brought away, and the wound will be ſoon healed by the firſt intention. The roller ſhould be cleaned and renewed as often as it is found ſullied; nor ſhould it be laid entirely aſide till the end of the third or fourth week after the operation. When the roller is removed, we may depend upon the ſtraps or tapes for keeping the parts together till the cure be quite accompliſhed. When the inflammatory ſymptoms are entirely gone, no medicines ought to be given which would debilitate the patient, nor is any thing more neceſſary than to keep the bowels gently open till a complete cure be made.

Sect. IV. *Of Amputating the Leg.*

The leg may be amputated for a diſeaſe in the foot at two different parts; the one a hand-breadth under the knee, the other a little above the ankle. The former makes a ſufficient ſupport for the body to reſt upon an artificial leg; but the latter does that equally well, and likewiſe preſerves the motions of the knee.

411 Amputation of the leg near the knee.

In performing the operation a little way under the knee, the patient is to be placed and ſecured in the ſame manner as in operating upon the thigh. The tourniquet is to be placed a little above the knee, with the cuſhion upon the artery in the ham. The ſurgeon places himſelf upon the inſide of the leg, and makes a circular inciſion through the integuments down to the muſcles. The place where the inciſion ſhould be made muſt depend upon the length of the limb; but in general it may be between ſix and ſeven inches under the top of the tibia in an adult, or far enough down upon the limb to ſave as much integuments as will cover the ſtump. After the integuments are cut through in the manner already directed, as much of the muſcles are to be divided by the knife as can be done by a circular inciſion; and the interoſſeous parts are to be divided by a ſcalpel or catline, (fig. 121.). The retractors are then to be applied, and the bone ſawed off immediately below the inſertion of the tendons of the flexor muſcles. In ſawing, the operator ought to begin upon both bones at the ſame time, that he may finiſh upon the tibia, leſt ſplinters ſhould be formed. The veſſels are next to be ſecured; the ſoft parts drawn over the bones; the adheſive plaſters and other bandages applied in the ſame manner as directed for amputating the thigh, only that here the roller need not be applied ſo high as in the former operation. Two or three turns above the knee, however, are neceſſary to prevent the dreſſings from ſlipping down.

412 At the ankle.

In amputating upon the ankle, the operator ſhould fix upon that ſpot which will leave the ſtump of ſuch a length as may be moſt convenient for being fitted with an artificial machine reſembling the other leg. Nine inches from the joint of the knee, in a leg of ordinary length, was found by Mr Wilſon, a late ingenious artificial limb-maker in Edinburgh, to be the beſt part ſuited to this purpoſe, on account of the equal preſſure it makes upon the ſurface of the leg, without making any upon the end of the tender ſtump. The operation is performed in the ſame manner as that a little below the knee.

Sect. V. *Of Amputating at the Joints of the Extremities.*

The circumſtances moſt to be attended to in performing amputation at the joints are, firſt to ſtop the circulation by the tourniquet; or, where that is impracticable, to take up the trunk of the artery by a ligature; to make a circular inciſion in ſuch a place as may, after the operation is over, be ſufficient to cover the wound: Then a longitudinal inciſion is to be made upon the oppoſite ſides of the limb, extending from the joint to the circular cut, and as deep as the bone, by which two flaps will be formed to cover that part of the joint which remains after the operation is finiſhed. The ligaments of the joint are next to be divided, and the affected limb or part of the limb removed.

Amputating at the Joints of the Extremities.

After this part of the operation, it was formerly a frequent practice to ſcrape off the remaining cartilage, to unite the parts more firmly together. But this is now found to be unneceſſary; for when the fleſh is applied properly to the bone, if it do not grow to it, the union at leaſt is ſo cloſe that it afterwards gives no inconvenience to the patient.

Any branches of arteries which may have been cut during the operation are now be ſecured; clotted blood is to be removed; and the muſcles and ſkin are to be brought into cloſe contact with the ends of the ligatures hanging out of the wound. The parts are to be retained by adheſive plaſters, or twiſted ſuture, or both; and proper bandages applied in ſuch a way that a cure may be made by the firſt intention.

413 Amputation at the ſhoulder joint.

Amputating the arm at the ſhoulder-joint has always been conſidered as a dangerous as well as a difficult operation. It ſhould never be attempted, when the ſame purpoſe can be accompliſhed by operating lower down. But caſes occaſionally occur, where the life of the patient cannot, in any other manner, be ſaved.

Amputation may become neceſſary here in conſequence of abſceſſes of the joint; caries of the humerus reaching to the joint; compound fractures, eſpecially thoſe from gunſhot wounds, extending to the head of the bone; and of mortification.

In performing the operation, the patient ſhould be laid upon a table of convenient height, covered with a mattreſs. He is then to be brought as near to the edge of it as poſſible, and ſecured by aſſiſtants. The circulation of the blood in the arm is next to be ſtopped, by an aſſiſtant preſſing ſtrongly with a firm compreſs over the ſubclavian artery where it paſſes over the firſt rib; or an inciſion may be made along the courſe of the artery, which may be ſecured after ſeparating from it the contiguous nerves. When the artery is compreſſed, it will readily be known whether the compreſſion proves effectual, by obſerving when the pulſe at the wriſt is entirely ſtopped. As ſoon as this is the caſe, a circular inciſion is to be made through the integuments at the inſertion of the deltoid muſcle into the humerus. An aſſiſtant then draws the ſkin a little back, and at the edge of the retracted ſkin the muſcles are to be cut in a circular direction to the bone.

If the artery has not been taken up at the beginning of the operation, it is now to be ſecured, as well as any branches which come in the way.

The amputation knife is now to be laid aſide, and the reſt of the operation finiſhed with a ſtrong ſcalpel. A perpendicular inciſion is next to be made at a little diſtance from the outſide of the artery, beginning at the acromion, and terminating in the circular inciſion, cutting as deep as the ſurface of the bone. A ſimilar inciſion is to be made upon the back part of the arm, ſo that the flaps may be nearly of an equal breadth. The arterial branches are here to be ſecured; the flaps are to be ſeparated from the bone, guarding againſt wounding the trunk of the artery; the flaps are to be ſupported by an aſſiſtant; and the capſular ligament of the joint is to be cut from the ſcapula: and thus the arm will be entirely ſeparated.

After the arm has been ſeparated, any arteries which appear about the joint are to be tied, and all the ligatures brought over the edges of the wound. The parts are to be cleared of clotted blood, and the two flaps drawn over the wound,

Amputating at the Joints of the Extremities.

wound, and secured by the twisted suture. A pledget of any emollient should then be applied, and a sufficient cushion of lint, with a compress of old linen, put over the whole. A moderate pressure is next to be applied by a flannel roller; by which the parts will be supported, their union facilitated, and matter most likely prevented from being lodged. The treatment is then the same with that after amputation in other parts of the extremities. For two or three days after the operation, it is necessary that an assistant sit with the patient to compress the artery in case a bleeding should ensue.

414 At the wrist.

When it is necessary to amputate the whole hand, the operation may be performed at the wrist, so as to leave as much of the member as possible; and the same rules hold here as in amputating at any of the rest of the joints. The tourniquet is to be applied to the artery in the arm, and the cure is to be completed by the first intention. When any of the carpal bones are affected, the sore will not heal till they either work out by suppuration, or are cut out by the knife. When the middle of any of the metacarpal bones is diseased, while their extremities are sound, the trepan may be applied, and the diseased parts removed, while the remaining sound parts are perserved. But if the whole bodies of one or two of these bones be affected, while the rest remain sound, all the affected bones ought to be removed. In performing the operation, an incision, is to be made along the course of the part affected; and if the operator have it in his choice, the incision should be made upon the back part, so as to save the great vessels and nerves situated in the palm. The integuments are then to be dissected, and turned to each side; after which the diseased bones or parts of bones are to be removed, guarding as much as possible against wounding the principal arteries or nerves which lie near them.

The diseased parts are next to be separated; any arteries which happen to be cut are to be secured; and, on account of the free communication which they have with neighbouring branches, they ought to be tied at both cut ends. If after this a bleeding still continue, compress, styptics, and other remedies proper for stopping blood, are immediately to be used. The sides of the wound are to be brought together, and an attempt made to cure them by the first intention.

415 At the joints of the fingers.

In amputating the fingers, it was formerly the practice to operate upon the bodies of the bones in the same manner as in the larger extremities; but at present the removal at the joints is more frequently practised.

In performing the operation, it is necessary to save as much skin as may cover the stump, and this ought to be done upon the side next the palm, so as to guard against the effects of friction. The general steps of the operation are the same with those for amputation of the larger joints.

A circular incision is to be made on the finger by a crooked bistoury, about the middle of the phalanx, and it may be carried at once to the bone. Another incision is to be made with a common scalpel at each side of the finger, beginning at the circular one and continuing it to the joint, by which two flaps will be left to cover the stump. The ligaments of the joint are now to be divided, and the bone removed. The blood-vessels are to be secured by ligature, and the flaps exactly applied to each other; but in order to protect the end of the bone completely, a small portion may be cut from the uppermost flap. The flaps are to be retained by adhesive plaster, or by the twisted suture; but if the latter be used, the tendons ought to be avoided. Over the sore an emollient pledget is to be applied, and then a compress and roller. If the disease be so situated, that instead of amputating at the cavity of the joint, the surgeon shall think proper to operate upon the body of the bone, flaps are to be formed as above, and the bone is to be divided by means of the small spring saw, fig. 122.

Amputating at the Joints of the Extremities.

416 At the hip joint.

The amputation of the thigh, at the hip joint, has always been considered as one of the most formidable operations in surgery; so much so, that very few cases appear on record of its having ever been put in practice. In the Medical Commentaries of Edinburgh, an instance is recorded where the thigh was amputated at this joint, and where the patient survived the operation 18 days, and then died from a different cause, when all risk of hemorrhagy was over, and when the sore had even a favourable appearance, which shows at least that the operation has been done with safety. It certainly ought never to be done, however, unless as the last resource, and when the life of the patient is in absolute danger; and then only when as much skin and muscles can be saved, as will cover the sore, and when there is also a probability of being able to stop the hemorrhagy, and prevent it from returning.

When the operation is to be performed, the patient is to be laid upon his back on a table, and properly secured by assistants; one of whom should be ready with a firm cushion to press, if necessary, upon the top of the femoral artery, just after it passes from behind Poupart's ligament to the thigh. A longitudinal incision is now to be made through the skin, beginning immediately under the ligament, and continuing it downwards along the course of the artery for about six or seven inches. The aponeurosis of the thigh is then to be divided by gentle scratches till a furrowed probe can be introduced, when the opening is to be dilated by means of a scalpel, till two or three inches of the artery be laid bare. A strong ligature is now to be put under the artery by the assistance of a curved blunt-pointed needle.

The part where the ligature should be passed is immediately above the origin of the arteria profunda; for if that artery be not affected by the ligature, the patient might suffer by the loss of blood during the rest of the operation. The ligature is now to be secured by a running-knot: Another ligature is to be introduced a little below the former, and likewise secured; the artery is then to be divided between the ligatures. A circular incision is now to be made through the integuments of the thigh, about six inches from its upper end. The retracted skin is then to be pulled at least an inch upwards; and at the edges of it the amputating knife is to be applied, so as to cut the muscles down to the bone. This being done, a cut is to be made upon the posterior part of the thigh, beginning a little higher than the great trochanter, and continuing it down to the circular incision, and as deep as the joint. A similar cut is to be made on the anterior part of the thigh, at a small distance from the artery, and this reaching likewise down to the bone. The two muscular flaps are to be separated from the bone and joint, and held back by an assistant. Every artery which appears is now to be secured. Then the capsular ligament, and next the round one, are to be separated from the acetabulum; by which means the limb will be removed from the body. The acetabulum and neighbouring bone are next to be examined; and if they appear sound, the case will be more favourable; but at any rate, a cure is to be attempted by the first intention. For which purpose, after removing all the clotted blood from the surface of the wound, and bringing the ligatures over the edges of the skin, the muscles are to be placed as nearly as possible in their natural situation; and drawing the flaps together, so as to cover the wound in the most accurate manner, they are to be kept in this situation by adhesive plaster, and

by

Removing the Ends of Carious Bones in the Joints.

by the twiſted ſuture and other dreſſings, as in amputating at the under part of the thigh. The dreſſings are to be retained by a broad flannel roller paſſed three or four times round the body, and ſpirally over the ſtump, and ſecured. The patient is then to be laid in bed on the ſound ſide, and treated as for amputation in other parts of the body; only that greater attention is neceſſary, as there is no aſſiſtance from a tourniquet. Uncommon attention will alſo be neceſſary to prevent inflammation, and every ſymptom of fever which may ſucceed to the operation.

417 At the joints of the foot.

When the foot is ſo much diſeaſed as to require amputation, the operation might be performed at the point of the ankle; but for the reaſons given, when treating of amputation of the leg, it is found better to do it above the ankle. When a conſiderable part remains ſound, it ought to be ſaved. If any of the tarſal bones are affected, theſe are to be removed. When the middle or whole body of any of the metatarſal bones are diſeaſed, they are to be removed in the ſame manner as directed for ſimilar operations in bones of the hand; and if even two of them remain ſound, provided they be ſo placed as to ſupport the toes, they ought to be preſerved, as it is known that, by proper treatment, an oſſeous matter may afterwards fill a conſiderable part, if not the whole, of the void; or if any cavity remain, it may be ſo ſtuffed that the uſe of the foot may ſtill be enjoyed.

In performing an operation of this kind, the patient ſhould be laid upon a table, and the tourniquet applied in the ham to prevent hemorrhagy. An inciſion is then to be made along the affected part; and if the ſeat of the diſeaſe admit it, the inciſion ſhould be made upon the upper ſide of the foot ſo as to ſave the ſole. The integuments are to be ſeparated and turned to each ſide, to allow the affected parts to be completely removed.

The principal veſſels and nerves are to be ſaved as much as poſſible; but if any particular artery be cut, it is to be ſecured, and the part treated as after the removal of ſimilar parts of the hand.

418 Of the toes.

The amputation of the toes is exactly ſimilar to that of the fingers.

Sect. V. *Of removing the Ends of Carious Bones in the Joints.*

In compound fractures, the ends of bones, when they protruded in ſuch a manner, that they could not otherwiſe be returned, have frequently been ſawed through; and their place has frequently been ſupplied by a renewal of bone, ſo as to preſerve the ordinary uſe of the limb. Many caſes have likewiſe happened, where a large part of the body of the bone has been thrown out by ſuppuration, and its place ſupplied; and a few are upon record, where either the whole of a bone, or that end next the joint, has been thrown out, and its place filled up with callus, ſo that no inconvenience has been felt. From theſe circumſtances, Mr White of Mancheſter was led to preſerve an arm by ſawing off the head of a diſeaſed humerus; and Mr Park of Liverpool, to ſave a limb, by ſawing off the ends of the bones, in a caſe of white ſwelling of the knee. When therefore it happens that the end of a bone is diſeaſed, while the other parts are ſound, the diſeaſed part may be removed, and the ſound one ſaved, ſo as in a great meaſure to preſerve the free uſe of the limb.

In performing the operation, the firſt ſtep ſhould be, to uſe ſuch means as may enable the operator to have a full management of the circulation of the part affected. Then a longitudinal inciſion of ſufficient length, and perhaps another acroſs it, may be neceſſary to be made through the ſoft parts of the joint; and this opening ought to be at a diſtance from the large blood-veſſels, that they may be in no danger of being injured. After the end of the diſeaſed bone is ſufficiently laid bare, it is either to be brought out of the joint, or a ſpatula or ſome other proper ſubſtance is to be introduced between the bone and ſoft parts, ſo as to defend the latter in time of ſawing the bone. After the diſeaſed part of the bone is removed, the arterial branches are to be ſecured, and the wound treated like any other wound of equal ſize.

Diminiſhing Pain in Surgical Operations.

During the cure the limb ought to be kept in the poſture moſt favourable for the removal of the bone, and afterwards for the preſervation of the natural motion of the joint.

In this way a limb may ſometimes be ſaved which would otherwiſe have been removed. But though the removal of the diſeaſed end of one bone may be readily effected, the removal of all that part of the bones which enters into the compoſition of a joint muſt be attended with ſo much inconvenience, that it can ſeldom be uſeful, unleſs it be where the ends of bones are deſtroyed by external violence; for then it appears that this operation may be performed with conſiderable ſucceſs.

Chap. XXXV. *Of Diminiſhing Pain in Surgical Operations.*

The pain induced by ſurgical operations may be leſſened in two different ways. The firſt is, by diminiſhing the natural ſenſibility of the ſyſtem; and for this purpoſe narcotics of different kinds, and particularly opium, have been uſed; but theſe are apt to induce diſagreeable ſymptoms, eſpecially ſickneſs and vomiting, which might be attended with bad conſequences after ſome operations. They are therefore ſeldom employed before an operation. When, however, they are given immediately after it, and repeated as circumſtances may require, they often give great relief.

The other method of diminiſhing pain is, by leſſening the ſenſibility of a particular part of the body. It has long been known, that the ſenſibility of any part may not only be leſſened, but entirely ſuſpended, by compreſſing the nerves which ſupply it. From a knowledge of this circumſtance, an inſtrument (fig. 123.) was invented ſome years ago by Mr James Moore of London, by which the principal nerves of a member might be ſo compreſſed as to render the parts below perfectly inſenſible. A difficulty, however, ariſes here; for as the nerves muſt be compreſſed at leaſt an hour previous to the operation, in order to render the parts quite inſenſible, and as it is extremely difficult to compreſs the nerves without at the ſame time affecting the veins, the latter are therefore in danger of being burſt. To prevent this inconvenience, Mr Moore propoſes to open a vein; but this might be attended with bad conſequences in weakly conſtitutions. Beſides, it is ſaid, that by compreſſing the nerves in this manner, although leſs pain may be felt in the time of the operation, it is proportionally greater after the compreſſion is removed. In certain parts of the body, however, where ſufficient compreſſion can be made upon the nerves without acting much upon the veins, it would appear that the method may be practiſed with advantage; though it has not yet been done, excepting in a few inſtances.

Chap. XXXVI. *Of Bandages.*

The proper application of bandages is an object of great importance in ſurgery: and though dexterity is only to be acquired in this branch by practice, yet a few general rules may be found uſeful. Bandages are employed for the retention of dreſſings, for ſtopping hemorrhagies, for removing

Bandages. moving deformities, and for effecting the union of divided parts. They ought to be formed of ſuch materials as are ſufficiently firm, while, at the ſame time, they give no uneaſineſs to the parts to which they are applied. They may be compoſed either of linen, cotton or flannel. Of late years the two laſt have been preferred by many for their warmth and elaſticity, on which account they are certainly moſt proper, eſpecially in winter; and likewiſe in caſes where the parts are liable to ſwelling and inflammation, as in wounds, luxations, and fractures. Beſides, they more readily abſorb any moiſture which may be diſcharged from the ſores.

When firſt applied, they ſhould be clean, ſufficiently ſtrong, and as free of ſeams as poſſible. They ſhould be ſo tightly applied as to anſwer the purpoſe for which they are intended, without being in danger of impeding the circulation. They ſhould be applied in ſuch a manner that they may be eaſily looſened, and the parts examined with as much accuracy as poſſible; and they ſhould be laid aſide as ſoon as the purpoſe for which they are intended is accompliſhed; for when longer continued, they frequently impede the growth of the parts upon which they are applied.

419 Bandages for the head. With reſpect to bandages for particular parts, we ſhall begin with the head, and then proceed to the trunk and extremities. The *couvre chef* of the French, which is a ſquare napkin folded cornerwiſe, is moſt frequently uſed where a bandage is wanted for the head; but a nightcap, having a band to go round the head, and another to tie under the chin, appears to be more ſuitable for this purpoſe. For making compreſſion on any particular part of the head, as for ſtopping of bleeding veſſels, the radiated bandage may be employed.

For keeping the edges of wounds together, as in caſes of longitudinal cuts of the head, or of any other parts, the uniting bandage is uſually employed, and is always to be preferred to ſutures, where it retains the edges of the wound with ſufficient exactneſs. For retaining dreſſings upon the eyes, ſeveral turns of a roller have been uſed, and it is termed *monoculus* or *binoculus* according to its being applied to one or both eyes; but the *couvre chef*, and the nightcap already mentioned, are leſs apt to ſlip, and therefore found more convenient for this purpoſe

420 For the face. For fractures of the noſe, or wounds there, or on any other part of the face, the uniting bandage anſwers beſt. And in caſes of fracture of the lower jaw, a four-headed roller is moſt convenient: the hole in the centre of the roller receives the chin, and aſſiſts in preventing the bangage from ſhifting. The two upper heads are to be carried backwards; and being made to paſs each other at the occiput, they are afterwards brought once or twice round the head. The two under heads of the roller being reflected over the chin, are then to be turned upwards and fixed on the upper part of the head.

421 For the neck. The bandages neceſſary for the neck are, the machine already mentioned after the operation of bronchotomy, and one uſed in caſes of wry neck. For every other purpoſe of bandaging a common roller may anſwer perfectly well.

For fractures of the ſcapula the application of a long roller may be of ſervice.

422 For the breaſt. For retaining dreſſings upon the thorax the napkin and ſcapulary are commonly, and very properly uſed; and when the napkin is employed merely for retaining dreſſings, it need not be longer than to paſs once round the body; but if it be uſed for making preſſure over a fractured rib, it ought to paſs two or three times round. For both purpoſes its breadth ought to be ſix or ſeven inches for an adult.

The ſame kind of bandages is alſo uſed for making preſſure on the abdomen, as in caſes of umbilical or ventral hernia; and to keep the bandage properly placed, a ſcapulary is uſed for preventing it from ſlipping down, and one or two ſtraps connected with it behind, are brought between the thighs, and fixed to it before to prevent it from moving up. A bandage of flannel, and different kinds of belts, are contrived for compreſſing the abdomen in the operation of tapping; and truſſes of various conſtructions are uſed for the retention of the protruded bowels in caſes of hernia.

Method of opening a dead Body.

423 For the belly.

Bandages of cotton or flannel are uſed for ſupporting the ſcrotum in the various diſeaſes which may occur there, as well as after the operations performed upon it.

424 For the ſcrotum and penis.

One of the beſt bandages for the penis is a linen or cotton bag, fixed by a roller round the body.

425 For the anus. For retaining dreſſings about the anus, or between that part and the ſcrotum, the T bandage is commonly uſed; and it is made either with one or two tails, according to the ſituation of the part to which it is to be applied.

426 For fractures. In ſimple fractures, and moſt of the other diſeaſes of the arm, fore-arm, and hand, the roller is the bandage commonly uſed; but in compound fractures of theſe parts, as well as in the different kinds of fractures of the lower extremities, the 12 or 18 tailed bandage is neceſſary.

427 For wounds of the extremities. For longitudinal wounds of the extremities, the uniting bandage is uſed with the ſame advantage as has been already mentioned for wounds of a ſimilar nature upon the head.

Chap. XXXVII. *The Method of opening a dead Body.*

Surgeons are often called, in order to inveſtigate the cauſe and ſeat of diſeaſes and death, either by the relations of the deceaſed, or the magiſtrates to whom a report is to be made; therefore, at the time of performing this operation, minutes ſhould be taken of what is obſerved. The inſtruments, and all things neceſſary, ſhould be diſpoſed in order, as for any other operation: as knives, a razor, a great and ſmall ſaw, ſciſſars ſtraight and curved, elevators, needles threaded, ſponges, tow, ſaw-duſt or bran, baſons with water, towels, and receivers for the viſcera when they are to be taken out of their cavities. The body is to be laid upon a ſuitable table, advantageouſly placed for the light, having a cloth thrown over the parts which decency demand ſhould be concealed, eſpecially in females.

When it is intended only to inſpect the abdomen and its contents, a longitudinal inciſion from the xiphoid cartilage to the os pubis, interſected by a tranſverſe one at the navel, will give a fair opportunity of anſwering theſe purpoſes, when the angles are reverſed. Should it be required to examine all the three cavities, and the parts contained in them, we are to begin by opening the head, making an inciſion quite croſs to the bone, from ear to ear; which ſection is preferable to the crucial, commonly made on this occaſion; then the ſcalp may be eaſily diſſected from the ſkull, and turned down over the face, and towards the neck, giving room for the ſaw. The head muſt be held very ſteadily by an aſſiſtant during the ſawing, which ſhould be begun on the middle of the frontal, proceeding to each temporal bone, and ſo to finiſh the circle upon the middle of the occipital bone; which may generally be done conveniently enough, by raiſing the head and inclining it forward after having proceeded as far as this bone; or the body may then be turned prone, ſhould that poſture be found more convenient to complete the circle. The cap of the ſkull is then to be raiſed with the elevator, occaſionally cutting the adheſions of the dura mater; after this the encephalon is to be removed, carefully ſeparating the other attachments of the membrane.

428 Method of opening the cranium.

In order to bring the thorax and abdomen, with the parts

Method of opening a dead Body.

contained in these cavities, under one view, an incision is to be made on each side of the sternum, in the course of the cartilages of the ribs which are annexed to it; dissecting from thence the muscles with the teguments, the space of two or three inches towards the spine; then cutting through the cartilages, which will be seen, and easily divided with a knife a little curved near the point; then the incisions are to be continued from the sternum through the abdominal cavity, in an oblique direction, to each ilium or inguen; after which the clavicles are to be separated from the sternum, or this bone divided at its superior cartilaginous junction, with a strong knife, dissecting it from the mediastinum, and turning it downwards with the muscles, &c. of the abdomen. This is the most eligible manner of opening these cavities, and gives an opportunity of sewing them up with a better appearance for any person's view afterwards. That kind of stitch called by sempstresses the *herring-bone* or *flat seam* has a very pretty and neat effect upon these occasions.

429 Of opening the thorax and abdomen.

If it is proposed to take out the thoracic and abdominal viscera together, for further examination, the diaphragm is first to be cut down to the spine on both sides; then, to avoid being incommoded with blood, &c. two very strong ligatures are to be passed round the œsophagus and large blood vessels, in which the trachea may be included; tying them strait, and then dividing these parts between the ligatures: the same measures are to be taken in respect to the inferior vessels upon the lumbar region, a little above the bifurcation of the aorta, including the vena cava; and also upon the rectum. After having observed these precautions, the viscera, with the diaphragm, are to be removed by a wary dissection, all the way close to the spine; and by gently drawing them at the same time, the separation will be greatly facilitated.

When the thoracic and abdominal viscera are to be taken out separately, in the first case ligatures must be made, as have been described upon the vessels, &c. just above the diaphragm, and in the other just below it, and upon the rectum.

430 When the body is become putrid, how it is to be managed.

Should we be called upon to perform this office when the body is become very putrid, it will be absolutely necessary to have such parts of it well washed with warm vinegar and brandy, and then sprinkled with lavender-water or some such odoriferous antiputrescent liquor, before the examination, in order to correct the stench, and defend us against the noxious quality of the effluvia; a precaution, the neglect of which may be attended with very direful effects.

Chap. XXXVIII. *Of Embalming dead Bodies.*

Embalming dead Bodies.

In the early ages of the world, the practice of embalming dead bodies was very common, particularly among the Egyptians; but it has long been disused in almost all countries, except for great personages. See Embalming. The following directions are taken from Mr. Gooch, to whom they were communicated by a person of great character, and well acquainted with the modern practice of embalming in Britain.

After evisceration, as has been directed in opening a dead body, and continuing the incision farther upwards, even into the mouth, and, if practicable, without cutting the skin of the neck, all the cavities are to be well cleansed, and the humidity sucked up with sponges, then washed with *tinct. myrrhæ*, and filled with spices compounded of fragrant herbs, aromatic drugs, and gums reduced to powder, not very fine, first restoring the heart to its former residence, after having opened its ventricles, cleansed and washed them with the tincture, stuffed them with the spices, and sewed them up; and then the cavities are to be stitched very close with the glover's or spiral suture. Large and deep incisions are also to be made in all the most fleshy parts, cleaning and washing them with the tincture in the same manner, filling them with the antiseptic spices, and stitching them up. Then the head, trunk, and limbs, are to be perfectly well covered with cerecloth; putting a piece under the chin, to be secured by sewing on the top of the head, after having well adjusted the cap of the skull, sewed the scalp together, and cleaned the mouth, as has been directed for the other parts, and putting in some of the spices. The cerecloth is to be prepared, according to art, with a conposition made of wax, rosin, storax, and painter's drying oil. After the application of the cerecloth, with great care and exactness, cut into suitable pieces according to the respective parts, and closing them well everywhere, the face being close shaved, is to be covered with some of the above composition melted, and laid on with a brush of a proper degree of heat, and of a moderate thickness; which may have a faint flesh-colour given it with vermilion; and when it is grown cold and stiff upon this part, it may be lightly covered with hard varnish; or this varnish, applied thick, may here serve the purpose alone. A cap is to be well adapted to the head, falling down upon the neck, and to be sewed under the chin, making a few circular turns about the neck with a roller of a proper breadth. All the rest of the corps is to be inclosed in a sheet, to be artfully cut, and sewed on very close and smooth, with the finest tape, and the *flat seam* mentioned in the preceding chapter; over which an appropriate dress is to be put, as the relations or friends think fit to direct and appoint, and then laid into the coffin, which should be in readiness: but when it is some great personage, who is to lie in state for public view before the funeral rites are solemnized, the dress-must be appropriated to his dignity and character. The brain and other viscera are to be put with some of the spices into a leaden box. Sometimes the heart, prepared as has been directed, to preserve it from putrefaction, is deposited in an urn by itself.

I N D E X.

Surinam ‖ Surname.

SURINAM, the capital of the Dutch ſettlements in Guiana, ſituated on a river of the ſame name, in N. Lat. 6. 16. W. Long. 56. 0. It gives name to the country for 100 miles round; and ſtands on a river of the ſame name, which is navigable for 30 leagues up the country. A ſettlement was formed at Surinam in 1650 by the Dutch, who preſerved poſſeſſion of it ever ſince. The chief trade conſiſts in ſugar, cotton, coffee of an excellent kind, tobacco, flax, ſkins, and ſome valuable drugs for dyeing. Four hundred and thirty plantations have been already formed on the banks of the Surinam and the adjacent country, which in 1775 yielded 24,120,000 weight of rough ſugar, which were ſold in Holland for 347,225 l. Sterling; 15,000,387 lb. weight of coffee, which ſold for 357,538 l; 970,000 lb. weight of cotton; 790,854 lb. weight of cocao; 152,844 lb. weight of wood for dyeing. The ſum total of theſe productions amounted to 822,905 Sterling, and was brought into the harbours of the republic in 70 veſſels. The number of ſlaves employed in the ſame year was 60,000, who belonged to 2824 maſters, excluſive of the women and children. The white people were of different countries and different religions.

Raynal's Hiſtory of the Settlements and Trade of the Eaſt and Weſt Indies.

Connected with Surinam, we may mention the colonies of Demerary, Iſſequibo, and Berbice, which lie a little to the weſt. The two firſt ſurrendered to the Britiſh troops in 1781; but being left defenceleſs, were retaken by a French frigate. Demerary has lately been taken a ſecond time by the army of Great Britain. It is conſidered as a valuable acquiſition, being a flouriſhing colony. In 1769 there were eſtabliſhed on the banks of the Demerary 130 habitations, in which ſugar, coffee, and cotton were ſucceſsfully cultivated, and ſince that period the number of plantations hath increaſed much.

Iſſequibo is a very inconſiderable ſettlement. Berbice, which lies between Demerary and Surinam, contains about 104 plantations, moſt of them ſmall, and ſcattered at great diſtances from one another upon the banks of the Berbice or of Conje. When Raynal publiſhed the laſt edition of his Hiſtory of Settlements and Trade in the Eaſt and Weſt Indies, the population conſiſted of 7000 ſlaves of every age and ſex, 250 white men, excluſive of the ſoldiers. The coffee, ſugar, and cotton produced was conveyed to Holland in four or five ſhips, and ſold for about 40 or 50,000 l.

SURMOUNTED, in heraldry, is when one figure is laid over another.

SURMULLET. See MULLUS.

SURNAME, that which is added to the proper name for diſtinguiſhing perſons and families. It was originally diſtinguiſhed from *ſirname*, which denotes the name of the *ſire* or progenitor: thus Macdonald, Robertſon are ſirnames expreſſing the ſon of Donald, the ſon of Robert. The word *ſurname*, again, ſignified ſome name ſuperadded to the proper name to diſtinguiſh the individual, as Artaxerxes *Longimanus*, Harold *Hareſoot*, Malcolm *Canmore*. From this it is evident that every ſirname was a ſurname, though the reverſe was not ſo. In modern times they are confounded; and as there is now no occaſion to preſerve the diſtinction, Dr Johnſon has rejected the word *ſirname* altogether. See NAME.

Surnames were introduced among all nations at an early period, and ſeem to have been formed at firſt by adding the name of the father to that of the ſon. This was the practice among the Hebrews, as appears from the Scriptures. Caleb is denominated the ſon of Jephunneh, and Joſhua the ſon of Nun. That the ſame thing was cuſtomary among the Greeks, every one who has read the poems of Homer muſt remember. We have an inſtance of it in the very firſt line of the Iliad: Αχιλλευς Πηληϊαδεω, "Achilles the ſon of Peleus." This is perhaps the general origin of ſurnames, for it has been common among moſt nations (A).

Surname

The Romans generally had three names. The firſt called *prænomen* anſwered to our Chriſtian name, and was intended to diſtinguiſh the individuals of the ſame family; the ſecond called *nomen* correſponded to the word *clan* in Scotland, and was given to all thoſe who were ſprung from the ſame ſtock; the third called *cognomen* expreſſed the particular branch of the tribe or clan from which an individual was ſprung. Thus Publius Cornelius Scipio, *Publius* correſponded to our names John, Robert, William; *Cornelius* was the name of the clan or tribe, as Campbell was formerly the name of all the Duke of Argyle's clients, and Douglas the name of the retainers of the Duke of Hamilton's progenitors. *Scipio* being added, conveyed this information, that Publius, who was of the tribe of the Cornelii, was of the family of the Scipios, one of the branches or families into which that tribe was divided. Reſpecting the three names which were common among the Romans, we may ſay that the firſt was a name and the other two ſurnames.

Du Cheſne obſerves, that ſurnames were unknown in France before the year 987, when the lords began to aſſume the names of their demeſnes. Camden relates, that they were firſt taken up in England, a little before the conqueſt, under King Edward the Confeſſor: but he adds, they were never fully eſtabliſhed among the common people till the time of Edward II.; till then they varied with the father's name; if the father, *e. gr.* was called *Richard*, or *Roger*, the ſon was called *Richardſon*, or *Hodgſon*; but from that time they were ſettled, ſome ſay, by act of parliament. The oldeſt ſurnames are thoſe we find in Domeſday-Book, moſt of them taken from places, with the addition of *de*; as Godefridus *de* Mannevilla, Walterus *de* Vernon, Robert *de* Oyly, &c. Others from their fathers, with *filius*, as Gulielmus *filius* Oſberni; others from their offices, as Eudo *Dapifer*, Gulielmus *Camerarius*, Giſlebertus *Cocus*, &c. But the inferior people are noted ſimply by their Chriſtian names, without any ſurnames at all.

They ſeem to have been introduced into Scotland in the time of William the Conqueror by the Engliſh who accompanied Edgar Atheling when he fled into that kingdom. Theſe had their proper ſurnames, as Moubray, Lovell, Liſle, uſing the particle *de* before them; which makes it probable that theſe ſurnames had been derived from the lands which their anceſtors or they themſelves had poſſeſſed. In Kenneth II's. time in 800 the great men had indeed begun to call their lands by their own names; but the ordinary diſtinctions then uſed were only perſonal, and did not deſcend to ſucceeding generations, ſuch as thoſe employed by the Hebrews and Greeks: For example, *John the ſon of William*; or the names of office, as Stewart; or accidental diſtinctions from complexion or ſtation, as Black, White,

(A) This might be ſupported by examples borrowed from many nations. The old Normans uſed *Fitz*, which ſignifies ſon; as Fitzherbert, Fitzſimmons, the ſon of Herbert, ſon of Simmons. The Iriſh uſed *O*; as O'Neal, the ſon of Neal. The Scotch Highlanders employed *Mac*; as Macdonald, the ſon of Donald. The Saxons added the word *ſon* to the end of the father's name, as Williamſon.

Surname ‖ Surrender.

White, Long, Short; or the name of their trade, as Taylor, Weaver.

It was long before any ſurnames were uſed in Wales, except that of ſon, as Evan ap Rice, Evan the ſon of Rice; Evan ap Howel, Evan the ſon of Howel: but many of them have at length formed ſeparate ſurnames, as the Engliſh and Scots, by leaving out the *a* in *ap*, and joining the *p* to the father's name: thus Evan ap Rice becomes Evan Price; Evan ap Howel, Evan Powel.—We are told, ſurnames were unknown in Sweden till the year 1514, and that the common people of that country uſe none to this day; and that the ſame is the caſe with the vulgar Iriſh, Poles, and Bohemians.

When we come to inquire into the etymology of ſurnames, we muſt allow that many of them were originally ſignificant of the qualities of mind, as Bold, Hardy, Meek; ſome of the qualities of body, as Strong, Low, Short; others expreſſive of the trade or profeſſion followed by the perſons to whom they were applied, as Baker, Smith, Wright; Butler, Page, Marſhal. But the greateſt number, at leaſt of the ancient ſurnames, were borrowed from the names of places. Camden ſays, that there is not a village in Normandy but has given its name to ſome family in England. He mentions as examples, Percy, Devereux, Tankervil, Mortimer, Warren, &c. They were introduced with William the Conqueror. Several have been derived from places in the Netherlands, as Gaunt, Tournay, Grandiſon; and many from the names of towns and villages in England and Scotland, as Wentworth, Markham, Murray, Aberdeen. Many have been formed from the names of animals, as quadrupeds, birds, fiſhes; from vegetables, and parts of vegetables, as trees, ſhrubs, flowers, and fruits; from minerals of different kinds. Others are formed from ſuch a variety of accidents that it is impoſſible to particularize them.

SURPLICE, the habit of the officiating clergy in the church of England. By Can. 58. every miniſter ſaying the public prayers, or miniſtering the ſacrament or other rites of the church, ſhall wear a decent and comely ſurplice with ſleeves, to be provided at the charge of the pariſh. But by 1 Eliz. c. 2. and 13 and 14 Car. II. the garb preſcribed by act of parliament, in the ſecond year of king Edward the Sixth, is enjoined; and this requires that in the ſaying or ſinging of matins and even ſongs, baptizing and burying, the miniſter in pariſh churches and chapels ſhall uſe a ſurplice. And in all cathedral churches and colleges, the archdeacon, dean, provoſts, maſters, prebendaries, and fellows, being graduates, may uſe in the choir, beſides their ſurplices, ſuch hoods as pertain to their ſeveral degrees. But in all other places every miniſter ſhall be at liberty to uſe a ſurplice or not. And hence in marrying, churching of women, and other offices not ſpecified in this rubric, and even in the adminiſtration of the holy communion, it ſeems that a ſurplice is not neceſſary. Indeed for the holy communion the rubric appoints a white ALB plain, which differs from the ſurplice in being cloſe ſleeved, with a veſtment or cope.

SURREBUTTER, in law, is ſecond rebutter; or the replication of the plaintiff to the defendant's rebutter.

SURREJOINDER, is a ſecond defence of the plaintiff's declaration, by way of anſwer to the defendant's rejoinder.

SURRENDER, in common law, a deed or inſtrument, teſtifying that the particular tenant of lands and tenements, for life or years, doth ſufficiently conſent and agree, that he who has the next or immediate remainder or reverſion thereof, ſhall have the preſent eſtate of the ſame in poſſeſſion; and that he hereby yields and gives up the ſame to him, ſo that the eſtate for life or years may merge or drown by mutual agreement of the parties. Of ſurrenders there are three kinds; a ſurrender properly taken at common law; a ſurrender of copyhold or cuſtomary eſtates; and a ſurrender improperly taken, as of a deed, a patent, &c. The firſt is the uſual ſurrender, and it is uſually divided into th in deed, and that in law.

Surrender ‖ Surry.

SURRENDER, in deed, in that which is really made by expreſs words in writing, where the words of the leſſee to the leſſor prove a ſufficient aſſent to ſurrender his eſtate back again.

SURRENDER, in law, is that wrought by operation of the law, and which is not actual.—As if a man have a leaſe of a farm for life or years, and during the term he accepts a new leaſe; this act is, in law, a ſurrender of the former.

SURRENDER of a bankrupt. See *Commission of Bankruptcy*.

Surrender of Copyholds is the yielding up of the eſtate by the tenant into the hands of the lord, for ſuch purpoſes as are expreſſed in the ſurrender: as to the uſe and behoof of A and his heirs, to the uſe of his own will, and the like. This method of conveyance is ſo eſſential to the nature of a copyhold eſtate, that it cannot poſſibly be transferred by any other aſſurance. No feoffment, fine, or recovery (in the king's courts) hath any operation upon it. If I would exchange a copyhold with another, I cannot do it by an ordinary deed of exchange at the common law, but we muſt ſurrender to each other's uſe, and the lord will admit us accordingly. If I would deviſe a copyhold, I muſt ſurrender it to the uſe of my laſt will and teſtament; and in my will I muſt declare my intentions, and name a deviſee, who will then be entitled to admiſſion. Blackſt. Comment. vol. ii.

Surrender of Letters Patent and Offices. A ſurrender may be made of letters patent to the king, ſo that he may grant the eſtate to whom he pleaſes, &c. and a ſecond patent for years to the ſame perſon for the ſame thing is a ſurrender in law of the firſt patent. 10 Rep. 66. If an officer for life accepts of another grant of the ſame office, it is in law a ſurrender of the firſt grant; but if ſuch an officer takes another grant of the ſame office to himſelf and another, it may be otherwiſe.

SURREPTITIOUS. See Subreptitious.

SURROGATE, in law, denotes a perſon that is ſubſtituted or appointed in the room of another.

SURRY, a county of England, bounded on the weſt by Berkſhire and Hampſhire, on the ſouth by Suſſex, on the eaſt by Kent, on the north by Middleſex, from which it is parted by the Thames, whence it had the name of *Suth-rey* from the Saxons, *i. e.* the country on the ſouth ſide of the river. It is 38 miles in length from eaſt to weſt, 23 in breadth from north to ſouth, and 112 in circumference. It contains 13 hundreds, 140 pariſhes, of which 35 are vicarages, 13 market-towns, 450 villages, 592,000 acres, and about 170,000 inhabitants. The members ſent from it to parliament are 14, of which two are ſent by each of the following boroughs, viz. Southwark, Bleechingley, Ryegate, Guildford, Gatton, Haſlemere, and two for the county. Camden's Britannia by Gough.

The air of this county, towards the middle, which conſiſts moſtly of hills and heath, is ſharp, but pure and wholeſome. About the ſkirts, where it is more level, and the ſoil richer, the air is milder, but alſo ſalubrious. In the middle parts the ſoil is barren enough in general; but towards the extremities, and where the country is open and champaign, it is fruitful in graſs and corn, particularly on the ſouth ſide in Holmſdale, in which meadows, woods, and corn-fields, are agreeably intermixed. The ſoil is alſo very fertile along the Thames, eſpecially towards London, where it greatly contributes to maintain plenty in the London

Surſolid ‖ Survivorſhip.

don markets. It has ſeveral rivers, abounding with fiſh, the chief of which are the Wye, the Mole, and the Wandle.

SURSOLID, or SURDESOLID, in arithmetic, the fifth power of a number, or the fourth multiplication of any number, conſidered as a root.

SURVEYING, the art of meaſuring land; that is, of taking the dimenſions of any tract of ground, laying down the ſame in a map or draught, and finding the content or area thereof. See GEOMETRY.

SURVEYOR, a perſon who has the overſight and care of conſiderable works, lands, or the like.

SURVEYOR, likewiſe denotes a gauger; as alſo a perſon who ſurveys lands, and makes maps of them.

SURVIVOR, in law, ſignifies the longeſt liver of joint tenants, or of any two perſons jointly intereſted in a thing.

SURVIVORSHIP, is that branch of mathematics which treats of reverſions payable provided one or more particular perſons ſurvive certain others. By reverſions are meant payments not to take place till ſome future period. Survivorſhip forms one of the moſt difficult and complicated parts of the doctrine of reverſions and life-annuities. It has been very fully treated of by Mr Thomas Simpſon in his Select Exerciſes; and brought to a ſtate of very great perfection by Dr Price and Mr Morgan, who have beſtowed a great deal of attention on this ſubject.

The calculations are founded on the expectation of lives at different ages, deduced from tables formed from bills of mortality, of which ſee ſeveral examples under the article *Bills of* MORTALITY. By the expectation of life is meant the mean time that any ſingle or joint lives at a given age is found to continue; that is, the number of years which, taking one with another, they actually enjoy, and may be conſidered as ſure of enjoying; thoſe who ſurvive that period enjoying as much more time in proportion to their number as thoſe who fall ſhort of it enjoy leſs. Thus, ſuppoſing 46 perſons alive all 40 years of age, and that one will die every year till they are all dead in 46 years, half 46 or 23 will be the *expectation* of each of them. If M. de Moivre's hypotheſis were true, that men always decreaſe in an arithmetical progreſſion, the expectation of a ſingle life is always half its complement (A), and the expectation of two joint lives one-third of their common complement. Thus, ſuppoſing a man 40, his expectation would be 23, the half of 46, his complement; the expectation of two joint lives, each 40, would be 15 years 4 months, or the third part of 46.

The number expreſſing the expectation, multiplied by the number of ſingle or joint lives (of which it is the expectation), added annually to a ſociety, gives the whole number living together, to which ſuch an annual addition would in time grow. Thus, ſince 19, or the third of 57, is the expectation of two joint lives, whoſe common age is 29, twenty marriages every year between perſons of this age would in 57 years grow to 20 times 19, or 380 marriages, always exiſting together. And ſince the expectation of a ſingle life is always half its complement, in 57 years 20 ſingle perſons added annually to a town will increaſe to 20 times 28.5, or 570; and when arrived at this number, the deaths every year will juſt equal the acceſſions, and no farther increaſe be poſſible. It appears from hence, that the particular proportion that becomes extinct every year, out of the whole number conſtantly exiſting together of ſingle or joint lives, muſt, wherever this number undergoes no variation, be exactly the ſame with the expectation of thoſe lives, at the time when their exiſtence commenced. Thus, was it found that a 19th part of all the marriages among any bodies of men, whoſe numbers do not vary, are diſſolved every year by the deaths of either the huſband or wife, it would appear that 19 was, at the time they were contracted, the expectation of theſe marriages. In like manner, was it found in a ſociety, limited to a fixed number of members, that a 28th part dies annually out of the whole number of members, it would appear that 28 was their common expectation of life at the time they entered. So likewiſe, were it found in any town or diſtrict, where the number of births and burials are equal, that a 20th or 30th part of the inhabitants die annually, it would appear that 20 or 30 was the expectation of a child juſt born in that town or diſtrict. Theſe expectations, therefore, for all ſingle lives, are eaſily found by a table of obſervations, ſhowing the number that die annually at all ages out of a given number alive at thoſe ages; and the general rule for this purpoſe is, to divide the ſum of all the living in the table, at the age whoſe expectation is required, and at all greater ages, by the ſum of all that die annually at that age and above it; or, which is the ſame, by the number (in the Table) of the living at that age; and half unity ſubtracted from the quotient will be the required expectation. Thus, in Dr Halley's table, given in the article ANNUITY, the ſum of all the living at 20 and upwards is 20,724, which, divided by 598, the number living at the age of 20, and half unity ſubtracted from the quotient, gives 34.15 for the expectation of 20.

Survivorſhip.

In calculating the value or expectation of joint lives, Mr de Moivre had recourſe to the hypotheſis, that the probabilities of life decreaſe in a geometrical progreſſion; believing that the values of joint lives, obtained by rules derived from it, would not deviate much from the truth. But in this he was greatly miſtaken; they generally give reſults which are near a quarter of the true value too great in finding the preſent value of one life after it has ſurvived another in a ſingle payment, and about $\frac{2}{3}$ths too great when the value is ſought in annual payments during the joint lives. They ought therefore to be calculated upon the hypotheſis (if they are calculated upon hypotheſis at all), that the probabilities of life decreaſe in arithmetical progreſſion, which is not very far from the truth. Even this hypotheſis never correſponds with the fact in the firſt and laſt periods of life, and in ſome ſituations not in any period of life. Dr Price and Mr Morgan therefore have given tables of the value of lives, not founded on any hypotheſis, but deduced from bills of mortality themſelves. Some of theſe we ſhall give at the end of this article. Mr Morgan has likewiſe given rules for calculating values of lives in this manner.

M. de Moivre has alſo fallen into miſtakes in his rules for calculating the value of reverſions depending on ſurvivorſhip: theſe have been pointed out by Dr Price in the third eſſay in the firſt volume of his Treatiſe on Reverſionary Payments; who has alſo given proper rules for calculating theſe values, the moſt important of which are comprehended in the following paragraphs.

I Method of finding the number of annuitants that will come on a ſociety.

Suppoſe a ſet of married men to enter into a ſociety in order to provide annuities for their widows, and that it is limited to a certain number of members, and conſtantly kept up to that number by the admiſſion of new members as the old ones are loſt; it is of importance, in the firſt place, to know the number of annuitants that after ſome time will come upon the eſtabliſhment. Now ſince every marriage produces either a widow or widower; and ſince all marriages taken together would produce as many widows as widowers, were every man and his wife of the ſame age, and the chance equal which ſhall die firſt; it is evident, that the number

(A) By the complement of a life is meant what it wants of 86, which M. de Moivre makes the boundary of human life. Thus if a man be 30, the complement of his life is 56.

Survivorſhip.

number of widows that have ever exiſted in the world, would in this caſe be equal to half the number of marriages. And what would take place in the world muſt alſo, on the ſame ſuppoſitions, take place in this ſociety. In other words, every other perſon in ſuch a ſociety leaving a widow, there muſt ariſe from it a number of widows equal to half its own number. But this does not determine what number, all living at one and the ſame time, the ſociety may expect will come to be conſtantly upon it. It is, therefore, neceſſary to determine how long the duration of ſurvivorſhip between perſons of equal ages will be compared with the duration of marriage. And the truth is, that, ſuppoſing the probabilities of life to decreaſe uniformly, the former is equal to the latter; and conſequently that the number of ſurvivors, or (which is the ſame, ſuppoſing no ſecond marriages) of widows and widowers alive together, which will ariſe from any given ſet of ſuch marriages conſtantly kept up, will be equal to the whole number of marriages; or half of them (the number of widows in particular) equal to half the number of marriages. Now it appears that in moſt towns the decreaſe in the probabilities of life is in fact nearly uniform. According to the Breſlaw Table of Obſervation (ſee ANNUITY), almoſt the ſame numbers die every year from 20 years of age to 77. After this, indeed, fewer die, and the rate of decreaſe in the probabilities of life is retarded. But this deviation from the hypotheſis is inconſiderable; and its effect, in the preſent caſe, is to render the duration of ſurvivorſhip longer than it would otherwiſe be. According to the London Table of Obſervations, the numbers dying every year begin to grow leſs at 50 years of age; and from hence to extreme old age there is a conſtant retardation in the decreaſe of the probabilities of life. Upon the whole, therefore, it appears that, according to the Breſlaw Table, and ſuppoſing no widows to marry, the number inquired after is ſomewhat greater than half the number of the ſociety; but, according to the London Table, a good deal greater. This, however, has been determined on the ſuppoſition that the huſbands and wives are of equal ages, and that then there is an equal chance who ſhall die firſt. But in reality huſbands are generally older than wives, and males have been found to die ſooner than females, as appears inconteſtibly from ſeveral of the tables in Dr Price's Treatiſe on Reverſions. It is therefore more than an equal chance that the huſband will die before his wife. This will increaſe conſiderably the duration of ſurvivorſhip on the part of the woman, and conſequently the number which we have been inquiring after. The marriage of widows will diminiſh this number, but not ſo much as the other cauſes will increaſe it.

2 When the number of annuitants arrives at its maximum.

If the ſociety comprehends in it from the firſt all the married people of all ages in any town, or among any claſs of people where the numbers always continue the ſame, the whole collective body of members will be at their greateſt age at the time of the eſtabliſhment of the ſociety; and the number of widows left every year will at a medium be always the ſame. The number of widows will increaſe continually on the ſociety, till as many die off every year as are added. This will not be till the whole collective body of widows are at their greateſt age, or till there are among them the greateſt poſſible number of the oldeſt widows; and therefore not till there has been time for an acceſſion to the oldeſt widows from the youngeſt part.

Let us, for the ſake of greater preciſion, divide the whole medium of widows that come on every year into different claſſes according to their different ages, and ſuppoſe ſome to be left at 56 years of age, ſome at 46, ſome at 36, and ſome at 26. The widows, conſtantly in life together, derived from the firſt claſs, will come to their greateſt age, and to a *maximum*, in 30 years, ſuppoſing, with M. de Moivre, 86 to be the utmoſt extent of life. The ſame will happen to the ſecond claſs in 40 years, and to the third in 50 years. But the whole body compoſed of theſe claſſes will not come to a *maximum* till the ſame happens to the fourth or youngeſt claſs; that is, not till the end of 60 years. After this the affairs of the ſociety will become ſtationary, and the number of annuitants upon it of all ages will keep always nearly the ſame. Survivorſhip.

If a ſociety begins with its complete number of members, but at the ſame time admits none above a particular age: If, for inſtance, it begins with 200 members all under 50, and afterwards limits itſelf to this number, and keeps it up by admitting every year, at all ages between 26 and 50, new members as old ones drop off; in this caſe, the period neceſſary to bring on the *maximum* of annuitants will be juſt doubled.

3 What a man ought to pay in a ſingle payment to entitle his widow to a certain annuity.

To determine the ſum that every individual ought to pay in a ſingle preſent payment, in order to intitle his widow to a certain annuity for her life, let us ſuppoſe the annuity 30 l. *per annum*, and the rate of intereſt four *per cent.* It is evident, that the value of ſuch an expectation is different, according to the different ages of the purchaſers, and the proportion of the age of the wife to that of the huſband. Let us then ſuppoſe that every perſon in ſuch a ſociety is of the ſame age with his wife, and that one with another all the members when they enter may be reckoned 40 years of age, as many entering above this age as below it. It has been demonſtrated by M. de Moivre and Mr Simpſon, that the value of an annuity on the joint continuance of any two lives, ſubtracted from the value of an annuity on the life in expectation, gives the true preſent value of annuity on what may happen to remain of the latter of the two lives after the other.

In the preſent caſe, the value of an annuity to be enjoyed during the joint continuance of two lives, each 40, is, by Table II. 9.826, according to the probabilities of life in the Table of Obſervations formed by Dr Halley from the bills of mortality of Breſlaw in Sileſia. The value of a ſingle life 40 years of age, as given by M. de Moivre, agreeably to the ſame table, is 13.20; and the former ſubtracted from the latter, leaves 3.37, or the true number of years purchaſe, which ought to be paid for any given annuity, to be enjoyed by a perſon 40 years of age, provided he ſurvives another perſon of the ſame age, intereſt being reckoned at four *per cent. per annum.* The annuity, therefore, being 30 l. the preſent value of it is 30 multiplied by 3.37, or 101 l. 2 s.

4 What he ought to pay in annual payments.

If, inſtead of a ſingle preſent payment, it is thought preferable to make annual payments during the marriage; what theſe annual payments ought to be is eaſily determined by finding what annual payments during two joint lives of given ages are equivalent to the value of the reverſionary annuity in preſent money. Suppoſe, as before, that the joint lives are each 40, and the reverſionary annuity 30 l. *per annum.* An annual payment during the continuance of two ſuch lives is worth, (according to Table II.) 9.82 years purchaſe. The annual payment ought to be ſuch as, being multiplied by 9.82, will produce 101.1 l. the preſent value of the annuity in one payment. Divide then 101.1 by 9.82, and 10.3 the quotient will be the annual payment. This method of calculation ſuppoſes that the firſt annual payment is not to be made till the end of a year. If it is to be made immediately, the value of the joint lives will be increaſed one year's purchaſe; and therefore, in order to find the annual payments required, the value of a preſent ſingle payment muſt be divided by the value of the joint lives increaſed by unity. If the ſociety prefer paying part of the value in a preſent ſingle payment on admiſſion, and the reſt in annual payments; and if they fix theſe annual payments

at

Survivorſhip.

at a particular ſum, the preſent ſingle payment paid on admiſſion is found by ſubtracting the value of the annual payment during the joint lives from the whole preſent value of the annuity in one payment. Suppoſe, for inſtance, the annual payments to be fixed at five guineas, the annuity to be 30l. the rate of intereſt four *per cent.* and the joint lives each 40; the value of the annuity in one preſent ſingle payment is 101.1 l. The value of five guineas or 5.25 *per annum*, is (5.25 multiplied by 9.82 the value of the joint lives) 51.55; which, ſubtracted from 101.1 l. gives l. 49.5, the anſwer.

If a ſociety takes in all the marriages among perſons of a particular profeſſion within a given diſtrict, and ſubjects them for perpetuity to a certain equal and common tax or annual payments, in order to provide life annuities for all the widows that ſhall reſult from theſe marriages; ſince, at the commencement of ſuch an eſtabliſhment, all the oldeſt, as well as the youngeſt, marriages are to be intitled equally to the propoſed benefit, a much greater number of annuitants will come immediately upon it than would come upon any ſimilar eſtabliſhment which limited itſelf in the admiſſion of members to perſons not exceeding a given age. This will check that accumulation of money which ſhould take place at firſt, in order to produce an income equal to the diſburſements at the time when the number of annuitants comes to a *maximum*; and therefore will be a particular burden upon the eſtabliſhment in its infancy. For this ſome compenſation muſt be provided; and the equitable method of providing it is, by levying fines at the beginning of the eſtabliſhment on every member exceeding a given age, proportioned to the number of years which he has lived beyond that age. But if ſuch fines cannot be levied, and if every payment muſt be equal and common, whatever diſparity there may be in the value of the expectations of different members, the fines muſt be reduced to one common one, anſwering as nearly as poſſible to the diſadvantage, and payable by every member at the time when the eſtabliſhment begins. After this, the eſtabliſhment will be the ſame with one that takes upon it all at the time they marry; and the tax or annual payment of every member adequate to its ſupport will be the annual payment during marriage due from perſons who marry at the mean age at which, upon an average, all marriages may be conſidered as commencing. The fines to be paid at firſt are, for every particular member, the ſame with the difference between the value of the expectation to him at his preſent age, and what would have been its value to him had the ſcheme begun at the time he married. Or, they are, for the whole body of members, the difference between the value of the common expectation, to perſons at the mean age of all married perſons taken together as they exiſt in the world, and to perſons at that age which is to be deemed their mean age when they marry.

5 Method of finding the preſent value of an annuity to be enjoyed by one life after the expiration of another.

Suppoſe we wiſh to know the preſent value of an annuity to be enjoyed by one life, for what may happen to remain of it beyond another life, after a given term; that is, provided both lives continue from the preſent time to the end of a given term of years; the method of calculating is this: Find the value of the annuity for two lives, greater by the given term of years than the given lives; diſcount this value for the given term; and then multiply by the probability, that the two given lives ſhall both continue the given term; and the product will be the anſwer. Thus, let the two lives be each 30, the term ſeven years, the annuity l. 10, intereſt four *per cent.* The given lives, increaſed by ſeven years, become each 37. The value of two joint lives, each 37, is (by Table II.) 10.25. The value of a ſingle life at 37 is (by the table under the article ANNUITY) 13.67. The former ſubtracted from the latter is 3.42, or the value of an annuity for the life of a perſon 37 years of age, after another of the ſame age, as has been ſhown above. 3.42 diſcounted for ſeven years (that is, multiplied by 0.76 the value of 1 l. due at the end of ſeven years) is 2.6. The probability that a ſingle life at 30 ſhall continue ſeven years is $\frac{49}{50}$ (B). The probability, therefore, that two ſuch lives ſhall continue ſeven years, is $\frac{2401}{2500}$, or in decimals 0.765; and 2.6 multiplied by 0.765, is 1.989, the number of years purchaſe which ought to be given for an annuity to be enjoyed by a life now 30 years of age, after a life of the ſame age, provided both continue ſeven years. The annuity then being 10l. its preſent value is l. 19.89.

Survivorſhip.

6 Method of finding the value of an annuity for what may happen to remain of one life after another, provided the life in expectation continues a given term.

Suppoſe the value is required of an annuity to be enjoyed for what may happen to remain of one life after another, provided the life in expectation continues a given time. 1. Find the preſent value of the annuity for the remainder of the life in expectation after the given time, which is done in this manner: Multiply the preſent value of the life at the given time by the preſent value of 1 l. to be received at that time, and multiply the product again by the probability that the life in expectation will continue ſo long. Let the given time which the life in expectation is to continue be 15 years, and let the perſon then be arrived at 50 years of age. A life at fifty, according to M. de Moivre's valuation of lives, and reckoning intereſt at four *per cent.* is worth 11.34 years purchaſe. The preſent value of 1 l. to be received at the end of 15 years, is 0.5553, and the probability that a life at 35 will continue 15 years is $\frac{146}{490}$. Theſe three values multiplied into one another give L. 4.44 for the preſent value of the life in expectation. 2. Find the value of the reverſion, provided both lives continue the given time, by the rule given in parag. 5th. 3. Add theſe values together, and the ſum will be the anſwer in a ſingle preſent payment. We ſhall now illuſtrate this rule by an example.

An annuity of 10l. for the life of a perſon now 30, is to commence at the end of 11 years, if another perſon now 40 ſhould be then dead; or, if this ſhould not happen at the end of any year beyond 11 years in which the former ſhall happen to ſurvive the latter: What is the preſent value of ſuch an annuity, reckoning intereſt at four *per cent.* and taking the probabilities of life as they are in Dr Halley's table, given in the article MORTALITY?

The value of 10l. *per annum*, for the remainder of the life of a perſon now 30, after 11 years is L. 69.43. The probability that a perſon 40 years of age ſhall live 11 years, is, by Dr Halley's table, $\frac{335}{445}$. The probability, therefore, that he will die in 11 years, is $\frac{335}{445}$ ſubtracted from unity (C), or $\frac{110}{445}$; which multiplied by l. 69.43, gives l. 17.16.—The value of the reverſion, provided both live 11 years, is 17 l. and this value added to the former, makes l. 34.16 the value required in a ſingle preſent payment; which payment divided by l. 11.43, the value of two joint lives aged 30 and 40, with unity added, gives 3 l.; or the value required in annual payments during the joint lives, the firſt payment to be made immediately.

(B) The probability that a given life ſhall continue any number of years, or reach a given age, is (as is well known) the fraction, whoſe numerator is the number of the living in any table of obſervations oppoſite to the given age, and denominator, the number oppoſite to the preſent age of the given life.

(C) For the difference between unity and the fraction expreſſing the probability that an event will happen, gives the probability that it will not happen.

The values of joint lives in theſe tables have been computed for only one rate of intereſt; and of ſingle lives in Table III. for only two rates of intereſt. The following rules will ſhow, that it would be a needleſs labour to compute theſe values (in ſtrict conformity to the obſervations) for any other rates of intereſt.

ACCOUNT, of a method of deducing, from the correct values (according to any obſervations) of any ſingle or joint lives at one rate of intereſt, the ſame values at other rates of intereſt.

PRELIMINARY PROBLEMS.

PROB. I. The expectation given of a ſingle life by any tables of obſervations, to find its value, ſuppoſing the decrements of life equal, at any given rate of intereſt.

Solution. Find the value of an annuity certain for a number of years equal to twice the expectation. Multiply this value by the perpetuity increaſed by unity, and divide the product by twice the expectation: The quotient ſubtracted from the perpetuity will be the value required.

Example. The expectation of a male life aged 10, by the Sweden obſervations, is 43.94. Twice this expectation is 87.88. The value of an annuity certain for 87.88 years is (reckoning intereſt at 4 *per cent.*) 24.200. The product of 24.200 into 26 (the perpetuity increaſed by unity) is 629.2, which, divided by 87.88, gives 7.159. And this quotient ſubtracted from 25 (the perpetuity) gives 17.84 years purchaſe, the value of a life aged ten, deduced from the expectation of life at that age, according to the Sweden obſervations. (See the Tables in Dr Price on Reverſions, vol. ii.).

PROB. II. Having the expectations given of any two lives by any table of obſervations, to deduce from thence the value of the joint lives at any rate of intereſt, ſuppoſing an equal decrement of life.

Solution. Find the difference between twice the expec-

tation

Survivorship.

tation of the youngeſt life and twice the expectation of the oldeſt life increaſed by unity and twice the perpetuity. Multiply this difference by the value of an annuity certain for a time equal to twice the expectation of the oldeſt life; and by twice the ſame expectation divide the product, reſerving the quotient.

From twice the perpetuity ſubtract the reſerved quotient, and multiply the remainder by the perpetuity increaſed by unity. This laſt product divided by twice the expectation of the youngeſt life, and then ſubtracted from the perpetuity, will be the required value.

When twice the expectation of the youngeſt life is greater than twice the expectation of the oldeſt life increaſed by unity and twice the perpetuity, the reſerved quotient, inſtead of being ſubtracted from twice the perpetuity, muſt be added to it, and the ſum, not the difference, multiplied by the perpetuity increaſed by unity.

Example. Let the joint lives propoſed be a female life aged 10, and a male life aged 15; and let the table of obſervations be the Sweden table for lives in general, and the rate of intereſt 4 *per cent.* Twice the expectations of the two lives are 90.14 and 83.28.

Twice the expectation of the oldeſt life, increaſed by unity, and twice the perpetuity, is 134.28, which leſſens by 90.14 (twice the expectation of the youngeſt life,) leaves 44.14 for the reſerved remainder. This remainder multiplied by 24.045 (the value of an annuity certain for 83.28 years), and the product divided by 83.28 (twice the expectation of the oldeſt life), gives 12.744, the quotient to be reſerved; which ſubtracted from double the perpetuity, and the remainder (or 37.255) multiplied by the perpetuity increaſed by unity (or by 26) gives 968.630, which divided by 90.14 (twice the expectation of the youngeſt life) and the quotient ſubtracted from the perpetuity, we have 14.254 for the required value.

The value of an annuity certain, when the number of years is a whole number with a fraction added (as will be commonly the caſe) may be beſt computed in the following manner. In this example the number of years is 83.28. The value of an annuity certain for 83 years is 24.035. The ſame value for 84 years is 24.072. The difference between theſe two values is 0.37; which difference multiplied by .28 (the fractional part of the number of years), and the product (.0103) added to the leaſt of the two values, will give 24.045 the value for 83.28 years.

General Rule. Call the correct value (ſuppoſed to be computed for any rate of intereſt) the firſt value. Call the value deduced (by the preceding problems) from the expectations at the ſame rate of intereſt, the ſecond value. Call the value deduced from the expectations for any other rate of intereſt the third value.

Then the difference between the firſt and ſecond values added to or ſubtracted from the third value, juſt as the firſt is greater or leſs than the ſecond, will be the value at the rate of intereſt for which the third value has been deduced from the expectations.

The following examples will make this perfectly plain.

Example I. In the two laſt tables the correct values are given of two joint lives among mankind at large, without diſtinguiſhing between males and females, according to the Sweden obſervations, reckoning intereſt at 4 *per cent.* Let it be required to find from theſe values the values at 3 *per cent.* and let the ages of the joint lives be ſuppoſed 10 and 10.

The correct value by Table IV. (reckoning intereſt at 4 *per cent.*) is 16.111. The expectation of a life aged 10 is 45.07. The value deduced from this expectation at 4 *per cent.* by Prob. II. is 14.539. The value deduced by the ſame problem from the ſame expectation at 3 *per cent.* is 16.808. The difference between the firſt and ſecond values is 1.602, which, added to the third value (the firſt being greater than the ſecond), makes 18.410, the value required. Survivorſhip.

Example II. Let the value be required of a ſingle male life aged 10, at 3 *per cent.* intereſt, from the correct value at 4 *per cent.* according to the Sweden obſervations.

Firſt, or correct value at 4 *per cent.* (by Table III.) is 18.674. The expectation of a male life aged 10 is 43.94.

The ſecond value (or the value deduced from this expectation by Prob. I.) is 17.838.

The third value (or the value deduced from the ſame expectation at 3 *per cent.*) is 21.277.

The difference between the firſt and ſecond is .836; which (ſince the firſt is greater than the ſecond) muſt be added to the third; and the ſum (that is, 22.113) will be the value required.

The third value at 5 *per cent.* is 15.286; and the difference added to 15.286 makes 16.122 the value of a male life aged 10 at 5 *per cent.* according to the Sweden obſervations. The exact value at 5 *per cent.* is (by Table III.) 16.014.

Again: The difference between 16.014 (the correct value at 5 *per cent.*), and 15.286 (the value at the ſame intereſt deduced from the expectation), is .728; which, added (becauſe the firſt value is greater than the ſecond) to 13.335 (the value deduced at 6 *per cent.* from the expectation) gives 14.063, the value of the ſame life, reckoning intereſt at 6 *per cent.*

Theſe deductions, in the caſe of ſingle lives particularly, are ſo eaſy, and give the true values ſo nearly, that it will be ſcarcely ever neceſſary to calculate the exact values (according to any given obſervations) for more than one rate of intereſt.

If, for inſtance, the correct values are computed at 4 *per cent.* according to any obſervations, the values at 3, $3\frac{1}{2}$, $4\frac{1}{2}$, 5, 6, 7, or 8 *per cent.* may be deduced from them by the preceding rules as occaſion may require, without much labour or any danger of conſiderable errors. The values thus deduced will ſeldom differ from the true values ſo much as a tenth of a year's purchaſe. They will not generally differ more than a 20th or 30th of a year's purchaſe. In joint lives they will differ leſs than in ſingle lives, and they will come equally near to one another whatever the rates of intereſt are.

The preceding tables furniſh the means of determining the exact differences between the values of annuities, as they are made to depend on the ſurvivorſhip of any male or female lives; which hitherto has been a *deſideratum* of conſiderable conſequence in the doctrine of life-annuities. What has made this of conſequence is chiefly the multitude of ſocieties lately eſtabliſhed in this and foreign countries for providing annuities for widows. The general rule for calculating from theſe tables the value of ſuch annuities is the following.

Rule. "Find in Table III. the value of a female life at the age of the wife. From this value ſubtract the value in Table IV. of the joint continuance of two lives at the ages of the huſband and wife. The remainder will be the value in a ſingle preſent payment of an annuity for the life of the wife, ſhould ſhe be left a widow. And this laſt value divided by the value of the joint lives increaſed by unity, will be the value of the ſame annuity in annual payments during the joint lives, and to commence immediately."

Example. Let the age of the wife be 24, and of the huſband 30. The value in Table III. (reckoning intereſt at 4 *per cent.*) of a female life aged 24, is 17.252. The value in Table IV. of two joint lives aged 24 and 30, is 13.455, which ſubtracted from 17.252 leaves 3.797, the

value

Surya, Sus.

value in a single present payment of an annuity of L. 1 for the life of the wife after the husband; that is, for the life of the widow. The annuity, therefore, being supposed L. 20, its value in a single payment is 20 multiplied by 3.797, that is, L. 75.94. And this last value divided by 14.455 (that is, by the value of the joint lives increased by unity), gives 5.25, the value in annual payments beginning immediately, and to be continued during the joint lives of an annuity of L. 20 to a wife aged 24 for her life, after her husband aged 30.

SURYA, the orb of the sun personified and adored by a sect of Hindoos as a god. He seems to be the same divinity with the Phœbus of Greece and Rome; and the sect who pay him particular adoration are called *Sauras*. Their poets and painters describe his car as drawn by seven green horses, preceded by Arun, or the *Dawn*, who acts as his charioteer, and followed by thousands of genii worshipping him and modulating his praises. He has a multitude of names, and among them twelve epithets or titles, which denote his distinct powers in each of the twelve months; and he is believed to have descended frequently from his car in a human shape, and to have left a race on earth, who are equally renowned in the Indian stories with the Heliadai of Greece: it is very singular, that his two sons called *Aswinau* or *Aswinicumarau*, in the dual, should be considered as twin-brothers, and painted like Castor and Pollux; but they have each the character of Æsculapius among the gods, and are believed to have been born of a nymph, who, in the form of a mare, was impregnated with the sun-beams.

Asiatic Researches, vol. i. p. 262 and 263.

SUS, the Hog, in zoology, a genus of quadrupeds belonging to the class of *mammalia* and order of *bellua*. There are four cutting teeth in the upper jaw, whose points converge; and, for the most part, six in the lower jaw, which stand forwards: There are two tusks in each jaw, those in the upper jaw being short, while those of the under jaw are long, and extend out of the mouth. The snout is prominent, moveable, and has the appearance of having been cut off, or truncated. The feet are armed with divided or cloven hoofs. There are six species; the scrofa, æthiopicus, tajassu, babyrussa, porcus, and africanus. The most remarkable are,

Gmelin's Animal Kingdom, by Kerr.

1. The *scrofa*, or common hog, having the body covered with bristles; two large teeth above and below. In a wild state, of a dark brinded colour, and beneath the bristles is a soft short hair; the ears short, and a little rounded. TAME: the ears long, sharp-pointed, and slouching; the colour generally white, sometimes mixed with other colours. In a tame state it is universal; except in the frigid zones, and in Kamtschatka, where the cold is very severe. Since its introduction into America by the Europeans, it abounds to excess in the hot and temperate parts. It is found wild in most parts of Europe. In the forests of South America there are vast droves, which derive their origin from the European kind relapsed into a state of nature; and are what Mr Bancroft, in his History of Guiana, describes as a particular species by the name of *Warree*. They cannot bear excessive cold; inhabit wooded countries; and are very swift. In America they are useful by clearing the country of rattle-snakes, which they devour without danger.

Of all quadrupeds, the hog is the most rude and brutal. The imperfections of his form seem to have an influence on his nature and dispositions. All his habits are gross; all his appetites are impure; all his sensations are confined to a furious lust, and a brutal gluttony. He devours indiscriminately every thing that comes in his way, even his own progeny the moment after their birth. This voraciousness seems to proceed from the perpetual cravings of his stomach, which is of an immoderate size; and the grossness of his appetites, it is probable, arises from the bluntness of his senses of taste and of feeling. The rudeness of the hair, the hardness of the skin, and the thickness of the fat, render these animals less sensible to blows. Mice have been known to lodge upon a hog's back, and to eat his skin and fat, without his showing any marks of sensibility. The other senses of the hog are very good. It is well known to the hunters that the wild boar hears and smells at a great distance; for, in order to surprise him, they are obliged to watch him in silence during the night, and to place themselves opposite to the wind, that he may not perceive the smell, which never fails to make him turn back.

Sus. Buffon's Natural History, vol. iii.

But the hog, though the most impure and filthy of all quadrupeds, is yet useful by the very sordidness of its manners; this alone devouring what is the refuse of all others, and contributing not only to remove what would be a nuisance to the human race, but also converting the most nauseous offals into the richest nutriment: for this reason its stomach is capacious, and its gluttony excessive: not that its palate is insensible to the difference of eatables; for where it finds variety, it will reject the worst with as distinguishing a taste as other quadrupeds.

The parts of this animal are finely adapted to its way of life. As its method of feeding is by turning up the earth with its nose for roots of different kinds, so nature has given it a more prone form than other animals; a strong brawny neck; eyes small, and placed high in the head; a long snout, nose callous and tough, and a quick sense of smelling to trace out its food. Its intestines have a strong resemblance to those of the human species. The external form of its body is very unwieldy; yet, by the strength of its tendons, the wild boar (which is only a variety of the common kind) is enabled to fly from the hunters with amazing agility: the back-toe on the feet of this animal prevents its slipping while it descends declivities, and must be of singular use when pursued. Yet, notwithstanding its powers of motion, it is by nature stupid, inactive, and drowsy; much inclined to increase in fat, which is disposed in a different manner from that of other animals, and forms a regular coat over the whole body. It is restless at a change of weather, and in certain high winds is so agitated as to run violently, screaming horribly at the same time: it is fond of wallowing in the dirt, either to cool its surfeited body, or to destroy the lice, ticks, and other insects with which it is infested. Its diseases generally arise from foul feeding and intemperance; measles, imposthumes, and scrophulous complaints, are reckoned among them. These are best prevented by keeping the animals, as the ancients strongly recommended, very clean in their sties; allowing them air, exercise, and a sufficiency of water. Linnæus observes, that its flesh is wholesome food for athletic constitutions, or those that use much exercise; but bad for such as lead a sedentary life: it is, however, of most universal use; and furnishes numberless materials for epicurism.

The boar, or male of these creatures, is chosen with great care, when intended for the propagation of his species; and is thus employed from the age of two to five years, and then either sold or fatted. The males not allotted to this use are castrated, sometimes at the age of six weeks, and sometimes when they are six months old; and then fed to a great size either for sale or for the use of the family. Sows are kept for breed generally from one year old to seven, and are then spayed and fatted. They have commonly more grease on their intestines than hogs, these being fattest on their backs.

As to the age of these animals, it is said that the life of the wild boar may be extended to twenty-five or thirty years.

Sus. Ariſtotle ſays, that hogs in general live twenty years; and adds, that both males and females are fertile till they arrive at the age of fifteen. They can engender at the age of nine or twelve months; but it is better to reſtrain them till they be eighteen months or two years. The firſt litter of the ſow is not numerous; and, when only one year old, her pigs are weak, and even imperfect. She may be ſaid to be in ſeaſon at all times. Though full, ſhe ſolicits the approach of the male. This may be regarded as an exceſs among animals; for almoſt every other ſpecies refuſe the male after conception. The ardour of the ſow, though almoſt perpetual, is however marked by paroxyſms and immoderate movements, which always terminate by her wallowing in the mire. She, at the ſame time, emits a thick whitiſh fluid. She goes four months with young; brings forth in the beginning of the fifth; and ſoon afterwards ſolicits the male, is impregnated a ſecond time, and of courſe brings forth twice a-year. The wild ſow, which every way reſembles the domeſtic kind, produces only once a-year. This difference in fertility is probably owing to want of nouriſhment, and the neceſſity of ſuckling her pigs much longer than the domeſtic ſow, which is never allowed to nurſe her young above fifteen days or three weeks. Only eight or nine of the litter are kept longer; the reſt are ſold. In fifteen days, pigs are excellent food.

As theſe creatures, though exceedingly voracious, will feed almoſt on any thing, they are bred and kept everywhere, and are quickly and cheaply fatted. In miry and in marſhy grounds (from which they are not averſe) they devour worms, frogs, fern, ruſh, and ſedge roots. In drier and in woody countries, they feed on hips, haws, ſloes, crabs, maſt, cheſnuts, acorns, &c. and on this food they will grow fleſhy and fat. They are a kind of natural ſcavengers, will thrive on the traſh of an orchard, the outcaſts of the kitchen, the ſweepings of barns and granaries, the offals of a market, and moſt richly on the refuſe of a dairy. If near the ſea, they will ſearch the ſhores for ſhell-fiſh; in the fields, they eat graſs; and in cities and large towns they are kept in great numbers, and ſupported chiefly by grains. It is evident that the facility of feeding them everywhere at a ſmall expence is a national benefit, more eſpecially in a country where the people are accuſtomed to eat fleſh daily, and could not perhaps perform their daily labour if they did not. It is no leſs obſervable, that notwithſtanding this facility of feeding, and the multitudes of ſwine maintained, they ſeldom fail of coming to a good market. In no part of Europe is the management of theſe creatures better underſtood than in Britain. The time of farrowing is adjuſted to the nature of the farm, the food it can ſupply; and the number of pigs ſold and kept are in like manner adjuſted. New kinds of food, more wholeſome and nutritive than what were uſed formerly, have been introduced, ſuch as turnips, carrots, clover, &c. They are in moſt places regularly managed and cloſely attended. Tuſſer, many years ſince, affirmed from his own experience, that a ſow might bring as much profit as a cow. In ſome counties, it is ſaid, a ſow dependent on a dairy hath produced, all expences deducted, about 10 l. in the ſpace of a year. It may be ſome ſatisfaction to the reader to know, that, on a nice calculation, the annual profits of a ſow in France are found to be between 50 and 60 livres.—In Britain, theſe animals in different counties are of very different ſizes. In Leiceſterſhire, Northamptonſhire, and Pembrokeſhire, they are very large. In Hampſhire, Wiltſhire, and wherever they can run in the woods, and feed on maſt and acorns, their fleſh is firmer and better. The Chineſe ſwine are common with us: they are ſmaller, blacker, and their legs ſhorter than ours: ſo that, when fat, their bellies literally touch the ground. They thrive exceedingly well with us, are very prolific, and their fleſh very fine and well taſted. Sus.

In conſidering the advantages derived from theſe creatures, it is to be obſerved, that the fleſh of all their different kinds, and at all ages, is looked upon as a very ſubſtantial and agreeable aliment; and of courſe, in their proper ſeaſons, the different ſorts of proviſions thus ſupplied are all of them very ſaleable. The wild boar was eſteemed a prime delicacy amongſt the Romans, and the fleſh of the tame was much more in favour with our anceſtors than with us; though BRAWN has ſtill many admirers, is made in the greateſt perfection, and conſidered as a rarity peculiar to Britain. Pork, though it might be wiſely prohibited in ſome warm countries, is found by experience equally nutritive and ſalutary here. As ſuch it furniſhes a very large proportion of that food which is vended in our markets. It takes ſalt better, and keeps longer, than the fleſh of any other animal; and the conſumption of it is prodigious when pickled or ſalted, more eſpecially in the foreign garriſons and in the ſea-ſervice. Our bacon is differently cured, ſo as to render it acceptable to all palates; and our hams are not at all inferior to thoſe of other countries. Freſh pork ſells nearly as dear as beef; the lard brings double or triple the price; the blood, the inteſtines, the feet, and the tongue, are all prepared as food. The fat of the inteſtines and web, which differs from common lard, is employed for greaſing axles of wheels, and for many other purpoſes. Sieves are made of the ſkin; and bruſhes, pencils, &c. of the briſtles. The dung is reputed next in value to that of ſheep. Mr Worlidge * propoſes that ſwine ſhould be turned into a cloſe well-paled, and planted with greens, pulſe, and roots, on which they may feed, and by their trampling and their dung raiſe a great quantity of excellent ſoil. Mr Mortimer † aſſures us that ſome, on poor light ſhallow land in Staffordſhire, ſow a ſmall white pea, which they never reap, but turn in ſo many hogs to eat them as they think they will fat; and there they lie day and night, and their dung will ſo enrich the land, that it will bring a good ſward upon it, and will graze many years afterwards. Our old huſbandmen had an ill opinion of this dung, as ſuppoſing it bred weeds, but it will probably not obtain much credit at preſent. In ſome places they waſh with hogs' dung for want of ſoap; which anſwers tolerably well, if the linen hangs long enough in the air to become thoroughly ſweet.

* Survey of Huſbandry, p. 171.

† Art of Huſbandry vol. i. p. 117.

The wild boar was formerly a native of Britain as appears from the laws of Hoel dda, who permitted his grand huntſman to chace that animal from the middle of November to the beginning of December. William the Conqueror puniſhed with the loſs of their eyes any that were convicted of killing the wild boar, the ſtag, or the roebuck; and Fitz-Stephen tells us, that the vaſt foreſt that in his time grew on the north ſide of London, was the retreat of ſtags, fallow-deer, wild boars, and bulls. Charles I. turned out wild boars in the New Foreſt, Hampſhire; but they were deſtroyed in the civil wars.

On the continent the wild boar is hunted with dogs, or killed by ſurpriſe during the night, when the moon ſhines. As he runs ſlowly, leaves a ſtrong odour behind him, and defends himſelf againſt the dogs, and often wounds them dangerouſly, fine hunting dogs are unneceſſary, and would have their noſe ſpoiled, and acquire a habit of moving ſlowly by hunting him. Maſtiffs, with very little training, are ſufficient. The oldeſt, which are known by the tract of their feet, ſhould only be attacked: A young boar of three years old is difficult to hunt down; becauſe he runs very far without ſtopping. But the older boars do not run far, allow

the

Sus. the dogs to run near, and often ſtop to repel them. During the day, he commonly remains in his ſoil, which is in the moſt ſequeſtrated part of the woods. He comes out in the night in queſt of food. In ſummer, when the grain is ripe, it is eaſy to ſurpriſe him among the cultivated fields, which he frequents every night. As ſoon as he is ſlain, the hunters cut off his teſticles, the odour of which is ſo ſtrong, that in a few hours it would infect the whole fleſh. The ſnout of an old boar is the only part that is eſteemed; but every part of the caſtrated and young boar, not exceeding one year fed, makes delicate eating. The pork of the domeſtic boar is ſtill worſe than that of the wild boar; and it can only be rendered fit for eating by caſtration and fattening. The ancients caſtrated the young boars which they could carry off from their mothers, and returned them to the woods, where they grew fat, and their pork was much better than that of domeſtic hogs. There are ſeveral varieties of the common hog.

2. The *æthiopicus*, or Ethiopian hog, with ſmall tuſks in the lower jaw, very large ones in the upper, in old boars bending towards the forehead in form of a ſemicircle: no fore teeth: noſe broad, depreſſed, and almoſt of a horny hardneſs: head very large and broad: beneath each eye a hollow, formed of looſe ſkin, very ſoft and wrinkled; under theſe a great lobe or wattle, lying almoſt horizontal, broad, flat, and rounded at the end, placed ſo as to intercept the view of any thing below from the animal. Between theſe and the mouth on each ſide, there is a hard callous protuberance. The mouth is ſmall: ſkin duſky: briſtles diſpoſed in faſciculi, of about five each; longeſt between the ears and on the beginning of the back, thinly diſperſed on the reſt of the back. Ears large and ſharp-pointed, inſide lined with long whitiſh hairs: tail ſlender and flat, not reaching lower than the thighs, and is covered with hairs diſpoſed in faſciculi. Body longer, and legs ſhorter, than in the common ſwine: its whole length 4 feet 9 inches; height before, 2 feet 2 inches: but in a wild ſtate, it grows to an enormous ſize.—Theſe animals inhabit the hotteſt parts of Africa, from Senegal to Congo, alſo the iſland of Madagaſcar. We know little of their nature; but they are repreſented as very fierce and ſwift, and that they will not breed with the domeſtic ſow.

3. The *tajaſſu*, pecary, or Mexican hog, with four cutting teeth above, and ſix below: two tuſks in each jaw; thoſe in the upper jaw pointing down, and little apparent when the mouth is ſhut; the others hid: length from noſe to the end of the rump about three feet: head not ſo taper as in common ſwine: ears ſhort and erect: body covered with briſtles, ſtronger than thoſe of the European kind, and more like thoſe of a hedge-hog; they are duſky, ſurrounded with rings of white; thoſe on the top of the neck and back are near five inches long, grow ſhorter on the ſides; the belly almoſt naked; from the ſhoulders to the breaſt is a band of white: no tail: on the lower part of the back is a gland, open at the top, diſcharging a fetid ichorous liquor; this has been by miſtake called a *navel*.—Inhabits the hotteſt parts of South America, and ſome of the Antilles: lives in the foreſts on the mountains: not fond of mire or marſhy places: leſs fat than the common hog. Theſe animals go in great droves. They are very fierce, and will fight ſtoutly with the beaſts of prey: the jaguar, or American leopard, is their mortal enemy; often the body of that animal is found with ſeveral of theſe hogs ſlain in combat. Dogs will ſcarce attack this animal: if wounded, it will turn on the hunters. They feed on fruits and roots; alſo on toads and all manner of ſerpents, which they hold with their fore-feet, and ſkin with great dexterity. The fleſh is reckoned very good food; but all writers agree that the dorſal gland muſt be cut out as ſoon as the animal is killed, or the fleſh will become ſo infected as not to be eatable. The Indian name of this ſpecies is *paquiras*, from whence ſeems to be derived that of *pecary*. There are more varieties of this ſpecies, the *tajaſſu minor* and the *patera*.

Sus ‖ Sussex.

4. The *babyruſſa*, or Indian hog, with four cutting teeth in the upper, ſix in the lower jaw; ten grinders to each jaw; in the lower jaw two tuſks pointing towards the eyes, and ſtanding near eight inches out of their ſockets; from two ſockets on the outſide of the upper jaw two other teeth, twelve inches long, bending like horns, their ends almoſt touching the forehead: ears ſmall, erect, ſharp-pointed: along the back are ſome weak briſtles; on the reſt of the body only a ſort of wool, ſuch as is on the lambs: the tail long, ends in a tuft, and is often twiſted: the body plump and ſquare. Inhabits Buero, a ſmall iſle near Amboina: it is alſo found in Celebes, but neither on the continent of Aſia or Africa; what M. de Buffon takes for it is the Ethiopian boar. They are ſometimes kept tame in the Indian iſles: live in herds: have a very quick ſcent: feed on herbs and leaves of trees; never ravage gardens like other ſwine: their fleſh well taſted. When purſued and driven to extremities, they ruſh into the ſea, ſwim very well, and even dive, and paſs thus from iſle to iſle. In the foreſts they often reſt their heads, by hooking their upper tuſks on ſome bough. The tuſks, from their form, are uſeleſs in fight.

SUSA, the ancient royal reſidence of the kings of Perſia, built by Darius Hyſtaſpis, according to Pliny; though he probably only reſtored it, being a very ancient city, founded by Tithonus father of Memnon. It was in compaſs 120 ſtadia, of an oblong quadrangular form, with a citadel called *Memnoneum*. In Scripture it is called *Suſan*, the royal citadel, from the great number of lilies growing in that diſtrict (Athenæus); ſituate on the river Uhlai, or Eulæus (Daniel): and the Spaniards call at this day a lily *aſuſena* (Pinedo). Suſa was the winter, as Ecbatana was the ſummer, reſidence of the kings of Perſia, (Xenophon, Strabo, Plutarch). Here the kings kept their treaſure, (Herodotus.) Now called *Tuſter*.

SUSPENSION, in Scots law. See LAW, n° clxxxv. 5, 6, and 7.

SUSSEX, a county of England, deriving its name from its ſituation in reſpect of the other Saxons, and called *Suſſex*, *i. e.* the country of the South Saxons, has Hampſhire on the weſt, the Britiſh channel on the ſouth, Surry on the north, and Kent on the eaſt. Its length is 65 miles, its breadth 30, and its circumference 170. It is divided into 6 rapes, and theſe into 65 hundreds, in which are 342 pariſhes, of which 123 are vicarages, one city, 16 market-towns, 1,140,000 acres, and about 120,000 ſouls. It has few good ports, though it lies along the channel for 65 miles, which is its greateſt length, the coaſt being encumbered in many places with rocks; and where it is more open, ſuch quantities of ſand are thrown upon it by the ſouth-weſt winds, and the harbours ſo choaked up, that they will not admit veſſels of any great draught or burden. The county is well watered by the rivers Arun, Adar, Ouſe, Rother, Lavant, Cuckmeer, Aſhburn, and Aſten, by which it is well ſupplied with fiſh, as well as from the ſea. Hence different places of the county are famed for different ſorts of fiſh, as the Arun for mullets which enter it from the ſea in ſummer in ſhoals, and by feeding upon a particular kind of herb become extremely delicious: Chicheſter for lobſters, Selſey for Cockles, Amberly for trout, Pulborough for eels, Rye for herrings, and the county in ge-

Gough's edition of Camden's Britannia, vol. i. p. 192.

Suſſex, Sutherland.

general for carp. It is remarkable, that all the rivers abovementioned riſe and fall into the ſea within the county.

The air, as well as the ſoil, is various in different parts of the country. Upon the coaſt the air is aguiſh, upon the hills and downs pleaſant and wholeſome; but ſomewhat moiſt and foggy in the valleys, the ſoil being deep and rich, and the vegetation in ſummer very vigorous. The downs in ſome places are very fertile in corn and graſs; in others they feed great flocks of ſheep, whoſe fleſh and wool are very fine; but of the latter no inconſiderable quantity is clandeſtinely exported to France. In the Weald and the valleys the roads are very deep, eſpecially in winter. In the north quarter are many woods, and ſome foreſts in other places; whence the king's yards are ſupplied with the largeſt and beſt timber in England, beſide what is made into charcoal and conſumed in the iron-works; for on the eaſt ſide is plenty of iron ore, with furnaces, forges, and mills for manufacturing it. The gunpowder of this county is ſaid to excel that of any other. Thoſe delicious birds called *wheat-ears* are bred in this ſhire; they are no bigger than a lark, but almoſt an entire lump of fat. That part now called the *Wild* or *Weald* of Suſſex, was anciently a mere deſert for hogs and deer, of great extent, taking in a part of Kent and Surry; and was called *Anderida Silva*, *Coid Andred*, and *Andradſwald*, from Anderida an adjoining city. This county is in the home-circuit and dioceſe of Chicheſter, giving title of earl to the family of Yelverton, and ſends 28 members to parliament, viz, two for the county, two for the city of Chicheſter, and two for each of the following towns, Horſham, Lewes, Bramber, Eaſt-Grinſtead, Midhurſt, Shoreham, Staining, Arundel, Haſtings, Rye, Winchelſea, and Seaford; of which the four laſt are cinque-ports.

SUTHERLAND, one of the moſt northerly counties of Scotland. Including Strathnavern, it borders on Caithneſs to the north and north-eaſt, is bounded by the ocean on the north, the country of Aſſynt on the weſt, Roſs on the ſouth, and by the German ſea on the eaſt and ſouth-eaſt. It ſtretches about 70 miles in length, and 40 in breadth; is generally hilly, tho' in many parts arable; well watered with ſmall rivers and ſtreams replete with fiſh, and exhibiting about 60 lakes, the habitation of various fiſh, ſwans, ducks, geeſe, &c. One of the largeſt of theſe is Lochſhin, extending 18 miles in length. Some of them are interſperſed with ſmall verdant iſlands, which in ſummer yield a very agreeable proſpect. On the coaſt are many commodious harbours, and all the bays ſwarm with fiſh; nay, the ſea in this place produces ſome valuable pearls. Sutherland affords iron-ſtone, free-ſtone, lime-ſtone, and ſlate, in abundance. Here are alſo quarries of marble, and mines of coal, though the people uſe turf and peat for fuel. Lead ore, impregnated with ſilver, and even ſome gold, hath been found in this province, together with cryſtals and pebbles.

The air is ſo temperate, and the ſoil ſo good, that ſaffron has here been brought to perfection. Many parts of the country are remarkably fruitful in corn, and the paſturage is excellent everywhere. Beſides three great foreſts, there are many ſmaller woods in Sutherland, abounding with deer and other game. On the hills are fed numerous flocks of ſheep and black cattle; ſmall, yet ſweet and juicy. There is one bird peculiar to this ſhire, called *knag*, which reſembles a parrot, and digs its neſt with its beak in the trunks of oaks. The northern part, called *Strathnavern*, and ſeparated from the reſt by a ridge of mountains, is bounded on the north by the Deucaledonian ſea, on the weſt by the channel called the *Minch*, on the eaſt by Caithneſs, and on the ſouth by Aſſynt. The length of it, from eaſt to weſt, amounts to 34 miles: but the breadth from north to ſouth does not exceed 12 in ſome places. It is very hilly; and the mountains are ſo high, that the ſnow remains on the tops of them till mid-ſummer. It is watered by Navern, from whence it derives its name: as this diſtrict gives a title to the eldeſt ſon of the earl of Sutherland. Here are ſeveral woods, frequented by deer and other game, which the people take great delight in hunting. Iron mines have been worked in ſome places, but to no great advantage. Strathnavern has many freſh water lakes or lochs; the chief of which are Loch Navern and Loch Lyel: there are ſeveral iſlands on the northern coaſt; and in various parts of the country we ſee monuments of victories obtained over the Danes or other foreign invaders. Sutherland boaſts of ſome towns, and a great many villages. The people are numerous, hardy, bold, and enterpriſing; courteous to ſtrangers; cheerful, open, frugal, and induſtrious. They, as well as their neighbours of Caithneſs, ſpeak the language, and wear the garb, uſed in the Lowlands of Scotland. They carry on a conſiderable ſalmon-fiſhery. They drive a traffic with their black cattle, ſheep, and horſes, at the neighbouring fairs; but export their corn, barley, ſalt, coal, ſalmon, ſalted beef, butter, cheeſe, wool-ſkins, hides, and tallow. Here are proviſions of all ſorts in plenty; and ſo cheap through all this country, that a gentleman may keep houſe and live much more ſumptuouſly for 200 l. a-year than he can live for three times the money in the ſouth of England.

Sutler ‖ Swallow.

SUTLER, in war, one who follows the army, and furniſhes the troops with proviſion. Sutlers pitch their tents, or build their huts, in the rear of each regiment, and about head-quarters.

SUTRIUM (anc. geog.), a famous city, and an ancient colony of the Romans, the key of Etruria: founded about ſeven years after the taking of Rome by the Gauls (Velleius). Now *Sutri* in St Peter's patrimony, on the river Pozzolo; ſurrounded on every ſide with rocks, 24 miles to the north-weſt of Rome.

SUTTON (Samuel), was born at Alfretton in Derbyſhire, and going into the army ſerved under the duke of Marlborough in Queen Anne's wars with great credit. He afterwards came to London, commenced brewer, and kept a coffee-houſe in Alderſgate-ſtreet, which was well frequented by the learned men of that time, by whom Mr Sutton was much reſpected, as a man of ſtrong natural parts and uncultivated genius. About the year 1740 he ſchemed a very ſimple and natural method for extracting the foul air from the wells of ſhips, by pipes communicating with the fire-places of the coppers; which operated as long as any fire was kept burning for the ſhip's uſe. He took out a patent in 1744, to ſecure the profits of his invention; and died about the year 1752.

Sutton's Air-pipes. See *Air pipes.*

SUTURE, in anatomy, a kind of articulation peculiar to the cranium or ſkull. See Anatomy, Part I. Sect. ii. *paſſim.*

Suture, in ſurgery, a method of uniting the lips of wounds together. See Surgery.

SWABBER, an inferior officer on board ſhips of war, whoſe employment it is to ſee that the decks are kept clean and neat.

SWABIA. See Suabia.

SWALLOW, in natural hiſtory, is claſſed under the genus of Hirundo, under which article the different ſpecies have been already deſcribed. Concerning this bird, one curious queſtion, however, ſtill remains to be diſcuſſed, What becomes of it in the winter? Upon this ſubject there are three opinions. Some ſay that it migrates to a warmer climate;

Queſtion, What becomes of ſwallows in winter?

Swallow. mate; ſome, that it retires to hollow trees and caverns, where it lies in a torpid ſtate; and others have affirmed, that it lies in the ſame ſtate in the bottom of lakes and under the ice. The firſt opinion is ſupported by Marſigli, Ray, Willoughby, Cateſby, Reaumur, Adanſon, Buffon &c. The firſt and ſecond opinion are both adopted by Pennant and White. The third is ſanctioned by Schæffer, Hevelius, Derham, Klein, Ellis, Linnæus, Kalm: and the ſecond and third have been ſtrongly defended by the honourable Daines Barrington.

Though we cannot help giving a preference to that opinion which appears the moſt probable, yet we do not think that any one of them is eſtabliſhed upon ſuch evidence as ſo curious a ſubject requires, and as the advanced ſtate of natural hiſtory would lead us to expect. We ſhall therefore ſtate the arguments upon which each opinion is founded as fairly and diſtinctly as we can, and as often as poſſible in the very words of their reſpective advocates. By doing ſo, we ſhall place the whole ſubject before the eyes of our readers, who will thus have an opportunity of examining it attentively, and of making ſuch obſervations and experiments as may lead to the truth.

2 First opinion ſtated that they migrate to warm climates.

Thoſe who aſſert that the ſwallow migrates to a warmer country in winter, argue in this manner: That many birds migrate, is a fact fully proved by the obſervations of natural hiſtorians (ſee MIGRATION). Is it not more probable, therefore, that ſwallows, which diſappear regularly every ſeaſon, retire to ſome other country, than that they lie in a ſtate of torpor in caverns or lakes? But this opinion does not reſt on probability, it is founded on facts.

We often ſee them collected in great flocks on churches, rocks, and trees, about the time when they annually diſappear. The direction of their flight has been obſerved to be ſouthward. Mr White, the ingenious hiſtorian of Selborne, travelling near the coaſt of the Britiſh Channel one morning early, ſaw a flock of ſwallows take their departure. At the beginning of his journey he was environed with a thick fog; but on a large wild heath the miſt began to break, and diſcovered to him numberleſs ſwallows, cluſtered on the ſtanding buſhes, as if they had rooſted there: as ſoon as the ſun burſt out, they were inſtantly on wing, and with an eaſy and placid flight proceeded towards the ſea. After this he ſaw no more flocks, only now and then a ſtraggler.

Natural Hiſtory of Selborne, p. 64.

Mr Laſkey of Exeter obſerved attentively the direction which a flock of ſwallows took in the autumn of 1793. On the 22d of September about ſeven o'clock in the morning, the wind being eaſterly, accompanied with a cold drizzling rain, Mr Laſkey's houſe was entirely covered with houſe-ſwallows. At intervals large flocks arrived and joined the main body, and at their arrival an unuſual chirping commenced. The appearance of the whole company was ſo lethargic, that he found it an eaſy matter to catch a conſiderable number of them, which he kept in a room all that day. By heating the room they all revived: he opened four of them, and found their ſtomachs quite full. The main body occupied the houſe top all day, except for two hours. About half an hour after nine on the morning of the 23d, there was a great commotion, with very loud chirping, and within a few minutes after, the whole multitude took their flight, in a direct ſouth-eaſt direction, having aſcended to a great height in the atmoſphere. He let go the birds which he had caught, at certain intervals till four o'clock, and they all flew toward the ſame quarter.

Gent. Mag. for 1796.

Not only has the direction of their flight been obſerved, but they have alſo been found on their paſſage at a great diſtance from land. Mr Adanſon informs us, that about 50 leagues from the coaſt of Senegal four ſwallows ſettled upon the ſhip on the 6th of October; that theſe birds were taken; and that he knew them to be European ſwallows, which, he conjectures, were returning to the coaſt of Africa. Sir Charles Wager's authority may alſo be appealed to: "Returning home (ſays he) in the ſpring of the year, as I came into ſoundings in our channel, a great flock of ſwallows came and ſettled on all my rigging: every rope was covered, they hung on one another like a ſwarm of bees; the decks and carving were filled with them. They ſeemed almoſt famiſhed and ſpent, and were only feathers and bones; but, being recruited with a night's reſt, took their flight in the morning." This vaſt fatigue proves that their journey muſt have been very great, conſidering the amazing ſwiftneſs of theſe birds: in all probability they had croſſed the Atlantic ocean, and were returning from the ſhores of Senegal, or other parts of Africa; ſo that this account from that moſt able and honeſt ſeaman, confirms the later information of Mr Adanſon.

Philoſophical Tranſactions, vol. liii.

Mr Kalm, who is an advocate for the opinion that ſwallows lie immerſed in lakes during the winter, acknowledges, that in croſſing the Atlantic from Europe a ſwallow lighted on the ſhip on the 2d September, when it had paſſed only two-thirds of the ocean. Since, therefore, ſwallows have been ſeen aſſembled in great flocks in autumn flying off in company towards ſouthern climes, ſince they have been found both in their paſſage from Europe and returning again, can there be any doubt of their annual migration? —For Mr Barrington's objections to this opinion, ſee MIGRATION, p. 5.

Kalm's Voyage, vol. i. p. 24.

3 Second opinion, that ſome lie in caverns in a torpid ſtate.

The ſecond notion (ſays Mr Pennant) has great antiquity on its ſide. Ariſtotle and Pliny give it as their belief, that ſwallows do not remove very far from their ſummer habitation, but winter in the hollows of rocks, and during that time loſe their feathers. The former part of their opinion has been adopted by ſeveral ingenious men; and of late ſeveral proofs have been brought of ſome ſpecies, at leaſt, having been diſcovered in a torpid ſtate. Mr Collinſon favoured us with the evidence of three gentlemen, eye-witneſſes to numbers of ſand martins being drawn out of a cliff on the Rhine, in the month of March 1762. And the honourable Daines Barrington communicated to us the following fact, on the authority of the late Lord Belhaven, That numbers of ſwallows have been found in old dry walls and in ſand-hills near his Lordſhip's ſeat in Eaſt Lothian; not once only, but from year to year; and that when they were expoſed to the warmth of a fire, they revived. We have alſo heard of the ſame annual diſcoveries, near Morpeth in Northumberland, but cannot ſpeak of them with the ſame aſſurance as the two former: neither in the two laſt inſtances are we certain of the particular ſpecies.

Pennant's Britiſh Zoology, vol. ii. p. 250.

"Other witneſſes crowd on us to prove the reſidence of thoſe birds in a torpid ſtate during the ſevere ſeaſon. Firſt, In the chalky cliffs of Suſſex; as was ſeen on the fall of a great fragment ſome years ago. Secondly, In a decayed hollow tree that was cut down, near Dolgelli, in Merionethſhire. Thirdly, In a cliff near Whitby, Yorkſhire; where, on digging out a fox, whole buſhels of ſwallows were found in a torpid condition. And, laſtly, The reverend Mr Conway of Sychton, Flintſhire, was ſo obliging as to communicate the following fact: A few years ago, on looking down an old lead mine in that country, he obſerved numbers of ſwallows clinging to the timbers of the ſhaft, ſeemingly aſleep; and on flinging ſome gravel on them, they juſt moved, but never attempted to fly or change their place: this was between All Saints and Chriſtmas.

"Theſe

Swallow.

"These are doubtless the lurking places of the later hatches, or of those young birds which are incapable of distant migrations. There they continue insensible and rigid; but like flies may sometimes be reanimated by an unseasonable hot day in the midst of winter: for very near Christmas a few appeared on the moulding of a window of Merton college, Oxford, in a remarkably warm nook, which prematurely set their blood in motion, having the same effect as laying them before a fire at the same time of year. Others have been known to make this premature appearance; but as soon as the cold natural to the season returns, they withdraw again to their former retreats.

"The above are circumstances we cannot but assent to, though seemingly contradictory to the common course of nature in regard to other birds. We must, therefore, divide our belief relating to these two so different opinions; and conclude, that one part of the swallow tribe migrate, and that others have their winter-quarters near home. If it should be demanded, why swallows alone are found in a torpid state, and not the other many species of soft-billed birds, which likewise disappear about the same time? reasons might be assigned:"

4 Third opinion, that some lie immersed in water.

The third opinion we shall state and support in the words of Mr Kalm. "Natural history (says he), as all other histories, depends not always upon the intrinsic degree of probability, but upon facts founded on the testimony of people of noted veracity.—Swallows are seldom seen sinking down into the water; swallows have not such organs as frogs or lizards, which are torpid during winter; *ergo*, swallows live not, and cannot live, under water.—This way of arguing, I believe, would carry us, in a great many cases, too far: for though it is not clear to every one, it may however be true; and lizards and frogs are animals of a class widely different from that of birds, and must therefore of course have a different structure; hence it is they are classed separately. The bear and the marmot are in winter in a torpid state, and have, however, not such organs as lizards and frogs; and nobody doubts of their being, during some time, in the most rigid climates, in a torpid state: for the Alpine nations hunt the marmots frequently by digging their holes up; and find them so torpid, that they cut their throats, without their reviving or giving the least sign of life during the operation; but when the torpid marmot is brought into a warm room, and placed before the fire, it revives from its lethargy. The question must therefore be decided by facts; nor are these wanting here. Dr Wallerius, the celebrated Swedish chemist, informs us, That he has seen, more than once, swallows assembling on a reed, till they were all immersed and went to the bottom; this being preceded by a dirge of a quarter of an hour's length. He attests likewise, that he had seen a swallow caught during winter out of a lake with a net, drawn, as is common in northern countries, under the ice; this bird was brought into a warm room, revived, fluttered about, and soon after died.

"Mr Klein applied to many farmers-general of the king of Prussia's domains, who had great lakes in their districts, the fishery in them being a part of the revenue. In winter the fishery thereon is the most considerable under the ice, with nets spreading more than 200 or 300 fathoms, and they are often wound by screws and engines on account of their weight. All the people that were questioned made affidavits upon oath before the magistrates. First, The mother of the countess Lehndorf said, that she had seen a bundle of swallows brought from the Frishe-Haff (a lake communicating with the Baltic at Pillaw), which, when brought into a moderately warm room, revived and fluttered about. Secondly, Count Schileben gave an instrument on stamped paper, importing, that by fishing on the lake belonging to his estate of Gerdauen in winter, he saw several swallows caught in the net, one of which he took up in his hand, brought it into a warm room, where it lay about an hour, when it began to stir, and half an hour after, it flew about in the room. Thirdly, Farmer general (Amtman) Witkouski made affidavit, that, in the year 1740, three swallows were brought up with the net in the great pond at Didlacken; in the year 1741 he got two swallows from another part of the pond, and took them home (they being all caught in his presence); after an hour's space they revived all in a warm room, fluttered about, and died in three hours after. Fourthly, Amtman Bonke says, that having had the estate of Kleskow in farm, he had seen nine swallows brought up in the net from under the ice, all which he took into a warm room, where he distinctly observed how they gradually revived; but a few hours after they all died. Another time his people got likewise some swallows in a net, but he ordered them to be again thrown into the water. Fifthly, Andrew Rutta, a master fisherman at Oletsko, made affidavit, in 1747, that 22 years ago, two swallows were taken up by him in a net, under the ice, and, being brought into a warm room, they flew about. Sixthly, Jacob Kosiulo, a master fisherman at Stradauen, made affidavit, that, in 1736, he brought up in winter, in a net, from under the ice of the lake at Raski, a seemingly dead swallow, which revived in half an hour's time in a warm room; and he saw, in a quarter of an hour after, the bird grow weaker, and soon after dying. Seventhly, I can reckon myself (says our author) among the eye-witnesses of this paradox of natural history. In the year 1735, being a little boy, I saw several swallows brought in winter by the fishermen from the river Vistula to my father's house; where two of them were brought into a warm room, revived, and flew about. I saw them several times settling on the warm stove (which the northern nations have in their rooms); and I recollect well, that the same forenoon they died, and I had them, when dead, in my hand. In the year 1754, after the death of my uncle Godefroy Wolf, captain in the Polish regiment of foot-guards, being myself one of his heirs, I administered for my co-heirs several estates called the *Staroſty of Diſchau*, in Polish Prussia, which my late uncle farmed under the king. In January, the lake of Lybshaw, belonging to these estates, being covered with ice, I ordered the fishermen to fish therein, and in my presence several swallows were taken, which the fishermen threw in again; but one I took up to myself, brought it home, which was five miles from thence, and it revived, but died about an hour after its reviving.

Swallow.

"These are facts attested by people of the highest quality, by some in public offices, and by others who, though of a low rank, however, made these affidavits upon oath. It is impossible to suppose indiscriminately that they were prompted, by views of interest, to assert as a fact a thing which had no truth in it. It is therefore highly probable, or rather incontestably true, that swallows retire in the northern countries, during winter, into the water, and stay there in a torpid state till the return of warmth revives them again in spring. The question therefore, I believe, ought for the future to be thus stated: The swallows in Spain, Italy, France, and perhaps some from England, remove to warmer climates; some English ones, and some in Germany and other mild countries, retire into clefts and holes in rocks, and remain there in a torpid state. In the colder northern countries the swallows immerse in the sea, in lakes, and rivers; and remain in a torpid state, under ice, during winter. There are still some objections to this latter

after-

Swallow. assertion, which we must remove. It is said, Why do not rapacious fish, and aquatic quadrupeds and birds, devour these swallows? The answer is obvious, swallows choose only such places in the water for their winter-retreat as are near reeds and rushes; so that sinking down there between them and their roots, they are by them secured against the rapaciousness of their enemies. But others object, Why are not these birds caught in such fresh waters as are continually harassed by nets? I believe the same answer which has been made to the first objection will serve for this likewise. Fishermen take care to keep off with their nets from places filled with reeds and rushes, for fear of entangling and tearing their net; and thus the situation of swallows under water, is the reason that they are seldom disturbed in their silent winter-retreats. What confirms this opinion still more is, that swallows were never caught in Prussia according to the abovementioned affidavits, but with those parts of the net which passed near to the reeds and rushes; and sometimes the swallows were yet fastened with their feet to a reed, when they were drawn up by the net. As to the argument taken from their being so long under water without corruption, I believe there is a real difference between animals suffocated in water and animals being torpid therein. We have examples of things being a long time under water; to which we may add the intense cold of these nothern regions, which preserves them. Who would have thought that snails and polypes might be dissected, and could reproduce the parts severed from their bodies, if it was not a fact? Natural history ought to be studied as a collection of facts, not as the history of our guesses or opinions. Nature varies in an infinite manner; and Providence has diversified the instinct of animals and their economy, and adapted it to the various seasons and climates."

5 This question ought to be determined, not by reasoning, but by experiment.

With Mr Kalm's concluding observations we heartily concur. Natural history ought to be studied as a collection of facts; and it was from this very notion that we have stated the abovementioned opinions so fully, and brought together the facts which the best advocates for each opinion have judged most proper for supporting them. We are sensible of the great improbability of the third opinion, and know that many arguments have been used to prove its absurdity: such as these, The swallow is lighter than water, and therefore cannot sink; if it moults at all, it must moult under water during its torpid state, which is very improbable; there is no instance of land animals living so long under water without respiration. Many other arguments of the same sort have been advanced, and certainly afford a short way of deciding the question; but unless they were sufficient to prove the immersion of swallows a physical impossibility, they are of no force when opposed to the evidence of testimony, if there be no cause to suspect the witnesses of inaccuracy or design. The true way to refute such an opinion is by accurate observation and experiment. We have not heard of any accurate inquiries being made by philosophers in those northern countries where swallows are said to pass the winter under water. The count de Buffon, indeed, shut up some swallows in an ice-house by way of experiment, which died in a few days; but as he does not tell us what precautions he took to make the experiment succeed, it is not intitled to any attention.

Gentleman's Magazine, May 1796.

Mr John Hunter made a very judicious experiment on the banks of the Thames, which is described by a correspondent in the Gentleman's Magazine, who asserts that he had it from Mr Hunter himself.

One year in the month of September, he prepared a room, with every accommodation and convenience which he could contrive, to serve as a dormitory for swallows, if they were disposed to sleep in winter. He placed in the centre a large tub of water with twigs and reeds, &c. which reached to the bottom. In the corners of the room he contrived artificial caverns and holes, into which they might retire; and he laid on the floor, or suspended in the air, different lengths of old wooden pipes, which had formerly been employed in conveying the water through the streets, &c.

Swallow. 6 Mr Hunter's experiment ingenious,

When the receptacle was rendered as complete as possible, he then engaged some watermen to take by night a large quantity of the swallows that hung upon the reeds in the Thames about the time of their departure. They brought him, in a hamper, a considerable number; and had so nicely hit the time of their capture, that on the very day following there were none to be seen.

He put the swallows into the room so prepared, where they continued to fly about, and occasionally perch on the twigs, &c. But not one ever retired into the water, the caverns, holes, or wooden pipes, or shewed the least disposition to grow torpid, &c. In this situation he let them remain till they all died but one. This, appearing to retain some vigour, was set at liberty; when it mounted out of sight, and flew away. All the birds lay dead scattered about the room; but not one was found asleep or torpid, or had, if the correspondent remembers, so much as crept into any of the receptacles he had so provided.

7 But not decisive with respect to northern climates.

This experiment was ingenious, and certainly does render the doctrine of immersion much more improbable; but it is not decisive; for it may still be urged by the advocates for that doctrine, as Mr Kalm has done, that it may only be in the colder countries where swallows retire into the water. We formerly said that none of the three opinions are supported by such evidence as to satisfy the mind completely. Opinions which respect events which happen every year ought to be confirmed by a great number of observations, and not by a few instances divested of almost all their concomitant circumstances. Can no better proofs be brought to prove the migration of swallows than those of Adanson and Sir Charles Wager, or the circumstances mentioned by Mr White and Mr Laskey respecting their disappearing? We ought not merely to know that some swallows have taken a southerly flight in autumn, that some have been found at a great distance from land in the spring, or in harvest; but we ought to know to what countries they actually retire. Before we can rest satisfied, too, that it is a general fact that swallows remain in a torpid state during winter, either in caverns or in the bottom of lakes, &c. we must have more proofs; we must know what species of swallows they are said to be, in what countries this event takes place, and several other circumstances of the same kind.

8 Many things yet remain to be done in order to determine this point.

We cannot help being of opinion that much remains to be done in order properly to ascertain what becomes of the swallows in Europe during winter. It would be necessary, in the first place, to know accurately what are the countries in which swallows are found. 2. Do they remain visible the whole year? or, if they disappear, at what season does this happen, and when do they appear again? 3. Do they ever appear while a strong north wind blows, or do they only come in great numbers with a south wind? We will endeavour to answer some of these questions in part; but must regret, that all the information on this subject which we have been able to cull from the best writers in natural history is very scanty; and we merely give it by way of specimen, hoping that future observations will soon render it more complete.

9 A few important facts stated.

There are five species which visit Britain during the summer months; the common or chimney swallow, the martin, sand martin, swift, and goat-sucker. The chimney swallow frequents almost every part of the old continent; being known (says Dr Latham) from Norway to the Cape

of

Swallow. of Good Hope on the one ſide, and from Kamtſchatka to India and Japan on the other. It is alſo found in all parts of North America, and in ſeveral of the Weſt Indian Iſlands. In Europe it diſappears during the winter months. It appears generally a little after the vernal equinox; but rather earlier in the ſouthern, and later in the northern latitudes. It adheres to the uſual ſeaſons with much regularity; for though the months of February and March ſhould be uncommonly mild, and April and May remarkably cold, it never deviates from its ordinary time. In the cold ſpring of 1740 ſome appeared in France before the inſects on which they feed had become numerous enough to ſupport them, and great numbers died †. In the mild and even warm ſpring of 1774 they appeared no earlier than uſual. They remain in ſome warm countries the whole year. Kolben aſſures us that this is the caſe at the Cape of Good Hope; but (he ſays) they are more numerous in winter. Some birds of this ſpecies live, during winter, even in Europe; for example, on the coaſt of Genoa, where they ſpend the night in the open country on the orange ſhrubs.

† Buffon's Natural Hiſtory of Birds, vol. vi. p. 527.

2. The *martins* are alſo widely diffuſed through the old continent; but the countries where they reſide or viſit have not been marked by naturaliſts with much attention. 3. The *ſand martins* are found in every part of Europe, and frequently ſpend the winter in Malta ‡. Two birds of this ſpecies were ſeen in Perigord in France, on the 27th December 1775, when there was a ſoutherly wind, attended with a little rain ‖. 4. The *ſwift* viſits the whole continent of Europe; has alſo been obſerved at the Cape of Good Hope, and in Carolina in North America. 5. The *goat-ſuckers* are not very common birds, yet are widely ſcattered. They are found in every country between Sweden and Africa: they are found alſo in India. In April the ſouth-weſt wind brings them to Malta, and in autumn they repaſs in great numbers.

Tranſactions of the Linnæan Society, vol. i.

Mr Markwick of Catsfield, near Battle in Suſſex, has drawn up an accurate table, expreſſing the day of the month on which the birds, commonly called *migratory*, appeared in ſpring, and diſappeared in autumn, for 16 years, from 1768 to 1783 inclusive. The obſervations were made at Catsfield. From this table we ſhall extract the dates for five years, and add the very few obſervations which we have been able to collect reſpecting the time when the ſwallow appears and diſappears in other countries.

§ Buffon, ibid.

Were tables of the ſame kind made in every different country, particularly within the torrid zone, it would be eaſy to determine the queſtion which we have been conſidering. To many, perhaps, it may not appear a matter of ſuch importance as to be worth the labour. We acknowledge it to be rather a curious than an important inquiry; yet it is one which muſt be highly gratifying to every mind that can admire the wiſdom of the Great Architect of nature. The inſtinct of the ſwallow is indeed wonderful: it appears among us juſt at the time when inſects become numerous; and it continues with us during the hot weather, in order to prevent them from multiplying too much. It diſappears when theſe inſects are no longer troubleſome. It is never found in ſolitude; it is the friend of man, and always takes up its reſidence with us that it may protect our houſes and our ſtreets from being annoyed with ſwarms of flies.

Swallow-Swammerdam.

Swallow-Wort, in botany. See Asclepias.

SWAMMERDAM (John), a celebrated and learned natural philoſopher, was the ſon of John James Swammerdam, an apothecary and famous naturaliſt of Amſterdam, and was born in 1637. His father intended him for the church, and with this view had him inſtructed in Latin and Greek; but he, thinking himſelf unequal to ſo important a taſk, prevailed with his father to conſent to his applying himſelf to phyſic. As he was kept at home till he ſhould be properly qualified to engage in that ſtudy, he was frequently employed in cleaning his father's curioſities, and putting every thing in its proper place. This inſpired our author with an early taſte for natural hiſtory; ſo that, not content with the ſurvey of the curioſities his father had purchaſed, he ſoon began to make a collection of his own, which he compared with the accounts given of them by the beſt writers. When grown up, he ſeriouſly attended to anatomical and medical ſtudies; yet ſpent part of the day and the night in diſcovering, catching, and examining the flying inſects proper to thoſe times, not only in the province of Holland, but in thoſe of Guelderland and Utrecht.—Thus initiated in natural hiſtory, he went to the univerſity of Leyden in 1651; and in 1663 was admitted a candidate of phyſic in that univerſity. His attention being now engaged by anatomy, he began to conſider how the parts of the body, prepared by diſſection, could be preſerved, and kept in conſtant order for anatomical demonſtration; and herein he ſucceeded, as he had done before in his nice contrivances for diſſecting and managing the minuteſt inſects. Our author afterwards made a journey into France, where he ſpent ſome time at Saumur, and where he became acquainted with ſeveral learned men. In 1667 he returned to Leyden, and took his degree of Doctor of Phyſic. The next year the grand duke of Tuſcany being in Holland in order to ſee the curioſities of the country, came to view thoſe of our author and his father; and on this occaſion Swammerdam made ſome anatomical diſſections of inſects in the preſence of that prince, who was ſtruck with admiration at our author's great ſkill in managing them, eſpecially at his proving that the future butterfly lay with all its parts neatly folded up in a caterpillar, by actually removing the integuments that covered the former, and extricating and exhibiting all its parts, however minute, with incredible ingenuity, by means of inſtruments of inconceivable fineneſs. On this occaſion the duke offered our author 12,000 florins for his ſhare of the collection, on condition of his removing them himſelf into Tuſcany, and coming to live at the court of Florence; but Swammerdam, who hated a court life, declined his highneſs's propoſal. In 1663, he publiſhed a General Hiſtory of Inſects. About this time, his father began to take offence at his inconſiderately neglecting the practice of phyſic, which might have ſupported him in affluence; and would neither ſupply him with money nor clothes. This reduced him to ſome difficulties. In 1675 he publiſhed his Hiſtory of the Ephemeras; and his father dying the ſame year, left him a fortune ſufficient for his ſupport;

Swan || Sweden.

port: But he did not long ſurvive him, for he died in 1682. Gaubius gave a tranſlation of all his works from the original Dutch into Latin, from which they were tranſlated into Engliſh, in folio, in 1758. The celebrated Boerhaave wrote his life.

SWAN, in ornithology. See ANAS.

SWANPAN, or Chineſe ABACUS; an inſtrument for performing arithmetical operations, deſcribed by Du Halde in his Hiſtory of China.

It is compoſed of a ſmall board, croſſed with 10 or 12 parallel rods or wires, each ſtrung with ivory balls, which are ſo divided by a partition in the middle, that two are on one ſide of it, and five on the other. The two in the upper part ſtand each for five units, and each of the five in the lower part for one. "In joining and ſeparating theſe balls, they reckon much as we do with counters; but, according to our author, more expeditiouſly than Europeans do even with figures." This is hardly credible; but if all the Chineſe weights and meaſures be decimally divided, as by his very lame deſcription of the *ſwanpan* they would appear to be, it is eaſy to conceive how computation may be made by this inſtrument very expeditiouſly. The inſtrument, too, may be ſo contrived as to ſuit any diviſion of weights and meaſures, and in that form be uſeful to the blind; but as we have elſewhere given deſcriptions of ſuperior inſtruments, for their accommodation (See BLIND) it is needleſs to offer in this place any improvement of the *ſwanpan*.

Gent Mag. for 1748.

SWANEMOTE, SWAINMOTE, or SWEINMOTE. See *FOREST-Courts*.

SWEARING. See OATH.

SWEAT, a ſenſible moiſture iſſuing from the pores of the ſkins of living animals.

The exceſs of it dries and weakens the body, deprives the humours of their watery parts, and induces the blood to an inflammatory and atrabiliary diſpoſition. A ſudden ſuppreſſion of it will equally hurt as well as a ſuppreſſion of perſpiration.

SWEATING SICKNESS, a diſorder which appeared in England about the year 1481, and was by foreigners called the *Engliſh ſweat*. It returned again in 1485; then in 1506; afterwards in 1517. It appeared again in 1528, or 1529, at which time alone it ſpread itſelf to the Netherlands and Germany: a circumſtance which ſhews the impropriety of calling it *the Engliſh ſweat*, in Latin *ſudor Anglicanus*; beſides, Sennertus takes notice, that it ſpread as far as Denmark, Norway, and France. It raged again in 1548. And the laſt return of it in London was in 1551, when it was ſo violent as in one day to take off 120 of the inhabitants of Weſtminſter. Some were ſeized abroad, and cut off in the road, others at home. Some when awake, others when faſt aſleep. Some died in a moment, and others in one, two, three, four, or more hours after they began to ſweat.

Valangin's Treatiſe on Dict, &c.

SWEDEN, one of the moſt northerly kingdoms of Europe, lying between Lat. 55. 20. and 69. 30. north, and between 12° and 32° eaſt from London. On the ſouth it is bounded by the Baltic, on the north by Daniſh Lapland, on the eaſt by Muſcovy, and on the weſt by the mountains of Norway, being 800 miles in length and 350 in breadth.

1 Early hiſtory uncertain.

The early hiſtory of Sweden is no leſs involved in fables than that of moſt other nations. Some hiſtorians have pretended to give regular catalogues of the princes who reigned in Sweden in very early times: but they differ ſo much among themſelves, that no credit can be given to them. However, all agree that ancient Scandinavia was firſt governed by judges elected for a certain time by the voice of the people. Among theſe temporary princes the country was divided, until, in the year of the world 2054, according to ſome, or 1951, according to others, Eric, or, if we believe Puffendorf, Suenon was raiſed to the ſupreme power, with the prerogatives of all the temporary magiſtrates united in his perſon for life, or until his conduct ſhould merit depoſition. Sweden.

From this very early period till the year 1366 of the Chriſtian era, the hiſtories of Sweden preſent us with nothing but what is common to all nations in their early periods, viz. the endleſs combats and maſſacres of barbarians, tending to no other purpoſe than the effuſion of blood. At the time juſt mentioned, however, Albert of Mecklenburg, having concluded a peace between Sweden and Denmark, which two kingdoms had been at violent war for ſome time before, was proclaimed king of Sweden. The peace was of ſhort duration, being broken in 1368; on which Albert entered into an offenſive and defenſive league with the earl of Holſtein, the Jutland nobility, the dukes of Selſwick, Mecklenburg, and the Hanſe-towns, againſt the kings of Denmark and Norway. Albert proved very ſucceſsful againſt Waldemar king of Denmark at that time, driving him entirely out of his dominions; but he himſelf was defeated by the king of Norway, who laid ſiege to his capital. Soon after this, a new treaty of peace was concluded, by which Albert was allowed to enjoy the crown of Sweden in peace. However, having formed a deſign of rendering himſelf abſolute, he fell under the diſpleaſure of his ſubjects, and Margaret of Norway was proclaimed queen of Sweden by the malecontents. A war immediately enſued, in which Albert was defeated and taken priſoner; but as the princes of Mecklenburg, the earls of Holſtein, and the Hanſe-towns, entered into a league in his favour, the war was ſo far from being extinguiſhed by this event, that it raged with more fury than ever.

2 Albert of Mecklenburg declared king in 1360.

3 War with Denmark and Norway.

4 Is defeated and taken priſoner by Margaret of Norway.

At length, in 1394, the contending parties came to an accommodation. Albert was ſet at liberty, on condition that he ſhould in three years ſurrender to Margaret all pretenſions to the city of Stockholm; and the Hanſe-towns engaged to pay the ſum of 60,000 marks of ſilver in caſe of Albert's breach of faith. Not long after this, Eric the ſon of Albert died; and he, having no other child, did not think it worth his while to contend for the kingdom of Sweden: he therefore acquieſced in the pretenſions of Margaret, and paſſed the remainder of his days at Mecklenburg.

5 Set at liberty.

Margaret died in 1415, and was ſucceeded by Eric of Pomerania. This prince's reign was cruel and oppreſſive to the laſt degree. The people were ruined by taxes; and the Danes being everywhere preferred to the offices of power, committed the greateſt cruelties. The conſequence of this was a revolt; and Charles Canutſon, grand mareſchal of Sweden and governor of Finland, having joined the malecontents, was declared commander in chief of their army. Eric was now formally depoſed, and commenced pirate: Canutſon was choſen regent: but beginning to oppreſs the people, and aſpiring openly at the crown, the Swedes and Danes revolted; in conſequence of which a revolution took place, and Chriſtopher duke of Bavaria, nephew to Eric, was choſen king of Denmark, Sweden, and Norway, in 1442.

6 Margaret is ſucceeded by Eric a cruel tyrant.

7 A general revolt takes place and Eric is depoſed.

On the acceſſion of the new prince, complaints againſt Canutſon were brought from all quarters; but, through the intereſt of his friends, he eſcaped the puniſhment due to him; and in 1448, Chriſtopher having died after a tyrannical reign of ſomewhat more than five years, he was raiſed to the throne at which he had ſo long aſpired. However, the kingdoms of Denmark and Norway refuſed to own allegiance to him; upon which a war immediately commenced.

Sweden.

In 1454 peace was concluded, and Denmark for the preſent freed from the Swediſh yoke. Neither did Canutſon long enjoy even the crown of Sweden itſelf. Having quarrelled with the archbiſhop of Upſal, the latter formed ſuch a ſtrong party that the king could not reſiſt him. Chriſtian king of Denmark was called to the throne of Sweden; and in 1459 once more united the three kingdoms. He enjoyed his dignity but a ſhort time; for having begun to oppreſs his ſubjects in an arbitrary manner, he was obliged to retire to Denmark in 1463. Katil biſhop of Lincoping, who had driven out the king, took upon himſelf the office of regent. Next year Chriſtian returned with a powerful army; but was defeated. The people then thought proper to recal Canutſon: but he, on his firſt acceſſion, having offended the warlike Biſhop Katil, was by him defeated, and obliged to renounce his right to the crown. After this the kingdom was rent into factions; between whom the moſt cruel civil wars took place, until the year 1467, when Canutſon was again recalled, and enjoyed the kingdom, though not without difficulty and oppoſition, till his death, which happened in 1470.

8 The three kingdoms united under Chriſtian king of Denmark, who proves a tyrant, and is driven out.

The confuſion in which the Swediſh affairs had been ſo long involved did not ceaſe on the death of Canutſon. Chriſtian again invaded Sweden; but was defeated by Steen Sture, nephew to the late king. After this the kingdom ſeems to have remained in peace till the year 1487, when the Ruſſians invaded Carelia, committing everywhere the greateſt ravages. Theſe were ſoon driven out: but in 1497, a rupture happening betwixt Sture and the ſenate, an offer was made of the Swediſh crown to John king of Denmark. This prince readily accepted the offer, and was crowned accordingly; but no ſooner was he ſeated on the throne than he became odious to the Swedes, from his partiality to the Danes. In a ſhort time he ſet out for Denmark, leaving his queen, with a ſtrong garriſon, in the citadel of Stockholm. He was no ſooner gone than the capital was inveſted: and though the queen made a noble defence, ſhe was at laſt obliged to capitulate, on condition of being allowed to paſs into Denmark. All the garriſon were made priſoners of war, and the queen herſelf was confined in a monaſtery till the following year.

9 John king of Denmark obtains the Swediſh crown, but is driven out.

The Swediſh affairs continued to be involved in the ſame dreadful confuſion as we have already related, until the year 1520, when a great revolution was effected by Guſtavus Ericſon, a nobleman of the firſt rank, who reſtored the kingdom to its liberty, and laid the foundation of its future grandeur. The occaſion of this great revolution was as follows: In 1518, Chriſtian king of Denmark invaded Sweden, with a deſign to ſubdue the whole country; but being defeated with great loſs by young Steen Sture, the regent at that time, he ſet ſail for Denmark. But meeting with contrary winds, he made ſeveral deſcents on the Swediſh coaſt, which he ravaged with all the fury of an incenſed barbarian. The inhabitants, however, bravely defended themſelves, and Chriſtian was reduced to the utmoſt diſtreſs; one half of his forces having periſhed with hunger, and the other being in the moſt imminent danger by the approach of a rigorous winter. He then thought of a ſtratagem, which had almoſt proved fatal to the regent; for having invited him to a conference, at which he deſigned either to aſſaſſinate or take him priſoner, Sture was about to comply, had not the ſenate, who ſuſpected the plot, interpoſed and prevented him. Chriſtian then offered to go in perſon to Stockholm in order to confer with Sture, upon condition that ſix hoſtages ſhould be ſent in his room. This was accordingly done; but the wind happening then to prove favourable, he ſet ſail for Denmark with the hoſtages, of whom Guſtavus Ericſon was one. Next year he returned; and having drawn Sture into an ambuſh, the regent received a wound of which he died ſome time after. The kingdom being thus left without a head, matters ſoon came to the moſt deſperate criſis. The army diſbanded itſelf; and the ſenate, inſtead of taking proper meaſures to oppoſe the enemy, ſpent their time in idle debates. Chriſtian in the mean time advanced into the heart of the kingdom, deſtroying every thing with fire and ſword; but on his arrival at Stragnez, he granted a ſuſpenſion of arms, to give the people time to deliberate on their ſituation, and to reflect that they might eaſily get rid of their troubles by electing him king. This they accordingly did; and Chriſtian proved one of the moſt bloody tyrants that ever ſat on the throne of any kingdom. Immediately after his coronation, he gave grand entertainments for three days; during which time he prejected the diabolical deſign of extirpating at once all the Swediſh nobility, and thus for ever preventing the people from revolting, by depriving them of their proper leaders. As the tyrant had ſigned articles, by which he promiſed indemnity to all who had borne arms againſt him, it became neceſſary to invent ſome cauſe of offence againſt thoſe whom he intended to deſtroy. To accompliſh his purpoſe, Guſtavus Trolle, formerly archbiſhop of Upſal, but who had been degraded from that dignity, in an oration before his majeſty lamented the demolition of Stecka, his place of reſidence, and the loſſes ſuſtained by the ſee of Upſal, amounting to near a million of money. He then proceeded in a bitter accuſation againſt the widow and the ſon-in-law of Sture the late regent, comprehending in the ſame accuſation about 15 of the principal nobility, the whole ſenate, and the burgers of Stockholm. The conſequence of this was, that above 60 of the principal nobility and people of firſt rank in Sweden were hanged up as traitors. Innumerable other cruelties were committed; part of which are owned by the Daniſh hiſtorians, and minutely related by thoſe of Sweden. At laſt he departed for Denmark, ordering gibbets to be erected, and cauſing the peaſants to be hanged on them for the ſlighteſt offences, all the way as he paſſed along; and it is related of him, that at Jencoping he cauſed two boys, one of ſeven and the other of nine years of age, to be whipped to death.

Sweden.

12 Is choſen king, and proves a moſt bloody tyrant.

13 Maſſacres the nobility, and cauſes gibbets to be erected as he paſſes along.

This monſtrous cruelty, inſtead of ſecuring him on the throne, exaſperated the whole nation againſt him. It has already been mentioned, that Guſtavus Ericſon, or, as he is commonly called, *Guſtavus Vaſa*, was among the number of the hoſtages whom Chriſtian had perfidiouſly carried to Denmark in 1519. Large promiſes had been made in order to reconcile him to Chriſtian, and threats had been uſed for the ſame purpoſe, but all in vain. Secret orders were given to ſtrangle him in priſon; but the officer to whom the aſſaſſination was committed remonſtrated to the king about the conſequences of it, and prevailed on him to change the ſentence of death into cloſe confinement in the caſtle of Copenhagen. Some of the hoſtages periſhed in conſequence of the rigorous treatment they met with; but Guſtavus withſtood all hardſhips. At laſt one Banner, a Daniſh nobleman, prevailed on the king to put him into his hands, in order to try whether or not he could prevail upon him to change his ſentiments. The king, however, told Banner, that he muſt pay 6000 crowns in caſe the priſoner ſhould make his eſcape. Banner generouſly aſſented; and having brought the noble priſoner to his fortreſs of Calo in Jutland, ſoon allowed him all the liberty he could deſire, and otherwiſe heaped favours upon him. All this, however, could not extinguiſh his remembrance of the cruelties of Chriſtian, and the deſire he had of being ſerviceable to his country. He therefore determined to make his eſcape; and the liberty he enjoyed ſoon put him in a capacity of effecting

14 Adventures of Guſtavus Vaſa or Ericſon.

15 He eſcapes from Denmark.

10 Chriſtian king of Denmark invades Sweden, but is defeated and driven out.

11 He treacherouſly carries off ſix hoſtages, of whom Guſtavus Ericſon is one.

Sweden. effecting it. Having one day mounted his horſe, under pretence of hunting as uſual in the foreſt, when he got at a proper diſtance, he changed his dreſs to the habit of a peaſant; and quitting his horſe, he travelled for two days on foot through by-paths, and over mountains almoſt impaſſable, arriving on the third at Flenſburgh. Here no one was admitted without a paſſport; and Guſtavus dreaded preſenting himſelf to the governor or the officer upon guard, for fear of being diſcovered. Happily for him, it chanced to be on that ſeaſon of the year when the merchants of Lower Saxony drove a conſiderable trade in cattle, which they purchaſe in Jutland. Guſtavus hired himſelf to one of theſe merchants; and under favour of his diſguiſe eſcaped out of the Daniſh territories, and arrived at Lubec.

16 Arrives at Lubec.

Banner was no ſooner acquainted with his eſcape, than he ſet out after him with the utmoſt diligence, found him at Lubec, and reproached him with great warmth as ungrateful and treacherous; but he was ſoon appeaſed by the arguments urged by Guſtavus, and eſpecially by the promiſe he made of indemnifying him in the loſs of his ranſom. Upon this Banner returned, giving out that he could not find his priſoner. Chriſtian was enraged at his eſcape, apprehending that he might reverſe all his deſigns in Sweden; and gave orders to Otho his general to make the ſtricteſt ſearch, and leave no means untried to arreſt him. Guſtavus applied to the regency for a ſhip to convey him to Sweden, where he hoped he ſhould be able to form a party againſt the Danes. He likewiſe endeavoured to draw the regency of Lubec into his meaſures; and reaſoned with ſo much zeal and ability, that Nicholas Gemins, firſt conſul, was entirely gained; but the regency could never be prevailed on to declare for a party without friends, arms, money, or credit. However, before his departure, the conſul gave him aſſurances, that if he could raiſe a force ſufficient to make head againſt the enemy in the field, he might depend on the ſervices of the republic, and that the regency would immediately declare for him. Guſtavus deſired to be landed at Stockholm; but the captain of the ſhip, either having ſecret orders to the contrary, or buſineſs elſewhere, ſteered a different courſe, and put him on ſhore near Calmar; a city hitherto garriſoned by the troops of Chriſtina widow of the regent. In truth, the governor held this place for his own purpoſes, and only waited to make the beſt terms he could with the Danes. When Guſtavus arrived, he made himſelf known to him and the principal officers of the garriſon, who were moſtly Germans, and his fellow-ſoldiers in the late adminiſtrator's army. He flattered himſelf that his birth, his merit, and connexions, would immediately procure him the command. But the mercenary band, ſeeing him without troops and without attendants, regarded him as a deſperate perſon devoted to deſtruction, refuſed to embrace his propoſals, and even threatened to kill or betray him, if he did not inſtantly quit the city.

17 Attempts in vain to draw the regency of Lubec over to his ſide.

18 He arrives at Calmar, but meets with an unfavourable reception.

Diſappointed in his expectations, Guſtavus departed with great expedition; and his arrival being now publicly known, he was again forced to have recourſe to his peaſant's diſguiſe to conceal him from the Daniſh emiſſaries diſperſed over the country to ſearch for him. In a waggon loaded with hay he paſſed through every quarter of the Daniſh army and at laſt repaired to an old family caſtle in Sudermania. From hence he wrote to his friends, notifying his return to Sweden, and beſeeching them to aſſemble all their forces in order to break through the enemy's army into Stockholm, at that time beſieged; but they, too, refuſed to embark in ſo hazardous and deſperate an attempt.

19 His friends refuſe to aſſiſt him.

Guſtavus next applied himſelf to the peaſants: but they Sweden. anſwered, that they enjoyed ſalt and herrings under the government of the king of Denmark; and that any attempts to bring about a revolution would be attended with certain ruin, without the proſpect of bettering their condition; for peaſants they were, and peaſants they ſhould remain, whoever was king. At length, after ſeveral vain attempts to throw himſelf into Stockholm, after that city was ſurrendered to the king, after the horrid maſſacre of the ſenate, and after running a thouſand dangers, and undergoing hardſhips and fatigues hardly to be ſupported by human nature, he formed the reſolution of trying the courage and affection of the Dalecarlians. While he was in the deepeſt obſcurity, and plunged in almoſt unſurmountable adverſity, he never relinquiſhed his deſigns nor his hopes. The news of the maſſacre had, however, very near ſunk him into deſpondency, as thereby he loſt all his friends, relations, and connections, and indeed almoſt every proſpect of ſafety to himſelf or deliverance to his country. It was this that inſpired the thought of going to Dalecarlia, where he might live with more ſecurity in the high mountains and thick woods of that country, if he ſhould fail in the attempt of exciting the inhabitants to revolt.

20 Applies in vain to the peaſants.

21 Arrives in Dalecarlia, is robbed by his guide, and obliged to work in the mines.

Attended by a peaſant, to whom he was known, he travelled in diſguiſe through Sudermania, Nericia, and Weſtermania, and, after a laborious and painful journey, arrived in the mountains of Dalecarlia. Scarce had he finiſhed his journey, when he found himſelf deſerted by his companion and guide, who carried off with him all the money he provided for his ſubſiſtence. Thus forlorn, deſtitute, half ſtarved, he entered among the miners, and wrought like a ſlave under ground, without relinquiſhing his hopes of one day aſcending the throne of Sweden. His whole proſpect for the preſent was to live concealed, and gain a maintenance, until fortune ſhould effect ſomething in his favour: nor was it long before this happened. A woman in the mines perceived, under the habit of a peaſant, that the collar of his ſhirt was embroidered. This circumſtance excited curioſity; and the graces of his perſon and converſation, which had ſomething in them to attract the notice of the meaneſt of the vulgar, afforded room for ſuſpicion that he was ſome perſon of quality in diſguiſe, forced by the tyranny of the government to ſeek ſhelter in theſe remote parts. The ſtory came to the ears of a neighbouring gentleman, who immediately went to the mines to offer his protection to the unfortunate ſtranger; and was aſtoniſhed on recognizing the features of Guſtavus, whoſe acquaintance he had been at the univerſity of Upſal. Touched with compaſſion at the deplorable ſituation of ſo diſtinguiſhed a nobleman, he could ſcarce refrain from tears; but however had preſence of mind enough not to make the diſcovery. At night he ſent for Guſtavus, made him an offer of his houſe, and gave him the ſtrongeſt aſſurances of his friendſhip and protection. He told him, he would meet with better accommodations, and as much ſecurity as in the mines; and that, ſhould he chance to be diſcovered, he would, with all his friends and vaſſals, take arms in his defence.

22 Is diſcovered and relieved.

This offer was embraced by Guſtavus with joy, and he remained for ſome time at his friend's houſe; but finding it impoſſible to induce him to take part in his deſigns, he quitted him, and fled to one Peterſon, a gentleman whom he had formerly known in the ſervice. By him he was received with all the appearance of kindneſs; and, on the very firſt propoſal made by Guſtavus, offered to raiſe his vaſſals. He even named the lords and peaſants whom he pretended to have engaged in his ſervice; but in a very few days after, he went ſecretly to a Daniſh officer, and gave him information of what had paſſed. The officer immediately

Sweden.

ately cauſed the houſe to be ſurrounded with ſoldiers, in ſuch a manner that it ſeemed impoſſible for Guſtavus to make his eſcape. In the interval, however, he eſcaped, being warned by Peterſon's wife of the treachery of her huſband, and by her direction fled to the houſe of a clergyman, her friend. By him Guſtavus was received with all the reſpect due to his own birth and merit; and left the domeſtic who conducted him ſhould follow the treacherous example of his maſter, he removed him to the church, and conducted him to a ſmall cloſet, of which he kept the key. Having lived for ſome time in this manner, Guſtavus began to conſult with his friend concerning the moſt proper method of putting their ſchemes in execution. The prieſt adviſed him to apply directly to the peaſants themſelves; told him that it would be proper to ſpread a report, that the Danes were to enter Dalecarlia in order to eſtabliſh new taxes by force of arms; and as the annual feaſt of all the neighbouring villages was in a few days to be held, he could not have a more favourable opportunity: at the ſame time he promiſed to engage the principal perſons of the dioceſe in his intereſt.

23 Has a very narrow eſcape from the Danes.

24 His cauſe eſpouſed by the peaſants of Dalecarlia.

Agreeable to this advice Guſtavus ſet out for Mora, where the feaſt was to be held. He found the peaſants already informed of his deſigns, and impatient to ſee him. Being already prepoſſeſſed in his favour, they were ſoon excited to an enthuſiaſm in his cauſe, and inſtantly reſolved to throw off the Daniſh yoke. In this deſign they were more confirmed by their ſuperſtition; ſome of their old men having obſerved that the wind had blown from the north while Guſtavus was ſpeaking, which among them was reckoned an infallible omen of ſucceſs. Guſtavus did not give their ardour time to cool, but inſtantly led them againſt the governor's caſtle; which he took by aſſault, and put the garriſon to the ſword. This inconſiderable enterpriſe was attended with the moſt happy conſequences. Great numbers of the peaſants flocked to his ſtandard; ſome of the gentry openly eſpouſed his cauſe, and others ſupplied him with money. Chriſtian was ſoon acquainted with what had paſſed; but deſpiſing ſuch an inconſiderable enemy, he ſent only a ſlender detachment under the command of one Soren Norby, to aſſiſt his adherents in Dalecarlia.

25 The Danes defeated.

Guſtavus advanced with 5000 men, and defeated a body of Danes commanded by one Meleen; but he was ſtrenuouſly oppoſed by the archbiſhop of Upſal, who raiſed numerous forces for king Chriſtian. The fortune of Guſtavus, however, ſtill prevailed, and the archbiſhop was defeated with great loſs. Guſtavus then laid ſiege to Stockholm; but his force being too inconſiderable for ſuch an undertaking he was forced to abandon it with loſs.

This check did not prove in any conſiderable degree detrimental to the affairs of Guſtavus; the peaſants from all parts of the kingdom flocked to his camp, and he was joined by a reinforcement from Lubec. Chriſtian, unable to ſuppreſs the revolt, wreaked his vengence on the mother and ſiſters of Guſtavus, whom he put to death with the moſt excruciating torments. Several other Swediſh ladies he cauſed to be thrown into the ſea, after having impoſed on them the inhuman taſk of making the ſacks into which they were to be incloſed. His barbarities ſerved only to make his enemies more reſolute. Guſtavus having aſſembled the ſtates at Wadſtena, he was unanimouſly choſen regent, the diet taking an oath of fidelity to him, and promiſing to aſſiſt him to the utmoſt. Having thus obtained the ſanction of legal authority, he purſued his advantages againſt the Danes. A body of troops appointed to throw ſuccours into Stockholm were totally cut in pieces; and the regent ſending ſome troops into Finland, ſtruck the Danes there with ſuch terror, that the archbiſhop of Upſal, together with Slahog and Baldenacker the Daniſh governors, fled to Denmark. Chriſtian received them but very coldly, apprehending that their flight might be prejudical to his affairs; and in a ſhort time the two governors were put to death, that the king might have an opportunity of charging them with being guilty of the cruelties which they had committed by his order. He then ſent expreſs orders to all his governors and officers in Finland and Sweden to maſſacre the Swediſh gentry without diſtinction. The Swedes made repriſals by maſſacring all the Danes they could find; ſo that the whole country was filled with bloodſhed and ſlaughter.

26 Horrid cruelty of King Chriſtian.

27 Succeſs of Guſtavus.

Sweden.

In the mean time Guſtavus had laid ſiege to the towns of Calmar, Abo, and Stockholm; but Norby found means to oblige him to raiſe all of them with great loſs. Guſtavus, in revenge, laid ſiege to the capital a third time, and petitioned the regency of Lubec for a ſquadron of ſhips and other ſuccours for carrying on the ſiege. This was complied with, but on very hard conditions, viz. that Guſtavus ſhould oblige himſelf, in the name of the ſtates, to pay 60,000 merks of ſilver as the expence of the armament; that, until the kingdom ſhould be in a condition to pay that ſum, the Lubec merchants trading to Sweden ſhould be exempted from all duties on imports or exports; that all other nations ſhould be prohibted from trading with Sweden, and that ſuch traffic ſhould be deemed illicit; that Guſtavus ſhould neither conclude a peace, nor even agree to a truce, with Denmark, without the concurrence of the regency of Lubec; and that in caſe the republic ſhould be attacked by Chriſtian, he ſhould enter Denmark at the head of 20,000 men. Upon theſe hard terms did Guſtavus obtain aſſiſtance from the regency of Lubec; nor did his dear-bought allies prove very faithful. They did not indeed go over to the enemy; but in a ſea-fight, where the Danes were entirely in the power of their enemies, they ſuffered them to eſcape, when their whole force might have been entirely deſtroyed. This treachery had well-nigh ruined the affairs of Guſtavus; for Norby was now making preparations effectually to relieve Stockholm; in which he would probably have ſucceeded: but at this critical period news arrived that the Danes had unanimouſly revolted, and driven Chriſtian from the throne; and that the king had retired into Germany, in hopes of being reſtored by the arms of his brother-in-law the emperor. On hearing this news, Norby retired with his whole fleet to the iſland of Gothland, leaving but a ſlender garriſon in Calmar. Guſtavus did not fail to improve this opportunity to his own advantage, and quickly made himſelf maſter of Calmar. Mean time Stockholm continued cloſely inveſted; but Guſtavus thought proper to protract the ſiege until he ſhould get himſelf elected king. Having for this purpoſe called a general diet, the firſt ſtep was to fill up the vacancy in the ſenate occaſioned by the maſſacres of Chriſtian. Guſtavus had the addreſs to get ſuch nominated as were in his intereſt; and of conſequence the aſſembly was no ſooner met, than a ſpeech was made, containing the higheſt encomiums on Guſtavus, ſetting forth in the ſtrongeſt light the many eminent ſervices he had done for his country, and concluding that the ſtates would ſhow themſelves equally ungrateful and blind to their own intereſt if they did not immediately elect him king. This propoſal was acceded to by ſuch tumultuous acclamations that it was impoſſible to collect the votes; ſo that Guſtavus himſelf acknowledged, that their affection exceeded his merit, and was more agreeable to him than the effects of their gratitude. He was urged to have the ceremony of his coronation immediately performed: but the king having ſome deſigns on the clergy, did not think proper to comply with their requeſt, as he would have been obliged to take an oath to preſerve them

28 He is choſen king of Sweden.

Sweden.

in their rights and privileges.—Indeed he had not been long ſeated on the throne before he incurred the diſpleaſure of that body; for having large arrears due to the army, with ſeveral other incumbrances, Guſtavus found it neceſſary to raiſe large contributions on the clergy. On this he was accuſed of avarice and hereſy before the pope's nuncio. Guſtavus took the proper methods for defending himſelf againſt theſe accuſations; and in a ſhort time after ſhowed a great partiality for the doctrines of Luther, which by this time had been preached and received by many people in Sweden. This embroiled him more than ever with the eccleſiaſtics; and it ſoon appeared, that either Guſtavus muſt reſign his throne, or the clergy ſome part of the power they had aſſumed. Matters were driven to extremities by the king's allowing the Scriptures to be tranſlated into the Swediſh language. In 1526, the king, finding them entering into a combination againſt the reformiſts, went to Upſal, and publicly declared his reſolution of reducing the number of oppreſſive and idle monks and prieſts, who, under pretence of religion, fattened on the ſpoils of the induſtrious people. At laſt, taking advantage of the war between the pope and Charles V. of Spain, he declared himſelf to be of the reformed religion, and eſtabliſhed it throughout his dominions; and at the ſame time, to humble the arrogance of the eccleſiaſtics, he gave the ſenators the precedency of them, and in many other reſpects degraded them from the dignities they formerly enjoyed. For ſome time the ſtates heſitated at ſupporting the king in his work of reformation; inſomuch, that at laſt he threatened to reſign the kingdom, which, he ſaid, was doomed to perpetual ſlavery either to its temporal or ſpiritual tyrants. On this the ſtates came into his meaſures, and retrenched the privileges of the eccleſiaſtics in the manner he propoſed. Several diſturbances, however, enſued. An impoſtor, who pretended to be of the family of Sture the former regent, having claimed the throne, the Dalecarlians revolted in his favour; but on the approach of a powerful army ſent by Guſtavus, they ſubmitted to his terms. Soon after, Lutheran profeſſors were eſtabliſhed in every dioceſe; upon which a new rebellion enſued. At the head of this was Thure Johanſon, who had married the king's ſiſter. Several of the nobility joined him; and the king of Denmark alſo acceded to their cauſe, thinking, by means of theſe diſturbances, to reunite the three kingdoms of Sweden, Denmark, and Norway, as they had formerly been. But Guſtavus prevailed, and the rebels were obliged to take refuge in Denmark. A freſh accident, however, had like to have embroiled matters worſe than before. The ſubſidy granted to the regency of Lubec was ſtill due; and for the payment of it the ſtates granted to the king all the uſeleſs bells of the churches and monaſteries. The people were ſhocked at the ſacrilege; and the Dalecarlians again betook themſelves to arms. Intimidated, however, by the courage and vigorous conduct of the king, they again ſubmitted, and were taken into favour. But tranquillity was not yet reſtored. Chriſtian having eſtabliſhed a powerful intereſt in Norway, once more made an attempt to recover his kingdoms, and was joined by the Dalecarlians; but being defeated by the Swediſh forces, he was forced to return to Norway, where, being obliged to capitulate with the Daniſh generals, he was kept priſoner all his life.

In 1542, Guſtavus having happily extricated himſelf out of all his troubles, prevailed on the ſtates to make the crown hereditary in his family; after which he applied himſelf to the encouragement of learning and commerce. A treaty was ſet on foot for a marriage between his eldeſt ſon Eric and Elizabeth queen of England. The prince's brother, duke John, went over to England, and reſided for ſome time at the court of London with great ſplendour. He returned, full of expectations of ſucceſs; but bringing with him no ſort of proofs in writing, his father ſoon perceived that he had been the dupe of Elizabeth's ſuperior policy. However, at laſt he allowed Prince Eric to go in perſon to England; but before he could embark, the death of Guſtavus made him lay aſide all thoughts of the voyage and marriage.

Guſtavus Vaſa died in 1560, and was ſucceeded by his ſon Eric XIV. The new king was a man poſſeſſed of all the exterior ornaments which give an air of dignity to the perſon; but he had neither the prudence nor the penetration of his father. He created the firſt nobility that were ever known in Sweden; which he had no ſooner done than he quarrelled with them, by paſſing ſome acts which they thought derogatory to their honour and dignity. The whole courſe of his reign was diſturbed by wars with Denmark, and diſputes with his own ſubjects. In the former he was unfortunate, and towards the latter he behaved with the greateſt cruelty. At laſt, by the torments of his own conſcience, it is ſaid, he run mad. He afterwards recovered his ſenſes, but was thereupon dethroned by his brothers; of whom Duke John, who had been hitherto kept priſoner by Eric, ſucceeded him in the kingdom.

This revolution took place in the year 1563, but with no great advantage to Sweden. Diſputes about religion between the king and his brothers, and wars with Muſcovy, threw matters into the utmoſt confuſion. At laſt prince Sigiſmund, the king's ſon, was choſen king of Poland which proved the ſource of much trouble to the kingdom. He was elected on the following conditions, viz. That there ſhould be a perpetual peace between the ſtates of Poland and Sweden; that, on the death of his father, prince Sigiſmund ſhould ſucceed to the throne of Sweden; that, on urgent occaſions, he might, with the conſent of the ſtates, return to Sweden; that he ſhould maintain, at his own expence, a fleet for the ſervice of Poland; that he ſhould cancel a debt which had been long due from the crown of Poland to Sweden; that, with the conſent of the ſtates, he ſhould build five fortreſſes on the frontiers of Poland; that he ſhould have liberty to introduce foreign ſoldiers into the kingdom, provided he maintained them at his own expence; that he ſhould not make uſe of Swediſh counſellors in Poland; that he ſhould have his body-guard entirely of Poles and Lithuanians; and that he ſhould annex to Poland that part of Livonia now ſubject to Sweden. In 1590 king John died; and as Sigiſmund was at a diſtance, every thing fell into the utmoſt confuſion: the treaſury was plundered, and the wardrobe quite ſpoiled, before even duke Charles could come to Stockholm to take the adminiſtration into his hands until king Sigiſmund ſhould return. This, however, was far from being the greateſt diſaſter which befel the nation at this time. It was known that the king had embraced the Popiſh religion, and it was with good reaſon ſuſpected that he would attempt to reſtore it upon his arrival in Sweden. Sigiſmund alſo was obliged, on leaving Poland, to promiſe that he would ſtay no longer in Sweden than was neceſſary to regulate his affairs. Theſe circumſtances ſerved to alienate the minds of the Swedes from their ſovereign even before they ſaw him; and the univerſal diſſatisfaction was increaſed, by ſeeing him attended, on his arrival in Sweden in 1593, by Malaſpina the pope's nuncio, to whom he made a preſent of 30,000 ducats to defray the expences of his journey to Sweden.

What the people had foreſeen was too well verified: the king refuſed to confirm the Proteſtants in their religious privileges, and ſhowed ſuch partiality on all occaſions to the Papiſts, that a party was formed againſt him; at the head of

of which was duke Charles his uncle. Remonſtrances, accompanied with threats, took place on both ſides; and at an interview between the king and Charles, the diſpute would have ended in blows, had they not been parted by ſome of the nobility. This, however, made ſuch an impreſſion upon Sigiſmund, that he was apparently reconciled to his brother, and promiſed to comply with the inclinations of the people in every reſpect, though without any inclination to perform what he had promiſed. The agreement, indeed, was ſcarce made, before Sigiſmund conceived the horrid deſign of murdering his uncle at the Italian comely acted the night after his coronation. The duke, however, having notice of the plot, found means to avoid it. This enraged the king ſo much, that he reſolved to accompliſh his deſigns by force; and therefore commanded a Poliſh army to march towards the frontiers of Sweden, where they committed all the ravages that could be expected from an enraged and cruel enemy. Complaints were made by the Proteſtant clergy to the ſenate: but no other reply was made them, than that they ſhould abſtain from theſe bitter invectives and reproaches, which had provoked the Catholics, until the king's departure; at which time they would be at more liberty.

40 Forms a deſign of murdering his uncle.

In 1595 Sigiſmund ſet ſail for Dantzic, leaving the adminiſtration in the hands of duke Charles. The conſequence of this was, that the diſſenſions which had already taken place being continually increaſed by the obſtinacy of the king, duke Charles aſſumed the ſovereign power; and in 1604 Sigiſmund was formally depoſed, and his uncle Charles IX. raiſed to the throne. He proved a wiſe and brave prince, reſtoring the tranquillity of the kingdom, and carrying on a war with vigour againſt Poland and Denmark. He died in 1611, leaving the kingdom to his ſon, the celebrated Guſtavus Adolphus.

41 Sigiſmund depoſed, and is ſucceeded by Charles IX.

Though Charles IX. by his wiſe and vigorous conduct had in a great meaſure retrieved the affairs of Sweden, they were ſtill in a very diſagreeable ſituation. The finances of the kingdom were entirely drained by a ſeries of wars and revolutions; powerful armies were preparing in Denmark, Poland, and Ruſſia, while the Swediſh troops were not only inferior in number to their enemies but the government was deſtitute of reſources for their payment.

42 State of Sweden on the acceſſion of Guſtavus Adolphus.

Though the Swediſh law required that the prince ſhould have attained his 18th year before he was of age, yet ſuch ſtriking marks of the great qualities of Guſtavus appeared, that he was allowed by the ſtates to take upon him the adminiſtration even before this early period. His firſt act was to reſume all the crown-grants, that he might be the better able to carry on the wars in which he was unavoidably engaged; and to fill all places, both civil and military, with perſons of merit. At the head of domeſtic and foreign affairs was placed chancellor Oxenſtiern, a perſon every way equal to the important truſt, and the chooſing of whom impreſſed mankind with the higheſt opinion of the young monarch's penetration and capacity.

43 He is allowed to aſſume the adminiſtration while yet a minor.

Soon after his acceſſion, Guſtavus received an embaſſy from James I. of Britain, exhorting him to make peace with his neighbours. This was ſeconded by another from Holland. But as the king perceived that the Daniſh monarch intended to take every opportunity of cruſhing him, he reſolved to act with ſuch vigour, as might convince him that he was not eaſily to be overcome. Accordingly he broke into Denmark with three different armies at once; and though the enemy's ſuperiority at ſea gave them great advantages, and the number of the king's enemies diſtracted his attention, he carried on the war with ſuch ſpirit, that in 1613 a peace was concluded upon good terms. This war being finiſhed, the king applied himſelf to civil polity, and made ſome reformations in the laws of Sweden. In 1615, hoſtilities were commenced againſt Ruſſia, on account of the refuſal of that court to reſtore ſome money which had been formerly lent them. The king entered Ingria, took Kexholm by ſtorm, and was laying ſiege to Pleſcow, when, by the mediation of James I. peace was concluded, on condition of the Ruſſians repaying the money, and yielding to Sweden ſome part of their territory. In this and the former war, notwithſtanding the ſhortneſs of their duration, Guſtavus learned the rudiments of the military art for which he ſoon became ſo famous. He is ſaid, indeed, to have catched every opportunity of improvement with a quickneſs of underſtanding ſeemingly more than human. In one campaign, he not only learned, but improved, all the military maxims of La Gardie, a celebrated general, brought the Swediſh army in general to a more ſteady and regular diſcipline than had formerly been exerciſed, and formed and ſeaſoned an invincible body of Finlanders, who had afterwards a very conſiderable ſhare in the victories of the Swedes.

44 He invades Denmark, and obliges the king to conclude a peace.

Sweden.

45 Ruſſia invaded with ſucceſs.

46 Extraordinary military genius of the king.

Peace was no ſooner concluded with Ruſſia, than Guſtavus was crowned with great ſolemnity at Upſal. Soon after this, Guſtavus ordered his general La Gardie to acquaint the Poliſh commander Codekowitz, that as the truce between the two kingdoms, which had been concluded for two years, was now expired, he deſired to be certainly informed whether he was to expect peace or war from his maſter. In the mean time, having borrowed money of the Dutch for the redemption of a town from Denmark, he had an interview on the frontiers with Chriſtian the king of that country. At this interview, the two monarchs conceived the utmoſt eſteem and friendſhip for each other; and Guſtavus obtained a promiſe, that Chriſtian would not aſſiſt Sigiſmund in any deſigns he might have againſt Sweden. In the mean time, receiving no ſatisfactory anſwer from Poland, Guſtavus began to prepare for war. Sigiſmund entered into a negotiation, and made ſome pretended conceſſions, with a view to ſeize Guſtavus by treachery; but the latter having intimation of his deſign, the whole negotiation was changed into reproaches and threats on the part of Guſtavus.

47 Has a friendly interview with the king of Denmark, and prepares for war with Poland.

Immediately after this, Guſtavus made a tour in diſguiſe through Germany, and married Eleonora the daughter of the elector of Brandenburg. He then reſolved to enter heartily into a war with Poland; and with this view ſet ſail for Riga with a great fleet, which carried 20,000 men. The place was well fortified, and defended by a body of veterans enthuſiaſtically attached to Sigiſmund. A dreadful bombardment enſued; the ſtreets were raked by the cannon, and the houſes laid in aſhes by the bombs; the moat was filled up, one of the half-moons taken by ſtorm, and the ſtrong fortreſs of Dunamund was reduced. The cannon having now effected a breach in another part of the walls, Guſtavus reſolved to make a general aſſault. For this purpoſe a flying bridge over the moat was contrived by his majeſty; for though the ditch was filled with faſcines and rubbiſh, it ſtill contained too much water to admit the paſſage of a large body of men. The ſoldiers, however, crowded on to the attack with ſo much impetuoſity, that the bridge gave way, and the attempt proved unſucceſsful. Next day the Swedes were repulſed in attempting to ſtorm another half-moon; and the king was obliged to proceed more ſlowly. By the middle of September, at which time the town had been inveſted for ſix weeks, two bridges were thrown over the river together with a ſtrong boom, while the Swedes had formed their mines under the ditch. The garriſon being now reduced to extremity, were obliged to capitulate;

48 Marries Eleonora daughter of the elector of Brandenburg.

49 Riga beſieged and taken.

Sweden. capitulate; and Guſtavus treated the inhabitants with great clemency.

After the reduction of Riga, the Swediſh monarch entered Courland, where he reduced Mittau; but ceded it again on the concluſion of a truce for one year. Sigiſmund, however, no ſooner had time to recover himſelf, than he began to form new enterpriſes againſt the Swedes in Pruſſia; but Guſtavus ſetting ſail with his whole fleet for Dantzic, where the king of Poland then reſided, ſo broke his meaſures, that he was obliged to prolong the truce for another year. Sigiſmund, however, was not yet appriſed of the danger he was in, and refuſed to liſten to any terms of accommodation: upon which Guſtavus entering Livonia, defeated the Poliſh general, and took Derpt, Hockenhauſen, and ſeveral other places of leſs importance; after which, entering Lithuania, he took the city of Birſen.

50 The Poles defeated and ſeveral places taken.

Notwithſtanding this ſucceſs, Guſtavus propoſed peace on the ſame equitable terms as before; but Sigiſmund was ſtill infatuated with the hopes that, by means of the emperor of Germany, he ſhould be able to conquer Sweden. Guſtavus finding him inflexible, reſolved to puſh his good fortune. His generals Horn and Thurn defeated the Poles in Semigallia. Guſtavus himſelf with 150 ſhips ſet ſail for Pruſſia, where he landed at Pillaw. This place was immediately delivered up to him; as were alſo Braunſberck, Frawenberg, Elbing, Marienberg, Mew, and Dirſchau, Stum, Chriſtburg, &c. Sigiſmund, alarmed at the great ſucceſſes of Guſtavus, ſent a body of forces to oppoſe him, and to prevent Dantzic from falling into his hands. In this he was attended with as bad ſucceſs as before. His troops were defeated before Marienberg, Mew, and Dirſchau; and in May 1627, Guſtavus arrived with freſh forces before Dantzic, which he would probably have carried, had he not been wounded in the belly by a cannon-ſhot. The Poles in the mean time recovered Mew; and the States of Holland ſent ambaſſadors to mediate a peace between the two crowns. Sigiſmund, however, depending upon the aſſiſtance of the emperor of Germany and king of Spain, determined to hearken to no terms, and reſolved to make a winter-campaign; but Guſtavus was ſo well intrenched, and all his forts were ſo ſtrongly garriſoned, that the utmoſt efforts of the Poles were to no purpoſe (A). The city of Dantzic in the mean time made ſuch a deſperate reſiſtance as greatly irritated Guſtavus. In a ſea-engagement the Swediſh fleet defeated that of the enemy; after which Guſtavus, having blocked up the harbour with his fleet, puſhed his advances on the land-ſide with incredible vigour. He made a ſurpriſing march over a moraſs 15 miles broad, aſſiſted by bridges of a peculiar conſtruction, over which he carried a ſpecies of light cannon invented by himſelf. By this unexpected manœuvre he got the command of the city in ſuch a manner, that the garriſon were on the point of ſurrendering, when, by a ſudden ſwell of the Viſtula, the Swediſh works were ruined, and the king was obliged to raiſe the ſiege. In other reſpects, however, the affairs of Guſtavus went on with their uſual good fortune. His general Wrangel defeated the Poles before Brodnitz, of whom 3000 were killed, and 1000 taken priſoners, with five pieces of cannon and 2000 waggons loaded with proviſions. At Stum the king gained another and more conſiderable victory in perſon. The emperor had ſent 5000 foot and 2000 horſe under Arnheim, who joined the main army commanded by the Poliſh general Coniecſpolſki, in order to attack the Swediſh army encamped at Quidzin. The enemy were ſo much ſuperior in number, that the friends of Guſtavus repreſented to him the imminent danger of attacking them. But the king being determined, the engagement began. The Swediſh cavalry charged with ſuch impetuoſity, contrary to their ſovereign's expreſs order, that they were almoſt ſurrounded by the enemy; but Guſtavus, coming up to their aſſiſtance, puſhed the enemy's infantry with ſo much vigour, that they gave way, and retreated to a bridge they had thrown over the Werder. But here they were diſappointed; for the Swedes had already taken poſſeſſion of the bridge. On this a new action enſued more bloody than the former, in which the king was expoſed to great danger, and thrice narrowly eſcaped being taken priſoner; but at laſt the Poles were totally defeated, with the loſs of a great many men, 22 pair of colours, five ſtands, and ſeveral other military trophies. The ſlaughter of the German auxiliaries was ſo great, that Arnheim ſcarce carried off one half of the troops he brought into the field. This defeat did not hinder the Poliſh general from attempting the ſiege of Stum; but here again he was attended by his uſual bad fortune. The garriſon ſallied out, and he was defeated with the loſs of 4000 men. The blame of this misfortune was laid upon Arnheim; who was recalled, and ſucceeded by Henry of Saxe Lawenburg and Philip count Mansfeldt. The change of general officers, however, produced no good conſequences to the Poles; a famine and plague raged in their camp, ſo that they were at laſt obliged to conſent to a truce for ſix years, to expire in the month of June 1635. The conditions were, that Guſtavus ſhould reſtore to Sigiſmund the towns of Brodnitz, Stum, and Dirſchau; that Marienberg ſhould remain ſequeſtrated in the hands of the elector of Brandenburg, to be reſtored again to Sweden in caſe a peace was not concluded at the end of the ſix years. Guſtavus, on his ſide, kept the port and citadel of Memel, the harbour of Pillaw, the town of Elbing, Brunſberg, and all that he had conquered in Livonia.

Sweden.

55 The Poles and Germans defeated with great ſlaughter in two engagements.

51 The Poles gain defeated, and great number of towns reduced by Guſtavus.

52 The Poles defeated a third time.

53 The Poles defeated by ſea, and Dantzic inveſted.

54 The king obliged by an inundation of the Viſtula to raiſe the ſiege.

56 They are again defeated, and obliged to conſent to a truce of ſix years.

Guſtavus having thus brought the war with Poland to an honourable concluſion, began to think of reſenting the conduct of the emperor in aſſiſting his enemies and oppreſſing the Proteſtant ſtates. Before embarking in ſuch an important undertaking, it was neceſſary that he ſhould conſult the diet. In this the propriety of engaging in a war with Germany was warmly debated; but, after much altercation, Guſtavus in a very noble ſpeech determined the matter, and ſet forth in ſuch ſtrong terms the virtuous motives by which he was actuated, that the whole aſſembly wept, and every thing was granted which he could require.

57 Guſtavus reſolves on a war with the emperor.

It was not difficult for Guſtavus to begin his expedition. His troops amounted to 60,000 men, hardened by a ſucceſſion of ſevere campaigns in Ruſſia, Finland, Livonia, and Pruſſia. His fleet exceeded 70 ſail, carrying from 20 to 40 guns, and manned with 6000 mariners. Embarking his

(A) In this campaign the practice of duelling became ſo prevalent in the Swediſh army, as to engage the king's attention, and to oblige him to ſuppreſs it by very rigorous edicts. Soon after theſe were paſſed, a quarrel aroſe between two general officers, who aſked his majeſty's permiſſion to decide their difference by the laws of honour. The king conſented, but wiſhed to be a ſpectator of their courage. He went to the place appointed, attended by a body of guards; and having ordered the executioner to be called, "Now gentlemen, ſaid he to the officers, fight until one dies;" adding to the executioner, "Do you immediately cut off the head of the other." On this the quarrel was dropped, and no more challenges were heard of in the camp.

his troops, he landed at Uſedom on the 24th of June 1630, the Imperialiſts having evacuated all the fortreſſes they poſſeſſed there; and the iſle of Rugen had been before reduced by general Leſly, in order to ſecure a retreat if ſortune ſhould prove unfavourable. Paſſing the frith, Guſtavus 58 Reduces Wolgaſt, Stetin, &c. formed Wolgaſt and another ſtrong fortreſs in the neighbourhood, leaving general Bannier with a garriſon for the defence of theſe conqueſts. He then proceeded to Stetin; which was no ſooner inveſted than it conſented to receive a Swediſh garriſon, and the king perſuaded the duke of Pomerania to enter into an alliance with him. In conſequence of this the Swediſh troops were received into ſeveral towns of Pomerania; and the moſt bitter enmity took place between the Imperialiſts and Pomeranians, each refuſing the other quarter.

Theſe ſucceſſes of Guſtavus ſtruck the empire with conſternation; for being already overwhelmed with civil diſſenſions, they were in no condition to reſiſt ſo impetuous an enemy. At this time alſo the Imperialiſts were without a general, the command of the army being diſputed by a number of canditates of very unequal merit; but at laſt count Tilly was fixed upon as the moſt proper perſon, and inveſted with the dignity of Veldt Mariſchal. In the mean time the king being reinforced by a conſiderable body of troops in Finland and Livonia under the conduct of Guſtavus Horn, defeated the Imperialiſts before Griffenhagen; taking the place ſoon after by aſſault. By this and ſome other conqueſts he opened a paſſage into Luſatia and Sileſia; but in the mean time count Tilly cut off 2000 Swedes at New Brandenburg, owing to the obſtinacy of their commander Kniphauſen, who had orders to evacuate the place and join the main army. This advantage, however, was ſoon overbalanced by the conqueſt of Franckfort on the Oder, which Guſtavus took, by aſſault, making the whole garriſon priſoners. Thus he commanded the rivers Elbe and Oder on both ſides, and had a fair paſſage not only to the countries already mentioned, but alſo to Saxony and the hereditary dominions of the houſe of Auſtria. Soon after this, Guſtavus laid ſiege to Landſberg, which he took by aſſault; though the number of ſoldiers he had with him was ſo inconſiderable, that he had thoughts of ſending to the main army for a reinforcement before the priſoners ſhould march out, being apprehenſive that they might give him battle in the open field, though they could not defend themſelves behind walls.

59 Count Tilly choſen general by the emperor.

60 Cuts off 2000 Swedes.

61 Franckfort and Landſberg taken by Guſtavus.

About this time the Proteſtant princes held a diet at Leipſic; to which Guſtavus ſent deputies, and conducted his negotiations with ſuch addreſs, as tended greatly to promote his intereſts. Immediately after this he reduced Gripſwald, and with it all Pomerania. Then marching to Guſtrow, he reſtored the dukes of Mecklenburg to their dominions. Here the Imperialiſts had tyrannized in ſuch a manner that Guſtavus was received as the deliverer of the people; and the ceremony of the duke's inauguration was in a ſhort time performed with great ſolemnity.

62 He reduces Pomerania, and reſtores the dukes of Mecklenburg.

All this time count Tilly was employed in the ſiege of Magdeburg; but now, being alarmed at the repeated ſucceſſes of the Swedes, he left Pappenheim with part of the army before that city, while he marched with the reſt into Thuringia, to attack the landgrave of Heſſe-Caſſel and the elector of Saxony. After a moſt obſtinate defence, Magdeburg fell into the hands of Pappenheim, where he committed all imaginable cruelties. Guſtavus formed a plan of recovering the city; but was obliged to abandon it, by Pappenheim's throwing himſelf into the place with his whole army, and by the progreſs which Tilly was making in Thuringia. Relinquiſhing this enterpriſe, therefore, he ordered Bannier to attack Havelſburg; which was done

63 Magdeburg taken by the Imperialiſts, and the inhabitants cruelly uſed.

with ſuch reſolution, that the place was forced in a few hours, and all the garriſon made priſoners. Werben was next obliged to ſubmit after an obſtinate conflict, in which many fell on both ſides.—Theſe ſucceſſes obliged count Tilly to attempt in perſon to check the progreſs of the Swedes. He detached the vanguard of his army, compoſed of the flower of the Imperial cavalry, within a few miles of the Swediſh camp. An action enſued, in which Bernſtein the Imperial general was defeated and killed, with 1500 of his men. Guſtavus after this advantage, placed himſelf in a ſituation ſo much ſuperior to his enemies, that count Tilly was fired with indignation, and marched up to the Swediſh lines to give him battle. Guſtavus kept within his works, and Tilly attacked his camp, though almoſt impregnably fortified, keeping up a moſt terrible fire from a battery of 32 pieces of cannon; which, however, produced no other effect, than obliging the Swediſh monarch to draw up his army behind the walls of Werben. Tilly had placed his chief hopes in being able to nail up the enemy's cannon, or ſet fire to their camp in divers quarters; after which he propoſed making his grand attack. With this view he bribed ſome priſoners; but they betrayed him, and told his deſign to Guſtavus. The king ordered fires to be lighted in different parts of his camp, and his ſoldiers to imitate the noiſe of a tumultous diſorderly rabble. This had the deſired effect. The count led his army to the breach made by the cannon; where he was received with ſuch a volley of grape ſhot as cut off the firſt line, and put the whole body into diſorder, ſo that they could never be brought back to the charge. In this confuſion the Imperial army was attacked by Bauditzen, and, after an obſtinate conflict, obliged to quit the field.

64 Havelſburg and Werben reduced, and the cavalry of the Imperialiſts defeated by the Swedes.

65 Count Tilly defeated by Guſtavus.

Soon after this action the queen arrived at the camp with a reinforcement of 8000 men; at the ſame time a treaty was concluded with Charles I. of England, by which that monarch allowed the marquis of Hamilton to raiſe 6000 men for the ſervice of Guſtavus. Theſe auxiliaries were to be conducted to the main army by a body of 4000 Swedes; and were in every thing to obey the king while he was perſonally preſent, but in his abſence were to be ſubject to the orders of the marquis. With theſe troops the king had reſolved to make a diverſion in Bremen: but the marquis finding it impoſſible for him to effect a junction with the Swediſh army, reſolved, without debarking his troops, to ſteer his courſe for the Oder, and land at Uſedom. Guſtavus was very much diſpleaſed at finding his project thus diſconcerted; however, making the beſt of the preſent circumſtances, he commanded the Britiſh troops to act on the Oder inſtead of the Weſer. The number of this little army was magnified exceedingly by report, inſomuch, that count Tilly had ſome thoughts of marching againſt them with his whole force; but on the departure of the marquis for Sileſia, he reinforced the army in that country with a large detachment, which was thought to contribute not a little to the defeat he ſoon after received.

66 A body of Britiſh ſoldiers comes to the aſſiſtance of the Swedes.

Ever ſince the late action Guſtavus had kept within his intrenchments, where his army was well provided with every thing. Tilly made ſeveral attempts to ſurpriſe or draw him to an engagement; but finding all his endeavours fruitleſs, he marched into Saxony, and laid ſiege to Leipſic. This precipitate meaſure proved highly advantageous to the Swediſh monarch; as thus the elector, who had been waveiing in his reſolutions, was now obliged to have recourſe to the Swedes, in order to preſerve himſelf from utter deſtruction. A treaty offenſive and defenſive was immediately concluded with Guſtavus: and the elector willingly promiſed every thing that was required of him; and among the reſt, that not only the prince his ſon, but he himſelf, ſhould

Sweden.

should reſide in the Swediſh camp, and engage his life and fortune in the common cauſe. Tilly, in the mean time, carried fire and ſword into the unhappy electorate. At the head of an army of 44,000 veterans, he ſummoned the city of Leipſic to ſurrender; denouncing the ſame vengeance againſt it as had been executed on Magdeburg, in caſe of a refuſal. By this the governor was ſo much intimidated, that he inſtantly ſubmitted; and alſo ſurrendered the caſtle of Paſſenberg, which was in a condition to have ſtood out till the arrival of the Swediſh army. The elector, enraged at the loſs of theſe valuable places, ordered his army to join the Swedes with all expedition, and preſſed the king ſo warmly to engage, that at laſt he yielded to his deſire. On the 7th of September 1631, Guſtavus led out his army in the moſt beautiful order, the Swedes forming one column on the right, and the Saxons another on the left; each amounting to 15,000 men. Tilly drew up his men in one vaſt column, poſſibly with a view of ſurrounding the flanks of the king's army; but every officer of experience in his army, from the excellency of the Swediſh diſpoſition, prognoſticated the event of the engagement. Guſtavus led on the troops againſt that wing of the Imperialiſts commanded by Pappenheim, whom he drove back to ſuch a diſtance, that he gained a point of the wind; by which the ſmoke fell upon their enemies and conſiderably embarraſſed them, at the ſame time that the Swedes were got without the reach of a battery which played furiouſly on their flank. General Bannier in the mean time cut in pieces the troops of Holſtein, and mortally wounded the duke who commanded them. Pappenheim led on his troops ſeven times to the charge, in hopes of regaining his former ſituation; but was as often repulſed by the Swedes. Tilly all this while engaged with the Saxons; but having at laſt driven them off the field, the whole ſtrength of the Imperial army was turned upon the Swediſh left wing commanded by General Horn. The Swedes ſuſtained the attack with the greateſt firmneſs, until the king detached general Teuffel with the centre to aſſiſt them. The Imperialiſts then were no longer able to ſtand their ground; but gave way everywhere except in the centre, which was compoſed of 18 regiments of veterans accuſtomed to victory, and deemed invincible. They made incredible efforts to maintain the reputation they had acquired; and, though ſwept off in great numbers by the Swediſh artillery, never ſhrunk or fell into confuſion. Four regiments, after their officers had been killed, formed themſelves, and retired to the ſkirt of a wood; where they were all to a man cut in pieces, without demanding quarter. Tilly retired at the head of 600 men, and eſcaped by the coming on of the night. Seven thouſand Imperialiſts lay dead on the field of battle; 4000 were taken priſoners; a fine train of artillery was loſt, with upwards of 100 ſtandards, enſigns, and other military trophies.—On this occaſion it was that the Scots regiment in the Swediſh ſervice firſt practiſed the method of firing in platoons; to which ſome aſcribe the aſtoniſhment and confuſion that appeared in the Imperial army. It is thought, however, that the Swediſh monarch diſplayed greater abilities in gaining this victory than improving it afterwards; for had he marched immediately to Vienna, before his enemies had time to recover their conſternation, it is ſuppoſed that the emperor would have been obliged to abandon his capital, and leave his hereditary dominions to the mercy of the conqueror. But Guſtavus apprehended that Tilly might fall upon the Saxons while he was ravaging the Auſtrian hereditary dominions; which would have deprived him not only of an ally, but of the free quarters which the elector had promiſed to his troops in caſe of a retreat. For this and ſome other reaſons he determined to penetrate into Franconia, where he reduced ſeveral places, particularly the fortreſs of Workburg. Tilly having collected his ſcattered troops, which formed an army ſtill ſuperior in number to that of Guſtavus, marched to the relief of this place; but came too late. He then directed his march towards Rottenberg, where four regiments were cut in pieces by a Swediſh detachment. After this the king reduced Hanau, Franckfort on the Maine, and Mentz; deſtroying a body of Spaniards, who had thrown themſelves in his way to obſtruct his paſſage.

Sweden.

The court of Vienna was now thrown in the utmoſt confuſion; and ſent everywhere begging aſſiſtance, and ſoliciting the Catholic princes to arm in defence of their religion. The emperor was moſt embarraſſed in finding out a general capable of oppoſing Guſtavus in the field; for the late misfortunes of count Tilly had entirely ſunk his reputation. Walleſtein, an old experienced officer, was made choice of; but as he had formerly been diſgraced, it was apprehended that he would not accept of the command of which he had once been deprived. This objection, however, was got over; and Walleſtein not only accepted of the command, but, at his own expence, augmented the army to 40,000 men.

During the whole winter the Swediſh army kept the field; and before the approach of ſummer had reduced Crantznach, Bobenhauſen, Kirchberg, Magdeburg, Gozlar, Northeim, Gottingen, and Dunderſtadt; while the landgrave William made great progreſs in Weſtphalia. Guſtavus Horn was repulſed before Bamberg; but ſoon had his revenge, by entirely deſtroying two regiments of Imperialiſts. To prevent the troops from being affected by the loſs before Bamberg, the king reſolved to give battle to Tilly, who was marching into Bavaria to prevent the Swedes from gaining a footing in that electorate. He purſued the Imperial general through a vaſt tract of country, defeated his rear-guard, and having reduced a variety of towns and fortreſſes on the Danube, penetrated as far as Ulm. Advancing to the river Leck, count Tilly poſted himſelf in a wood on the oppoſite ſide, to diſpute his paſſage. Guſtavus endeavoured to diſlodge him by a regular fire from 70 pieces of cannon. The ſlaughter was dreadful; and Tilly himſelf, being wounded by a cannon-ball in the knee, died a few days before he was to have been ſuperſeded by Walleſtein. The following night the Imperial army evacuated the poſt; part retiring to Ingoldſtadt, and others to Newburg. Guſtavus immediately croſſed the river, and ſeized the towns of Rain and Newburg, which the enemy had abandoned. Augſburg next ſubmitted; and from the inhabitants of this place Guſtavus exacted an oath of fidelity, not only to himſelf but to the crown of Sweden. This meaſure gave the greateſt offence to many of the Germanic body, and made them imagine that the king of Sweden had other views than the defence of the Proteſtant cauſe.

From Augſburg the Swedes advanced towards Ratiſbon; but were diſappointed in their deſign of getting poſſeſſion of that city, by reaſon of the Bavarians having thrown a very numerous garriſon into the place.—In the mean time, ambaſſadors arrived from Denmark, offering the mediation of that crown for obtaining a laſting peace between the contending parties. Guſtavus, however, replied, that no ſuch peace could take place till the Catholic princes thought proper to grant the Proteſtants full and ample ſecurity for their enjoyment of future tranquillity. But the ambaſſadors had no inſtructions to propoſe any thing farther, and thus the negotiation vaniſhed. Guſtavus now, reſolving to retort upon themſelves the cruelties which the Bavarians had inflicted on the Proteſtants, laid the towns of Morzbourg, Frieſengen, and Landſhut, in aſhes. The inhabitants of Munich ſaved themſelves by ſubmiſſion; but as the peaſants in that

neighbourhood had collected themſelves into bodies in order to murder the ſtragglers from the Swediſh army, Guſtavus burnt their houſes, and defeated the forces of the elector, who had been joined by a conſiderable body of militia.

While Guſtavus was thus employed, Walleſtein had aſſembled a vaſt army. He was ſtrongly ſolicited by the elector of Bavaria to come to his aſſiſtance; but, in revenge of the elector's having formerly obtained the command for count Tilly in preference to himſelf, he drew off towards Bohemia to encounter the Saxons. Arnheim, who commanded the Saxon forces in that place, was the enemy of Guſtavus, who had formerly rallied him for his cowardice. He therefore permitted Walleſtein to gain an eaſy victory, in hopes that his maſter, the elector of Saxony, a prince entirely devoted to his pleaſures, might be induced to relinquiſh the friendſhip of ſuch a reſtleſs and warlike ally as Guſtavus; and indeed he uſed all the eloquence of which he was maſter to detach him from the Swediſh cauſe. Several advantages, in the mean time, were gained by the Imperialiſts. Pappenheim defeated the archbiſhop of Bremen's cavalry at Werden; and three Swediſh regiments were cut off near Kadingen. Pappenheim, however, was forced to retire, and withdraw his forces from Stade; of which the Swedes took poſſeſſion. Walleſtein and the elector of Bavaria, who had now joined their forces, threatened Guſtavus with greatly ſuperior numbers. At laſt, however, the king, being reinforced with 15,000 men, no longer declined the engagement; but Walleſtein was too wiſe to truſt the fate of the empire to a ſingle engagement againſt ſuch an enemy as the king of Sweden. Guſtavus attacked his camp, but was repulſed with the loſs of 2000 men; which cauſed a general murmuring and diſcontent againſt his raſhneſs. Several other misfortunes happened to the Swedes; and at laſt, after various manœuvres, Walleſtein bent his courſe towards Miſnia, in order to oblige the elector of Saxony to declare againſt the Swedes, and to draw them out of Bavaria. Guſtavus, notwithſtanding the inconſtancy of Auguſtus, immediately ſet out to aſſiſt him. With incredible diligence he marched to Miſnia, where the Imperialiſts were aſſembling their whole ſtrength. Hearing that the enemy were encamped at Weſenfells, and that Pappenheim had been detached with a ſtrong corps, Guſtavus reſolved to engage them before they could effect a junction. With this view he marched to Lutzen, where he attacked Walleſtein with incredible fury. The Swediſh infantry broke the Imperialiſts in ſpite of their utmoſt efforts, and took all their artillery. The cavalry not being able to paſs the river ſo expeditiouſly as the king thought neceſſary, he led the way, attended only by the regiment of Smaaland and the duke of Saxe-Lauwenburg. Here, after charging impetuouſly, he was killed, as Puffendorff alleges, by the treachery of the duke; who, being corrupted by the emperor, ſhot him in the back during the heat of the action. The news of his death was in an inſtant ſpread over both armies. The courage of the Imperialiſts revived, and they now made themſelves ſure of victory. But the Swedes, eager to revenge the death of their beloved monarch, charged with ſuch fury that nothing could reſiſt them. The Imperialiſts were defeated a ſecond time, juſt as Pappenheim, with his freſh corps, came up to their aſſiſtance. On this the battle was renewed, but the Swedes were ſtill irreſiſtible. Pappenheim was mortally wounded, and his army finally routed, with the loſs of 9000 killed in the field and in the purſuit.

76 The Saxon troops defeated by Walleſtein.

77 Guſtavus attacks his camp, and is repulſed with loſs.

78 Battle of Lutzen.

79 Guſtavus killed.

80 The Imperialiſts totally defeated.

81 Chriſtina, an infant, proclaimed queen of Sweden.

The victory of Lutzen proved more unfortunate to Sweden than the greateſt defeat. The crown devolved upon Chriſtina, an infant of ſix years old; the nation was involved in an expenſive foreign war, without any perſon equal to the arduous taſk of commanding the armies, or regulating domeſtic affairs, as Guſtavus had done. However, Chriſtina the daughter of Guſtavus was immediately proclaimed queen. The regency devolved on the grand bailiff, the mariſchal, the high-admiral, the chancellor, and the treaſurer of the crown. Oxenſtiern was inveſted with the chief management of affairs, and conducted himſelf with the greateſt prudence. He was greatly embarraſſed indeed by the diviſions among the Proteſtant princes, which became more violent after the death of Guſtavus; but, in ſpite of all difficulties, he went on purſuing the intereſt of his country, and planning the means of retaining the Swediſh conqueſts. Matters went on pretty ſucceſsfully till the year 1634, when, through the raſhneſs of the Swediſh ſoldiers, they were defeated at Nordlingen, with the loſs of 6000 men killed on the ſpot, a number of priſoners, and 130 ſtandards, with other military trophies, taken by the enemy. Oxenſtiern's conſtancy was ſhaken by this dreadful blow; but he applied himſelf diligently to repair the loſs, by recruiting the army, and rendering the allies faithful. The latter proved the moſt difficult taſk. The death of Guſtavus, and the defeat at Nordlingen, had thrown them into deſpair; and every one was deſirous of making the beſt terms he could with the emperor. The Saxons not only renounced their alliance with Sweden, but openly commenced war againſt it; and though the regency would gladly have conſented to an honourable peace, the enemy were now too much fluſhed with ſucceſs to grant it. Oxenſtiern had no other reſource than an alliance with France, and the bravery of his generals. In 1635, he went in perſon to the court of Louis, and concluded a treaty; which, however, anſwered no purpoſe, as it was never obſerved. The enemy, in the mean time, puſhed their good fortune. They ſurpriſed Philipſburg, where the French had laid up vaſt magazines; and reduced Spires, Augſburg, Treves, Wurtſburg, Cobourg, and ſome other places. To complete the misfortunes of Sweden, it was expected that the Poles would immediately invade Pruſſia. To prevent this, La Gardie was diſpatched thither with a powerful army; but as it was impoſſible to reſiſt ſo many enemies at once, the chancellor purchaſed the friendſhip of Poland for 26 years by ceding that duchy to the republic. Thus he got rid of a powerful enemy; and the Swediſh affairs began to revive by a victory which general Bannier gained over the Saxons, in conſequence of which they were driven beyond the Elbe.

Early in the ſpring of 1636, the Saxons made ſome motions as if they intended to cut off Bannier's communication with Pomerania. This he prevented by a ſtratagem; defeated a body of the enemy; and obliged the Saxons to retire. Soon after this he drove them out of their winter-quarters with conſiderable loſs; at which time alſo a conſiderable body of Imperialiſts who came to their aſſiſtance were diſperſed. In Weſtphalia general Kniphauſen beat the Imperialiſts with the loſs of 1500 men, but he himſelf was killed in the purſuit, and his army obliged to repaſs the Weſer. Some advantages were alſo gained in the neighbourhood of Minden by General Leſly, who had aſſembled a conſiderable army. In Alſace, Bernard duke of Saxe-Weymar defeated count Gallas the Imperial general, and diſperſed his army. But when every thing ſeemed thus ſucceſsful for the Swedes, the city of Magdeburg, contrary to the expectation of every body, ſurrendered for want of powder, which the garriſon had wantonly conſumed. The Saxons alſo made ſome conqueſts on the Elbe, which obliged Bannier to recal general Leſly from Weſtphalia to march againſt them. The Saxons fixed on a moſt convenient ſituation, whence they hoped to deſtroy the Swediſh army without coming to a battle. But Bannier, reſolving to hazard

every thing rather than ſuffer his army to be waſted by famine, advanced towards Perleberg, a place cloſely blocked up by the enemy. Here he drove from an advantageous poſt four regiments of Saxon cuiraſſiers, having killed or taken priſoners 400 men; after which he ſoon forced them to a general engagement. The numbers were very unequal, Bannier's army amounting to 9000 horſe and 7000 foot, and the Saxons to 15,000 horſe and 13 battalions of foot. The battle began with great fury; the right wing of the Swedes was almoſt oppreſſed by numbers before the left could come to their aſſiſtance. They were ten times driven back, and as often returned to the charge. At laſt they made ſuch a deſperate effort, that the enemy were entirely broken and defeated. Five thouſand were killed on the ſpot, 3000 wounded, and as many taken priſoners, together with 150 colours and ſtandards, and ſeveral pieces of cannon.

88 The Saxons entirely defeated by Bannier.

Thus ended the campaign of 1636, in a manner highly honourable to the Swedes. Some fruitleſs negotiations were ſet on foot during the winter; but theſe coming to nothing, Bannier quitted his winter-quarters very early in the ſeaſon; and falling upon eight regiments of Saxons cantoned at Eulenburg, purſued them to Torgau, where he obliged them to ſurrender at diſcretion. Another party of Saxons was defeated in the neighbourhood of Leipſic; after which he propoſed inveſting that city. But in this project he was diſappointed by the Imperialiſts penetrating into Thuringia. He then called in all his detachments, with a view to prevent them from croſſing a river named *Sala*; but in this alſo he was diſappointed. However, he had the good fortune to defeat 2000 Imperialiſts near Pegau, and to deſtroy ſeveral detachments that attempted to obſtruct his march. Yet, notwithſtanding all theſe ſucceſſes, Bannier found his ſituation every day more ſtraitened from the continual increaſe of the enemy's forces; which obliged him at laſt to retreat into Pomerania, out of which he ſoon drove count Gallas.

89 Eight regiments of Saxons taken priſoners.

90 Bannier defeats the Imperialiſts but is obliged to retire.

The affairs of the Swedes were now once more reduced to the brink of ruin, through the unguarded conduct of general Wrangel, who had alſo an army in Pomerania. After Bannier had driven count Gallas out of the province as abovementioned. Wrangel, imagining himſelf perfectly ſecure, cantoned his troops, and extended his quarters, the better to accommodate his army. But Gallas, being informed of this proceeding, ſuddenly returned, ravaged all Upper Pomerania, and reduced the towns of Uſedom, Dermmin, and Wollin; after which, leaving garriſons in the fortreſſes, he returned to his winter-quarters in Saxony.

91 Pomerania ravaged by the Imperialiſts.

This unfortunate campaign counterbalanced all the advantages of the former. Wrangel was ſo ſtruck with the ſuddeneſs, of the blow that he could take no meaſures for oppoſition. Some of the Swediſh allies again fell off, and took up arms againſt them. In 1638, the Swediſh affairs again began to revive in this quarter, through the excellent conduct of Bannier, who defeated count Gallas with the loſs of 3000 men killed and taken priſoners. Purſuing his good fortune, he ſo haraſſed the count, that he obliged him in great haſte to repaſs the Elbe, and take ſhelter in the hereditary dominions of Auſtria. Great as Bannier's exploits had been, however, they were eclipſed by thoſe of duke Bernard. That general had ſo increaſed his army in the Proteſtant cantons of Switzerland, and in Franche Comte, that he found himſelf in a condition to act without the aſſiſtance of the French, who indeed were but treacherous allies. Advancing to the Rhine, he ſeized on Seckingen and Laſſuburg, and laid ſiege to Rheinfield. The Imperialiſts, in conjunction with the troops of Bavaria, advanced to the relief of the place. An engagement enſued, in which the victory was diſputed: the enemy threw ſuccours into the city, and the duke withdrew his army. Within a month he gave them battle a ſecond time; and ſo completely defeated them, that only one Imperial officer above the rank of a captain eſcaped being killed or taken priſoner. He then renewed the ſiege of Rheinfield; which he reduced, as well as ſeveral other important places. Advancing to Briſac, he blocked it up with a deſign of forcing the garriſon to ſurrender by famine. General Gotz, with 12,000 men, attempted to throw in 1000 waggons of proviſions; but he was defeated, with the loſs of all his men except 2500. Duke Charles of Lorrain, with 4000 men, joined the remains of Gotz's army, in order to relieve the town; but being ſurpriſed by Bernard, his whole army was cut in pieces. A third attempt was made by Gotz, but it proved as unſucceſsful as the former; and the place being reduced to great ſtraits, was obliged to capitulate.

92 The Imperialiſts defeated by Bannier.

93 Exploits of the duke of Saxe-Weymar.

Sweden.

In January 1639, the two victorious generals Bernard and Bannier prepared to attack the enemy on their own ground. Bannier made an irruption into the territories of Anhalt and Halberſtadt. Leaving his infantry behind, he puſhed on with his cavalry, and ſurpriſed Salis, grand-maſter of the Imperial artillery. After a bloody conflict, the Swedes gained a complete victory, ſeven regiments of the enemy being cut in pieces. Next entering Saxony, he defeated four regiments of the enemy, obliging a much larger body to take ſhelter under the cannon of Dreſden. Hearing that the Saxons were encamped near Chemnitz, where they waited to be joined by the Imperialiſts, he reſolved to attack them before this junction could be effected. The ſame good fortune ſtill attended his arms, and the Saxons were almoſt all killed or taken. Bannier next entering into Bohemia, laid the country under contribution; after which, returning croſs the Elbe, he fell on general Hofskirk, who was encamped near Brandeiz with 10 regiments of horſe and ſeveral battalions of foot. Him he defeated with the loſs of 2000 men. The remains of the Imperial forces were purſued to the walls of Prague, and the generals Hofskirk and Montecuculi were taken priſoners. Yet, notwithſtanding theſe conſtant ſucceſſes, the enemies of Bannier multiplied daily. He had expected an inſurrection in his favour in Sileſia or Bohemia; but no ſuch event took place. The Proteſtant princes, overawed by the enemy, did not ſend him the neceſſary aſſiſtance. Undiſmayed, however, by difficulties or danger, Bannier performed wonders. He defeated a body of Imperialiſts at Glatz; three times he drove the Saxons from their camp at Firn; and yet was forced to evacuate the place, becauſe he could not ſpare a garriſon. His army being deſtitute of the means of recruiting, was conſiderably diminiſhed in number; yet with it he reduced a number of towns, and obtained a variety of other important advantages, when on a ſudden all his hopes were blaſted by the death of the duke of Saxe-Weymar; poiſoned, as was ſuppoſed, by the French, who were deſirous of getting the town of Briſac into their hands, from which the duke prevented them.

94 Bannier defeats the enemy in ſeveral engagements.

95 Death of the duke of Saxe-Weymar.

The difficulties to which Bannier was now reduced proved extreme. The French monarch took upon him to diſpoſe of the army and conquests of Bernard as he thought proper. Briſac, and other places of importance, he kept to himſelf; after getting poſſeſſion of which, the French endeavoured, as much as poſſible, to ruin the army. In the mean time, the Imperial army under Piccolomini, in the Netherlands, was prodigiouſly augmented; and the arch-duke Leopold-William, in quality of generaliſſimo, was aſſembling his whole ſtrength to cruſh the Swedes at once. Bannier, however, did not deſpair. George duke of Lunenburg having conceived ſome diſguſt at the emperor, Bannier hoped

96 Treachery of the French.

Sweden.

to gain him over: he therefore approached nearer to his country; by which alſo he drew towards the armies of Weymar and Heſſe. In his way he cut in pieces a body of 3000 Croats. General Konigſmark routed the Imperialiſts at Gera; a ſecond time at Scholen; and a third time entirely defeated them near Leipſic. Bannier was very preſſing on the allies to join him; and at leaſt, in 1640, he was joined by the Weymar army under the dukes of Longueville and Gubrien, a body of Ruſſians led by general Melander and the troops or Lunenburgh commanded by general Klitzing. The army now amounted to 22 battalions of infantry and 22,000 horſe; ſo that they were much more than a match for their enemies had they been under the ſole direction of Bannier. But unanimity was wanting; every one would be ſupreme in the command; and Bannier, the beſt general of them all, had the leaſt influence. Inſtead of thoſe maſterly and deciſive ſtrokes by which the Swedes had hitherto diſtinguiſhed themſelves, the armies continued looking at one another, each ſuffering the rigours of famine. At laſt Bannier, reſolving to expoſe his troops no longer, ſet out for Thuringia, through Franconia, to ſeize an advantageous poſt on the Maine; but as he advanced to the Sala, he found the Imperialiſts entrenched on the other ſide. Finding it impoſſible to force a paſſage, he took the road through Heſſe, where his troops ſuffered greatly by famine. Here he propoſed to fight the enemy; but the Landgrave and duke of Lunenburg refuſed their conſent. Upon this he threatened to leave them to the mercy of the confederates, and thus obliged them to be ſomewhat more pliant. None of thoſe brilliant ſucceſſes, however, now attended the operations of the Proteſtant allies: the campaigns of 1640 and 1641 were ſpent in uſeleſs marches and countermarches; ſerving only to bring the army into the greateſt dangers, from which they were as conſtantly relieved by the active and intrepid Bannier. At laſt this brave general, worn out with perpetual fatigues, died of a fever in the year 1641, leaving the Swediſh army in a worſe ſituation than ever.

97 Imperialiſts defeated by Konigſmark.

98 Death of Bannier.

99 A Swediſh detachment cut in pieces.

The Imperialiſts were too well acquainted with the abilities of Bannier, not to take advantage of the opportunity offered by his death. A Swediſh detachment was cut in pieces at Quidlenberg. The Swediſh army, accuſtomed only to be obedient to Bannier, became mutinous, and Piccolomini reſolved to fall upon them with his whole force. But the four generals, Wrangel, Konigſmark, Wittemberg, and Pfal, having convinced the ſoldiers of the neceſſity of defending themſelves, made ſuch excellent diſpoſitions, that the Imperialiſts durſt not attack them. Piccolomini then detached part of his army to attack the Heſſians in their quarters; but Wrangel and Konigſmark threw themſelves in their way, and defeated them with the loſs of 2000 men. This victory, however, did not retrieve the Swediſh affairs. Diſſentions and mutiny began again to take place in the army to ſuch a degree as threatened its diſſolution. In 1642 general Toſtenſon was ſent from Sweden, with a large ſum of money and a ſtrong reinforcement, to take upon him the ſupreme command. This general was inferior in abilities to none of his predeceſſors, and deſigned without loſs of time to come to an engagement; but the Weymar army ſeparating from him, put an end to that deſign, and obliged him to remain for a conſiderable time inactive. He was alſo confined to his chamber for ſome time by a dangerous gout; and thus a report of his death being ſpread, the Imperialiſts were encouraged to begin a long march through roads ſcarce paſſable, in hopes of ſurpriſing the Swediſh army without a general. Torſtenſon having intelligence of this, ſeized an advantageous poſt, which could not be forced; and thus obliged the enemy to retreat, after having

100 The Imperialiſts defeated.

101 General Torſtenſon takes the command of the Swediſh army.

ſuffered as much by their fatiguing march as if they had fought a bloody battle. Then joining general Stalhanch, who had been driven by the Imperialiſts out of Sileſia, he reduced the town of Great Glogau, with a number of other important places; after which he laid ſiege or Schweidnitz. The duke of Saxe-Lawenburgh, at the head of all his cavalry, endeavoured to throw in ſuccours; but was defeated with the loſs of 3000 men. He himſelf was taken priſoner, and died of chagrin a few days after. In conſequence of this defeat Schweidnitz ſurrendered at diſcretion; and Torſtenſon having ſent a detachment to inveſt the city of Neiſſe, proceeded with the reſt to drive the enemy entirely out of Sileſia. This he effectually performed; obliging them to retire over barren mountains, almoſt famiſhed for want of proviſions, and haraſſed by his light troops; ſo that this lately formidable army was almoſt entirely ruined. With his victorious troops the Swediſh general then poured into Moravia; where, in five days, he reduced the ſtrong town of Olmutz (which not long ago ſuſtained a ſiege of as many weeks by the late king of Pruſſia). Litta and Newſtadt ſhared the ſame fate; after which, the Swedes, returning ſuddenly to Sileſia, made themſelves maſters of Oppelein and Brieg, and laid ſiege to Breſlau. Here the garriſon made ſuch an obſtinate defence, that the Imperialiſts had time to aſſemble under the conduct of the archduke Leopold, and come to their relief. As Torſtenſon was greatly inferior in number, he raiſed the ſiege; but appeared ſo formidable in his retreat, that the enemy durſt neither attack him, nor attempt to prevent his encamping in a very advantageous ſituation. The Imperialiſts took this opportunity of laying ſiege to Glogau; but after having loſt a great number of men, they were forced to abandon the enterpriſe on the junction of Wrangel with Torſtenſon; by which means the Swedes were once more in a condition to face their enemies in the field.

Sweden.

102 Reduces ſeveral towns.

103 Drives the Imperialiſts out of Sileſia, and takes Olmutz, &c.

Torſtenſon now projected an irruption into Bohemia, and putting his army into winter-quarters in that country; but in this he was prevented by the vigilance of the enemy: however, he reduced the city of Zittau, where, for the firſt time, a cartel for priſoners was eſtabliſhed; by which means the Swediſh army was conſiderably augmented. Thus diſappointed in his deſigns on Bohemia, Torſtenſon directed his courſe to Leipſic, which he intended to inveſt. The Imperial generals aſſembled their whole force, and ſet out to relieve that important place. The two armies ſoon came in ſight of each other; and a furious cannonading was the prelude to a general engagement. A ſingle bullet had almoſt proved fatal to the Swediſh cauſe. It carried away the furniture of Torſtenſon's horſe, killed the count Palatine's horſe, pierced general Rabenau through the body, took off the head of a celebrated counſellor named *Crabbe*, and carried away the leg of a private ſoldier. The Swedes, as ſoon as the armies came up, behaved with their wonted reſolution, and after an obſtinate conflict obtained a complete victory; 5000 of the enemy being killed on the ſpot, 3000 wounded, and as many taken priſoners. This victory was followed by the immediate ſurrender of Leipſic; and in all probability the Swedes would have finally triumphed over all their enemies, had not a rupture with Denmark enſued. Torſtenſon and Horn behaved with their uſual valour in Holſtein and Schonen, while general Konigſmark diſtinguiſhed himſelf in Germany; but the ruin of the Weymar army, which was totally defeated with the loſs of one half its number at Dettingen by the Bavarians, proved a dreadful blow, from which the Swedes could ſcarce recover themſelves. Indeed, notwithſtanding the valour and ſucceſs of the Swedes, their affairs in Germany muſt have gone to wreck in the campaigns of 1643 and 1644, had not the

104 Entirely defeats them at Leipſic.

105 War with Denmark.

106 The Swedes defeated at Dettingen.

French

Sweden.

French under Condé and Turenne made a moſt powerful diverſion, and performed ſuch exploits as immortalized the names of theſe two generals.

107 An advantageous peace with Denmark.

In 1645, the war againſt Denmark was puſhed with ſuch vigour, that a peace, very honourable and advantageous for Sweden, was concluded; and thus Torſtenſon was again at liberty to act againſt the Imperialiſts. He now took meaſures for carrying the war into the heart of the Auſtrian dominions. Hatfield aſſembled a conſiderable army to oppoſe the Swedes; and the emperor came in perſon to Prague to animate his troops. The two armies came in ſight at Jancowitz, and both prepared for an engagement. The valour of the Swedes once more prevailed; and they totally defeated their enemies. Four thouſand of the Imperialiſts were killed on the ſpot, among whom were general Hatfield and a great number of officers; and near 5000 were taken priſoners. No great advantages, however, were derived from this victory. Some towns indeed were reduced; but at laſt Torſtenſon was obliged to retire into Moravia, where he put his army into winter-quarters; and in the beginning of the year 1646 reſigned the command to Wrangel.

108 The imperialiſts entirely defeated at Jancowitz.

109 Torſtenſon reſigns the command to Wrangel.

The new general conducted the Swediſh affairs with great ability and ſucceſs; till at laſt the Imperialiſts, finding themſelves finally unable to drive the Swedes out of Germany, concluded a peace with them in 1648. This was the memorable treaty of Weſtphalia, by which the Germanic conſtitution was ſettled upon its ancient principles, and thoſe implacable diſputes which had ſo long torn the empire were ended; the duchies of Bremen and Verden, all the Upper and part of Lower Pomerania, the city of Wiſmar and the iſle of Rugen, were aſſigned to Sweden, and a gratification of five millions of crowns was given to the army.

110 Treaty of Weſtphalia.

Sweden now enjoyed ſome years of repoſe. Charles Guſtavus, count Palatine, having gained the favour of Chriſtina, was appointed generaliſſimo of the forces, and heir-apparent to the crown. A marriage was propoſed between them; but the queen would never liſten to this or any other propoſal of the kind. In 1650, the ceremony of the queen's coronation was performed; but in four years thereafter, ſhe reſigned the crown in favour of Guſtavus. (See the article CHRISTINA).

111 Charles Guſtavus appointed heir to the crown of Sweden.

The new king found himſelf involved in conſiderable difficulties on his acceſſion to the throne. The treaſury was quite exhauſted; great part of the revenue was appointed for the ſupport of Chriſtina's houſehold; the people were oppreſſed with taxes; and the nation having been diſarmed for ſeveral years, began to loſe its reputation among foreigners. To remedy theſe evils, Charles propoſed to reſume all the crown lands which had been alienated by grants to favourites during the late reign; to repeal a duty which had been laid upon ſalt; to put the kingdom in a poſture of defence; and to enter upon a war with ſome neighbouring ſtate. Under a pretence, therefore, that Caſimir king of Poland had queſtioned his title to the throne, he began to make preparations for invading that kingdom. Several embaſſies were ſent from Poland to Stockholm; but ſome point of ceremony always diſappointed them of an audience of the king; ſo they were obliged to return without their errand. As ſoon as matters were in readineſs, General Wittemberg made an irruption into Poland from the ſide of Pomerania. The Poles oppoſed him with an army of 15,000 men; but inſtead of fighting, they began to negotiate, and in a ſhort time entirely diſperſed themſelves. Charles himſelf ſoon followed with a powerful army, and purſued his march without obſtruction, all the cities throwing open their gates to him as he approached, and offering to ſupply him with neceſſaries. As he advanced to Cracow, Caſimir reſolved to make one effort to ſave his capital. His army amounted only to 10,000 men; and theſe were unfortunately ſuch as had never ſtood fire. After a feeble reſiſtance, they fled with precipitation, having loſt 1000 men killed and taken priſoners. A few days after this Charles defeated the Poles a ſecond time, about eight leagues from Cracow; upon which Caſimir fled with his family to Oppelen in Sileſia. The capital was then inveſted; and though defended with the utmoſt valour by Stephen Czarneſki, was in a ſhort time obliged to capitulate. Thus in leſs than three months Charles apparently became maſter of Poland; but it ſoon became evident that the Poles had no intention of abandoning their former ſovereign.

112 State of Sweden on the acceſſion of Charles.

113 War with Poland reſolved on.

Sweden.

114 The Poles defeated, and the kingdom reduced.

In 1656 a war took place with the elector of Brandenburg. While Charles was employed in the conqueſt of Poland, that prince had invaded the Royal and Ducal Pruſſia, and reduced the moſt conſiderable towns with little oppoſition. The king of Sweden took umbrage at his progreſs; and having marched againſt him, defeated his forces in ſeveral ſlight encounters, and obliged him to own that he was a vaſſal of Sweden. Theſe rapid conqueſts alarmed all Europe; and the different powers ſought for means of driving the Swedes out of Poland, which they had ſo unexpectedly and unjuſtly ſeized. The Poles were no ſooner aſſured that they ſhould be aſſiſted, than they everywhere revolted and maſſacred the Swedes. Caſimir returned from Sileſia; and thoſe very troops and generals who had before ſubmitted to Charles without oppoſition, now ranged themſelves under the banners of his antagoniſt. Charles immediately marched from Pruſſia to chaſtiſe the inſolence of the Poles, and totally defeated a body of 12,000 men under the command of Czarneſki. This did not hinder all the Poles incorporated with his troops to deſert; which conſiderably reduced his army; and the campaign being performed in the depth of winter, he was at laſt obliged to retreat to Pruſſia. In his march he was haraſſed by the Poles; and a body of 4000 Swedes was ſurpriſed and defeated by them at Warka. This loſs, however, was ſoon after recompenſed by a complete victory gained by Adolphus the king's brother and General Wrangel over Czarneſki. In the mean time the king was taking meaſures for laying ſiege to Dantzic; but was prevented by the Dutch, who threatened to oppoſe him, unleſs a proper regard was paid to their intereſt. Charles accordingly granted them advantageous terms; and afterwards gained over the elector of Branden burg, by ceding to him the ſovereignty of Pruſſia, that he might be at liberty to turn his whole ſtrength againſt Poland.

115 War with the elector of Brandenburg.

116 The Poles revolt.

117 Charles gains a victory, but is obliged to retire.

118 Concludes a treaty with the Dutch and the elector of Brandenburg.

By the treaty juſt concluded with the elector, the latter was to aſſiſt Charles in his war with Poland; but the elector had ſo procraſtinated matters, that the Poles, having obtained aſſiſtance from the Tartars, had reduced the city of Warſaw. The two princes, however, now marched in concert againſt their enemies, who were encamped in a ſtrong ſituation in the neighbourhood of the city abovementioned, their camp being fronted by the Viſtula. The Poles were driven from their entrenchments with prodigious ſlaughter, and a vaſt number taken priſoners. The Poles and Tartars then laboured to break the alliance; with which view they entered Ducal Pruſſia, and defeated the electoral army, taking prince Radzivil and other perſons of diſtinction priſoners. The Swedes ſoon had their revenge. General Steinboeck attacked the ſame Poliſh army at Philippowa, and overthrew it with ſuch ſlaughter as obliged the Poles for that ſeaſon to quit the field. A more formidable enemy than the Poles now began to make their appearance. The Ruſſians invaded the provinces of Carelia, Ingermania, and Livonia;

119 The Poles and Tartars defeated with great ſlaughter.

Sweden.

Livonia; while the elector of Brandenburg began to waver in his fidelity. To preserve this only ally at such a critical juncture, Charles was obliged to give him more advantageous terms than those already mentioned; while the Russians were repulsed in the provinces of Carelia and Ingermania. But in Lavonia they had better success, two important fortresses falling into their hands; after which they laid siege to Riga. For seven months they battered the walls of this city, without once venturing to pass the ditch or storm the practicable breaches. The besieged, under the command of Magnus de la Gardie and Simon Helmfield, defended themselves with the greatest intrepidity; cutting off many thousands of the enemy in the sallies they made. At last they attacked the Russian camp, drove them out of it with great slaughter, and obliged them to raise the siege with precipitation.

120 The Russians invade the Swedish dominions.

121 Are defeated before Riga.

Charles, notwithstanding the number of his enemies, was now become so formidable by the valour and discipline of his troops, that whole armies often fled on the very news of his approach. At last, in 1657, the Poles, finding they could not resist him in the field, contented themselves with harassing the Swedes on their march, and cutting off the foragers and convoys. This proved much more destructive to the Swedes than their former method; so that Charles was obliged to enter into an alliance with Ragotski prince of Transylvania, by assigning him certain provinces in his neighbourhood, in order to furnish himself with irregular troops, who might fight the Poles in their own way. This, however, proved of no real advantage; for the confederates, after spending a whole campaign in Luthuania, were obliged to return without accomplishing more than the reduction of a single fortress; upon which Charles returned with the Swedish army to Prussia.

122 Charles enters into an alliance with Ragotski prince of Transylvania.

Leopold, the young king of Hungary, having beheld for a long time the Swedes with a jealous eye, now resolved to declare for Poland. The more effectually to curb the ambition of the Swedish monarch, he solicited the king of Denmark to come to a rupture with him. This was instantly complied with, and the Danes invaded Bremen. Charles hastened to oppose this new enemy; which gave such offence to Ragotski, that he neglected to take the proper measures for his own defence in the absence of the Swedes, and suffered his army to be destroyed by the Poles and Tartars. At the same time the Turks invaded Transylvania, under pretence that Ragotski, being a vassal of the Grand Signior, had no right to invade Poland without his leave. Ragotski opposed them in the field; where he was defeated and killed, leaving Charles destitute of the only ally on whom he could have depended.

123 Leopold king of Hungary declares against Sweden.

124 Ragotski's army destroyed by the Poles and Tartars.

125 He is defeated and killed by the Turks.

The king, however, not dismayed by this misfortune, traversed Pomerania and the duchy of Mecklenburg; after which he fell upon Holstein, while general Wrangel with another corps entered the duchy of Bremen. The latter executed his measures with the utmost vigour and intrepidity. In 15 days he retook all the towns which the enemy had reduced; defeated and drove the Danish army out of the country, killing 3000 of their best soldiers. In Holstein the king reduced several fortresses, laid Itzehoe in ashes, defeated a body of Danes, and laid siege to Frederic-Udda, into which the Danes had thrown a strong garrison. The conduct of this siege he left to Wrangel, he himself retiring to Wismar in order to observe the situation of affairs in Poland; but no sooner was he gone than Wrangel attacked the place with such fury, that he became master of it in two hours. In the province of Halland the Swedes were defeated; but the enemy derived no advantage from their victory: at sea the fleets met, and maintained a hot engagement for two days, without any considerable advantage on either side. In Poland matters went on much worse. The house of Austria had now declared for Casimir; a German army entered Poland, and reduced Cracow, though not without great loss to themselves. Czarneski entered Pomerania, where he butchered the unhappy peasants without mercy; but on the approach of Charles he fled as usual, having gained nothing by his expedition but the character of a cruel barbarian.

126 Bravery and success of general Wrangel.

Sweden.

127 The house of Austria declares against Sweden.

The king of Sweden was now surrounded by enemies. The elector of Brandenburg had declared against him; and he had besides to engage the armies of Austria, Poland, Russia, and Denmark, in the field. In this dangerous situation he resolved to attack Denmark, in such a manner as should oblige that power to come to a speedy accommodation. His designs were forwarded by a very early frost, which enabled him to transport his troops without the expence and trouble of shipping. Having passed over on the ice to the island of Funen, he cut in pieces a body of 4000 Danish soldiers and 500 peasants. The whole island was reduced in a few days; after which he passed to Langland, then to Laaland, after that to Falstre, and lastly to Zealand. The Danes were terrified at this unexpected invasion, and were giving themselves up to despair, when Charles offered to conclude a peace upon equitable terms. The king of Denmark very gladly consented; but with a design to renew the war as soon as he thought it could be done with safety. By this treaty, called the *treaty of Roschild*, concluded on the 12th of March 1658, the provinces of Schonen, Halland, and Bleking, Lyster, and Huwen, the isle of Bornholm, the baillages of Bahadus and Drontheim in Norway, were yielded to Sweden, and a free passage through the Sound was granted to the Swedish ships.

128 Charles invades Denmark with great success.

129 Peace concluded.

No sooner was Charles retired, than the king of Denmark began to act against him in an underhand manner; on which, resolving to anticipate him in his designs, he appeared unexpectedly with a fleet before Copenhagen. Had he given the assault immediately, before the inhabitants had time to recover from their surprise, it would probably have surrendered at once; but, by landing at the distance of 17 miles, he gave them time to prepare for their defence: the siege proved extremely tedious, and at last the place was relieved by a Dutch fleet. On this Charles converted the siege into a blockade, which continued till the end of the war. Wrangel reduced the strong fortress of Cronenburg; and the Swedish forces were so judiciously posted, that all Denmark was in a manner blocked up; when, in 1660, king Charles died of an epidemical fever: and thus an end was put, for that time, to all the ambitious designs of Sweden.

130 The war renewed, and Copenhagen besieged.

131 Death of Charles Gustavus.

The new king Charles XI. was a minor at the time of his father's death; and as the kingdom was involved in a dangerous war with so many enemies, the regency determined to conclude a peace, if it could be obtained on reasonable terms. A treaty was accordingly concluded at Oliva; by which Casimir renounced his pretensions to the crown of Poland, and that republic gave up all pretensions to Livonia. Bornholm and Drontheim were ceded to Denmark; and an equivalent in Schonen remained with Sweden. During the minority of the king, nothing remarkable occurs in the history of Sweden. In 1672 he entered into alliance with Louis XIV. which two years after involved him in a war with the elector of Brandenburg. At first the Swedes carried all before them; and general Wrangel having fallen sick, they continued their conquests under another named *Mardenfeldt*. Almost all the towns in Brandenburg were reduced, when the elector arrived with an army to the relief of his distressed subjects. He retook several towns, defeated Mardenfeldt in a general engagement, and soon after forced them to abandon all their conquests. In conjunction with

132 Charles XI.

133 Treaty of Oliva.

134 War with Brandenburg.

135 The Swedes defeated by land and sea.

Sweden. with the Danes, he then invaded the Swediſh dominions: many places of importance were reduced; and, in 1676, Sweden received a moſt deſtructive blow by the defeat of her fleet in an engagement with the combined fleets of Denmark and Holland. Soon after this the king took the government into his own hands, and in ſome degree reſtored the fortune of Sweden; but though matters went on in a more proſperous way where the king commanded in perſon, the ſame loſſes and diſgrace attended the Swediſh arms in every other quarter. In Pomerania, count Kongiſmark loſt every place of importance excepting Stralſund, Stetin, and Gripſwald. In 1678, the Swediſh fleet was defeated in two engagements. At Landſcroon a moſt obſtinate battle was fought from ten in the morning till ſix at night; when both parties were obliged, by their fatigue, to retire to their reſpective camps. At Oldeval in Norway, the Swedes were defeated; and the Danes laid deſolate the iſlands of Oeland Smaaland, Unno, and Kuno; while the electoral troops and Imperialiſts reduced count Kongiſmark to the utmoſt diſtreſs in the neighbourhood of Stralſund.

136 Their affairs everywhere go to wreck.

In this deplorable ſituation of affairs count Konigſmark found an opportunity of attacking his enemies to ſuch advantage, that he obtained a complete victory; after which he ravaged the duchy of Mecklenburg. Yet notwithſtanding this ſucceſs, he could not prevent the elector from reducing Stalſund; after which he was obliged to evacuate Pomerania; and, to complete his diſtreſs, the fleet which tranſported the Swediſh army from Pomerania was wrecked on the coaſt of Bornholm; by which accident 2000 perſons were drowned and the remainder plundered and taken priſoners by the Danes, though they had been furniſhed with paſſports from king Frederic.

In this unproſperous ſituation of affairs a peace was concluded at St Germain's between France and her enemies, by which the Swedes and Danes were left to decide their quarrel by themſelves. Denmark was by no means a match for Sweden, even in the diſtreſſed ſituation to which ſhe was reduced: for which reaſon a treaty was inſtantly concluded, on terms much more favourable to Sweden than could have been expected; and the peace was confirmed by a marriage between Charles and Ulrica Eleonora, daughter to the king of Denmark. From this time the Swediſh monarch applied himſelf to the reformation of the ſtate; and by artfully managing the diſputes between the nobility and peaſants, he obtained a decree of the ſtates empowering him to alter the conſtitution as he pleaſed. Being thus inveſted with abſolute power he proceeded to take ſome very extraordinary meaſures. In 1685 it was projected to liquidate the public debts by raiſing the nominal value of money, without adding any thing to its intrinſic value. This was put in execution the following year, by which the creditors of the government loſt upwards of nine millions of crowns. This, with ſome other arbitrary ſteps taken about the ſame time, diſguſted all the nobility, merchants, and crown-creditors. In Livonia they were highly reſented; and remonſtrances were repeatedly ſent by the hands of deputies, who had orders to inſiſt upon their privileges confirmed by many acts of the king's predeceſſors. The deputies could obtain nothing, ſo that the diet was aſſembled. On their report the body of nobility reſolved to draw up a ſtronger remonſtrance than any of the former, to be preſented to the king by captain Patkul one of the deputies, who had already diſtinguiſhed himſelf by his boldneſs and attachment to liberty. His public ſpirit, however, produced no other effect than to procure his own deſtruction. An accuſation was drawn up againſt all the remonſtrants, but eſpecially Patkul. He was ſentenced to loſe his right hand, then to be deprived of his life, honours, and eſtates; to have the latter confiſcated to the crown, and his papers burnt by the hands of the common executioner. The accuſation was declared unjuſt by the univerſity at Leipſic: but notwithſtanding this, Patkul was obliged to fly his country, to avoid the execution of his rigorous ſentence; which, however, fell upon him with redoubled fury in the ſubſequent reign, of which an account is given under the article PATKUL.

137 Peace concluded.

138 Charles becomes abſolute.

139 Diſguſts many of his ſubjects.

140 Boldneſs and misfortunes of Captain Patkul.

Sweden.

141 Charles XI. dies and is ſucceeded by his ſon Charles XII.

On the 15th of April 1697, died Charles XI. leaving his crown to his ſon, the celebrated Charles XII. at that time a minor. On his acceſſion he found himſelf under the tuition of his grandmother Eleonora, who had governed the kingdom during the minority of the late king. Though Charles was at that time only 15 years of age, he inſtantly ſhowed a deſire of taking the government into his own hands. His counſellors, count Piper and Axel Spaire, ſignified his deſire to the queen-regent. They were by her referred to the ſtates; and there all were unanimous: ſo that the queen, finding that oppoſition would be vain, reſigned her power with a good grace; and Charles was inveſted with abſolute authority in three days after he had expreſſed his deſire of reigning alone. He was ſcarce ſeated on the throne when a powerful combination was formed againſt him. King Auguſtus of Poland formed deſigns on Livonia; the king of Denmark revived the diſputes he had with the duke of Holſtein, as a prelude to a war with Sweden; and Peter the Great of Muſcovy began to form deſigns upon Ingria, formerly a province of Ruſſia. In 1699 the king of Denmark marched an army into Holſtein. Charles ſent a conſiderable body of troops to the duke's aſſiſtance; but before their arival the Danes had ravaged the country, taken the caſtle of Gottorp, and laid cloſe ſiege to Tonningen. Here the king of Denmark commanded in perſon; and was aſſiſted by the troops of Saxony, Brandenburg, Wolfenbuttle, and Heſſe-Caſſel. England and Holland, as guarantees of the laſt treaty with Denmark, in concert with Sweden, joined Charles againſt this confederacy, and ſent fleets to the Baltic. They propoſed a termination of the war upon equitable terms; but theſe were haughtily refuſed by the Daniſh monarch, who deſpiſed the youth and inexperience of Charles, and relied too much upon the alliance he had formed with Saxony, Brandenburg, Poland, and Ruſſia. The town of Tonningen, however, reſiſted all his efforts; and when he ordered the place to be ſtormed, he had the mortification to ſee his troops driven headlong from the walls by a handful of Swedes under general Bannier.

142 He takes the government into his own hands at the age of 15.

143 A powerful combination formed againſt him.

144 Holſtein ravaged by the Danes.

145 They are repulſed at Tonningen.

In the year 1700, Charles, having entruſted the affairs of the nation with a council choſen out of the ſenate, ſet out on the 8th May from his capital, to which he never afterwards returned. He embarked at Carlſcroon, and defeated the fleet of the allies. Having made a deſcent on the iſland of Zealand, he defeated a body of cavalry that oppoſed his march, and then proceeded to inveſt Copenhagen by ſea and land. The king of Denmark then ſaw the neceſſity there was either of having his capital deſtroyed, or of doing juſtice to the duke of Holſtein. He choſe the latter; and a treaty was concluded in eleven days, upon much the ſame terms as formerly. Charles, being thus at liberty to turn his arms againſt the other princes who had conſpired his deſtruction, reſolved to lead his army againſt Auguſtus king of Poland; but on his way he received intelligence that the czar of Muſcovy had laid ſiege to Narva with 100,000 men. On this he immediately embarked at Carlſcroon, though it was then the depth of winter, and the Baltic ſcarce navigable; and ſoon landed at Pernaw in Livonia with part of his forces, the reſt being ordered to Reval. His army did not exceed 20,000 men; but they were the beſt ſoldiers in Europe, while the Ruſſians were only an undiſciplined multitude.

146 Charles ſets out from Stockholm, and defeats the fleet of the allies.

147 Obliges the Danes to make peace.

148 Marches againſt the Ruſſians.

Sweden.

multitude. The czar, however, had thrown very poſſible obſtruction in the way of his antagoniſt. Thirty thouſand men were poſted in a defile on the road, to oppoſe his paſſage; and this corps was ſuſtained by a body of 20,000 others, poſted ſome leagues nearer Narva. The czar himſelf had ſet out to haſten the march of a reinforcement of 40,000 men, with whom he intended to attack the Swedes in flank and rear. But the celerity and valour of the Swedes baffled every endeavour. With 4000 foot and an equal number of horſe the king ſet out, leaving the reſt of the army to follow him at their leiſure. With theſe he attacked and defeated the Ruſſian armies one after another, puſhing his way to the czar's camp, which he give immediate orders for attacking. This camp was fortified by lines of circumvallation and contravallation, by redoubts, by 150 pieces of braſs cannon placed in front; and was defended by an army of 80,000 men; yet ſo violent was the attack of the Swedes, that in three hours the entrenchments were carried; the king with 4000 men that compoſed the wing he commanded in perſon, purſued a flying army of 50,000 to the river Narva. The bridge broke down by the weight of the fugitives, and the river was inſtantly covered with their bodies. Great numbers returned in deſpair to their camp, where they defended themſelves for a while; but at laſt the generals Gallowin and Frederowitz, who commanded them, ſurrendered. Thirty thouſand were killed in the intrenchments and in the purſuit, or drowned in the river; 20,000 ſurrendered at diſcretion, and were diſmiſſed unarmed; while the reſt were totally diſperſed. An hundred and fifty pieces of fine cannon 28 mortars, 151 pair of colours, 20 ſtandards, and all the baggage of the enemy, were taken. Among the priſoners were the duke de Croy, the prince of Georgia, and ſeven other generals. Charles behaved with the greateſt generoſity to the conquered. Being informed that the tradeſmen of Narva had refuſed credit to the officers whom he detained priſoners, he ſent 1000 ducats to the duke of Croy, and to every other officer a proportionable ſum.

149 Defeats two Ruſſian armies, and attacks the Czar's camp.

250 The camp forced, and the Ruſſians defeated with great ſlaughter

151 Generoſity of Charles.

Peter was advancing with 40,000 men to ſurround the Swedes, when he received intelligence of the dreadful defeat at Narva. He was greatly chagrined; but, comforting himſelf when the hopes that the Swedes would in time teach the Ruſſians to beat them, he returned to his own dominions, where he applied himſelf with the utmoſt diligence to the raiſing of another army. He evacuated all the provinces which he had invaded, and for a time abandoned all his great projects, thus leaving Charles at liberty to proſecute the war againſt Poland.

152 Treaty between the Czar and king of Poland.

As Auguſtus had expected an attack, he endeavoured to draw the czar into a cloſer alliance with him. The two monarchs had an interview at Birſen, where it was agreed that Auguſtus ſhould lend the czar 50,000 German ſoldiers, to be paid by Muſcovy; that the czar ſhould ſend an equal number of his troops to be trained up to the art of war in Poland; and that he ſhould pay the king three millions of ſix-dollars in the ſpace of two years. Of this treaty Charles had notice, and by means of his miniſter count Piper entirely fruſtrated the ſcheme.

153 Charles marches againſt the Saxons.

In 1701, as early as the ſeaſon permitted, Charles, having received a reinforcement from Sweden, took the field, and appeared ſuddenly on the banks of the Duna, along which the Saxon army was poſted to receive him. The king of Poland at that time being ſick, the army was commanded by Ferdinand duke of Courland, mariſchal Stenau, and general Paykel, all officers of valour and experience. They had fortified certain iſlands in the mouth of the river, and taken every other precaution againſt an attack; the ſoldiers were hardy, well diſciplined, and nearly equal to the Swedes in number; yet Charles, having paſſed the river in boats with high ſides to ſcreen the men from the fire of the enemy, attacked them with ſuch fury, that they were entirely defeated, with the loſs of 2500 killed on the ſpot, and 1500 taken priſoners. All the Saxon baggage, 36 pieces of cannon, five pair of colours, and ſix ſtandards, fell into the hands of the Swedes.

Sweden.

154 And entirely defeats them.

This victory was followed by the ſurrender of all the towns and fortreſſes in the duchy of Courland. The king then paſſed into Lithuania; where every town opened its gates to him. At Birſen, an army of 20,000 Ruſſians retired with the utmoſt percipitation on the news of his approach. Here Charles preceiving that the kingdom of Poland was greatly diſaffected to Auguſtus, began to project the ſcheme of dethroning him by means of his own ſubjects. This ſcheme he executed with more policy than he ever ſhowed on any other occaſion. The manner of putting it in execution was concerted between Radziewiſchi, cardinal primate of Poland, and count Piper. Intrigues and cabals were held at the houſe of the treacherous eccleſiaſtic, while he was publiſhing circular letters to keep the people in their duty to the king. The diet being filled with Swediſh partiſans, became tumultuous, and broke up in confuſion. The affairs of the kingdom then fell into the hands of the ſenate; but here the Swediſh party was as ſtrong as in the diet. It was agreed that they ſhould ſend an embaſſy to Charles; that the poſpolite ſhould mount, and be ready againſt all events; but the chief regulations reſpected the king's authority, which it was determined at any rate to retrench. Auguſtus, reſolving rather to receive laws from the victorious Charles than from his own ſubjects, ſent an embaſſy to him, committing the management of the whole to the counteſs of Konigſmark, a native of Sweden, and a lady famous for her wit and beauty. But the king refuſed to ſee her; on which ſhe returned chagrined and diſappointed, to Warſaw. The ambaſſadors of the ſenate inſtantly obtained an audience; and were aſſured by Charles, that he took arms againſt the Saxons in defence of the liberties of the Poles, whom he ſhould always regard as his beſt friends. Conferences were appointed to be held at Kinſchin; but Charles ſoon after altered his mind, and told the ambaſſadors he would hold them at Warſaw.

154 Forms a ſcheme for dethroning Auguſtus.

156 Confuſions in Poland.

157 Auguſtus attempts to treat, but in vain.

Auguſtus, in the mean time, finding his ſcheme of peace fruſtrated had recourſe to the ſenate; but met with ſuch a rough anſwer from them, that he determined once more to apply to Charles. To him therefore he ſent his charmberlain; but a paſſport being forgot the ambaſſador was arreſted. Charles continued his march to Warſaw, which ſurrendered on the firſt ſummons; but the citadel held out for ſome days. Auguſtus, finding at laſt that no dependence was to be had on the Poles, determined to truſt his fortune wholly to the Saxon army and the nobility of the palatinate of Cracow, who offered to ſupport him to the utmoſt of their power. The Saxon army was now advanced to the frontiers, and Auguſtus immediately put himſelf at the head of it. Being joined by the nobility of Cracow, he found his forces to amount to 30,000 men, all brave and well-diſciplined. With theſe he marched in queſt of his enemy; who did not decline the combat, though he had with him only 12,000 men. Though the Saxons were ſtrongly poſted, having their front covered by a moraſs, beſides being fortified with palliſadoes and chevaux de friſe, they were attacked with irreſiſtible impetuoſity, and entirely defeated, with the loſs of 4000 killed, 2000 made priſoners, and all their baggage and cannon. This victory was followed by the loſs of Cracow: after which Charles ſet out in purſuit of the flying army, with a deſign of preventing them from reaſſembling; but his horſe falling under him, he had the misfortune

158 Makes a ſecond application to no purpoſe.

195 Warſaw taken.

160 The Saxons entirely defeated.

161 Cracow taken.

Sweden.

fortune to break his thigh, by which he was confined ſix weeks; and thus Auguſtus obtained ſome reſpite. The interval he made the beſt uſe of. Having convoked a diet firſt at Marienburg, and then at Lublin, from them he obtained the following reſolutions; that an army of 50,000 men ſhould be raiſed by the republic for the ſervice of the prince; that ſix weeks ſhould be allowed the Swedes to determine whether they were for war or peace; and that the ſame time ſhould be granted to the turbulent and diſcontented nobles of Poland to make their conceſſions. To counteract the effects of theſe reſolutions, Charles aſſembled another diet at Warſaw; and while the two aſſemblies diſputed concerning their rights and privileges, he recovered of his wound, received a ſtrong reinforcement from Pomerania, and utterly defeated and diſperſed the remains of the Saxon army.

162 Remains of the Saxon army entirely defeated.

The ill fortune of Auguſtus continued ſtill to perſecute him. In 1704 he was formally depoſed by the diet, and the crown conferred by Charles on Staniſlaus Lecſinſky palatine of Poſnania. Auguſtus, however, did not yet tamely give up his kingdom. His adherents daily ſkirmiſhed with the Swedes; and Auguſtus himſelf, being reinforced by 9000 Ruſſians, retook Warſaw, and was very near ſurpriſing the new king, who lived in perfect ſecurity in the city while Charles fought in his cauſe. Count Horn, with 1500 Swedes, vigorouſly defended the citadel; but at laſt, finding it no longer tenable, he was obliged to ſurrender at diſcretion. The reduction of Warſaw was among the laſt advantages gained by Auguſtus in the courſe of this war. His troops were now compoſed of Saxon recruits and undiſciplined Poles, who had no attachment to his perſon, and were ready on all occaſions to forſake him. Charles and Staniſlaus advanced with the victorious army; the Saxons fled before them, and the towns for ſeveral miles round ſent their ſubmiſſions. The Poles and Saxons were under the command of Schullemberg, a moſt ſagacious and experienced general, who uſed every expedient to check the progreſs of the Swedes, by ſeizing on the advantageous poſts, ſacrificing ſmall parties to the ſafety of the whole, and to miſlead the enemy, &c. However, with all his conduct and caution, he found himſelf outwitted, and Charles in the neighbourhood of his camp ready to fall upon him, while he thought him at 50 leagues diſtance. The Swediſh monarch attacked him with a ſuperior army, but entirely compoſed of horſe. Schullemberg had poſted his men in ſuch a manner as rendered it impoſſible to ſurround them. His firſt rank being armed with pikes and fuſees, preſented a kind of rampart of bayonets; the ſecond line ſtooping over the firſt who kneeled, fired over their heads, while the third rank, who ſtood upon their feet, kept up an inceſſant fire, by which the Swediſh horſe were exceedingly galled and put in diſorder. Charles loſt the opportunity of cutting off the whole Saxon army, by omitting to order his men to diſmount. This was almoſt the firſt time that infantry had been regularly oppoſed to cavalry, and the ſuperiority of the former was evident. After the engagement had continued about three hours, the Saxons retreated in good order; which no enemy had ever done before in any engagement with Charles. The Swedes purſued their enemies towards the Oder, and forced them to retreat through thick woods, almoſt impervious even to infantry. The Swediſh horſe, however, puſhed their way, and at laſt incloſed Schullemberg between a wood and the river, where Charles had no doubt of obliging him to ſurrender at diſcretion, or die ſword-in-hand, as having neither boats nor bridges; but the genius of Schullemberg ſupplied every defect. In the night he ordered planks and floats of trees to be faſtened together; upon which he carried over his troops, while the Swedes were employed in diſlodging 300 men, which he had placed in a wind mill, for the purpoſe of defending his flank and keeping the enemy in play. Charles ſpoke of this retreat with admiration, and ſaid he had been conquered by Schullemberg.

163 Auguſtus formally depoſed, and Staniſlaus raiſed to the throne.

164 Warſaw retaken by Auguſtus.

165 Excellent conduct of his general Schullemberg.

166 His engagement with the Swedes.

167 His fine retreat.

No material advantage, however, reſulted from this to Auguſtus; who was again obliged to leave Poland, and fortify the capital of his hereditary dominions, which he expected every moment to ſee inveſted. In the mean time, however, the Ruſſians having recovered their ſpirits, fell upon the Swedes in Livonia with the utmoſt fury. Narva, Dorpt, and ſeveral other towns, were taken, and the inhabitants and garriſons treated with great barbarity. Soon after, an army of 100,000 Ruſſians entered Poland. Sixty thouſand Coſſacks under Mazeppa entered the country at the ſame time, and ravaged every thing with the fury of barbarians. Schullemberg too, perhaps more formidable than either, advanced with 14,000 Saxons and 7000 Ruſſians, diſciplined in Germany, and reputed excellent ſoldiers. Could numbers have determined the event of war, the Swedes muſt certainly have been at this time overpowered. Inſtead of this, however, Charles ſeemed to triumph over his enemies with more eaſe the more numerous they were. The Ruſſians were defeated ſo faſt, that they were all diſperſed before one party had notice of the misfortunes of another. The defeating an army of 40,000 men ſcarcely obſtructed the march of the Swedes, while their aſtoniſhed enemies looked upon theſe actions as the effects of witchcraft, and imagined that the king of Sweden had dealings with infernal ſpirits. With theſe apprehenſions they fled beyond the Boriſthenes, leaving the unhappy Auguſtus to his ill fate. Schullemberg, with all his ſkill and experience, ſucceeded no better. The Swediſh general Renſchild engaged and defeated him in half an hour, though the Swedes were vaſtly inferior in number, and their enemies poſted in a moſt advantageous ſituation. Nothing could be more complete than this victory. Whole regiments of Saxons threw down their arms, and begged their lives in the moſt ſuppliant poſture. Six thouſand were ſlain in the field, and 7000 taken priſoners. Thirty-ſix pieces of cannon, 11,000 muſkets, 40 pair of colours and ſtandards, with all the Saxon baggage, fell into the hands of the Swedes: and the conſequences were ſtill more important; for now a paſſage was opened into Saxony, and Auguſtus ſeemed to be in as great danger of loſing his hereditary dominions as he had been of loſing Poland. This extraordinary victory, indeed, is ſaid to have been owing to a panic which ſeized the troops of Schullemberg: however, it was looked upon with admiration, and thought to make the renown of Renſchild equal to that of his ſovereign. Charles himſelf was jealous, and could not help exclaiming, "Surely Renſchild will not compare himſelf with me!" But the cruelty of this general ſullied his reputation; for ſix hours after the engagement, he cauſed 1000 Ruſſians to be maſſacred in cold blood, to revenge, as he ſaid, the cruelties they had committed in Poland.

168 Auguſtus leaves Poland.

169 The Ruſſians take ſeveral towns in Livonia, and invade Poland.

170 Aſtoniſhing ſucceſs of Charles againſt them.

171 Schullemberg entirely defeated by Renſchild.

172 Cruelty of the Swediſh general.

Soon after this victory, which was gained on the 12th of February 1706, Charles entered Saxony at the head of 24,000 men. The diet at Ratiſbon declared him an enemy to the empire if he croſſed the Oder. But to this declaration no regard was paid. Charles purſued his march; while Auguſtus was reduced to the condition of a vagrant in Poland, where he poſſeſſed not a ſingle town beſides Cracow. Into this city he threw himſelf with a few Saxon, Poliſh, and Ruſſian regiments, and began to erect ſome fortifications for its defence; but the approach of the Swediſh general Meyerfeldt, and the news of the invaſion of Saxony, diſconcerted all his meaſures, and threw him into deſpair. The Ruſſians indeed were his faithful allies; but he dread-

173 Charles invades Saxony.

Sweden.

ed them almoſt as much as the Swedes: ſo that he was reduced to the neceſſity of writing a letter to Charles with his own hand, begging for peace on whatever terms he thought proper to grant. However, as he was then at the mercy of the Ruſſians, this tranſaction was concealed with the greateſt care. His emiſſaries were introduced to the Swediſh court in the night-time; and being preſented to Charles, received the following anſwer: That king Auguſtus ſhould for ever renounce the crown of Poland, acknowledge Staniſlaus, and promiſe never to reaſcend the throne, ſhould an opportunity offer; that he ſhould releaſe the princes Sobieſki, and all the Swediſh priſoners made in the courſe of the war; ſurrender Patkul, at that time reſident at his court as ambaſſador for the Czar of Muſcovy, and ſtop proceedings againſt all who had paſſed from his into the Swediſh ſervice. Theſe articles Charles wrote with his own hand, and delivered to count Piper, ordering him to finiſh them with the Saxon ambaſſadors.

174 Auguſtus begs for peace on any terms.

175 Charles's anſwer.

176 Auguſtus, in conjunction with the Ruſſians, defeats and takes priſoners a whole Swediſh army.

Auguſtus all this time was obliged to continue a ſhow of war, though he had neither ability nor inclination to carry it on. He was joined by prince Menzikoff with 30,000 Ruſſians; which obliged him, contrary to his inclination, to come to an engagement with Meyerfeldt, who commanded 10,000 men, one half of whom were Swedes. As at this time no diſparity of numbers whatever was reckoned an equivalent to the valour of the Swedes, Meyerfeldt did not decline the combat, though the army of the enemy was four times as numerous as his own. With his countrymen he defeated the enemy's firſt line, and was on the point of defeating the ſecond, when Staniſlaus, with the Poles and Lithuanians, gave way. Meyerfeldt then perceived that the battle was loſt; but he fought deſperately, on purpoſe to avoid the diſgrace of a defeat. At laſt, however, he was oppreſſed by numbers, and forced to ſurrender; ſuffering the Swedes, for the firſt time to be conquered by their enemies. The whole army were taken priſoners excepting major-general Kraſſau; who having repeatedly rallied a body of horſe formed into a brigade, at laſt broke through the enemy, and eſcaped to Poſnania.—Auguſtus had ſcarce ſung *Te Deum* for this victory, when his plenipotentiary returned from Saxony with the articles of the treaty abovementioned. The king heſitated and ſcrupled, but at laſt ſigned them; after which he ſet out for Saxony, glad at any rate to be freed from ſuch an enemy as the king of Sweden, and from ſuch allies as the Ruſſians.

177 But is obliged to reſign the crown of Poland.

The Czar Peter was no ſooner informed of this extraordinary treaty, and the cruel execution of his plenipotentiary Patkul *, than he ſent letters to every court in Chriſtendom, complaining of this groſs violation of the law of nations. He intreated the emperor, the queen of Britain, and the States-General, to revenge this inſult on humanity. He ſtigmatized the compliance of Auguſtus with the opprobrious name of *puſillanimity*; exhorted them not to guarantee a treaty ſo unjuſt, but to deſpiſe the menaces of the Swediſh bully. So well, however, was the proweſs of the king of Sweden known, that none of the allies thought proper to irritate him, by refuſing to guarantee any treaty he thought proper. At firſt, Peter thought of revenging Patkul's death by maſſacring the Swediſh priſoners at Moſcow; but from this he was ſoon deterred, by remembering that Charles had many more Ruſſian priſoners than he had of Swedes. Giving over thoughts of revenging himſelf in this way, therefore, in the year 1707 he entered Poland, at the head of 60,000 men. Advancing to Leopold, he made himſelf maſter of that city, where he aſſembled a diet and ſolemnly depoſed Staniſlaus with the ſame ceremonies which had been uſed with regard to Auguſtus. The country was now reduced to the moſt miſerable ſituation; one party through fear, adhered to the Swedes; another was gained over, or forced by Peter to take part with him: a violent civil war took place between the two, and great numbers of people were butchered, while cities, towns, and villages, were laid in aſhes by the frantic multitude. The appearance of a Swediſh army under king Staniſlaus and general Lewenhaupt put a ſtop to theſe diſorders, Peter himſelf not caring to ſtand before ſuch enemies. He retired, therefore, into Lithuania, giving as the cauſe of his retreat, that the country could not ſupply him with proviſions and forage neceſſary for ſo great an army.

* See the article Patkul.

178 Czar Peter complains to all the ſtates in Europe.

179 Invades Poland and formally depoſes Staniſlaus.

Sweden.

180 Retires into Lithuania.

In the mean time Charles had taken up his reſidence in Saxony, where he gave law to the court of Vienna, and in a manner intimidated all Europe. He declared himſelf the protector of the Proteſtant intereſt in Germany, particularly of the emperor's Proteſtant ſubjects in Sileſia. He deſired, or rather *commanded*, the emperor to renew and confirm to them all the liberties granted by the treaties of Weſtphalia, but ſince that time reclaimed or eluded at the treaty of Ryſwick. The emperor durſt not refuſe; and upwards of 100 churches were given to the Proteſtants. On this occaſion the emperor is reported to have ſaid, that "had Charles deſired him to become a Lutheran, he did not know whether he could have refuſed." One would indeed have imagined that Charles had ſome thoughts of converting, or at leaſt dethroning, the Pope himſelf; for being incenſed at the conſtant oppoſition of the court of Rome, whoſe weakneſs and intrigues he deſpiſed, he one day told the emperor's miniſter, that "the Swedes had conquered Rome before now, and he might one day demand an inventory of the effects left there by queen Chriſtina." At laſt, ſatiated with the glory of having dethroned one king, ſet up another, and ſtruck all Europe with terror and admiration, Charles began to evacuate Saxony, in purſuit of his great plan, the dethroning Czar Peter, and conquering the vaſt empire of Ruſſia. While the army was on full march in the neighbourhood of Dreſden, he took the extraordinary reſolution of viſiting king Auguſtus with no more than five attendants. Though he had no reaſon to imagine that Auguſtus either did or could entertain any friendſhip for him, he was not uneaſy at the conſequences of thus putting himſelf entirely in his power. He got to the palace door of Auguſtus before it was known that he had entered the city. General Fleming having ſeen him at a diſtance, had only time to run and inform his maſter. What might be done in the preſent caſe immediately occurred to the miniſter; but Charles entered the elector's chamber in his boots before the latter had time to recover from his ſurpriſe. He breakfaſted with him in a friendly manner, and then expreſſed a deſire of viewing the fortifications. While he was walking round them, a Livonian, who had formerly been condemned in Sweden, and ſerved in the troops of Saxony, thought he could never have a more favourable opportunity of obtaining pardon. He therefore begged of king Auguſtus to intercede for him, being fully aſſured that his majeſty could not refuſe ſo ſlight a requeſt to a prince in whoſe power he then was. Auguſtus accordingly made the requeſt; but Charles refuſed it in ſuch a manner, that he did not think proper to aſk it a ſecond time. Having paſſed ſome hours in this extraordinary viſit, he returned to his army, after having embraced and taken leave of the king he had dethroned.

181 Imperious behaviour of Charles.

182 Submiſſive behaviour of the emperor to him.

183 Charles viſits king Auguſtus.

The armies of Sweden, in Saxony, Poland, and Finland, now exceeded 70,000 men; a force more than ſufficient to have conquered all the power of Muſcovy, had they met them on equal terms. Peter, who had his army diſperſed in ſmall parties, inſtantly aſſembled it on receiving notice of the king of Sweden's march, was making all poſſible prepara-

184 Marches againſt the Ruſſians.

tions

Sweden.

tions for a vigorous reſiſtance, and was on the point of attacking Staniſlaus, when the approach of Charles ſtruck his whole army with terror. In the month of January 1708 he paſſed the Niemen, and entered the ſouth gate of Grodno juſt as Peter was quitting the place by the north gate. Charles at this time had advanced to ſome diſtance before the army at the head of 600 horſe. The Czar having intelligence of his ſituation, ſent back a detachment of 2000 men to attack him: but they were utterly defeated; and this diſappointment was followed by the total evacuation of Lithuania. The king purſued his flying enemies in the midſt of ſnow and ice, over mountains, rivers, moraſſes, and through almoſt every obſtacle that could be ſurmounted by human power. He had foreſeen all difficulties, and determined to ſurmount them all. As he knew that the country could not furniſh proviſions ſufficient for the ſubſiſtence of his army, he had provided a great quantity of biſcuit, on which his men chiefly ſubſiſted till they came to the banks of the Berezine, in view of Boriſſow. Here the Czar was poſted, and Charles deſigned to bring him to a battle; after which he could penetrate with the greater eaſe into Ruſſia. Peter, however, did not think proper to come to an action; but retreated towards the Boriſthenes, whither he was purſued by Charles as ſoon as he had refreſhed his army. The Ruſſians had deſtroyed the roads and deſolated the country; nevertheleſs the Swediſh army advanced with great celerity, and in their way defeated 20,000 of the enemy, though entrenched to the teeth. This victory, conſidering the circumſtances in which it was gained, was one of the moſt glorious the Swedes ever obtained. The memory of it is preſerved by a medal ſtruck in Sweden, with this inſcription, *Sylvæ, Paludes, Aggeres, Hoſtes, victi.*

185 Defeats and drives them out of Lithuania.

186 Gains a remarkable victory.

When the Ruſſians had repaſſed the Boriſthenes, which ſeparates Poland from Muſcovy, the Czar, finding himſelf cloſely purſued by an enemy with whom he was not able to cope, determined at laſt to propoſe peace. Propoſals were accordingly made; but Charles returned no other anſwer than that he would treat at Moſcow; which being reported to Peter, he coolly replied, "My brother Charles affects to play Alexander, but he will not find in me a Darius." However, he did not think proper to venture an engagement, but continued his retreat; and Charles purſued ſo cloſe, that he was daily ſkirmiſhing with the rear of the enemy. In theſe actions the Swedes had generally the advantage, though in the main theſe victories proved detrimental, by weakening the army in a country where it was impoſſible to recruit. Near Smolenſko, the king, with only ſix regiments, defeated a body of 10,000 horſe and 6000 Calmucks. In this engagement he was expoſed to the utmoſt danger, the enemy having ſeparated him from his troops. With one regiment only, he fought with ſuch fury as diſperſed the enemy, and drove them before him, at the time they thought themſelves ſure of taking him priſoner. Two aids-de-camp that fought near him were killed; his horſe was killed, as was alſo an equerry while he preſented another. The enemy had broke through the regiment, and got quite up to the king; who is ſaid to have on this occaſion killed 12 men with his own hand without receiving a wound.

187 The Czar ſues for peace, but receives an haughty anſwer.

188 Another deſperate engagement.

By the 3d of October 1708 Charles was within 100 leagues of Moſcow; but the Czar had made the roads impaſſable, either by laying them under water, digging deep ditches, or covering them with the wood of whole foreſts. He had alſo deſtroyed the villages on every ſide, and taken away every poſſibility of ſubſiſting an army. The ſeaſon was alſo far advanced; the intenſe ſevere weather was approaching; ſo that the Swedes were threatened with all the miſeries of cold and famine, at the ſame time that they were expoſed to the attacks of an enemy greatly ſuperior in number, who, from their knowledge of the country, had almoſt conſtant opportunities of haraſſing and attacking them by ſurpriſe. For theſe reaſons the king reſolved to paſs thro' the Ukrain, where Mazeppa, a Poliſh gentleman, was general and chief of the nation. Mazeppa having been affronted by the Czar, readily entered into a treaty with Charles, whom he promiſed to aſſiſt with 30,000 men, great quantities of proviſions and ammunition, and with all his treaſures, which were immenſe. The Swediſh army advanced towards the river Diſna, where they had to encounter the greateſt difficulties; a foreſt above 40 leagues in extent, filled with rocks, mountains, and marſhes. To complete their misfortunes, they were led 30 leagues out of the right way; all the artillery was ſunk in bogs and marſhes; the proviſion of the ſoldiers, which conſiſted of biſcuit, was exhauſted; and the whole army ſpent and emaciated when they arrived at the Diſna. Here they expected to have met Mazeppa with his reinforcement; but inſtead of that, they perceived the oppoſite banks of the river covered with a hoſtile army, and the paſſage itſelf almoſt impracticable. Charles, however, was ſtill undaunted; he let his ſoldiers by ropes down the ſteep banks; they croſſed the river either by ſwimming or on rafters haſtily put together; drove the Ruſſians from their poſt, and continued their march. Mazeppa ſoon after appeared, having with him about 6000 broken remains of the army he had promiſed. The Ruſſians had got intelligence of his deſigns, defeated and diſperſed his adherents, laid his towns in aſhes, and taken all the proviſions collected for the Swediſh army. However, he ſtill hoped to be uſeful by his intelligence in an unknown country; and the Coſſacks, out of revenge, crowded daily to the camp with proviſions.

Sweden.

190 Reſolves to paſs thro' the Ukrain.

191 Meets with great difficulties.

192 Defeats the Ruſſians, and is joined by Mazeppa in great diſtreſs.

Greater misfortunes ſtill awaited the Swedes. When Charles entered the Ukrain, he had ſent orders to general Lewenhaupt to meet him with 15,000 men, 6000 of whom were Swedes, and a large convoy of proviſions. Againſt this detachment Peter now bent his whole force, and marched againſt him with an army of 65,000 men. Lewenhaupt had received intelligence that the Ruſſian army conſiſted only of 24,000; a force to which he thought 6000 Swedes ſuperior, and therefore diſdained to entrench himſelf. A furious conteſt enſued; in which the Ruſſians were defeated with the loſs of 15,000 men. The Swedes continued their march; but, by the treachery of their guide, were led into a marſhy country, where the roads were made impaſſable by deep ditches and trees laid acroſs. Here he was again attacked by the Czar with his whole army. Lewenhaupt had ſent a detachment of two battalions to diſpute the paſſage of the enemy over a moraſs; but finding they were likely to be overpowered, he marched at the head of the whole infantry to their relief. Another deſperate battle enſued; when at laſt the Ruſſians were put in diſorder, and on the point of being totally defeated, when the Czar gave orders to the Coſſacks and Calmucks to fire upon all the Ruſſians who fled. "Even kill me (ſaid he) if I ſhould be ſo cowardly as to turn my back." On this the battle was renewed with great vigour; but notwithſtanding theſe poſitive orders, and the example of the Czar himſelf, the Ruſſians were a third time put in diſorder, after loſing 6000 men, when general Baver arrived with a ſtrong reinforcement of freſh Ruſſian troops. The engagement was again renewed, and continued without intermiſſion till night. The Swedes took poſſeſſion of an advantageous poſt; but were next morning attacked by the Ruſſians. Lewenhaupt had formed a kind of rampart of his waggons, but was obliged to ſet fire to them, in order to prevent their falling into the hands of the enemy, and at the ſame time to cover his retreat by the ſmoke. The Ruſſians, however, came ſoon enough

193 Deſperate encounters between General Lewenhaupt and the Ruſſians.

194 All the Swediſh proviſions burnt or taken by the Ruſſians.

189 Charles arrives within 100 leagues of Moſcow, but finds the roads impaſſable.

Sweden. enough to ſave 5000 waggons of thoſe proviſions deſigned for the diſtreſſed Swedes. A ſtrong detachment was ſent to purſue Lewenhaupt; but ſo terrible did he appear, that the Ruſſian general offered him an honourable capitulation. This was refuſed with diſdain; and the battle renewed with the ſame vigour as before. The Swedes, though reduced to 4000, again defeated their enemies, and killed 5000 on the ſpot. After this, Lewenhaupt was ſuffered to purſue his march without moleſtation, but alſo without cannon or proviſions. Prince Menzikoff, indeed, was detached to haraſs him; but ſuch was the formidable appearance of the Swedes even in their diſtreſs, that he was afraid to attack them: ſo that at laſt the 4000 arrived ſafe in the camp of Charles, after having killed upwards of 30,000 of the enemy on their march.

195 Lewenhaupt joins the main army in ſpite of all oppoſition.

This, we may ſay, was the laſt effort of Swediſh valour. The difficulties they had now to undergo exceeded what human nature could bear; yet ſtill they hoped, by conſtancy and courage, to overcome every obſtacle. In the ſevereſt winter known for a long time even in Ruſſia, they made long marches, clothed like ſavages in the ſkins of wild beaſts; all the draught-horſes periſhed; thouſands of ſoldiers dropped dead with cold and hunger: ſo that by the month of February 1709, the whole army was reduced to 18,000 Swedes. Amidſt numberleſs difficulties theſe penetrated at laſt to Pultowa, a town on the eaſtern frontier of the Ukrain, where the Czar had laid up magazines; and of theſe Charles reſolved to get poſſeſſion. Mazeppa adviſed the king to inveſt the place, in conſequence of his having correſpondence with ſome of the inhabitants, by whoſe means he hoped it would be ſurrendered. However, he was deceived; the beſieged made an obſtinate defence, the Swedes were repulſed in every aſſault, and 8000 of them were defeated, and almoſt entirely cut off, in an engagement with a party of Ruſſians. To complete his misfortunes, Charles received a ſhot from a carabine in his heel, which ſhattered the bone. For ſix hours after he continued calmly on horſeback, giving orders, till he fainted with the loſs of blood; after which he was carried into his tent. It was imagined that amputation would be neceſſary, as the wound had already begun to mortify; but one Newman undertook to ſave the limb. It was told the king that deep inciſions would be neceſſary. "Fall to work then (ſaid he), cut boldly and fear nothing." He held out his leg while the operation was performing; never changed countenance; and while the dreſſing was laid on, ordered an aſſault for the next morning.

196 Extreme diſtreſs of the Swedes.

197 Charles beſieges Pultowa.

198 A detachment of 8000 Swedes entirely defeated and cut off.

For ſome days the Cazar, with an army of 70,000 men, had lain at a ſmall diſtance, haraſſing the Swediſh camp, and cutting off the convoys of proviſion; but now intelligence was received, that he was advancing as if with a deſign of attacking the lines. In this ſituation, Charles, wounded, diſtreſſed, and almoſt ſurrounded by enemies, is ſaid to have, for the firſt time, aſſembled a grand council of war; the reſult of which was, that it was expedient to march out and attack the Ruſſians. Voltaire, however, totally denies that the king relaxed one jot of his wonted obſtinacy and arbitrary temper: but that, on the 7th of July, he ſent for general Renſchild, and told him, without any emotion, to prepare for attacking the enemy next morning.

199 The Swedes haraſſed by an army of 70,000 Ruſſians.

The 8th of July 1709 is remarkable for the battle which decided the fate of Sweden. Charles having left 8000 men in the camp to defend the works and repel the ſallies of the beſieged, began to march againſt his enemies by break of day with the reſt of the army, conſiſting of 26,000 men, of whom 18,000 were Coſſacks. The Ruſſians were drawn up in two lines behind their intrenchments, the horſe in front, and the foot in the rear, with chaſms to ſuffer the horſe to fall back in caſe of neceſſity. General Slippenbach was diſpatched to attack the cavalry; which he did with ſuch impetuoſity, that they were broken in an inſtant. However, they rallied behind the infantry, and returned to the charge with ſuch vigour, that they diſordered the Swedes in their turn, and took Slippenbach priſoner. Charles was now carried in his litter to this ſcene of confuſion. The troops were animated by his preſence, and returned to the charge; the battle became doubtful, when general Creuk was diſpatched by Charles to attack the enemy in flank. Creuk miſtook his way, or, according to others, who had the beſt opportunities of information, was bribed by Ruſſian gold, which occaſioned the loſs of the battle. Peter now diſpatched prince Menzikoff with a ſtrong detachment, to poſt himſelf between the Swedes and Pultowa, to cut off their communication with their camp, and to fall upon their rear. He executed his orders with great ſucceſs; cut off a corps de reſerve of 3000 men; and thus decided the fortune of the day. The king, however, had ranged his remaining troops in two lines; the foot in the centre, and the horſe in the two wings. They had already been twice rallied, and were now attacked with fury on all ſides. Charles, in his litter, with his ſword drawn in one hand, and a piſtol in the other, ſeemed to be everywhere preſent. New misfortunes, however, awaited him. A cannon ball killed both horſes in the litter; and ſcarce were others put in their place, when a ſecond broke the litter itſelf in pieces, and overturned the king. The ſoldiers now believing him killed, fell back in conſternation. The firſt line was broke, and the ſecond fled. Charles did every thing in his power to reſtore order; but the Ruſſians preſſed ſo hard, that rallying was impoſſible, eſpecially as powder was alſo wanting. Renſchild and ſeveral other general officers were taken priſoners; and the king himſelf muſt have fallen into the hands of the enemy, had not count Poniatowſki drawn up 500 horſe, ſurrounded the royal perſon, and with deſperate fury broke through ten regiments of the enemy. With theſe the king arrived on the banks of the Boriſthenes. The Ruſſians forced the Swediſh camp, where they found ſix millions in ſpecie; but could not hinder Lewenhaupt, with 4000 foot and all the remaining cavalry, from retreating to the banks of the Boriſthenes. This, however, availed them but little; for being purſued by prince Menzikoff, they were obliged, for want of boats or bridges, to ſurrender at diſcretion. Charles fled in a mean calaſh, attended by a little troop inviolably attached to his perſon, ſome on foot, and ſome on horſeback. They were obliged to croſs a ſandy deſert, where neither herb nor tree was to be ſeen, and where the burning heat and want of water were more intolerable than the extremities of cold they had formerly ſuffered. The whole had almoſt periſhed for want of water, when a ſpring was fortunately diſcovered; after which they reached Oczakow, a town in the Turkiſh dominions, the baſhaw of which ſupplied the king with every neceſſary. It was ſome time, however, before boats could be got ready for tranſporting the whole of the king's attendants; by which accident 500 Swedes and Coſſacks fell into the hands of the enemy. This loſs affected him more than all his other misfortunes. He ſhed tears at ſeeing acroſs the river Bog the greater part of his few remaining friends carried into captivity, without having it in his power to aſſiſt them. The baſhaw waited upon him to apologize for the delay, and was ſeverely reprimanded by Charles, as if he had been his own ſubject.

203 Battle of Pultowa.

201 The Swedes entirely defeated.

202 The camp taken, and the Swediſh army almoſt all killed or taken.

203 Charles arrives ſafe in Turkey.

The king remained but a few days at Oczakow, when the ſeraſquier of Bender ſent an aga to compliment him on his arrival in the Turkiſh dominions, and to invite him to that city.

Sweden.

city. Here he was treated with the utmoſt hoſpitality: the Turks practiſed to its utmoſt extent their generous maxim of regarding as ſacred the perſons of unfortunate princes who had taken ſhelter in their dominions: and perhaps regarded him, notwithſtanding his misfortunes, as an ally that might be uſeful to themſelves againſt the Ruſſians. Every one, indeed, regarded him in his diſtreſs. The French king offered him a ſafe paſſage from the Levant to Marſeilles, from whence he might eaſily return to his own dominions. But Charles was too obſtinate to receive advice. Puffed up with the notion of imitating Alexander the Great, he diſdained to return except at the head of a numerous army; and he yet expected, by means of the Turks, to dethrone his adverſary the Czar. Negotiations for this purpoſe, indeed, were carried on in the Turkiſh divan; and it was propoſed to eſcort Charles with a numerous army to the frontiers of Poland: but the revolution which took place there quickly put an end to all ſuch projects. Auguſtus thought himſelf no longer bound to obſerve the treaty which he had made, than Charles was at hand to force him to it. After the battle of Pultowa, therefore, he entered Poland, and took every meaſure, in concert with the Czar, for the recovery of his kingdom. Staniſlaus was not able to ſtand before ſuch enemies, but was obliged to leave his dominions and fly to Bender, in the diſguiſe of a Swediſh officer, in order to ſhare the fortune of Charles.—It was not in Poland alone that the Swediſh affairs began to ſuffer in conſequence of the defeat at Pultowa. The Danes quickly invaded the province of Schonen with an army of 13,000 foot and 2500 horſe. Only 13,000 Swediſh forces remained to defend all the territories poſſeſſed by Charles in Germany; and of theſe only a ſmall part were allotted for the defence of Schonen. The regency of Sweden, however, exerted themſelves to the utmoſt to repel this ungenerous invaſion; and having collected an army of 12,000 militia and 8000 regulars, diſpatched them under general Steenboek into Schonen. Some Saxon troops were incorporated in this army; and among theſe a prodigious deſertion took place, which the general found it impoſſible to prevent; and thus the Danes gained ſeveral advantages, and at laſt took Chriſtianſtadt. Their inſolence on this ſucceſs was ſo great, that the Swedes demanded to be inſtantly led againſt them. Here the good fortune of Sweden ſeemed once more to revive. The Danes were driven from a very ſtrong ſituation, with the loſs of 8000 killed and taken priſoners, beſides a vaſt number wounded. The king received the intelligence of this victory with the greateſt exultation; and could not help exclaiming, "My brave Swedes, ſhould it pleaſe God that I once more join you, we ſhall conquer them all!"

204 Is kindly received, and his hopes of conquering Ruſſia begin to revive.

205 Auguſtus recovers the kingdom of Poland.

206 The Danes invade Sweden;

207 But are utterly defeated.

In the mean time, Charles, by means of his agents the count Poniatowſki and the Sieur Neugebar, uſed his utmoſt efforts to procure a rupture between the Porte and Ruſſia. For a long time the money beſtowed by Peter on the vizirs and janiſaries prevailed; but at laſt, in 1711, the grand ſignior, influenced by his mother, who was ſtrongly in the intereſt of Charles, and had been wont to call him *her lion*, determined to avenge his quarrel with Peter. He therefore gave orders to the vizir to fall upon the Ruſſians with an army of 200,000 men. The vizir promiſed obedience; but at the ſame time profeſſed his ignorance in the art of war, and diſlike to the preſent expedition. The khan of Crim Tartary, who had been gained over by the reputation and preſents of the king of Sweden, had orders to take the field with 40,000 of his men, and had the liberty of aſſembling his army at Bender, that Charles might ſee that the war was undertaken upon his account. The Czar, on theſe news, left the ſiege of Riga, where he had continued for ſome months; and with 24,000 men entered Moldavia, where he was joined by Cantemir a vaſſal of the Porte. The vizir marched againſt him with a prodigious army, and, through the negligence of the Czar, cooped him up in ſuch a manner that he could neither advance nor retreat. In this deſperate ſituation, he perceived that he was now in as bad a ſituation as Charles at Pultowa; and gave orders for breaking through the enemy with fixed bayonets. The deſponding ſpiritleſs ſoldiers, however, were little diſpoſed to execute theſe orders; when Catharine, wife to the czar, without his knowledge, ſet on foot a treaty with the vizir; and having ſoon obtained his conſent, had the peace ſigned in ſix hours; by which means, in all probability the whole Ruſſian army was ſaved.

208 The Turks declare war againſt the Ruſſians.

Sweden.

209 The Czar brought into a deſperate ſituation, but is relieved by a treaty.

The new treaty was moſt violently oppoſed by count Poniatowſki and the khan of Tartary. The former had made the king acquainted with the ſituation of both armies; on which he inſtantly ſet out from Bender, filled with the hopes of fighting the Ruſſians, and taking ample vengeance. Having ridden 50 leagues poſt, he arrived at the camp juſt as the czar was drawing off his half-famiſhed troops. He alighted at Poniatowſki's tent; and being informed of particulars, inſtantly flew in a rage to the vizir, whom he loaded with reproaches, and accuſed of treachery. Recollecting himſelf, however, he propoſed a method by which the fault might be remedied; but finding his propoſal rejected, he poſted back to Bender, after having by the groſſeſt inſults ſhowed his contempt of the vizir.

210 Rage of Charles on this occaſion.

The violent behaviour of Charles did not promote his intereſt. The vizir perceived that his ſtay in Turkey might prove fatal to himſelf; and therefore determined to get him out of the country as ſoon as poſſible, either by fair means or foul. Succeeding vizirs adopted the ſame plan; and at laſt the grand ſignior himſelf wrote a letter to the king, in which he deſired him to depart by next winter, promiſing to ſupply him with a ſufficient guard, with money, and every thing elſe neceſſary for his journey. Charles gave an evaſive anſwer, and endeavoured to procraſtinate his journey, as well to gratify his own ſtubborn temper, as becauſe he diſcovered a correſpondence between Auguſtus and the khan of Tartary, the object of which, he had reaſon to believe, was to betray him to the Saxons. When he was therefore again preſſed to fix the day of his departure, he replied, that he could not think of going before his debts were paid. Being aſked how much was neceſſary for this purpoſe, he replied, 1000 purſes (A). Twelve hundred purſes were inſtantly ſent to the ſeraſquier at Bender, with orders to deliver them to the king of Sweden, but not before he ſhould have begun his journey. By fair promiſes, however, Charles perſuaded him to part with the money; after which, inſtead of ſetting out, he ſquandered away his treaſure in preſents and gratifications, and then demanded 1000 purſes more before he would ſet out. The ſeraſquier was aſtoniſhed at this behaviour. He ſhed tears; and, turning to the king, told him, that his head would be the forfeit of having obliged him with the money. The grand ſignior, on being acquainted with this ſhameful behaviour of Charles, flew into a rage, and called an extraordinary divan, where he himſelf ſpoke, a thing very unuſual for the Turkiſh monarchs. It was unanimouſly agreed that ſuch a troubleſome

211 The Grand Signior deſires him to depart.

218 Extreme insensibility of Charles.

some guest ought to be removed by force should other means fail. Orders were therefore positively sent to Charles to depart; and, in case of refusal, to attack him in his quarters. Nothing could equal his obstinacy on this occasion: in spite of the menaces of his enemies, in spite of the intreaties of his friends, he persisted in his resolution; and at last determined to resist, with 300 Swedes, being all the attendants he had, an army of 20,000 janisaries well armed and furnished with cannon. At length he was attacked in good earnest; though it must be owned, that even in this extremity, the Turks showed their regard to him, and were tender of his life, which the king did not return at all in a similar manner. Most of the Swedes surrendered at once, perhaps as thinking it the only method of saving the king's life. This misconduct, however, had a quite contrary effect. Charles became the more obstinate, the more desperate his affairs seemed to be. With 40 menial servants only, and the generals Hord and Dardorff, he determined to defend himself to the last extremity. Seeing his soldiers lay down their arms, he told the generals, "We must now defend the house. Come, (adds he with a smile), let us fight *pro aris et focis*." The house had been already forced by the Tartars, all but a hall which was near the door, and where his domestics had assembled themselves. Charles forced his way through the janisaries, attended by the generals Hord and Dardoff, joined his people, and then barricaded the door. The moment he entered, the enemy, who were in the house, threw down their booty, and endeavoured to escape at the windows. Charles pursued them from room to room with much bloodshed, and cleared the house in a few minutes. He then fired furiously from the windows, killed 200 of the Turks in a quarter of an hour, so that the bashaw who commanded them asw at length forced to set the house on fire. This was done by arrows with lighted matches shot into the roof; but Charles instead of quitting it, gave orders for extinguishing the fire in which he himself assisted with great diligence. All efforts, however, were vain: the roof fell in; and Charles, with his few faithful companions, was ready to be buried in the ruins. In this extremity one called out that there was a necessity for surrendering. "What a strange fellow! (cries the king), who would rather be a prisoner with the Turks than mix his ashes with those of his sovereign." Another had the presence of mind to cry out, that the chancery was but 50 paces off, had a stone roof, and was proof against fire. Pleased with the thoughts of again coming to blows, the king exclaimed, "A true Swede! Let us take all the powder and ball we can carry." He then put himself at the head of his troops, and sallied out with such fury that the Turks retreated 50 paces; but falling down in the hurry, they rushed in upon him, and carried him by the legs and arms to the bashaw's tent.

This extraordinary adventure, which favours not a little of insanity, happened on the 12th of February 1713. He was now kept prisoner, with all his retinue: and in this situation he was visited by the unfortunate Stanislaus. The latter, as we have already observed, came in the disguise of a Swedish officer, and had indeed served in the Swedish army in Pomerania, for which reason he was arrested in the Turkish dominions; but being known at Bender, notice was sent to the bashaw who was conducting the king of Sweden to Adrianople. The bashaw communicated the news to Baron Fabricius, a favourite of Charles, who immediately imparted it to the king. "Dear Fabricius, (says this inflexible monarch), run and tell him never to make peace with Augustus; we shall soon have a change in our affairs."

Such were the considerations that still occurred to the mind of Charles; however, at last he seemed inclined to submit to his fate, and began seriously to think of returning to his kingdom, now reduced to the most deplorable situation. His habitation was now fixed at Demotica, a small town about six leagues from Adrianople. Here he was allowed provisions for his own table and those of his retinue; but only 25 crowns a-day in money, instead of 500 which he had received at Bender. During his residence here he received a deputation from Hesse-Cassel, soliciting his consent to the marriage of the landgrave with Eleonora princess royal of Sweden; to which he readily agreed: a deputation was also sent him by the regency of Sweden, requesting that he would prepare for returning to his own dominions, which were ready to sink under a ruinous war in his absence. What determined him, however, more than any thing to hasten his return, was the following accident. The new grand vizir Ibrahim Molla, having for private reasons determined to come to a rupture with the czar, invited Charles to a conference, in the style and with the familiarity of an equal. Charles was so much chagrined at this indignity, that he sent his chancellor Mullern to meet the vizir, with a pretence that he was sick. To avoid giving offence to this minister, Charles was obliged to keep his bed during his residence at Demotica, which was for 10 months after. At last, this vizir being strangled, and the Swedish interest at the Porte thereby entirely ruined, he determined to quit Turkey at all events. His departure was to be negotiated by his favourite Grothusen, whom he vested with the character of ambassador extraordinary; sending him to Adrianople with a train of 14 persons richly dressed. To equip this retinue the king was reduced to the most mortifying shifts, and to the necessity of borrowing money from usurers at 50 *per cent.* The great object was, to obtain from the vizir money and a passport. Grothusen was received with all the respect due to his rank; but the vizir started difficulties. With regard to the passport, he said, it could be of no use until the consent of the court of Vienna was first obtained; and as to money, he said, "his master knew how to *give* when he thought proper, but it was beneath his dignity to *lend;* that the king should have every necessary provided for his journey, and possibly the Porte might make some pecuniary present but he would not have it expected." The imperial minister, however, removed every difficulty with regard to the passport, by granting it in the most full and ample manner, in the name of the emperor, the princes and states of Germany. He sent also a present to the king, consisting of a tent of scarlet richly embroidered with gold; a sabre, the handle of which was studded with jewels; and eight fine horses richly caparisoned. Money, the article most wanted, was entirely forgotten; however, the day was fixed for Charles's departure, and the vizir appointed 60 carriages loaded with all kinds of provisions, and several companies of janisaries and other troops to attend him to the frontiers of Transylvania.

On the 14th of October 1714, Charles quitted his bed at Demotica, and set out for Sweden. All the princes through whose territories he was to pass, had given orders for his entertainment in the most magnificent manner; but the king, perceiving that these compliments only rendered his imprisonment and other misfortunes more conspicuous, suddenly dismissed his Turkish attendants, and assembling his own people, bid them take no care about him, but make the best of their way to Stralsund. After this he set out post, in the habit of a German officer, attended only by Colonel During. Keeping the by-roads through Hungary, Moravia, Austria, Bavaria, Wirtemberg, the Palatinate, Westphalia, and Mecklenburg, he arrived on the 21st of November at midnight before the gates of Stralsund. Being unknown, he was admitted with difficulty; but being soon recognized by

by the governor, the greateſt tokens of joy were ſhown all over the town. In the midſt of the tumult Charles went to bed. He had been booted for 16 days, and now his legs were ſwelled to ſuch a degree that it was neceſſary to cut his boots off. Having ſlept for ſome hours, he aroſe, reviewed his troops, and gave orders for renewing the war with redoubled vigour.

224 Arrives at Stralſund, and is received with the utmoſt joy.

Sweden was now in the greateſt diſtreſs. We have already mentioned, that on the news of the defeat at Pultowa, the Danes had invaded Schonen, but were defeated by General Steenboek. This victory, however, did not put an end to the war. On the contrary, the kings of Denmark and Poland, with the czar of Muſcovy, entered into ſtricter bonds of amity than ever. They dreaded the return of Charles to his own dominions, and apprehended that numberleſs victories would ſoon efface the remembrance of Pultowa. They determined, therefore, to make the beſt uſe of their time; and perhaps Charles never took a more imprudent reſolution than obſtinately to remain ſo long in the Turkiſh dominions. The kings of Denmark and Poland invaded Pomerania; but after laying ſiege in vain to Stralſund, Wiſmar, and other places, they were obliged to retire with diſgrace into winter-quarters. In 1712, the king of Denmark invaded and reduced Bremen and Verden; but the ſame year met with a terrible defeat from Steenboek, with the loſs of a vaſt number killed and wounded, and almoſt all their artillery taken. The following year, however, this general being purſued, and ſurrounded by the united forces of the Ruſſians, Danes, and Saxons, was obliged to throw himſelf into the neutral town of Tommingen; where he was beſieged, and obliged to ſurrender at diſcretion, with his whole army. The conſequence of this diſaſter was an invaſion of Finland by the czar: which province he totally reduced, after defeating the Swedes in ſeveral engagements. Indeed, the Swediſh forces were now ſo much reduced, that they were unable to cope with almoſt any enemy. The return of Charles, however, ſeemed to give new life to the whole nation. Though the number of inhabitants was viſibly diminiſhed, the levies he had ordered were completed in a few weeks: but the hands left to cultivate the earth conſiſted of the infirm, aged, and decrepid; ſo that a famine was threatened in conſequence of the military rage which had ſeized all the youth of the kingdom.

225 Diſtreſſed ſituation of Sweden.

226 Steenboek defeats the Danes, but is afterwards taken priſoner with his whole army.

The preſence of Charles did not now produce thoſe conſequences which the allies had feared. The kingdom was too much reduced to be able to furniſh the neceſſary ſupplies of men and money; and though the king's courage and military ſkill were not in the leaſt diminiſhed, the efforts he made, inſtead of reſtoring Sweden to its ſplendour, ſerved entirely to ruin it. In 1715, Pruſſia declared againſt him, on account of his demanding back the town of Stetin, which that monarch had ſeized. To complete his embarraſſment, the elector of Hanover, George I. of Britain, alſo became his enemy. The forces of Denmark, Pruſſia, Saxony, and Hanover, joined to inveſt Wiſmar, while a body of 36,000 men formed the ſiege of Stralſund; at the ſame time that the czar, with a fleet of 20 large ſhips of war, and 150 tranſports, carrying 30,000 men, threw every part of the Swediſh coaſt into the greateſt conſternation. The heroiſm of Charles could not prevail againſt ſo many enemies; yet he was ſtill ſo dreadful, that the prince of Anhalt, with 12,000 brave troops, did not think himſelf a match for this furious enemy when at the head of only 2000, till he had entrenched his army behind a ditch, defended by chevaux de frize. It appeared, indeed, that his precaution was not unneceſſary; for in the night Charles with his men clambered up the ditch, and attacked the enemy in his uſual manner. Numbers, however, at laſt prevailed; and Charles was obliged to retire, after having ſeen his favourite Grothuſen, General Dardorff, and During, the companions of his exile, killed by his ſide, he himſelf being wounded in the breaſt.

227 The king is unable to retrieve the Swediſh affairs.

228 Is encompaſſed on all ſides by enemies.

229 His deſperate valour.

Sweden.

230 Stralſund beſieged.

This raſh attempt was made in order to ſave Rugen, from whence the town of Stralſund was ſupplied with proviſions. The place was well fortified, and garriſoned with 9000 men, with Charles himſelf at their head; but nothing could reſiſt the efforts of the enemy. The houſes were laid in aſhes by the bombs; the walls miſerably ſhattered, and large breaches made in them by the cannon; ſo that by the 17th of December it was propoſed to give the aſſault. The attack on the horn-work was deſperate: the enemy was twice repulſed; but at laſt, by dint of numbers, effected a lodgment. The next day Charles headed a ſally, in which he dealt terrible deſtruction among the beſiegers, but was at length overpowered and obliged to retreat into the town. At laſt his officers, apprehending that he muſt either fall into the hands of the enemy, or be buried in the ruins of the place, intreated him to retire. A retreat, however was now almoſt as dangerous as to remain in the town, on account of the fleets of the enemy with which the ſea was covered; and it is thought that this very circumſtance induced the king to conſent to it. Setting out, therefore, in a ſmall boat with ſails and oars, he paſſed all the enemy's ſhips and batteries, and arrived ſafe at Yſtedt in Schonen.

231 And taken, in ſpite of the utmoſt efforts of the king.

232 Charles invades Norway to no purpoſe.

To revenge himſelf for theſe loſſes, Charles invaded Norway with an army of 25,000 men. The Danes were every where defeated and purſued with that vigour for which the king of Sweden was ſo remarkable; but ſtrong reinforcements arriving from Denmark, and proviſions failing, he was at laſt obliged to retire, and evacuate the country. Soon after this the Swedes loſt Wiſmar; but when every thing ſeemed to go to wreck, Baron Goertz the chief miniſter and favourite of Charles found means to ſet on foot a treaty with the czar of Muſcovy, by which the moſt formidable of all Charles's enemies was taken off. The miniſter found means to work upon the inflexible and ſtubborn temper of Charles, by repreſenting to him that the ceſſion of certain provinces to Peter would induce him to aſſiſt him in his projects of again dethroning Auguſtus, and of replacing James on the throne of Britain; which laſt ſcheme he had projected out of revenge for the elector of Hanover having ſeized on the duchies of Bremen and Verden. In conſequence of the conferences between the czar and Goertz, the former engaged to ſend into Poland an army of 80,000 men, in order to dethrone that prince whom he had ſo long defended. He engaged alſo to furniſh ſhips for tranſporting 30,000 Swedes to Germany and 10,000 into Denmark. This treaty, however, was not fully ratified; and the king's death, which happened in 1718, put a final ſtop to all the great proſpects of Sweden.

234 A treaty with the Czar of Muſcovy projected.

234 Charles invades Norway again, and lays ſiege to Frederickſhall.

The king had reſolved on the conqueſt of Norway before he dethroned Auguſtus; and as no difficulties ever deterred him, he marched his army into that cold and barren country in the month of October, when the ground was covered with froſt and ſnow. With 18,000 men he formed the ſiege of Frederickſhall, though the ſeverity of the froſt rendered it almoſt impoſſible to break ground. Charles, however, reſolved to form trenches; and his ſoldiers cheerfully obeyed, digging into the ground with the ſame labour as if they had been piercing a rock. On the 11th of December the king viſited the trenches in the midſt of a terrible fire from the enemy, imagining that his men might be animated by his preſence. He took his poſt in the moſt dangerous ſtation he could chooſe, ſtanding upon a gabion and leaning with his arm over the parapet, while the enemy were firing chain ſhot at the very ſpot where he ſtood. He was intreated

235 His extreme raſhneſs in conſequence of which he is killed.

Sweden. treated to change his ſtation; but he remained obſtinate, as if he had been proof againſt cannon bullets. At laſt he was ſeen to fall on the parapet with a deep groan. A ſmall cannon-ball had ſtruck him on the temple, beat in the left eye, and forced the right eye quite out of its ſocket; his right hand in the mean time graſped the hilt of his ſword, as if he had meant to revenge the blow (c).

236 Account of the Swediſh affairs from the death of Cha. XII. to the year 1771.

Charles XII. was ſucceeded by his ſiſter the princeſs Ulrica Eleonora, wife to the hereditary prince of Heſſe. On this occaſion the ſtates took care to make a previous ſtipulation for the recovery of their liberties, and obliged the princeſs to ſign a paper to this purpoſe before entering on the government. Their firſt care was to make a peace with Great Britain, which the late king intended to have invaded. The Swedes then, to prevent their farther loſſes by the progreſs of the Ruſſian, the Daniſh, the Saxon, and other arms, made many great ſacrifices to obtain peace from thoſe powers. The French, however, about the year 1738, formed a dangerous party in the kingdom, under the name of the *Hots*; which not only broke the internal quiet of the kingdom, but led it into a ruinous war with Ruſſia, by which the province of Finland was loſt. Their Swediſh majeſties having no children, it was neceſſary to ſettle the ſucceſſion; eſpecially as the duke of Holſtein was deſcended from the queen's eldeſt ſiſter, and was, at the ſame time, the preſumptive heir to the empire of Ruſſia. Four competitors appeared; the duke of Holſtein Gottorp, prince Frederic of Heſſe Caſſel nephew to the king, the prince of Denmark, and the duke of Deux-Ponts. The duke of Holſtein would have carried the election, had he not embraced the Greek religion, that he might mount the throne of Ruſſia. The czarina interpoſed, and offered to reſtore all the conqueſts ſhe had made from Sweden, excepting a ſmall diſtrict in Finland, if the Swedes would receive the duke of Holſtein's uncle, Adolphus Frederic biſhop of Lubec, as their hereditary prince and ſucceſſor to their crown. This was agreed to; and a peace was concluded at Abo, under the mediation of his Britannic majeſty. This peace was ſo firmly adhered to by the czarina, that his Daniſh majeſty thought proper to drop all reſentment for the indignity done his ſon. The prince-ſucceſſor married the princeſs Ulrica, third ſiſter to the king of Pruſſia; and in 1751 entered into the poſſeſſion of his new dignity, which proved to him a crown of thorns. Through a ſtrange medley of affairs and views of intereſt, the French had acquired vaſt influence in all the deliberations of the Swediſh ſenate, who of late have been little better than penſioners to that crown. The intrigues of the ſenators forced Adolphus to take part in the late war againſt Pruſſia: but as that war was diſagreeable not only to the people, but alſo to the king of Sweden, the nation never made ſo mean an appearance; and upon Ruſſia's making peace with the king of Pruſſia, the Swedes likewiſe made their peace, upon the terms of leaving things as they ſtood at the beginning of the war. Adolphus died diſpirited in 1771, after a turbulent reign of twenty years; and was ſucceeded by his ſon Guſtavus. The moſt remarkable tranſaction of this reign is the revolution which took place in the government in the year 1772, by which the king, from being the moſt limited became one of the moſt deſpotic monarchs in Europe. Ever ſince the death of Charles XII. the whole power of the kingdom had been lodged in the ſtates; and this power they had on all occaſions moſt grievouſly abuſed. Guſtavus therefore determined either to ſeize on that power of which they made ſuch a bad uſe, or periſh in the attempt. The revolution was effected in the following manner. On the morning of the 19th of Auguſt 1772, a conſiderable number of officers, as well as other perſons known to be attached to the royal cauſe, had been ſummoned to attend his majeſty. Before ten he was on horſeback, and viſited the regiment of artillery. As he paſſed through the ſtreets he was more than uſually courteous to all he met, bowing familiarly to the loweſt of the people. On the king's return to his palace, the detachment which was to mount guard that day being drawn up together with that which was to be relieved, his majeſty retired with the officers into the guard-room. He then addreſſed them with all that eloquence of which he is ſaid to have been a perfect maſter; and after inſinuating to them that his life was in danger, he expoſed to them in the ſtrongeſt colours the wretched ſtate of the kingdom, the ſhackles in which it was held by means of foreign gold, and the diſſenſions and troubles ariſing from the ſame cauſe which had diſtracted the diet during the courſe of fourteen months. He aſſured them that his only deſign was to put an end to theſe diſorders; to baniſh corruption, reſtore true liberty, and revive the ancient luſtre of the Swediſh name, which had been long tarniſhed by a venality as notorious as it was diſgraceful. Then aſſuring them in the ſtrongeſt terms that he diſclaimed for ever all abſolute power, or what the Swedes call *ſovereignty*, he concluded with theſe words: "I am obliged to defend my own liberty and that of the kingdom, againſt the ariſtocracy which reigns. Will you be faithful to me, as your forefathers were to Guſtavus Vaſa and Guſtavus Adolphus? I will then riſk my life for your welfare and that of my country."

Sweden.

237 Guſtavus aſcends the throne.

238 Account of the revolution in 1772, by which he became deſpotic.

The officers, moſt of them young men, of whoſe attachment the king had been long ſecure, who did not thoroughly perhaps ſee into the nature of the requeſt his majeſty made them, and were allowed no time to reflect upon it, immediately conſented to every thing, and took an oath of fidelity to him.

239 Reſolution of a Swediſh officer.

Three only refuſed. One of theſe, Frederic Cederſtrom, captain of a company of the guards, alleged he had already and very lately taken an oath to be faithful to the ſtates, and conſequently could not take that which his majeſty then exacted

(c) Such is the account given by Voltaire of the untimely death of this northern hero. Many perſons, however, who had the beſt opportunities of procuring authentic information at the time, have declared that they believed he was aſſaſſinated by a Frenchman who was among his attendants. The famous earl of Peterborough, who, in his rapid marches and fearleſs intrepidity, bore no ſmall reſemblance to Charles XII. aſſured biſhop Berkely, that he had no doubt of the Swediſh monarch's having been aſſaſſinated; and Mr Wraxall, in the account of his Travels through Sweden, gives ſuch arguments for the truth of that opinion as leave very little doubt in our minds. It muſt be confeſſed, however, that Mr Coxe reaſons plauſibly in ſupport of the other opinion; and perhaps at this diſtance of time nothing can be ſaid with certainty on this queſtion, but what has been ſaid by Johnſon:

His fall was deſtined to a barren ſtrand,
A petty fortreſs, and a *dubious hand.*
He left the name, at which the world grew pale,
To paint a moral, or adorn a tale.

Vanity of Human Wiſhes.

Sweden. exacted of him. The king, looking at him ſternly, anſwered, "Think of what you are doing." "I do, replied Cederſtrom; and what I think to-day, I ſhall think to-morrow: and were I capable of breaking the oath by which I am already bound to the ſtates, I ſhould be likewiſe capable of breaking that your majeſty now requeſts me to take."

The king then ordered Cederſtrom to deliver up his ſword, and put him in arreſt.

His majeſty, however, apprehenſive of the impreſſion which the proper and reſolute conduct of Cederſtrom might make upon the minds of the other officers, ſhortly afterwards ſoftened his tone of voice; and again addreſſing himſelf to Cederſtrom, told him, that as a proof of the opinion he entertained of him, and the confidence he placed in him, he would return him his ſword without inſiſting upon his taking the oath, and would only deſire his attendance that day. Cederſtrom continued firm; he anſwered, that his majeſty could place no confidence in him that day, and that he begged to be excuſed from the ſervice.

While the king was ſhut up with the officers, Senator Ralling, to whom the command of the troops in the town had been given two days before, came to the door of the guard-room, and was told that he could not be admitted. The ſenator inſiſted upon being preſent at the diſtribution of the orders, and ſent to the king to deſire it; but was anſwered, he muſt go to the ſenate, where his majeſty would ſpeak to him.

The officers then received their orders from the king; the firſt of which was, that the two regiments of guards and of artillery ſhould be immediately aſſembled, and that a detachment of 36 grenadiers ſhould be poſted at the door of the council-chamber to prevent any of the ſenators from coming out.

But before the orders could be carried into execution, it was neceſſary that the king ſhould addreſs himſelf to the ſoldiers; men wholly unacquainted with his deſigns, and accuſtomed to pay obedience only to the orders of the ſenate, whom they had been taught to hold in the higheſt reverence.

240 The king gains over the ſoldiers. As his majeſty, followed by the officers, was advancing from the guard room to the parade for this purpoſe, ſome of them more cautious, or perhaps more timid than the reſt, became, on a ſhort reflection, apprehenſive of the conſequences of the meaſure in which they were engaged: they began to expreſs their fears to the king, that unleſs ſome perſons of greater weight and influence than themſelves were to take a part in the ſame cauſe, he could hardly hope to ſucceed in his enterpriſe. The king ſtopped a while, and appeared to heſitate. A ſerjeant of the guards overheard their diſcourſe, and cried aloud,—"It ſhall ſucceed—Long live Guſtavus!" His majeſty immediately ſaid, "Then I will venture;"—and ſtepping forward to the ſoldiers, he addreſſed them in terms nearly ſimilar to thoſe he had made uſe of to the officers, and with the ſame ſucceſs. They anſwered him with loud acclamations: one voice only ſaid, No; but it was not attended to.

In the mean time ſome of the king's emiſſaries had ſpread a report about the town that the king was arreſted. This drew the populace to the palace in great numbers, where they arrived as his majeſty had concluded his harangue to the guards. They teſtified by reiterated ſhouts their joy at ſeeing him ſafe; a joy which promiſed the happieſt concluſion to the buſineſs of the day.

The ſenators were now immediately ſecured. They had from the window of the council chamber beheld what was going forward on the parade before the palace; and, at a loſs to know the meaning of the ſhouts they heard, were coming down to inquire into the cauſe of them, when 30 grenadiers, with their bayonets fixed, informed them it was his majeſty's pleaſure they ſhould continue where they were. They began to talk in a high tone, but were anſwered only by having the door ſhut and locked upon them. Sweden.

241 Secures the ſenators, and becomes maſter of the whole power in the kingdom.

The moment the ſecret committee heard that the ſenate was arreſted, they ſeparated of themſelves, each individual providing for his own ſafety. The king then mounting his horſe, followed by his officers with their ſwords drawn, a large body of ſoldiers, and numbers of the populace, went to the other quarters of the town where the ſoldiers he had ordered to be aſſembled were poſted. He found them all equally willing to ſupport his cauſe, and to take an oath of fidelity to him. As he paſſed through the ſtreets, he declared to the people, that he only meant to defend them, and ſave his country; and that if they would not confide in him, he would lay down his ſceptre, and ſurrender up his kingdom. So much was the king beloved, that the people (ſome of whom even fell down upon their knees) with tears in their eyes implored his majeſty not to abandon them.

242 Summons an aſſembly of the ſtates; The king proceeded in his courſe, and in leſs than an hour made himſelf maſter of all the military force in Stockholm. In the mean time the heralds, by proclamation in the ſeveral quarters of the city, ſummoned an aſſembly of the States for the enſuing morning, and declared all members traitors to their country who ſhould not appear. Thither his majeſty repaired in all the pomp of royalty, ſurrounded by his guards, and holding in his hand the ſilver ſceptre of Guſtavus Adolphus. In a very forcible ſpeech, he lamented the unhappy ſtate to which the country was reduced by the conduct of a party ready to ſacrifice every thing to its ambition, and reproached the ſtates with adapting their actions to the views of foreign courts, from which they received the wages of perfidy. "If any one dare contradict this, let him riſe and ſpeak."—Conviction, or fear, kept the aſſembly ſilent, and the ſecretary read the new form of government, which the king ſubmitted to the approbation of the ſtates. It conſiſted of fifty-ſeven articles; of which the following five were the chief.

243 Which accepts a new form of government. 1. The king has the entire power of convoking and diſſolving the aſſembly of the ſtates as often as he thinks proper. 2. His majeſty alone has the command of the army, fleet, and finances, and the diſpoſal of all offices civil and military. 3. In caſe of an invaſion, or of any preſſing neceſſity, the king may impoſe taxes, without waiting for the aſſembly of the ſtates. 4. The diet can deliberate upon no other ſubjects than thoſe propoſed by the king. 5. The king ſhall not carry on an offenſive war without the conſent of the ſtates. When all the articles were gone through, the king demanded if the ſtates approved of them, and was anſwered by a general acclamation. He then diſmiſſed all the ſenators from their employments, adding, that in a few days he would appoint others; and concluded this extraordinary ſcene by drawing out of his pocket a ſmall book of pſalms, from which, after taking off the crown, he gave out Te Deum. All the members very devoutly added their voices to his, and the hall reſounded with thankſgivings, which it is to be feared never roſe to heaven, if ſincerity was neceſſary to their paſſport.

244 The king makes a good uſe of his power. The power thus obtained the king employed for the good of his ſubjects. He took care that the law ſhould be adminiſtered with impartiality to the richeſt noble and the pooreſt peaſant, making a ſevere example of ſuch judges as were proved to have made juſtice venal. He gave particular attention and encouragement to commerce, was a

Sweden.

liberal and enlightened patron of learning and ſcience, and laboured ſtrenuouſly to introduce into his kingdom the moſt valuable improvements in agriculture that had been made in foreign countries.

245 Reforms the army and navy.

But while thus active in promoting the arts of peace, he was not inattentive to thoſe of war. The fleet, which he found decayed and feeble, he in a few years reſtored to a reſpectable footing, and, beſides changing the regulations of the navy, he raiſed a new corps of ſailors, and formed them to the ſervice by continual exerciſe. The army, which, as well as the navy, had been neglected during the ariſtocracy, was next to be reformed. The king began by giving cloaks, tents, and new arms to all the regiments. Afterwards, under the direction of Field Marſhal Count de Heſſenſtein, a new exerciſe was introduced, and ſeveral camps were formed, in which the ſoldiery were manœuvred by the king himſelf. The ſale of military offices, which had been permitted for many years, was entirely ſuppreſſed; and the king provided not only for the re-eſtabliſhment of diſcipline and good order in the army, but for the future welfare of the individuals which compoſed it. Theſe warlike preparations were neceſſary to a plan which he had formed for entirely aboliſhing the power of the ariſtocracy, and freeing Sweden from the factions which had long been formed in it by the court of St Peterſburg. The change which he had introduced into the conſtitution was very inimical to the intrigues of that court: and the Ruſſian ambaſſador exerted himſelf openly to bring about a rupture between the king and the diſcontented nobles. Guſtavus ordered him to quit the kingdom in eight days, and immediately prepared for war with Ruſſia. To this apparently raſh enterpriſe he was incited by the Ottoman Porte, at that time unable to oppoſe the armies of the two empires; and his own ambition, together with the internal ſtate of his kingdom, powerfully concurred to make him lend every aſſiſtance to his ancient ally. It is needleſs for us to enter into a detail of the particulars of that war, which, as well as the aſtoniſhing activity and military ſkill diſplayed by the Swediſh monarch, are freſh in the memory of all our readers. Suffice it to ſay, that neither Guſtavus Adolphus nor Charles XII. gave greater proofs of undaunted courage and military conduct in their long and bloody wars than were given by Guſtavus the III. from the end of the year 1787 to 1790, when peace was reſtored between the courts of St Peterſburg and Stockholm. Had his army remained faithful, it ſeems in a high degree probable that he would have penetrated to the metropolis of the Ruſſian empire in the firſt campaign; and when he was deſerted by that army, and his councils diſtracted by new hoſtilities commenced againſt him by the Danes, the vigour and reſources of his mind never forſook him. When the court of Copenhagen was compelled, by the means of England and Pruſſia, to withdraw its troops from the territories of Sweden, the king attacked Ruſſia with ſuch vigour both by ſea and land, diſplayed ſuch addreſs in retrieving his affairs when apparently reduced to the laſt extremity, and renewed his attacks with ſuch pertinacious courage, that the empreſs lowered the haughtineſs of her tone, and was glad to treat with Guſtavus as an equal and independent ſovereign.

246 His conduct in the war with Ruſſia.

247 Not an arbitrary deſpot, tho' in ſome actions artful and inſidious.

The king of Sweden was now at liberty to cheriſh again the arts of peace, and to humble the haughty ſpirit of the nobles. For his attempting to deprive thoſe men of that power which they had for many years employed againſt their country, he has been held up to the world as a deſpot who trampled on the liberties of his ſubjects; as a man without ſincerity of patriotiſm; and, in one word, as a perjured tyrant, who overthrew the conſtitution which he had ſworn to maintain. That he was not troubled with a ſcrupulous conſcience, when ſo artfully conducting the revolution of 1772, muſt be acknowledged; nor can it be denied, that in his treaties with other powers be ſometimes endeavoured to overreach them: but if the neceſſities of ſtate could in any caſe be an apology for falſehood, they would ſufficiently apologize for the duplicity of Guſtavus. He was engaged in the arduous enterpriſe of freeing his ſubjects from an ariſtocratic tyranny ſupported by a foreign power the moſt formidable in the north; he had been forced into a war with that power, and, as there is reaſon to believe, promiſed aſſiſtance which he never received, and it cannot excite wonder nor great indignation, that, as ſoon as he could make an honourable peace, he embraced the opportunity without paying much regard to the intereſts of an alliance, which tamely looked on while he was ſtruggling with difficulties apparently unſurmountable. That the revolution which he effected in his own country was calculated to promote the general good of the people, is unqueſtionable; and to gain ſuch an object he might ſurely reſtore the crown to its ancient ſplendor, without bringing upon his government the odious epithet of *deſpotiſm*.

Sweden.

248 The revolution beneficial.

249 Produces a conſpiracy againſt the king's life.

The nobles, however, continued diſcontented, and a conſpiracy was planned againſt Guſtavus under his own roof. He had entered into the alliance that was formed againſt the revolutionary government of France; and to raiſe an army which he was to lead in perſon to co-operate with the emperor and the king of Pruſſia, he was obliged to negotiate large loans, and to impoſe upon his ſubjects heavy taxes. The nobles took advantage of that circumſtance to prejudice the minds of many of the people againſt the ſovereign who had laboured ſo long for their real good. On the 16th of March 1792 he received an anonymous letter, warning him of his immediate danger from a plot that was laid to take away his life, requeſting him to remain at home, and avoid balls for a year; and aſſuring him that, if he ſhould go to the maſquerade for which he was preparing, he would be aſſaſſinated that very night. The king read the note with contempt, and at a late hour entered the ball room. After ſome time he ſat down in a box with the compte D'Eſſen, and obſerved that he was not deceived in his contempt for the letter, ſince had there been any deſign againſt his life, no time could be more favourable than that moment. He then mingled, without apprehenſion, among the crowd; and juſt as he was preparing to retire in company with the Pruſſian ambaſſador, he was ſurrounded by ſeveral perſons in maſks, one of whom fired a piſtol at the back of the king, and lodged the contents in his body. A ſcene of dreadful confuſion immediately enſued. The conſpirators, amidſt the general tumult and alarm, had time to retire to other parts of the room: but one of them had previouſly dropped his piſtols and a dagger cloſe by the wounded king. A general order was given to all the company to unmaſk, and the doors were immediately cloſed; but no perſon appeared with any particular diſtinguiſhing marks of guilt. The king was immediately conveyed to his apartment; and the ſurgeon, after extracting a ball and ſome ſlugs, gave favourable hopes of his majeſty's recovery.

250 The king dangerouſly wounded.

Suſpicions immediately fell upon ſuch of the nobles as had been notorious for their oppoſition to the meaſures of the court. The anonymous letter was traced up to colonel Liljehorn, major in the king's guards, and he was immediately apprehended. But the moſt ſucceſsful clue that ſeemed to offer was in conſequence of the weapons which had fallen from the aſſaſſin. An order was iſſued, directing all the armourers, gunſmiths, and cutlers in Stockholm, to give every information in their power to the officers of juſtice concerning the weapons. A gunſmith who had repaired the piſtols readily recognized them to be the ſame which

Sweden. he had repeated ſome time ſince for a nobleman of the name of Ankarſtrom, a captain in the army; and the cutler who had made the dagger referred at once to the ſame perſon.

251 The king dies. The king languiſhed from the 17th to the 29th of March. At firſt the reports of his medical attendants were favourable; but on the 28th a mortification was found to have taken place, which terminated his exiſtence in a few hours. On opening his body, a ſquare piece of lead and two ruſty nails were found unextracted within the ribs.

252 His behaviour before his death. During his illneſs, and particularly after he was made acquainted with the certainty of his approaching diſſolution, Guſtavus continued to diſplay that unſhaken courage which he had manifeſted on every occaſion during his life. A few hours before his deceaſe he made ſome alterations in the arrangement of public affairs. He had before, by his will, appointed a council of regency; but convinced, by recent experience, how little he could depend on the attachment of his nobles and being alſo aware of the neceſſity of a ſtrong government in difficult times, he appointed his brother, the duke of Sudermania, ſole regent, till his ſon, who was then about fourteen, ſhould have attained the age of eighteen years. His laſt words were a declaration of pardon to the conſpirators againſt his life. The actual murderer alone was excepted; and he was excepted only at the ſtrong inſtance of the regent, and thoſe who ſurrounded his majeſty in his dying moments. Immediately on the death of the king, the young prince was proclaimed by the title of Guſtavus IV.

253 Puniſhment of the conſpirators. Ankarſtrom was no ſooner apprehended, than he confeſſed with an air of triumph, that he was the perſon "who had endeavoured to liberate his country from a monſter and a tyrant." Suſpicions at the ſame time fell on the counts Horn and Ribbing, baron Pechlin, baron Ehrenſvard, baron Hartmanſdorf, Von Engerſtrom the royal ſecretary, and others; and theſe ſuſpicions were confirmed by the confeſſion of Ankarſtrom. After a very fair and ample trial, this man was condemned to be publicly and ſeverely whipped on three ſucceſſive days, his right hand and his head to be cut off, and his body impaled; which ſentence he ſuffered not till the 17th of May, long after the death of the king. —His property was given to his children, who, however, were compelled to change their name.

The counts Horn and Ribbing were condemned to loſe their right hands, and to be decapitated. Col. Liljehorn and lieutenant Ehrenſvard were alſo to be beheaded.—All theſe conſpirators were degraded from the rank of nobles, and their property declared to be confiſcated. Major Hartmanſdorf was to forfeit his rank in the army and to be impriſoned for one year. Engerſtrom was to ſuffer perpetual impriſonment, and baron Pechlin and ſecretary Lilleſtrahle to be impriſoned during pleaſure. Four others, accuſed of being concerned in the conſpiracy, were pardoned, and ſome were acquitted.

254 Diviſion of Sweden. The kingdom of the Sweden, in its preſent ſtate, is divided into the following provinces: 1. Sweden Proper. 2. Gothland. 3. Finland. 4. Swediſh Lapland. And, 5. The Swediſh iſlands. Great abatements muſt be made for the lakes and unimproved parts of Sweden, which are ſo extenſive that the habitable part is confined to narrow bounds.

255 Climate, ſoil, &c. The face of Sweden is pretty ſimilar to thoſe of its neighbouring countries; only it has the advantage of navigable rivers.

The ſame may be ſaid with regard to its climate, ſoil, &c. Summer burſts from winter; and vegetation is more ſpeedy than in ſouthern climates. Stoves and warm furs mitigate the cold of winter, which is ſo intenſe, that the noſes and extremities of the inhabitants are ſometimes mortified. The Swedes, ſince the days of Charles XII. have been at incredible pains to correct the native barrenneſs of their country, by erecting colleges of agriculture, and in ſome places with great ſucceſs. The ſoil is much the ſame with that of Denmark and ſome parts of Norway, generally very bad, but in ſome valleys ſurpriſingly fertile. The Swedes, till of late years, had not induſtry ſufficient to remedy the one, nor improve the other. The peaſants now follow the agriculture of France and England; and ſome late accounts ſay, that they rear almoſt as much grain as maintains the natives. Gothland produces wheat, rye, barley, oats, peaſe, and beans; and in caſe of deficiency, the people are ſupplied from Livonia and the Baltic provinces. In ſummer, the fields are verdant, and covered with flowers; and produce ſtrawberries, raſpberries, currants, and other ſmall fruits. The common people know, as yet, little of the cultivation of apricots, peaches, nectarines, pine-apples, and the like high-flavoured fruits; but melons are brought to great perfection in dry ſeaſons.

Sweden produces cryſtals, amethyſts, topazes, prophyry, lapis lazuli, agate, cornelian, marble, and other foſſils. The chief wealth of the country, however, ariſes from her mines of ſilver, copper, lead and iron. The laſt-mentioned metal employs no fewer than 450 forges, hammering-mills, and ſmelting-houſes. A kind of a gold mine has likewiſe been diſcovered in Sweden; but ſo inconſiderable, that from the year 1741 to 1747, it produced only 2398 gold ducats, each valued at 9s. 4d. ſterling. The firſt gallery of one ſilver mine is 100 fathoms below the ſurface of the earth; the roof is ſupported by prodigious oaken beams, and from thence the miners deſcend about 40 fathoms to the loweſt vein. This mine is ſaid to produce 20,000 crowns a-year. The product of the copper mines is uncertain; but the whole is loaded with vaſt taxes and reductions of the government, which has no other reſources for the exigences of ſtate. Thoſe ſubterraneous manſions are aſtoniſhingly ſpacious, and at the ſame time commodious for their inhabitants, ſo that they ſeem to form a hidden world. The water-falls in Sweden afford excellent conveniency for turning mills for forges; and for ſome years the exports of iron from Sweden brought in 300,000l. ſterling. Dr Buſching thinks that they conſtituted two-thirds of the national revenue. It muſt, however, be obſerved, that the extortions of the Swediſh government, and the importation of American bar-iron into Europe, and ſome other cauſes, have greatly diminiſhed this manufacture in Sweden; ſo that the Swedes very ſoon muſt apply themſelves to other branches of trade and improvements, eſpecially in agriculture.

256 Animals. The animals differ little from thoſe of Norway and Denmark, only the Swediſh horſe are known to be more ſerviceable in war than the German. The fiſhes found in the rivers and lakes of Sweden are the ſame which thoſe in other northern countries, and taken in ſuch quantities, that their pikes (particularly) are ſalted and pickled for exportation. The train-oil of the ſeals, taken in the gulph of Finland, is a conſiderable article of exportation.

257 Character of the Swedes. There is a great diverſity of characters among the people of Sweden; and what is peculiarly remarkable among them, they have been known to have different characters in different ages. At preſent, their peaſants ſeem to be a heavy plodding race of men, ſtrong and hardy; but without any other ambition than that of ſubſiſting themſelves and their families as well as they can: they are honeſt, ſimple, and hoſpitable; and the mercantile claſſes are much of the ſame caſt; but great application and perſeverance is diſcovered among them all. One could form no idea that the modern Swedes are the deſcendants of thoſe who, under Guſtavus Adolphus and Charles XII. carried terror in their

Sweden. names through the moſt diſtant countries, and ſhook the foundations of the greateſt empires. The principal nobility and gentry of Sweden are naturally brave, polite, and hoſpitable; they have high and warm notions of honour, and are jealous of their national intereſts. The dreſs of the common people is almoſt the ſame with that of Denmark: the better ſort are infatuated with French modes and faſhion. The common diverſions of the Swedes are, ſkating, running races in ſledges, and ſailing in yachts upon the ice. They are not fond of marrying their daughters when young, as they have little to ſpare in their own life-time. The women go to plough, threſh out the corn, row upon the water, ſerve the brick layers, carry burdens, and do all the
258 common drudgeries in huſbandry.

Religion. Chriſtianity was introduced here in the 9th century. Their religion is Lutheran, which was propagated among them by Guſtavus Vaſa, about the year 1523, as we have already related. The Swedes are ſurpriſingly uniform and unremitting in religious matters; and have ſuch an averſion to Popery, that caſtration is the fate of every Roman Catholic prieſt diſcovered in their country. The archbiſhop of Upſal has a revenue of about 400 l. a year; and has under him thirteen ſuffragans, beſides ſuperintendants, with moderate ſtipends. No clergyman has the leaſt direction in the affairs of ſtate; but their morals, and the ſanctity of their lives, endear them ſo much to the people, that the government would repent making them its enemies. Their churches are neat, and often ornamented. A body of eccleſiaſtical laws and canons direct their religious economy. A converſion to Popery, or a long continuance under excommunication, which cannot paſs without the king's per-
259 miſſion, is puniſhed by impriſonment and exile.

Language. The Swediſh language is a dialect of the Teutonic, and reſembles that of Denmark. The Swediſh nobility and gentry are, in general, more converſant in polite literature than thoſe of many other more flouriſhing ſtates. They have of late exhibited ſome noble ſpecimens of their munificence for the improvement of literature and ſcience, particularly natural hiſtory.

260 Manufactures, &c. The Swediſh commonalty ſubſiſts by agriculture, mining, grazing, hunting, and fiſhing. Their materials for traffic are the bulky and uſeful commodities of maſts, beams, and other ſorts of timber for ſhipping; tar, pitch, bark of trees, potaſh, wooden utenſils, hides, flax, hemp, peltry, furs, copper, lead, iron, cordage, and fiſh.

Even the manufacturing of iron was introduced into Sweden ſo late as the 16th century; for till that time they ſold their own crude ore to the Hanſe-towns, and bought it back again manufactured into utenſils. About the middle of the 17th century, by the aſſiſtance of the Dutch and Flemings, they ſet up ſome manufactures of glaſs, ſtarch, tin, woollen, ſilk, ſoap, leather-dreſſing, and ſaw-mills. Bookſelling was at that time a trade unknown in Sweden. They have ſince had ſugar-baking, tobacco-plantations, and manufactures of ſail-cloth, cotton, fuſtian, and other ſtuffs; alſo of linen, alum, brimſtone, paper-mills, and gunpowder-mills. Vaſt quantities of copper, braſs, ſteel, and iron, are now wrought in Sweden, dug from mines, ſome of them more than 1100 feet deep. The iron mine of Dannemora, which is much the moſt profitable of any of thoſe with which every part of Sweden abounds, is ſaid to yield 60lb. of metal in a 100lb. of ore, and the others about 30lb. The iron extracted from this is known in Europe under the name of *Oregrund*; which name is derived from a ſea-port on the Baltic. A large portion of it is employed by different nations for making the beſt ſteel. The mine was diſcovered in 1470. The unwrought ore was firſt ſold to the merchants of Lubeck. It was not until the reign of Guſtavus Vaſa that the Swedes worked it themſelves. It is aſſerted, Sweden. that the mine of Dannemora yields about 40,000 ſtones of bar-iron *per* year, which is ſuppoſed to be one tenth part of the quantity which all the iron-mines of Sweden produce. Of this product, amounting to 400,000 ſtones, 300,000 are annually exported; the remainder is manufactured at home. It is calculated that no leſs than 25,600 men are employed in mining, and the branches immediately connected with it, *viz.* 4000 for breaking the rocks, either by exploſion or manual labour; 10,000 to hew timber and burn it into charcoal; 2000 are employed in ſmelting; 1800 in tranſporting the metal from the furnaces to the forges; 600 in tranſporting ſand, fuel, &c. 4000 for tranſporting the charcoal, and 2400 at the forges. They have alſo foundaries for cannon, forgeries for fire-arms and anchors, armories, wire and flatting-mills, mills alſo for fulling, and for boring and ſtamping: and of late they have built many ſhips for ſale.

There are likewiſe in Sweden ſome ſilver mines, of which that of *Salha*, or *Salhberg*, is the richeſt as well as the moſt ancient. It exiſted ſo early as 1188, and, during the whole of the 14th century, it yielded 24,000 marks of ſilver *per annum*. In the 15th century the quantity was diminiſhed to 20,000. In the reign of Charles X. it gave only 2000, and it furniſhes at preſent ſtill leſs, the ore yielding only one ounce of pure metal *per* quintal. The chief gallery where the pureſt ſilver was obtained having fallen in, is not yet cleared, notwithſtanding their inceſſant labour. They are alſo digging pits in a perpendicular direction, in order to arrive at the principal vein, which extends itſelf from the north to the ſouth-eaſt. Formerly lead employed in ſeparating the metal was imported from England; but the mine furniſhes at preſent a ſufficient quantity for the purpoſe.

Certain towns in Sweden, being 24 in number, are called *Staple-towns*, where the merchants are allowed to import and export commodities in their own ſhips. Thoſe towns which have no foreign commerce, though lying near the ſea, are called *land-towns*. A third kind are termed *mine-towns*, as belonging to mine-diſtricts. The Swedes, about the year 1752, had greatly increaſed their exports, and diminiſhed their imports, moſt part of which arrive or are ſent off in Swediſh ſhips; the Swedes having now a kind of navigation act like that of the Engliſh. Thoſe promiſing appearances were, however, blaſted by the madneſs and jealouſies of the Swediſh government; and the people ſo oppreſſed with taxes, that ſome important revolution was daily expected in that kingdom.

261 Revenues. The revenue of Sweden, ſince the unfortunate wars of Charles XII. has been greatly reduced. Her gold and ſilver ſpecies, in the reign of Ad. Frederic, aroſe chiefly from the king's German dominions. Formerly, the crown-lands, poll-money, tithes, mines, and other articles, are ſaid to have produced a million ſterling. The payments that are made in copper, which is here the chief medium of commerce, is extremely inconvenient; ſome of thoſe pieces being as large as tiles; and a cart or wheelbarrow is often required to carry home a moderate ſum. The Swedes, however, have gold ducats, and eight-mark pieces of ſilver, valued each at 5s. 2d. (ſterling) and the ſubſidies paid them by France help to increaſe their currency.

262 Military ſtrength. No country in the world has produced greater heroes or braver troops than the Swedes; and yet they cannot be ſaid to maintain a ſtanding army, as their forces conſiſt of a regulated militia. The cavalry is clothed, armed, and maintained, by a rate raiſed upon the nobility and gentry, according to their eſtates; and the infantry by the peaſants. Each province is obliged to find its proportion of ſoldiers, according

Sweden-borg.

according to the number of farms it contains; every farm of 60l. or 70l. *per annum* is charged with a foot-soldier, furniſhing him with diet, lodging, and ordinary clothes, and about 20s. a-year in money; or elſe a little wooden houſe is built him by the farmer, who allows him hay and paſturage for a cow, and ploughs and ſows land enough to ſupply him with bread. When embodied, they are ſubject to military law, but otherwiſe to the civil law of the country. It may therefore literally be ſaid, that every Swediſh ſoldier has a property in the country he defends. This national army is thought to amount to above 50,000 men. Sweden formerly could have fitted out 40 ſhips of the line.

SWEDENBORG (Emanuel), was born at Stockholm on the 29th of January 1689. His father was biſhop of Weſt-Gothia; member of a ſociety for the propagation of the Goſpel, formed on the plan of that of England; and preſident of the Swediſh church in Pennſylvania and London. To this laſt office he was appointed by Charles XII. who ſeems to have had a great regard for the biſhop, and to have continued that regard to his ſon.

Of the courſe of young Swedenborg's education we have procured no account; but from the character of the father, it may be ſuppoſed to have been pious; and by his appearing with reputation as an author, when but 20 years of age, it is proved to have been ſucceſsful. His firſt work was publiſhed in 1709; and the year following he ſent into the world a collection of pieces on different ſubjects, in Latin verſe, under the title of *Ludus Heliconius, ſive Carmina Miſcellanea quæ variis in locis cecinit.* The ſame year he began his travels, firſt into England, and afterwards into Holland, France, and Germany; and returning to Stockholm in 1714, he was two years afterwards appointed to the office of aſſeſſor in the Metallic College by Charles XII. who honoured him with frequent converſations, and beſtowed upon him a large ſhare of his favour. At this period of his life Swedenborg devoted his attention principally to phyſic and mathematical ſtudies; and in 1718 he accompanied the king to the ſiege Frederickſhall, where he gave an eminent proof that he had not ſtudied in vain. Charles could not ſend his heavy artillery to Frederickſhall from the badneſs of the roads, which were then rendered much worſe than uſual by being deeply covered with ſnow. In this extremity Swedenborg brought the ſciences to the aid of valour. By the help of proper inſtruments he cut through the mountains, and raiſed the valleys which ſeparated Sweden from Norway, and then ſent to his maſter two galleys, five large boats, and a ſloop, loaded with battering pieces, to be employed in the ſiege. The length of this canal was about two miles and a half. The execution of this great work, however, did not occupy all his time. In 1716 he had begun to publiſh eſſays and obſervations on the mathematical and phyſical ſciences, under the title of *Dædalus Hyperboreus;* and he found leiſure during the ſiege to complete his intended collection, and alſo in the ſame year to publiſh an introduction to algebra, under the whimſical title of *The Art of the Rules.*

At the ſiege of Frederickſhall he loſt his patron Charles; but found another in Ulrica Eleonora, the ſiſter and ſucceſſor of that hero, by whom in 1719 he was ennobled, and took of courſe his ſeat among the ſenators of the equeſtrian order in the triennial aſſemblies of the ſtates. His promotion did not leſſen his ardour for the ſciences; for he publiſhed in the ſame year *A Method to fix the Value of Money, and to determine the Swediſh Meaſures in ſuch a Way as to ſuppreſs all the Fractions and facilitate the Calculations.* About the ſame time he gave the public a treatiſe on *the Poſition and Courſe of the Planets;* with another on *the Heights of the Tides, and Flux and Reflux of the Sea;* which, from information gathered in different parts of Sweden, appeared to have been greater formerly than when he wrote.

Swedenborg.

As Swedenborg continued, under the new ſovereign, to hold the office of aſſeſſor to the Metallic College, he thought it neceſſary, for the diſcharge of his duty, to make a ſecond journey into foreign countries, that he might himſelf examine their mines, particularly thoſe of Saxony and Harts. During theſe travels, which were undertaken for the improvement of the manufactures of his native country, he printed at Amſterdam, 1. *Prodromus principiorum Naturalium, ſive novorum tentaminum, Chemiam et Phyſicam experimentalem geometrice explicandi.* 2. *Nova obſervata & inventa circa Ferrum & Ignem, præcipue naturam Ignis Elementarum, una cum nova Camini inventione.* 3. *Methodus nova inveniendi Longitudines locorum terræ marique ope Lunæ.* 4. *Modus conſtruendi receptacula navalia, vulgo en Suedois, Dockybynadder.* 5. *Nova conſtructio aggeris aquatici.* 6. *Modus explorandi virtutes Navigiorum.* And at Leipſic and Hamburg, 7. *Miſcellanea obſervata circa res naturales, præſertim Mineralia, Ignem, & Montium ſtrata.*

European Magazine, 1785. July.

This journey was made, and theſe tracts publiſhed, in the compaſs of a year and a half; and perhaps there has not been another man, Linnæus excepted, who has done ſo much in ſo ſhort a time. After his return in 1722, Swedenborg divided his time ſo equally between the duties of his office and his private ſtudies, that in 1733 he finiſhed his grand work, entitled *Opera Philoſophica & Mineralia*, and had it printed under his own direction in 1734, part at Dreſden and part at Leipſic; in which year he alſo went to inſpect the mines of Auſtria and Hungary. This work is divided into three volumes folio; the title of the firſt is *Principia rerum Naturalium ſive novorum tentaminum, Phænomena Mundi elementaris philoſophice explicandi.* The ſecond, *Regnum ſubterraneum ſive Minerale de Ferro;* and the third, *Regnum ſubterraneum ſive Minerale de Cupro, & Orichalco;* all of them written with great ſtrength of judgment, and ornamented with plates, to facilitate the comprehenſion of the text.

In the year 1729 he was enrolled among the members of the Society of Sciences at Upſal, and was, probably about the ſame time, made a Fellow of the Royal Academy of Sciences at Stockholm; nor were ſtrangers leſs willing than his own countrymen to acknowledge the greatneſs of his merit. Wolfius, with many other learned foreigners, were eager to court his correſpondence. The Academy of St Peterſburg ſent him, on the 17th of December 1734, a diploma of aſſociation as a correſpondent member; and ſoon afterwards the editors of the *Acta Eruditorum* at Leipſic found in his works a valuable ſupplement to their own collection.

By many perſons the approbation of learned academies would have been highly valued; but by Baron Swedenborg it was conſidered as of very little importance. "Whatever of worldly honour and advantage may appear to be in the things before mentioned, I hold them (ſays he) but as matters of low eſtimation, when compared to the honour of that holy office to which the Lord himſelf hath called me, who was graciouſly pleaſed to manifeſt himſelf to me, his unworthy ſervant, in a perſonal appearance, in the year 1743, to open in me a ſight of the ſpiritual world, and to enable me to converſe with ſpirits and angels; and this privilege has continued with me to this day. From that time I began to print and publiſh various unknown *Arcana*, which have been either ſeen by me or revealed to me, concerning heaven and hell, the ſtate of men after death, the true wor-

ſhip

Swedenborg.

ſhip of God, the ſpiritual ſenſe of the Scriptures, and many other important truths tending to ſalvation and true wiſdom."

We ſhall not affront the underſtandings of our readers by making upon this account of the Baron's *call* ſuch reflections as every perſon of a ſound mind will make for himſelf; but it is rather remarkable, that a man who had devoted the better part of his life to the ſtudy of ſuch ſciences as generally fortify the mind againſt the deluſions of fanaticiſm, and who had even excelled in theſe ſciences, ſhould have fallen into ſuch a reverie as this. After this extraordinary call, the Baron dedicated himſelf wholly to the great work which, he ſuppoſed, was aſſigned him, ſtudying diligently the word of God, and from time to time publiſhing to his fellow-creatures ſuch important information as was made known to him concerning another world. Among his various diſcoveries concerning the ſpiritual world, one is, that it exiſts not in ſpace. "Of this (ſays he) I was convinced, becauſe I could there ſee Africans and Indians very near me, although they are ſo many miles diſtant here on earth; nay, that I could be made preſent with the inhabitants of other planets in our ſyſtem, and alſo with the inhabitants of planets that are in other worlds, and revolve about other ſuns. By virtue of ſuch preſence (*i. e.* without real ſpace), not of place, I have converſed with apoſtles, departed popes, emperors, and kings; with the late reformers of the church, Luther, Calvin, and Melancthon, and with others from diſtant countries."

Swedenborg's Univerſal Theology, vol. i. p. 87.

Notwithſtanding the want of ſpace in the ſpiritual world, he tells us, "that after death a man is ſo little changed that he even does not know but he is living in the preſent world; that he eats and drinks, and even enjoys conjugal delight as in this world; that the reſemblance between the two worlds is ſo great, that in the ſpiritual world there are cities, with palaces and houſes, and alſo writings and books, employments and merchandizes; that there is gold, ſilver, and precious ſtones there. In a word (he ſays), there is in the ſpiritual world all and every thing that there is in the natural world, but that in heaven ſuch things are in an infinitely more perfect ſtate."

Ibid. N° 734.

Such was his zeal in the propagation of theſe whimſical and ſometimes ſenſual doctrines, that he frequently left his native country to viſit diſtant cities, particularly London and Amſterdam, where all his theological works were printed at a great expence, and with little proſpect or probability of a reimburſement. "Wherever he reſided when on his travels, he was (ſays one of his admirers) a mere ſolitary, and almoſt inacceſſible, though in his own country of a free and open behaviour. He affected no honour, but declined it; purſued no worldly intereſt, but ſpent his time in travelling and printing, in order to communicate inſtruction and benefit to mankind. He had nothing of the preciſe in his manner, nothing of melancholy in his temper, and nothing in the leaſt bordering on enthuſiaſm in his converſation or writings." This is too much. We believe he was an inoffenſive viſionary; of his converſation we cannot judge; but the ſpecimens that we have given of his writings are frantic enthuſiaſm. He died at London, March 29th, in the year 1772; and after lying in ſtate, his remains were depoſited in a vault at the Swediſh church, near Radcliff-Highway.

Short Account, &c. p. 11. and Harley's Preface to the Treatiſe on Influx.

Though Baron Swedenborg's followers appear not to have been numerous during his life, they have increaſed ſince his death; and a ſect ſubſiſts at preſent in England which derives its origin from him, and is called *The New Jeruſalem Church*. The diſcriminating tenets of this ſect ſeem to be the following: "Holding the doctrine of one God, they maintain that this one God is no other than Jeſus Chriſt, and that he always exiſted in a human form; that for the ſake of redeeming the world, he took upon himſelf a proper human or material body, but not a human ſoul; that this redemption conſiſts in bringing the hells or evil ſpirits into ſubjection, and the heavens into order and regulation, and thereby preparing the way for a new ſpiritual church; that without ſuch redemption no man could be ſaved, nor could the angels retain their ſtate of integrity; that their redemption was effected by means of trials, temptations, or conflicts with evil ſpirits; and that the laſt of them, by which Chriſt glorified his humanity, perfecting the union of his divine with his human nature, was the paſſion of the croſs. Though they maintain that there is but one God, and one divine perſon, they hold that in this perſon there is a real Trinity; conſiſting of the divinity, the humanity, and the operation of them both in the Lord Jeſus; a Trinity which did not exiſt from all eternity, but commenced at the incarnation. They believe that the Scriptures are to be interpreted not only in a literal but in a ſpiritual ſenſe, not known to the world till it was revealed to B. Swedenborg; and that this ſpiritual ſenſe extends to every part of Scripture, except the Acts of the Apoſtles. They believe that there are angels attending upon men, reſiding, as B. Swedenborg ſays, in their affections; that temptation conſiſts in a ſtruggle between good and bad angels within men; and that by this means God aſſiſts men in theſe temptations, ſince of themſelves they could do nothing. Indeed B. Swedenborg maintains, that there is an univerſal influx from God into the ſouls of men, inſpiring them eſpecially with the belief of the divine unity. This efflux of divine light on the ſpiritual world he compares to the efflux of the light from the ſun in the natural world.

Swedenborg || Swietenia.

Prieſtley's Letters to the New Jeruſalem Church, p. 4. &c.

"There are (ſays B. Swedenborg) two worlds, the natural and the ſpiritual, entirely diſtinct, though perfectly correſponding to each other; that at death a man enters into the ſpiritual world, when his ſoul is clothed with a body, which he terms *ſubſtantial*, in oppoſition to the preſent *material* body, which, he ſays, is never to riſe out of the grave."

SWEEP, in the ſea-language, is that part of the mould of a ſhip where ſhe begins to compaſs in the rung-heads. alſo when the hauſer is dragged along the bottom of the ſea to recover any thing that is ſunk, they called this action *ſweeping for it*.

SWEET, in the wine trade, denotes any vegetable juice, whether obtained by means of ſugar, raiſins, or other foreign or domeſtic fruit, which is added to wines with a deſign to improve them.

SWEIN-MOT. See *Forest Courts*.

SWERTIA, Marsh Gentian, in botany: A genus of plants belonging to the claſs of *pentandria*, and to the order of *digynia*; and in the natural ſyſtem ranging under the 20th order, *rotaceæ*. The corolla is wheel-ſhaped. There are nectariferous pores at the baſes of the ſegments of the corolla. The capſule is unilocular and bivalve. There are ſix ſpecies; the perennis, difformis, rotata, carinthiaca, corniculata, dichotoma. The perennis is a native of England. It is diſtinguiſhed by radical oval leaves. It flowers in Auguſt.

SWIETENIA, Mahogany, in botany: A genus of plants belonging to the claſs of *decandria*, and to the order of *monogynia*; and in the natural ſyſtem arranged under the 54th order, *Miſcellaneæ*. The calyx is quinquefid. There are five petals; the nectarium is cylindrical, ſupporting the antheræ with its mouth. The capſule is five-celled, woody, and opening at the mouth. The ſeeds are imbricated and winged. There is only one ſpecies, the mahagoni, which is a native of the warmeſt parts of America, and grows alſo

in

Swietenia, Swift. in the iſland of Cuba, Jamaica, Hiſpaniola, and the Bahama iſlands. It abounded formerly in the low lands of Jamaica, but it is now found only on high hills and places difficult of acceſs.

London Medical Journal. It thrives in moſt ſoils, but varies in texture and grain according to the nature of the ſoil. On rocks it is of a ſmaller ſize, but very hard and weighty, of a cloſe grain, and beautifully ſhaded; while the produce of the low and richer lands is obſerved to be more light and porous, of a paler colour and open grain; and that of mixed ſoils to hold a medium between both. The tree grows very tall and ſtraight, and is uſually four feet in diameter; the flowers are of a reddiſh or ſaffron colour, and the fruit of an oval form, and about the ſize of a turkey's egg.

Brown's Natural Hiſtory of Jamaica. The wood is generally hard, takes a fine poliſh, and is found to anſwer better than any other ſort in all kinds of cabinet ware. It is now univerſally eſteemed, and ſells at a good price; but it is pity that it is not cultivated in the more convenient waſte lands of Jamaica. It is a very ſtrong timber, and anſwers very well in beams, joiſts, plank, boards, and ſhingles; and has been frequently put to thoſe uſes in Jamaica in former times. It is ſaid to be uſed ſometimes in ſhip-building; a purpoſe for which it is remarkably adapted, if not too coſtly, being very durable, capable of reſiſting gun ſhots, and burying the ſhots without ſplintering.

The ſeed-veſſels are of a curious form, conſiſting of a large cone ſplitting into five parts, and diſcloſing its winged ſeeds, diſpoſed in the regular manner of thoſe of an apocynum. The ſeeds being winged, are diſperſed on the ſurface of the ground, where ſome falling into the chinks of the rocks, ſtrike root; then creep out on the ſurface of it, and

Philoſophical Tranſactions, n° 484. ſeek another chink, into which they creep and ſwell to ſuch a ſize and ſtrength, that at length the rock ſplits, and is forced to admit of the root's deeper penetration; and with this little nutriment the tree increaſes to a ſtupendous ſize in a few years.

The firſt uſe to which mahogany was applied in England, was to make a box for holding candles. Dr Gibbons, an eminent phyſician in the latter end of the laſt and beginning of the preſent century, had a brother, a Weſt India captain, who took over ſome planks of this wood as ballaſt. As the Doctor was then building him a houſe in King-ſtreet, Covent-Garden, his brother thought they might be of ſervice to him. But the carpenters, finding the wood too hard for their tools, they were laid aſide for a time as uſeleſs. Soon after, Mrs Gibbons wanting a candle-box, the Doctor called on his cabinet maker (Wollaſton in Long-Acre) to make him one of ſome wood that lay in his garden. Wollaſton alſo complained that it was too hard. The Doctor ſaid he muſt get ſtronger tools. The candle-box was made and approved; inſomuch, that the Doctor then inſiſted on having a bureau made of the ſame wood, which was accordingly done; and the fine colour, poliſh, &c. were ſo pleaſing, that he invited all his friends to come and ſee it. Among them was the ducheſs of Buckingham. Her Grace begged ſome of the ſame wood of Dr Gibbons, and employed Wollaſton to make her a bureau alſo; on which the fame of mahogany and Mr Wollaſton was much raiſed, and things of this ſort became general. This account was given by Henry Mill, Eſq; a gentleman of undoubted veracity.

SWIFT (Dr Jonathan), ſo univerſally admired as a wit and claſſical writer of the Engliſh language, was born in Dublin on November 30th 1667. His father was an attorney, and of a good family; but dying poor, the expence of his ſon's education was defrayed by his friends. At the age of ſix young Swift was ſent to the ſchool of Kilkenny, whence he was removed in his 15th year to Trinity College, Dublin. Swift.

In his academical ſtudies (ſays Dr Johnſon) he was either not diligent or not happy. The truth appears to be, that he deſpiſed them as intricate and uſeleſs. He told Mr Sheridan, his laſt biographer, that he had made many efforts, upon his entering the college, to read ſome of the old treatiſes on logic writ by Smegleſius, Keckermannus, Burgerſdicius, &c. and that he never had patience to go thro' three pages of any of them, he was ſo diſguſted at the ſtupidity of the work. When he was urged by his tutor to make himſelf maſter of this branch, then in high eſtimation, and held eſſentially neceſſary to the taking of a degree, Swift aſked him, What it was he was to learn from thoſe books? His tutor told him, The art of reaſoning. Swift ſaid, That he found no want of any ſuch art; that he could reaſon very well without it; and that, as far as he could obſerve, they who had made the greateſt proficiency in logic had, inſtead of the art of reaſoning, acquired the art of wrangling; and inſtead of clearing up obſcurities, had learned how to perplex matters that were clear enough before. For his own part, he was contented with that portion of reaſon which God had given him; and he would leave it to time and experience to ſtrengthen and direct it properly; nor would he run the riſk of having it warped or falſely biaſſed by any ſyſtem of rules laid down by ſuch ſtupid writers, of the bad effects of which he had but too many examples before his eyes in thoſe reckoned the moſt acute logicians. Accordingly, he made a firm reſolution, that he never would read any of thoſe books; which he ſo pertinaciouſly adhered to, that though his degree was refuſed him the firſt time of ſitting for it, on account of his not anſwering in that branch, he went into the hall a ſecond time as ill prepared as before; and would alſo have been ſtopped a ſecond time, on the ſame account if the intereſt of his friends, who well knew the inflexibility of his temper, had not ſtepped in, and obtained it for him; though in a manner little to his credit, as it was inſerted in the College Regiſtry, that he obtained it *ſpeciali gratia*, "by ſpecial favour;" where it remains upon record.

"He remained in the college near three years after this, not through choice, but neceſſity, little known or regarded. By ſcholars he was reckoned a blockhead; and as the lowneſs of his circumſtances would not permit him to keep company with perſons of an equal rank with himſelf, upon an equal footing, he ſcorned to take up with thoſe of a lower claſs, or to be obliged to thoſe of a higher. He lived therefore much alone, and his time was employed in purſuing his courſe of reading in hiſtory and poety, then very unfaſhionable ſtudies for an academic; or in gloomy meditations on his unhappy circumſtances. Yet, under this heavy preſſure, the force of his genius broke out, in the firſt rude draught of the Tale of a Tub, written by him at the age of 19, though communicated to nobody but his chamber fellow Mr Waryng; who, after the publication of the book, made no ſcruple to declare, that he had read the firſt ſketch of it in Swift's hand-writing when he was of that age."

In 1688, being, by the death of Godwin Swift his uncle, who had chiefly ſupported him, left without ſubſiſtence, he went to conſult his mother, who then lived at Leiceſter, about the future courſe of his life; and, by her direction, ſolicited the advice and patronage of Sir William Temple, whoſe father had lived in great friendſhip with Godwin Swift. Temple received him with great kindneſs, and was ſo much pleaſed with his converſation, that he detained him two years in his houſe, and recommended him to king William, who offered to make him a captain of horſe. This not ſuiting his diſpoſition, and Temple not having it quickly in

Swift. in his power to provide for him otherwiſe, Swift left his patron (1694) in diſcontent; having previouſly taken his maſter's degree at Oxford, by means of a teſtimonial from Dublin, in which the words of diſgrace were omitted. He was reſolved to enter into the church, where his firſt preferment was only L. 100 a-year, being the prebend of *Kilroot* in *Connor*; which ſome time afterwards, upon Sir William Temple's earneſtly inviting him back to his houſe at Moorpark, he reſigned in favour of a clergyman far advanced in years and burdened with a numerous family. For this man he ſolicited the prebend, to which he himſelf inducted him.

In 1699 Swift loſt his patron Sir William Temple, who left him a legacy in money, with the property of his manuſcripts; and, on his death-bed, obtained for him a promiſe from the king of the firſt prebend that ſhould become vacant at Weſtminſter or Canterbury. That this promiſe might not be forgotten, Swift dedicated to the king the poſthumous works with which he was entruſted, and for a while attended the court; but ſoon found his ſolicitations hopeleſs. He was then invited by the earl of Berkely to accompany him into Ireland, where, after ſuffering ſome cruel diſappointments, he obtained the livings of Laracor and Rathbeggin in the dioceſe of Meath; and ſoon afterwards invited over the unfortunate Stella, a young woman of the name of Johnſon, whoſe life he contrived to embitter, and whoſe days, though he certainly loved her, we may confidently affirm that he ſhortened by his caprice.

This lady is generally believed to have been the daughter of Sir William Temple's ſteward; but her niece, a Mrs Hearn, aſſured Mr Berkeley, the editor of a volume of letters intitled *Literary Relics*, that her father was a merchant, and the youngeſt brother of a good family in Nottinghamſhire; that her mother was the intimate friend of lady Gifford, Sir William's ſiſter; and that ſhe herſelf was educated in the family with his niece, the late Mrs Temple of Moorpark by Farnham*. This ſtory would be intitled to the fulleſt credit, had not Mrs Hearn affirmed, in the ſame letter, that, before the death of Sir William Temple, Mrs Johnſon's little fortune had been greatly injured by the South-ſea bubbles, which are known to have injured no perſon till the year 1720: (See COMPANY, II. 1.) When one part of a narrative is ſo palpably falſe, the remainder will always be received with heſitation. But whether Miſs Johnſon was the daughter of Temple's ſteward or of the friend of lady Gifford, it is certain that Sir William left her L. 1000; and that, accompanied by Mrs Dingley, whoſe whole fortune amounted to an annuity of L. 27 for life, ſhe went, in conſequence of Swift's invitation, to Laracor. With theſe two ladies he paſſed his hours of relaxation, and to them he opened his boſom; but they never reſided in the ſame houſe, nor did he ſee either without a witneſs.

* See Inquiry into the Life of Dean Swift, prefixed to Literary Relics, printed in 1789, for Elliot and Kay.

In 1701 Swift publiſhed *A Diſcourſe of the Conteſts and Diſſenſions in Athens and Rome*. It was his firſt work, and indeed the only which he ever expreſsly acknowledged. According to his conſtant practice he had concealed his name; but after its appearance, paying a viſit to ſome Iriſh biſhop, he was aſked by him if he had read that pamphlet, and what its reputation was in London. Upon his replying that he believed it was very well liked in London; "Very well liked!" ſaid the biſhop with ſome emotion. "Yes, Sir, it is one of the fineſt tracts that ever was written, and biſhop Burnet is one of the beſt writers in the world." Swift, who always hated Burnet with ſomething more than political rancour, immediately queſtioned his right to the work, when he was told by the biſhop that he was "a young man;" and ſtill perſiſting to doubt of the juſtice of Burnet's claim, on account of the diſſimilarity of the ſtyle of the pamphlet from that of his other works, he was told that he was "a very poſitive young man," as no perſon in England but biſhop Burnet was capable of writing it. Upon which Swift replied, with ſome indignation, I am to aſſure your lordſhip, however, that biſhop Burnet did *not* write the pamphlet, for I wrote it myſelf. And thus was he forced in the heat of argument to avow what otherwiſe he would have for ever concealed. Swift.

Early in the enſuing ſpring king William died; and Swift, on his next viſit to London, found queen Anne upon the throne. It was generally thought, upon this event, that the Tory party would have had the aſcendant; but, contrary to all expectation, the Whigs had managed matters ſo well as to get entirely into the queen's confidence, and to have the whole adminiſtration of affairs in their hands. Swift's friends were now in power; and the Whigs in general, knowing him to be the author of the Diſcourſe on the Conteſts, &c. which was written in defence of king William and his miniſters againſt the violent proceedings of the houſe of commons, conſidered themſelves as much obliged to him, and looked upon him as faſt to their party. But Swift thought with the Whigs only in the ſtate; for with reſpect to the church his principles were always thoſe of a Tory. He therefore declined any intimate connection with the leaders of the party, who at that time profeſſed what was called *low church principles*. But what above all ſhocked him, ſays Mr Sheridan, was their inviting Deiſts, Freethinkers, Atheiſts, Jews, and Infidels, to be of their party, under pretence of moderation, and allowing a general liberty of conſcience. As Swift was in his heart a man of true religion, he could not have borne, even in his private character, to have mixed with ſuch a motely crew. But when we conſider his principles in his political capacity, that he looked upon the church of England, as by law eſtabliſhed, to be the main pillar of the newly erected conſtitution, he could not, conſiſtently with the character of a good citizen, join with thoſe who conſidered it more as an ornament than a ſupport to the edifice; and could therefore look on with compoſure while it was undermining, or could even open the gate to a blind multitude, to try, like Sampſon, their ſtrength againſt it, and conſider it only as ſport. With ſuch a party, neither his religious nor political principles would ſuffer him to join; and with regard to the Tories, as is uſual in the violence of factions, they had run into oppoſite extremes, equally dangerous to the ſtate. He was therefore during the earlier part of the queen's reign of no party, but employed himſelf in diſcharging the duties of his function, and in publiſhing from time to time ſuch tracts as he thought might be uſeful. In the year 1704 he publiſhed the *Tale of a Tub*, which, conſidered merely as a work of genius, is unqueſtionably the greateſt which he ever produced; but the levity with which religion was thought to be there treated, raiſed up enemies to him among all parties, and eventually precluded him from a biſhopric. From that period till the year 1708, he ſeems to have employed himſelf in ſolitary ſtudy; but he then gave ſucceſſively to the public *The Sentiments of a Church of England man*, the ridicule of aſtrology under the name of *Bickerſtaff*, the *Argument againſt aboliſhing Chriſtianity*, and the defence of the *Sacramental Teſt*.

Soon after began the buſy and important part of Swift's life. He was employed (1710) by the primate of Ireland to ſolicit the queen for a remiſſion of the firſt fruits and twentieth parts to the Iriſh clergy. This introduced him to Mr Harley, afterwards earl of Oxford, who, though a Whig himſelf, was at the head of the Tory miniſtry, and in great need of an auxiliary ſo able as Swift, by whoſe pen he and the other miniſters might be ſupported in pamphlets, poems,

Swift. poems, and periodical papers. In the year 1710 was commenced the *Examiner;* of which Swift wrote 33 papers, beginning his firſt part of it on the 10th of November 1711. The next year he publiſhed *the Conduct of the Allies* ten days before the parliament aſſembled; and ſoon afterwards, *Reflections on the barrier Treaty.* The purpoſe of theſe pamphlets was to perſuade the nation to a peace, by ſhowing that "mines had been exhauſted and millions deſtroyed" to ſecure the Dutch and aggrandize the emperor, without any advantage whatever to Great Britain. Though theſe two publications, together with his *Remarks on the Biſhop of Sarum's Introduction to the third Volume of his Hiſtory of the Reformation,* certainly turned the tide of popular opinion, and effectually promoted the deſigns of the miniſtry, the beſt preferment which his friends could venture to give him was the deanery of St Patrick's which he accepted in 1713. In the midſt of his power and his politics he kept a journal of his viſits, his walks, his interviews with miniſters, and quarrels with his ſervant, and tranſmitted it to Mrs Johnſon and Mrs Dingley, to whom he knew that whatever befel him was intereſting; but in 1714 an end was put to his power by the death of the queen, which broke down at once the whole ſyſtem of Tory politics, and nothing remained for him but to withdraw from perſecution to his deanery. Swift.

In the triumph of the Whigs, Swift met with every mortification that a ſpirit like his could poſſibly be expoſed to. The people of Ireland were irritated againſt him beyond meaſure; and every indignity was offered him as he walked the ſtreets of Dublin. Nor was he only inſulted by the rabble, but perſons of diſtinguiſhed rank and character forgot the decorum of common civility to give him a perſonal affront. While his pride was hurt by ſuch indignities, his more tender feelings were alſo often wounded by baſe ingratitude. In ſuch a ſituation he found it in vain to ſtruggle againſt the tide that oppoſed him. He ſilently yielded to it, and retired from the world to diſcharge his duties as a clergyman, and attended, to the care of his deanery. That no part of his time might lie heavy on his hands, he employed his leiſure hours on ſome hiſtorical attempts relating to the change of the miniſters and the conduct of the miniſtry; and completed the hiſtory of the four laſt years of the queen, which had been begun in her lifetime, but which he never publiſhed. Of the work which bears that title, and is ſaid to be his, Dr Johnſon doubts the genuineneſs; and it certainly is not ſuch as we ſhould have expected from a man of Swift's ſagacity and opportunities of information.

In the year 1716 he was privately married to Mrs Johnſon by Dr Aſhe biſhop of Clogher; but the marriage made no change in their ſituation, and it would be difficult to prove (ſays Lord Orrery) that they were ever afterwards together but in the preſence of a third perſon. The dean of St Patrick's lived in a private manner, known and regarded only by his friends, till about the year 1720 that he publiſhed his firſt political pamphlet relative to Ireland, intitled *A propoſal for the Univerſal Uſe of Iriſh Manufactures;* which ſo rouſed the indignation of the miniſtry that they commenced a proſecution againſt the printer, which drew the attention of the public to the pamphlet, and at once made its author popular.

Whilſt he was enjoying the laurels which this work had wreathed for him, his felicity, as well as that of his wife, was interrupted by the death of Mrs Van Homrigh, and the publication of his poem called *Cadenus and Vemſſa,* which brought upon him much merited obloquy. With Mrs Van Homrigh he become acquainted in London during his attendence at court; and finding her poſſeſſed of genius and fond of literature, he took delight in directing her ſtudies, till he got inſenſibly poſſeſſion of her heart. From being proud of his praiſe, ſhe grew fond of his perſon; and deſpiſing vulgar reſtraints, ſhe made him ſenſible that ſhe was ready to receive him as a huſband. She had wit, youth, beauty, and a competent fortune to recommend her; and for a while Swift ſeems to have been undetermined whether or not he ſhould comply with her wiſh. She had followed him to Ireland, where ſhe lived in a houſe about twelve miles diſtant from Dublin; and he continued to viſit her occaſionally, and to direct her ſtudies as he had done in London; but with theſe attentions ſhe was not ſatisfied, and at laſt ſent him a letter written with great ardour and tenderneſs, inſiſting that he ſhould immediately accept or refuſe her as a wife. His anſwer, which probably contained the ſecret of his marriage, he carried himſelf; and having indignantly thrown it on the lady's table inſtantly quitted the houſe, we believe without ſpeaking to her, and returned to Dublin to reflect on the conſequences of his own conduct. Theſe were dreadful. Mrs Van Homrigh ſurvived her diſappointment but a few weeks; during which time ſhe cancelled a will that ſhe had made in his favour, and ordered the poem to be publiſhed in which Cadenus had proclaimed her excellence and confeſſed his love. Swift.

His patriotiſm again burſt forth in 1724 to obſtruct the currency of Wood's halfpence; and his zeal was crowned with ſucceſs. Wood had obtained a patent to coin 180,000 l. in halfpence and farthings for the kingdom of Ireland; and was about to turn his braſs into gold, when Swift finding that the metal was debaſed to an enormous degree, wrote letters under the name of *M. B. Drapier* to ſhow the folly of giving gold and ſilver for coin not worth a third part of its nominal value. A proſecution was carried on againſt the printer; and lord Carteret, then lord-lieutenant, iſſued proclamation, offering L. 300 for diſcovering the author of the fourth letter. The day after it was publiſhed there was a full levee at the caſtle. The lord-lieutenant was going round the circle, when Swift abruptly entered the chamber, and puſhing his way through the crowd, never ſtopped till he got within the circle; where, with marks of the higheſt indignation in his countenance, he addreſſed the lord-lieutenant with the voice of a Stentor, that re-echoed though the room, "So, my lord-lieutenant, this is a glorious exploit that you performed yeſterday, in iſſuing a proclamation againſt a poor ſhop-keeper, whoſe only crime is an honeſt endeavour to ſave his country from ruin. You have given a noble ſpecimen of what this devoted nation is to hope for from your government. I ſuppoſe you expect a ſtatue of copper will be erected to you for this ſervice done to Wood." He then went on for a long time, inveighing in the bittereſt terms againſt the patent, and diſplaying in the ſtrongeſt colours all the fatal conſequences of introducing that execrable coin. The whole aſſembly were ſtruck mute with wonder at this unprecedented ſcene. For ſome time a profound ſilence enſued. When lord Carteret, who had liſtened with great compoſure to the whole ſpeech, made this fine reply, in a line of Virgil's:

Res dura, & regni noviſtas me talia cogunt
Moliri.

For this time Swift was known by the name of *the Dean* and was known by the populace as the champion, patron, and inſtructor of Ireland.

In 1727 he returned to England; where, in conjunction with Pope, he collected three volumes of miſcellanies; and the ſame year he ſent into the world his *Gulliver's Travels,* a production which was read by the high and the low, and filled every reader with a mingled emotion of merriment and amazement. Whilſt he was enjoying the reputation of this work, he was ſuddenly called to a home of ſorrow. Poor Stella was ſinking into the grave; and after a lanquiſhing decay

Swift. decay of about two months, died in her 44th year, on January 28. 1728. How much he wiſhed her life is ſhown by his papers; nor can it be doubted that he dreaded the death of her whom he loved moſt, aggravated by the conſciouſneſs that himſelf had haſtened it. With her vaniſhed all his domeſtic enjoyments, and of courſe he turned his thoughts more to public affairs; in the contemplation of which he could ſee nothing but what ſerved to increaſe the malady. The advances of old age, with all its attendant infirmities; the death of almoſt all his old friends; the frequent returns of his moſt diſpiriting maladies, deafneſs and giddineſs; and, above all, the dreadful apprehenſions that he ſhould outlive his underſtanding, made life ſuch a burden to him, that he had no hope left but a ſpeedy diſſolution, which was the object of his daily prayer to the Almighty.

The ſeverity of his temper increaſing, he drove his acquaintance from his table, and wondered why he was deſerted. In 1732, he complains, in a letter to Mr Gay, that "he had a large houſe, and ſhould hardly find one viſitor if he was not able to hire him with a bottle of wine:" and, in another to Mr Pope, "that he was in danger of dying poor and friendleſs, even his female friends having forſaken him; which," as he ſays, "vexed him moſt." Theſe complaints were afterwards repeated in a ſtrain of yet greater ſenſibility: "All my friends have forſaken me.

"*Vertiginoſus, inops, ſurdus, male gratus amicis.*

"Deaf, giddy, helpleſs, left alone,

"To all my friends a burden grown."

The fits of giddineſs and deafneſs to which he had been ſubjected from his boyiſh years, and for which he thought walking or riding the beſt remedy, became more frequent and violent as he grew old; and the preſentiment which he had long entertained of that wretchedneſs which would inevitably overtake him towards the cloſe of life, clouded his mind with melancholy and tinged every object around him. How miſerable he was rendered by that gloomy proſpect, we may learn from the following remarkable anecdote mentioned by Mr Faulkner in his letter to lord Cheſterfield. "One time, in a journey from Drogheda to Navan, the dean rode before the company, made a ſudden ſtop, diſmounted his horſe, fell on his knees, lifted up his hands, and prayed in the moſt devout manner. When his friends came up, he deſired and inſiſted on their alighting; which they did, and aſked him the meaning. "Gentlemen," ſaid he, "pray join your hearts in fervent prayers with mine, that I may never be like this oak-tree, which is decayed and withered at top while the other parts are ſound." In 1736, while he was writing a ſatire called the *Legion Club* againſt the Iriſh parliament, he was ſeized with ſo dreadful a fit of his malady, that he left the poem unfiniſhed; and never after attempted a compoſition that required a courſe of thinking. From this time his memory gradually declined, his paſſions perverted his underſtanding, and, in 1741, he became utterly incapable of converſation; and it was found neceſſary to appoint legal guardians to his perſon and his fortune. He now loſt all ſenſe of diſtinction. His meat was brought to him cut into mouthfuls; but he would never touch it while the ſervant ſtaid; and at laſt after it ſtood perhaps an hour, would eat it walking; for he continued his old habit, and was on his feet ten hours a-day. During next year a ſhort interval of reaſon enſuing, gave hopes of his recovery; but in a few days he ſunk into lethargic ſtupidity, motionleſs heedleſs, and ſpeechleſs after a year of total ſilence, however, when his houſe-keeper told him that the uſual illuminations were preparing to celebrate his birth, he anſwered "It is all folly; they had better let it alone." He at laſt ſunk into a perfect ſilence, which continued till the 29th of October 1745, when he expired without a ſtruggle, in his 78th year. The behaviour of the citizens on this occaſion gave the ſtrongeſt proof of the deep impreſſion he had made on their minds. Though he had been ſo many years to all intents and purpoſes dead to the world, and his departure from that ſtate ſeemed a thing rather to be wiſhed than deplored, yet no ſooner was his death announced, than they gathered from all quarters, and forced their way in crowds into the houſe, to pay the laſt tribute of grief to their departed benefactor. Nothing but lamentations was heard all around the quarter where he lived, as if he had been cut off in the vigour of his years. Happy were they who firſt got into the chamber where he lay, to procure, by bribes to the ſervants, locks of his hair, to be handed down as ſacred relics to their poſterity; and ſo eager were numbers to obtain at any price this precious memorial, that in leſs than an hour his venerable head was entirely ſtripped of all its ſilver ornaments, ſo that not a hair remained. By his will, which was dated in May 1740, juſt before he ceaſed to be a reaſonable being, he left about L. 1200 in ſpecific legacies; and the reſt of his fortune, which amounted to about L. 11,000, to erect and endow an hoſpital for lunatics and idiots. He was buried in the moſt private manner, according to directions in his will, in the great aiſle of St Patrick's cathedral, and, by way of monument, a ſlab of black marble was placed againſt the wall, on which was engraved the following Latin epitaph, written by himſelf: Swift.

Hic depoſitum eſt corpus
JONATHAN SWIFT, S. T. P.
Hujus Eccleſiæ Cathedralis
Decani:
Ubi ſæva indignatio
Ulterius cor lacerare nequit.
Abi, viator,
Et imitare, ſi poteris,
Strenuum pro virili libertatis vindicem.
Obiit anno (1745)
Menſis (Octobris) die (29.)
Ætatis anno 78.

Swift undoubtedly was a man of native genius. His fancy was inexhauſtible; his conceptions were lively and comprehenſive; and he had the peculiar felicity of conveying them in language equally correct, free and perſpicuous. His penetration was as quick as intuition; he was indeed the critic of nature; and no man ever wrote ſo much, and borrowed ſo little.

As his genius was of the firſt claſs, ſo were ſome of his virtues. The following anecdote will illuſtrate his filial piety. His mother died in 1710, as appears by a memorandum in one of the account-books which Dr Swift always made up yearly, and on each page entered minutely all his receipts and expences in every month, beginning his year from November 1. He obſerved the ſame method all his lifetime till his laſt illneſs. At the foot of that page which includes his expences of the month of May 1710, at the glebe houſe of Laracor in the county of Meath, where he was then reſident, are theſe remarkable words, which ſhow at the ſame time his filial piety, and the religious uſe which he thought it his duty to make of that melancholy event. "*Mem.* On Wedneſday, between ſeven and eight in the evening, May 10. 1710, I received a letter in my chamber at Laracor (Mr Percival and Jo. Beaumont being by) from Mrs F—, dated May 9. with one incloſed, ſent by Mrs Worral at Leiceſter to Mrs F—, giving an account that my dear mother, Mrs Abigail Swift, died that morning, Monday April 24. 1710, about ten o'clock, after a long ſickneſs: being ill all winter, and lame; and extremely ill about a month or ſix weeks before her death. I have now loſt my barrier between me and death. God grant I may live to be as well prepared for

Swift. for it as I confidently believe her to have been! If the way to heaven be through piety, truth, juſtice, and charity, ſhe is there. J. S" He always treated his mother, during her life, with the utmoſt duty and affection; and ſhe ſometimes came to Ireland to viſit him after his ſettlement at Laracor.

The liberality of the dean hath been a topic of juſt encomium with all his admirers; nor could his enemies deny him this praiſe. In his domeſtic affairs, he always acted with ſtrict economy. He kept the moſt regular accounts; and he ſeems to have done this chiefly with a view to increaſe his power of being uſeful. "His income, which was little more than L 700 *per annum*, he endeavoured to divide into three parts, for the following purpoſes. Firſt, to live upon one-third of it. Secondly, to give another third in penſions and charities, according to the manner in which perſons who received them had lived: and the other third he laid by, to build an hoſpital for the reception of idiots and lunatics." "What is remarkable in this generous man, is this (ſays Mr F.) that when he lent money upon bond or mortgage, he would not take the legal intereſt, but one *per cent.* below it."

His charity appears to have been a ſettled principle of duty more than an inſtinctive effort of good nature: but as it was thus founded and ſupported, it had extraordinary merit, and ſeldom failed to exert itſelf in a manner that contributed moſt to render it beneficial. He did not laviſh his money on the idle and the worthleſs. He nicely diſcriminated characters, and was ſeldom the dupe of impoſition. Hence his generoſity always turned to an uſeful account: while it relieved diſtreſs, it encouraged induſtry, and rewarded virtue. We dwell with great pleaſure on this truly excellent and diſtinguiſhing part of the dean's character: and for the ſake of his charity we can overlook his oddities, and almoſt forgive his faults. He was a very peculiar man in every reſpect. Some have ſaid, "What a man he would have been, had he been without thoſe whims and infirmities which ſhaded both his genius and his character!" But perhaps the peculiarities complained of were inſeparable from his genius. The vigour and fertility of the root could not fail now and then of throwing out ſuperfluous ſuckers. What produced theſe, produced alſo the more beautiful branches, and gave the fruit all its richneſs.

It muſt be acknowledged, that the dean's fancy hurried him into great abſurdities and inconſiſtencies, for which nothing but his extraordinary talents and noble virtues, diſcovered in other inſtances, could have atoned. The rancour he diſcovered on all occaſions towards the diſſenters is totally unjuſtifiable. No ſect could have merited it in the degree in which he always ſhowed it to them; for, in ſome inſtances, it bordered on downright perſecution. He doubtleſs had his reaſons for expoſing their principles to ridicule, and might perhaps have ſufficient grounds for ſome of his accuſations againſt their principal leaders in Ireland; but nothing could juſtify his virulence againſt the whole body. In a ſhort poem on one claſs of diſſenters he beſtowed a ſtricture upon Betteſworth, a lawyer eminent for his inſolence to the clergy, which, from a very conſiderable reputation, brought him into immediate and univerſal contempt. Betteſworth, enraged at his diſgrace and loſs, went to the dean, and demanded whether he was the author of that poem? "Mr Betteſworth (anſwered he), I was in my youth acquainted with great lawyers, who, knowing my diſpoſition to ſatire, adviſed me, if any *ſcoundrel* or *blockhead* whom I had lampooned ſhould aſk, 'Are you the author of this paper?' to tell him that I was not the author; and therefore, I tell *you*, Mr Betteſworth, that I am not the author of theſe lines."

Swift has been accuſed of irreligion and miſanthropy, on account of his Tale of a Tub, and his Yahoos in Gulliver's Travels; but both charges ſeem to be ill-founded, or at leaſt not ſupported by that evidence. The *Tale of a Tub* holds up to ridicule ſuperſtitious and fanatical abſurdities; but it never attacks the eſſentials of religion: and in the ſtory of the *Yahoos*, diſguſting we confeſs, there appears to us as little evidence that the author hated his own ſpecies, as in the poems of *Strephon and Chloe*, and the *Ladies' Dreſſing Room*, that he approved of groſſneſs and filth in the female ſex. We do not indeed, with his fondeſt admirers, perceive the moral tendency of the Voyage to the Houyhnhnms, or conſider it as a ſatire admirably calculated to reform mankind; but neither do we think that it can poſſibly corrupt them, or lead them to think meanly of their rational nature. According to Sheridan, "the deſign of this apologue is to place before the eyes of man a picture of the two different parts of his frame, detached from each other, in order that he may the better eſtimate the true value of each, and ſee the neceſſity there is that the one ſhould have an abſolute command over the other. In your merely animal capacity, ſays he to man, without reaſon to guide you, and actuated only by a blind inſtinct, I will ſhow you that you would be degraded below the beaſts of the field. That very form, that very body, you are now ſo proud of, as giving you ſuch a ſuperiority over all other animals, I will ſhow you, owe all their beauty, and all their greateſt powers, to their being actuated by a rational ſoul. Let that be withdrawn, let the body be inhabited by the mind of a brute, let it be prone as theirs are, and ſuffered like theirs to take its natural courſe, without any aſſiſtance from art, you would in that caſe be the moſt deformed, as to your external appearance, the moſt deteſtable of all creatures. And with regard to your internal frame, filled with all the evil diſpoſitions and malignant paſſions of mankind, you would be the moſt miſerable of beings, living in a continued ſtate of internal vexation, and of hatred and warfare with each other.

"On the other hand, I will ſhow another picture of an animal endowed with a rational ſoul, and acting uniformly up to the dictates of right reaſon. Here you may ſee collected all the virtues, all the great qualities, which digniſy man's nature, and conſtitute the happineſs of his life. What is the natural inference to be drawn from theſe two different repreſentations? Is it not evidently a leſſon to mankind, warning them not to ſuffer the animal part to be predominant in them, leſt they reſemble the vile Yahoo, and fall into vice and miſery; but to emulate the noble and generous Houyhnhnm, by cultivating the rational faculty to the utmoſt; which will lead them to a life of virtue and happineſs."

Such *may* have been the author's intention; but it is not ſufficiently obvious to produce the proper effect, and is indeed hardly conſiſtent with that incapability under which he repreſents the Yahoos of ever acquiring, by any culture, the virtues of the noble Houyhnhnms.

With reſpect to his religion, it is a fact unqueſtionable, that while the power of ſpeech remained, he continued conſtant in the performance of his private devotions; and in proportion as his memory failed, they were gradually ſhortened, till at laſt he could only repeat the Lord's prayer, which he continued to do till the power of utterance for ever ceaſed. Such a habit as this could not have been formed but by a man deeply impreſſed with a conviction of the truth and importance of revelation.

The moſt inexcuſable part of Swift's conduct is his treatment of Stella and Vaneſſa, for which no proper apology can be made, and which the vain attempts of his friends have only tended to aggravate. One attributes his ſin-

Swift, Swimming.

gular conduct to a peculiarity in his conſtitution; but if he knew that he was incapable of fulfilling the duties of the married ſtate, how came he to tie one of the ladies to himſelf by the marriage ceremony, and in the moſt explicit terms to declare his paſſion to the other? And what are we to think of the ſenſibility of a man who, ſtrongly attached as he ſeems to have been to both, could without ſpeaking, fling a paper on the table of the one, which "proved (as our author expreſſes it) her death-warrant," and could throw the other, his beloved Stella, in her laſt illneſs, into unſpeakable agonies, and "never ſee her more, for only adjuring him, by their friendſhip, to let her have the ſatisfaction of dying at leaſt, though ſhe had not lived his acknowledged wife?" Another apologiſt inſinuates, upon ſomething like evidence, that Stella bore a ſon to Swift, and yet labours to excuſe him for not declaring her his wife, becauſe ſhe had agreed at the marriage that it ſhould remain a ſecret from all the world unleſs the diſcovery ſhould be called for by *urgent neceſſity*; but what could be meant by the term *urgent neceſſity* unleſs it alluded to the birth of children, he confeſſes that it would be hard to ſay. The truth we believe to be what has been ſaid by Johnſon, that the man whom Stella had the misfortune to love was fond of ſingularity, and deſirous to make a mode of happineſs for himſelf, different from the general courſe of things and the order of Providence; he wiſhed for all the pleaſures of perfect friendſhip, without the uneaſineſs of conjugal reſtraint. But with this ſtate poor Stella was not ſatisfied: ſhe never was treated as a wife, and to the world ſhe had the appearance of a miſtreſs. She lived ſullenly on, hoping that in time he would own and receive her. This, we believe, he offered at laſt to do, but not till the change of his manners and the deprivation of his mind made her tell him, that "it was too late."

The natural acrimony of Swift's temper had been increaſed by repeated diſappointments. This gave a ſplenetic tincture to his writings, and amidſt the duties of private and domeſtic life it too frequently appeared to ſhade the luſtre of his more eminent virtues.—The dean hath been accuſed of avarice, but with the ſame truth as he hath been accuſed of infidelity. In detached views, no man was more liable to be miſtaken. Even his genius and good ſenſe might be queſtioned, if we were only to read ſome paſſages of his writings. To judge fairly and pronounce juſtly of him as a man and as an author, we ſhould examine the uniform tenor of his diſpoſition and conduct, and the general nature and deſign of his productions. In the latter he will appear great, and in the former good; notwithſtanding the puns and puerilities of the one, and the abſurdities and inconſiſtencies of the other.

SWIFT, in ornithology. See HIRUNDO.

SWIMMING, the art of ſuſpending one's ſelf on water, and at the ſame time making a progreſſive motion thro' it.

1 Swimming not natural to man.

As ſwimming is not natural to man, it is evident that at ſome period it muſt have been unknown among the human race. Nevertheleſs there are no accounts of its origin to be found in the hiſtory of any nation; nor are there any nations ſo barbarous but that the art of ſwimming is known among them, and that in greater perfection than among civilized people. It is probable, therefore, that the art, though not abſolutely natural, will always be acquired by people in a ſavage ſtate, from imitating the brute animals, moſt of whom ſwim naturally. Indeed ſo much does this appear to be the caſe, that very expert ſwimmers have recommended it to thoſe who wiſhed to learn the art, to keep ſome frogs in a tub of water conſtantly beſide them, and to imitate the motions by which they move thro' that element.

2 Depends on a ſimple principle.

The theory of ſwimming depends upon one very ſimple principle; namely, that if a force is applied to any body, it will always move towards that ſide where there is the leaſt reſiſtance. Thus, if a perſon ſtanding in a boat puſhes with a pole againſt the ſide or any other part of the veſſel in which he ſtands, no motion will enſue; for as much as he preſſes in one direction with the pole, juſt ſo much does the action of his feet, on which the preſſure of the pole muſt ultimately reſt, puſh the veſſel the other way: but if, inſtead of the ſide of the veſſel, he puſhes the pole againſt the ſhore, then only one force acts upon it, namely, that of the feet; which being reſiſted only by the fluid water, the boat begins to move from the ſhore. Now the very ſame thing takes place in ſwimming, whether the animal be man, quadruped, bird or fiſh. If we conſider the matter ſimply, we may ſuppoſe an animal in ſuch a ſituation that it could not poſſibly ſwim; thus, if we cut off the fins and tail of a fiſh, it will indeed float in conſequence of being ſpecifically lighter than the water, but cannot make any progreſſive motion, or at leaſt but very little, in conſequence of wriggling its body; but if we allow it to keep any of its fins, by ſtriking them againſt the water in any direction, the body moves the contrary way, juſt as a boat moves the contrary way to that in which the oars ſtrike the water. It is true that as the boat is but partly immerged in the water, the reſiſtance is comparatively leſs than when a frog or even any other quadruped ſwims; but a boat could certainly be rowed with oars tho' it was totally immerged in water, only with leſs velocity than when it is not. When a man ſwims, he in like manner ſtrikes the water with his hands, arms, and feet; in conſequence of which the body moves in a direction contrary to the ſtroke. Upon this principle, and on this only, a man may either aſcend, deſcend, or move obliquely, in any poſſible direction in the water. One would think, indeed, that as the ſtrength of a man's arms and legs is but ſmall, he could make but very little way by any ſtroke he could give the water, conſidering the fluidity of that element. Nevertheleſs it is incredible what expert ſwimmers will perform in this way; of which Mr Forſter gives a moſt remarkable inſtance in the inhabitants of Otaheite; whoſe agility, he tells us, was ſuch, that when a nail was thrown overboard, they would jump after it into the ſea, and never fail to catch it before it came to the bottom.

As to the practice of ſwimming, there are but few directions which can be given. The great obſtacle is the natural dread which people have of being drowned; and this it is impoſſible to overcome by any thing but accuſtoming ourſelves to go into the water. With regard to the real danger of being drowned, it is but little; and on innumerable occaſions ariſes entirely from the terror abovementioned, as will appear from the following obſervations by Doctor Franklin.

3 Obſervations by Dr Franklin.

"1ſt, That though the legs, arms, and head, of a human body, being ſolid parts, are ſpecifically ſomewhat heavier than freſh water, yet the trunk, particularly the upper part, from its hollowneſs, is ſo much lighter than water, as that the whole of the body, taken together, is too light to ſink wholly under water, but ſome part will remain above until the lungs become filled with water; which happens from drawing water into them inſtead of air, when a perſon in the fright attempts breathing while the mouth and noſtrils are under water.

"2dly, That the legs and arms are ſpecifically lighter than ſalt water, and will be ſupported by it; ſo that a human body would not ſink in ſalt water though the lungs were filled as above, but from the greater ſpecific gravity of the head.

"3dly, That therefore a perſon throwing himſelf on his back in ſalt water, and extending his arms, may eaſily lie

ſo

Swimming so as to keep his mouth and noſtrils free for breathing; and by a ſmall motion of his hands may prevent turning, if he ſhould perceive any tendency to it.

"4thly, That in freſh water, if a man throws himſelf on his back near the ſurface, he cannot long continue in that ſituation, but by a proper action of his hands on the water. If he uſes no ſuch action, the legs and lower part of the body will gradually ſink till he comes into an unright poſition; in which he will continue ſuſpended, the hollow of the breaſt keeping the head uppermoſt.

"5thly, But if in this erect poſition the head is kept upright above the ſhoulders, as when we ſtand on the ground, the immerſion will, by the weight of that part of the head that is out of the water, reach above the mouth and noſtrils, perhaps a little above the eyes, ſo that a man cannot long remain ſuſpended in water with his head in that poſition.

"6thly, The body continued ſuſpended as before, and upright, if the head be leaned quite back, ſo that the face looks upwards, all the back part of the head being then under water, and its weight conſequently in a great meaſure ſupported by it, the face will remain above water quite free for breathing, will riſe an inch higher every inſpiration, and ſink as much every expiration, but never ſo low as that the water may come over the mouth.

"7thly, If therefore a perſon unacquainted with ſwimming, and falling accidentally into the water, could have preſence of mind ſufficient to avoid ſtruggling and plunging, and to let the body take this natural poſition, he might continue long ſafe from drowning, till perhaps help would come; for as to the clothes, their additional weight while immerſed is very inconſiderable, the water ſupporting it; though when he comes out of the water, he would find them very heavy indeed."

4 His method of learning to ſwim, The method of learning to ſwim is as follows: The perſon muſt walk into water ſo deep that it will reach to the breaſt. He is then to lie down gently on the belly, keeping the head and neck perfectly upright, the breaſt advancing forward, the thorax inflated, and the back bent; then withdrawing the legs from the bottom, and ſtretching them out, ſtrike the arms forwards in uniſon with the legs. Swimming on the back is ſomewhat ſimilar to that on the belly; but with this difference, that although the legs are employed to move the body forwards, the arms are generally unemployed, and the progreſſive motion is derived from the movement of the legs. In diving, a perſon muſt cloſe his hands together, and, preſſing his chin upon his breaſt, make an exertion to bend with force forwards. While in that poſition, he muſt continue to move with rapidity under the ſurface; and whenever he chooſes to return to his former ſituation, he has nothing to do but bend back his head, and he will immediately return to the ſurface.

It is very common for novices in the art of ſwimming to make uſe of corks or bladders to aſſiſt in keeping the body above water. Some have utterly condemned the uſe of theſe; however, Dr Franklin allows that they may be of ſervice for ſupporting the body while one is learning what is called the *ſtroke*, or that manner of drawing in and ſtriking out the hands and feet that is neceſſary to produce progreſſive motion. "But (ſays he) you will be no ſwimmer till you can place confidence in the power of the water to ſupport you: I would therefore adviſe the acquiring that confidence in the firſt place, eſpecially as I have known ſeveral who, by a little of the practice neceſſary for that purpoſe, have inſenſibly acquired the ſtroke, taught as it were by nature.

5 And of acquiring confidence. "The practice I mean is this: Chooſing a place where the water deepens gradually, walk coolly into it till it is up to your breaſt: then turn round your face to the ſhore, and throw an egg into the water, between you and the ſhore; it will ſink to the bottom, and be eaſily ſeen there, if the water is clear. It muſt lie in the water ſo deep as that you cannot reach it to take it up but by diving for it. To encourage yourſelf in order to do this, reflect that your progreſs will be from deeper to ſhallower water; and that at any time you may, by bringing your legs under you, and ſtanding on the bottom, raiſe your head far above the water: then plunge under it with your eyes open, throwing yourſelf towards the egg, and endeavouring, by the action of your hands and feet againſt the water, to get forward till within reach of it. In this attempt you will find that the water buoys you up againſt your inclination; that it is not ſo eaſy a thing to ſink as you imagined; that you cannot but by active force get down to the egg. Thus you feel the power of the water to ſupport you, and learn to confide in that power; while your endeavours to overcome it, and to reach the egg, teach you the manner of acting on the water with your feet and hands; which action is afterwards uſed in ſwimming to ſupport your head higher above water, or to go forward through it."

6 Swimming a pleaſant and uſeful exerciſe. As ſwimming is a healthy exerciſe and a pleaſant amuſement, and as a dexterity in it may frequently put it in a man's power to ſave his own life and the lives of his fellow-creatures, perhaps of his deareſt friends, it can neither be uſeleſs nor unintereſting to conſider a few of the evolutions which a ſwimmer muſt be maſter of, that he may move in any direction without difficulty, without danger, and without being unneceſſarily fatigued.

7 How to turn to the right or left. There are ſeveral different ways of turning one's ſelf in ſwimming. You may do it in this way: Turn the palm of the right hand outwards, extend the arm in the ſame manner, and make a contrary movement with the left hand and left arm; then, by a gradual motion, incline your head and whole body to the left ſide, and the evolution will be finiſhed. There is another way which is eaſier ſtill: Bend your head and body toward that ſide to which you are going to turn. If you wiſh to turn to the left, incline the thumb and the right hand toward the bottom, bend the fingers of the right hand, ſtretch it out, and uſe it for driving away the water ſidewiſe, or, which is the ſame thing, for puſhing yourſelf the contrary way. At the ſame time, with your left hand, the fingers being cloſe, puſh the water behind you, and all at once turn your body and your face to the left, and the manœuvre will be accompliſhed. If you wiſh to turn to the right, you muſt do with your right hand what you did with your left, and with your left what you did with your right. You muſt be careful when turning yourſelf never to ſtretch out your legs, and be ſure that the water be ſo deep that you be in no danger of hurting yourſelf.

8 How to turn from the belly to the back. When you are ſwimming on your belly, and wiſh to turn on your back, draw your feet in quickly, and throw them before you; ſtretch out your hands behind you, and keep your body firm and ſteady. When you wiſh to turn from ſwimming on your back, fold your feet at once under your body as if you were throwing them to the bottom, and at the ſame inſtant dart your body forwards, that you may fall upon your belly.

9 The eyes ought to be turned towards heaven. In ſwimming, the eyes ought to be turned towards heaven. This is a moſt important rule, and to the neglect of it many of the accidents which befal ſwimmers are owing. For when they bend their eyes downwards, they inſenſibly bend their head too, and thus the mouth being too deep in the water, may admit a quantity of it in breathing; beſides, the more the body is ſtretched, it covers a greater part of the ſurface of the water, and conſequently its ſpecific gravity is leſs. Any perſon who will make the experiment will find it;

Swimming. it impoſſible to dive while he keeps his head erect and his eyes fixed on the heavens (A).

10 How to ſwim on the back,

The eaſieſt poſture in ſwimming is lying on the back. When you wiſh to ſwim in this poſture, lay yourſelf ſoftly on your back, and raiſe your breaſt to the ſurface of the water, keeping your body extended in the ſame line. Put your hands eaſily over the upper part of your thighs, and throw out your legs and draw them in alternately, keeping them within two feet of the ſurface. In this way you may advance in any direction you pleaſe. You may perhaps not like having ſo much of your head under water; there is, however, no way of ſwimming ſo eaſy, ſo ſafe, and ſo little fatiguing. If you wiſh to ſwim with great rapidity, you may uſe your arms as well as your feet; and you will find this the eaſieſt way of breaking the force of the waves.

11 And advance forwards.

In ſwimming on the back, one may advance forward as well as backward. For this purpoſe the body muſt be kept ſtraight and extended; the breaſt inflated, ſo that the hollow of the back may aſſume a ſemicircular form. The hands muſt recline over the upper parts of the thighs. It is alſo neceſſary to raiſe the legs one after another, and draw them in ſtrongly towards the hams, and then leave them ſuſpended in the water. This way of ſwimming is not only pleaſant, but may ſerve to reſt you when fatigued.

12 How to ſwim on one ſide.

When you are tired with ſwimming on your back and belly, you may ſwim on one ſide. When you wiſh to do this, ſink a little your left ſide and raiſe your right; you will immediately find yourſelf on your left ſide. Move then your left hand without either raiſing or ſinking it; you have only to ſtretch it and draw it back, as in a ſtraight line, on the ſurface of the water. Independent of the pleaſure which this kind of motion will give you, you will have the ſatisfaction of ſeeing both ſides of the river.

13 How to ſwim on the belly without the aſſiſtance of the hands.

It is poſſible to ſwim on the belly without the aſſiſtance of the hands. For this purpoſe you muſt keep your breaſt erect, your neck ſtraight, and fix your hands behind your head, or upon your back, while you move forward by employing your feet. This way is not without its advantages. It is an excellent reſource when the arms are ſeized with a cramp, or with any indiſpoſition which makes it painful to exert them. This in ſome caſes may be preferable to ſwimming on the back; for while in that attitude, one cannot ſee before them without turning every inſtant. If one of your legs be ſeized with a cramp, take hold of it with the hand oppoſite to it, and uſe the other hand and leg to advance or ſupport yourſelf.

14 How to ſwim with the hands joined.

A very ancient and graceful mode of ſwimming, is that of ſwimming with the hands joined. When you wiſh to put this in practice, join your hands, keeping the thumbs and fingers towards heaven, ſo that they may appear above the water; then draw them back and puſh them forwards alternately from your breaſt. This method of ſwimming may be uſeful in ſeveral circumſtances, but above all if you are entangled with graſs or weeds. Your hands will then open a paſſage for you.

15 With the hands elevated.

As a perſon may ſometimes have occaſion to carry ſomething in his hand in ſwimming, which he is anxious to preſerve from the water, he may ſwim eaſily with one hand and hold a parcel in the other, as Cæſar ſwam with his Commentaries at Alexandria; or one may ſwim with both hands elevated. To perform this well, the ſwimmer muſt raiſe his breaſt, and keep it as much inflated as he can, at the ſame time that he ſupports the arms above the water. It muſt not be concealed, that this method of ſwimming is attended with ſome danger to one who is not dexterous at the art; for if one ſhould imprudently draw in his breaſt, when his arms are raiſed, he would immediately ſink to the bottom.

Swimming || Swingle.

16 How to riſe to the ſurface after diving.

Every one knows that when a man plunges into the water, and when he has reached the bottom, he has nothing to do but to give a ſmall ſtroke with his foot againſt the ground, in order to riſe; but an experienced ſwimmer, if he miſſes the ground, has recourſe to another expedient, which is very pretty, and which has not been conſidered with ſufficient attention. We ſuppoſe him at a conſiderable depth, when he perceives that he cannot reach the bottom. In ſuch a caſe, he firſt puſhes his hands before his face, at the height of his forehead, with the palms turned outwardly; then holding the fore part of his arm vertically, he makes them move backwards and forwards from right to left; that is to ſay, theſe two parts of his arms, having the elbow as a kind of pivot, deſcribe very quickly, both the hands being open, and the fingers joined, two ſmall portions of a circle before the forehead, as if he would make the water retire, which he in fact does; and from theſe ſtrokes given to the water, there reſults an oblique force, one part of which carries the ſwimmer upwards.

There are many artificial methods of ſupporting one's ſelf in water, but we have not room to deſcribe them.—Thoſe who wiſh to ſee a full account of them may conſult the *Encyclopédie Methodique*.

Swimming of Fiſh. A great proportion of the inhabitants of the waters have an air-bladder, by which they poiſe themſelves. Their movements chiefly depend upon their tail. See Comparative Anatomy, n° 147, 155; and Ichthyology, n° 3.

SWINDLER, a word which has been lately adopted into the Engliſh language, derived from the German word *ſchwindel*, "to cheat." Swindling has now become ſo common in ſeveral of the great towns of this country, that it is unfortunately too well known to require any deſcription.

SWINE, in zoology. See Sus.

Swine-Stone. See *Swine-Stone*.

SWINGING, a kind of exerciſe ſtrongly recommended to perſons in conſumption by ſome phyſicians, and diſapproved of by others. See Medicine, p. 224.

SWING-TREE of a waggon, is the bar faſtened acroſs the fore-guide, to which the traces of the horſes are faſtened.

Swing-Wheel, in a royal pendulum, that wheel which drives the pendulum. In a watch or balance clock it is called the crown-wheel.

SWINGLE, in the fire-works in England, the wooden ſpoke which is fixed to the barrel that draws the wire, and which,

(A) An intereſting queſtion occurs here, which deſerves to be conſidered. Since the body, when ſpread upon the ſurface, can be ſupported with ſo little exertion, and frequently without any at all, as in ſwimming on the back, how comes it to paſs that a perſon when drowned ſinks and frequently riſes again ſome time afterwards? The reaſon is this: In the act of drowning, the lungs are filled with water, and conſequently the body, being ſpecifically heavier, ſinks. It is well known that the human body contains a great quantity of air: this air is at firſt compreſſed by the water; and while this is the caſe the body remains at the bottom: but as ſoon as the air by its elaſticity endeavours to diſengage itſelf from the compreſſion, the body is ſwelled and expanded, becomes ſpecifically lighter than the water, and conſequently riſes to the top.

Switz, Switzerland.

which, by its being forced back by the cogs of the wheel, is the occaſion of the force with which the barrel is pulled.

SWITZ, or SCHWEITS, the capital of one of the cantons of Switzerland, to which it gives name, ſeated on the eaſt ſide of the lake Lucern, in N. Lat. 46. 55. E. Long. 8. 30.

SWITZERLAND, or SWISSERLAND, is bounded on the north by Swabia; on the eaſt by Tirol; on the ſouth by Savoy and the Milaneſe; and on the weſt by France, being about 260 miles long and 100 broad. It is divided into 13 cantons, viz. *Berne*, *Zurich*, *Schaffhauſen*, *Baſil*, *Lucerne*, *Underwalden*, *Uri*, *Switz*, *Friburg*, *Zug*, *Soleure*, *Glaris*, and *Appenzel*. See theſe articles.

The Swiſs were anciently called *Helvetii*; and being ſubdued by the Romans, they continued in ſubjection to that power till the empire declined, when they became a part of the kingdom of Burgundy. After that they fell under the dominion of the Franks, then of the Germans; but being oppreſſed by the latter, they threw off the yoke, and erected ſeveral ſtates and republics, which, at the treaty of Weſtphalia in 1648, were recognized as free and independent. The cantons of Switz, Uri, and Underwalden, having, as early as the year 1308, entered into a confederacy in the canton of Switz, and having alſo obtained their firſt victory, in 1315, over Leopold archduke of Auſtria in the ſame canton, its name was given to the whole confederacy, which it ſtill retains. The other cantons ſucceſſively acceded to this aſſociation, but ſome of them not until upwards of 100 years after. With reſpect to the government and conſtitution of theſe cantons, ſome of them are ariſtocracies and ſome democracies. In the former, both the legiſlative and executive power is lodged in the burghers or citizens of the capital of each canton; and of theſe there are ſeven, viz. Zurich, Berne, Baſil, Friburg, Soleure, and Schaffhauſen; an account of the moſt important of which may be ſeen under their reſpective names. In the others, the legiſlative power is lodged in the whole body of the people; and every male above 16, whether maſter or ſervant, has a vote in making laws and in the choice of magiſtrates. For what concerns the whole Helvetic body, there are diets ordinary and extraordinary: the former are held annually, and the others upon particular emergencies; and both are ſummoned by the city of Zurich, which appoints the time and place of their meetings. Beſides the general diets ſince the Reformation, there have been particular diets of the two religions, at which all public affairs of conſequence that regard the two parties are treated ſeparately; for though a ſenſe of their common intereſt obliges them to ſtudy to maintain the league and union, yet it is certain, that the mutual confidence between the cantons is in ſome meaſure loſt through the zeal of each party for their particular opinions, eſpecially of the Roman Catholics. The annual general diets are held always at Frauenfeld or Baden, principally to regulate the affairs of the common bailiages. Lucern takes the lead of the Roman Catholic cantons, being the moſt powerful of that denomination; but Zurich, tho' leſs powerful than that of Berne, takes the precedence of all the other cantons, both Proteſtant and Popiſh. Theſe cantons do not make one commonwealth, but are ſo many independent ſtates, united together by ſtrict alliances for their mutual defence. The extraordinary diets or congreſſes are held at Aldorf. Each canton uſually deputes two envoys both to the ordinary and extraordinary, to which alſo the abbot and the town of St Gall, and the town of Biel, ſend repreſentatives as allies. To the 13 cantons belong in common 21 bailiages, two towns, and two lordſhips. The allies, or incorporated places as they are called, are the abbot and town of St Gall, the three Griſon leagues, the republic of the Valais, the towns of Mulhauſen and Biel, the principality of Neuenberg or Neufchatel, Geneva, and the biſhop of Baſil. Of theſe the abbot and town of St Gall, and the town of Biel, are regarded as members of the Helvetic body, but the reſt only as allies. Switzerland.

As to the air, ſoil, and produce of Switzerland, that part of the canton of Berne to the eaſt of the lake of Geneva, together with the cantons of Uri, Switz, Underwalden, Glaris, Appenzel, and part of the canton of Lucern, conſiſt of ſtupendous mountains, whoſe tops are ſaid to be from 9000 to 12,000 feet above the level of the ſea, conſiſting of craggy inacceſſible rocks, of which ſome are quite bare, while others are always covered with ice and ſnow. Among the mountains are many excellent medicinal and other ſprings, cold and warm baths, water-falls, craggy precipices, deep narrow valleys, and caverns. They yield alſo a great variety of herbs, thickets, and buſhes, in the upper parts; and in the lower, rich paſtures and woods. The higheſt are thoſe in the canton of Uri. Many of the valleys are covered with lakes, or watered by brooks and rivers. In ſome of them are towns, villages, woods, vineyards, and corn-lands. Both on the mountains and in the valleys the air is extremely cold in winter; but in ſummer it is very pleaſant, cool, and refreſhing on the former, but exceſſively hot in the latter. Sometimes it is winter on the north ſide of a mountain when it is ſummer on the other; nay, flowers may be gathered ſometimes with one hand, and ſnow with the other. Prodigious maſſes of ice and ſnow often fall from them in winter, and do a great deal of damage (ſee GLACIER); and moſt of the ſtreams and rivers take their riſe from the thawing of the ice and ſnow on their ſides and tops. From the riſing or deſcending of the clouds, with which they are commonly enveloped, the inhabitants can, for the moſt part, pretty exactly foretel the changes of the weather; ſo that they ſerve them inſtead of weather-glaſſes. The other and lower parts of Switzerland are very pleaſant and fertile, being diverſified with vineyards, corn-fields, meadows, and paſture-grounds. The mountains in theſe are but mole-hills in compariſon of the others: there is neither ſnow nor ice on them in ſummer; and they frequently afford not only good paſturage, but arable ground. Many petrifactions are found both among theſe and the others, with a variety of foſſils. The ſands of the rivers yield gold-duſt, particularly thoſe of the Rhine, the Emmet, and the Aar, the Reuſs, the Arve, and the Inn. The metals of this country being generally found to be brittle, the only mines that are worked are a few iron ones. In the lower parts of Switzerland they ſow rye, oats, barley, ſpelt, flax, and hemp. Wines of various ſorts are alſo produced in ſome of them, with a variety of fruits. Of wood for fuel and other uſes there is generally plenty; in ſome places, however, they are obliged to burn ſheeps dung, and in others a kind of heath and ſmall ſhrubs. In the valleys they cultivate ſaffron with ſucceſs. The Switzers derive their principal ſubſiſtence from their flocks and herds of cattle, which in ſummer graze upon the mountains. Their cheeſe is much eſteemed, eſpecially that of Berne and Griers in the canton of Friburg. Great numbers of horſes are alſo bred here, and bought up for the French cavalry. Beſides the abovementioned rivers, the Rhone and the Teſin have their ſources in this country. The lakes are very numerous; but the chief are thoſe of Geneva, Neufchatel, Biel, Zurich, Thun, Brien, Conſtance, and Lucern. Both rivers and lakes abound with fiſh, and afford a cheap water-carriage. Switzerland is not ſo populous as many other countries in Europe; and the Popiſh cantons leſs ſo than the Proteſtant. The total number of the inhabitants is computed at two millions.

The language generally ſpoken here is the German, in which alſo all public affairs are tranſacted; but in thoſe parts

Switzerland.

parts of the country that border on Italy or France, a corrupt French or Italian prevails. The two predominant religions are Calviniſm and Popery. Of the former are the cantons of Zurich and Berne, the town of St Gall, Geneva, Muhlhauſen, and Biel, the principality of Neufchatel, the greater part of Baſil, Schaffhauſen, the country of the Griſons, the Thurgau, Toggenburg, Glaris, and the Rhine valley; the frontiers of Appenzel, with a ſmall part of Solothurn, and ſome places in the countries of Baden and Sargans. The reſt of the Swiſs cantons, allies and dependents, are Popiſh. For the education of youth there is an univerſity at Baſil, and academies at Zurich, Berne, Lauſanne, and Geneva, beſides gymnaſiums and ſcholæ illuſtres, both in the Popiſh and Proteſtant cantons. There are alſo ſocieties among them for the improvement of the German language and the ſciences.

The principal manufactures are ſnuff and tobacco, linen of ſeveral ſorts, lace, thread, ſilk, and worſted ſtockings, neckcloths, cotton ſtuffs, gloves, handkerchiefs, ſilks of ſeveral ſorts, gold and ſilver brocades, a variety of woollen manufactures, hats, paper, leather of all ſorts, earthen wares, porcelain, toys, watches, clocks, and other hardwares, &c. The trade of Switzerland is greatly promoted by many navigable lakes and rivers. In ſome of the above manufactures, and in cheeſe, butter, ſheep, horſes, black cattle, hides, and ſkins, the exports are conſiderable; and as the imports are chiefly grain and ſalt, with ſome American and Aſiatic goods, there is probably a large balance in their favour. In ſome parts of Switzerland dreſs is reſtrained by ſumptuary laws.

The public revenues are in general very inconſiderable, ariſing chiefly from the uſual regalia, appropriated everywhere to the ſovereign, the demeſnes, and public granaries, voluntary contributions, the ſale of ſalt, and a land-tax; in the Proteſtant cantons, from the church-lands alſo that were ſeized at the Reformation. Except in Zurich, Berne, Baſil, and Schaffhauſen, where the people are more induſtrious, have a greater trade, and are richer than in the others, they defray the ordinary charges, and that is all.

The cantons never keep any ſtanding troops, except for a few garriſons; but their militia is reckoned to be the beſt regulated of any in Europe. Every male from 16 to 60 is enrolled, and about one third of them regimented. They muſt all provide themſelves with arms, cloathing, and accoutrements, and appear on the ſtated days for exerciſe; and the ſeveral cantons and diſtricts muſt be furniſhed with a ſufficient train of artillery, and all the other implements of war. The Switzers of the ſeveral cantons are allowed to engage in the ſervice of ſuch foreign princes and ſtates as are in alliance with thoſe cantons, or with whom they have made a previous agreement. Such ſtates, paying an annual ſubſidy to the reſpective cantons, are allowed to make levies. Every man enliſts voluntarily, and for what number of years he pleaſes; at the expiration of which he is at liberty to return home. A great many thus always returning from foreign ſervice, Switzerland is never unprovided with able and experienced officers and ſoldiers. With reſpect to their character, they are a brave, honeſt, hoſpitable, hardy people; very true to their engagements, friendly, and humane. In ſhort, there is not a people in Europe whoſe national character is better. In their perſons they are generally tall, robuſt, and well-made; but their complexions are none of the beſt, and thoſe that live in the neighbourhood of the mountains are ſubject to wens. The women are ſaid to be generally handſome and well-ſhaped, ſenſible and modeſt, yet frank, eaſy, and agreeable in converſation. Few of the peaſants are miſerably poor; many of them are rich, eſpecially in the Proteſtant cantons, and that of Berne in particular.

SWIVELS, a kind of ring made to turn round in a ſtaple, or other ring. Theſe are uſed when a ſhip lies at her moorings; alſo in tedders for cattle, that they may turn round without unwarping the tedder. Swivels || Sydenham

Swivel-Cannon, is a ſmall piece of artillery belonging to a ſhip of war, which carries a ſhot of half a pound, and is fixed in a ſocket on the top of the ſhip's ſide, ſtern, or bow, and alſo in her tops. The trunnions of this piece are contained in a ſort of iron crotch, of which the lower end terminates in a cylindrical pivot reſting in the ſocket, ſo as to ſupport the weight of the cannon. The ſocket is bored in a ſtrong piece of oak, reinforced with iron hoops, in order to enable it to ſuſtain the recoil. By means of this frame, which is called the *swivel*, and an iron handle on its caſcable, the gun may be directed by the hand to any object. It is therefore very neceſſary in the tops, particularly when loaded with muſket balls, to fire down on the upper decks of the adverſary in action.

SWOONING. See MEDICINE, n° 274.

SWORD, an offenſive weapon worn at the ſide, and ſerving either to cut or ſtab. Its parts are, the handle, guard, and blade; to which may be added the bow, ſcabbard, pummel, &c.

Sword of State, which is borne before the king, lords, and governors of counties, cities, or boroughs, &c. For or before the king, it ought to be carried upright; the hilt as low as the bearer's waiſt, the blade up between his eyes. For or before a duke, the blade muſt decline from the head, and be carried between the neck and the right ſhoulder. For or before an earl, the blade is to be carried between the point of the ſhoulder and the elbow: and for or before a baron, the blade is to be borne in the bend of the arm. This ceremonial form no leſs denotes the dignity of a governor than the coronet ſet on his coat of arms.

Sword-Fiſh. See XIPHIAS.

SWORN BROTHERS *(fratres jurati)*, perſons who, by mutual oath, covenanted to ſhare each others fortune. Formerly, in any notable expedition to invade and conquer an enemy's country, it was the cuſtom for the more eminent ſoldiers to engage themſelves by reciprocal oaths to ſhare the rewards of their ſervice. This practice gave occaſion to the proverb of *ſworn brothers* or *brethren in iniquity*, becauſe of their dividing plunder and ſpoil.

SYCAMORE-TREE, in botany. See ACER.

SYCOPHANT, an appellation given by the ancient Athenians to thoſe who informed of the exportation of figs contrary to law; and hence it is ſtill uſed in general for all informers, paraſites, flatterers, cheats, &c.

SYDENHAM (Dr Thomas), an excellent Engliſh phyſician, was the ſon of Willian Sydenham of Winford Eagle in Dorſetſhire, and was born there about the year 1624. He ſtudied at Magdalen-hall, Oxford; but left that univerſity when Oxford was garriſoned for king Charles I. and went to London: where, becoming acquainted with Dr Thomas Cox, an eminent phyſician, that gentleman perſuaded him to apply himſelf to the ſtudy of phyſic; accordingly, after the garriſon was delivered up to the parliament, he retired again to Magdalen-hall, entered on the ſtudy of medicine, and in 1648 was created bachelor of phyſic. Soon after, he was made a fellow of All-Souls college, and continued there ſeveral years: when, leaving the univerſity, he ſettled at Weſtminſter, became doctor of his faculty at Cambridge; grew famous for his practice; and was the chief phyſician in London from the year 1660 to 1670; at which period he began to be diſabled by the gout. He died in 1689. His works are highly eſteemed both at home and abroad. He was famous for his cool regimen in the ſmall-pox; for giving the bark after the paroxyſm in agues; and

Syderopœcilus Sylla.

for his uſe of laudanum. He regulated his practice more by his own obſervations and inquiries, than by the method either of his predeceſſors or contemporaries.

SYDEROPŒCILUS, in natural hiſtory, the name of a ſtone mentioned by the ancients. It was found in Arabia, and ſeems to have obtained this name from its being ſpotted with a ferruginous colour. The deſcriptions of the ancients are, however, in this, as in many other inſtances, too ſhort to ſuffer us to gueſs what ſtone they meant.—This might poſſibly be a granite with ſpots of this peculiar colour.

SYENE, an ancient city of Egypt, ſituated, according to Mr Bruce, in north latitude 24° 0′ 45″. Pliny and Strabo both ſay that it lay directly under the tropic of Cancer. Whether Mr Bruce's authority be ſufficient to overturn the evidence of Pliny and Strabo, we ſhall leave to others to determine.

Syene is remarkable for being the place where the firſt attempt was made to meaſure the circumference of the earth. This was done by Eratoſthenes, whom Ptolemy Euergetes had invited from Athens to Alexandria. In this attempt two poſitions were aſſumed, viz. that Alexandria and Syene were exactly 5000 ſtadia diſtant from each other, and that they were preciſely under the ſame meridian; but both theſe are denied by Mr Bruce, who has made many obſervations on the ſubject, which our limits will not allow us to take notice of at preſent. He tells us, that there is at Aſuan an obeliſk erected by Ptolemy Euergetes, the patron of Eratoſthenes, without hieroglyphics, directly facing the ſouth, with its top firſt cut into a narrow neck, then ſpread out like a fan into a ſemicircular form, with pavements curiouſly levelled to receive the ſhade, and make the ſeparation of the true ſhadow from the penumbra as diſtinct as poſſible. This is ſuppoſed by Mr Bruce to have been conſtructed with a deſign to vary the experiment of Eratoſthenes with a larger radius; and the inquiry concerning the dimenſions of the earth, in our author's opinion, was the occaſion of many obeliſks being erected in this kingdom; a demonſtration of which is, that the figure of the top is varied; being ſometimes very ſharp, and ſometimes a portion of a circle, in order to get rid of the great impediment ariſing from the penumbra, which makes it difficult to determine the length of the ſhadow with preciſion. It is now called *Aſſouan*.

SYLLA (Lucius Cornelius), was deſcended from the illuſtrious family of the Scipios. His behaviour in his younger years by no means correſponded with the excellent education which he had received. But debauchery, inſtead of bringing along with it infamy and ruin, its uſual attendants, ſerved only to increaſe the wealth of this fortunate Roman; for Nocopolis, a rich courtezan, whoſe affections he had gained, left him heir to her great eſtate.—He learned the art of war under Marius, whom he attended to Numidia in quality of queſtor. Though hitherto unaccuſtomed to arms, he became in a ſhort time the moſt ſkilful ſoldier in the army, while by his polite and obliging behaviour he gained the love and eſteem of every body. His courage and dexterity contributed a great deal towards the ſucceſs of the war; it was his eloquence in particular that perſuaded Bocchus to deliver up Jugurtha. He ſerved afterwards in the ſocial war, where his actions entirely eclipſed thoſe of every other commander. As a reward for this conduct he was raiſed to the prætorſhip. It is pretended by ſome that Sylla purchaſed this dignity; and that when he threatened one day to make uſe of the powers of *his* office againſt Strabo the father of Pompey, that Roman replied with a ſmile, "You are in the right to ſay ſo; your office is certainly *yours*, ſince you purchaſed it." Be this as it may, after the concluſion of the ſocial war he was made conſul, and ſoon after declared general of the army which was to be ſent againſt Mithridates king of Pontus. Marius, at that time the moſt renowned of the Roman generals, expected that the management of this war would have been committed to him, and was therefore much exaſperated at the diſappointment. The people were perſuaded by his intrigues to reverſe the former decree, and ſubſtitute him in place of Sylla. Upon this he ſent down officers to take the command of the army; but Sylla by this time had gained over the ſoldiers; who inſtead of obeying the decree of the people, ſlew Marius's officers, and intreated Sylla to lead them inſtantly to Rome. Accordingly he entered the city ſword in hand ſlew Sulpicius the conſul, obliged Marius to flee, new-modelled the laws, and afterwards marched into the Eaſt, and immediately laid ſiege to Athens; for that city, together with the reſt of Greece, had fallen into the power of Mithridates. He wrote to the Amphyctions, who were aſſembled at Delphi, to ſend him all the gold which was depoſited in the temple of Apollo, becauſe he ſtood in need of money; promiſing, at the ſame time, to reſtore it again at the end of the war. When he received this treaſure, he obſerved, with an air of raillery, that he now no longer deſpaired of victory, ſince the gods themſelves furniſhed him with money to pay his troops. Famine ſoon obliged the Athenians to think of a ſurrender. Their ambaſſadors waited on Sylla, and began to harangue about Theſeus and Codrus, and Marathon and Salamis, —when he interrupted them, and exclaimed, "Go, repeat theſe fine orations in your ſchools; I have come hither, not to learn your hiſtory, but to chaſtiſe rebels." Athens was at laſt taken by aſſault, and Sylla was upon the point of deſtroying it, when he recollected its ancient glory, and ſpared (as he ſaid) the living for the ſake of the dead. After burning the Piræus, he gained two deciſive victories over the generals of Mithridates. In the ſecond battle, which was fought at Orchomenus, he was almoſt defeated; his troops began to flee, when, leaping from his horſe, he ſnatched up a ſtandard, and advanced againſt the enemy, crying out. "I will die here glorioufly; and, ſoldiers, when you are aſked where you abandoned your general, anſwer, at Orchomenus." This reproach recalled the courage of the Romans; they followed him to the charge, and gained a complete victory. Mithridates, humbled by theſe diſaſters, ſent ambaſſadors to ſue for peace.

Sylla.

Mean time Cinna had declared againſt Sylla in Italy; and Marius returning from baniſhment, had taken the moſt ſevere vengeance on all his enemies. Sylla was declared a traitor; his laws were reverſed, his friends murdered, and the government new-modelled. The news of theſe tranſactions induced Sylla to conclude a treaty with Mithridates, and march directly to Rome. His approach terrified the Romans. Marius and Cinna were both dead; but the conſuls made vigorous preparations to oppoſe him. A civil war was begun; but Sylla in the end ſubdued all his enemies, and entirely ruined the Marian faction. He entered Rome at the head of his victorious army, and publicly aſſumed the ſurname of *Happy*. Happy, indeed, had he ceaſed to live when he ceaſed to conquer. The remainder of his life contains nothing elſe but a catalogue of the moſt abominable cruelties. He declared that every one who expected pardon for their late offences, muſt gain it by deſtroying the enemies of the ſtate. The ſword of the aſſaſſin was thus unſheathed, and murder encouraged as the path to power and diſtinction. The nobleſt of the Romans were everywhere maſſacred; ſlaves were rewarded for cutting off their maſters; children were ſeen dragging their parents to execution; and brothers claiming a recompenſe for the mur-

Sylla ‖ Syllabus.

der of brothers. Sylla ordered 8000 wretches, who had thrown themſelves upon his clemency, to be butchered in the Campus Martius. In the mean time he entered the ſenate-houſe, and began to talk with great coolneſs about his exploits. The ſenate, alarmed at the horrid outcries of the ſufferers, at firſt thought that the city was given up to be plundered; but Sylla informed them, with an unembarraſſed air, that it was only ſome criminals puniſhed by his orders, and that they needed not be apprehenſive about their own fate.

To carry on theſe cruelties with the appearance of juſtice, he commanded the people to elect him dictator. He kept this office for more than two years; and then, to the amazement of all, laid it down, and offered to ſtand his trial before the people. Soon afterwards he retired into the country, and plunged headlong into every kind of debauchery. Nor did he relinquiſh his cruelty together with his power: His wife falling ill in the midſt of a ſumptuous feaſt, he divorced her immediately; and ordered her to be carried away, leſt her death ſhould interrupt the feſtivity of his houſe.

He died of the morbus pedicularis, in the 60th year of his age. His body, according to his orders, was burnt. A little before his death he wrote his epitaph; the tenor of which was that no man had ever exceeded him in doing good to his friends or injury to his enemies.

His perſon was elegant, his air noble, his manners eaſy and apparently ſincere. He was fond of pleaſure, but fonder of glory; indulging without ſcruple in ſenſual delights, but never ſuffering them to interrupt his ſerious buſineſs: He was eloquent, liberal, crafty, inſinuating; a profound maſter of diſſimulation; he ſpoke of himſelf with modeſty, while he laviſhed praiſes on every other perſon: He ſtooped even to an acquaintance with the meaneſt ſoldier, and conſtantly adapted himſelf to the humours, purſuits and opinions, of thoſe with whom he converſed. Such was his character during the earlier part of his life; but when ſucceſs had raiſed him above the neceſſity of diſſimulation, he diſplayed a hideous train of vices, which his ambition had formerly taught him to conceal.—It was Sylla who recovered the works of Ariſtotle at the taking of Athens.

SYLLABLE, in grammar, one or more letters pronounced by a ſingle impulſe of the voice, forming a complete ſound, and conſtituting a word or a part of a word. No ſingle letter can form a ſyllable except a vowel. The longeſt ſyllable in the Engliſh language is the word *ſtrength*.

The moſt natural way of dividing words into ſyllables is, to ſeparate all the ſimple ſounds of which any word conſiſts, ſo as not to divide thoſe letters which are joined cloſe together according to the moſt accurate pronunciation.

SYLLABUB, a kind of compound drink, moſt uſual in the ſummer ſeaſon; ordinarily made of white wine and ſugar, into which is ſquirted new milk with a ſyringe or wooden cow. Sometimes it is made of canary in lieu of white wine; in which caſe the ſugar is ſpared, and a little lemon and nutmeg are added in lieu of it. To prepare it the beſt way, the wine and other ingredients, except the milk, are to be mixed over night, and the milk or cream added in the morning. The proportion is, a pint of wine to three of milk. For

Syllabub, *whipt*, to half a pint of white wine or Reniſh is put a pint of cream, with the whites of three eggs. This they ſeaſon with ſugar, and beat with birchen rods, or work with a ſyringe. The froth is taken off as it riſes, and put into a pot; where, after ſtanding to ſettle two or three hours, it is fit to eat.

SYLLABUS, in matters of literature, denotes a table of contents, or an index of the chief heads of a book or diſcourſe.

SYLLOGISM, in logic, an argument or term of reaſoning, conſiſting of three propoſitions; the two firſt of which are called *premiſes*; the laſt, the *concluſion*. See Logic, Part III. Syllogiſm ‖ Sympathy.

SYLVIA, in natural hiſtory, a new genus of birds, belonging to the order of paſſeres, formed by Dr Latham by limiting the motacilla to the wagtail, and arranging the other ſpecies, formerly claſſed under that genus, under the ſylvia.

The motacilla he thus deſcribes: The beak is ſubulated, ſlender, and ſomewhat indented at the point. The tongue ſeems torn at the end, and the tail is long. He thus characterizes the ſylvia: The beak is ſubulated, ſtraight, and ſmall; the mandibles are nearly equal. The noſtrils are obovate, and a little depreſſed. The exterior toe is joined at the under part of the baſe of the middle one. The tongue is cloven, and the tail is ſmall. He makes 13 ſpecies of the motacilla, and 174 ſpecies of the ſylvia. See Motacilla.

SYMBOL, a ſign or repreſentation of ſomething moral, by the figures or properties of natural things. Hence ſymbols are of various kinds; as hieroglyphics, types, enigmas, parables, fables, &c.

SYMMACHUS, a citizen and ſenator of ancient Rome, and conſul in the year 391, has left us ten books of epiſtles; from which, as well as from other things, we collect, that he was a warm oppoſer of the Chriſtian religion. He was baniſhed from Rome by Valentinian on ſome account or other, but afterwards recalled and received into favour by Theodoſius. Ammianus Marcellinus ſpeaks of him as a man of great learning and modeſty. Scioppius, Pareus, and other learned men, have written notes upon the epiſtles of Symmachus: we know of no later edition of them than that of Frankfort, 1642, 8vo. Ambroſe biſhop of Milan wrote againſt Symmachus, and ſo did the Chriſtian poet, Prudentius.

SYMMETRY, the juſt proportion of the ſeveral parts of any thing, ſo as to compoſe a beautiful whole.

Symmetry, in painting. See Painting, Part I. Sect. III.

SYMONDSBOROUGH, a remarkable large barrow of Flints, near Wellington in Devonſhire, in the northern extremity of Hemyock. The common people have a notion that a king called *Symon* was buried here. The tradition of the country plainly ſhows that it was the burial-place of ſome perſon or perſons of eminence.

SYMPATHETIC, ſomething that acts or is acted upon by ſympathy. Thus we ſay, ſympathetic diſeaſes, inks, &c.

Sympathetic Inks. See *Sympathetic Ink.*

SYMPATHY, an agreement of affections and inclinations, or a conformity of natural qualities, humours, temperaments, which make two perſons delighted and pleaſed with each other.

Sympathy, alſo denotes the quality of being affected by the affection of another; and may ſubſiſt either between different perſons or bodies, or between different parts of the ſame body. It is either ſimilar or diſſimilar; ſimilar, when the affection or action in the ſympathiſer is ſimilar to the affection or action in the ſympathant; and diſſimilar, when thoſe are different.—Sympathy, too, is often an imitative faculty, ſometimes involuntary, frequently without conſciouſneſs: thus we yawn when we ſee others yawn, and are made to laugh by the laughing of another.

Sympathy, according to Dr Jackſon *, relates to the operations of the affections of the mind, to the operations of the imagination, and to the affections of the external ſenſes. * Treatiſe on Sympathy.

1. The paſſions and affections of the mind produce in the body different ſenſations and impreſſions, and, as ſympathies

of

Sympathy

of conſciouſneſs, determine in general the ſpirits to thoſe parts which labour moſt, or are moſt apt to be affected. Thus fear and anger determine to the heart; luſt to the eyes, &c.; joy, pity, wonder, and the like, to the head. See PASSION, page 14.

The affections of the mind of one perſon will often work upon the ſpirits of many. Thus whole companies are ſometimes diſpoſed to be ſad and melancholy, or merry and jovial, when any one is preſent much inclined to either of thoſe ſtates of mind; and it has been obſerved, that old people, who have loved the company of the young, and have been converſant continually with them, have generally lived long. But young people muſt not conclude from this, that the company and converſation of the grave and old will operate upon their living and ſenſitive principle, thro' the affections of their mind, and diſpoſe them to be ſhort-lived. On the contrary, by thus improving their underſtanding, they will be more enabled to fortify their conſtitution and reſiſt the ravages of youthful indulgence.

It may alſo be further obſerved, that thoſe tender ſympathetic affections which lay hold of the mind, at the repreſentation of theatrical performances, originate from the ſame principle, while they are to be conſidered as the ſureſt teſt of juſt execution in the actor, and of the expreſſive language of the author. Indeed all ſtage-effect depends on ſympathy.

It has been ſaid, that the paſſions of the mind are occaſionally infectious, particularly ſome of them. Thus *fear* and *ſhame* are ſometimes very ſuddenly ſo. We frequently may have occaſion to ſee, that the ſtarting of one will make another ready to ſtart. Again, when one man is out of countenance in company, others will often bluſh in his behalf. However, the ſerious paſſions may ſurely be ſo under the control of reaſon as to reſiſt infection, whatever may be the caſe of temporary, muſcular, or nervous attraction.

2. Our author is inclined to think, that a connection between the affections and ſenſations of the female mind and uterus, is very materially concerned in the proceſs of generation, and probably can alone give efficacy to thoſe actions and impreſſions ſubſervient to conception, through the ſympathizing affections of the mind. But this is a ſubject of which we know ſo little, that the ſpeculations of even the moſt diſtinguiſhed philoſophers reſpecting it have been nothing but the wild ravings of imagination.

With reſpect to the depravity and force of the imagination in the production of ſympathies, they always operate moſt upon "weak minds and ſpirits, and therefore moſt on women, ſuperſtitious and fearful perſons, ſick people, children, and young creatures." "Their effects, however, ſometimes fail to appear, becauſe they are encountered and overcome by the mind and ſpirit before they work any manifeſt effects."

Such effects are obviated upon the ſame principle which eſtabliſhes the prevention of bodily diſeaſe: "for in infection and contagion from body to body (as, for example, during the plague), the miaſma may be received; but from the ſtrength and good diſpoſition of the body, it is expelled and wrought out before it has had ſufficient time to form the diſeaſe."

It has been ſaid, and many are of the opinion, that the force of imagination doth often forward the end propoſed. Thus, for inſtance, it has been put as a queſtion, "Whether a man, when he conſtantly and ſtrongly believes that ſuch a thing ſhall be (as that ſuch a one will love him, and the like), helps any thing to the effecting the thing deſired?" Certainly not in the manner which has been advanced, namely, "by a ſecret operation on the ſpirit of another." If he ſucceeds, it is either becauſe he perſevered, or becauſe his perſeverance and earneſtneſs (and not any occult operation) makes him at length be attended to. Sympathy Symphonia.

There is not a doubt but the force of imagination often gives energy to our actions. It may, however, unleſs we are much on our guard, eaſily delude us aſide from reaſon. It has been the tree which has yielded the fruits of ſuperſtition in former times, and which has often fed the human mind with the moſt extravagant notions of ſympathy. Sympathies of this kind, ſuch as the power of charms, and the like, are now pretty generally exploded.

3. The five ſenſes, *hearing*, *taſting*, *ſmelling*, *feeling*, and *ſeeing*, are conſcious of a ſympathetic impreſſion from odious objects. "1. A diſagreeable ſound will ſet the teeth on edge, and make all the body ſhiver. 2. The ſwallowing of a nauſeous medicine will be attended with a ſhaking of the head and neck. 3. Diſagreeable ſmells produce nearly the ſame effect, which are leſs perceived, becauſe there is a remedy at hand by ſtopping the noſe. 4. If you come ſuddenly out of the ſun into the ſhade, the ſenſe of feeling is diſturbed by a chillneſs or ſhivering of the whole body. 5. And even ſudden darkneſs produces a propenſity to ſhivering.

There is a very apparent reaſon why a ſympathy ſhould take place between the eyes. Hence their motions are ſynchronous. It may be ſaid, that cuſtom and habit diſpoſe the eyes to move one and the ſame way; "for when one eye moveth towards the noſe, the other eye moveth from the noſe."

Though the eyes are by nature prone to move in concert, cuſtom will, however, deſtroy this natural concert, and produce the contrary effect. Thus ſome people can ſquint when they will. Our author therefore gives this caution to mothers and nurſes: "Let them not ſuffer infants to ſit with a candle placed behind them: for both their eyes will be diſpoſed to move outwards, as affecting to ſee the light of the candle, which may bring on the habit of ſquinting."

It appears as a quality in the ſenſes of hearing and ſeeing, "that the inſtrument of each ſeparate ſenſe has a ſympathy and ſimilitude to that which giveth the reflection." Thus it has been obſerved, "that the eye will ſympathize with a cryſtal glaſs or water, and the ear with caves and ſuch hollow places as are ſuited to report echo."

Sympathies have been compared to uniſons of ſound in muſic. Uniſons of ſound produce agreeable ſympathetic feelings; the reverſe produce diſagreeable feelings. "All concords and diſcords of muſic are (no doubt) ſympathies and antipathies of ſound." Moreover, "they are ſaid to work as well by report of ſound as by motion."

The moſt agreeable as well as odious objects operate in a ſecondary way, in producing thoſe ſympathetic impreſſions and actions which they commonly give riſe to. An increaſed ſecretion of ſaliva often takes place at the ſight of a favourite diſh: and the running of water from a bottle, or otherwiſe, will ſometimes affect individuals of a particular temperament, with an involuntary propenſity to void urine.

Many have attempted to account for the remarkable ſympathy which takes place between parts of the body ſeemingly unconnected with each other; but as theſe attempts are merely conjectures, without any ſolid principles to reſt on, we paſs them over as the dreams of ingenious men. It would be fortunate for ſcience, if men would confine themſelves to thoſe ſubjects which can be known, and never draw concluſions till they have eſtabliſhed principles.

SYMPHONIA, in botany; a genus of plants, belonging to the claſs of *monodelphia*, and order of *pentandria*.—There is one piſtil. The corolla is globular, and the berry five celled. There is only one ſpecies yet diſcovered, the globulifera.

Symphony ‖ Synagogue.

SYMPHONY, in muſic, properly denotes a conſonance or concert of ſeveral ſounds agreeable to the ear, whether vocal or inſtrumental, called alſo *harmony*. See HARMONY.

SYMPHYSIS, in anatomy, one of the kinds of junctures or articulation of the bones. See ANATOMY, n° 2.

Cutting the SYMPHYSIS *of the Pubes*. See MIDWIFERY, Part II. Chap. VII.

SYMPHYTUM, COMFREY, in botany: A genus of plants belonging to the claſs of *pentandria*, and order of *monogynia*; and in the natural ſyſtem, ranging under the 41ſt order *aſperifoliæ*. The limb of the corolla is tubular and ventricoſe, and the throat is ſhut with awl ſhaped rays. There are three ſpecies; the officinale, tuberoſum, and orientale.—The officinale is a Britiſh plant. The ſtem is about two feet high, round, branched, green, and rough. The radical leaves are very large and rough; thoſe on the ſtalk are decurrent, and alternate. The flowers grow on looſe ſpikes, and are either of a yelloviſh or purple colour. It grows on the banks of rivers, and flowers from May to October.

SYMPLOCE, *συμπλοκη*, in rhetoric a figure, where the ſame word is repeated ſeveral times in the beginning and end of a ſentence, including the ANAPHORA and EPITROPHE: thus, *Quis legem tulit? Rullus. Quis majorem populi partem ſuffragiis privavit? Rullus. Quis comitiis præfuit? Idem Rullus.*

SYMPLOCOS, in botany: A genus of plants belonging to the claſs of *polyadelphia*, and to the order of *polyandria*; and in the natural ſyſtem ranging under thoſe the order of which has not been determined. The calyx is quinquefid and inferior: the corolla is pentapetalous: the ſtamina are attached to the tube of the corolla in a fourfold ſeries. Only one ſpecies, the martinicenſis, is mentioned by Linnæus; but l'Heritier of the Academy of Sciences at Paris had added four more, the ciponima, arechea, tinctoria, and alſtonia.

SYMPOSIARCH, in antiquity, the director or manager of an entertainment. This office was ſometimes performed by the perſon at whoſe charge the entertainment was provided; ſometimes by another named by him; and at other times, eſpecially in entertainments provided at the common expence, he was elected by lot, or by the ſuffrages of the gueſts.

SYMPTOM, in medicine, any circumſtance which indicates the exiſtence, nature, or ſtage of a diſeaſe. Pain, waking, drowſineſs, convulſions, ſuppreſſion of urine, difficulties of breathing and ſwallowing, coughs, diſtaſtes, nauſeas, thirſts, ſwoonings, faintings, looſeneſs, coſtiveneſs, dryneſs and blackneſs of the tongue, are the principal *ſymptoms* of diſeaſes. See MEDICINE, n° 41, and 58.

SYMPTOMATICAL, in medicine, is a term often uſed to denote the difference between the primary and ſecondary cauſes in diſeaſes: thus a fever from pain is ſaid to be ſymptomatical, becauſe it ariſes from pain only.

SYNÆRESIS, CONTRACTION, in grammar, a figure whereby two ſyllables are united in one; as *vemens* for *vehemens*.

SYNAGOGUE, among the Jews, was a place where people met to worſhip God. Authors are not agreed about the time when the Jews firſt began to have ſynagogues:—Some will have them as old as the Ceremonial Law, and others fix their beginning to the times after the Babyloniſh captivity. They erected ſynagogues not only in towns and cities, but alſo in the country, eſpecially near rivers, that they might have water for their purifications and ceremonious waſhings. No ſynagogue was built in any town, unleſs there were ten perſons of leiſure in it; but there might be many in one town, or in one quarter of a town, provided it was very populous. Jeruſalem is ſaid to have contained 480. The chief things belonging to a ſynagogue were, 1. The ark or cheſt, made after the model of the ark of the covenant, containing the *Pentateuch*. 2. The pulpit and deſk in the middle of the ſynagogue, in which he that was to read or expound the law ſtood. 3. The ſeats or pews for the people. 4. The lamps to give light at evening ſervice, and the feaſt of dedication. 5. Rooms or apartments for the utenſils and alms cheſts. The ſynagogue was governed by a council or aſſembly, over whom was a preſident, called *The Ruler of the Synagogue*. Theſe are ſometimes called *Chiefs of the Jews*, *The Rulers*, *the Prieſts* or *Elders*, *the Governors*, *The Overſeers*, *The Fathers of the Synagogue*. Their buſineſs was to puniſh the diſobedient by cenſures, by excommunication, or by penalties, ſuch as fines and ſcourging; to take care of the alms, which are frequently called by the name of righteouſneſs. The chief ruler, or one of the rulers, gave leave to have the law read and expounded, and appointed who ſhould do it. In every ſynagogue, there were ſeveral miniſters who had different offices aſſigned to them. Service was performed three times a day, viz. in the morning, in the afternoon, and at night; at the time of morning ſacrifice, evening ſacrifice, and after the evening ſacrifice on Mondays, Thurſdays and Saturdays, there was a more forcible obligation upon the people to attend than upon the other days. There are ſynagogues at London, Amſterdam, Rotterdam, Avignon, Metz, &c.

Synalœpha ‖ Syncopation. Wilſon's Archæological Dictionary.

SYNALŒPHA, in grammar, a contraction of ſyllables, performed principally, by ſuppreſſing ſome vowel or diphthong at the end of a word, on account of another vowel or diphthong at the beginning of the next. As, *ill' ego*, for *ille ego*, &c.

Conticuer' omnes intentiqu' ora tenebant. Virg.

It is called by the Latins *colliſio*.

SYNARTHROSIS, SYNCHONDROSIS, } See ANATOMY, n° 2.

SYNCELLUS, or SINCELLUS, an ancient officer in the family of the patriarchs, and other prelates of the eaſtern church. The word, in the corrupt Greek, *συγκελλος*, ſignifies a perſon who lies in the chamber with another; a *chamber-fellow*, or *chum*. The ſyncellus was an eccleſiaſtic, who lived with the patriarch of Conſtantinople, to be a witneſs of his conduct; whence it is, that the ſyncellus was alſo called the *patriarch's eye*, becauſe his buſineſs was to obſerve and watch. The other prelates had alſo their ſyncelli, who were clerks living in the houſe with them, and even lying in the ſame chamber, to be witneſſes of the purity of their manners. Afterwards the office degenerated into a mere dignity; and there were made ſyncelli of churches.—At laſt it became a title of honour, and was beſtowed by the emperor on the prelates themſelves; whom they called *pontifical ſyncelli*, and *ſyncelli Auguſtales*.

SYNCHRONISM denotes the happening of ſeveral things at the ſame time. See CHRONOLOGY.

SYNCOPATION, in muſic denotes a ſtriking or beating of time, whereby the diſtinction of the ſeveral times or parts of the meaſure is interrupted. However, it is more properly uſed for the connecting the laſt note of any meaſure, or bar, with the firſt of the following meaſure, ſo as only to make one note of both. A ſyncope is ſometimes alſo made in the middle of a meaſure. Syncopation is alſo uſed when a note of one part ends or terminates on the middle of a note of the other part. This is otherwiſe denominated *binding*. It is likewiſe uſed for a driving note; that is, when ſome ſhorter note at the beginning of a meaſure, or half meaſure, is followed by two, three, or more longer notes before another ſhort note occurs,

Syncope ‖ Syngnathus.

curs, equal to that which occaſioned the driving, to make the number even, *e. gr.* when an odd crotchet comes before two or three minims, or an odd quaver before two, three, or more crotchets. In ſyncopated or driving notes, the hand or foot is taken up, or put down, while the note is ſounding.

SYNCOPE, FAINTING; a deep and ſudden ſwooning, wherein the patient continues without any ſenſible heat, motion, ſenſe, or reſpiration, and is ſeized with a cold ſweat over the whole body; all the parts, in the mean time, turning pale and cold, as if he was dead. See MEDICINE, n° 98. and 272.

SYNCOPE, in grammar, an eliſion or retrenchment of a letter or ſyllable out of the middle of a word, as *caldus* for *calidus*.

SYNDIC, in government and commerce, an officer, in divers countries, intruſted with the affairs of a city or other community, who calls meetings, makes repreſentations and ſolicitations to the miniſtry, magiſtracy, &c. according to the exigence of the caſe.

SYNECDOCHE, in rhetoric, a kind of trope frequent among orators and poets. See ORATORY, n° 56.

SYNECPHONESIS, in grammar, a coalition, whereby two ſyllables are pronounced as one; being much the ſame as SYNALOEPHA and SYNÆRESIS.

SYNEUROSIS. See ANATOMY, n° 2.

SYNGENESIA, (συν and γενεσις, "congeneration)," the name of the 19th claſs in Linnæus's artificial ſyſtem; comprehending thoſe plants which have the anthers united into a cylinder. The orders are ſix: 1. Polygamia æqualis. 2. Polygamia ſuperflua. 3. Polygamia fruſtranea. 4. Polygamia neceſſaria. 5. Polygamia ſegregata. 6. Monogamia. The five firſt orders contain the compound flowers, and form a claſs truly natural.

SYNGNATHUS, PIPE-FISH, according to Linnæus, a genus belonging to the claſs of *amphibia*, and order of *nantes*, but arranged by Gmelin more properly under the claſs of *piſces*, and order of *branchioſtegi*. The head is ſmall; the roſtrum ſomewhat cylindrical, long, and turned up at the point, where the mouth is placed, which is covered with a lid or valve. The gills are covered in the ſame manner. The body is covered with a ſtrong cruſt, and has no ventral fins. There are eight ſpecies; the tetragonus, typhele, acus, pelagicus, æquoreous, ophidion, barbarus, and hippocampus. Three of theſe are found in the Britiſh ſeas, *viz.*

1. The *barbarus*, or long pipe-fiſh. One deſcribed by Sir Robert Sibbald, was two feet in length; that examined by Mr Pennant only 16 inches. The noſe was an inch long, compreſſed ſidewiſe, and the end of the lower mandible turned up; the aperture of the mouth was very ſmall. The irides were red; behind each eye was a deep brown line. The body, in the thickeſt part, was about equal to a ſwan's quill, hexangular from the end of the dorſal fin; from thence to the tail, quadrangular. The belly was ſlightly carinated, and marked along the middle with a duſky line. Under the tail, commencing at the anus, is a ſulcus or groove ſix inches and a half long, covered by two longitudinal valves, which concealed a multitude of young fiſh. On cruſhing this part, hundreds may be obſerved to crawl out.

2. The *acus*, or ſhorter pipe-fiſh, is thicker than the former, yet it has been ſeen of the length of 16 inches. The middle of the body in ſome is hexangular, in others heptangular. The mouth is formed like that of the former: the irides are yellow: cloſe behind the head are the pectoral fins, which are ſmall and ſhort. On the lower part of the back is one narrow fin; beyond the vent the tail commences, which is long and quadrangular. At the extremity is a fin round and radiated. The body is covered with a ſtrong cruſt, elegantly divided into ſmall compartments. The belly is white; the other parts are brown. Synocha ‖ Synonymous.

3. The *ophidion*, or little pipe-fiſh, ſeldom exceeds five inches in length, is very ſlender, and tapers off to a point. It wants both the pectoral and tail fins; is covered with a ſmooth ſkin, not with a cruſt as the two former kinds are. The noſe is ſhort, and turns a little up; the eyes are prominent. On the back is one narrow fin. This ſpecies is not viviparous: on the belly of the female is a long hollow, to which adhere the eggs, diſpoſed in two or three rows. They are large, and not numerous. The ſynonym of *ſerpent* is uſed in ſeveral languages to expreſs theſe fiſh: the French call one ſpecies *orueul*, from a ſort of ſnake not unlike the blindworm: the Germans call it *meherſchlange*; and the corniſh the *ſea-adder*.

The Sea-horſe, which was claſſed by Artedi under the Syngnathus, is now, by latter ichthyologiſts, arranged under TRICHECUS; which ſee.

SYNOCHA, and SYNOCHUS, in medicine, the names of two ſpecies of continued fever. See MEDICINE, n° 164.

SYNOD, in aſtronomy, a conjunction or concourſe of two or more ſtars or planets, in the ſame optical place of the heavens.

SYNOD ſignifies alſo a meeting or aſſembly of eccleſiaſtical perſons to conſult on matters of religion.

Of theſe there are four kinds, viz. 1. *General*, or *œcumenical*, where biſhops, &c. meet from all nations. Theſe were firſt called by the emperors, afterwards by Chriſtian princes; till in latter ages the pope uſurped to himſelf the greateſt ſhare in this buſineſs, and by his legates preſided in them when called. 2. *National*, where thoſe of one nation only come together, to determine any point of doctrine or diſcipline. The firſt of this ſort which we read of in England, was that of Herudford or Hertford, in 672, and the laſt was that held by cardinal Pole, in 1555. 3. *Provincial*, where thoſe only of one province meet, now called the *convocation*. 4. *Dioceſan*, where thoſe of but one dioceſe meet, to enforce canons made by general councils, or national and provincial *ſynods*, and to conſult and agree upon rules of diſcipline for themſelves. Theſe were not wholly laid aſide, till by the act of ſubmiſſion, 25. Hen. VIII. c. 19. it was made unlawful for any *ſynod* to meet, but by royal authority. See COUNCIL and CONVOCATION.

SYNODS, *Provincial, in the Government of the Church of Scotland.* See PRESBYTERIANS, n° 14.

SYNODALS, or SYNODIES, were pecuniary rents (commonly of two ſhillings), paid to the biſhop, or archdeacon, at the time of their Eaſter viſitation, by every pariſh prieſt. They were thus called, becauſe uſually paid in ſynods; becauſe anciently biſhops uſed to viſit and hold their dioceſan ſynods once.—For the ſame reaſon, they are ſometimes alſo denominated *ſynodalica*; but more uſually, *procurations*.

SYNODICAL, ſomething belonging to a ſynod. Thus, ſynodical epiſtles are circular letters written by the ſynods to the abſent prelates and churches; or even thoſe general ones directed to all the faithful, to inform them of what had paſſed in the ſynod.

SYNOECIA, in Grecian antiquity, a feaſt celebrated at Athens in memory of Theſeus's having united all the petty communities of Attica into one ſingle commonwealth; the ſeat whereof was at Athens, where all the aſſemblies were to be held. This feaſt was dedicated to Minerva; and, according to the ſcholiaſt on Thucydides, it was held in the month *Metagitnion*.

SYNONYMOUS, is applied to a word or term that has the ſame import or ſignification with another.

Several

Synovia || Syracuſe.

Several works have been compoſed for the expreſs purpoſe of explaining ſynonymous words. In 1777 a work was publiſhed on the Latin ſynonyma at Paris by M. Gardin Dumeſnil. The abbé Girard publiſhed one on the ſynonymous terms of the French language many years ago. Another was publiſhed on the ſame ſubject in the year 1785 by the abbé Roubaud. An account of the Engliſh ſynonyma was publiſhed by an anonymous author in 1766; which is a cloſe imitation, and in ſome parts a literal tranſlation, of the abbé Girard's *Synonymes François*. We recollect, too, of ſeeing ſome eſſays of Mrs Piozzi on the ſame ſubject.

SYNOVIA, in medicine, a term uſed by Paracelſus and his ſchool for the nutritious juice proper and peculiar to each part. Thus they talk of the ſynovia of the joints, of the brain, &c.

SYNTAX, in grammar, the proper conſtruction or due diſpoſition of the words of a language into ſentences and phraſes. See GRAMMAR and LANGUAGE.

SYNTHESIS, in logic, denotes a branch of method, oppoſite to analyſis.

In the ſyntheſis or ſynthetic method, we purſue the truth by reaſons drawn from principles before eſtabliſhed or aſſumed, and propoſitions formerly proved; thus proceeding by a regular chain, till we come to the concluſion. Such is the method in Euclid's Elements, and moſt demonſtrations of the ancient mathematicians, which proceed from definitions and axioms, to prove propoſitions, &c. and from thoſe propoſitions proved to prove others. This method we alſo call *compoſition*, in oppoſition to *analyſis* or *reſolution*. See ANALYSIS.

SYPHILIS. See MEDICINE, n° 350.

SYPHON. See HYDROSTATICS, n° 25, 26. Some uncommon phenomena in nature may be accounted for upon the principles of the ſyphon; as for inſtance, that of reciprocating ſprings. See PNEUMATICS, n° 373.

1 At what time built.

SYRACUSE, once a celebrated city of Sicily, and the capital of the iſland. It was built, according to Thucydides and Strabo, by Archias, one of the Heraclidæ, who came from Corinth into Sicily in the ſecond year of the 11th Olympiad, deriving its name from a neighbouring marſh named *Syraco*.

2 Government originally monarchical.

What form of government firſt prevailed in the city is not known. Many have ſuppoſed it originally to have been governed by kings: but if this was the caſe, the monarchical government muſt have continued only for a very ſhort time; ſince Ariſtotle, Diodorus Siculus, and Juſtin, mention it as being very early ſubject to a democracy.

3 Soon becomes democratical.

The hiſtory, however, is obſcure and unimportant till the time of Gelon, when it firſt began to make a conſpicuous figure.

4 Gelon ſeizes on the ſovereignty.

Gelon was born in the city of Gela in Sicily, of the family of Telines, who had been created prieſt of the infernal gods. He ſignalized himſelf in a war carried on by Hippocrates tyrant of Gela againſt the Syracuſians, whom he defeated in a pitched battle, and had well nigh taken their city afterwards. Having thus become very powerful among his countrymen, he ſoon found means to ſeize on the ſovereignty for himſelf. In a ſhort time, having put himſelf at the head of ſome Syracuſian exiles, he marched towards that place, where he was received with loud acclamations by the faction to which they belonged; and by their means obtained poſſeſſion of the city.

5 Takes ſeveral cities, and removes the inhabitants to Syracuſe.

Gelon, in order to people the capital of his new dominions, firſt demoliſhed the neighbouring city of Camarina, and tranſplanted the inhabitants to Syracuſe. Soon after, entering into a war with the Megareans, he defeated them, took and raſed their cities, and in like manner tranſplanted the people. Syracuſe thus became very powerful, and full of inhabitants; and the friendſhip of Gelon was courted both by Athens and Lacedæmon at the time of the Perſian invaſion. His aſſiſtance, however, was afterwards rejected, as he inſiſted upon being made commander in chief either of the fleet or the army. In the mean time the Carthaginians had entered into a treaty with the Perſians; by which it was agreed, that the former ſhould attack thoſe of the Greek name in Sicily and Italy, in order to divert them from aſſiſting one another. Sicily was accordingly invaded by the Carthaginians with a vaſt army; but they were utterly overthrown by Gelon, as is related under the article CARTHAGE, n° 7.—9. After this victory, the people out of gratitude obliged him to take upon himſelf the title of king; which till that time he had refuſed. A decree alſo paſſed without oppoſition, by which the crown was ſettled on his two brothers Hiero and Thraſybulus after his death.

Syracuſe.

6 Defeats the Carthaginians, and takes the title of king.

7 His excellent reign.

The new king, inſtead of keeping his ſubjects in greater awe, ſtudied the more to make them happy as he found his power increaſed; and, according to Diodorus Siculus, was the firſt man who became more virtuous by being raiſed to a throne. He was particularly famous for his honeſty, truth, and ſincerity; is ſaid never to have wronged the meaneſt of his ſubjects, nor ever to have promiſed a thing which he did not perform.

8 Gelon dies and is ſucceeded by Hiero.

Gelon died in the year 471 B. C. after having reigned three or four years; and was ſucceeded by his brother Hiero, whoſe character is differently drawn by different hiſtorians. He was twice engaged in a war with the Agrigentines, and drove from their habitations the people of Catana and Naxus, ſettling in their room a colony of Syracuſians and Peloponneſians. He is highly celebrated in the odes of Pindar; and it is certain that his court was the reſort of men of wit and learning, to whom he behaved in the moſt courteous manner and with the greateſt liberality.

9 Thraſybulus, a tyrant.

In 459 B. C. Hiero was ſucceeded by Thraſybulus; who proving a tyrant, was in ten months driven out, and a popular government reſtored; which continued for the ſpace of 55 years. Several perſons continued for ſome time to aſpire at the ſovereign power; and to rid themſelves of theſe aſpiring geniuſes, the inhabitants made a law not unlike that of the oſtraciſm at Athens. By this law they were to write on a leaf the names of thoſe whom they ſuppoſed to be powerful enough to aſpire at the crown; and when the leaves were counted, he who had the moſt ſuffrages againſt him was, without further inquiry, baniſhed for five years. This method of weakening the intereſts of the overgrown citizens was called *petaliſm*, from the Greek word πεταλον, ſignifying a leaf; but being found to be productive of great inconveniences, by driving out of the country all thoſe who were moſt capable of governing the commonwealth, the law was repealed ſoon after it had been enacted.

10 Popular government reſtored.

11 Petaliſm introduced, but ſoon after aboliſhed.

12 The Siculi ſubdued.

About this time the Syracuſians entered into a war with the Siculi, which terminated in the total ſubjection of the latter; after which Syracuſe became ſo powerful, that it in a manner gave law to the whole iſland. The Greek cities indeed enjoyed a perfect liberty; but they all acknowledged Syracuſe as their metropolis: by degrees, however, the latter began to aſſume ſuch an authority over them as was totally inconſiſtent with liberty; and this occaſioned many wars, which involved them in much diſtreſs and danger. They began with the Leontines, whoſe territory they laid waſte, and reduced their city to great ſtraits. Leontini was an Athenian colony; and this furniſhed the Athenians, who had already meditated the conqueſt of Sicily, with a pretence to attack the Syracuſians with their whole force. Under colour of aſſiſting their countrymen, therefore, they ſent a fleet of 250 ſail to Sicily: but the Leontines, ſenſible

13 Syracuſians become haughty.

14 Invaded by the Athenians without ſucceſs.

that

Syracuſe. that their pretended allies aimed at nothing leſs than the conqueſt of the whole iſland, concluded a peace with Syracuſe; and the diſappointed Athenians vented their rage upon thoſe who had adviſed and conducted the expedition.

15 A new invaſion. In 416 B. C. a diſpute happening between the inhabitants of Egeſta and Selinus concerning ſome lands which the latter had ſeized, the Egeſtines applied for aſſiſtance to Agrigentum, Syracuſe, and even to Carthage. But as none of theſe ſtates choſe to intereſt themſelves in their quarrel, they applied at laſt to the Athenians, who joyfully accepted of the opportunity of again interfering in the affairs of Sicily. Though the Egeſtines were but an inconſiderable people, they had engaged to pay all the troops that ſhould be employed in the war; but this appearing doubtful to the Athenians, they ſent ambaſſadors to inquire into the ſtate of the iſland in general, and particularly that of Egeſta. The

16 Athenians impoſed on by the Egeſtines. Egeſtines impoſed on theſe ambaſſadors by producing a great number of gold and ſilver veſſels which they had borrowed for the purpoſe; ſo that the populace of Athens, dreaming of nothing but conqueſts to be made without any expence, became obſtinately bent on the war. Nicias, a man of great influence at Athens, attempted to ſhow, that as Athens was then engaged in a dangerous war with Sparta, it was impoſſible to ſpare a force ſufficient to reduce the iſland; but the contrary opinion being eſpouſed by Alcibiades, at that time the moſt eloquent ſpeaker in Athens, Nicias was over-

17 Ill-grounded confidence of the Athenians. ruled, and obliged to engage in the expedition. The force he required was only 5000 land forces and 100 galleys, with which, however inadequate to the purpoſe it may ſeem, the Athenians were ſo ſure of ſucceſs, that the officers, before they ſet ſail, had a conference with the ſenate concerning the diſpoſal of the Sicilians. In this conference it was agreed, that the Selinuntines and Syracuſians their ſuppoſed allies ſhould be carried off and ſold for ſlaves, and the reſt obliged to pay an annual tribute and live according to the Athenian laws.

With theſe ſanguine expectations the Athenian forces embarked to the number of 7000; for ſuch was their eagerneſs for the expedition, that 2000 more enliſted themſelves than Nicias had required. They firſt ſailed to the iſland of Egina, and from thence to Corcyra, where they had appointed the place of rendezvous for their allies and the tranſports. On their arrival they ſet ſail again, and landed on the coaſt of Italy, with a view to engage ſome of the Italian cities in their quarrel; but finding this impoſſible, they ſent ſome ſhips to cruiſe off the coaſt of Sicily, in order to find out a proper place for landing, and at the ſame time to know what treaſure the Egeſtines could contribute towards carrying on

18 Find out the deceit of the Egeſtines. the war, which had been undertaken for their ſake. Theſe, on their return, acquainted the generals, that the Egeſtines had impoſed on them, and were a poor indigent people, who had only 30 talents in the treaſury. On this information a council of war was called, in which Nicias gave it as his opinion that they ſhould ſail to Selinus, which had been the firſt occaſion of this expedition; and then, if the Egeſtines performed their promiſe, and ſupplied the army with a month's pay, to oblige the Selinuntines and Egeſtines to come to an agreement, and then return to Athens without engaging in ſuch an expenſive war. Alcibiades, however, again oppoſed Nicias; thinking it highly diſhonourable to return home without doing any thing, after having been at the expence of fitting out an armament. He therefore, urged, that they ſhould ſolicit the cities of Sicily to enter into a confederacy againſt the Syracuſians and Selinuntines; and, in caſe they found them diſpoſed to come into their meaſures, to attack either Syracuſe or Selinus. Another of the Athenian generals was for laying ſiege immediately to Syracuſe; but the opinion of Alcibiades prevailing, they ſet ſail for Sicily. Having accordingly landed in that iſland, they reduced ſeveral places; but Alcibiades in the mean time being recalled, Nicias and Lamachus were left to conduct the war as they beſt could. At firſt they were ſucceſsful, poſſeſſing themſelves of a ſtrong poſt, and put the Syracuſians to flight; ſoon after which they received conſiderable ſupplies both of men, money, and proviſions, from Athens, as well as from their Sicilian allies. The Syracuſians alſo received aſſiſtance from the Lacedæmonians under the command of an experienced officer named *Gylippus*. Before theſe arrived, the Athenians had poſſeſſed themſelves of an important poſt named *Epipolæ*, which being a very ſteep hill, ſtood without the city and commanded it. Immediately after this the city was inveſted in form. The inhabitants made frequent and vigorous ſallies; but were always repulſed with loſs. In one of theſe ſallies Lamachus was ſlain; and thus Nicias became ſole commander. He then cauſed the canals to be cut by which water was conveyed into the city; upon which the Syracuſians began to think of capitulating. From this, however, they were ſoon after prevented by the arrival of Gylippus with the Spartan auxiliaries. On this they prepared for making vigorous ſallies, in order to facilitate the entrance of Gylippus. While they were making theſe preparations, Gylippus himſelf appeared at the head of 3000 foot and 200 horſe. Making directly for Epipolæ, where Nicias had fortified himſelf in a caſtle named *Labdalon*, he drew up his ſmall army under the walls; and ſent an herald to Nicias, letting him know that he would allow him only five days to leave Sicily. To this meſſage Nicias returned no anſwer; but Gylippus ſoon after attacked the fort, carried it by ſtorm, and put to the ſword all the Athenians that were in it. This opened for him a way into the city, where he was received with loud acclamations.

Syracuſe.

19 Reduce ſeveral places.

20 Defeat the Syracuſians, and poſſeſs themſelves of a ſtrong poſt.

21 Syracuſe inveſted.

22 Gylippus arrives with ſome Spartans to the relief of Syracuſe.

23 Takes a fort and enters the city.

The fortune of the war was again changed. The Athenians gained an advantage by land, but were next day defeated with conſiderable loſs. The Syracuſians received freſh ſupplies from Corinth, and the Athenians from their own country. Many engagements both by ſea and land took place, in which the ſucceſs was ultimately in favour of the Syracuſians. At laſt the Athenian affairs were totally ruined by the loſs of a ſea-fight, in which 60 of their ſhips were taken or deſtroyed, and the reſt left quite unſerviceable. In this deſperate ſituation it was determined to abandon their ſhips, and retire that very night to the city of their confederates. The Syracuſian commander, ſuſpecting that this would be the caſe, ordered all his forces to be in readineſs to prevent them from effecting their purpoſe. But as the people were then in the height of their rejoicing for the late victory, they refuſed to take up arms again until they had reſted for ſome days. On this Hermocrates the general ſent to the Athenian camp ſome horſemen, who were to paſs for friends, and to adviſe Nicias not to quit his camp, which was well fortified, ſince the Syracuſians lay in ambuſh for him, and had ſeized on all the paſſes leading to the cities of their allies. To this falſe advice Nicias gave too eaſy credit, and did not march out till the third day, when his antagoniſt Hermocrates had prevailed upon his forces to march out. The Athenians and their allies alſo marched out to the number of no leſs than 40,000; but finding themſelves ſhut up on all ſides and being obliged to fight their way through every outlet, they ſoon ſunk into the deepeſt deſpair. Nicias did his utmoſt to encourage them; and at laſt ſucceeded ſo far that they marched out in two bodies, both drawn up in proper order. The vanguard led by Nicias continued to keep together, and advanced in good order; but half the rear, commanded by Demoſthenes, loſt their way in the night, and were obliged to ſurrender. Ni-

24 Athenians totally defeated at ſea.

26 Haraſſed in their retreat.

27 Part of the army ſurrenders.

cias

Syracuſe.

cias being informed of this misfortune, offered to pay the whole expence of the war, provided he was allowed to march off with his men. But this being rejected, he ſet out, tho' galled all the way by ſhowers of darts from his enemies. Arriving at a river called *Aſmarus*, they ruſhed into it without any order; in which confuſion the Syracuſian cavalry attacked them ſo deſperately, that 18,000 periſhed, and the river for many miles was dyed with their blood. On this occaſion the Athenians were ſo preſſed with thirſt, that, unmindful of their danger, they drank the waters of the river all bloody as they were, which gave their enemies the better opportunity of ſlaughtering them without reſiſtance. The remainder ſurrendered, on the ſingle condition of having their lives ſaved; but the terms were ſhamefully broken by the Syracuſians. The generals were firſt ignominiouſly whipt, and then put to death: the common ſoldiers were thruſt down into quarries, where they were allowed only two ſmall meaſures of flour and one of water a-day; and where, being crowded upon one another, they ſuffered inexpreſſible miſeries for many months. Moſt of them periſhed by this cruel treatment, and the few who ſurvived were ſold for ſlaves.

28 The reſt defeated with great ſlaughter.

29 The remainder ſurrender, and are cruelly uſed.

30 New invaſion by the Carthaginians.

The war was ſcarce ended, when a new and formidable invaſion by the Carthaginians took place; but the event of that expedition was as unfortunate to the Carthaginians as the former had been, of which a particular account is given under the article CARTHAGE, n° 12. *et ſeq.*

31 Riſe of Dionyſius.

In the mean time, however, a conſiderable revolution had happened in Syracuſe. The city of Agrigentum had been taken by the Carthaginians, and of the few inhabitants who eſcaped, ſome fled to Syracuſe, where they accuſed the Syracuſian commanders of having betrayed the city into the hands of the enemy. Dionyſius, a man of great valour and addreſs, but who had become very obnoxious to the populace; took this opportunity of attempting to retrieve his credit. He therefore ſupported the accuſations brought againſt his countrymen by the Agrigentines, and even impeached the magiſtrates as having a ſecret intelligence with the enemy, and attempting to introduce an oligarchy. As his ſpeech was entirely levelled againſt the more wealthy citizens, it was very agreeable to the lower claſs: the commanders were inſtantly degraded; and others, among whom was Dionyſius, were appointed. Having once gained this point, he began to conſider how he might get all his colleagues turned out. For this purpoſe he never joined in any council of war with the other commanders, nor imparted to them his reſolutions, giving out that he could not truſt them, and that they had more regard for their own intereſt than the welfare of their country. But while he was proceeding in this manner, the more prudent part of the citizens, perceiving what he aimed at, complained of him to the ſenate and magiſtrates, and fined him as a diſturber of the public peace. According to the laws, the fine was to be paid before he could ſpeak in public, and the circumſtances of Dionyſius did not allow him to diſcharge it. In this dilemma he was aſſiſted by Philiſtus the hiſtorian, a man of great wealth, who not only paid this fine for him, but encouraged him to ſpeak his mind freely, as it became a zealous citizen to do, promiſing to pay all the fines that ſhould be laid upon him.

Being extricated out of this difficulty, Dionyſius next proceeded to inveigh, with all the eloquence he was maſter of, againſt thoſe who by means of their power or intereſt were able to oppoſe his deſigns, and by degrees brought them into diſcredit. His next ſcheme was to get thoſe exiles recalled whom the nobility had baniſhed at different times; as thinking that they would ſupport him with all their power, as well out of gratitude as out of hatred to the oppoſite party. Having gained this point alſo, he next found means to ingratiate himſelf with the ſoldiery to ſuch a degree, that, under pretence of taking proper meaſures for reſiſting the Carthaginians, he was choſen commander in chief, with abſolute and unlimited power. This was no ſooner done, than, pretending that his life was in danger, he choſe out 1000 men for his guard, whom he attached to his intereſt by great promiſes. As no perſon durſt now oppoſe him, he poſſeſſed himſelf of the citadel, where all the arms and proviſions were kept; after which he publicly took the title of king of Syracuſe in the year 404 B. C.

Syracuſe.

32 Is choſen generaliſſimo.

33 Becomes king of Syracuſe.

The Syracuſians did not tamely ſubmit to their new maſter: but Dionyſius managed matters ſo well, that their frequent revolts anſwered no other purpoſe than more certainly to entail ſlavery on themſelves; and he was allowed to poſſeſs the throne without much oppoſition till his death, which happened in the year 366 B. C.

On the death of Dionyſius, he was ſucceeded by his ſon, called alſo *Dionyſius*. He was naturally of a mild and peaceable temper, averſe from cruelty, and inclined to learning; but his father, to whom all merit, even in his own children, gave umbrage, ſtifled as far as poſſible his good qualities by a mean and obſcure education. He no ſooner aſcended the throne, than Dion, brother to Ariſtomache the other wife of Dionyſius the Elder, undertook to correct the faults of his education, and to inſpire him with thoughts ſuitable to the high ſtation in which he was placed. For this purpoſe he ſent for the philoſopher Plato, under whoſe care he immediately put the young king. This inſtantly produced a reformation on Dionyſius; but the courtiers, dreading the effects of the philoſoper's inſtructions, prevailed on him to baniſh Dion, and to keep Plato himſelf in a kind of impriſonment in the citadel. At laſt, however, he ſet him at liberty; upon which Plato returned to his own country.

34 Dionyſius II.

35 Put under the care of Plato by his uncle Dion, whom he baniſhes.

Dion, in the mean time, viſited ſeveral of the Grecian cities, and at laſt took up his reſidence in Athens; but the honours which were everywhere paid him, raiſed ſuch jealouſies in the breaſt of the tyrant, that he ſtopped his revenue, and cauſed it to be paid into his own treaſury. In a ſhort time Dionyſius again ſent for Plato; but finding it impoſſible to diſſolve the friendſhip between him and Dion, diſgraced, and placed him in a very dangerous ſituation, in the midſt of aſſaſſins who hated him. Not daring, however, to offer him any violence, he allowed him ſoon after to depart; revenging himſelf on Dion, whoſe eſtate he ſold, and gave his wife Arete in marriage to Timocrates one of his own flatterers.

36 Uſes Plato ill, and provokes Dion to revenge.

Dion now reſolved to revenge himſelf on the tyrant for the many injuries he had ſuſtained, and at once to deliver his country from the oppreſſion under which it groaned. He began with raiſing foreign troops privately, by proper agents, for the better execution of his deſign. Many Syracuſians of diſtinction entered into his ſcheme, and gave him intelligence of what paſſed in the city; but of the exiles, of whom there were upwards of 1000 diſperſed up and down Greece, only 25 joined him; ſo much were they awed by the dread of the tyrant. The troops were aſſembled at the iſland of Zacynthus, in number only about 800; but who had all been tried on many occaſions, were well diſciplined, and capable of animating by their example the forces which Dion hoped to find in Sicily. When they were about to ſail, Dion acquainted them with his deſign, the boldneſs of which at firſt occaſioned no ſmall conſternation among them; but Dion ſoon removed their fears, by telling them that he did not lead them as ſoldiers, but as officers, to put them at the head of the Syracuſians and all the people of Sicily, who were ready to receive them with open

37 Dion raiſes troops for dethroning the tyrant.

38 His force very ſlender at firſt.

Syracuſe. arms. Having then embarked in two ſmall trading veſſels, they arrived in 12 days at Cape Pachynum near Syracuſe. Their pilot adviſed them to land immediately, leſt they ſhould be overtaken by a violent ſtorm, which he perceived was approaching; but Dion, judging it improper to land ſo near the enemy, commanded him to put to ſea again, and double the Cape.—This was no ſooner done that the ſtorm came on; and the two veſſels were driven on the coaſt of Africa, where they were in great danger of being loſt. At laſt they arrived at the port of Minoa, not far from Agrigentum. Here they received intelligence that Dionyſius had ſet ſail for Italy, attended by a fleet of 80 galleys. On this Dion reſolved to take advantage of the tyrant's abſence; and immediately ſet ſail for Syracuſe. On his march he prevailed upon the inhabitants of Agrigentum, Gela, Camarina, and other cities, to join him. As ſoon as he entered the territories of Syracuſe, multitudes flocked to him; and as nobody appeared to oppoſe him, he boldly entered the city, where he quickly found himſelf at the head of 50,000 men. As ſoon as he had landed in Sicily, Timocrates, to whom his wife Arete had been given by Dionyſius, and to whom the care of the city had been left, diſpatched a courier to let the tyrant know the danger in which he was. The meſſenger, when almoſt at his journey's end, found himſelf ſo much oppreſſed by fatigue, that he could not help lying down on the ground to take ſome reſt. In the mean time, a wolf, ſmelling ſome meat which he had in his wallet, came to the place and carried off the bag in which was the meat, together with the diſpatches. By this means Dionyſius was prevented from receiving a timely account of Dion's arrival; ſo that when he entered the citadel by ſea, ſeven days after Dion's arrival, he found his affairs in a deſperate ſituation. Upon this he had recourſe to artifice; and having amuſed the Syarcuſians by a feigned negotiation, until he obſerved that they kept a negligent guard, he attacked them all at once with ſuch fury, that he had almoſt taken the city. But Dion encouraged the ſoldiers by his example ſo much, that he at laſt obtained a complete victory; for which they preſented him with a crown of gold.

39 Is in great danger.

40 Enters Syracuſe without oppoſition.

41 Dionyſius arrives, but is totally defeated.

42 Ingratitude of the Syracuſians to Dion.

It was not long, however, before the ungrateful Syracuſians began to think of conferring quite different rewards on their benefactor. Dionyſius had the addreſs to render him ſuſpected by the multitude; at the ſame time that Heraclides, an excellent officer, but a ſecret enemy to Dion, did all that lay in his power to ſink his credit. In a ſhort time Dionyſius was obliged to fly into Italy: after which Heraclides, in order to ingratiate himſelf with the populace, propoſed a new diviſion of lands; inſinuating, that they could never enjoy perfect liberty as long as there was ſo much inequality in wealth and power among the citizens. This ſcheme was oppoſed by Dion, in conſequence of which a general combination was formed againſt him; and he was deſerted by all excepting the foreign troops whom he had brought with him into the iſland. The Syracuſians ſolicited even theſe to abandon the cauſe of their general: but their offers were rejected with diſdain; and Dion, with his faithful adherents, getting clear of the tumultuous and riotous populace, took the road to Leontini. The rabble purſued him, but were ſoon driven back: and Dion reſided for ſome time at Leontini, where he was received with all the reſpect due to his character.

43 He is obliged to leave the city.

In the mean time, the citadel ſtill continued in the hands of the adherents of Dionyſius. Being blocked up on all ſides, they were reduced to great ſtraits, and were actually making propoſals of capitulation, when Nypſius, an experienced general, and greatly attached to Dionyſius, appeared with a numerous ſquadron of galleys, and a large fleet of

44 A new advantage gained over the Dionyſians.

transports laden with proviſions. The general landed his men, and got them into the citadel; but almoſt all his galleys and ſhips laden with corn were ſunk or taken. This victory prevented the ruin of the Syracuſians; for, giving themſelves up to feaſting and debauchery, the enemy ſallied out in the night time from the citadel, and maſſacred the citizens without mercy. Being thus made ſenſible of the error they had committed, an embaſſy was ſent to Dion, intreating him to return and ſave the city a ſecond time. To this he agreed without heſitation; and inſtantly ſet out on his march, but in the mean time, as the ſoldiers of Dionyſius ſatiated with ſlaughter, had retired into their fortreſs, the urgrateful Syracuſians began to repent of their having ſent an embaſſy to Dion. The chief commanders, therefore, ſent meſſengers to ſtop his march; but as ſome of his friends ſent deputies to him at the ſame time, deſiring him to pay no regard to the former meſſage, he proceeded on his journey. The infatuated multitude ſeized the gates in order to diſpute his entrance; but they paid dear for their frenzy. The Dionyſians again ſallied out upon them, and made ſuch ſlaughter, that one would have thought they had left none alive in the city. As the troops of the tyrant well knew that Dion was haſtening to the relief of the city, they uſed their utmoſt endeavours to deſtroy it entirely before his arrival; for, after they had murdered all the inhabitants they could find, they ſet fire to the houſes, by which great numbers periſhed. During this confuſion Dion unexpectedly arrived; and having briſkly attacked the enemy, at laſt defeated them with great ſlaughter, driving the remainder into the citadel. During the reſt of the night, inſtead of refreſhing themſelves after their fatigues, they aſſiſted in extinguiſhing the fire; which was not done without great danger and difficulty. The citadel ſoon after ſurrendered; and Dion allowed Apollocrates the tyrant's ſon, who commanded there, to retire with five galleys to his father. As ſoon as Dion entered the citadel, he was met by his ſiſter and wife Arete, whom he received with affection, notwithſtanding her having lived ſo long with Timocrates. He then left the Syracuſians in poſſeſſion of the citadel, rewarded his followers, diſmiſſed his guards, and continued to live like a private citizen.

Syracuſe.

45 The inhabitants maſſacred by the garriſon of the citadel.

46 A ſecond maſſacre, and the city ſet on fire.

47 The Dionyſians defeated with great ſlaughter by Dion

As ſoon as Dion had got poſſeſſion of the city, Heraclides had ſubmitted to him, and been received into favour; but as his ſeditious and turbulent behaviour ſtill continued, Dion at laſt gave orders to put him to death. This action, however neceſſary, ſo affected the mind of Dion, that he became melancholy; and ever after imagined himſelf haunted by a frightful ſpectre, reſembling a woman of gigantic ſtature, with the haggard looks and air of a fury. In a ſhort time after he loſt his life, through the baſe treachery of Calippus, or Gylippus, who pretended to be his intimate friend, and who immediately after cauſed his wife and ſiſter to be carried to priſon.

48 Dion becomes melancholy, and is murdered.

Calippus having thus removed Dion, ſoon made himſelf maſter of Syracuſe, where he commited all manner of cruelties; but was driven out, and forced to fly to Rhegium, where he was murdered with the ſame dagger which had killed Dion. In 350 B. C. Dionyſius again made himſelf maſter of Syracuſe; and being exaſperated by his paſt misfortunes, tyrannized worſe than ever. The Syracuſians firſt had recourſe to Icetas tyrant of Leontini; but as the Carthaginians took this opportunity to invade them with a powerful fleet and army, they were obliged to apply to the Corinthians. By them Timoleon, a celebrated commander, was ſent to the aſſiſtance of the Syracuſians, whom he found in a very diſtreſſed ſituation; Icetas being maſter of the city, the Carthaginians of the harbour, and Dionyſius of the citadel. As all parties were equally the enemies of Dionyſius,

49 Dionyſius reſtored.

Syracuſe.

50 Surrenders to Timoleon, and keeps a ſchool at Corinth.

ſius, he found it impoſſible to hold out, and therefore ſurrendered himſelf to Timoleon, by whom he was ſent to Corinth; where at laſt he was reduced to the neceſſity of teaching a ſchool for his ſupport.

After the expulſion of the tyrant, Timoleon withdrew to Catana, leaving only 400 Corinthians under the command of an experienced officer named *Leon*, to guard the citadel. Theſe were immediately beſieged by Icetas and the Carthaginians, but Timoleon found means to relieve them in ſpite of all oppoſition; and having diſperſed emiſſaries through the army of Mago the Carthaginian general, exhorting the mercenary Greeks to forſake him, he was ſo much intimidated, that in ſpite of all the remonſtrances Icetas could make, he ſet ſail for Africa, leaving his colleague to carry on the war in the beſt manner he could.

51 Cowardice of the Carthiginians.

The day after the departure of Mago, Timoleon aſſaulted the city ſo briſkly, that the troops of Icetas were driven from the walls, and the Corinthians became maſters of the place. Timoleon, by ſound of trumpet, invited the inhabitants to come and aſſiſt in demoliſhing the citadel and other caſtles, which he called the *neſts of tyrants*; after which he cauſed edifices to be erected in the place where the citadel had ſtood, for the adminiſtration of juſtice. He found the city in a moſt miſerable ſituation: for many having periſhed in the wars and ſeditions, and others having fled to avoid the oppreſſion of tyrants, Syracuſe, once ſo wealthy and populous, was now become almoſt a deſert; inſomuch that the horſes were fed on the graſs which grew on the market-place. Timoleon ſupplied the city with inhabitants from Corinth and other cities of Greece, at the ſame time that great multitudes from Italy and the other parts of Sicily reſorted thither. Timoleon diſtributed the lands among them *gratis*; but ſold the houſes, and with the money ariſing from the ſale eſtabliſhed a fund for the ſupport of the poor. Having thus reſtored Syracuſe, he in like manner delivered all the Greek cities of Sicily from the tyrants who had taken poſſeſſion of them, all of whom he put to death. After this he reſigned his authority, and led a retired life, honoured in the higheſt degree by the Syracuſians, and by all the cities in Sicily. After his death he was honoured as a god; the expence of his funeral was defrayed by the public; ſports, with horſe-races and gymnaſtic exerciſes, were held annually on the day of his death; and it was decreed, that whenever the Syracuſians were at war with the barbarians, they ſhould ſend to Corinth for a general.

52 Citadel of Syracuſe and other forts demoliſhed by Timoleon.

53 He repeoples the city.

54 Dies, and is honoured as a god.

For 20 years the Syracuſians enjoyed the fruits of Timoleon's victories; but new diſturbances ariſing, in a ſhort time another tyrant ſtarted up, who exceeded all that had gone before him in cruelty and other vices. This was the celebrated Agathocles, of whoſe exploits againſt the Carthaginians a full account is given under the article CARTHAGE, n° 33—53. He was poiſoned by one Mœnon in the year 289 B. C. after having reigned 28 years, and lived 95.—A ſucceſſion of tyrants followed, till at laſt the city, being held by two rivals, Tœnion and Soſiſtratus, who made war within the very walls, Pyrrhus king of Epirus was invited into Sicily, in order to put an end to theſe diſtractions. He willingly complied with the invitation; and was everywhere received with loud acclamations, as the deliverer not only of Syracuſe, but of all Sicily. As he had a fine army of 30,000 foot and 5000 horſe, with a fleet of 200 ſail, he drove the Carthaginians from place to place, till he left them only the two ſtrong poſts of Eryx and Lilybæum. The former of theſe he took by aſſault, and was himſelf the firſt man who mounted the walls, after having killed a great number of Africans with his own hand. The Mamertines likewiſe, who had conquered a conſiderable part of the iſland, were everywhere defeated and driven out, till at laſt they were ſhut up in the city of Meſſana. The Carthaginians, alarmed at the rapidity of his conqueſts, ſent ambaſſadors with propoſals of peace upon very advantageous terms; but Pyrrhus, puffed up with the expectation of reducing the whole iſland, refuſed to hearken to any terms unleſs they would inſtantly abandon it. So firm was he in the belief of this, that he cauſed his ſon take upon him the title of *king of Sicily*; but in the mean time, having diſpleaſed the Sicilians by his arbitrary behaviour, they deſerted from him in ſuch numbers that he was glad to ſet out for Italy, for which retreat the embaſſies he received from the Samnites, Tarentines, and other Italians, furniſhed him with an honourable pretext. He embarked in the ſhips which he had brought with him from Italy; but was met at ſea by the Carthaginians, who ſunk 70 of his veſſels, and diſperſed or took the reſt; ſo that he ſaved himſelf in Italy only with 12 veſſels, the poor remains of a fleet of 200 ſail. No ſooner were the Mamertines appriſed of his departure, than they diſpatched a body of 18,000 men to haraſs him after his landing. Theſe, having paſſed the ſtraits before him, poſted themſelves in the road which Pyrrhus muſt take in marching by land to Tarentum; and concealing themſelves among woods and rocks, attacked him unexpectedly, and with great reſolution. But Pyrrhus behaved on this occaſion with his uſual bravery. The attack being made on his rear, he haſtened thither, and made a dreadful ſlaughter of the enemy, till a wound on his head obliged him to retire. As he was ſuppoſed to be diſabled by this wound, a proud Mamertine, of an extraordinary ſize, and ſhining in bright armour, advanced, and with a loud voice challenged the king of Epirus if he was yet alive, to a ſingle combat. Pyrrhus immediately turned about, and making a dreadful appearance by reaſon of the blood which ran down his face, flew at this new champion, on whoſe head he diſcharged ſuch a furious blow, that he cleft his body aſunder; one half falling to the right, and the other to the left. This incredible feat, which has ſince been aſcribed to other warriors, perhaps with as much truth as to Pyrrhus, ſo much intimidated the Mamertines, that they allowed his troops to continue their march unmoleſted.

55 Syracuſe again falls under the power of tyrants.

56 Pyrrhus king of Epirus invited into Sicily.

57 Conquers a great part of the iſland.

58 Behaves in a haughty manner, and is obliged to return into Italy.

59 Haraſſed by the Mamertines.

60 Aſtoniſhing exploit of Pyrrhus.

After the departure of Pyrrhus, Hiero the ſon of Hierocles, a deſcendant of Gelon the firſt king of Syracuſe, was choſen general of the forces, along with another named *Artemidorus*. The two generals had nothing more at heart than to put an end to the confuſion and diſorder which reigned in the city; for which reaſon they entered it at the head of their forces. On this occaſion Hiero diſcovered extraordinary talents for government. By mere dint of inſinuation and addreſs, without ſhedding blood, or hurting a ſingle citizen, he calmed the minds of the people; reconciled the factions; and ſo gained the affections of all, that he was inveſted with the whole civil as well as military power in the ſtate. Soon after this, he married the daughter of one of the firſt citizens; and having diſtinguiſhed himſelf by his exploits againſt the Mamertines, was unanimouſly elected king of Syracuſe, in the year 265 B. C.

61 Hiero choſen general of the Syracuſian forces.

62 Is elected king of Syracuſe.

Some time after Hiero's acceſſion to the throne, he again defeated the Mamertines, and reduced them to ſuch ſtraits, that they were obliged to call in the Romans to their aſſiſtance. The conſequences of this have been fully related under the articles ROME and CARTHAGE. Hiero, who had allied himſelf with the Carthaginians being himſelf defeated by the Romans, and finding his allies unable to protect him againſt the power of that republic, concluded an alliance with them; and continued faithful to them even in the time of the ſecond Punic war, when they were in the greateſt diſtreſs. In his reign flouriſhed the celebrated mathematician Archimedes, whoſe genius he employed in fortifying the

63 Lives in ſtrict friendſhip with the Romans.

Syracuſe. the city of Syracuſe, by innumerable machines, in ſuch a manner as rendered it abſolutely impregnable to every method of attack known at that time.

64 Hieronymus allies with the Carthaginians.

Hiero died about 211 B. C. and was ſucceeded by his grandſon Hieronymus: but he imprudently forſook the counſels of his grandfather, and entered into an alliance with the Carthaginians. Soon after this he was murdered, in conſequence of his tyranny and cruelty, and the greateſt diſorders took place in the city; which Hannibal, though then in Italy, found means to foment, in hopes of keeping the Syracuſians in his intereſt. This indeed he effected; but as his own affairs in Italy began to decline*, he could not prevent Marcellus from landing in Sicily with a formidable army, which the Sicilians could by no means reſiſt. Syracuſe was ſoon inveſted; but the machines invented by Archimedes baffled all attempts to take it by aſſault. It was 22 miles in compaſs, and conſiſted properly of five cities in one, viz. Ortygia, Acradina, Tyche, Neapolis, and Epipolæ.—Ortygia was a ſmall iſland very near the continent, and might be called the *citadel of Syracuſe*, being joined to Acradina by a bridge. The immenſe preparations which the conſul had made for taking the city by ſtorm, could not have failed to accompliſh his purpoſe, had the place been otherwiſe defended than by the contrivance of Archimedes. The Roman fleet conſiſted of 60 quinqueremes, beſides a far greater number of other ſhips. The decks were covered with ſoldiers armed with darts, ſlings, and bows, to drive the beſieged from the ramparts, which on the ſide of Acradina were waſhed by the ſea, and to facilitate the approach to the walls. But a machine of Marcellus's own invention was what he chiefly depended on. He had faſtened together ſidewiſe eight galleys of different lengths, which made but one large body, and were rowed only by the oars of the outermoſt galleys. Theſe eight galleys thus joined, ſerved only as a baſis for a machine, which was raiſed up higher than the higheſt towers of the walls, and had at the top a platform guarded with parapets in front and on each ſide. This machine was called a *ſambuca*, from its reſemblance to a muſical inſtrument of that name, not unlike an harp. The conſul's deſign was to bring his ſambuca to the foot of the walls of Acradina; but, while it was at a conſiderable diſtance (and it advanced very ſlow, being moved only by two ranks of rowers), Archimedes diſcharged from one of his engines a vaſt ſtone, weighing, according to Plutarch's account, 1250 pounds, then a ſecond, and immediately after a third; all which, falling upon the ſambuca with a dreadful noiſe, broke its ſupports, and gave the galleys upon which it ſtood ſuch a violent ſhock that they parted, and the machine which Marcellus had raiſed upon them at a vaſt trouble and expence was battered to pieces. At the ſame time, ſeveral other machines, which were not viſible without the walls, and conſequently did not leſſen the confidence of the Romans in the aſſault, played inceſſantly upon their ſhips, and overwhelmed them with ſhowers of ſtones, rafters, and beams pointed with iron; inſomuch that Marcellus, being at a loſs what to do, retired with all poſſible haſte, and ſent orders to his land-forces to do the ſame; for the attack on the land-ſide was attended with no better ſucceſs, the ranks being broken and thrown into the utmoſt confuſion by the ſtones and darts, which flew with ſuch noiſe, force, and rapidity, that they ſtruck the Romans with terror, and daſhed all to pieces before them.

* See Carthage, n° 123.

65 Syracuſe inveſted.

66 Great force of the Romans by ſea and land.

67 Machine invented by Marcellus.

68 Deſtroyed by Archimedes.

69 Incredible effects of the machines of Archimedes.

Marcellus, ſurpriſed, though not diſcouraged, at this artificial ſtorm, which he did not expect, held a council of war, in which it was reſolved, the next day before ſun-riſe, to come up cloſe under the wall, and keep there. They were in hopes by this means to ſecure themſelves againſt the terrible ſtorm of ſtones and darts which fell on the ſhips when at a diſtance. But Archimedes had prepared engines which were adapted to all diſtances. When the Romans therefore had brought their ſhips cloſe under the wall, and thought themſelves well covered, they were unexpectedly overwhelmed with a new ſhower of darts and ſtones, which fell perpendicularly on their heads, and obliged them to retire with great precipitation. But they were no ſooner got at ſome diſtance, than a new ſhower of darts overtook them, which made a dreadful havock of the men, while ſtones of an immenſe weight, diſcharged from other machines, either diſabled or broke in pieces moſt of their galleys. This loſs they ſuſtained, without being able to revenge it in the leaſt on the enemy. For Archimedes had placed moſt of his engines behind the walls, and not only out of the reach, but even out of the ſight, of the enemy; ſo that the Romans were repulſed with a dreadful ſlaughter, without ſeeing the hand that occaſioned it; as if they had been fighting, to uſe Plutarch's expreſſion, not with men, but with the gods themſelves. What moſt haraſſed the Romans in the attack by ſea, was a ſort of crow with iron claws, faſtened to a long chain, which was let down by a kind of lever. The weight of the iron made it fall with great violence, and drove it into the planks of the galleys. Then the beſieged, by a great weight of lead at the other end of the lever, weighed it down, and conſequently raiſed up the iron of the crow in proportion, and with it the prow of the galley to which it was faſtened, ſinking the poop at the ſame time into the water. After this the crow letting go its hold all of a ſudden, the prow of the galley fell with ſuch force into the ſea, that the whole veſſel was filled with water, and ſunk. At other times, the machines, dragging ſhips to the ſhore by hooks, daſhed them to pieces againſt the points of the rocks which projected under the walls. Other veſſels were quite lifted up into the air, there whirled about with incredible rapidity, and then let fall into the ſea, and ſunk, with all that were in them. How theſe ſtupendous works were effected, few, if any, have hitherto been able to comprehend.

Syracuſe.

The troops under the command of Appius ſuffered no leſs in this ſecond attack than the fleet. In the whole ſpace of ground which the army, when formed, took up, the laſt files as well the as firſt were overwhelmed with ſhowers of darts and flints, againſt which they could not poſſibly defend themſelves. When they had with infinite trouble brought the mantelets and covered galleries, under which they were to work the rams, near the foot of the wall, Archimedes diſcharged ſuch large beams and ſtones upon them as cruſhed them to pieces. If any brave Roman ventured to draw too near the wall, iron hooks were immediately let down from above, which, taking hold of his clothes or ſome part of his body, lifted him up in the air and daſhed out his brains with the fall. Marcellus, though at a loſs what to do, could not however forbear expreſſing himſelf with pleaſantry: Shall we perſiſt, ſaid he to his workmen, in making war upon this Briareus, upon this giant with an hundred hands? But the ſoldiers were ſo terrified, that if they ſaw upon the walls only a ſmall cord, or the leaſt piece of wood, they immediately turned their backs and fled, crying out, that Archimedes was going to diſcharge ſome dreadful machine upon them.

70 The ſiege turned into a blockade.

The conſuls, finding themſelves thus defeated in every attempt, turned the ſiege into a blockade, reduced moſt of the other places in the iſland, and defeated the forces which were ſent againſt them; and at laſt Marcellus made himſelf maſter of Syracuſe itſelf, of which the following account is given by Mr Hooke. "He took the opportunity of a feſtival, when the ſoldiers and citizens had drunk plentifully, to make a detachment ſcale the walls of Tyche, in that part

71 Mr Hooke's account of the taking of Syracuſe.

Syracuſe. of it which was neareſt to Epipolæ, and which was ill-guarded. He preſently after poſſeſſed himſelf of Epipolæ; whereupon the inhabitants of Neapolis, as well as Tyche, ſent deputies to him, and ſubmitted. Marcellus granted life and liberty to all of free condition, but gave up thoſe quarters of the city to be plundered.

"Notwithſtanding this, there was a great deal yet to do. Acradina and Ortygia, which were ſtrongly fortified, ſtill held out; Hippocrates and Hamilco arrived with their troops to the relief of the beſieged; and the Romans were forced to exert all their bravery and ſkill to maintain the advantages they had gained.

"But now a plague made terrible havock in both armies. At the firſt breaking out of the peſtilence the Sicilians, who ſerved under Hippocrates and Hamilco, diſbanded themſelves, and returned to their reſpective homes; but all the Carthaginian ſoldiers periſhed, together with thoſe two generals. The Romans ſuffered leſs by the infection; becauſe, having been a long time before Syracuſe, they were ſeaſoned to the air and water of the country.

"About this time Bomilcar arrived on the coaſt of Sicily from Carthage, with a fleet of 130 galleys and 700 ſhips of burden; but was long hindered by contrary winds from doubling the Cape of Pachynum. Epicydes, fearing the Carthaginian might ſail back to Africa, left the command of Acradina to the generals of the mercenaries, and went to Bomilcar, in order to perſuade him to fight the Roman fleet. The admiral would not engage, but ſailed away to Tarentum with all his galleys, ordering his ſhips of burden to return to Africa. Epicydes, thus fruſtrated of his hopes, and knowing himſelf unable to defend a city already half taken, retired to Agrigentum; whereupon the Syracuſians maſſacred the commanders appointed by him, choſe new prætors to govern in the town, and ſent deputies to Marcellus to treat of peace. In the mean time, the deſerters, fearing to be given up to the vengeance of the Romans, perſuaded the mercenaries that they alſo would have the ſame fate. Inſtantly the ſoldiers ran to arms, put to death the new prætors, together with many of the Syracuſians, and plundered part of the city. After this ſlaughter they choſe ſix generals, three to command in Acradina, and three in Ortygia. Upon the return of the deputies from Marcellus, the mercenaries finding that their caſe was different from that of the deſerters, and that there was no deſign againſt their lives, became perfectly ſatisfied, and the negotiation went on. During the courſe of the treaty, Marcellus found means to corrupt Mericus, a Spaniard, one of the ſix generals choſen by the ſoldiers, and engaged him to admit the Romans into that part of the city where he commanded. Mericus, the better to accompliſh this deſign, feigned an extraordinary zeal for the preſervation of that place; pretended not to like that deputies ſhould have leave to go out and in at pleaſure; and propoſed, that for the greater ſecurity of the town, each general ſhould have a diſtinct quarter aſſigned him, and be reſponſible for any neglect of duty in it. The motion was agreed to; and upon the diviſion, that diſtrict of Ortygia which extended from the fountain of Arethuſa to the mouth of the great port fell to his care. Marcellus, informed of what was done, took his meaſures accordingly. He ſent a body of troops to that ſide where Mericus commanded, and the Spaniards admitted them at the gate of Arethuſa. At the ſame time, the proconſul ordered a falſe attack to be made on Acradina; which drawing almoſt all the ſoldiers of the garriſon thither, Ortygia was in a manner left defenceleſs. Foreſeeing this, he had detached another party of ſoldiers to take advantage of it. Theſe entered Ortygia almoſt without fighting; upon which the deſerters made their eſcape, the Romans giving them way; and the Syracuſians in Acradina, thus delivered from the fear of the deſerters, immediately opened their gates to Marcellus, who thereby became maſter of the whole city. Syracuſe.

72 The city plundered, and Archimedes killed.

"And now the conqueror, who is ſaid to have wept during the ſiege with compaſſion for the inhabitants, gave up both Ortygia and Acradina to be plundered by his army, after he had ſecured the late king's treaſures for the uſe of his republic, and the ſtatues, paintings, and principal ornaments of Syracuſe to illuſtrate his triumph. The ſoldiers had orders to ſpare the lives of the citizens; but they were cruel in their avarice, ſlew many of them, and among the reſt the incomparable Archimedes. He was very intent on a demonſtration in geometry, and calmly drawing his lines, when a ſoldier entered the room, and clapped a ſword to his throat. "Hold! (ſaid Archimedes) one moment, and my demonſtration will be finiſhed." But the ſoldier, equally regardleſs of his prayer and his demonſtration, killed him inſtantly. There are different accounts of the manner of his death; but all agree that Marcellus regretted it extremely, and ſhowed a ſingular favour to his relations for his ſake."

73 Syracuſe deſtroyed by the Saracens.

The city of Syracuſe continued ſubject to the weſtern empire till its declenſion, when the iſland of Sicily, being ravaged by different barbarians, the capital alſo underwent various revolutions; till at laſt, in the 9th century, it was ſo deſtroyed by the Saracens, that very few traces of its ancient grandeur are now to be ſeen. "The ancient city of Syracuſe was of a triangular form, and conſiſted of five parts or towns. The circuit, according to Strabo, amounted to 180 ſtadia, or 22 Engliſh miles and four furlongs. An account (ſays Mr Swinburne) which I once ſuſpected of exaggeration; but, after ſpending two days in tracing the ruins, and making reaſonable allowances for the encroachments of the ſea, I was convinced of the exactneſs of his meaſurement. Travels in the two Sicilies, vol. ii. p. 327, &c.

"At preſent it is ſtrongly fortified towards the land, and the ditches of the baſtions form the communications between the two havens. It is very weak towards the ſea, but the ſhelves render it hazardous to debark on that ſide. The garriſon is one of the beſt appointed in the kingdom, but the heights of Acradina command the works.

"About eighteen thouſand inhabitants are now contained in it. The dwellings are far from being memorials of ancient Syracuſan architecture or opulence. In any other ſituation they might be thought tolerable; but to obſervers who reflect on the ſtyle of thoſe buildings that probably once covered the ſame ground, the preſent edifices muſt have a mean appearance. The ancient temple of Minerva is now turned into a cathedral. The walls of the cella are thrown down, and only as much left in pillars as is neceſſary to ſupport the roof; the intercolumniations of the peryſtile are walled up. This temple is built in the old Doric proportions uſed in the reſt of Sicily; its exterior dimenſions are 185 feet in length and 75 in breadth. There are alſo ſome remains of Diana's temple, but now ſcarcely diſcernible. Beſides theſe, there are few ruins in the iſland; and one is ſurpriſed that any ſhould exiſt in a place which has been ſo often laid waſte by enemies, and ſo often ſhaken by earthquakes.

"Every object here imprints a melancholy ſenſation on the mind, while it draws a compariſon between the preſent humble ſtate of things and their once flouriſhing condition. The ancients have left pompous deſcriptions of the traffic carried on in this well ſituated port, the almoſt incredible wealth poſſeſſed by its citizens, and the ſplendid edifices upon which they laviſhed a great part of their riches. I had already viewed (ſays Mr Swinburne) the deſert ſites

of

Syria.

of many great ancient cities, and had as often mourned over their remains, but never did I feel the impreſſion of pity and regret ſo ſtrong as in wandering among the ruins of Syracuſe."

SYRIA, a very ancient kingdom of Aſia, lying between the Mediterranean on the weſt, the Euphrates on the eaſt, and Arabia Deſerta, Phœnicia, and Peleſtine, on the ſouth.

1 Names, diviſions, &c. of ancient Syria.

In ancient times this country was called *Aram*, from Aram the youngeſt ſon of Shem, who ſettled here; but in proceſs of time the name came to be changed into *Syria*, from one *Syrus*, according to ſome; though others think it is only a contraction of the word *Aſſyria*. At firſt it was undoubtedly parcelled out into ſeveral petty ſtates; all of which ſeem afterwards to have been reduced under ſubjection to the four principal ones, Zobah, Damaſcus, Hamath, and Geſhur. Afterwards the whole country was divided into two parts only, viz. Cœleſyria and Phœnicia; though the Phœnicians, Idumeans, Jews, Gazites, and Azotites, or the whole country of the Philiſtines, was included. After the death of Alexander, Syria, in the great extent of the word, was divided, according to Strabo, into Comagene, Seleucis of Syria, Cœleſyria, Phœnice on the ſea-coaſt, and Judea in the midland. Ptolemy, however, ſubdivides theſe; and in the Proper Syria reckons only Comagene, Pieria, Cyrrhiſtica or Cyrrheſtica, Seleucis, Caſſiotis or Caſiotis, Chalybonitis, Chalcidice or Chalcidene, Apamene, Laodicene, Phœnicia Mediterranea, Cœleſyria and Palmyrene.

The hiſtory of the ancient Syrians, till the time of their being carried away by the kings of Aſſyria, is totally unknown, excepting a few particulars which may be gathered from Scripture, and which it is needleſs here to repeat. During the continuance of the Aſſyrian, Babylonian, and Perſian monarchies, the hiſtory of this country affords nothing remarkable; but after the death of Alexander, it gave name to a very conſiderable empire, which makes a conſpicuous figure in ancient hiſtory. At this time, however, it was not confined to Syria properly ſo called, but comprehended all thoſe vaſt provinces of the Upper Aſia which formed the Perſian empire; being, in its full extent, bounded by the Mediterranean upon one ſide, and the river Indus on the other. The firſt king was Seleucus, one of the generals of Alexander the Great; who, after the death of that conqueror, being made governor of Babylon, was tempted, by the example of Alexander's other captains, to ſet up for himſelf. Eumenes, who had ſincerely at heart the intereſt of Alexander's family, ſolicited his aſſiſtance againſt Antigonus, who had openly revolted; but Seleucus not only refuſed this aſſiſtance, but attempted to deſtroy Eumenes himſelf with his whole army, by cutting the ſluices of the Euphrates, and laying under water the whole plain where they were encamped. Eumenes, however, found means to eſcape the danger without the loſs of a man. Upon this Seleucus endeavoured to gain over his troops: but finding that impoſſible, he made a truce with Eumenes, and granted him a ſafe paſſage through his province; but at the ſame time ſent an expreſs to Antigonus, deſiring him to fall upon him before he was joined by the governors of Upper Aſia. Antigonus did not fail to follow his advice; but having prevailed againſt Eumenes through treachery, he next thought of bringing Seleucus himſelf under ſubjection. On his return to Babylon, therefore, after having been feaſted with his whole army by Seleucus, he demanded of him an account of the revenues of his province. Receiving an unfavourable anſwer to this queſtion, Antigonus was ſo much exaſperated, that Seleucus, not thinking himſelf a match for him at that time, thought proper to fly into Egypt.

2 Seleucus the firſt king of Syria after Alexander the Great.

3 Attempts to deſtroy Eumenes.

4 Obliged by Antigonus to fly into Egypt.

By the flight of Seleucus, Antigonus was left maſter of all his provinces; but his ſon Demetrius being afterwards defeated by Ptolemy at Gaza, Seleucus began to think of recovering what he had loſt. Being furniſhed by Ptolemy with 1000 foot and 200 horſe, he ſet out with that ſlender force to attempt the recovery of Babylon. Nothing could have a more deſperate appearance than this undertaking; yet Seleucus was not diſcouraged. On his arrival at Carrhæ in Meſopotamia, partly by force and partly by perſuaſion, he prevailed on the Macedonians who garriſoned that place to revolt from Antigonus and join him. Being thus reinforced, he entered the territories of Babylon, where new ſupplies were continually added to his army; his ancient ſubjects flocking to him from all parts, and declaring themſelves ready to ſtand by him with their lives and fortunes. This happened in conſequence of the lenity with which they had been treated by Seleucus; whereas Antigonus was univerſally deteſted on account of his ſeverity.—As he approached the city, thoſe who favoured Antigonus retired into the citadel, but were ſoon obliged to ſurrender; and in that fortreſs Seleucus found his children, friends, and domeſtics, whom Antigonus had kept priſoners ever ſince his flight into Egypt.

Syria.

5 Attempts the recovery of Babylon with a very ſlender force.

6 Becomes maſter of the city.

Seleucus having thus made himſelf maſter of Babylon, in the year 312 B. C. began to prepare for encountering Antigonus, who he knew would ſoon attack him with all his force. Nicanor, governor of Media under Antigonus, firſt advanced againſt him at the head of 10,000 foot and 7000 horſe: but Seleucus, with only 3000 foot and 400 horſe, having drawn him into an ambuſh, cut off almoſt the whole of his army, and ſuch of the ſoldiers as had eſcaped the ſlaughter willingly enliſted under his banner.

7 Defeats Nicanor, and reduces Media and Suſiana.

The conſequence of this victory was the ſubmiſſion of all Media and Suſiana; which alarming Antigonus, he ſent his ſon Demetrius with an army of 5000 Macedonian foot, 10,000 mercenaries, and 4000 horſe. Seleucus was then in Media; and Patrocles, whom he had left to take care of Babylon, finding his force inadequate to that purpoſe, compelled the inhabitants to leave the city and diſperſe themſelves in the adjacent countries, while he himſelf, with what troops he had, retired into two forts, which he thought could eaſily be defended. When therefore Demetrius entered Babylon, he was ſurpriſed to find it deſerted, upon which he inſtantly attacked the forts. One was quickly reduced; but as the other held out till the expiration of the time which had been allowed him by his father, he left 5000 foot and 1000 horſe under the command of Archelaus to carry on the ſiege. With the reſt he marched away, ſuffering his ſoldiers to live at diſcretion as he went along; which ſo provoked the Babylonians, that they were ever after attached to Seleucus as if he had been their natural prince.

On the return of Seleucus to Babylon, he eaſily drove out the troops left by Antigonus, recovered the caſtle which he had garriſoned, and ſettled his authority on ſuch a firm foundation, that it could never afterwards be moved. Having then marched again into Media, he defeated and killed with his own hand Nicanor or Nicator, whom Antigonus had ſent againſt him; after which, having ſettled the affairs of Media, he reduced all Perſia, Bactria, and Hyrcania, ſubjecting to his new empire theſe and all the other provinces on this ſide the Indus which had been conquered.

8 Nicanor again defeated and killed.

Seleucus being now maſter of all the countries which lie between the Euphrates and the Indus, took the title of king of Babylon and Media. But, not ſatisfied with theſe poſſeſſions, ample as they were, he croſſed the Indus, in order to conquer thoſe regions which had ſubmitted to Alexander beyond that river. But, during the time that the generals of Alexander had been making war upon his family and upon

Syria.

on one another, one Sandracottus, a native of India, had driven out the Macedonians, and made himſelf maſter of the whole country. He oppoſed Seleucus with an army of 600,000 men and a prodigious number of elephants; which intimidated the Macedonian ſo much, that he offered to leave Sandracottus in quiet poſſeſſion of his dominions, provided he would furniſh him with 500 elephants. To this Sandracottus readily aſſented; upon which Seleucus marched back into the weſt againſt Antigonus, and, in conjunction with Lyſimachus and Ptolemy, engaged and totally defeated and killed him at Ipſus. After this Seleucus marched into Upper Syria, which he reduced entirely, and built the city of Antioch on the Orontes. In the ſame country he built ſeveral other cities; one of which he called *Seleucia*, from his own name; another *Apamea*, from his wife Apama, the daughter of one Artabazus a Perſian; and a third *Laodicea*, from his mother Laodice. He firſt entered into an alliance with Demetrius, and married Stratonice his daughter; but ſoon after aſſiſted Lyſimachus and Ptolemy to deprive him of the beſt part of his dominions. Thus Demetrius being reduced ſo low that he could give him no farther jealouſy, Seleucus betook himſelf to the building of another city which he called likewiſe *Seleucia*, and which ſtood on the place where the city of Bagdad now ſtands. Beſides theſe, he built a great many others; 16 of which he called *Antioch*, from the name of his brother Antiochus; nine *Seleucia*, from his own name; three *Apamea*, from Apama his firſt wife; one *Stratonicea*, from his ſecond wife Stratonice; and ſix *Laodicea*, from his mother Laodice.

9 Cedes India to Sandracottus for 500 elephants.

10 Defeats Antigonus, and builds many cities.

In 284 Seleucus entered into a war with Lyſimachus, with whom he had hitherto lived in ſtrict amity. Out of 36 general officers left by Alexander the Great, they two only ſurvived, and both were upwards of 70 years old. Nevertheleſs they were both filled with the ambition and animoſity of young men. The two armies met at a place called *Curopedion* in Phrygia, where an obſtinate engagement took place. Victory was long doubtful: but at laſt Lyſimachus was run through with a ſpear, and died on the ſpot; on which his troops betook themſelves to flight, and left Seleucus maſter of their baggage. This victory added to the poſſeſſions of Seleucus all thoſe provinces which had formerly been ſubject to Lyſimachus. The former exulted much in his good fortune; being chiefly pleaſed that he was now the laſt of Alexander's captains, and by this victory became, as he ſtyled it, *the conqueror of conquerors*; and on this account he is generally called *Nicator*, or *the conqueror*. His triumph, however, on this occaſion, was but ſhort-lived; for, ſeven months after, as he was marching towards Macedon to take poſſeſſion of that kingdom, he was treacherouſly murdered by Ptolemy Ceraunus, on whom he had conferred innumerable favours. Philetærus prince of Pergamus purchaſed his body at a great price from Ptolemy, and ſent it to his ſon Antiochus; who, with extraordinary pomp, burned it in Seleucia on the ſea-coaſt, erecting on the place a magnificent chapel which he called from his ſurname *Nicatorium*.

11 Defeats and kills Lyſimachus.

12 Is himſelf treacherouſly murdered.

13 Antiochus Soter.

Seleucus was ſucceeded by his ſon Antiochus Soter, who held the empire 19 years. He reſigned to Antigonus Gonatus all pretenſions to the crown of Macedon; and having engaged in a war with Eumenes king of Pergamus, he was defeated by him, and obliged to yield up part of his dominions. He died in 261 B. C. and was ſucceeded by his ſon Antiochus Theos; who having engaged in a war with Ptolemy Philadelphus king of Egypt, the Parthians and Bactrians took an opportunity, to revolt, and could never afterwards be reduced. In 246 B. C. he was poiſoned by his wife Loadice, whom he had divorced for Berenice daughter to Ptolemy, with whom he made peace on the revolt of the Bactrians. On the death of Ptolemy, Antiochus divorced Berenice, and took back Laodice; who, to ſecure herſelf againſt the effects of his fickle diſpoſition, poiſoned him, as we have juſt mentioned, and raiſed to the throne her own ſon, named *Seleucus Callinicus*. Not thinking herſelf ſafe, however, as long as Berenice lived, Laodice began immediately to concert meaſures, for putting both her and her ſon to death. Berenice attempted to ſave herſelf by retiring to Daphne, where ſhe ſhut herſelf up in an aſylum built by Seleucus Nicator. There ſhe was cloſely beſieged by the ſons of Seleucus; of which the cities of Aſia having intelligence, formed a confederacy in her favour. Her brother the king of Egypt alſo haſtened to her relief with a conſiderable army; but before either of theſe could come to her aſſiſtance, both ſhe and her ſon were barbarouſly murdered, with all the Egyptians who attended them.

14 Antiochus Theos.

15 Seleucus Callinicus.
